fragile texture, and of so little weight, that in passing from one river to another, the boatmen carry them on their heads across their portages. They are mostly covered with bark, the pieces of which are sewed together with a kind of grass. This bark is generally not more than a quarter of an inch in thickness; yet, in these frail vessels, the Indians and Canadians do not hesitate to descend very dangerous rapids. The Esquimaux are exceedingly dexterous in the management of their canoes. These consist of a light, wooden frame, covered with seal-skins, sewed together with sinews. The skins are not only extended round the bottom and sides, but likewise over the top, forming a complete deck, and having only one opening to admit the Indian to his seat. To this hole a flat hoop, rising about four inches, is fitted, to which is fastened the surrounding skin. The paddle is about 10 feet long, light, and flat at each end. In the Esquimaux language, the canoe is called a *kaiak*, or *man's boat*, to distinguish it from *umiak*, the *woman's boat*, which latter is a large boat for transporting the women with their families and possessions. The Greenlanders and Esquimaux use the same kind of canoes, and it is astonishing, when we consider their insignificant construction, at what a distance from the regions they commonly inhabit, these people, especially the former, are found in them. In the islands of the South Sea, the natives have a double canoe, united by a strong platform, serving in this way as one vessel. Such a canoe is capable of carrying a number of persons, and a considerable lading. Captain Cook gives us a full account of the different kinds of canoes used in Otaheite.—E. A.

Canoe Birch (*Betula papyracea*). By the French Canadians *Bouleau Blanc*, white birch, and *Bouleau à Canot*, canoe birch: it is known to the American also by these denominations, and sometimes by that of *paper birch*. The heart or perfect wood of this tree, when first laid open, is of a reddish hue, and the sap is perfectly white. It has a fine glossy grain, with a considerable share of strength; that it is but little employed is attributed partly to its speedy decay when exposed to the succession of dryness and moisture, and partly to the existence, in the countries which produce it, of several species of wood, which are far preferable for the uses of the carpenter and the wheelwright. It is sometimes employed by cabinet-makers for tables which are stained in imitation of mahogany. But the most important purpose for which it is employed, and one in which it is replaced by the bark of no other tree, is the construction of canoes. To procure proper pieces, the largest and smoothest trunks are selected: in the spring two circular incisions are made several feet apart, and two longitudinal ones on opposite sides of the tree; after which, by introducing a wooden wedge, the bark is easily detached. These plates are usually ten or twelve feet long, and two feet nine inches broad. Great use is made of these canoes by the Indians and by the French Canadians in their long journeys into the interior of the country; they are very light, and are easily transported on the shoulders from one lake or river to another, which is called the *portage*. A canoe calculated for four persons, with their baggage, weighs from forty to fifty pounds; some of them are made to carry fifteen passengers. Such are the ordinary uses of the bark and of the wood of this tree.—*Michx's Sylva Americana*.

Cantharides, or Spanish Fly (Fr. *Cantharides*, *Monches d'Espagne*; Ger. *Spanische Fliegen*; It. *Cantharelle*; Lat. *Cantharis*; Russ. *Hischpanski muchi*; Sp. *Cantharidas*). This insect is found on a variety of shrubs in Spain, Italy, France, etc. Those used in England are imported partly from Sicily, but principally from Astracan, packed in casks and small chests: the most esteemed come from St. Petersburg. The best are of a lively fresh color, a small size, and not mouldy. They are frequently adulterated with the

Melolontha vitis; but this is distinguishable by its form, which is squarer than the cantharis, and by its black feet. If they be properly dried and protected from the air, they may be kept for a very long period.—*Trotson's Dispensatory*. There were four new varieties of cantharides from India shown at the London Exhibition of 1851.

Canton, one of the greatest emporiums in the East, ranking, as a port of trade, either before, or immediately after, Calcutta, in the province of Quantong, in China; being, previously to 1843, the only place in that empire open by authority to European traders: lat. 23° 7' 10" N., lon. 113° 14' E. Canton stands on the eastern bank of the Pekin River, which flows from the interior in a navigable stream of 300 miles to this city, where it is rather broader than the Thames at London Bridge; falling, after an additional course of 80 miles, into the southern sea of China. Near its junction with the sea, it is called by foreigners Bocca Tigris. The town is surrounded by a thick wall, partly of stone and partly brick, and is divided into two parts by another wall running east and west. The northern division is called the old, and the southern the new city. In the old city is the Mantchou or Tartar general, with his garrison of Mantchou troops. The lieutenant governor or Fooyuen's office is also in the old city, but the governor and hoppo (principal customs officer) reside in the new city, not far from the river.

All foreign commerce is conducted in the southwest suburb, where the foreign factories are situated; and which, with the other suburbs, is probably not less populous than the city itself. The residence of Europeans is confined to a very small space, on the banks of the river; which might, however, be as pleasant as a crowded mercantile place can well be, were it not for the great number of small *doelling boats* which cover the face of the river. The people who occupy the larger portion of these boats are said to have come originally from the south; and being a foreign and despised race, were not, at first, allowed to dwell on shore; but most of the distinctions between them and the rest of the people have been abolished. Although Canton is situated nearly in the same parallel of latitude as Calcutta, there is a considerable difference in their temperature; the former being much the coolest, and requiring fires during the winter months. The streets are very narrow, paved with little round stones, and flagged close to the sides of the houses. The front of every house is a shop, and those of particular streets are laid out for the supply of stangers. China Street is appropriated to Europeans; and here the productions of almost every part of the globe are to be found. One of the shop-keepers is always to be found sitting on the counter, writing with a camel-hair brush, or calculating with his swampan, on which instrument a Chinese will perform operations in numbers with as much celerity as the most expert European arithmetician. This part of Canton being much frequented by the seamen, every artifice is used by the Chinese retailers to attract their attention; each of them having an English name for himself painted on the outside of his shop, besides a number of advertisements composed for them by the sailors in their own peculiar idiom. The latter, it may be supposed, are often duped by their Chinese friends, who have, in general, picked up a few sea phrases, by which the seamen are induced to enter their shops; but they suit each other extremely well, as the Chinese dealers possess an imperturbable command of temper, laugh heartily at their jokes without understanding them, and humor the seamen in all their sallies. Ships only ascend the river as far as Whampoa, about 15 miles below Canton, loading and unloading by means of native boats.

The Chinese, considered as traders, are eminently active, persevering, and intelligent. They are, in

fact, a highly commercial people; and the notion that was once very generally entertained of their being peculiarly characterized by a contempt of commerce and of strangers is as utterly unfounded as any notion can possibly be. Business is transacted at Canton with great dispatch; and nowhere in the world may cargoes be sold and bought, loaded and unloaded, with more business-like speed and activity. Provisions and refreshments of all sorts are abundant in Canton, and, in general, of an excellent quality; nor is the price exorbitant. Every description of them, dead and alive, is sold by weight. It is a curious fact that the Chinese make no use of milk, either in its liquid state, or in the shape of curds, butter, or cheese. Among the delicacies of a Chinese market are to be seen horse-flesh, dogs, cats, hawks, and owls. The country is well supplied with fish from the numerous canals and rivers by which it is intersected.

Foreign Factories.—These extend for a considerable way along the banks of the river, at the distance of about 100 yards. They are named, by the Chinese, *hongs*, and resemble long courts, or closes, without a thoroughfare, which generally contain four or five separate houses. They are built on a broad quay, and have a parade in front. This promenade is railed in, and is generally called *Respondentia Walk*; and here the European merchants, commanders, and officers of the ships meet after dinner and enjoy the cool of the evening. The English hong, or factory, far surpasses the others in elegance and extent. This, with the American and Dutch hongs, are the only ones that keep their national flags flying. The neighborhood of the factories is occupied with warehouses for the reception of European goods, or of Chinese productions, until they are shipped. In 1822, during a dreadful conflagration that took place at Canton, the British factories and above 10,000 houses were destroyed; on which occasion the East India Company's loss was estimated at £500,000 sterling, three-fifths in woollens.

For the space of four or five miles opposite to Canton the river resembles an extensive floating city, consisting of bunts and vessels ranged parallel to each other, leaving a narrow passage for others to pass and repass. In these the owners reside with their families, the latter rarely visiting the shore. All the business at Canton with Europeans is transacted in a jargon of the English language. The sounds of such letters as B, D, R, and X are unknown in China. Instead of these they substitute some other letter, such as L for R, which occasions a Chinese dealer in rice to offer for sale in English a rather unmarketable commodity. The name mandarin is unknown among the Chinese, the word used by them to denote a person in authority being *quan*. Mandarin is a Portuguese word derived from the verb *mandar*, to command.—HAMILTON'S *East India Gazetteer*; MITCHELL'S *Orient. Commerce*; *Companion to Anglo-Chinese Calendar*, &c.

The trade of Canton is retrograding, while that of Shanghai is increasing; and indeed it is not unlikely that the latter will in time supplant Canton in the European trade, as it enjoys the additional advantage of being nearer the tea districts. Canton was no doubt fixed upon by the Chinese government for the European trade, as being the most distant from the capital, Peking.

Formerly only a limited number of merchants, called the hong or security merchants, were allowed to trade with foreigners. They were commonly men of large property, and were famed for integrity in their transactions. All foreign cargoes passed through the hands of these merchants, and by them also the return cargoes were furnished. They became security for the payment of duties, and it was treason for any other merchant to engage in the trade with foreigners. This severe law, however, has recently been abolished, and foreigners may now deal with any merchant they think fit to employ.

All goods are sold by weight in China—even articles of food, such as hogs, fowls, and the like.

The foreign trade of Canton is very extensive; but the great article of export is tea, for which the demand in Europe has been increasing for upward of a century. This article was formerly monopolized by the East India Company; and from their accounts it appears that they imported annually into England about 50,000,000 of pounds. But this monopoly was abolished in 1834, and the commerce with China was thrown open to all. The other exports are raw silk and silk manufactures, nankeen cloth, cassia, lignea, etc. The principal imports are cotton and woolen goods, earthen-ware, iron, steel, etc. In 1848, 176 British vessels of 78,975 tons, with goods of the value of 8,653,088 dollars, left, and 171 of 72,315 tons, with goods to the value of 6,534,597 dollars, entered the port of Canton. The Americans, French, and Dutch, also carry on a considerable trade with Canton.

Although situated in the same parallel of latitude as Calcutta, the climate of Canton is much cooler, and is considered superior to that of most places situated between the tropics. The thermometer, during the months of July and August, averages from 80° to 88°; and in January and February from 50° to 60°. The highest recorded observation in 1831 was 94° in July, and the lowest 29° in January. In shallow vessels ice sometimes forms at Canton a line or two in thickness. A fall of snow, nearly two inches deep, occurred at Canton in February, 1835, and remained on the ground three hours—a circumstance so unusual that the citizens hardly knew its proper name. Fogs are common during February and March. Most of the rain falls during May and June, but it is nothing in comparison of a rainy season in Calcutta. July, August, and September are the regular monsoon months, the wind coming from the southwest, with frequent showers, which allay the heat. In the succeeding months the northerly winds commence, with some interruptions at first; but from October to January the temperature is agreeable, the sky clear, and the air invigorating. Few large cities are more healthy than Canton; no epidemics nor malaria prevail there, though much of the town is built upon piles.

The intercourse between China and Europe by the way of the Cape of Good Hope began in 1517, when Emanuel, king of Portugal, sent a fleet of eight ships, with an ambassador, who was conveyed to Peking, and who obtained the sanction of the emperor to establish a trade at Canton. It was in 1596, in the reign of Queen Elizabeth, that the English first attempted, with two ships, to open an intercourse with China; but they were lost in the outward voyage. About 1634 several English ships visited Canton; but a misunderstanding having occurred with the Chinese authorities, by the treachery of the Portuguese, a rupture and a battle took place, and it was with difficulty that this misunderstanding was rectified. China was again visited in 1673 by an English ship that was refused admission into Japan. In 1677 a factory was established at Amoy; but in 1680 the factory was destroyed by an irruption of the Tartars, and it was not till 1685 that the emperor permitted any trade with the Europeans. Upon the union of the two East India companies in London, an imperial edict was issued, restricting the European commerce to the port of Canton. Tea was first imported about the year 1667. This is one of the five Chinese ports opened to Europeans by the treaty of 1842.—E. H.

GENERAL REGULATIONS UNDER WHICH THE BRITISH TRADE (AND TRADING TO ALL FOREIGNERS) IS TO BE CONDUCTED AT THE FIVE PORTS OF CANTON, AMOY, FOO-CHOW-FOO, NINGPO, AND SHANGHAI.

1. *Pilots*.—Whenever a British merchantman shall arrive off the five ports open to trade, viz., Canton, Foo-chow-foo, Amoy, Ningpo, or Shanghai, pilots shall be allowed to take her immediately into port; and in like manner, when such British ship shall have settled all legal duties and charges, and is about

to return home, pilots shall be immediately granted to take her out to sea, without any stoppage or delay. Regarding the remuneration to be given these pilots, that will be equitably settled by the British consul appointed to each particular port, who will determine it with due reference to the distance gone over, the risk run, &c.

2. *Custom-house Guards*.—The Chinese Superintendent of Customs at each port will adopt the means that he may judge most proper to prevent the revenue suffering by fraud or smuggling. Whenever the pilot shall have notified any British merchantman into port, the superintendent of customs will depute one or two trusty custom-house officers, whose duty it will be to watch against fraud on the revenue. These will either live in a boat of their own, or stay on board the English ship, as may best suit their convenience. Their food and expenses will be supplied them from day to day from the custom-house, and they may not exact any fee whatever from either the commander or consignee. Should they violate this regulation, they shall be punished proportionately to the amount so exacted.

3. *Masters of Ships reporting themselves on Arrival*.—Whenever a British vessel shall have cast anchor at any one of the above-named ports, the captain will, within four-and-twenty hours after arrival, proceed to the British consulate and deposit his ship's papers, bills of lading, manifest, &c. in the hands of the consul; failing to do which he will subject himself to a penalty of 500 dollars. For presenting a false manifest the penalty will be 500 dollars. For breaking bulk and commencing to discharge before due permission shall be obtained, the penalty will be 500 dollars, and confiscation of the goods so discharged. The consul, having taken possession of the ship's papers, will immediately send a written communication to the superintendent of customs, specifying the register tonnage of the ship, and particulars of the cargo she has on board; all of which being done in due form, permission will then be given to discharge, and the duties levied as provided for in the tariff.

4. *Commercial Dealings between English and China Merchants*.—It having been stipulated that English merchants may trade with whatever native merchants they please, should any Chinese merchant fraudulently abscond, or incur debts which he is unable to discharge, the Chinese authorities, upon complaint being made thereof, will of course do their utmost to bring the offender to justice; it must, however, be distinctly understood that if the defaulter really can not be found, or be dead or bankrupt, and there be not wherewithal to pay, the English merchants may not appeal to the former customs of the Hong merchants paying for one another, and can no longer expect to have their losses made good to them.

5. *Tonnage Dues*.—Every English merchantman, on entering any one of the above-mentioned five ports, shall pay tonnage dues at the rate of five maces per register ton, in full at all charges. These dues formerly levied on entry and departure, of every description, are henceforth abolished.

6. *Import and Export Duties*.—Goods, whether imported into or exported from any one of the above-mentioned five ports, are henceforward to be taxed according to the tariff as now fixed and agreed upon, and no further sums are to be levied beyond those which are specified in the tariff. All duties incurred by an English merchant vessel, whether on goods imported or in the shape of tonnage dues, must first be paid up in full; when done, the superintendent of customs will grant port clearance, and this being shown to the British consul, he will thereupon return the ship's papers, and permit the vessel to depart.

7. *Examination of the Goods at the Custom-house*.—Every English merchant having cargo to load or discharge must give due intimation thereof, and hand particulars of the same to the consul, who will immediately dispatch a recognized linguist of his own establishment to communicate the particulars to the superintendent of customs, that the goods may be examined, and neither party subjected to loss. The English merchant must have a properly qualified person on the spot, to attend to his interests when his goods are being examined for duty; otherwise, should there be complaints, these can not be attended to. Regarding such goods as are subject by the tariff to an *ad valorem* duty, if the English merchant can not agree with the Chinese officer in fixing a value, then each party shall call two or three merchants to look at the goods, and the highest price at which any of these merchants would be willing to purchase shall be assumed as the value of the goods. To fix the tare on any article, such as tea: if the English merchant can not agree with the custom-house officer, then each party shall choose 50 many chests out of every 100, which, being first weighed in gross, shall afterward be tared, and the average tare upon these shall be assumed as the tare upon the whole, and upon this principle shall the tare be fixed upon all other goods in packages. If there should still be any disputed points which can not be settled, the English merchant may appeal to the

consul, who will communicate the particulars of the case to the superintendent of customs, that it may be equitably arranged. But the appeal must be made on the same day, or it will not be regarded. While such points are still open, the superintendent of customs will delay to insert the same in his books, thus affording an opportunity that the merits of the case may be duly tried and sifted.

8. *Manner of paying the Duties.*—It is herein-before provided, that every English vessel that enters any one of the five ports shall pay all duties and tonnage dues before she be permitted to depart. The superintendent of customs will select certain shroffs, or banking establishments of known stability, to whom he will give licenses authorizing them to receive duties from the English merchants on behalf of government, and the receipts of these shroffs for any money paid them shall be considered as a government voucher. In the paying of these duties, different kinds of foreign money may be made use of; but as foreign money is not of equal purity with sycee silver, the English consuls appointed to the different ports will, according to time, place, and circumstances, arrange with the superintendent of customs at each port what coins may be taken in payment, and what percentage may be necessary to make them equal to standard or pure silver.

9. *Weights and Measures.*—Sets of balance-yards for the weighing of goods, of money weights, and of measures, prepared in exact conformity to those hitherto in use at the custom-house of Canton, and duly stamped and sealed in proof thereof, will be kept in possession of the superintendent of customs, and also at the British consulate, at each of the five ports, and these shall be the standard by which all duties shall be charged, and all sums paid to government. In case of any dispute arising between British merchants and the Chinese officers of customs regarding the weights or measures of goods, reference shall be made to these standards, and disputes decided accordingly.

10. *Lighters or Cargo Boats.*—Whenever an English merchant shall leave to load or discharge cargo, he may hire whatever kind of lighter or cargo boat he pleases, and the sum to be paid for such boat can be settled between the parties themselves, without the interference of government. The number of these boats shall not be limited, nor shall a monopoly of them be granted to any parties. If any smuggling take place in them, the offenders will, of course, be punished according to law. Should any of these boat people, while engaged in conveying goods for English merchants, fraudulently abscond with the property, the Chinese authorities will do their best to apprehend them; but, at the same time, the English merchants must take every due precaution for the safety of their goods.

11. *Transhipment of Goods.*—No English merchant ships may tranship goods without special permission; should any urgent case happen where transhipment is necessary, the circumstances must first be submitted to the consul, who will give a certificate to that effect, and the superintendent of customs will send a special officer to be present at the transhipment. If any one presumes to tranship without such permission being asked for and obtained, the whole of the goods so illicitly transhipped will be confiscated.

12. *Subordinate Consular Officers.*—At any place selected for the anchorage of the English merchant ships, there may be appointed subordinate consular officers, of approved good conduct, to exercise due control over the seamen and others. He must exert himself to prevent quarrels between the English seamen and the natives, this being of the utmost importance. Should any thing of the kind unfortunately take place, he will in the like manner do his best to arrange it amicably. When sailors go on shore to walk, officers shall be required to accompany them; and should disturbances take place, such officers will be held responsible. The Chinese officers may not induce natives from coming alongside the ships to sell clothes, or other necessaries to the sailors living on board.

Opium.—A motion having been entertained that opium being legally imported into China, under the provisions of this tariff, on paying an *ad valorem* duty of 5 per cent., the following proclamation has been issued on the subject:

PROCLAMATION.—It having been brought to my notice that such a step has been contemplated as sending vessels with opium on board into the ports of China to be opened by treaty to foreign trade, and demanding that the said opium shall be admitted to importation, by virtue of the concluding clause of the new tariff, which provides for all articles not actually enumerated in that tariff passing at an *ad valorem* duty of 5 per cent., I think it expedient, by this proclamation, to point out to all whom it may concern, that opium being a article the traffic in which is well known to be declared illegal and contrary to the laws and imperial edicts of China, any person who

may take such a step will do so at his own risk, and will, if a British subject, meet with no support or protection from her Majesty's consuls or other officers. This proclamation will be translated and published in Chinese, so that no one may plead ignorance of it.

GOVERNMENT-HOUSE, VICTORIA, this 1st day of August, 1843.

But, notwithstanding this proclamation, and in defiance of the strong denunciation of smuggling in the proclamation of the 2d day of July it is distinctly stated in Hong Kong papers that there was, on the 21st day of September, 1843, almost in sight of the consular flags, a "fleet of British vessels openly engaged in the vending of opium to the Chinese!" This certainly is a curious commentary on the above proclamation; and it were much to be wished, seeing that the trade can not be suppressed, that it were legalized on opium paying a reasonable duty. The consuls for the United States have salaries.—See CONSULS. The payment of British consuls by fees is much, and we believe justly, objected to at Canton. Supposing, however, that the treaty with China is bona fide carried into effect, still it may be doubted whether the trade with that empire will ever be so extensive as many suppose. We believe, indeed, that China will afford a most extensive outlet for various descriptions of manufactured goods, provided we can bring away equivalents suitable for the European and other foreign markets. But this, we incline to think, will be no easy matter. Excepting tea, China has few articles suitable for extensive use in Europe, other than silk and silver. Chinese silk is, however, losing ground as compared with that of Italy and Turkey, while it is most probable that the enhancement of its price, consequent to any great increase in the exportation of silver, would in no very long time bring it to a close. Tea is the grand equivalent which the Chinese have to exchange for our products, and this trade is increasing very rapidly.—For the exports of tea to the United States for the last ten years, see CHINA.

Hong Kong.—The island of this name, ceded to England by the above treaty, is situated on the northern side of the entrance from the sea to the estuary of the Canton River, being separated from the main land by a narrow channel having 14 fathoms water. It stretches about 8 miles from east to west, and is of a very irregular figure, having several promontories, and being deeply indented with bays. It consists principally of a series of high hills, the highest having an elevation of about 1200 feet. Victoria, the principal British settlement on the north side of the island, is lat. 22° 16' 27" N., long. 114° 10' 48" E., has the advantage of an excellent roadstead, with from 8 to 7 fathoms water and good holding ground. There are also numerous well-sheltered roads and bays with deep water on the south side of the island, which, indeed, appears, from its position and other advantages, extremely well fitted for a naval station. Every thing, however, will depend on the fact of its being healthy, of which, we are sorry to observe, grave doubts are entertained. Should these happily prove unfounded, it is probable that in no very lengthened period a considerable portion of the trade which is at present centred in Canton will be transferred to Hong Kong; and, under the above condition, it can hardly fail to become an important entrepôt not merely for trade with the Canton River, but with China generally.

In 1814 the total population of Hong Kong (consisting of Chinese) was 19,463; while on the 31st of December, 1853, the Chinese population was 37,536; Europeans and Americans, 476; other races, 1005. In 1853, 1103 square-rigged vessels, carrying in all 447,053 tons, arrived in Victoria harbor. Of these vessels 201 imported, and 154 exported goods into and from the colony, being an increase over 1802 of 74 and 79 vessels respectively; while the total tonnage of vessels arrived as compared with the preceding year shows an increase of 13,670 tons.—See HONG KONG.

TARIFF OF DUTIES ON EXPORTS FROM CHINA, ESTABLISHED IN PURSUANCE OF THE ABOVE TREATY, IN CHINESE AND MERCANTILE CURRENCY (DOLLARS AND CENTS), REDUCED INTO THEIR EQUIVALENT RATES IN STERLING MONEY, ACCORDING TO ENGLISH WEIGHTS AND MEASURES.

Currency.—Doubts having been entertained respecting the value of the coins current in Hong Kong and its dependencies, the following rates at which such coins are made legal tender were issued by proclamation dated the 1st of May, 1884.

“The gold mohor of the East India Company’s mint, coined since the 1st day of September, 1835, at the rate of 29s. 3d. sterling money of the United Kingdom

“The dollar of Spain, Mexico, or American States, at the rate of 4s. 2d. sterling

“The rupee of the British India Company’s territories, as used since the 1st day of September, 1835, at the rate of 1s. 10d. sterling; and the half rupee, quarter rupee, and a sixth of rupee pieces in proportion.

“The cash, or copper coin current in China, at the rate of 188 cash for 1s. sterling.”

The following proviso establishes, with respect to silver currency, the principle that prevails in England:

“Provided that nothing herein contained shall be deemed or taken to render it compulsory on any person to accept at any one payment a larger amount in silver coins of the United Kingdom of lower denomination than 1s., or in the half quarter, or eighth rupee sterling herebefore mentioned, than the equivalent to 20s. sterling money, or a larger amount in copper coins of the United Kingdom, or in the Chinese copper coins herebefore mentioned, than the equivalent to 1s. sterling.”

ESTIMATES.—Chinese Weights, per standard: 1 picul = 16 catties = 1600 taels = 133½ lb., a cirdupois; 1 tael = 583½ grains Troy; 400 lb. avoirdupois = 3 picul; 1 cwt. avoirdupois = 84 catties; 1 lb. avoirdupois = 12 taels.

Chinese Measures: 1 chang = 141 English inches, or

arrival in the roads, the pilot goes on shore to report her at the office of the kean-min-foo, who, when he has received answers to his inquiries, gives a permit for her to pass through the Bogue, and orders a river pilot on board. This pilot seldom repairs on board the vessel before 24 hours have elapsed. When arrived, the vessel proceeds through the Bogue, and up the Canton River to Whampoa.

Every ship that enters the port requires the service of a linguist and comprador before she can commence unloading. The master used to be required to give a written declaration, in duplicate, solemnly affirming that the ship has brought no opium. All the trade with foreigners used to be confined to the hong or security merchants; but this restriction has recently been abolished; and foreigners may now deal with any merchant or other party they think fit to employ. The linguists are government interpreters, who procure permits for delivering and taking in cargo, transact all the custom-house business, and keep accounts of the duties. All the minor charges of the government, also, are paid by them; in consideration of which they receive a fee of about \$173 previously to the vessel's departure. When a vessel wishes to discharge or receive cargo, the linguist is informed a day or two previously what kind of goods are to be received or discharged, and in what quantities. He then applies for a permit, which being issued, the lighters or chop-boats proceed to Whampoa, where they usually arrive on the evening of the second or morning of the third day. For a single boat the linguist used to receive a fee of \$23; but if a permit be obtained for from two to six boats at a time, the fee for each boat was only 11 taels 2 mace 6 cand., or about \$15.

When the goods are ready to be landed from or sent to the ship, the hoppo (principal custom-house officer) sends a domestic, a writer, and a police runner; the hong merchant who has secured the ship sends a domestic, called a court-going man (one who attends at the public offices on ordinary occasions in behalf of his master); and the linguist sends an accountant and interpreter to attend at the examination of the goods. The hong merchants used to be held responsible by government for all duties, whether on imports or exports in foreign vessels; and therefore, when goods were purchased, it was customary for the parties, before fixing the price, to arrange between themselves who was actually to pay the duties. Of an import cargo, each chop-boat, according to rule, which, however, is not rigidly enforced, should contain—of woollens, camlets, and long-ells, 140 bales; tin, 500 bars; lead, 600 pigs; Bombay cotton, 55 bales; Bengal cotton, 80 bales; betel-nut, pepper, etc., 300 piculs.

Of export goods, a chop-boat should take—of tea, 600 chests; of other sorts of goods, 500 piculs. If more than this, the hong merchant gives to the chop-boat, for each additional picul, \$64. In calculating the duties on export goods, 90 catties are considered 100. The woollens, long-ells, and camlets, are measured by the chang of 10 covids, without any deduction; and single articles are numbered.

If, after entering the port, any persons tranship goods, it is considered that the one ship sold them to the other; and in that case the same duty has to be paid as if the goods were brought up to Canton. Provisions are not included in this regulation. Ships' boats are not allowed to carry up or down any thing chargeable with duty. Gold, silver, copper, and iron are prohibited to be exported; a few culinary utensils are the only exceptions. When it is desired to export treasure, the hong merchant must make an estimate of the value of the import and export cargoes, and whatever balance there may be in favor of the ship may then be shipped off as treasure. If more cargo be sent to a ship than she can take on board, and she wishes it to be shipped on board another, it must be done within 3 days after announcing the goods at the

custom-house, and a hong merchant must state it to government; if granted, a hong merchant and linguist are ordered to go to Whampoa and take an account of each goods; all which, with the expense of boats, runners, etc., at Whampoa, costs 40 or 50 dollars.—*Companion to Anglo-Chinese Calendar*, p. 99-101.

Hong Merchants.—Previously to the commencement of the new system, it had been the invariable practice, enforced by law, that all foreign vessels arriving in the port should employ, as broker or agent, a hong or security merchant, who became, by doing so, responsible to the government for the duties. These merchants, who were but few in number, were the only individuals in the empire legally authorized to trade with foreigners, a privilege for which they had to pay very largely. But after an arrangement had been made with any particular hong merchant for securing a ship, her captain or supercargo might deal with any other hong merchant, or even with any outside merchant (or merchant not belonging to the hong); pleased. The peculiar duty of the hong merchant was to pay the duties on both the inward and outward cargoes; and hence arose the practice of foreigners buying all goods for export duty paid, and selling all the goods brought with them free of duty, the duties being, in both cases, paid by the hong merchants who had secured the ship; and hence, also, the ignorance of most foreigners as to the amount of the duties. But now that the privilege of the hong merchants has been abolished, the duties will have to be paid to the Chinese authorities by the parties importing and exporting, in the same way as in this country.

Port Charges are fixed under the new treaty at five mace per register ton, in full of all charges; so that the complex system that previously obtained for charging those duties is now, in so far at least as British ships are concerned, at an end. Vessels importing rice or other grain into any of the five ports open to British vessels, are liable to no charges whatever: but if they take away an export cargo, they then have to pay the duties on such cargo agreeably to the tariff, and one moiety of the tonnage dues, or 2½ mace per ton.

The whole number of vessels arriving at Canton in 1854 was 320, with the tonnage of 154,157. Of this number, 137 were British, 65 American, 23 Dutch, 21 Spanish, 11 Danish, and 18 Persian. The latter, we imagine, are all engaged in kidnapping, a system which condemns hundreds of Chinese to a speedy death among the guano islands of Callara. These vessels brought in the same year goods to the value of £795,255, constituting Canton a good, but not a first-rate customer to Europe. Of cotton goods our merchants purchased \$2,706,425; of rice, \$300,000 worth; and every thing else in infinitesimal quantity. Fish-maws, beche-de-mer, cloves, shark-fins, sandal-wood, liquors, appear to meet with the readiest sale in the great sea-port of China. The exports make a little better appearance; but still they are far from large. The tea trade has flown to Shanghai, the value exported from Canton being in 1854 only \$4,627,552, but a fraction of the export at the northern port. Silk is sold to the value of about \$1,140,000, and curiosities make up the remainder. Bamboo and rattan ware, bone and ivory toys, China dishes and lacquered ware, mother-of-pearl and marble slabs, preserves and drugs, sugar-candy and pitchera, all testify to the ingenuity of the Chinese, and the boundless opulence of certain classes in Europe and America. The whole amounts only to £1,445,308 a year, and this endures an exorbitant weight of taxation.

The tonnage paid by British ships alone amounted to £117,834, or nearly 10 per cent. *ad valorem* upon the whole movement of British trade in that port. The customs dues of Calcutta, heavy as we believe them to be, are a trifle when compared to those of Canton, which average very nearly 17 rupees a ton.—*Hong Kong Government Gazette*.

Foreign Merchants.—These consist of British, American, French, Dutch, Danish, Swedish, Spanish, and Portuguese, with Parsee and India Mohammedan British subjects. The Americans, French, and Dutch have each consular agents recognized by the imperial government. The same privileges have been, or are to be, conceded to all foreigners that have been granted to the English.

RATES OF COMMISSION IN CHINA, AGREED UPON IN NOVEMBER, 1861, AND REVISED BY THE CHAMBER OF COMMERCE, MARCH, 1868.

1. On all sales of opium, cotton, cochineal, camphor baros, birds' nests, diamonds, and other precious stones, pearls, ships, houses..... 8 per cent.
2. On sales of all other goods..... 5 per cent.
3. On returns, if in goods..... 2 1/2 per cent.
4. On returns, if in treasure, bullion, or bills..... 1 per cent.
5. On purchases, not being returns for goods sold:
 - 1st. Of raw silk..... 8 per cent.
 - 2d. Of manufactures..... 5 per cent.
 - 3d. Of all other goods..... 5 per cent.
6. On inspecting tows, whether for returns or otherwise, an additional charge of..... 1/2 per cent.
7. On sale, purchase, or shipment of bullion..... 1 per cent.
8. On drawing, sale, or negotiation of bills when not involving responsibility as drawer or indorser..... 1 per cent.
9. On drawing, sale, or negotiating of bills when guaranteed by the agent as drawer or indorser, and not covered by adequate security..... 2 1/2 per cent.
10. On purchasing bills, or effecting remittance by bills, of the agent or otherwise..... 1 per cent.
11. On negotiating loans or respondentia..... 2 per cent.
12. On guaranteeing bills, bonds, or other engagements..... 2 1/2 per cent.
13. On guaranteeing sales when especially required without including responsibility for remittances..... 2 1/2 per cent.
14. On guaranteeing both sales and remittance of proceeds..... 1 per cent.
15. On bills of exchange, returned protested..... 1 per cent.
16. On letters of credit for mercantile purposes..... 2 1/2 per cent.
17. On all advances of money for purposes of trade, whether the goods are consigned to the agent or not, and where a commission of 5 per cent. is charged..... 2 1/2 per cent.
18. On ordering goods or superintending the fulfillment of contracts, where no other commission is derived..... 2 1/2 per cent.
19. On all goods, treasure, etc., consigned, and afterward withdrawn or sent to auction, and for goods consigned for additional delivery to others..... 1/2 commission.
20. On procuring freight, or advertising as agents, or owners, or commanders, on the amount of freight, whether the same passes through the hands of the agent or not..... 5 per cent.
21. On receiving inward freight..... 1 per cent.
22. On ships' disbursements..... 2 1/2 per cent.
23. On chartering ships for other parties..... 2 1/2 per cent.
24. On effecting insurance, or writing orders for insurance..... 1/2 per cent.
25. Settling insurance losses, total or partial, and on procuring return of premium..... 1 per cent.
26. Debts, where a process at law or arbitration is necessary, 2 1/2 per cent. and if recovered..... 5 per cent.
27. Collecting house rent..... 2 1/2 per cent.
28. Acting for the estates of persons deceased, as executors or administrators..... 5 per cent.
29. The management of the estates of others, on the amount returned for liquidated, the agent..... 2 1/2 per cent.
30. All cash receipts, not serving for the purchase of goods, and not otherwise specified above..... 1 per cent.
31. Shroffing..... 2 per mill.
32. Transshipping goods..... 1 per cent.
33. All advances not particularly liquidated, the agent having the option of charging a second commission, as upon a fresh advance, provided the charge does not occur twice in the same year..... 1 per cent.
34. At the option of the agent, on the amount debited or credited within the year, including interest, and excepting only items on which a commission of 5 per cent. has been charged..... 1 per cent.

N.B.—This charge not to be applied to paying over a balance due on an account made up to a particular period, unless where such balance is withdrawn without reasonable notice.

Opium, which is by far the most profitable of all the articles imported into China, is excluded from the

official account of imports, which comprises those articles only that are legally admissible. Although, however, it be nominally excluded, opium is openly, systematically, and easily introduced; & the trade in it being, in fact, as safe and as regular as that in any other commodity, while it is incomparably more extensive. Notwithstanding the efforts that have sometimes been made to effect its exclusion, the imports have continued rapidly to increase. In 1816-17 they amounted to only 3210 chests, whereas in 1829-30 they had increased to about 14,000 chests; and they are now estimated at about 54,000 chests, worth about \$33,000,000. So rapid an increase in the production and consumption of a drug is, perhaps, unparalleled in the history of commerce. It is probable, however, that its importation will shortly receive a check; for it is believed that the Chinese, aware at last of the impotency of the attempts to prevent its introduction, are about to legalize its importation and culture in the empire. And as the soil in many parts of China is understood to be well suited to the growth of the poppy, there can be little doubt that its cultivation will be rapidly extended. Should this expectation be realized, it will produce a very important change in the trade of China. On the whole, however, we incline to think that the change will be beneficial. It will go far to restore the balance between the imports and exports without draining China of her bullion; and it will enable her to purchase larger quantities of the manufactures and other products of this and other countries. The change in question, supposing it to be realized, will, however, seriously affect India, which furnishes almost all the opium sent to China, and the culture and sale of which, besides affording employment and subsistence to a large population, yields a net revenue to the East India Company of considerably more than £3,000,000 a year!

Shanghai is situated in the southern part of the province of Kiang-Su, at a considerable distance from the sea, on the River Woo-Sung, in about lat. 31° 10' N., long. 120° 50' E. The river, which may be navigated by large ships for a considerable distance above the town, crosses the grand canal, and, consequently, makes Shanghai an *entrepôt* for all the vast and fertile countries traversed by the canal and by the great rivers with which it is connected; and hence the present importance of this emporium, as evinced by the extent of our trade with it in 1848; and hence, also, the infinitely greater importance to which its commerce will hereafter most probably attain.

EXPORTS OF TEA FROM CHINA.

	Black Tea.	Green Tea.	Total.
	Pounds.	Pounds.	Pounds.
To Great Britain, 1848-49.....	28,768,500	8,479,200	47,247,700
To Great Britain, 1849-50.....	35,848,900	8,120,400	53,969,300
To Great Britain, 1850-51.....	55,696,800	8,056,600	63,753,400
To United States, 1851-52.....	13,501,513	20,965,915	34,467,428

From this statement it will be seen that the amount of the exports of black tea to Great Britain is increasing very fast, at the rate of 20 per cent. per annum; and was in 1850-51 seven times as great as the exports of green tea; while the exports of black tea to the United States were only two-thirds the exports of green tea.

EXPORTS OF TEA FROM CHINA.

Year ending June.	United States.	Great Britain.
	Pounds.	Pounds.
1854.....	27,807,000	77,217,000
1855.....	31,515,000	86,509,000
1856.....	40,240,000	91,635,000

Trade with the Indian Islands, etc.—In his evidence before the select committee of the House of Commons, Mr. Crawford gave the following details with respect to the native foreign trade with China:

"The principal part of the junk or shipping trade is carried on by the four contiguous provinces of Canton, Fokien, Chekiang, and Kiamnan. No foreign trade is permitted with the island of Formosa; and I have no means of ascertaining the ex-

tent of the traffic which may be conducted between China, Cochin, and the Leeward Islands. The following are the countries with which China carries on a trade in junks: viz, Japan, the Philippines, the Soc-Joo Islands, Celebes, the Moluccas, Borneo, Java, Sumatra, Singapore, Hilo, the east coast of the Malayan peninsula, Siam, Cochin China, Cambodia, and Tonquin; and these may, in all, employ about 322 junks. The ports of China at which this trade is conducted are, Canton, Teho-tcheou, Nanking, Hock-tcheou, Suicheng, Kongsam, Changlin, and Hainan, in the province of Canton; Amoy and Chincheu, in the province of Fokien; Ningpo and Slang-hai, in the province of Chekiang; and Soucheou, in the province of Kiannan. The above estimate does not include a great number of small junks belonging to the island of Hainan, which carry on trade with Tonquin, Cochin China, Cambodia, Siam, and Singapore. Those for Siam amount yearly to about 50, and for the Cochin Chinese dominions to about 42; these alone would bring the total number of vessels carrying on a direct trade between China and foreign countries to 507. The trade with Japan is confined to the port of Ningpo, in Chekiang, and expressly limited to 10 vessels; but as the distance from Nankasak is a voyage of no more than four days, it is performed twice a year. With the exception of this branch of trade, the foreign intercourse of the two provinces, Chekiang and Kiannan, which are famous for the production of raw silk, teas, and nankeens, is confined to the Philippine Islands, Tonquin, Cochin China, Cambodia, and Siam; and none of this class of vessels, that I am aware of, have ever found their way to the western parts of the Indian Archipelago. The number of these trading with Siam is 24, all of considerable size; those trading with the Cochin Chinese dominions, 16, also of considerable size; and those trading with the Philippines, 5; making in all 45, of which the average burden does not fall short of 17,000 tons. Besides the junks now described, there is another numerous class, which may be denominated the colonial shipping of the Chinese. Wherever the Chinese are settled in any numbers, junks of this description are to be found: such as in Java, Sumatra, the Moluccas, Malacca, etc.; but the largest commerce of this description is conducted from the Cochin Chinese dominions, especially from Siam, where the number was estimated to amount to 200. Several junks of this description from the latter country come annually to Singapore, of which the burden is not less than from 300 to 600 tons. The junks which trade between China and the adjacent countries are some of their own and built in China; but a considerable number also in the latter countries, particularly in Siam and Cochin China. Of those carrying on the Siamese trade, indeed, no less than 81 out of the 89, of considerable size, were represented to me as being built and owned in Siam. The small junks, however, carrying on the trade of Hainan, are all built and owned in China. The junks, whether colonial or trading direct with China, vary in burden from 2000 piculs to 15,000, or they dead weight from 120 to 900 tons. Of those of the last size, I have only seen three or four, and these were at Siam, and the same which were commonly employed in carrying a mission and a tribute yearly from Siam to Canton. Of the whole of the large class of junks, I should think the average burden will not be exceeded at 500 tons each, which would make the total tonnage employed in the native foreign trade of China between 60,000 and 70,000 tons, exclusive of the small junks of Hainan, which, estimated at 150 tons each, would make in all about 80,000 tons.

The junks built in China are usually constructed of fir and other inferior woods. When they arrive in Cambodia, Siam, and the Malayan Islands, they commonly furnish themselves with masts, rudders, and wooden anchors, of the superior timber of those countries. The junks built in Siam are of a superior class of vessels, the planks and upper works being invariably teak. The cost of ship-building is highest at the port of Amoy, in Fokien, and lowest in Siam. At these places, and at Chang-lin, in Canton, the cost of a junk of 3000 piculs, or 476 tons burden, was stated to me, by several commanders of junks, to be as follows: at Siam, \$7400; Chang-lin, \$16,000; Amoy, \$21,000. A junk of the size just named has commonly a crew of 90 hands, consisting of the following officers, besides the crew: a commander, a pilot, an accountant, a captain of the helm, a captain of the anchor, and a captain of the hold. The commander receives no pay, but has the advantage of the cabin accommodation for passengers, reckoned on the voyage between Canton and Singapore worth 150 Spanish dollars. He is also the agent of the owners, and receives a commission, commonly of 10 per cent., on the profits of such share of the adventure, generally a very considerable one, in which they are concerned. The pilot receives for the voyage \$200 of wages, and 50 piculs of freight out and home. The helmsman has 15 piculs of freight and no wages. The captains of the anchor and the hold have 9 piculs of freight each; and the seamen 7

piculs each. None of these have any wages. The officers and seamen of the colonial junks are differently rewarded. In a Siamese junk, for example, trading between the Siamese capital and Singapore, of 6000 piculs burden, the commander and pilot had each \$100 for the voyage, with 12 piculs of freight apiece. The accountant and helmsman had half of this allowance, and each seaman had \$13, with 5 piculs of freight. In construction and outfit, Chinese junks are clumsy and awkward in the extreme. The Chinese are quite unacquainted with navigation, saving the knowledge of the compass; notwithstanding this, as their pilots are expert, their voyages short, and as they hardly ever sail except at the height of the monsoons, when a fair and steady 7 or 8 knots' breeze carries them directly from port to port, the sea risk is very small. During 13 years' acquaintance with this branch of trade, I can recollect hearing of but four ships wrecked; and in all these instances the crews were saved. The construction and rigging of a Chinese junk may be looked upon as her proper registry, and they are a very effectual one; for the least deviation from them would subject her at once to foreign charges and foreign duties, and to all kinds of suspicion. The colonial junks, which are of a more commodious form and outfit, if visiting China, are subjected to the same duties as foreign vessels. Junks built in Siam, or any other adjacent country, if constructed and fitted out after the customary model, are admitted to trade to China upon the same terms as those built and owned in the country. If any part of the crew consist of Siamese, Cochin Chinese, or other foreigners, the latter are admitted only at the port of Canton; and if found in any other part of China, would be seized and taken up by the police exactly in the same manner as if they were Europeans. The native trade of China conducted with foreign countries is not a clandestine commerce, unacknowledged by the Chinese law, but has in every case at least the express sanction of the emperor or governor of the province, who, on petition, decides the number of junks that shall be allowed to engage in it, and even enumerates the articles which it shall be legal to export and import. At every port, also, where such a foreign trade is sanctioned, there is a hong or body of security merchants, as at Canton; a fact which shows clearly enough that this institution is paced of the laws or customs of China, and not a peculiar restraint imposed upon the intercourse with Europeans. The Chinese junks properly constructed pay no import duty, and no customs or present duties, however, are paid upon goods exported and imported, which seem to differ at the different provinces. They are highest at Amoy, and lowest in the island of Hainan. The Chinese traders of Siam informed me that they carried on the richest and easiest trade, subject to the fewest restrictions, in the ports of Ningpo and Slang-hai, in Chekiang, and Soucheou, in Kiannan. Great dexterity seems every where to be exercised by the Chinese in evading the duties. One practice, which is very often followed, will afford a good example of this. The coasting-trade of China is nearly free from all duties and other imposts. The merchant takes advantage of this; and, intending in reality to proceed to Siam or Cochin China, for example, clears a junk out for the island of Hainan, and thus avoids the payment of duties. When she returns she will the four or five days of the month of the port, until a regular bargain be made with the custom-house officers for the reduction of duties. The threat held out in such cases is to proceed to another port, and thus deprive the public officers of their customary perquisites. I was assured of the frequency of this practice by Chinese merchants of Cochin China, as well as by several commanders of junks at Singapore. From the last-named persons I had another fact of some consequence, as connected with the Chinese trade; viz., that a good many of the junks carrying on trade with foreign ports to the westward of China often proceed on voyages to the northward in the same season. In this manner they stated that about 20 considerable junks, besides a great many small ones, proceeded annually from Canton to Soucheou, one of the capitals of Kiannan, and in wealth and commerce the rival of Canton, where they sold about 200 chests of opium at an advance of 50 per cent. beyond the Canton price. Another place where the Canton junks, to the number of five or six, repair annually, is Chincheu, in the province of Canton, within the Gulf of Pechey, or Yellow Sea, and as far north as the 37th degree of latitude. — *Appendix, Report of 1830, p. 298.*

A Chinese ship or junk is seldom the property of one individual. Sometimes 40, 50, or even 100 different merchants purchase a vessel, and divide her into as many different compartments as there are partners, so that each knows his own particular part of the ship, which he is at liberty to fit up and secure as he pleases. The hull-heads, by which these divisions are formed, consist of stout planks, so well caulked as to be com-

pletely water-tight. A ship thus formed may strike on a rock, and yet sustain no serious injury; a leak springing in one division of the hold will not be attended with any damage to articles placed in another; and, from her firmness, she is qualified to resist a more than ordinary shock. A considerable loss of stowage is, of course, sustained; but the Chinese exports generally contain a considerable value in small bulk. It is only the very largest class of junks that have so many owners; but even in the smallest class the number is very considerable.—See CHINA.

Canvas (Fr. *Toile à voile*; Ger. *Segeltuch*; It. *Canvazzo*, *Lona*; Russ. *Parusnoe polatno*, *Parusina*; Sp. *Lona*), unbleached cloth of hemp or flax, chiefly used for sails for shipping.

Caoutchouc. "This substance, which has been improperly termed elastic gum, and vulgarly, from its common application to rub out pencil marks on paper, *India rubber*, is obtained from the milky juice of different plants in hot countries. The chief of these are the *Jatropha elastica*, and *Ureola elastica*. The juice is applied in successive coatings on a mould of clay, and dried by the fire or in the sun; and when of a sufficient thickness, the mould is crushed and the pieces shaken out. Acids separate the caoutchouc from the thinner part of the juice at once, by coagulating it. The juice of old plants yields nearly two-thirds of its weight; that of younger plants less. Its color, when fresh, is yellowish-white, but it grows darker by exposure to the air. The elasticity of this substance is its most remarkable property; when warmed, as by immersion in hot water, slips of it may be drawn out to 7 or 8 times their original length, and will return to their former dimensions nearly. Cold renders it stiff and rigid, but warmth restores its original elasticity. Exposed to the fire, it softens, swells up, and burns with a bright flame. In Cayenne it is used to give light as a candle."—*Ure's Diet.* See INDIA RUBBER.

Caoutchouc has become an article of very considerable importance. M. de la Condamine, who was one of the first to communicate authentic information with respect to it, mentions that, owing to its being impervious to water, it was made into boots by the Indians.—*Journal de la Rivière des Amazones*, p. 76. It is now employed in a similar way here. Means have, within these few years, been discovered of reducing it to a state of solution; and when thin filaments of it are spread over cloth or any other substance, it is rendered impervious alike to air and water. Air-cushions and pillows are manufactured in this way; as are waterproof cloaks, now in very extensive demand, hats, boots, shoes, etc. It is also extensively used in the manufacture of braces and other articles which it is desirable should possess considerable elasticity; and there can be little doubt that it will be employed still more extensively, and in a still greater variety of ways.

The great variety of purposes to which its elasticity and imperviousness to water and to air have occasioned its application are too numerous and familiar to be particularized in this place. The extent of its employment in Britain in the several branches of manufacture is shown by the quantity of caoutchouc imported, which, for the year ending January 5, 1854, amounted to 17,326 cwt. The total quantity exported from Para alone, in 1852, was 32,860 cwt., and 116,465 pairs of shoes. The manufacture of caoutchouc, for the manufacture of elastic fabrics, such as cloth, cord, tape, braces, etc., is an important and increasing branch of our national industry. This operation has been made the subject of various patents, all modifications more or less perfect of our general principle, namely, that of reducing it to threads by means of steel edges acting either on the bottle caoutchouc compressed in a mould, on the solid eak, or by cutting it when stretched on a mandrel of wood, which is set in rapid revolution. In this operation water is allowed to trickle over the cutting blades in order to prevent the cohesion that would

otherwise impede their progress. In this manner thread of 5000 yards to a pound weight is produced. Previous to its employment in the manufacture of textile fabrics, it is necessary to render the thread inelastic, which is effected by winding it tightly on reels and allowing it to remain in that condition until nearly deprived of its elasticity—which is afterward restored by exposing it to the action of a heated smoothing-iron. Sheets are sometimes cut from the solid cake, and may likewise be obtained of any size, and of extreme tenacity, by spreading a solution in naphtha upon cloth previously sized, stripping it off when dry. The use of rollers, with a piece of cloth similarly prepared and superimposed on the varnished surface of the first, may also be employed in this operation.—E. D.

Cap. The Romans went for many ages without regular covering for the head, and hence the heads of all the ancient statues appear bare. But at one period the cap was a symbol of liberty, and when the Romans gave it to their slaves it entitled them to freedom. In Italy was sometimes used as a mark of infamy; the cap the Jews were distinguished by a yellow cap, and in France those who had been bankrupts were forever after obliged to wear a green cap. The general use of caps and hats is referred to the year 1449; the first seen in these parts of the world being at the entry of Charles VII. into Rouen, from which time they took the place of chaperons or hoods. A statute was passed that none should sell any hat above 20d. (40 cents) nor cap above 2s. 8d. (66 cents), 5 Henry VII., 1489.—*ILLUSTR.*

Cape Hatteras, a headland, North Carolina. Lat. 35° 15' 12" N., long. 75° 30' 54" W. The lighthouse was built in 1798 of brown sand-stone. The light is fixed, elevated 112 feet above the sea, and is visible for a distance of 17 nautical miles. Very dangerous shoals extend off from this point 10 nautical miles.

Cape Haytien, formerly *Cape François*, and *Cape Henry*, a sea-port town of the island of Hayti, on its north coast, 90 miles north of Port au Prince. Lat. 19° 40' N., long. 69° 54' W. Population probably from 12,000 to 16,000. Previously to the Haytian revolution it was a handsome city, and it still has some fine buildings, with a secure and tolerably defended harbor, and a considerable trade, chiefly with the United States, Great Britain, France, and Germany.

Cape Henlopen, Delaware, a headland on the south side of the entrance to Delaware Bay. Lat. 38° 46' 36" N., long. 75° 4' 42" W. The lighthouse shows a fixed white light elevated 170 feet above the sea, and is visible for a distance of 18½ nautical miles.

Cape Henry, Virginia, a headland on the south side of the entrance to Chesapeake Bay. Lat. 36° 55' 30" N., long. 76° 0' 12" W. The lighthouse, built in 1791, is the leading mark for vessels bound into Chesapeake Bay. It shows a fixed white light elevated 120 feet above the sea, and is visible for a distance of 18 nautical miles.

Cape of Good Hope, an important colony of Great Britain, occupying the south part of the peninsula of Africa, between lat. 29° 41' and 34° 51' S., and long. 17° 10' and 27° 32' E.; bounded on the south and east by the Indian Ocean, and on the west by the Atlantic Ocean, on the north by the countries of the Namaquas, Griquas, and other Hottentot tribes, and on the northeast by British Kaffraria. Length, west to east (Cape peninsula to Kelskamma River), 550 miles; average breadth, 250 miles. Area, estimated at 110,000 square miles. Population in 1850, 261,436, mostly Africans, Dutch, negroes, and a small number of Hottentots. The country is formed of a series of territories rising in successive stages from south to north. Bays, Helena, Table, False (the west part of which forms Simon's Bay), St. Sebastian, Mossel, Plettenberg, and Algoa. Streams are numerous but rapid, mostly dry in summer, and unfit for navigation; the

chief are, on the east and south coast, Keiskamma, Great Fish, Bushman, Sunday, Camtoos, and Breede; on the west, Berg and Elephant or Oliphant; and on the north, several small streams tributary to the Orange. The climate is mild and healthy, but very dry; rains irregular, often falling in torrents on the coast, but rare in the plains of the interior. Snow falls only in the mountains, and is not permanent, even on the most elevated. December and January are the warmest, and June and July the coldest months. Mean temperature at Cape Town—in summer, 58°-3; in winter, 76°-6 Fahrenheit. The greater number of diseases are unknown at the Cape; the most common are consumption and apoplexy. Few of the inhabitants attain an advanced age. Soil fertile where sufficiently watered, but the general appearance of the country is sterile and monotonous. The arid steppes or *Karoo* of the interior are destitute of trees, and covered with an ephemeral vegetation, only after heavy rains. The flora of the colony is of a peculiar character, comprising 1200 species, which, however, are more remarkable for the variety and beauty of their flowers than for their uses. The most valuable is the aloe, the produce of which has been exported in one year to the amount of \$12,000; a species of soda, found in the Karoo, is employed by the natives in the manufacture of soap, and canoes are made from the covering of the waxberry. European grains, and the fruits of temperate and tropical regions, have been successfully introduced. Corn is raised more than requisite for consumption, and the cultivation of the vine is an important source of wealth; a good white wine is produced in the interior, but only the small vineyard at the foot of Table Mountain produces the celebrated liqueur called *Constantia*. Cattle-rearing is the chief branch of rural industry; and the introduction of the Merino sheep has rendered the rural trade of the colony important. The value of produce of the colony exported in 1840 amounted to £359,517. The coasts abound with mackerel and herrings, and in 1842 the whale and seal fishery employed 144 boats. Some of the wild animals of Africa are still met with, but the larger species decrease in proportion as civilization extends. The lion, hyena, buffalo, hippopotamus, and zebra, are occasionally seen; the rhinoceros is rare, and the elephant is driven beyond the boundary. The ostrich and eagle are found in the mountains, and snakes are numerous. The commerce of the colony is extensive; the ports are Cape Town and Simon's Town in the west, and Fort Elizabeth in the east. Total value of exports in 1844, £350,735, of which £29,6217 were to the United Kingdom. Imports same year, £1,123,061. In 1845, 35 ships (3713 tons) and 307 men belonged to the colony; and in 1847, 791 ships (209,426 tons) entered, and 782 ships (205,618 tons) cleared from its ports. The colony consists of an east and a west province, and these are divided into 14 districts; viz., Cape Division and Stellenbosch in the southwest; Zwillingdam, George, Uitenhage, and Albany, on the south coast; Clanwilliam on the northwest; Worcester and Beaufort, Graaf Reynet, and Somerset in the interior; Ceresberg on the northeast; Cradock and Victoria on the east. The capitals have the same names as the districts, except Graham's Town, which is the capital of Albany, and Fredericksburg, of Victoria district. Stellenbosch is the chief wine, and Zwillingdam the principal corn-growing district; the others are mostly appropriated to grazing. Government is administered by a Parliament, composed of the governor, legislative Council of 16 members, and a House of Assembly of 46 members, elected for a term of five years. (*Salary of governor and commander-in-chief, £5000.*) The Dutch founded the colony at the Cape in 1648, which was taken by the British in 1795.—See CAPE TOWN.

The hoers or farmers of the Cape colony, descendants of the original Dutch settlers, have lost much of their ancestral industry and cleanliness; they are affect-

ionate in their family relations, and strict in religious observances, but prejudiced and illiterate. Education has been long neglected in the colony; the only institutions of importance were, till lately, the South African college, and the South African institution at Cape Town; but a comprehensive system, embracing primary and classical schools, was instituted by the government in 1839. In 1847 of the districts are missionary schools supported by the great Protestant societies. In 1842 there were 40 public and 102 private schools, attended by 2700 children. The colonial grants in the same year were, for educational purposes, £6021, and for religious purposes, distributed among the different sects, £10,481. Slavery was abolished in 1833. The English language is alone used in the courts of law, but the Dutch is also taught in the government schools. The money in use is exclusively British; and Dutch weights and measures are nearly superseded by the English. The peace of the colony is frequently interrupted by incursions of the Kaffers, and other savage tribes on the frontier.

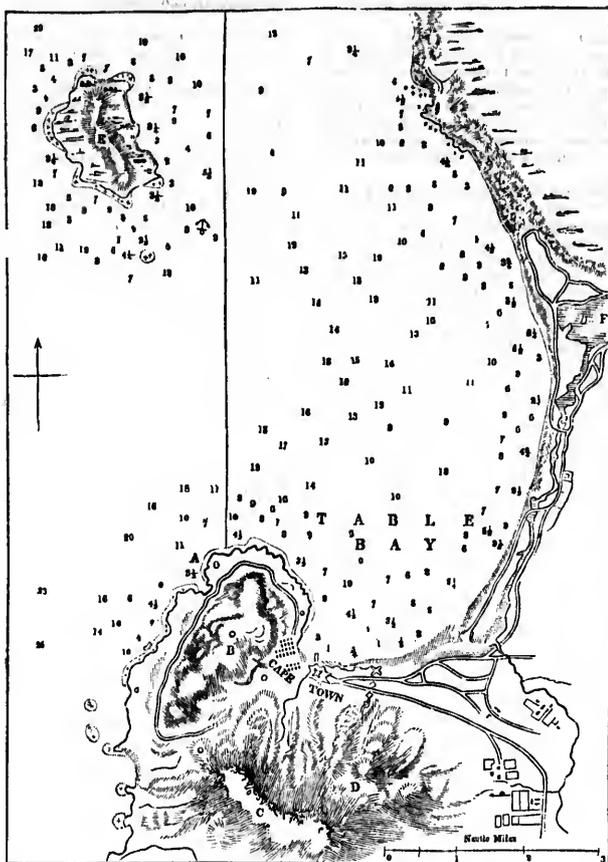

Capers (Fr. *Cappres*; Germ. *Kappern*; Du. *Kappers*; It. *Cappari*; Sp. *Acaparras*; Russ. *Kapersca*; Lat. *Capparis*), the pickled buds of the *Capparis spinosa*, a low shrub, generally growing out of the joints of old walls and the fissures of rocks, in most of the warm parts of Europe. Capers are imported from different parts of the Mediterranean; the best from Toulon, in France. Some small salt capers come from Majorca, and a few flat ones from the neighborhood of Lyons. In 1852, 117,067 pounds of capers were retained for consumption.

Cape Town, the capital of the British territory in South Africa, at the bottom of Table Bay, about 32 miles north from the Cape of Good Hope, and on the western side of the territory to which it gives its name; lat. 33° 55' 56" S., long. 18° 21' E. The town was founded by the Dutch in 1650; and remained, with the territory subject to it, in their possession till it was taken by the British in 1795. It was restored to the Dutch by the treaty of Amiens; but being again captured by the British in 1806, it was finally ceded to them in 1815. The streets are laid out in straight lines, crossing each other at right angles; many of them being watered by canals, and planted on each side with oaks. The population in 1842 amounted, according to the statement in the *Cape Almanac*, to 22,543, of whom about a third were blacks. The town is defended by a castle of considerable strength. Table Bay is capable of containing any number of ships; but it is exposed to the westerly winds, which, during the months of June, July, and August, throw in a heavy swell, that has been productive of many distressing accidents. This, in fact, is the great drawback upon Cape Town, which in all other respects is most admirably fitted for a commercial station. At the proper season, however, or during the prevalence of the easterly monsoon, Table Bay is perfectly safe; while the cheapness and abundance of provisions, the healthiness of the climate, and, above all, its position, render it a peculiarly desirable resting-place for ships bound to or from India, China, Australia, &c.

The plan of Table Bay on the opposite page is taken from the survey of the Cape of Good Hope, executed by Lieutenant Vidal and others, under the direction of Captain Owen.

Port Instructions.—Art. 1. On the arrival of merchant vessels in Table Bay, a proper berth will be pointed out to the masters thereof by the port captain when he boards them; and no master of a merchant vessel shall shift his berth without permission from the port captain, unless in case of extreme emergency, when he must report his having done so as early as possible at the port-office.

Art. 2. Should it be the intention of a master of a vessel to discharge or receive on board any considerable quantity of merchandise, a berth will be pointed

PLAN OF TABLE BAY. BY LIEUTENANT VIDAL, R. N.—See p. 268.

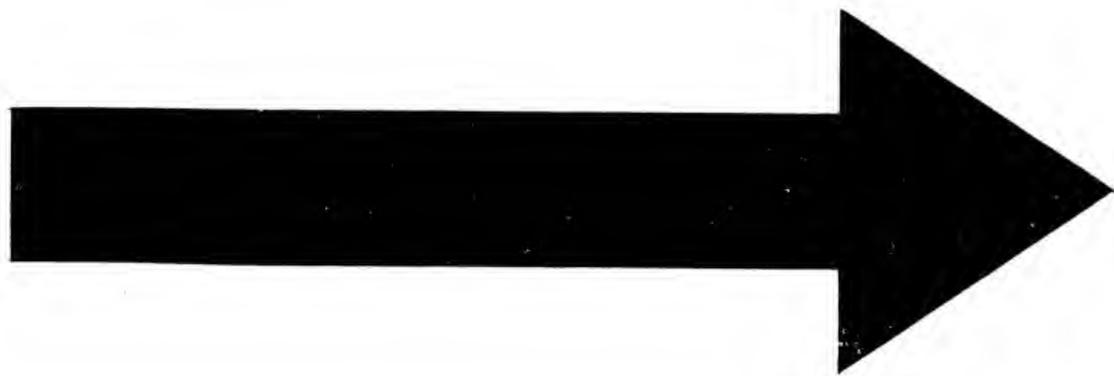

References to the Plan.—A, light-house, furnished with double lights. They may be seen clearly off deck at 10 miles' distance; but they do not appear double till within 6 or 7 miles to the westward; from the northward only one light is seen. B, Lion's Rump. C, Table Mountain. D, Devil's Peak, in lat. $35^{\circ} 57' 2''$. E, Robbin Island. F, Salt River. The figures denote the soundings in fathoms.

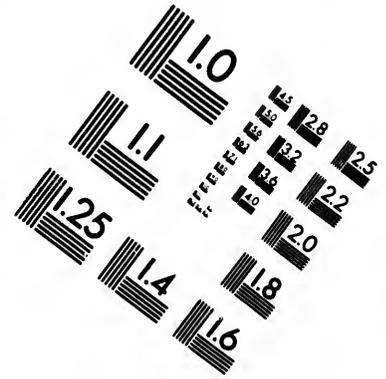

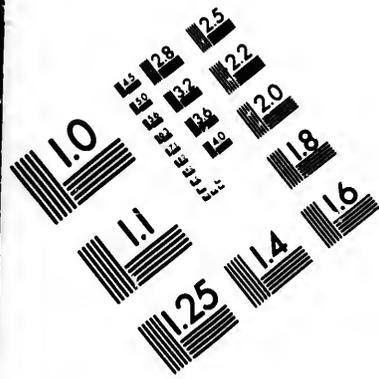

out to him as close to the jetty, or other landing-place, as the safety of the vessel and other circumstances will admit. And the master will then moor with two bower anchors, with an open hawse to the north-northeast, taking especial care, in so mooring, not to overlay the anchors of any other ship, or in any way to give the vessel near him a foul berth. Ships and vessels touching in Table Bay for water and refreshments alone may ride at single anchor in the outer anchorage; but in this case it is particularly recommended to veer out 80 or 90 fathoms, if they ride by a chain cable, as the liability of starting or fouling the anchor, or breaking the chain, will thereby be greatly lessened; and if riding by a rope or coir cable, to run out a stream or good kedg, to steady the ship; and in both cases the other bower anchor should be kept in perfect readiness to let go. When the vessel is properly moored with bower anchors, or well secured with a bower and stream anchor, and with good cables, buoys, and buoy-ropes, the master will then take the exact place of the ship

by the bearings of two landmarks, and the depth of the water; and should accident occur, by which the vessel may drift from this situation, or lose her anchors, a good bearing and depth of water must be taken at the time, and the same must be notified in writing to the port captain. It is particularly recommended that vessels be kept as snug as possible, to counteract the effects of the periodical winds, which at times blow with considerable violence.

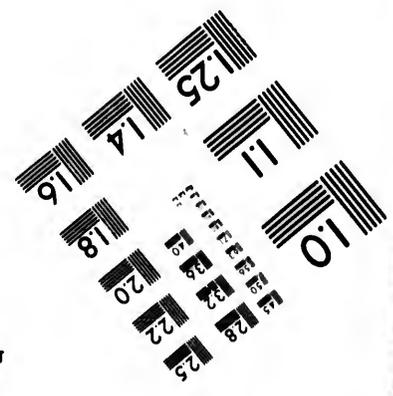

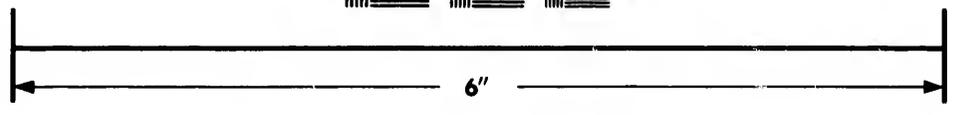

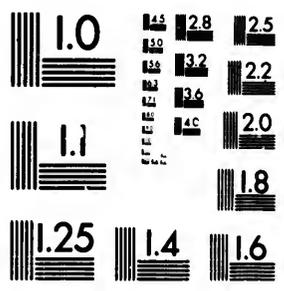

The district subject to Cape Town is of very great extent, and contains every variety of soil, from the richest level land to the wildest mountain, and tracts destitute of even the appearance of vegetation. The climate fluctuates between the two extremes of rain and drought. On the whole, its advantages and disadvantages seem to be pretty equally balanced; and the prospects which it holds out to the industrious emigrant, if not very alluring, are certainly not discouraging.

Population.—According to the official returns, the

population of the Cape Colony in 1847 consisted of 167,995.

Produce.—Large quantities of corn of a very good description are produced in the immediate neighborhood of Cape Town, and in other parts of the colony; but agriculture is crippled by the Dutch law of succession, which, by dividing a man's property equally among his children, hinders the accumulation of capital in masses, and the formation of proper farming establishments.—*THOMSON'S Travels in Southern Africa*, p. 824.

The Mauritius and Rio Janeiro are the principal markets for the corn of the Cape. The exports of wool have increased very rapidly within the last ten years, and it now forms by far the most important article sent from the colony. The native breed of sheep is very inferior; its fleeces is worth nothing, and it is remarkable only for the size of the tall, which sometimes weighs 20 lbs. ! But fine-wooled Spanish merinos, Saxon and English sheep, succeed remarkably well, and their wool fetches a high price. The eastern district of Albany is especially suitable for sheep.

Large quantities of wine, and of what is called brandy, are produced at the Cape; but, with the exception of Constantia, they are very inferior. The effect of allowing the importation of Cape wines into the United Kingdom at a comparatively low duty is, not to occasion their direct consumption, but to cause them to be employed as a convenient means of adulterating others; so that, besides being injurious to the revenue, such reduction of duty promotes fraud-

ulent practices, and detracts from the comforts of the public.

Considerable quantities of hides, skins, and horns are exported. They are principally brought from Algoa Bay, on the eastern side of the colony; and the trade has increased very fast during the last six or seven years. Aloes are an important product; and horses, butter, beef, ivory, argol, and various other articles, are among the exports. The latter also include dried fish, whale and seal oil, etc., the Cape fisheries being of considerable value.

The imports at the Cape consist of woollens, cottons, hardware, earthen-ware, furniture, haberdashery, soap, paper, books, and portions of most articles used in this country. Piece goods and teak timber are imported from India, tea from China, sugar from India, the Mauritius, etc.

Trade.—The trade between the colonists and the independent natives is subjected to various restraints, of which it is not always very easy to discover the policy. The sale of gunpowder and fire arms to the natives has been prohibited; a regulation which might have been a judicious one, had they not been able to obtain them from any one else. The Americans have, however, traded with the eastern coast, and have liberally supplied the natives with these and various other articles; so that by keeping up the regulation in question, the English exclude themselves from participating in what might be an advantageous trade. But since they have taken possession of Natal, this intercourse may perhaps have been stopped.

ACCOUNT OF THE QUANTITIES AND VALUES OF THE STAPLE ARTICLES, THE PRODUCE OF THE COLONY OF THE CAPE OF GOOD HOPE, EXPORTED IN THE YEAR ENDING 5TH JANUARY, 1847.

By an act passed by the colonial government of the Cape of Good Hope, it is provided, "That it shall be lawful for the proper officers of customs to deliver, from any of the bonded warehouses in this colony, any articles whatsoever duty warehoused

therein, being original packages as imported, to be shipped free from customs duty as stores for the use of any vessel, not being then on any voyage from any one port to any other port of this colony: such delivery and shipment shall be un-

of anchoring a ship during a calm, when out of soundings, to prevent her drifting when a strong current is running against her.

Supposing a ship of from 500 to 600 tons in a calm, with the current running three knots against her, and out of soundings; let go the kedg anchor, having previously secured two pieces of canvas to it as per figure, No. 1 and 2; veer out 40 to 50 fathoms of 3 to 4 inch hawser; then lower the quarter boat or cutter, and stop the above hawser to the ring in the bow and stern of the boat; then veer from the ship 70 to 80 fathoms on the hawser, between the boat and ship; put on a snatch-block to traverse, with one or two pigs of ballast, to be used according to the strength of the current.

Supposing that the current at from 40 to 50 fathoms deep is running in a different direction from that of the surface—as has been frequently observed in clear water at sea—it is plain that a great strain is taken off the anchor by using the boat, inasmuch as the whole strain would be on the hawser *b c*, the greater part of which is borne by hawser *a b*; that if the ship rode immediate at *b*, the whole of the strain being at *b c*, would naturally require a greater weight to hold her; in fact, a bower anchor with 60 fathoms of cable would not be sufficient, besides the difficulty of again recovering the anchor.

If the surface and deep current should happen to run in the same direction, the ship would not then separate from the boat; all would drift together. This plan for anchoring, there is every reason to suppose, will answer near the equator, or at any place at a distance from the main land, but it is not intended for a tide way.—E. B.

Captain (Fr. *capitaine*; It. *capitano*, from the Latin

caput), literally a head, or chief officer; but the term is used in particular to denote an officer holding a certain rank in the army or the navy.

In the army, a captain is the officer who commands a troop of cavalry, or a company of infantry, or of artillery. His full pay in British cavalry regiments is 14s. 7d. a day; in the infantry 11s. 7d. Captains in the Life and Foot Guards rank with the colonels of other regiments, and their full pay is 15s. a day. *Captain General*, the commander-in-chief of an army, or of the militia. *Captain Lieutenant* is an officer who, with the rank of captain, but the pay of Lieutenant, commands a troop or company in the name and place of some other person. Thus the colonel of a regiment being usually captain of the first company, that company is commanded by his deputy under the title of captain Lieutenant. *Captain of a ship of war*, the officer who commands a ship of the line or a frigate. Officers who command smaller vessels are called commanders. In ships of the line a commander is also appointed with the captain; the former is therefore second captain. The charge of a captain in the navy is very comprehensive, inasmuch as he is not only answerable for any bad conduct in the military government, navigation, and equipment of the ship he commands, but also for any neglect of duty or mismanagement on the part of his inferior officers, whose several charges he is appointed to superintend and regulate. *Captain of a merchant ship*, he who has the direction of the ship, crew, lading, &c.

Caracas, or **Caracacas**, the capital city of Venezuela, South America, department and province of Caracas, lat. $10^{\circ} 30' 18''$ N., long. $67^{\circ} 4' 45''$ W., on a declivity 2880 feet in elevation, and 16 miles south-southeast of La Guayra, its port, on the Caribbean Sea. Population estimated from 35,000 to 50,000. It is regularly built, well supplied with water, and has a healthy climate. Mean temperature of June 72° , February 68° – 2 Fahrenheit. Principal buildings, a cathedral, the fine church of Alta Gracia, and three hospitals. Exports from La Guayra consist principally of cacao, cotton, indigo, tobacco, coffee, hides, and live cattle. By the earthquake of 1812, 12,000 persons perished; since which time most of its houses have been constructed of sun-dried bricks. It is the seat of a university, and the residence of the principal merchants, on whose account the trade of La Guayra is conducted. It is the birth-place of Bolivar. The province lies between lat. $7^{\circ} 38'$ and $10^{\circ} 26'$ N., and long. $65^{\circ} 30'$ and 68° W. Area, 2842 square leagues. Population, 242,888. Surface partly mountainous and partly flat; the former toward the sea-coast, where several deep indentations occur, and form good harbors; the latter in the interior, and on the south, where the country stretches out into vast plains. It produces the best cacao, and all tropical fruits are grown in perfection. It is divided into 16 cantons.

Carat, the weight which expresses the degree of fineness of gold. The word is also written *caract*, *carrai*, *karract*, and *karrat*. Its origin is contested; but the most probable opinion is that of Kennet, who derives it from *caractea*, a term which anciently denoted any weight, and came afterward to be appropriated to that which expresses the fineness of gold and the gravity of diamonds. Carats are not real determinate

weights, but only imaginary. The whole mass, whatever be the weight, is conceived to be divided into twenty-four carats; and as many twenty-four parts as it contains of pure gold, it is called *gold of so many carats*, or *so many carats fine*. Thus, gold of eighteen carats is a mixture, of which eighteen parts are pure gold, and the other six of inferior metal. Carat is also a certain weight which goldsmiths and jewelers use for weighing precious stones and pearls. In this sense the word is supposed by some to be derived from the Greek *κεράσιον*, a fruit which in Latin is called *siliqua*, the *carob bean*, each of which may weigh above four grains of wheat; and hence the Latin *siliqua* has been used for the weight of four grains. This carat weighs four grains; but they are sometimes lighter than the grains of other weights. Each of these grains is subdivided into $\frac{1}{2}$, $\frac{1}{3}$, $\frac{1}{4}$, etc. See WEIGHTS and MEASURES.—E. B.

Caravan, an organized company of merchants, or pilgrims, or both, who associate together in many parts of Asia and Africa, that they may travel with greater security through the deserts and other places infested with robbers; or where the road is naturally dangerous. The word is derived from the Persian *keravan*, or *carvan*, a trader or dealer.—SHAW'S *Travels in the Levant*, p. 9, 4to ed.

Every caravan is under the command of a chief or aga (*caravan-bashi*), who has frequently at his disposal such a number of troops or forces as is deemed sufficient for its defense. When it is practicable, they encamp near wells or rivulets, and observe a regular discipline. Camels are used as a means of conveyance, almost uniformly, in preference to the horse or any other animal, on account of their wonderful patience of fatigue, eating little, and subsisting three or four days or more without water. There are generally few camels in a caravan than men.—See CAMEL.

The commercial intercourse of Eastern and African nations has been principally carried on, from the remotest period, by means of caravans. During antiquity, the products of India and China were conveyed either from Suez to Rhinocortura, or from Busorah, near the head of the Persian Gulf, by the Euphrates, to Babylon, and thence by Palmyra, in the Syrian desert, to the ports of Phœnicia, on the Mediterranean; where they were exchanged for the European productions in demand in the East. Sometimes, however, caravans set out directly from China, and, occupying about 250 days in the journey, arrived on the shores of the Levant, after traversing the whole extent of Asia.—GIBBON, vol. vii. p. 93. The formation of caravans is, in fact, the only way in which it has ever been possible to carry on any considerable internal commerce with Asia or Africa. The governments that have grown up in those continents have seldom been able, and seldom indeed have they attempted, to render travelling practicable or safe for individuals. The wandering tribes of Arabs have always infested the immense deserts by which they are intersected; and those only who are sufficiently powerful to protect themselves, or sufficiently rich to purchase an exemption from the predatory attacks of these freebooters, can expect to pass through territories subject to their incursions, without being exposed to the risk of robbery and murder.

Since the establishment of the Mohammedan faith, religious motives, conspiring with those of a less exalted character, have tended to augment the intercourse between different parts of the Eastern world.

The numerous camels of each caravan are loaded with those commodities of every country which are of easiest carriage and readiest sale. The holy city is crowded during the month of Dhuahajja, corresponding to the latter part of June and the beginning of July, not only with zealous devotees, but with opulent merchants. A fair or market is held in Mecca and its vicinity on the twelve days that the pilgrims

are allowed to remain in that city, which used to be one of the best frequented in the world, and continues to be well attended. "Few pilgrims," says Burckhardt, "except the mendicants, arrive without bringing some productions of their respective countries for sale; and this remark is applicable as well to the merchants, with whom commercial pursuits are the main object, as to those who are actuated by religious zeal; for, to the latter, the profits derived from selling a few articles at Mecca diminish, in some degree, the heavy expenses of the journey. The Moggrebyns (pilgrims from Morocco and the north coast of Africa) bring their red bonnets and woolen cloaks; the European Turks, shoes and alippers, hardware, embroidered stuffs, sweetmeats, amber, trinkets of European manufacture, knit silk purses, etc.; the Turks of Anatolia bring carpets, silks, and Angora shawls; the Persians, Cashmere shawls and large silk handkerchiefs; the Afghans, tooth-brushes, called *Mesonak Kattary*, made of the spongy boughs of a tree growing in Bokhara, beads of a yellow soap-stone, and plain coarse shawls manufactured in their own country; the Indians, the numerous productions of their rich and extensive region; the people of Yemen, snakes for the Persian pipes, sandals and various other works in leather; and the Africans bring various articles adapted to the slave-trade. The pilgrims are however, often disappointed in their expectations of gain; want of money makes them hastily sell their little adventures at the public auctions, and often obliges them to accept very low prices."—*Travels in Arabia*, vol. ii. p. 21.

The two principal caravans which yearly rendezvous at Mecca are those of Damascus and Cairo. The first is composed of pilgrims from Europe and Western Asia; the second of Mohammedans from all parts of Africa. The Syrian caravan is said by Burckhardt to be very well regulated. It is always accompanied by the pacha of Damascus, or one of his principal officers, who gives the signal for encamping and starting by firing a musket. On the route, a troop of horsemen ride in the front, and another in the rear to bring up the stragglers. The different parties of pilgrims, distinguished by their provinces or towns, keep close together. At night torches are lighted, and the daily distance is usually performed between three o'clock in the afternoon and an hour or two after sunrise on the following day. The Bedouins or Arabs, who carry provisions for the troops, travel by day only, and in advance of the caravans; the encampment of which they pass in the morning, and are overtaken in turn and passed by the caravan on the following night, at their own resting-places. The journey with these Bedouins is less fatiguing than with the great body of the caravan, as a regular night's rest is obtained; but their bad character deters most pilgrims from joining them.

At every watering-place on the route is a small castle and a large tank, at which the camels water. The castles are garrisoned by a few persons, who remain the whole year to guard the provisions deposited there. It is at these watering-places, which belong to the Bedouins, that the sheikhs of the tribe meet the caravan, and receive the accustomed tribute for allowing it to pass. Water is plentiful on the route; the stations are nowhere more distant than 11 or 12 hours' march; and in winter pools of rain-water are frequently found. Those pilgrims who can travel with a litter, or on comfortable camel-saddles, may sleep at night, and perform the journey with little inconvenience; but of those who, from poverty, or the desire of speedily acquiring a large sum of money, induce to follow the caravan on foot, or to hire themselves as servants, many die on the road from fatigue.—*Travels in Arabia*, vol. ii. p. 8-9. The caravan which sets out from Cairo for Mecca is not generally so large as that of Damascus; and its route along the shores of the Red Sea is more dangerous and fatiguing. But many of the African and Egyptian merchants and pilgrims sail from Suez, Cos-

seir, and other ports on the western shore of the Red Sea, for Djidda, whence the journey to Mecca is short and easy. The Persian caravan for Mecca sets out from Bagdad; but many of the Persian pilgrims are now in the habit of embarking at Bussorah, and coming to Djidda by sea. Caravans from Bagdad and Bussorah proceed to Aleppo, Damascus, and Diarbeker, laden with all sorts of Indian, Arabian, and Persian commodities; and large quantities of European goods, principally of English cottons, imported at Bussorah, are now distributed throughout all the eastern parts of the Turkish empire by the same means. The intercourse carried on in this way is, indeed, every day becoming of more importance.

The commerce carried on by caravans in the interior of Africa is widely extended, and of considerable value. Besides the great caravan which proceeds from Nubia to Cairo, and is joined by Mohammedan pilgrims from every part of Africa, there are caravans which have no object but commerce, which set out from Fea, Algiers, Tunis, Tripoli, and other states on the sea-coast, and penetrate far into the interior. Some of them take as many as 60 days to reach the place of their destination; and as their rate of traveling may be estimated at about 18 miles a day at an average, the extent of their journeys may easily be computed. As both the time of their outset and their route is known, they are met by the people of the countries through which they travel, who trade with them. Indian goods of every kind form a considerable article in this traffic; in exchange for which the chief commodity the inhabitants have to give is slaves. Three distinct caravans are employed in bringing slaves and other commodities from Central Africa to Calro. One of them comes direct from Mourzouk, the capital of Fezzan, across the Libyan desert; another from Senaar; and the third from Darfur. They do not arrive at stated periods, but after a greater or less interval, according to the success they have had in procuring slaves, ivory, gold dust, drugs, and such other articles as are fitted for the Egyptian markets. The Mourzouk caravan is said to be under the best regulations. It is generally about 50 days on its passage; and seldom consists of less than 100, or of more than 800, travelers. The caravans from Senaar and Darfur used formerly to be very irregular, and were sometimes not seen in Egypt for two or three years together; but since the occupation of the former by the troops of Mohammed Ali, the intercourse between it and Egypt has become comparatively frequent and regular. The number of slaves imported into Egypt by these caravans is said to amount at present to about 10,000 a year. The departure of a caravan from Darfur is looked upon as a most important event; it engages for a while the attention of the whole country, and even forms a kind of era.—BROWN'S *Travels in Africa*, 2d ed. p. 78. A caravan from Darfur is considered large if it has 2000 camels and 1000 slaves. Many of the Moorish pilgrims to Mecca cross the sea from Souakin and Massowah to the opposite coast of Arabia, and then travel by land to Mecca; and Burckhardt states, that of all the poor pilgrims who arrive in the Hedjaz, none bear a more respectable character for industry than those from Central Africa.

Caravans are distinguished into *heavy* and *light*. Camels loaded with from 500 to 750 lbs. form a heavy caravan; light caravans being the term applied to designate those formed of camels under a more moderate load, or perhaps only half loaded. The mean daily rate at which heavy caravans travel is about 18 miles, and that of light caravans 22 miles.

The safety of a caravan depends materially on the conduct of the *caravan-bachi*, or leader. Niebuhr says, that when the latter is intelligent and honest, and the traveler understands the language, and is accustomed to the Oriental method of traveling, an excursion through the desert is rarely either disagreeable or dan-

gerous. But it is not unusual for the Turkish pachas to realize considerable sums by selling the privilege of conducting caravans; and it is generally believed in the East that leaders so appointed, in order to indemnify themselves, not unfrequently arrange with the Arabian sheikhs as to the attack of the caravans, and share with them in the booty. At all events, a leader who has paid a large sum for the situation, even if he should be honest, must impose proportionally heavy charges on the association. Hence the best way in traveling with caravans is, to attach one's self to one conducted by an active and experienced merchant, who has a considerable property embarked in the expedition. With ordinary precaution, the danger is then very trifling. It would be easy, indeed, were there any thing like proper arrangements made by government, to render traveling by caravans, at least on all the great routes, abundantly secure.—NIEBUHR, *Voyage en Arabie*, tome ii. p. 194, ed. Amst. 1780.

No particular formalities are required in the formation of a caravan. Those that start at fixed periods are mostly under the control of government, by whom the leaders are appointed. But, generally speaking, any dealer is at liberty to form a company and make one. The individual in whose name it is raised is considered as the leader, or *caravan-bachi*; unless he appoint some one else in his place. When a number of merchants associate together in the design, they elect a chief, and appoint officers to decide whatever controversies may arise during the journey.—For further details with respect to caravans, see the *Modern Part of the Universal History*, vol. xiv. p. 214-243; ROBERTSON'S *Disquisition on Ancient India*, Note 54; REISS' *Cyclopedic*, art. *Caravan*, most of which is copied from Robertson, though without a single word of acknowledgment; BURCKHARDT'S *Travels in Arabia*, vol. ii. *passim*; UNQUIHANT on *Turkey and its Resources*, p. 137, 161, etc.

Caravanseraï, a large public building or inn appropriated for the reception and lodgment of the caravans. Though serving in lieu of inns, there is this radical difference between them—that, generally speaking, the traveler finds nothing in a caravanseraï for the use either of himself or his cattle. He must carry all his provisions and necessaries with him. They are chiefly built in dry, barren, desert places; and are mostly furnished with water brought from a great distance and at a vast expense. A well of water is, indeed, indispensable to a caravanseraï. Caravanserais are also numerous in cities; where they serve not only as inns, but as shops, warehouses, and even exchanges.

Caraway-seed (Fr. *Carvi*, *Cumin des prés*; Ger. *Keummel*, *Brodtkimmel*; It. *Carvi*), a small seed, of an oblong and slender figure, pointed at both ends, and thickest in the middle. It is the produce of a biennial plant (*Carum carvi*), with a taper root like a parsnip, but much smaller. It should be chosen large, new, of a good color, not dusty, and of a strong agreeable smell. It is principally used by confectioners. The stem rises from two to three feet in height, and produces numerous umbels of small whitish or reddish flowers; and each flower is succeeded by two single-seeded capsules, which are the caraway-seeds of commerce. These have a strong peculiar odor, with an aromatic bitter taste, and yield, on distillation, about 4 per cent. of a volatile oil, on which their properties depend.

Carboy, a large globular bottle of green glass, protected by wicker-work; used chiefly for holding acids and highly corrosive liquids. The average capacity of these bottles is 12 gallons.

Carbuncle (Ger. *Karfunkel*; Fr. *Escarbouille*; It. *Caroachio*; Sp. *Carbunculo*; Lat. *Carbunculus*), a precious stone of the ruby kind, of a very rich glowing blood-red color, highly esteemed by the ancients.—See RUBY.

Card (Fr. *Cardes*; Ger. *Karditschen*, *Karden*, *Wollkratzten*; It. *Cardis*; Russ. *Bardü*; Sp. *Cardae*), an in-

strament, or comb, for arranging or sorting the hairs of wool, cotton, etc. Cards are either fastened to a flat piece of wood, and wrought by the hand; or to a cylinder, wrought by machinery.—See PLAYING CARDS.

Cardamoms (Fr. *Cardamomes*; Ger. *Kardamom*; It. *Cardamomi*; Sp. *Kardimomos*; Hind. *Gujarati elach*), seed capsules produced by a plant, of which there are different species growing in India, Cochinchina, Siam, and Ceylon. The capsules are gathered as they ripen; and when dried in the sun, are fit for sale. The small capsules, or lesser cardamoms, are produced by a particular species of the plant, and are the most valuable. They should be chosen full, plump, and difficult to be broken; of a bright yellow color; a piercing smell; with an acrid, bitterish, though not very unpleasant taste; and particular care should be taken that they are properly dried. They are reckoned to keep best in a body, and are therefore packed in large chests, well jointed, pitched at the seams, and otherwise properly secured, as the least damp greatly reduces their value. The best cardamoms are brought from the Malabar coast. They are produced in the recesses of the mountains by felling trees, and afterward burning them; for wherever the ashes fall in the openings or fissures of the rocks, the cardamom plant naturally springs up. In Sonda, Balagat, and other places where cardamoms are planted, the fruit or berry is very inferior to that produced in the way now mentioned. The Malabar cardamom is described as a species of bulbous plant, growing 3 or 4 feet high. The growers are obliged to sell all their produce to the agents of government at prices fixed by the latter, varying from 550 to 700 rupees the candy of 600 lbs. avoirdupois; and it is stated that the contractor often puts an enhanced value on the coins with which he pays the mountaineers; or makes them take in exchange tobacco, cloths, salt, oil, betel-nut, and such necessary articles, at prices which are frequently, no doubt, estimated above their proper level. Such a system ought assuredly to be put an immediate end to. Not more than one hundredth part of the cardamoms raised in Malabar are used in the country. They are sent in large quantities to the ports on the Red Sea and the Persian Gulf to Sind, up the Indus, to Bengal, Bombay, etc. They form a universal ingredient in curries, pillaus, etc. The market price, at the places of exportation on the Malabar coast, varies from 800 to 1200 rupees the candy.—MILNUN'S *Orient. Commerce*, and the valuable evidence of T. H. Baber, Esq., before Parliament, 1830.

Cardinal Points, in *Cosmography*, are the four intersections of the horizon with the meridian and the prime vertical circle, or *North and South, East and West*. The cardinal points, therefore, coincide with the four cardinal regions of the heavens, and are 90° distant from each other. The intermediate points are called *collateral points*.

Cards, or Playing Cards (Du. *Kaarten, Speelkarden*; Fr. *Cartes à jouer*; Ger. *Karten, Spiel Karten*; It. *Carte da giuoco*; Russ. *Kartzi*; Sp. *Cartas, Naipes*; Sw. *Kort*), manufactured of pieces of paste-board, having various devices, and arranged in packs, generally of 32 pieces in a pack and used for playing numerous games.—See PLAYING CARDS.

Carreening (Fr. *ch Faire abbattre carrièr*), heaving a vessel down on one side, by applying a strong purchase to the masts, so that the vessel may be cleared from any filth that adheres to it by breaching. A *half carreen* takes place when it is not possible to come at the bottom of the ship, so that only half of it can be carreened.

Caribbean Sea, that part of the Atlantic Ocean lying between the coasts of Central and South America and the islands of Cuba, Hayti, Porto Rico, and the Leeward and Windward Islands.

Caribbee Islands, in its more extended sense, is applied to the whole of the West Indies; but strictly

it only comprehends that cluster of islands stretching from Porto Rico to the coast of South America, and known as the Leeward and Windward Islands.

Carline, or Caroline, a silver coin current at Naples, worth about 4d. sterling.

Carlines, or Carlines, in a ship, two pieces of timber ranging fore and aft from one beam to another directly over the keel. On these rest the ledges to which the planks of the deck are fixed. Carline knees are timbers lying athwart the ship, from the sides to the hatchway, and serving to sustain the deck.

Carmine (Ger. *Karmin*; Du. *Karmyn*; Fr. *Carmin*; It. *Carminio*; Lat. *Carminium*), a powder of a very beautiful red color, bordering upon purple, and used by painters in miniature. It is a species of lake, and is formed of finely pulverized cochineal. It is very high priced.

Carnelian. See AGATE.

Carpet, Carpets (Ger. *Teppiche*; Du. *Tappeten, Vloer-tappeten*; Fr. *Tapis*; It. *Tappeti*; Sp. *Alfombras, Alcatifas, Tapetes*; Russ. *Kovrû, Kilimi*), is supposed to be derived from Cairo (whence also the French *Cairas*, a Turkey carpet), and from the Latin *tapes*, tapestry, corresponding to the Italian *carpetta* and the Dutch *karpet*. It is legitimately applied to an article of manufacture used for covering the floors of chambers or spreading on the ground, although, while it was a novelty in Europe, tables also were covered with it. Carpets and rugs were manufactured at a very remote period in Egypt, India, and China; but those of Persia and Turkey are the most celebrated. They were originally used for sitting and reclining upon, as may still be observed in Eastern countries, where they constitute the entire furniture of the people. In Egypt they were first applied to religious purposes by the priests of Heliopolis, and were also used to garnish the palaces of the Pharaohs. It was also a custom of antiquity to place them under the couches of guests at banquets. Sardinian carpets are mentioned by Plato, the comic poet, as being disposed in this manner—"beneath the Ivory feet of purple-cushioned couches." The carpets of the Homeric age were generally white or plain cloths; but they were also sometimes produced with various colors and embroidered designs. At the supper of Iphicrates, purple carpets were spread on the floor; and at the magnificent banquet of Ptolemy Philadelphus (an account of which is given by Callixenus of Rhodes) we learn that underneath 200 golden couches "were strewed purple carpets of the finest wool, with the carpet pattern on both sides; and there were handsomely embroidered rugs, very beautifully elaborated with figures. Besides this," he adds, "thin Persian cloths covered all the centre space where the guests walked, having most accurate representations of animals embroidered on them."—*Athenæus*, v. 26. The Babylonians, who were very skillful in weaving cloths of divers colors (PLINY, viii. 48), delineated upon their carpets entire groups of human figures, together with such fabulous animals as the dragon, the sphinx, and the griffin. These were numbered among the luxuries of Heliogabalus. On the tomb of Cyrus was spread a purple Babylonian carpet, and another covered the bed whereon his body was placed.—ARRIAN, vi. 29. These carpets were exported in considerable quantities to Greece and Rome, where they were highly esteemed. Carthage was also noted by Hieronippus, Antiphanes, and others, for its magnificent carpets.

"Carpets were in use, at least in some kind, as early as the days of Amos, about 800 B.C.—Amos, ii. 8. Carpets were spread on the ground, on which persons sat who dwelt in tents; but when first used in houses, even in the East, we have no record. In the twelfth century carpets were articles of luxury; and in England, it is mentioned as an instance of Becket's splendid style of living, that his sumptuous apartments were every day in winter strewn with clean straw or hay; about A.D. 1160. The manufacture of woollen

carpets was introduced into France from Persia, in the reign of Henry IV., between 1589 and 1610. Some artisans who had quitted France in disgust went to England, and established the carpet manufacture about 1750. There, as with most nations, Persian and Turkey carpets, especially the former, are most prized. The famous Axminster, Wilton, and Kidderminster manufacture is the growth of the last hundred years. The manufacture of Kidderminster and Brussels carpets has much advanced within fifteen years, at Lowell, Massachusetts, and Thomsonville, Connecticut."—

HAYDN.

Sir J. Gardiner Wilkinson gives us an account of an ancient carpet-rug of Egyptian manufacture. "This rug," he tells us, "is made, like many cloths of the present day, with woollen threads on linen strings. In the centre is the figure of a boy in white, with a goose above, the hieroglyphic of a 'child,' upon a green ground, around which is a border composed of red and blue lines," etc.—*Manners and Customs of the Ancient Egyptians*, vol. iii. p. 141-2. He further informs us that there are in the Turin Museum some specimens of worked worsted upon linen, "in which the linen threads of the weft had been picked out, and colored worsted sewed on the warp." In these two examples we have evidence of the existence, at a very early time, of a system of tapestry-weaving. The ancient carpet manufacture of the Asiatic countries may resolve itself under the appellation of needle-work. Of this, the present process of carpet-weaving in Persia and Turkey, and the tapestry manufacture of France, may be considered as fitting examples. The tapestry, as is well known, consists of woollen or other threads sewed on the strings of the warp by means of small shuttle-needles. The Persian carpet is formed by knotting into the warp tuft after tuft of woollen yarn, over each row of which a woof shot is passed, the fingers being here employed instead of the shuttle-needles, as the fabric is of a coarser description. In both methods the principle is the same. Both are formed in looms of very simple construction, the warp threads are arranged in parallel order, whether upright or horizontal, and the fabric and pattern are produced by colored threads, hand-wrought upon the warp. This may be designated the hand-wrought or needle-work method, which only makes one stitch or loop at a time, in contradistinction to the machine-wrought process, the result of mechanical appliances, whereby a thousand stitches are effected at once. Herein lies the essential difference between the ancient and modern, the simple and complex carpet manufacture.

Persia.—In Persia there are entire tribes and families whose only occupation is that of carpet-weaving. These dispose of their productions at the bazars to native merchants, who remove them to Smyrna or Constantinople, where they meet with European purchasers. The trade in real Persian carpets is, however, very limited, owing to their small size. They are seldom larger than hearth-rugs, long and narrow. Very many of them, moreover, are considerably tarnished by exposure in bazars, if they have not indeed been already used. To render them more salable they are cleaned. This is done by cropping the surface, which in some cases is shaved quite close to the knot; hence a great proportion of those brought to this country have not their original richness and depth of pile. Felted carpets or *nurmas* are also made in Persia, but do not constitute an export commodity. Sir Henry Bethune, late Persian ambassador, had in his possession a very singular specimen of this felt carpeting, in which colored tufts of worsted had been inserted during the process of manufacture, producing a regular pattern when finished.

Turkey.—The greater part of those Turkey carpets imported into Western Europe are manufactured at Ushak or Ouchak, in the province of Aidin, about six days' journey from Smyrna, and rugs principally at

Kulah or Koula, an adjacent village. In the provinces of Hoodavendighlar, Adana, and Nish, numerous households are employed in their production, as also in the districts of Bozab, the city of Aleppo, and the villages of Trebizoud. Here and there, throughout Caramania, such carpets are also made. The Turcomans of Tripoli, the women of Candia, and the peasantry of Tunis and Algiers, are likewise engaged in their fabrication. In none of these places, however, does any large manufactory exist; the carpets are the work of families and households. These carpets are woven in one piece, and there is this notable peculiarity in their manufacture, that the same pattern is never again exactly reproduced; no two carpets are quite alike. The patterns are very remarkable, and their origin is unknown even to Mussulmans. The Turkey carpet pattern represents Inlaid jeweled work, which accords with Eastern tales of jewels and diamonds. If this were rightly understood, it would prevent such speculations as those of Mr. Redgrave in his Great Exhibition Report on Design, where he remarks, that "the Turkish carpets are generally designed with a flat border of flowers of the natural size, and with a centre of larger forms conventionalized in some cases even to the extent of obscuring the forms—a fault to be avoided." This is doubtless a very ingenious mode of accounting for the curious forms of a Turkey carpet; but these, however fantastic, are never obscured, nor are there any flowers, flat or otherwise, in the borders or elsewhere. The great beauty of these carpets lies in the equal balance of color, of dull neutral shades, somewhat sombre in effect.

India.—Generally throughout British India the carpet manufacture is carried on. At Benares and Moorshedabad are produced velvet carpets with gold embroidery. A very elaborate carpet, sent from Cashmere to the Great Exhibition by Maharajah Goolab Singh, was composed entirely of silk, and excited great admiration. In every square foot of this carpet, we are informed, there were at least 10,000 ties or knots. Silk embroidered hookah carpets are made at Lahore, Mooltan, Khyrpoor, Tanjore, and Bengal; cotton carpets, or *astrunjees* at Rungpore, Agra, and Sasseram; printed cotton carpets at Ahmedabad; printed floor-cloth at Meoltan. Woollen carpets are far more extensively manufactured; some of which come from Ellore, Mirzapore, and Goruckpore; but the principal manufacture is at Masulipatan, 292 miles north from Madras. There the capital and enterprise of Great Britain have lent their aid to the rather tardy movements of the natives, and this article is now in general demand. Of late years linen warp has been introduced instead of cotton, and the fabric is thereby much improved. The designs of the Indian carpets have more regularity than those of Turkey, and the colors are mostly warm negatives, enlivened with brilliant hues interspersed. For the introduction of Masulipatan carpets, as of many others, the English are indebted to the firm of Watson, Bell, & Co., whose Indian connection is the sole means of obtaining these beautiful fabrics.—E. B.

The total value of Persian, Turkey, and Indian carpets imported into England may be computed at about £20,000 per annum.

Oriental carpets were first introduced into Spain by the Moors; and at a later date the Venetians imported them into Italy, and supplied Western Europe with this luxurious manufacture. We have frequent mention of them during the Middle Ages, and their costliness and magnificence are celebrated in the illuminated pages of fabliaux and romances. They were spread in the presence-chambers of royalty, before the high altars of chapels and cathedrals, in the bowers of "ladies faire," and on the summer grass. Many articles of furniture were also covered with them—beds, couches, tables, and regal faldestols; but here it becomes difficult to distinguish between carpet and tap-

estry.

stry, both being used promiscuously. Tapestry of Baldekine or Baldachine (from Baldak, ancient name of Bagdad), was a carpet inwrought with gold and silver threads. Such were carried on poles, and uplifted as a canopy over the host, and over great personages in procession. The troubadours had carpets of gold embroidery which they laid upon the grass beneath them. Hearth-rugs and throne carpets, gorgeously emblazoned with heraldic centre-pieces, were the handiwork of high-born dames during the romance period. To some of these were attached fringes, but such were more usually composed of the fag-ends of the warp, like those of Persia, India, and Turkey. A black velvet carpet, "fringed with silver and gold, and lined with taffeta," is enumerated in the inventory of Archbishop Parke's household furniture in 1577. Rushes were strewn on the floor of Queen Mary's presence-chamber, and that of Elizabeth had the additional covering of a Turkey carpet. Long prior to this, however, Eastern carpets had been introduced. In the reign of Edward VI. we read that before communion-tables were placed

"Carpets full gay,
That wrought were in the Orient."

Checked matting appears to have been very generally used about the fifteenth century. The same article is produced in many parts of Asia from the grassy fibres of the ratan. A superior description is now made from cocoa-nut fibre and Manilla flax. In Lydgate's metrical life of St. Edmund (MS. Harl. No. 2278) is a representation of the room wherein that saint was born; the floor is covered with checked matting, and a fringed hearth-rug of Gothic design is before the fire-place. Carpets composed entirely of leather strips interlaced together may be seen in our antiquarian museums. A sample of this description was lately prepared for the inspection of the new houses of Parliament, and offered as a covering for their halls and passages, but was rejected.

France.—In the reign of Henry IV. the carpet manufacture appears to have been introduced from Persia into France. Colbert, the minister of Louis XIV., established the manufactory at Beauvais in 1664, which is now in the hands of the French government, and produces very artistic specimens. A variety of these, "in Turkish, Peruvian, and Chinese styles," was exhibited in London in 1851. The national manufactory of Gobelins, which likewise sent its beautiful carpets and tapestry to the great exhibition, was established shortly after that of Beauvais. It was purchased in 1677 by Colbert from the Gobelins family, whose progenitors, a century ago (Gilles and Jean Gobelins), brought their art, as was supposed, from Flanders. An attempt was made, in the time of Henry VIII., by William Sheldon, to start this manufacture in England; but under the patronage of James I. it was more successfully established, with the superintendence of Sir Francis Crane, at Mortlake, in Surrey, where both carpets and tapestry were produced. Toward this object the sum of £2676 sterling was contributed by its royal patron, and French weavers were brought over to assist. But it does not appear that any thing considerable was effected until after the revocation of the edict of Nantes in 1685, when artisans of every trade fled to England, among whom were tapestry and carpet weavers, who settled in various parts. About the year 1750, Mr. Moore was awarded a premium by the Society of Arts for the best imitation Turkey carpets; and Parisot conducted an establishment for their manufacture at Paddington, under the patronage of the Duke of Cumberland. Subsequently, carpets were wrought on the same principle at Axminster, in Devonshire, whence the name; and afterward at Wilton, where they are still manufactured. The board of trustees for the encouragement of arts and manufactures in Scotland offered prizes for the best Persian and Turkey carpets. About ninety

years previously they had been made in the vicinity of Holyrood Palace. These expensive and magnificent carpets are now made in many parts of Europe, but more particularly at the Gobelins manufactory, at Aubusson and Felletin, in the department of Creuse, at the manufactory royal de tapis de tournal in Belgium, and at Deventer in the Netherlands. They are also made in London and Kidderminster.

Hitherto we have been treating of the simple hand-wrought or needle-work process, which implies great expense and waste of time and labor, and is therefore not calculated to supply a general demand. The machine-wrought fabric now claims our attention; and first in order, the common ingrain, Kidderminster, or Scotch carpet, which is made in many parts of Scotland, the north of England, and in the United States. This consists of worsted warp traversed by woolen weft, and is woven in pieces about a yard wide. It is composed of two distinct webs interlaced together at one operation, and is therefore a double or two-ply carpet, similar on either side. In this article only two colors can with propriety be introduced, as otherwise it has a striped or mixed appearance. A pure or plain color can only be obtained where the weft traverses the warp of the same color. Suppose a crimson figure on a maroon ground; the one web is maroon, the other is crimson, and the pattern is produced by these intersecting and decussating each other at points predetermined; thus what is crimson on one side is maroon on the other, and *vice versa*. One beam contains the warp of both plies, arranged in two tiers, which is passed through the *mails* or metallic eyes of the harness—two threads through each eye—and thence through the reed. The harness draws up certain warp threads, to admit of the passage of the shuttle with the weft, the pattern depending upon such warp threads as are so drawn up. This was formerly effected by means of a revolving barrel, whose surface was studded with pins, which by rotation acted upon the warp threads. These studs being arranged so as to produce one pattern, a separate barrel, or a new arrangement of the studs, was requisite for every other pattern. But this machine is now superseded by the more efficient Jacquard apparatus, which produces the pattern by means of an endless chain of perforated cards working against parallel rows of needles. This double fabric is also made in France, and aprigs of divers colors inserted. A detailed account of this process, with elaborate diagrams, is given by M. Roland de la Platière, in the *Encyclopédie Méthodique*. An improvement upon the Kidderminster carpet is the triple or three-ply fabric, the invention of Mr. Thomas Morton, of Kilmarnock. This is composed of three distinct webs, which, by interchanging their threads, produce the pattern on both sides. A variety of color is thus obtained, and the texture is of great thickness and durability. Figured Venetian carpeting is of similar description; here the wool is completely covered by a heavy body of warp. Dutch carpeting is much inferior in quality, and was originally made of cow-hair, but now of the coarsest wool. Neither fabric has great capabilities of design; simple diced patterns are wrought in the Venetian, stripes and checkers in the Dutch.

The Brussels carpet is a very superior texture. It is composed of worsted and linen, and has a rich corded appearance. The figures are raised entirely from the warp, by inserting a series of wires between the linen foundation and the superficial yarn. These wires are afterward withdrawn, leaving a looped surface. In this manufacture there is a great waste of material, and the colors are usually limited to five. Each color has its continuous layer of thread, running from end to end of the web, which rises to the surface at intervals indicated by the design, and then sinks into the body of the fabric. Thus there are five layers or covers, only a fifth part of which is visible; and owing to the irregularity of their ascent to the surface, they can

not be placed upon one beam, but each thread is wound on a separate bobbin, with a weight attached to give a proper tension. These bobbins are arranged in five frames jutting out behind the loom, two hundred and sixty bobbins in each frame for the ordinary width. Additional frames are requisite for additional colors introduced; but where more than five are engaged the pattern is rather indistinct. The threads of all the bobbins are then drawn through the harness, heddles, and reed, to unite with the linen yarn in the compound fabric, the Jacquard machine being employed to produce the pattern. Brussels carpets were first introduced into Wilton about a century ago, from Tournai, in Belgium. Kidderminster is now the chief seat of this manufacture, where upward of 2000 looms are in operation.

Moquette or Wilton carpets are woven in the same manner, and differ only in this, that the loops are cut open into an elastic velvet pile. To effect this, the wires are not circular as in the Brussels fabric, but flat, and furnished with a groove in the upper edge, whereas in the sharp point of a knife is inserted and drawn across the yarn, cutting the pile. These carpets, besides being manufactured in many parts of England and Scotland, are also made in France.

Recent Improvements.—We now proceed to describe a very ingenious improvement in this branch of carpet manufacture, the invention of Mr. Richard Whytock, of Edinburgh. This is a combination of the arts of printing and weaving, at the same time simplifying both. These arts may be said to be combined when any *worsted fabric is printed*; but here the process is reversed, the threads being printed before they are in cloth. This, to be sure, is the case when warps are printed and then woven; but the grand novelty of this invention is that the *threads are printed before even the warp is formed*. One thread, or two treated as one, in some cases miles in length, are colored by steps of half an inch, faster than a swift runner would make the distance. When these threads have been all part-colored in this manner, they form the elements, as it were, of the intended design or fabric. Singly, they exhibit no regular figure or pattern; but when arranged in their proper order, ready for the weaver's beam, the figure comes into view, much elongated of course, inasmuch as eighteen feet of the warp will sometimes be gathered into four feet of cloth, in order to secure the due proportions of the intended object. It has been said that the two combined arts of printing and weaving are simplified by this contrivance. With regard to the weaving: *First*, The loom occupies only one-third of the space in length that the Brussels loom requires. *Second*, The latter must have 1300 little beams or bobbins, from which the worsted pile has to be gathered; whereas this loom requires only one beam for the whole of the worsted threads. *Third*, While the Brussels or Wilton, on a web of twenty-seven inches, requires for the best fabric 2800 threads, only 700 are here requisite—one layer instead of five—to produce as good or a better surface. *Lastly*, While the number of colors in succession lengthwise, on the old principle, must not exceed six or seven, upward of twenty or thirty can be introduced by the new method. Then, again, as a simplification of the printing process: whereas formerly a change of blocks was required for every change of pattern, in this new process the same blocks serve for all patterns, as the pen serves for every form of type. Many of these manufacturers who are now availing themselves of this invention do not see wherein its true economy consists. If an object, say a rosebud, recurs a thousand times in the length of a web, at intervals of four feet, the block printer must apply his block a thousand times to point the opening bud; but here the buds are congregated, so that one stroke may dye them all. If it be desired to have a thousand buds in the length of the web, let a thread be wound round a hollow cylinder a thousand times, and a trav-

ersing wheel charged with color be passed across the coil. The threads, when uncolored, will be found to be marked in a thousand places, exactly where it is wanted to tip the opening bud with red from end to end of the web. Design-paper, whereon the pattern is indicated in small squares, serves as a guide to the printer; each square being one stroke of the color-pulley. After the threads are thus streaked across with color, they are removed from the cylinder or drum, and the dyes are fixed by the action of steam. The threads are then arranged in setting-frames, according to the squares of the design-paper, to constitute the warp of the projected web. The Jacquard is now so far at a discount, and the loom restored to nearly the same simplicity as of old, when

"Between two trees the web was hung."

The principle here referred to is only in its infancy. The works of the first masters may yet be multiplied by this process, if they will condescend to furnish the cartoons. Already flowers are produced which the botanist can classify without mistake.

Like every other improvement, this invention met with considerable opposition, particularly on the part of manufacturers and dealers. During the first fourteen years, the number of looms employed gradually increased from one to fifty-six, the greatest number in operation at Lasswade in 1847. Now, so extensive is the manufacture in England, that one house produces to the extent of half a million sterling per annum, having upward of three hundred looms at work by steam-power. It is gratifying to learn that these power-looms, instead of throwing out of employment, engage more operatives with better wages and easier work. Messrs. Henderson and Widnell of Lasswade, John Crossley and Sons of Halifax, Pardee, Hoomans, and Pardee of Kidderminster, and Sutherland and Ted of Lanark, are the principal manufacturers engaged upon this patent. An extraordinary consequence upon the introduction of this article is that it has not interfered with other branches of the carpet manufacture, not one of which appears to have been diminished. There is, therefore, an addition to the trade of the country, to the whole amount of its produce, itself no mean result; the whole trade being at least doubled, as far as fine carpets are concerned. Whytock's carpets are known under the designation of Patent Tapestry and Velvet Pile Carpets. Rugs, table-covers, fine velvets, and tapestry hangings, are wrought on the same principle.

Another great improvement in carpet-making, which originated also in Scotland, was patented by Mr. James Templeton, of Glasgow. It is on the chenille principle, and consists of a process of double weaving. First a thin striped fabric is made; and this, when cut up, is again woven into a denser fabric for carpets, rugs, and table-covers. The chenille stripes, like the parti-colored threads in Whytock's invention, form the elements of the second fabric, only these elements go to compose the woof instead of the warp, as in the former case. Extremely beautiful carpets have been made on this principle, and these being woven in large squares, have interested much with the Tournai or Axminster carpets, having the same depth of pile, without being so expensive. Hitherto, however, the manufacture has been confined to the place where it originated.

Patent wool mosaic is another novelty. This manufacture was introduced into England from Germany. It is produced by cementing with caoutchouc a close velvet pile on a plain cloth. Messrs. John Crossley and Sons of Halifax have brought out some admirable specimens of this mosaic-work, in carpets, rugs, and hangings for walls; but as yet this method has been more extensively applied to the manufacture of small articles. A very cheap description of carpet is now made near Manchester. It is first woven in plain colors by steam-power, under Seivier's patent, by Bright & Co. It is then printed with colored blocks by machinery patented by Burch & Co. This article has a

large export sale. The carpet manufacture is rapidly increasing in Great Britain. Upward of 6000 looms, it is computed, are now in operation, upon every description.

It remains to speak of carpet design. This matter is regulated by prevailing fashion and caprice, under the ever-varying semblance of good taste. There are revolutions in decorative art as in all things else, and in these carpet design is involved. An acute observer can discover here symptomatic indications of national or individual character. The supremacy of Gothic architecture, in our day, implies the revival of mediæval art. Simple ornamental designs, in quiet and subdued coloring, are now about to take the place of their

more brilliant predecessors. Many colors will only be tolerated in Moorish and Arabesque ornament, or in the *bisarra* Turkey carpet.—E. B.

The production of carpets is carried on extensively in the United States, especially in Massachusetts, Rhode Island, Connecticut, New York, and New Jersey. In Massachusetts alone, in 1850, the capital invested in this branch of business amounted to \$2,264,000, and the annual product about \$1,400,000, in which 1600 persons were employed. Our manufacture of carpets is increasing, and will probably equal the demand when the production of wool shall supply the wants of our manufacturers. Of the imports into this country fully nine-tenths came from Great Britain.

IMPORTS OF CARPETS INTO THE UNITED STATES.

The duty on carpets and carpeting, and carpet-bags and oil-cloth imported into the United States is 30 per cent. *ad valorem*. On straw matting, worsted carpet-bags, and carpet binding, 25 per cent.

Carriages. The invention of them is ascribed to Erichonius of Athens, who produced the first chariot about 1486, B.C. Carriages were known in France in the reign of Henry II. A.D. 1547; but they were of very rude construction, and rare. They seem to have been known in England in 1553; but not the art of making them. Close carriages of good workmanship began to be used by persons of the highest quality at the close of the sixteenth century. Henry IV. had one, but without straps or springs. Their construction was various; they were first made in England in the reign of Elizabeth, and were then called whirlicotes. The Duke of Buckingham, in 1619, drove six horses; and the Duke of Northumberland, in rivalry, drove eight. They were first let for hire in Paris, in 1650, at the Hôtel Flacré; and hence their name.—HAYDN. Premiums at the World's Fair held in London were given to the makers of carriages in the United States, as they were superior in lightness and strength, with an equal finish. New York carriages are very celebrated.

Carriers are persons undertaking for hire to carry goods from one place to another. Proprietors of carts and wagons, masters and owners of ships, hoymen, lightermen, bargemen, ferry-men, etc., are denominated common carriers. The master of a stage-coach who only carries passengers for hire is not liable for goods; but if he undertake to carry goods and passengers, then he is liable for both as a common carrier. The post-master-general is not a carrier in the common acceptation of the term, nor is he subjected to his liabilities.

Duties and Liabilities of Carriers.—Carriers are bound to receive and carry the goods of all persons for a reasonable hire or reward; to take proper care of them in their passage; to deliver them safely, and in the same condition as when they were received (excepting only such losses as may arise from the act of God); or, in default thereof, to make compensation to the owner for whatever loss or damage the goods may have received while in their custody, that might have been prevented. Hence a carrier is liable, though he be robbed of the goods or they be taken from him by irresistible force; and though this may seem a hard rule, yet it is the only one that could be safely adopted; for if a carrier were not liable for losses unless it could be shown that he had conducted himself dishonestly or negligently, a door would be opened for every species of fraud and collusion, inasmuch as it would be impossible, in most cases, to ascertain whether the facts were such as the carrier represented. On the same principle a carrier has been held accountable for goods accidentally consumed by fire while in his warehouse. In delivering the opinion of the Court of

King's Bench on a case of this sort, Lord Mansfield said: "A carrier, by the nature of his contract, obliges himself to use all due care and diligence, and is answerable for any neglect. But there is something more imposed upon him by custom, that is, by the common law. A common carrier is in the nature of an insurer. All the cases show him to be so. This makes him liable for every thing except the act of God and the king's enemies; that is, even for inevitable accidents, with these exceptions. The question then is, *What is the act of God?* I consider it to be laid down in opposition to the act of man; such as lightning, storms, tempests, and the like, which could not happen by any human intervention. To prevent litigation and collusion, the law presumes negligence except in those circumstances. An armed force, though ever so great and irresistible, does not excuse; the reason is, for fear it may give room for collusion, which can never happen with respect to the act of God. We all, therefore, are of opinion that there should be judgment for the plaintiff."—*Forward v. Pittard*, 1 T. R. 27. A carrier is not obliged to have a new carriage for every journey; it is sufficient if he provide one that, without any extraordinary accident, may be fairly presumed capable of performing the journey. A carrier may be discharged from his liability by any fraud or concealment on the part of the individual employing him, or of the bailer; as if the latter represent a parcel as containing things of little or no value, when, in fact, it contains things of great value. But when the carrier has not given a notice limiting his responsibility, and when he puts no questions with respect to the parcel to the bailer, the latter need not say any thing with respect to it; and though the bailer should represent the thing delivered to the carrier as of no value, yet, if the latter know it to be otherwise, he will be responsible in the event of its being lost or damaged. If the bailer deliver goods imperfectly packed, and the carrier does not perceive it, he is not liable in the event of a loss occurring; but if the defect in the package were such that the carrier could not but perceive it, he would be liable. On this principle a carrier was made to answer for the loss of a greyhound that had been improperly secured when given to him. A carrier may refuse to admit goods into his warehouse at an unreasonable time, or before he is ready to take his journey; but he can not refuse to do the ordinary duties incumbent on a person in his situation. It is felony if a carrier open a parcel and take goods out of it with intent to steal them; and it has been decided that if goods be delivered to a carrier to be carried to a specified place, and he carry them to a different

place, and dispose of them for his own profit, he is guilty of felony; but the embezzlement of goods by a carrier without a felonious taking merely exposes to a civil action.

A carrier is always, unless there be an express agreement to the contrary, entitled to a reward for his care and trouble. In some cases his reward is regulated by the Legislature, and in others by a special stipulation between the parties; but though there be no legislative provision or express agreement, he can not claim more than a reasonable compensation.

Commencement and Termination of Liability.—A carrier's liability commences from the time the goods are actually delivered to him in the character of carrier. A delivery to a carrier's servant is a delivery to himself, and he will be responsible. The delivery of goods at an inn yard or warehouse, at which other carriers put up, is not a delivery so as to charge a carrier, unless a special notice be given him of their having been so delivered, or some previous intimation to that effect.

"In New York it was held that placing goods on the wharf without notice to the consignee is not a delivery to the consignee, so as to discharge the carrier, even though there was a usage to deliver goods in that manner. The carrier must not leave or abandon the goods on the wharf, even though there be an inability or refusal of the consignee to receive them."—*KENT'S Commentaries*.

A carrier's liability ceases when he vests the property committed to his charge in the hands of the consignee or his agents, by actual delivery; or when the property is resumed by the consigner, in pursuance of his right of stopping it *in transitu*. It is in all cases the duty of the carrier to deliver the goods. The leaving goods at an inn is not a sufficient delivery. The rule in such cases, in deciding upon the carrier's liability, is to consider whether any thing remains to be done by the carrier, as such; and if nothing remains to be done, his liability ceases, and conversely.

A carrier has a lien upon goods for his hire. Even if the goods be stolen, the rightful owner is not to have them without paying the carriage.

For further details as to this subject, see *JEREMY on the Law of Carriers*, passim; *CHITTY'S Commercial Law*, vol. iii. p. 369-386; *BURNS' Justice of the Peace*, title *Carriers*; and *KENT'S Commentaries*, Lect. XL. There are some excellent observations with respect to it in *SIR WILLIAM JONES'S Essay on the Law of Bailments*.—For an account of the regulations as to the conveyance of passengers in stage-coaches in England, see *M'CULLOCH'S Dictionary*.

Carrot (*Daucus carota*, Linn.), a biennial plant, a native of Britain. Though long known as a garden plant, its introduction into agriculture has been comparatively recent. The uses of the carrot in domestic economy are well known.

Cart, a carriage with two wheels, drawn commonly by horses, and used to carry heavy goods, etc. The word seems formed from the French *charrette*, or the Latin *carreta*, a diminutive of *carrus*. *Carts of War*, a peculiar kind of artillery anciently in use among the Scotch. In an act of Parliament, passed in 1456, they are thus described: "It is thought speidfull, that the king may request to certain of the great burrows of the land that are of any myght, to mak carts of weir, and in ilk cart twa gunnis, and ilk eak to have twa chalmers, with the remnant of the graith that offiers thereto, and an cunnand man to shute thame." By another act passed in 1471, the prelates and barons are commanded to provide such carts of war against their old enemies the English.—E. B.

Cartagena (*Carthago Nova*, or "New Carthage," it having been a principal colony of the Carthaginians), a celebrated city and sea-port, and the chief naval arsenal of Spain, on a noble bay of the Mediterranean sea, province, and 27 miles south-southeast of Murcia. Lat.

37° 36' 5" N., long. 0° 56' 36" W. Population 27,727; in 1786 it contained 60,000 inhabitants. It occupies the declivity of a hill, and a small plain extending to the harbor, which is one of the best in the Mediterranean, and protected from all winds by surrounding heights, and by an island on the south, which, as well as the city, is strongly fortified. The city, though dull, dilapidated, and unhealthy, owing to an adjacent swamp, has some good streets and houses, numerous churches and convents, a marine school, large royal hospital, foundling hospital, town-hall and custom-house, observatory, theatre, circus, etc. In its western division, an arsenal, docks for building men-of-war, and a *bagne* for galley-slaves. Its port communicates with the Segura River, by the Lorca Canal. Its manufactures of cordage and canvas, with trade in barilla and agricultural produce, have decayed, but it still has a valuable tonny fishery, and a glass factory recently established by an English house; and in 1843, 14 new smelting works had been set up here. The mines of Cartagena, originally wrought by the Carthaginians, were re-discovered a few years ago; and in 1839 the new mine of *La Carmen* was opened successfully by a joint-stock company. Since then, drainages and mining have proceeded vigorously. Cartagena was taken by Scipio b.c. 208, at which period Livy states that it was one of the richest cities in the world. It was ruined by the Goths; and its modern importance dates only from the time of Philip II.

Cartagena, or Carthage, a strongly fortified city and sea-port of New Granada, South America, of which republic it is the chief naval arsenal, capital of the province, on a sandy peninsula in the Caribbean Sea. Lat. of the dome 10° 25' 36" N., long. 75° 34' W. Population 10,000, nine-tenths of whom are a mixed black race. It is well laid out, and built mostly of stone. It has a massive citadel, several churches, a college with about 200 pupils, various seminaries, and two hospitals. The temperature is very high, from 80° to 86° Fahrenheit, but the air dry and healthy. Its excellent port is defended by two forts, and is the only harbor on the north coast of New Granada adapted for repairing vessels. Cartagena is the principal depot for the produce of the provinces watered by the Cauca and Magdalena Rivers, and is connected with the Magdalena by a canal. It exports sugar, cotton, coffee, tobacco, hides, specie, bullion, etc. Under the Spaniards, this city was the seat of a captain general, and of one of the three tribunals of the Inquisition in America. It was the first town that proclaimed independence, and in 1815 endured a most vigorous siege, and was subdued only by famine. Population of the province, 108,783.

Cartridge, in the military art a case of pasteboard or parchment, holding the exact charge of a fire-arm. The cartridges for muskets, carbines, and pistols, contain both the powder and ball. Those made for cannon and mortars are cases of pasteboard or tin, sometimes of wood; and simple flannel bags have been found convenient in practice. *Cartridge-box*, a case of wood or turned iron, covered with leather, with cells for holding a dozen or more cartridges. It is worn upon a belt thrown over the left shoulder, and hangs a little below the pocket-hole on the right side.—E. B.

Carving. We have Scriptural authority for its early introduction.—See Exodus xxxi. The art of carving is first mentioned in profane history 772 n.c., and is referred to the Egyptians. It was first in wood, next in stone, and afterward in marble and brass. Diponius and Scyllia were eminent carvers and sculptors, and opened a school of statuary, 568 n.c.—*PLINY*. See *article WOOD*. Carvers of meat were called by the Greeks *deribares*, as mentioned by Homer.—*HAYDN*.

Case, in *Printing*, a large, flat, oblong frame or box, placed aslope, and divided into numerous little square compartments, each containing a number of

types of the same kind, whence the compositor takes the particular letters he requires in composing his matter.

Cash-hardening, the process of converting the superficies or outer part of iron into steel. This is effected by placing the article in a box with some animal or vegetable charcoal, and exposing it to a red heat. It differs only from the making of steel in the shorter duration of the process. Iron tools, etc., when thus treated, combine the toughness of iron with the hardness of steel.

Cash, in *Commerce*, means the coin, bank bills, drafts, bonds, and all immediately negotiable paper in an individual's possession.

Cash Account, in *Book-keeping*, an account to which nothing but cash is carried on the one hand, and from which all the disbursements of the concern are drawn on the other. The balance is *the cash in hand*. When the credit side more than balances the debit or disbursement side, the account is said to be *in cash*; when the contrary, to be *out of cash*. *Cash account*, in *Banking*, is the name given to the account of the advances made by a banker in Scotland to an individual who has given security for their repayment.

Cashew-nuts (Ger. *Akjunüsse*, *Westindische Anarkiden*; Du. *Catsjoemooten*; Fr. *Noix d'acajou*; It. *Acaju*; Sp. *Nucce daaju*; Port. *Nozes d'acaju*), the produce of the *Anacardium occidentale*. They are externally of a grayish or brownish color, of the shape of a kidney, somewhat convex on one side, and depressed on the other. The shell is very hard; and the kernel, which is sweet and of a very fine flavor, is covered with a thin film. Between this and the shell is lodged a thick, blackish, inflammable oil, of such a caustic nature in the fresh nuts, that if the lips chance to touch it, blisters immediately follow. The kernels are used in cooking, and in the preparation of chocolate.

Cashier, a cash-keeper; he who receives and pays the debts of a society. In the generality of foundations the cashier is called *treasurer*. In a banking institution the cashier is the officer who superintends the books, payments, and receipts of the bank. He also signs or countersigns the notes, and superintends all the transactions under the order of the directors.

Cashmere, a kingdom in Northern India, so called from its principal division, the celebrated valley of that name, and comprehending within its limits the various territories which constitute the dominions of Gholab Singh. Its boundaries are, the Karakorum Mountains on the north; Thibet on the east; the British possessions of Spiti, Lahoul, and the Punjab on the south; and the Hazareh country on the west. It extends from lat. 32° 17' to lat. 36°, and from long. 73° 20' to long. 79° 40'; its extreme length from east to west being 350 miles, and its breadth about 270. Area about 25,000 square miles. The population has been estimated at 750,000. Within its limits are included the valley of Cashmere, and the provinces of Jamoo, Ladakh, Bultit or Iskardoh, Chamba, and some others. Cashmere was long famed for the manufacture of shawls, which are distributed all over northern and western Asia, and are exported in great quantities to Europe. These shawls owe their peculiar beauty and fine texture to the wool which is brought from Thibet, lying at a distance of a month's journey to the northeast. The wool forms the inner coat with which the goat is covered, and the breed is peculiar to Thibet; all attempts to introduce it into India or Persia having invariably failed. The wool, which is originally of a dark gray color, is bleached in Cashmere by a preparation of rice flour. The process of manufacture is very slow, not more than one inch being added to the finest shawls in the course of a day. It is estimated that about 16,000 looms were at one time employed in this manufacture; but of late years the demand has declined, owing to the decay of the Persian and Ottoman empires, and

the desolation and poverty of the Eastern countries. When Cashmere was tributary to Afghanistan, a great portion of the public revenue was exacted in shawls. The yarn into which the wool is spun is dyed with various colors, and, after being woven, the piece is once washed, and the border, in which is displayed a variety of figures and colors, is attached to the shawls in so dexterous a manner that it is hardly possible to discover the junction. The price varies in proportion to the quality. A species of writing-paper is also made in Cashmere, which is highly praised throughout the East, and was formerly a great article of traffic; as were also its lacquered ware, cutlery, and sugar. A wine resembling Madeira is manufactured, and a spirituous liquor is distilled from the grape. The internal intercourse of the country is chiefly maintained by means of the numerous streams which intersect it, and which are navigated in long and narrow boats moved by paddles.—E. B.

Cashmere Shawls. The district from whence come these costly shawls is described as being "the happy valley, and a paradise in perpetual spring." The true Cashmere shawls can be manufactured of no other wool than that of Thibet. They were first brought to England in 1666; but they were well imitated by the spinning at Bradford, and the looms of Huddersfield. Shawls for the omrah's, of Thibetian wool, cost 150 rupees each, about the year 1650.—BERNIEN.

Caspian Sea, the *Mare Hyrcanum* of the ancients, derives its name from the Caspi, a tribe who settled on its shores. Among the Orientals it is known under a variety of names; by the Russians it is called the Sea of Astracan, and by the Turks Bahri-Gong. It is situated between 36° 35' and 47° 25' N. lat., and 46° 15' and 55° 10' E. long., is the largest inland lake in the world, and has no outlet to the ocean. It is surrounded by the Russian governments of Astracan and Orenberg, the Caucasian countries, Persia, and Tartary; its greatest length is about 760 miles, and its greatest breadth about 400 from east to west; generally, however, only half that breadth, and where narrowest not more than 120 miles across. Its estimated area is from 120,000 to 140,000 square miles. There are no tides in this sea, nor are there any regular currents; but the high winds which occasionally blow over its large surface cause considerable and irregular agitations in its motions. The mean depth of the Caspian Sea is from 400 to 600 feet, and in some places is found to be 2700 feet; but its waters are every where very shallow near the shore, especially toward the west. Vessels drawing 9 or 10 feet water are thus compelled to unload far from the shore, excepting near Bakou and some other parts of the lake. Navigation is, in general, dangerous, owing to the frequency and violence of the east and west winds; and the contracted space forces the navigator to beat about in order to avoid the sand banks concealed near its shores. The waters of the Caspian have a slightly bitter taste, communicated by the naphtha which abounds in the surrounding countries, and is carried into it by the streams which it receives; but they are not so salt as those of the ocean, in consequence of the great volume of water poured into it by the Volga and its other tributaries. Horses do not refuse to drink along the shores and near the mouths of the rivers.—E. B.

Cassia. There are four species of cassia in the market; viz., *Cassia Lignea*, or *Cassia Bark*; *Cassia Fistula*; *Cassia Buda*; and *Cassia Senna*.
1. *Cassia Lignea*, or *Cassia Bark* (Fr. *Casse*; Ger. *Cassia*; Port. *Cassia lenhoa*; Arab. *Seleek*; Hind. *Tuj*; Malay, *Kayu-jeji*), the bark of a tree (*Laurus Cassia*, Linn.) growing in Sumatra, Borneo, the Malabar coast, Philippine Islands, etc.; but chiefly in the provinces of Quantong and Kingi, in China, which furnish the greatest part of the cassia met with in the markets. The tree grows to the height of 50 or 60

feet, with large, spreading, horizontal branches. The bark resembles that of cinnamon in appearance, smell, and taste, and is very often substituted for it; but it may be readily distinguished; it is thicker in substance, less quilled, breaks shorter, and is more pungent. It should be chosen in thin pieces; the best being that which approaches nearest to cinnamon in flavor: that which is small and broken should be rejected. A good deal of the casia in the Indian markets is brought from Borneo, Sumatra, and Ceylon. Malabar casia is thicker and darker-colored than that of China, and more subject to foul packing; each bundle should be separately inspected.—AINSLIE'S *Materia Indica*, MILBURN'S *Orient. Com.*, etc. See CINNAMON.

2. *Cassia Buds*, the dried fruit or berry of the tree (*Laurus Cassia*) which yields the bark described in the previous article. They bear some resemblance to a clove, but are smaller, and, when fresh, have a rich cinnamon flavor. They should be chosen round, fresh, and free from stalk and dirt. Cassia buds are the produce of China.—MILBURN'S *Orient. Com.*; *Anglo-Chinese Calendar*; and *Parl. Paper*, No. 257, Sess. 1843.

3. *Cassia Fistula* (Fr. *Casse*; Ger. *Rhonkasia*; It. *Polpa di cassia*; Lat. *Cassia pulpa*; Arab. *Khyar sheber*) is a tree which grows in the East and West Indies, and Egypt (*Cassia fistula*, Lina.). The fruit is a woody, dark-brown pod, about the thickness of the thumb, and nearly two feet in length. It is exported principally from the West Indies, packed in casks and cases; but a superior kind is brought from the East Indies, and is easily distinguished by its smaller smooth pod, and by the greater blackness of the pulp.

Castanet (Spanish *Castaneta*, or rather *Castañeta*, probably from *Castaña*, a chestnut), an instrument much used by the Spaniards and Moors as an accompaniment to their dances and guitars. It is composed of two small pieces of ebony, or other well-dried hard wood, shaped like spoons, which are placed together with the concavities inward, fastened by a string to the thumb, and beat with the middle finger, so as to produce a rattling sound. This instrument is very similar to the ancient *cratium*, which appears to have consisted, in its original form, of two pieces of reed, which made a clattering noise when shaken with the hand.—E. B.

Casting, the running of liquid metal into a mould prepared for that purpose. *Casting in Sand or Earth*, is the running of metals between two frames or moulds filled with sand or earth, in which the figure that the metal is to take has been impressed en creux, by means of the pattern. *Casting*, among sculptors, implies the taking of casts and impressions of figures, busts, medals, leaves, or the like. The method of taking casts of figures and busts is most generally by the use of plaster of Paris, that is, alabaster, obtained by a gentle heat. The advantage of using this substance in preference to others is, that notwithstanding a slight calcination reduces it to a pulverized state, it becomes again a tenacious and cohering body by being moistened with water, and afterward suffered to dry. By this means either a concave or a convex figure may be given by a paper mould or model to it when wet, and retained by the hardness it acquires when dry; and, from these qualities, it is fitted for the double purpose of making casts, and moulds for forming casts. The particular manner of making casts depends on the form of the subject to be taken. Where there are no projecting parts it is very simple and easy, as likewise where there are such as form only a right or any greater angle with the principal surface of the body; but where parts project in lesser angles, or form a curve inclined toward the principal surface of the body, the work is more difficult.—E. B.

Castor (Fr. *Castoreum*; Ger. *Kastoreum*; It. *Castoreo*; Sp. *Castoreo*), the produce of the beaver. In the

inguinal region of this animal are found four bags, a large and a small one on each side: in the two large ones there is contained a softish, grayish-yellow, or light-brown substance, which, on exposure to the air, becomes dry and brittle, and of a brown color. This is castor. It has a heavy but somewhat aromatic smell, not unlike musk; and a bitter, nauseous, and subacrid taste. The best comes from Russia; but of late years it has been very scarce; and all that is now found in the shops is the produce of Canada. The goodness of castor is determined by its sensible qualities; that which is black is insipid, inodorous, oily, and unfit for use. Castor is said to be sometimes counterfeited by a mixture of some gummy and resinous substances; but the fraud is easily detected by comparing the small and taste with those of real castor.—THOMSON'S *Dispensatory*.

Castor-oil (Fr. *Huile du Ricin*; Ger. *Ricinusohl*; It. *Olio di Ricino*; Sp. *Ricinosel*) is obtained from the seeds of the *Ricinus communis*, or *Palma Christi*, an annual plant found in most tropical countries, and in Greece, the south of Spain, etc. The oil is separated from the seeds either by boiling them in water, or by subjecting them to the action of the press. It is said that though the largest quantity of oil may be procured by the first method, it is less sweet, and more apt to become rancid, than that procured by expression, which, in consequence, is the process now most commonly followed. Good expressed castor-oil is nearly inodorous and insipid; but the best leaves a slight sensation of acrimony in the throat after it is swallowed. It is thicker and heavier than the fat oils, being viscid, transparent, and colorless, or of a very pale straw color. That which is obtained by boiling the seeds has a brownish hue; and both kinds, when they become rancid, thicken, deepen in color to a reddish-brown, and acquire a hot, nauseous taste. It is very extensively employed in the materia medica as a cathartic.—THOMSON'S *Dispensatory*.

Culture and Manufacture of Castor-oil.—Southern Illinois is the source whence all the castor beans are brought that are sold or manufactured in St. Louis. The ground is prepared as for other crops, and when there is no longer any danger from the spring frosts the seeds are planted in hills and rows, much in the manner of planting Indian corn, with the exception that there is but one seed put into each hill, and that at every fourth row a space is left sufficiently wide to admit of the passage of a team for the purpose of gathering the crop. Unlike the cereal grains, the *ricinus* bears at the same time flowers and fruit, and the severity of our climate, which renders it in this latitude an annual plant, destroys its vitality while yet decked with bloom. The ripening commences in August, and the crop is gathered at intervals from this date until the plants are destroyed by frost.

The yield, of course, varies with the quality of the soil and the care of the culture. Twenty-five bushels from an acre of ground is considered a very large crop, and is but seldom obtained. From sixteen to twenty bushels per acre is a very fair yield in a season not marked by drought or other unfavorable feature.

The primitive mode of making castor-oil was by putting the (bruised) beans in a bag, and placing the same in a kettle of water, and as the beans were boiled the oil came to the surface and was skimmed off. Subsequently there were adopted the screw and lever presses, and other devices for pressing the beans, and many mills sprang up throughout the southern part of Illinois, some of which remain in use until this time. The beans are first kiln-dried, and then pressed without grinding, the oil thus obtained being called "cold pressed," to distinguish it from the boiled oil (that obtained by boiling the beans in water).

About ten years ago, the St. Louis manufacturers commenced using the ordinary hydraulic press, increasing the yield from the raw material, and work-

ing the beans with greater rapidity and economy. About two years since there was introduced a new press, which has brought the business to a greater state of perfection, by increasing the product of oil from the bean 87 per cent. over the ordinary hydraulic press, and securing other advantages in the economy of labor and fuel. One of these presses will work 150,000 bushels of beans per annum, producing as much as 400,000 gallons of oil. It is said that one of these presses worked on castor-oil, in connection with others on linseed-oil, furnishes sufficient combustible refuse from the castor bean to supply fuel for the works; and in this way the fuel from the bean is of sufficient value to pay all the expenses of manufacturing the oil. The amount saved in Latourette's establishment by burning the above refuse, when in full operation, is about fifty dollars per week. After the oil is pressed from the beans, it is clarified by boiling in large kettles with a small portion of water, and when perfectly clear is allowed to cool, and is then drawn off into barrels ready for market. During the months of July, August, and September, 1854, there were manufactured thirty-two thousand gallons of castor-oil at this establishment alone. The manufacture of the oil, which, in 1850, was largely carried on in Illinois, is now mostly effected in the city of St. Louis.

	1850.	1851.	1852.	1853.
Crop in bushels.....	250,000	160,000	90,000	65,000
Factories in St. Louis...	2	2	2	3
Factories in Illinois...	18	7	5	3
Barrels of oil made...	9,000	7,000	5,500	4,200
Equivalent in gallons...	350,000	285,000	192,000	147,000

The estimated crop of beans for 1854 was but 10,000 bushels, being almost a total failure; arising from the excessive drought that prevailed during the summer over that part of the country. The number of mills in operation in 1854 was only five, and those only employed part of the time. These statements exhibit a gradual decline in the amount of oil produced, which arises partly from the decreased crops, and partly, probably, from a limitation in the demand. The price of oil in 1852-'53 was as low as 60 to 80 cents per gallon, and is at present about \$1 25 by the barrel, which, with the short crop of the past year, will probably prove an inducement to the farmers to again turn their attention to raising the beans. It has been stated that castor-oil had been used on one of the Western railroads for oiling the axles of cars, and probably also on the locomotives. Since the rise in the price of whale oil, the attention of machinists has been turned to various substitutes, and it is probable that the non-drying quality of the castor-oil, when pure, will render it very valuable for lubricating purposes, if it can be produced at a sufficiently low price.—*American Journal of Pharmacy*, 1855.

Catechu (Fr. *Cachou*; Ger. *Kaschu*; Hind. *Cat, Gambir*), a brown astringent substance, formerly known by the name of *Terra Japonica*, because supposed to be a kind of earth. It is, however, a vegetable substance obtained from two plants; viz. the *Mimos*, or more correctly the *Acacia catechu*, and the *Uncaria gambir*. The first of these is a tree from 20 to 30 feet high, found in abundance in many of the forests of India, from 16° of lat. up to 30°. The places most remarkable for its production are the Burmese territories; a large province on the Malabar coast called the Concan; and the forests skirting the northern part of Bengal, under the hills which divide it from Nepal. The catechu is obtained from this tree by the simple process of boiling the heart of the wood for a few hours, when it assumes the look and consistency of tar. The substance hardens by cooling; is formed into small balls or squares; and being dried in the sun, is fit for the market. Joinson, in his "*Chemistry of Common Life*," says, "In the most relaxing climates of the East this strongly astringent substance acts beneficially upon

the system." Perron, the traveler, states that he preserved his health during a long and difficult voyage by the habitual use of betel, while his companions, who did not use it, died, mostly of dysentery.

Cat-head, a strong timber projecting from either bow of a ship, to which the anchor is raised and secured.

Cat's Eye, a mineral of a beautiful appearance, brought from Ceylon. Its colors are gray, green, brown, red, of various shades. Its internal lustre is shining, its fracture imperfectly conchoidal, and it is translucent. From a peculiar play of light, arising from white fibres interspersed, it has derived its name. The French call the appearance *chatoyant*. It scratches quartz, is easily broken, and resists the blow-pipe. It is set by the jewelers as a precious stone.

Cat Skins. The skin or fur of the cat is used for a variety of purposes, but is principally dyed and sold as false sable. It appears from evidence taken before a late Committee of the House of Commons, that it is a common practice in London to decoy the animal and kill it for the sake of its skin. The fur of the wild-cat is, however, far more valuable than that of the domestic cat. The wild-cat skins imported into Europe are brought almost wholly from the territories of the Hudson's Bay Company. The animal from which they are taken is a good deal larger than the English wild-cat, and is sometimes called the *loup serrier*, or Canadian lynx.

Cattle, a collective term applied to designate all those quadrupeds that are used either as food for man or in tilling the ground. By *neat* or *horned cattle* is meant the two species included under the names of the ox (*bos*) and the buffalo (*buffalus*); but as the latter is principally confined to Asiatic countries, it is the former only that we have here in view. The raising and feeding of cattle, and the preparation of the various products which they yield, have formed, in all countries emerged from the savage state, an important branch of industry. It would be quite inconsistent with the objects and limits of this work to enter into any details with respect to the different breeds of cattle raised in this or other countries. They are exceedingly various. In Great Britain and in this country they have been vastly improved, both in the weight of carcass, the quality of the beef, and the abundance of the milk, by the extraordinary attention that has been given to the selection and crossing of the best breeds, according to the objects in view. This sort of improvement began about the middle of last century, or rather later, and was excited and very much forwarded by the skill and enterprise of two individuals—Mr. Bakewell, of Dishley; and Mr. Culley, of Northumberland, England. The success by which their efforts were attended roused a spirit of emulation in others; and the rapid growth of commerce and manufactures since 1760 having occasioned a corresponding increase in the demand for butcher's meat, improved systems of breeding, and improved breeds, have been very generally introduced. But the improvement in the size and condition of cattle has not been alone owing to the circumstances now mentioned. Much of it is certainly to be ascribed to the great improvement that has been made in their feeding. The introduction and universal extension of the turnip and clover cultivation has had, in this respect, a most astonishing influence, and has wonderfully increased the food of cattle, and consequently the supply of butcher's meat.

Among the various races of cattle existing among us, where strict regard is paid to breeding with a definite object in view, a preference is given to the Durhams or short horns, the Herefords, the Ayrshires, and the Devons. The Durhams, from their rapid growth, early maturity, and capability of taking on fat, are adapted only for high keeping, or to the richest pastures of the Middle and Northern States, and those of Ohio, Kentucky, and other parts of the West. The

males; when judiciously crossed with the other breeds, or with the common cows of the country, often beget the best of milkers, and for this purpose they have been especially recommended. The Herefords, on the contrary, from their peculiar organization, are better adapted for poor or indifferent pastures, and regions subject to continued drought; and for this reason they are well suited for California, New Mexico, Texas, and other parts of the South. The oxen of this breed are good in the yoke, and the cows, when properly fed, give an abundance of milk. The Ayrshires are best suited for a cool, mountainous region, or a cold, rigorous climate. They succeed well in Massachusetts, New Hampshire, and Vermont, and are highly prized for their tameness, docile tempers, and rich milk. The Devons, from their hardihood, comparatively small size, and peculiar structure, appear to be adapted to almost every climate, and to all kinds of pasturage. From their stoutness, good tempers, honesty, and quickness of action, they make the best teams, and in this respect their chief excellence consists. The cows make fair milkers, and their flesh very good beef. They also possess great aptitude to take on fat.—See ABATTOIR.

Caulking, or Caubking, the driving of oakum or old rope untwisted into the seams between the planks in a ship's deck or sides, to prevent the entrance of water or leakage. The seams are then covered with melted pitch or resin, to keep the oakum from rotting.

Cavendish, Thomas, was the son of a gentleman of good estate in Suffolk, England, but having impoverished himself by early extravagance, with a view to retrieve his affairs he fitted out three vessels for a predatory expedition against the Spanish American colonies, for which he sailed in July, 1585. After ravaging the western coasts, and taking a Spanish vessel richly laden, he sailed across the South Sea, and returned to England by way of the Cape of Good Hope, in September, 1588, having circumnavigated the globe in a shorter time than any preceding adventurer. The great wealth which he acquired from this undertaking prompted him to engage in another voyage, on which he embarked in August, 1591. Tempestuous weather, sickness, and other causes contributed to render this scheme unfortunate; and Cavendish himself died on the coast of Brazil on his passage home, in 1592.

Caviar (Fr. *Caviar*, *Caviad*; Ger. *Kaviar*; It. *Caviario*, *Caviate*; Sp. *Caviario*; Russ. *Ikra*; Lat. *Caviarium*), a substance prepared in Russia, consisting of the salted roe of large fish. The best, which is made of the roe of the sturgeon, appears to consist entirely of the eggs, and does not easily become fetid. It is packed in small casks or kegs, the inferior sort being in the form of dry cakes. Caviar is highly esteemed in Russia, and considerable quantities are exported to other countries. It is principally made of the roe of the sturgeon caught in the Wolga, in the neighborhood of Astrachan, as many as 30,000 barrels of caviar having been exported from that city in a single season.—See *Geog. Dict.* art. ASTRACHAN.

Cayenne, a sea-port town, and the capital of French Guiana, on the west point of the island of same name, at the mouth of the Cayenne or Oyanoque River, in the Atlantic. Lat. 4° 56' 5" N., long. 52° 30' W. Population 6000. It is built mostly of wood, and consists of an old town, with the government-house and Jesuits' college, and the new town, with wide and clean streets, large warehouses, and good residences, between which two divisions is a large open space planted with orange-trees. Harbor shallow: it has two quays, and is protected by a fort and several batteries. Cayenne is the seat of a court of assize, and the centre of all the trade of French Guiana. Exports to France amount to 8,000,000 francs, and imports thence to 5,000,000 francs. The island of Cayenne, in the Atlantic, separated from the continent of South America by a narrow channel, is 80 miles in circumference; chief products, sugar, cotton, coffee, and fruits. Population (excl. of the

town of Cayenne) 8000. First settled by the French in 1625, but they left it in 1654. It was afterward successively in the hands of the English, French, and Dutch. These last were expelled by the French in 1677. Cayenne was taken by the British, January 12, 1809, but was restored to the French at the peace in 1814. In this settlement is produced the capsicum baccatum, or Cayenne pepper, so esteemed in Europe.

—HAYDN.
Cayenne Pepper is prepared from several varieties of capsicum, a genus of salsaceous plants which produce a fleshy-colored fruit. This fruit contains an extremely pungent principle, that exists in greatest activity in the seed. The capsicum from which the Cayenne is procured is a native of the East India and America. The principal Indian species is *C. frutescens*, and the American *C. annuum*. The capsicum enters largely into the seasoning of food and the preparation of pickles; and is also used in medicine, both internally and externally. The pods may be preserved in vinegar, or in a dry state in salt. The strongest variety of Cayenne pepper comes from the West Indies, and is prepared from the *capsicum baccatum* (bird pepper).

Cedar (Germ. *Zeder*; Du. *Ceder*; Fr. *Cèdre*; It. and Sp. *Cedro*; Russ. *Kedr*; Lat. *Cedrus*). The Cedar of Lebanon, or great cedar (*Pinus cedrus*), is famous in Scripture: it is a tall, majestic-looking tree. "Behold," says the inspired writer, "the Assyrian was a cedar in Lebanon with fair branches, and with a shadowing shroud, and of a high stature; and his top was among the thick boughs. His height was exalted above all the trees of the field, and his boughs were multiplied, and his branches became long. The fir-trees were not like his boughs, and the chestnut-trees were not like his branches, nor any tree in the garden of God was like unto him in beauty."—*Ezekiel*, xxxi, 3, 5, 8. The cedar grows to a very great size. The timber is resinous, has a peculiar and powerful odor, a slightly bitter taste, a rich yellowish brown color, and is not subject to the worm. Its durability is very great; and it was on this account (*propter aternitatem*, Vitruvius, lib. ii. § 9) employed in the construction of temples and other public buildings, in the formation of the statues of the gods, and as tablets for writing upon. In the time of Vitruvius, cedars were principally produced in Crete, Africa, and some parts of Syria.—*Loc. cit.* Very few are now found on Lebanon; but some of those that still remain are of immense bulk, and in the highest preservation. Cedar exceeds the oak in toughness, but is very inferior to it in strength and stiffness. Some very fine cedars have been produced in England.

There are several other kinds of timber that are usually called cedar: thus a species of cypress is called white cedar in America; and the cedar used by the Japanese for building bridges, ships, houses, etc., is a kind of cypress, which Thunberg describes as a beautiful wood, that lasts long without decay. The *Juniperus orycedrus* is a native of Spain, the south of France, and the Levant; it is usually called the brown-berried cedar. The Bermudian cedar (*Juniperus Bermudiana*), a native of the Bermuda and Bahama islands, is another species that produces valuable timber for many purposes; such as internal joiners' work, furniture, and the like. The red cedar, so well known from its being used in making black-lead pencils, is produced by the Virginian cedar (*Juniperus Virginiana*), a native of North America, the West India islands, and Japan. The tree seldom exceeds 45 feet in height. The wood is very durable, and, like the Cedar of Lebanon, is not attacked by worms. It is employed in various ways, but principally in the manufacture of drawers, wardrobes, etc., and as a cover to pencils. The internal wood is of a dark red color, and has a very strong odor. It is of a nearly uniform texture, brittle, and light.—See *TRENGOLD'S Principles of Carpentry*.

Cements. The substances used for producing cohesion between different materials are very various. They are mostly, however, soft, or semi-fluid, and harden in the course of time. The number employed is very great. We can mention only a few. The joints of iron pipes and the flanges of steam-engines are cemented with a mixture composed of sulphur and muriate of ammonia, together with a large quantity of iron shippings. The putty of glaziers is a mixture of linseed oil and powdered chalk. Plaster of Paris, dried by heat, and mixed with water, or with resin and wax, is used for uniting pieces of marble. A cement composed of brick-dust and resin, or pitch, is employed by turners, and some other mechanics, to confine the material on which they are working. Common paint, made of white-lead and oil, is used to cement China ware. So also are resinous substances, such as mastic and shellac, or isinglass dissolved in proof-spirit or water. The paste of book-binders and paper-hangers is made by boiling flour. Rice-glue is made by boiling ground rice in soft water to the consistency of a thin jelly. Waters are made of flour, isinglass, yeast, and white of eggs, dried in thin layers upon tin plates, and cut by a circular instrument. They are colored by red-lead, etc. Sealing-wax is composed of shellac and resin, and is commonly colored with vermilion. Common glue is mostly employed for uniting wood, and similar porous substances. It does not answer for surfaces not porous, such as those of metals, and is not durable if exposed to water. The cements mostly used in building are composed of lime and sand. Lime is procured by burning substances in which it exists in combination with carbonic acid, such as limestone, marbles, chalk, and shells. By this process, the carbonic acid is driven off, and quicklime is obtained. The quicklime is elaked by mixture with water, after which it swells and cracks, becomes hot, and assumes the form of a white and impalpable powder. This is a hydrate of lime, and contains about three parts of lime to one of water. When intended for mortar, it should immediately be mixed with sand, and used without delay, before it imbibes carbonic acid anew from the atmosphere. The lime adheres to and unites the particles of sand. Cements thus made increase in strength and solidity for an indefinite period. Fresh sand, wholly silicious and sharp, is the best. That taken from the sea-shore is unfit for making mortar, as the salt is apt to deliquesce and weaken the mortar. The amount of sand is always greater than that of the lime. From two to four parts of sand are used, according to the quality of the lime and the labor bestowed on it. Water cements, called also *Roman cements*, harden under water, and consolidate almost immediately on being mixed. Common mortar dissolves or crumbles away if laid under water before it has had time to harden; but certain rocks, which have an argillaceous as well as a silicious character, communicate to lime or mortar the property of hardening in a very few minutes, both in and out of water. The ancient Romans, in making their water cements, employed a peculiar earth, obtained at the town of Puteoli. This they called *pulvis Puteolanus*. It is the same as is now called *Puzzolana*, and is evidently of volcanic origin. The Dutch, in their great aquatic structures, have mostly employed a substance denominated *tarras, terras, or trass*, found near Andernach, in the vicinity of the Rhine. It is said to be a kind of decomposed basalt, but resembles puzzolana. It is very durable in water, but inferior to the other kinds in the open air. Baked clay and the common green-stones afford the basis of very tolerable water cements, when mixed with lime. Some of the ores of manganese may be used for the same purpose. Some limestones calcined, and mixed with sand and water, also afford water cements, usually in consequence of containing some argillaceous earth. Some cements, of great hardness and permanency, have been obtained

from mixtures into which animal and vegetable substances enter, such as oil, milk, mearlage, etc. The name of *maltha* or *mastic* is given them. They are not much used. The principal manufacturing places of cement in the United States are in the State of New York, along the Delaware and Hudson Canal.

Census is now almost solely used to denote that enumeration of the people made at intervals in most European countries, and in Britain decennially. The term had its origin in Rome, where a group of the many functions performed by the high officer called censor received the name of *census*. An enumeration of the people was only one of them, but they were chiefly of a statistical character. They were especially directed to fiscal objects; and it does not appear that the enumeration of the people was then deemed of value as a source of statistical knowledge which might influence morals and legislation. It was connected with the Servian constitution, which apportioned the rights and duties of citizens to the amount of property, dividing them into six classes, which were subdivided into centuries by a mixed ratio of wealth and numbers.

The Roman census must have been minute and full. It indicated not only the number and respective classes of all free persons, but their domestic position as husbands and wives, fathers and mothers, and sons and daughters. The slaves and freedmen were indicated in connection with the possessions of the head of the house, and landed property was analyzed into several classes, according to its character and produce. The important practical effect of the census caused it to be conducted at intervals generally so frequent as every fifth year. It was followed by a sacrifice of purification or lustration, whence the term of five years came to be denoted a *lustrum*.

While the word census was thus applied to the taxation of the Middle Ages, it will readily be understood that in its modern sense it received no practical application, since neither taxation nor the adjustment of social rank required a numbering of the people; and the statistic or economic ends of such a process were as little known as they had been to the Romans. Under the despotic governments of the Continent, however, the tendency to central organization for purposes of administration and police prepared the way for statistical inquiries into the numbers of the inhabitants of particular areas whenever there should occur an occasion for enumerating them. It was in Britain, with its abstinent government and unrestrained people, that the want of population statistics became most flagrantly conspicuous. It is difficult at present to realize the idea that, long after Adam Smith's day, the number of the inhabitants of the British empire could only be guessed at, as the populousness of China is at the present day; and, as in all matters of statistics, which have their own simple solution through specific inquiry, the guesses about the population of the empire were not only vague but extravagantly contradictory. During the eighteenth century, the most trust-worthy geographers were generally those who did not venture on an estimate of the population even in those European states which had the best means of enumeration at their command.

The first effort to take a census of the population of Great Britain was made in 1801; it did not then extend to Ireland. The success which attended this and the two succeeding efforts was mainly owing to the zeal and ability of Mr. Rickman, the assistant clerk of the House of Commons. Where there is an organization like that in many of the European states for preserving a constant official record of all the fluctuations of the population, not only in their absolute numbers throughout a whole territory but in the relative numbers in its respective parts as they may be affected by fluctuations, systematic arrangements are thus prepared not only for obtaining a general census at any one moment, but for checking its accuracy and

classifying its elements. But to deal at once with the raw material in the self-governed British empire, required great ingenuity and sagacity. A census, to be accurate, must be taken on a uniform system, and must be taken simultaneously.

The enumerations of 1841 and 1851 in England were much facilitated by the uniform system of registration of births, marriages, and deaths, established in 1836, which not only afforded the means of checking the accuracy of the returns, but provided a prompt and skilled machinery accustomed to statistical work. Far more dependence could now be placed on the discretion and skill of the officers to whom the local duties were committed; and the returns were made more minute and complete. Scotland and Ireland are perhaps the only considerable countries in Christian Europe where there is no uniform system of registration. In Scotland it was necessary to adopt the clumsy method of employing the parish schoolmasters to perform the local duty in the country districts. In Ireland the first attempt at a general census was made in 1811, but it was decidedly unsuccessful. It was repeated in 1821, but went no further than a bare enumeration of doubtful accuracy. The census there taken in 1831 was subject to correction in 1834, to make it the basis of the new system of national education. In the two subsequent enumerations the aid of the admirable constabulary force, and the use of an ordnance survey, nearly complete in 1841, have gone far to supply the want of permanent local statistical machinery. The census of 1851 was taken on the 31st day of March, the previously-distributed schedules being then collected.

POPULATION AND NUMBER OF INHABITANTS TO THE SQUARE MILE OF VARIOUS AMERICAN AND EUROPEAN COUNTRIES.

Countries.	Population.	Density.
United States	23,191,876	74.0
Canada	1,849,103	5.31
Mexico	7,661,919	7.87

Denmark	2,290,597	101.92
Switzerland	2,892,740	160.65
Greece	916,266	55.70

The United States.—There have been seven enumerations of the inhabitants of the United States, the period and aggregate results of which are as follows:

Census of 1790	3,929,827
Census of 1800	5,305,125
Census of 1810	7,239,814
Census of 1820	9,498,131
Census of 1830	12,866,010
Census of 1840	17,069,453
Census of 1850	23,191,876

At the close of 1857, the total population of the United States, upon the supposition that its average ratio of increase has been maintained, or nearly so, may be stated in round numbers at 28,600,000.

The present population of the Union may be said to consist of, first, the number who were in the country on the formation of the government in 1789, and their descendants; second, of those who have come into the country since that period by immigration, and their descendants (of this class much will be said under the head of NATIVITIES); third, of those who have been brought in by annexation, as in Louisiana, Florida, New Mexico, etc., and their descendants. It is sufficient to say of the last class, that Louisiana, when purchased, had 77,000 inhabitants, including 53,000

slaves; Florida about 10,000; California and New Mexico about 60,000; and that Texas and Oregon only brought back into the Union citizens who had emigrated thither but a short time before. The number of Indians (taxed) domesticated and absorbed in the population can not be ascertained. The colonial population was swelled, in 1765, by the extension of the boundary to the Mississippi, and the introduction of 2000 French residents of the territory incorporated.

Cent, a contraction of the Latin *centum*, a hundred, is used in commerce to denote a certain rate by the hundred; thus 10 per cent. profit or 10 per cent. loss upon the sale of any merchandise implies that the seller has gained or lost \$10 on every \$100 of the price at which he bought that merchandise. The rate is termed *percentage*.—See DOLLAR.

Cent is also the name of a copper coin of the United States, equal to the hundredth part of a dollar, or rather more than a halfpenny English money. The copper coinage of the United States to the end of 1858 amounted to \$1,518,987. We have of that ponderous currency about 1590 tons of 2000 pounds avoirdupois. This circulation is almost entirely confined to the Northern and Middle States, as it is rejected by the South and West. According to the laws establishing the Mint of the United States, "of the copper coins, the weight of the cent shall be one hundred and sixty-eight grains, and the weight of the half cent eighty-four grains; and the cent shall be considered of the value of one hundredth part of a dollar, and the half cent the value of one two-hundredth part of a dollar. Copper bullion shall be purchased for the Mint, from time to time, by the treasurer, under instructions from the director; the cost shall be paid from the fund hereinafter provided for; and the copper bullion shall be of good quality, and in the form of planchets fit for passing at once into the hands of the chief coiners. The copper planchets shall be delivered, from time to time, by the treasurer to the chief coiners, to be by him coined; and all such copper shall be returned to the treasurer by the chief coiners, weight for weight, without allowance for waste. It shall be the duty of the treasurer of the Mint to deliver the copper coins, in exchange for their legal equivalent in other money, to any person who shall apply for them: *Provided*, That the sum asked for be not less than a certain amount, to be determined by the director, and that it be not so great as in his judgment to interfere with the capacity of the Mint to supply other applicants. The copper coins may, at the discretion of the director, be delivered in any of the principal cities and towns of the United States, at the cost of the Mint for transportation. The money received by the treasurer in exchange for copper coins shall form a fund in his hands, which shall be used to purchase copper planchets, and to pay the expense of transportation of copper coins; and if there be a surplus, the same shall be appropriated to defray the contingent expenses of the Mint. No copper coins or pieces whatsoever, except cents and half cents, shall pass current as money, or shall be paid, or offered to be paid, or received in payment for any debt, demand, claim, matter, or thing whatsoever; and all copper coins or pieces, except the cents and half cents, which shall be paid, or offered to be paid, or received in payment, contrary to the prohibition aforesaid, shall be forfeited, and every person by whom any of them shall have been so paid, or offered to be paid, or received in payment, shall also forfeit the sum of ten dollars, and the said forfeiture and penalty shall and may be recovered, with costs of suit, for the benefit of any person or persons by whom information of the incurring thereof shall have been given."—See COINS, COINAGE.

According to the acts of Congress prior to 1850, the gold and silver coins of the United States were legal tender to any extent, but by the law of 1853, authorizing the debased silver coins, the latter are receivable in small sums only. Copper coins are not by statute le-

gal tender to any amount. Frequent suggestions in Congress have been recently made to reduce the weight of the copper coins, but thus far without effect.

Cereal Grasses (*Lat. cerea*, corn), grasses which produce the bread crops; such as wheat, rye, barley, oats, maize, rice, and millet.

Cette, a commercial and fortified sea-port town of France, department of Hérault, capital of the canton, at the head of the railroad from Beaucaire, between the Mediterranean and the lagoon of Thau, 17 miles southwest of Montpellier. Lat. of light-house, 43° 29' 48" N., long. 8° 42' 16" E. Population 16,613. It is a fortress of the first class, defended by a citadel; principal edifices, Church of St. Louis, public baths, and library. Its harbor is spacious and secure, from 16 to 19 feet in depth, formed by two piers with a breakwater in front, defended by two forts, one on either pier. A broad and deep canal, bordered with quays and warehouses, connects the port with the lagoon of Thau and the canal du Midi, and with canals leading to the Rhone, by which means Cette has an extensive traffic with the interior. Imports comprise Benicarlo wine from Spain, for mixing with French wines for the English and other markets. It has a large establishment where is manufactured sulphate of soda, magnesia, and potash, from sea-water. The exports consist of about 36,000 tons of wine, and 4000 ditto of brandy annually, with almonds, Montpellier verdigris, salt from adjacent salt-works, and sirups, liquors, soap, perfumery, and glass-ware, the products of its own factories. Cette is the entrepôt for an extensive coasting-trade, and possesses much foreign commerce. It has ship-building yards, and an active oyster and anchovy fishery, and is the residence of various European consuls. It is wholly of modern origin, having been founded by Louis XIV. at the base of the ancient *Mons Seltus* (whence its name). Steamboats to Marseilles daily.

Ceylon, an island in the Indian Ocean, situated at the southern extremity of the Coromandel coast, from which it is separated by the Gulf of Manaar. It lies between lat. 5° 54' and 9° 50' N., and long. 79° 50' and 82° 10' E. Its length is 270 miles, and its greatest breadth 145 miles. It is of an oval form, pointing north and south; its broadest part being at its southern extremity, where also is to be found the great mass of its high lands. It is distant from Cape Comorin, the southernmost point of the Indian peninsula, about 175 miles. The most important cultivation is that of coffee, a branch of industry which, since the year 1841, has assumed a position of great and growing prominence. Coffee was an article of growth and export from Ceylon so far back as the time of the Portuguese, but like the cinnamon it grew wild without any attempt at cultivation. Patches of it were to be seen around the Kandian villages in wild luxuriance, and the berry gathered before ripe, and imperfectly cured, seldom possessed much flavor, and was lightly esteemed as an article of European commerce. Coffee cultivation on the West Indian plan was first commenced by Sir E. Barnes, the then governor of Ceylon, in 1824, who hoped by his example to introduce coffee-planting by Europeans into the island.

The *Cocos nucifera*, or cocoa-nut palm, is a native of the island, and may justly be considered the most valuable of its trees. It grows in vast numbers along the entire sea-coast of the west and south sides of the island, and furnishes almost all that a Singhalese villager requires. Its fruit, when green, supplies food and drink; when ripe, it yields oil. Its sap gives him toddy and arrack. The fibrous casing of the fruit, when woven, makes him ropes, nets, and matting. The nut-shells form drinking-vessels, spoons, etc. The plaited leaves serve as plates and dishes, and as thatch for his cottages. The dried flower-stalks are used as torches, the large leaf-stalks as garden fences. The trunk of the tree sawn up is employed for every possible purpose, from knife-handles to door-posts; hollow-

ed out, it forms alike a canoe or a coffin. There are four kinds of this palm; the common, the king cocoa-nut, the dwarf, and the Maldivé sorts. The Palmyra and Areca palms grow luxuriantly and abundantly, the former in the northern, the latter in the western and central districts. The one is valuable chiefly for its timber, of which large quantities are exported to the Indian coasts; the other supplies the betel-nut, in such common use among natives of the Eastern tropics as a masticatory. The export trade in this latter to India and Eastern ports is very considerable, amounting in some years to £12,000. Next in importance to the cocoa-nut palm among the indigenous products of Ceylon is the cinnamon-plant, yielding the well-known spice of that name.—See CINNAMON. The fruits indigenous to Ceylon are few and insignificant. Others of more value have been introduced with success from various tropical and extra-tropical countries; among these are the citron, orange, lime, shaddock, banana, pomegranate, custard apple, guava, grape, rambutan, alligator-pear, etc.

Pearl Fishery.—Although the once far-famed and lucrative pearl fishery of this island has ceased since the year 1837, it will be well to give in this place a passing notice of the pearl-oyster, especially as a survey of the "banks" or beds off Aripo, made in 1852, holds out promise of a good fishing at no distant date. The banks on which these oysters are usually found lie off the northern part of the west coast of Ceylon, at a distance of from 16 to 20 miles from the shore. They extend for many miles north and south, varying considerably in their size and productiveness. The oyster arrives at maturity in its seventh year; the pearl within is then of full growth, and if the fish be not then taken up, it will shortly die, and the pearl be lost. The fishery, which is in the hands of the local government, took place in the month of March, when the water was perfectly calm, and most favorable for the work of the divers. It was formerly rented to native speculators, who paid a certain sum for the privilege of fishing with a fixed number of divers during a given period. In 1797 and the following year, the rental of the fishery realized £128,982 and £142,780 respectively. Since that time the government have fished on their own account, selling the produce of each boat by auction on the beach before the fish could be examined. This mode, however, had not proved so lucrative as the old method; the annual returns never having exceeded £87,000, and frequently falling as low as £19,000; in some cases, indeed, amounting to but a few hundred pounds sterling. Various causes have been assigned for the failure of these fisheries. It may, however, be properly attributed to the mismanagement of an inspector of the pearl banks, who in 1836 took charge of them, and, from neglecting to attend to the instructions given him by his predecessors, caused the wrong beds to be fished. The result was a complete fallow of the fishery; the oysters which should have been brought up were left to die; young beds were disturbed, and from that time this large source of revenue has been lost to the island. A survey of the pearl banks made in March, 1853, induced the local government to look for a fishery of some extent in 1855 or the following year.—E. B.

However, the pearl fishery of Ceylon continues to engross a large share of public attention. The importance of any discovery which would enable us to preserve and fish the mature oysters is evident from the statement made by Captain Stuart, that from the fifth to the sixth year the pearl-oyster doubles in value, and again doubles should he survive the seventh year. The pearl-oyster, though called the mother-of-pearl shell, and though its interior surface is beautifully lined with the pearly secretion, is valueless as "mother-of-pearl." The latest intelligence from the scene of the fisheries is as follows:

17th Sale.—205,000 oysters brought on shore on the 7th (by 42 boats) were sold at rates varying from 15 to

18 rupees per 1000, and produced £315. Total receipts £9990.—*Overland Colombo Observer*, April 18th, 1855.

The trade of Ceylon has been greatly augmented since the opening of the cinnamon trade and the commencement of coffee planting. In 1832 the imports amounted to £251,222; the exports to £163,587. In 1842 the imports and exports amounted to £622,447 and £421,418 respectively. In 1852 those amounts were £1,000,474 and £948,400. The largest increase in exported produce has been in coffee, which from 17,287 cwt. in 1831 grew to 77,475 cwt. in 1841, and to 287,919 cwt. in 1851. In 1854 the crops of native and plantation kinds are expected to amount to 500,000 cwt. The cinnamon trade of Ceylon forms a remarkable exception to the rule that by the removal of fiscal restrictions the consumption of articles will be increased. Cinnamon is now exported from Ceylon duty free, yet the annual demand for the spice is found to be no greater than when burdened with an export duty of 3s. the lb. When the island was transferred from the administration of the East India Company to that of the crown in 1802, the government entered into a contract with the company by which the latter acquired the exclusive privilege of exporting cinnamon from the colony. It was agreed that the Ceylon government should deliver annually 400,000 pounds of cinnamon, for which the company was to grant a credit of £60,000, making the price of the cinnamon 3s. per pound. In 1814 the company agreed to allow to the Ceylon government a sum of £200,000 sterling for surplus profits on their sales of cinnamon; and to give in futuro £101,000 sterling annually, instead of £60,000, for a supply of 400,000 pounds of that commodity. This contract was entered into for seven years, and it does not appear that during this period the stipulated quantity of cinnamon was ever delivered. In 1821 the exclusive privilege of exporting cinnamon was given up by the company; and in 1833 the government abandoned their monopoly of the trade, throwing it open to the public, but levying a duty of 3s. per pound on its exportation.

In 1835 an inferior or third sort was allowed to be shipped on payment of 2s. the pound. Two years later, the duty on the best sorts was lowered to 2s. 6d.; and in 1843 the duty on all kinds was fixed at 1s. It was since reduced to 4d.; and in 1853 the article was declared duty free. These periodical reductions of duty were in all cases followed by heavy shipments of the spice; the sole effect of which has been to overstock the European markets, and reduce its price beyond the reduction of duty. The annual European consumption is at the present time precisely what it was fifty years ago; thus proving that articles of mere luxury are not affected by the laws which govern the consumption of the necessities of life. Of the exports, four-fifths are to Great Britain; of the imports, one-third is from the United Kingdom, and the remainder chiefly from India. The imported goods from Great Britain consist of cotton manufacture, glass-ware, hardware, millinery, hosiery, metals, tools, beer, wines, &c.; those from India are mainly rice and coarse cotton cloth. The exports to Europe being larger than the imports thence, the balance of value is drawn for by bills of exchange, a part of which are negotiated in India to pay for rice, the rest for rupees sent down to Ceylon to pay the Malabar coolies on the coffee estates, who carry three-fourths of their earnings out of the island. The trade of Ceylon is carried on by upward of twenty European firms, and eight or nine native houses; the latter confining their transactions to British India. Besides these, there are nearly a dozen European estate agents in Kandy, and a great number of small native dealers, called "Chitters," in connection with Madras and Bombay firms. There are no export duties, and the duty on imports is 5 per cent. on the declared value, with some few exceptions, such as arms, wines, spirits, and grain. In 1862 the revenue derived from customs duties was £121,354.

The coasting and Indian trade is carried on by country-built brigs and *dhomies*, a craft peculiar to Ceylon. Of the former there are 56, of 8178 tons in the aggregate, and 559 *dhomies*, of a tonnage equal to 24,270 tons, belonging to the island. The value of the former is £6 per ton, and of the latter £1 per ton. In 1836 the custom-house shipping entries gave 1831 vessels inward, and 1200 outward; in 1852 they gave 8140 inward, and 8074 outward. The banking business of the island is conducted by branches of the Oriental Bank Corporation of London, and the Mercantile Bank of Bombay, in Colombo and Kandy. The former establishment possesses the privilege of issuing notes of 10s. and upward.—E. B.

Chaff. The husk or withered calyx of grasses, and more especially of the bread crops. The term is also applied to straw or hay cut into very short lengths, and used for mixing with corn, roots, or other food for horses or cattle. This kind of chaff, in greater lengths, is also used for mixing with mortar on some parts of the Continent, more particularly in Germany and Russia; and it is used as a substitute for hair in making plaster for rooms. Both stubble and cut hay were used by the ancient Egyptians in making bricks.

Chain, in *Surveying*, a measure of length, composed of a certain number of links made of iron wire, serving to take the distance between two or more places. Gunter's chain contains 100 such links, each measuring 7 92-100 inches, consequently equal to 66 feet, or four poles.

Chaldron, a dry English measure of 36 coal bushels; 21 chaldrons make a score. The coal bushel is 194 inches wide from the outside, and 8 1/2 inches deep. It contains 2217.6 cubic inches; but when heaped, 2815.5, making the chaldron 58.66 cubic feet. There are 12 sacks of coal in a chaldron; and if 5 chaldrons be purchased at the same time, the seller must deliver 63 sacks: the 3 sacks additional are called the *ingrain*. But coals are now sold in 20 cwt. and almost every where else by the ton of 20 cwt. avoirdupois. The Newcastle chaldron of coals is 53 cwt., and is exactly double the London chaldron.

Chaleurs, Bay of, an inlet of the Gulf of St. Lawrence, in North America. Lat. 48° N., long. 65° W. Length from east to west about 90 miles; breadth varies from 12 to 20 miles. It separates Canada East from New Brunswick, and at its western extremity receives the Ristigouche River. This bay possesses great advantages for the prosecution of the fisheries. The entire bay may be considered one great harbor, as throughout its entire breadth and extent there is not a single rock, reef, or shoal. During the summer it literally swarms with fish of every description known on the shores of this portion of America; and its ancient name of "*Ecketaun Nemauchi*"—the sea of fish—well denotes its character.

Chalk (from *calx*), in Latin called *creta*, a species of carbonate of lime, found abundantly in Britain, France, Norway, and other parts of Europe. The island of Candia is said to have received its ancient name of *Creta* from the quantity of chalk found there. Chalk is used as an anti-acid; and from the readiness with which it imbibes liquids, it is much employed as an absorbent. When powdered and freed from gritty particles by washing, it forms the substance called *whitening*, or Spanish white, used to polish metallic utensils and glass. It is prepared as follows: mix chalk that has been well triturated with a large quantity of water, allow the silicious and ferruginous particles to subside, and then decant the supernatant fluid into a very fine sieve or linen bag, where the whitening will be deposited.—*Black Chalk*, a mineral used by artists for drawing. It is a variety of bituminous shale, the *schiste graphique* of Italy.—*French Chalk*, steatite or soapstone, a hydrated silicate of magnesia and alumina. It occurs of several colors, as white, brown, green, &c. and is used in the preparation of crayons, the manu-

facture of basis of cerdurated clared redd, or E. B.

Chamber of Assurance, in France, denotes a society of merchants and others for carrying on the business of insurance; but in Holland it signifies a court of justice, where causes relating to assurances are tried.

Chamber of Commerce. An assembly of merchants and traders, where affairs relating to trade are treated of. There are several establishments of this sort in most of the chief cities.—See BOARD OF TRADE.

Chamomile Flowers. The flower-heads of the *Anthemis nobilis*, or common chamomile. They are used in medicine in consequence of their bitter extract, which is strengthening, and of their essential oil, which is aromatic and stimulant.

Champagne, one of the most esteemed and celebrated of the French wines. An official report, made by the directors of the indirect taxes for the department of Marne, furnishes the following information as to the trade in champagne between the 1st of April, 1846, and the 1st of April, 1847. The produce is distributed among the arrondissements of Chalons, Epervay, and Rheims. On the 1st of April last there were in the cellars of the wholesale dealers 18,815,867 bottles of this wine; viz. at Chalons, 4,404,237 bottles; at Epervay, 5,710,753; and at Rheims, 8,600,877. The number of bottles sold and delivered between the 1st of April, 1846, and the 1st of April, 1847, were, at Chalons, 2,497,355; at Epervay, 2,187,553; at Rheims, 4,090,577; making a total of 8,775,485 bottles. These quantities were thus distributed:

Champlain Lake lies between the States of New York and Vermont. It extends from Whitehall, New York, to the 46th degree of north latitude 102 miles, and thence about 24 miles to St. John's, in Canada, to which point it is navigable, making its whole length 126 miles. Its breadth is from one-fourth of a mile to 13 miles; but, including the expanse which contains its large islands, it is 15 miles wide. Its broadest part, unobstructed by islands, is opposite Burlington, Vermont. Its chief islands are North Hero, South Hero, and La Motte, which, with some smaller islands, and the peninsula of Alburg, constitute Grand Isle county, Vermont. This lake was discovered by Samuel Champlain, a French nobleman, in 1609. It was the theatre of many important military operations, in the French, Revolutionary, and the war of 1812. The scenery along its shores is highly picturesque, and rendered grand by the lofty mountains at a little distance from it on both sides. It forms an important medium of commerce, and is navigated by steamboats, and by many sloops, generally from 80 to 100 tons burthen. It receives a number of considerable rivers. Its outlet is Sorelle or Richelleu River, the navigation of which has been improved by the works of the Chambly Canal (Canada), so as to afford an easy communication for large vessels with the St. Lawrence River. The Champlain Canal, 64 miles long, connects it with the Hudson River on the south, and cost \$1,079,872. It abounds with fish, among which are salmon, lake shad, pike, and other fish. It is generally frozen entirely over, and is passed on the ice, in winter. The broad lake closes in January or February, and opens early in March. The narrow parts continue frozen considerably longer. It has three light-houses on its coasts. It comprises the collection districts of Burlington and Champlain. Ag-

gregate tonnage in 1853, 1,461,749. The aggregate shipping in 1851 measured 197,500 tons, and employed 11,850 men. The commerce of the lake in the same year amounted to \$26,390,895; and the enrolled tonnage was, of steam, 4157 tons, and 8983 tons of sailing vessels.

Chanks, or Chank Shells, common conch shells (*Voluta pyrum*), are fished up by divers in the Gulf of Manaar, on the coast opposite Jaffnapatam, in Ceylon, in about two fathoms water; and at Travancore, Tuticoreen, and other places. Large fossil beds of chanks have also been found. They are of a spiral form, and constitute a considerable article of trade in India, where they are in extensive demand all over the country. They are sawn into narrow rings or bracelets, and are worn as ornaments on the arms, legs, fingers, etc., by the Hindoo women; many of them are also buried with the bodies of opulent and distinguished persons. Those which, from being taken with the fish, are called *green chanks*, are most in demand. The *white chank*, which is the shell thrown upon the beach by strong tides, having lost its gloss and consistency, is not worth the freight up to Calcutta. The value of the green chank depends upon its size. A chank, opening to the right, called in Calcutta the right-handed chank, is so highly prized as sometimes to sell for 400 or 500, or even 1000 rupees.—BULL'S *Commerce of Bengal*, and private communications.

The fishery of chanks used to be monopolized by government, who formerly let the banks for from £3000 to £4000 a year. But of late years the fishery, partly from the poaching of the fishermen of the contiguous coasts, and partly from a decrease in the supply of chanks, declined so that the rental of the banks fell off to from £300 to £400 a year. And this smaller sum was not paid, as formerly, for a license to dive for live chanks, but for permission to dig up the dead shells along the shores of the Gulf of Manaar. Under these circumstances government have wisely abandoned the chank monopoly, which, without being of any value in a financial point of view, obstructed the employment of the inhabitants on the shores of the Gulf.—See the valuable Report of Sir J. E. TENNENT, p. 55, of *Papers on Ceylon*, presented to Parliament in 1848.

Charcoal (Fr. *Charbon de bois*; Ger. *Reine Kohle*; It. *Carbone di legna*; Sp. *Carbon de lena*; Lat. *Carbo ligni*), a sort of artificial coal, consisting of wood burned with as little exposure to the action of the air as possible. "It was customary among the ancients to char the outside of those stakes which were to be driven into the ground or placed in water, in order to preserve the wood from spoiling. Now-made charcoal, by being rolled up in clothes which have contracted a disagreeable odor, effectually destroys it. When boiled with meat beginning to putrefy, it takes away the bad taint; it is, perhaps, the best tooth-powder known. When putrid water at sea is mixed with about one-ninth of its weight of charcoal powder, it is rendered quite fresh; and a much smaller quantity of charcoal will serve, if the precaution be taken to add a little sulphuric acid previously to the water. If the water casks be charred before they are filled with water, the liquor remains good in them for years; this precaution ought always to be taken for long sea voyages. The same precaution, when attended to for wine-casks, will be found very much to improve the quality of the wine."—THOMSON'S *Chemistry*. Common charcoal intended merely for fuel is prepared by cutting pieces of wood from one to three inches in diameter into lengths of from one to three feet, forming them into a conical pile, and covering them with turf or clay; leaving two or three small holes close to the ground for lighting the wood, and boring through the turf in the upper part of the cone, a few other small holes for the escape of the smoke. The pile being lighted at the several holes along the bottom, continues burning with a slow smouldering flame for a week or two, and is allowed to cool before

the turf is removed. In the case of very high winds, the holes to the windward are stopped, to prevent combustion from going on with too great rapidity. Charcoal obtained by distilling beach-wood, log-wood, willow, and other woods which are free from resin, is called *cylinder charcoal*. The charcoal employed in the manufacture of gunpowder is now always so prepared.

Charge d'Affaires. The third or lowest class of foreign ministers, according to the regulations adopted at the Congress of Vienna.

Chariots. The invention of chariots and the manner of harnessing horses to draw them, is ascribed to Erichonius of Athens, 1488 B.C. Chariot-racing was one of the exercises of Greece. The chariot of the Ethiopian officer, mentioned in *Acts vii. 27, 28, 31*, was, it is supposed, something in the form of our modern chaise with four wheels. Cassar relates that Cassibelanus, after dismissing all his other forces, retained no fewer than 4000 war chariots. Those of the ancients were like the modern phaetons, and drawn by one horse.—HAYDN.

Charleston, city, port of entry, and capital of Charleston district, South Carolina. It is the metropolis of the State, and the twelfth city in population in the United States. Situated in 32° 46' 33" N. lat., and 79° 55' 38" W. long. from Greenwich, England; 2° 56' 3" W. long. from Washington; 124 miles south-southeast from Columbia; 110 miles from Savannah, Georgia; 165 miles from Wilmington, North Carolina; 547 miles from Washington; 587 miles from Baltimore; 684 miles from Philadelphia; 773 miles from New York, and 589 miles from Boston. The population in 1790 was 16,859; in 1800, 18,712; in 1810, 24,711; in 1820, 24,780; in 1830, 30,289; in 1840, 29,261; as in 1850, 42,985; to which may be properly added the inhabitants of the Neck, north of the city, but lying without the charter limits, which contains about 15,000 inhabitants. Charleston is on a peninsula, formed by the confluence of Ashley and Cooper Rivers, which unite immediately below the city, and form a spacious and convenient harbor, communicating with the ocean at Sullivan's Island, seven miles southeast of the city. The city is defended by Fort Pinckney, two miles below, and Fort Johnson, four miles; and by Fort Moultrie on Sullivan's Island. The city is divided into eight wards, and is built on ground but slightly elevated, being only about nine feet above the level of the harbor at high tides. It extends from Battery Point on the south to the city limits on the north, a distance of three miles, and at an average width of one and a quarter mile. Meeting Street, the principal street, is sixty feet wide, and extends for a distance of three miles nearly in a direct line north; the cross-streets run nearly parallel to each other, and at right angles to Meeting Street, and extend from east to west, and from Ashley to Cooper Rivers. The houses built within a few years are of brick; none are now allowed to be constructed but of this material or of stone. The wooden houses are generally kept well painted, and most of them have piazzas extending to the roof, tastefully arranged with vines and creepers. Those in the suburbs are surrounded by gardens, planted with orange, peach, and other ornamental and useful trees, and a profusion of vines and shrubbery.

Charleston is a great mart for cotton, rice, and tobacco; and rice especially, as it is the heart of the rice-growing region, forms the great staple, of which it exports 125,000 tierces annually. There is a line of steamers with New York weekly, a line with Baltimore and Philadelphia, and also with Havana and Cuba. Tonnage of the port in 1852, 42,658 tons. The light-house at the entrance of Charleston harbor is on Light-house Island, and west of the ship channel. Lat. 32° 41' 54" N., long. 79° 32' 30" W. from Greenwich. The tower is 102 feet high, shows a revolving light elevated 125 feet above the surface of the sea, and is visible for a distance

of 16½ nautical miles. There is also a beacon, which with the light is used as a range to cross the main bar, and two others, the Morris Island and Sullivan's Island beacons. By its being the port of an extensive system of railroads, it drains supplies from a wide range of territory; besides almost the entire State of South Carolina, it comprises a large portion of North Carolina, Georgia, and East Tennessee. Charleston was first settled in 1680. A colony of French refugees, exiled in 1690, in consequence of the revocation of the edict of Nantes, fled to South Carolina, and a portion of them settled in Charleston, from whom some of its most respectable inhabitants have descended. At the close of the year 1779 the city was captured by the British, who held it until the following May.

—HUNT'S Merchants' Magazine.

Port.—Charleston harbor is spacious and convenient; but the entrance to it is incommoded by a range of sand banks, stretching from Sullivan's Island on the north to Folly Island on the south, about 2½ leagues. There are several channels through these banks, but only three, the middle or direct channel, the ship channel, and Lawford channel, between the latter and the main land, that ought to be attempted by ships of considerable burden. The entrance to the ship channel is in lat. 32° 40'. The depth of water on the shallowest part of the bar at ebb-tide is 12 feet, and at flood-tide from

17 to 18 feet; while the depth in the middle channel at low water does not exceed 9 feet, and in Lawford channel it does not exceed 10 or 11 feet. A light-house has been erected on the south point of Light-house Island, bearing from the middle of the bar of the ship channel northwest by west half west. It is 80 feet high, having a revolving light, alternately brilliant and obscure, the period of obscuration being double that of brilliancy; but on approaching the light, the latter gains upon the former, and within $\frac{1}{2}$ league it is never wholly dark: The light may be seen in fine weather at from 3 to 4 leagues off. After getting into the channel, which is marked by the breakers and buoys on each side, the proper course for a ship to steer is to stand the light-house to bear northwest by west, and to bring direct for it till you get within the banks, when the course is north by west. But it is unnecessary to enter into further details on these points, as all ships entering Charleston harbor are bound, provided they are piloted by a licensed pilot off the bar, to pay him full pilotage fees, whether they accept his services or not. In point of fact, however, they are always accepted; for the shifting of the sands, the influence of the tides, &c., render the entrance so difficult to those not perfectly familiar with it, that even the packet ships that sail regularly to and from New York uniformly heave to without the bar for a pilot.—See *Plan of Charleston Harbor*, reduced from the original survey of Major H. Bache.

Ships usually moor alongside quays or wharfs, where they are in perfect safety.

Shipping Charges.—The charges of a public nature paid by ships entering this port differ but little in amount on a native and a foreign ship. On a vessel supposed to be of 300 tons burden, entering, unloading, taking on board a mixed cargo and clearing out, they would be as under:

	¢	cts.	qts.	d.
Fee on entry at the custom-house.....	2	00	0	11 ½
Surveyor's fee on a foreign ship.....	5	00	1	1 ½
Surveyor's fee on a native ship.....	3	00	0	12 ½
Harbor-master's fee.....	2	00	0	3 ½
Portwarden's survey, when required.....	10	00	2	2 ½
Fees, on clearance at the custom-house, } of a native ship.....	3	50	0	14 11 ½
Do, of a foreign ship.....	2	70	0	11 ½
Pilotage inward and outward, supposing } the ship to draw 14 feet of water.....	50	00	10	13 ½
Wharfage per diem.....	1	00	0	4 ½

The difference in the fees on the clearance at the custom-house of a native and a foreign ship is owing to the former being obliged to give certain bonds which are not required of the latter.

The greater or smaller tonnage of the ship makes no difference on any of the above charges except that of pilotage, which is in proportion to her draught of water, and is the same whether for a foreign or a native ship.

Rates of Commission.—The rates of commission or brokerage usually charged and allowed at Charleston on transacting different sorts of business, are as follows, viz.:

- For selling domestic produce, $2\frac{1}{2}$ per cent.
- For selling foreign merchandise, 5 per cent.
- For guaranteeing either of these sales, $2\frac{1}{2}$ per cent. additional is commonly allowed.

For purchasing with funds in hand, or drawing domestic bills for reimbursement, $2\frac{1}{2}$ per cent.

For purchasing goods and drawing foreign bills for reimbursement, 5 per cent. is charged.

For the sale of real or personal estate the regular charge is 5 per cent.; but where the property to be sold is of any considerable value, the parties in general enter into an agreement beforehand, and a much lower rate of commission is allowed.—See SOUTH CAROLINA.

Chart, or Sea-chart, a hydrographical map, or a projection of some part of the earth's superficies in *piano*, for the use of navigators. Charts differ very considerably from geographical or land-maps, which are of no use in navigation. Nor are sea-charts all of

the same kind; some being what are called plane charts, others Mercator charts, and others globular charts. *Plane Chart*: is a representation of some part of the superficies of the terraqueous globe, in which the meridians are supposed parallel to each other, the parallels of latitude at equal distances, and consequently the degrees of latitude and longitude every where equal to each other. *Mercator's Chart* is that where the meridians are straight lines, parallel to each other, and equidistant; the parallels also straight lines, and parallel to each other; but the distance between them increasing from the equinoctial toward either pole, in the ratio of the secant of the latitude to the radius. *Globular Chart*, a meridional projection, in which the distance of the eye from the plans of the meridian, upon which the projection is made, is supposed to be equal to the sine of the angle 45° . This projection comes the nearest of all to the nature of the globe, because the meridians are placed at equal distances; the parallels also are nearly equidistant, and consequently the several parts of the earth have their proper proportion of magnitude, distance, and situation, nearly the same indeed as on the globe itself. *Hydrographic Charts*, sheets of large paper on which several parts of the land and sea are described, with their respective coasts, harbors, sounds, flats, rocks, shelves, sands, &c., together with the longitude and latitude of each place, and the points of the compass. *Scenographic Charts* represent the spots, appearances, and macula of the moon. *Topographic Charts*, draughts of small parts of the earth, or of particular places. Anaximander, of Miletus, was the inventor of geographical and celestial charts, about 750 n.c. Modern sea-charts were brought to England by Bartholomew Columbus, with a view to illustrate his brother's theory respecting a Western Continent, 1489. Mercator's chart, in which the world is taken as a plane, was drawn 1556.—E. B.

Charter-party, the name given to a contract in writing between the owner or master of a ship and the freighter, by which the former hires or lets the ship, or a part of the ship, under certain specified conditions, for the conveyance of the goods of the freighter to some particular place or places. Generally, however, a charter-party is a contract for the use of the whole ship; it is in commercial law what an indenture is at common law.—See AFFREIGHTMENT.

No precise form of words, or set of stipulations, is requisite in a charter-party. The forms subjoined to this article are those most commonly in use; but these may, and, indeed, in many cases must, be varied, to suit the views and intentions of the parties. A charter-party is generally under seal; but sometimes a printed or written instrument is signed by the parties, called a *memorandum of a charter-party*; and this, if a formal charter-party be not afterward executed, is binding. The stamp in either case is the same. Charter-parties, when ships are let or hired at the place of the owners' residence, are generally executed by them, or some of them; but when the ship is in a foreign port, it must necessarily be executed by the master, and the merchant or his agent, unless the owners have an agent in such port, having proper authority to act for them in such matters. A charter-party made by the master in his name, when he is in a foreign port in the usual course of the ship's employment, and therefore under circumstances which do not afford evidence of fraud; or when it is made by him at home, under circumstances which afford evidence of the expressed or implied assent of the owners, is binding upon the latter. But according to the law of England, no direct action can be maintained upon the instrument itself against the owners, unless it be signed and sealed by them, or unless they authorize the master (or agent, as the case may be) to enter into the contract, and unless it be distinctly expressed in the charter-party that he acts only as agent. When a ship is chartered by several owners to several persons, the charter-party should be

executed by each, or they will not be liable to an action for non-performance. But if the charter-party be not expressed to be made between the parties, but runs thus: "This charter-party indented, witnesseth, that C., master of the ship W., with consent of A. and B., the owners thereof, lets the ship to freight to E. and F.," and the instrument contains covenants by E. and F. to and with A. and B.; in this case A. and B. may bring an action upon the covenants expressed to be made with them; but unless they seal the deed, they can not be sued upon it. This, therefore, is a very proper form. The general rule of law adopted in the construction of this, as of other mercantile instruments, is, that the interpretation should be liberal, agreeable to the real intention of the parties, and conformable to the usage of trade in general, and of the particular trade to which the contract relates. The charter-party usually expresses the burden of the ship; and by the famous French Ordinance of 1681, it is required to do so. According to Molloy (book ii. c. 4, § 8), if a ship be freighted by the ton, and found of less burden than expressed, the payment shall be only for the real burden; and if a ship be freighted for 200 tons, or thereabout, the addition of thereabout (says the same author) is commonly reduced to *five* tons, more or less; but it is now usual to say so many tons "register measurement." The usual covenant that the ship shall be seaworthy, and in a condition to carry the goods, binds the owners to prepare and complete every thing to commence and fulfill the voyage. But though the charter-party contained no such covenant, the owner of the vessel would be, at common law, bound, as a *carrier*, to take care that the ship should be fit to perform the voyage; and even though he should give notice, limiting his responsibility from losses occasioned to any cargo put on board his vessel, unless such loss should arise from want of ordinary care, etc., he would be liable if his ship were not sea-worthy.—See SEAWORTHY.

In all maritime transactions expedition is of the utmost consequence; for even by a short delay the object or season of a voyage may be lost; and therefore, if either party be not ready by the time appointed for the loading of the ship, the other may seek another ship or cargo, and bring an action to recover the damages he has sustained. The manner in which the owner is to lade the cargo is, for the most part, regulated by the custom and usage of the place where he is to lade it, unless there be any express stipulation in the charter-party with respect to it. Generally, however, the owner is bound to arrange the different articles of the cargo in the most proper manner, and to take the greatest care of them. If a cask be accidentally staved in letting it down into the hold of the ship, the master must answer for the loss. If the owner covenants to load a full and complete cargo, the master must take as much on board as he can do with safety, and without injury to the vessel. The master must not take on board any contraband goods, whereby the ship or cargo may be liable to forfeiture and detention; nor must he take on board any false or colorable papers; but he must take and keep on board all the papers and documents required for the protection and manifestation of the ship and cargo by the law of the countries from and to which the ship is bound, by the law of nations in general, or by any treaties between particular states. If the master receive goods at the quay or beach, or send his boat for them, his responsibility commences with the receipt in the port of London. With respects to goods intended to be sent coastwise, it has been held that the chief responsibility of the wharinger ceases by the delivery of them to the mate of the vessel upon the wharf. As soon as he receives the goods, the master must provide adequate means for their protection and security; for even if the crew be overpowered by a superior force, and the goods taken while the ship is in a port or river within the country, the master and owners are liable for the loss, though they may have committed neither

fraud nor fault. This may seem a harsh rule; but it is necessary, to put down attempts at collusive or fraudulent combinations. The master must, according to the terms of the charter-party, commence the voyage without delay, as soon as the weather is favorable, but not otherwise.

Sometimes it is covenanted and agreed upon between the parties that a specified number of days shall be allowed for loading and unloading, and that it shall be lawful for the freighter to detain the vessel a further specified time, on payment of a daily sum as *demurrage*.—See DEMURRAGE. If the vessel be detained beyond both periods, the freighter is liable to an action on the contract. The rate of demurrage mentioned in the charter-party will, in general, be the measure of the damages to be paid; but it is not the absolute or necessary measure; more or less may be payable, as justice may require, regard being had to the expense and loss incurred by the owner. When the time is thus expressly ascertained and limited by the terms of the contract, the freighter is liable to an action for damages if the thing be not done within the time, *although this may not be attributable to any fault or omission on his part*; for he has engaged that it shall be done.—ANNOT on the Law of Shipping, part iii. c. 1. If there has been any undertaking or warranty to sail with convoy, the vessel must repair to the place of rendezvous for that purpose; and if the master neglect to proceed with convoy, he will be answerable for all losses that may arise from the want of it. The owners or master should sail with the ship for the place of her destination with all due diligence, and by the usual or shortest course, unless in cases of convoy, which the master must follow as far as possible. Sometimes the course is pointed out in the charter-party. A deviation from the usual course may be justified for the purpose of repairs, or for avoiding an enemy or the perils of the sea, as well as by the sickness of the master or mariners, and the mutiny of the crew. By an exception in the charter-party, not to be liable for injuries arising from the act of God and the king's enemies, the owner or master is not responsible for any injury arising from the sea or the winds, unless it was in his power to prevent it, or it was occasioned by his imprudence or gross neglect. "The question," said Lord Mansfield, in an action brought by the East India Company, "is, whether the owners are to pay for the damage occasioned by the storm, the act of God; and this must be determined by the intention of the parties and the nature of the contract. It is a charter of freight. The owners let their ships to hire, and there never was an idea that they insure the cargo against the perils of the sea. What are the obligations of the owners which arise out of the fair construction of the charter-party? Why, that they shall be liable for damages incurred by their own fault or that of their servants, as from defects in the ship, or improper stowage, etc. If they were liable for damages occasioned by storms, they would become insurers." The House of Lords confirmed this doctrine by deciding (20th of May, 1788) that the owner is not liable to make satisfaction for damage done to goods by storm. The charterer of a ship may lade it either with his own goods, or, if he have not sufficient, may take in the goods of other persons, or (if not prevented by a clause to that effect in the charter-party) he may wholly underlet the ship to another.—For further details, see ANNOT on the Law of Shipping, part iii. c. 1; CHUTEY'S Commercial Law, vol. iii. c. 9, etc.; and the ARTICLES BILL OF LADING, FREIGHT, and MASTER.

Forms of Charter-parties.—The following is one of the most usual forms of a charter-party:

This charter-party, indented, made, etc., between A. B., etc., mariner, master, and owner of the good ship or vessel, called, etc., now riding at anchor, etc., of the burden of 200 tons, or thereabout, of the one part, and C. D. of, etc., merchant, of the other part, witnesseth, that the said A. B., for the consid-

eration hereinafter mentioned, both granted, and to freight let, and by these presents doth grant, and to freight let, unto the said C. D., his executors, administrators, and assigns, the whole tonnage of the hold, stern, sheels, and half-deck of the said ship or vessel, called, &c., from the port of London, to, etc., in a voyage to be made by the said A. B. with the said ship, in a manner hereinafter mentioned, (that is to say,) to sail with the first fair wind and weather that shall happen after, &c., next, from the port of London with the goods and merchandise of the said C. D., his factors or assigns, on board, to, etc., aforesaid (the act of God, the king's enemies, fire, and all and every other dangers and accidents of the seas, rivers, and navigation, of whatever nature and kind, in so far as ships are liable thereto, during the said voyage, always excepted), and there unlade and make discharge of the said goods and merchandise; and also shall there take into and on board the said ship again the goods and merchandise of the said C. D., his factors or assigns, and shall then return to the port of London with the said goods, in the space of, etc., limited for the end of the said voyage. In consideration whereof, the said C. D., for himself, his executors, and administrators, doth covenant, promise, and grant, to and with the said A. B., his executors, administrators, or assigns, by these presents, that the said C. D., his executors, administrators, factors, or assigns, shall and will ever and truly pay, or cause to be paid, unto the said A. B., his executors, administrators, or assigns, for the freight of the said ship and goods, the sum of, etc. (or so much per ton), within twenty-one days after the said ship arrived, and goods returned, and discharged at the port of London aforesaid, for the end of the said voyage; and also shall and will pay for demurrage (if any shall be by default of him, the said C. D., his factors or assigns) the sum of, etc., per day, daily, and every day, as the same shall grow due. And the said A. B., for himself, his executors and administrators, doth covenant, promise, and grant, to and with the said C. D., his executors, administrators, and assigns, by these presents, that the said ship or vessel shall be ready at the port of London to take in goods by the said C. D., on or before, etc., next coming. And the said C. D., for himself, his, etc., doth covenant and promise, within ten days after the said ship or vessel shall be thus ready, to have his goods on board the said ship, to proceed on in the said voyage; and also, on arrival of the said ship at, etc., within, etc., days to have his goods ready to put on board the said ship, to return on the said voyage. And the said A. B., for himself, his executors and administrators, doth further covenant and grant, to and with the said C. D., his executors, administrators, and assigns, that the said ship or vessel now is, and at all times during the voyage shall be, to the best endeavors of him, the said A. B., his executors and administrators, and at his and their own proper costs and charges, in all things made and kept stiff, staunch, strong, well-appeared, furnished, and provided, as well with men and mariners sufficient and able to sail, guide, and govern the said ship, as with all manner of rigging, boats, tackle, and apparel, furniture, provision, and appurtenances, fitting and necessary for the said men and mariners, and for the said ship during the voyage aforesaid. In witness, etc.

The great variety of circumstances under which different voyages are made produce a corresponding diversity in charter-parties. The charter-party of which the following is a copy affords a good example of the more complex species of these instruments.

It is in this day mutually agreed between Mr. T. R. Bann, owner of the good ship or vessel called the *Mormad*, William Henkler, master, of the measurement of 472 tons, or thereabout, now in the River Thames, and Mr. David Thomson, of the firm of Messrs. Thomson, Passmore, & Thomson, of Mauritius, merchants, that the said ship, being tight, staunch, and strong, and every way fitted for the voyage, shall, with all convenient speed, sail and proceed to Calcutta, with leave to take convicts out to New South Wales, and from thence troops, merchandise, or passengers, to the aforesaid port of Calcutta, with leave to touch at Madras on her way thither, if required on owner's account, or so near thereto as she may safely get, and there load, from the factors of the said merchants at Calcutta, a full and complete cargo of rice, or any other lawful goods which the charterer engages to ship, and proceed with the same to Port Louis, in the Isle of France, and deliver the same free of freight; afterwards load there a full and complete cargo of sugar in bags, or other lawful merchandise of as favorable tonnage, which the charterer engages to ship, not exceeding what she can reasonably stow and carry over and above her tackle, apparel, provisions, and furniture; and, being so loaded, shall therewith proceed to London, or so near thereto as she may safely get, and de-

liver the same on being paid freight, viz., for such quantity of sugar equal to the actual quantity of rice, or other goods, that may be shipped at Calcutta, at the rate of £5 12s. 6d. per ton of 20 cwt. net, shipped there; and should the vessel deliver more net sugar in the port of London than the quantity of rice, or other goods, actually shipped in Calcutta, the owner to be paid on the excess at the regular current rate of freight for sugar which other vessels, loading at the same time at Port Louis, receive; the tonnage of the rice, wheat, or grain, to be reckoned at 30 cwt. net per ton; that of other goods at the usual measurement (the act of God, the king's enemies, fire, and all and every other dangers and accidents of the seas, rivers, and navigation, of whatever nature and kind sever, during the said voyage, always excepted). The freight to be paid on unloading and right delivery of the cargo, as is customary in the port of London. Ninety running days are to be allowed the said merchant (if the ship is not sooner dispatched) for loading the ship at Calcutta, discharging the cargo at Port Louis, and loading the cargo there; the said lay days to commence on the vessel being ready to receive cargo, the master giving notice in writing of the same at Calcutta, and to continue during the loading there; and from the time of her arrival at Port Louis, and being ready to discharge, till the final loading at that port, and to be discharged in the port of London with all possible dispatch; and 20 days on demurrage over and above the said laying days, at £12 per day. Penalty for non-performance of this agreement, £4000. The cargo to be brought to and taken from alongside at the expense and risk of the merchant. The necessary cash for the disbursements of the vessel at Calcutta, not exceeding £250, to be advanced by the charterer's agents; they taking the master's drafts on the owner for the same at the regular current rate of exchange, and at three months' sight; and if the said bills be not regularly accepted and paid when due, the same to be deducted from the freight payable by this charter-party. The vessel to be disbursed at Port Louis by the chartering agents; sum not to exceed £300, free of commission; and the amount to be deducted from the freight at the final settlement at the port of London. Captain not to ship goods without consent. In the event of the ship being prevented, by damage or any other cause, reaching the Mauritius on or before the 1st day of January, 1843, the charterer or his agents shall be at liberty to employ the vessel for one or two voyages to Calcutta, at the rate of £2 per ton of rice, or other goods, delivered at Mauritius. Fifty running days, to load and discharge, to be allowed on each voyage; it being understood that the charterer or his agents shall load the ship, as before agreed, either at the end of the first or second voyage, as the case may be. The freight on the intermediate voyages (if any) to be paid on delivery of the cargo, in cash, or by bills on London at usance, at the option of the master. The vessel to be addressed, both at Calcutta and Isle of France, to the agents of the charterer. In witness whereof, the said parties have hereunto set their hands and seals, at London, the 2d day of December, 1841.

Signed, sealed, and delivered, in the presence of
(Signed) E. FOSTER.

THOS. B. BANN, (L.A.)
D. THOMSON, (L.A.)

Chase. In nautical language, pursuit; also the vessel pursued.

Chaser. The vessel pursuing; also guns at the head and stern for firing when in chase.

Chay, or Choy Root, the roots of a small biennial, rarely triennial, plant, growing spontaneously in light, dry, sandy ground near the sea; and extensively cultivated, especially on the coast of Coromandel. The cultivated roots are very slender, and from one to two feet in length, with a few lateral fibres; but the wild are shorter, and supposed to yield one-fourth part more of coloring matter, and of a better quality. The roots are employed to dye the durable reds for which the Indian cotton yarn and chintzes have been long famous, and which can only be equalled by the Turkey red.

Chay root forms a considerable article of export from Ceylon. Only a particular set of people are allowed to dig it. It used to be all bought up by government, who paid the diggers a fixed price of 75 or 80 rix-dollars a candy, and sold it for exportation at about 175 rix-dollars.—BENTOLACCI's *Ceylon*, p. 270.

This root has been introduced into Europe, but with no success. Dr. Bancroft suspects it may be injured by the long voyage; but he adds, that it can produce no effect which may not be more cheaply produced from madder. It is a very bulky article, and is con-

sequently burdened with a very heavy freight.—*Parmesan Cheese*, vol. ii. p. 282-303.

Checks, Cheques, or Drafts, are orders addressed to some person, generally a banker, directing him to pay the sum specified in the check to the person named in it, or bearer, on demand.

In point of form, checks nearly resemble bills of exchange. They are assignable by delivery only; and are payable instantly on presentation, without any days of grace being allowed. But by the custom of some places, a banker has until five of the afternoon of the day on which a check is presented for payment, to return it; so that where a check was returned before five, with a memorandum of "canceled by mistake" written under it, it was held a refusal to pay. If a check upon a banker be lodged with another banker, a presentment by the latter at the clearing-house is sufficient. Checks are usually taken conditionally as cash; for unless an express stipulation be made to the contrary, if they be presented in due time and not paid, they are not a payment. It is difficult to define what is the due or reasonable time within which checks, notes, or bills should be presented. A man, as Lord Ellenborough has observed, is not obliged to neglect all other business that he may immediately present them; nevertheless, it is the safest plan to present them without any avoidable delay; and if received in the place where payable, they had better be presented that day, or next at farthest. If a check be not presented within a reasonable time, the party on whom it is drawn will be justified in refusing to pay it; and the holder will lose his recourse upon the drawer.—*CHITTY on Commercial Law*, vol. iii. p. 591; *WOOLRYCH on Commercial Law*. See **BILLS OF EXCHANGE**.

Cheese (Germ. *Käse*; Du. *Kaas*; Fr. *Fromage*; It. *Formaggio*, *Cacio*; Sp. *Queso*; Russ. *Syr*; Lat. *Caseus*). The curd of milk compressed into solid masses of different sizes and shapes; and, when intended for keeping, salted and dried, and sometimes colored and flavored. It is almost always made from the milk of cows, but occasionally from that of ewes, and sometimes, though very rarely, from the milk of goats. The following are the principal British cheeses: *Brickbat*, formed of new milk and cream, chiefly in Wiltshire, in the autumn, and sold in little square pieces about the size of brickbats. *Cheddar*, round thick cheeses, weighing about 150 or 200 lbs., with a spongy appearance, and the eyes or vesicles filled with a rich oil. *Cheshire*, large, round, thick cheeses, commonly weighing from 100 to 200 pounds each; solid, homogeneous, and dry and friable rather than viscid. They are made from the whole of the milk and cream; the morning's milk being mixed with that of the preceding evening previously warmed. *Derbyshire* is a small, white, rich cheese. *Dunlop*, originally made in Ayrshire, but now general throughout Scotland, is large, round, white, buttery, and weighs from 30 to 60 pounds. This and the Derbyshire cheese are very much alike in form, color, and flavor. *Gloucester*, large, round, and mild; buttery rather than friable. There are two kinds, the single and double Gloucester; the single is made of the milk deprived of about half the cream, and the double of the milk with the whole of the cream. *Green or Sage* cheese may be made of any of the other kinds, by mixing the milk before it has curdled with a decoction of sage leaves, among which some put a few flowers of marigold and leaves of parsley. In the Highlands of Scotland the leaves or seeds of lovage are added to the sage, which communicate a very strong flavor. *Lincolnshire* is made of new milk and cream; it is quite soft, not above two inches thick, and will not keep more than two or three months. *Norfolk*, the weight is generally from 30 to 50 pounds; the curd is dyed yellow with annatto or saffron; and though not a rich cheese, it is considered a good keeper. *Soft or Slip-coat* is a small, soft, rich cheese, which might almost be

mistaken for butter, if it were not white, and which must be eaten in a week or two after making. *Stilton*, so named from the town in Huntingdonshire where it was first brought into notice, but which is made principally in Leicestershire. It is solid, rich, buttery, and white; and, unlike all the other cheeses which have been mentioned, it is twice as high as it is broad. It is much improved by keeping, and is seldom used before it is two years old. It is the dearest of all English cheeses, the price being generally to that of Cheddar as 2 to 1, or 2 to 1½. In order to induce premature decay, and the consequent appearance of age in these cheeses, it is said the makers sometimes bury them in masses of fermenting straw. *Cottenham*, so named from a town in Cambridgeshire; it differs chiefly from the cream cheese of Stilton in being flat, broader, and superiorly flavored. The flavor is said to be owing to the rich grasses which grow on the fens. *Suffolk*, or *skim-milk*, is round and thin, weighing from 25 to 30 pounds each, and is the best-keeping cheese made in England. *Wiltshire* resembles the Cheshire; but is poorer, and of inferior flavor. It is apt to become scabby, to prevent which it is generally coated over with red paint. *Yorkshire*, or *Cream Cheese*, is the same as the slip-coat cheese, already mentioned.

European Cheeses.—The most remarkable of these are the following: *Parmesan* is chiefly made at Parma and other places in Lombardy, of the curd of skimmed milk hardened by heat. Its flavor is said to be owing to the rich pastures of that part of Italy, where all plants, from the greater quantity of bright sunshine than in Britain, have doubtless their aromatic properties greatly increased. *Swiss cheese* is of various kinds; but the chief sorts are the Gruyere or Jura cheese, and Schabziger or green cheese; the last is flavored with the seeds and leaves of the mellot (*Melilotis officinalis*). *German cheeses* are of different kinds; but none are celebrated, unless we except that of Westphalia, which is made up into round balls or short cylinders, under a pound weight each. The peculiar flavor which this cheese acquires arises from the curd being allowed to become putrid before it is compressed. In Holland very good cheese is made, particularly the Edam and Gouda cheeses: the former is very salt, and keeps well at sea. In many parts of the Continent, and even in the interior of Poland and Russia, there are imitations of English cheese made; but what may be called the indigenous cheese of the Russian empire is nothing more than salted curd put into a bag and powerfully pressed, and taken to market as soon as it is made, in the same manner as butter is. In some places, instead of a press, the whey is forced out of the curd by putting it into a long cloth midway between the two ends, while a person at each end twists the cloth in an opposite direction, and thus wrings out the whey. In some miserable Russian villages the curd is exposed for sale in small lumps, retaining the marks of the fingers, which shows that no other pressure has been employed than what can be given with the hand. In France the Roquefort cheese is the most esteemed, and next that of Neuchâtel. The former somewhat resembles Stilton, but is much inferior; and the latter is a cream cheese, seldom exceeding a quarter of a pound in weight.—See *JOHNSON'S Lectures on Chemistry*.

Cheese, in the United States, except for local consumption, is manufactured principally in New York and Ohio. The New York Orange county cheese, when new, is equal to any of the mild cheeses; but it does not acquire by age that richness of flavor that English cheese does. The Ohio cheese is produced at a very low price, and is taking a rank among the important products of that agricultural State. The prairies of the West, affording wild grasses of great nutriment and fine flavor, are exceedingly well adapted for the production of cheese of good quality, and at a price that excludes foreign cheese from the market, except for epicurean tastes.

Fully one-half of these imports came from France.
—See BUTTER.

Chemistry and Distilling. Introduced into Europe by the Spanish Moors about A.D. 1150; they had learned them from the African Moors, and these from the Egyptians. In Egypt they had, in very early ages, extracted salts from their bases, separated oils, and prepared vinegar and wine; and embalming was a kind of chemical process. The Chinese also claim an early acquaintance with chemistry; but the fathers of true chemical philosophy were, Bacon, Boyle, Hooke, Mayow, Newton, etc. The modern character of chemistry was formed under Beecher and Stahl, who perceived the connection of the atmosphere and the gases with the production of phenomena. Bergman and Scheele were contemporary with Priestley in England, and Lavoisier in France; then followed Thomson, Davy, and other distinguished men.—HAYDN.

Cherbourg, a commercial and fortified sea-port town of France, and nearly opposite the western extremity of the Isle of Wight, 10 miles east-south-east of Cape la Hague. Latitude of Fort Royal, 49° 40' 3" N., longitude 1° 35' W. Population, 22,460. Its climate is remarkably mild. Its naval docks are cut out of solid rock; and it has a commercial harbor lined with stone quays. Its roadstead, defended by several large forts and batteries, is now one of the best in the Channel, being sheltered by a *digue*, or breakwater, 411 yards in length (or considerably more than twice as long as the Plymouth breakwater), begun under Louis XVI., and completed in 1810. Cherbourg has a maritime tribunal, a national academic society, commercial college, naval school, and museums; sugar and soda refineries, and tanneries; and an active trade in eggs, cattle, lard, butter, wine, and other produce, exported to England and the Channel Islands. It was the last place in Normandy resigned by the English. Charles X. embarked here with his family, on quitting France, August 16, 1830. The first French transatlantic steamer arrived at New York from Cherbourg, 8th July, 1847.

Cherries. They were brought from Pontus, to Lucullus, to Rome, about 70 B.C. Apricots from Epirus; peaches from Persia; the finest plums from Damascus and Armenia; pears and figs from Greece and Egypt; eltrons from Media; and pomegranates from Carthage, 114 B.C. The cherry-tree was first planted in Britain, it is said, about A.D. 100. Fine kinds were brought from Flanders, and planted in Kent, and with such success that an orchard of thirty-two acres produced in one year £1000, A.D. 1540.

Cherry-tree (*Cerasus Virginiana*). The wild-cherry tree is one of the largest productions of the American forest. In the Atlantic as well as the Western States, this tree is known only by the name which we have adopted. It is more or less abundant as the soil and climate are more or less favorable to its growth, to which the extremes of heat and cold in the seasons, and of dryness and humidity in the soil, are alike unpropitious. It abounds in Illinois, in New York, and in Upper Canada; but it is nowhere more profusely multiplied nor more fully developed than beyond the mountains in the States of Ohio, Kentucky, and Tennessee. The perfect wood is of a dull, light red tint,

which deepens with age. It is compact, fine-grained, and brilliant, and no' liable to warp when perfectly seasoned. It is extensively employed by cabinet-makers for every species of furniture, and when chosen near the ramification of the trunk it rivals mahogany in beauty. This wood is generally preferred to the black walnut, whose dim complexion with time becomes nearly black. On the banks of the Ohio it is employed in ship-building, and the French of Illinois use it for the felloes of wheels.—BROWN'S *Sylva Amer.*

Chesapeake Bay (Maryland), is 190 miles long, and from 7 to 20 broad, and generally 9 fathoms deep, being the largest bay in the United States. Its entrance is wholly in the State of Virginia, between Cape Charles on the north and Cape Henry on the south, which are about 12 or 15 miles apart. But the bay lies mostly in Maryland, dividing the State into two parts, called the Eastern and the Western Shore. It has several commodious harbors, and a safe and easy navigation. It receives the waters of the Potomac, Rappahannock, and James rivers, which are all large and navigable; also of the Susquehanna and York rivers.

Chestnut (*Fagus castanea*), a forest tree growing abundantly in most parts of the southern countries of Europe. It is long-lived, grows to an immense size, and is very ornamental. The wood is hard and compact; when young, it is tough and flexible; but when old, it is brittle, and often shaky. The chestnut contains only a very small proportion of sap-wood; and hence the wood of young trees is found to be superior to even the oak in durability. It is doubtful whether the roof of Westminster Hall be of oak or chestnut, the two woods being, when old, very like each other, and having been formerly used almost indifferently in the construction of buildings. A good deal of chestnut has been planted in England within the last thirty years.—TREDGOLD'S *Principles of Carpentry*.

Chestnut (*Castanea vesca*). The American chestnut does not venture beyond the 44th degree of latitude. It is found in New Hampshire, between the 43d and 44th degrees; but such is the severity of the winter, that it is less common than in Connecticut, New Jersey, and Pennsylvania. It is the most multiplied in the mountainous districts of the Carolinas and of Georgia, and abounds in the Cumberland Mountains and in East Tennessee. The coolness of the summer and the mildness of the winter in these regions are favorable to the chestnut; the face of the country, also, is perfectly adapted to a tree which prefers the sides of mountains, or their immediate vicinity, where the soil in general is gravelly, though deep enough to sustain its perfect development. It is a stranger in Vermont, the State of Maine, and a great part of New York, to the maritime parts of Virginia, to the Carolinas, Georgia, the Floridas, Louisiana, and as far as the mouth of the Ohio. The American chestnut sometimes attains the height of 70 or 80 feet, with a circumference of 15 or 16 feet. The wood is strong, elastic, and capable of enduring the succession of dryness and moisture. Its durability renders it especially valuable for posts, which should be made of trees less than ten inches in diameter, and charred before they are set in the earth. It is also used for rails, and is said to last more than fifty years. For shingles this wood is superior to any kind of oak, though it has the same defect of warping. It is not extensively used for staves, and its pores, like those of the red-oak, are so open, that it is proper only for dry wares. The chestnut is little esteemed for fuel, and is not much used; it is filled with air, and snaps when it burns. The coal is excellent.—BROWN'S *Sylva Americana*.

Chestnuts (Fr. *Châtaigne*; Ger. *Kastanien*; It. *Castagne*; Sp. *Cast. s.*), the fruit of the chestnut-tree. In some parts of Europe they are frequently used as a substitute for bread, and form a large proportion of the food of the inhabitants. This is particularly the

Chicory, or Succory, the wild endive, or *Cichorium Intybus* of Linnaeus. This plant is found growing wild on calcareous soils in England, and in most countries of Europe. In its natural state the stem rises from one to three feet high, but when cultivated it shoots to the height of five or six feet. The root, which runs deep into the ground, is white, fleshy, and yields a milky juice. In Germany, the Netherlands, and France, chicory has long been extensively cultivated for the sake of its root, which is used as a substitute for coffee. When prepared on a large scale, the roots are partially dried, and sold to the manufacturers of the article, who wash them, cut them in pieces, kiln-dry them, and grind them between fluted rollers into a powder, which is packed up in papers containing from two ounces to three or four pounds. The powder has a striking resemblance to dark ground coffee, and a strong odor of liquorice. It is largely used in Prussia, Brunswick, and other parts of Germany; but as it wants the essential oil and the rich aromatic flavor of coffee, it has little in common with the latter except its color, and has nothing to recommend it except its cheapness. Chicory is now grown in Westchester county, New York.

Chili. The republic of Chili occupies that long strip of land which lies on the southwestern side of South America, extending from 24° to 55° 59' S. lat.; and from 69° to 72° W. long. It is bounded west by the Pacific Ocean, and east by the Andes, by which it is separated from the Argentine Confederation. On the north, Chili is separated from Bolivia by the extensive desert of Atacama; and it extends southward to the extreme limits of that Archipelago which embraces all the islands between Chiloe and the Straits of Magellan. Reckoning its length from the desert of Atacama to Cape Horn, it comprehends 36 degrees of latitude. Its average breadth is only 150, and where greatest not more than 210 geographical miles. The superficial area of Chili is computed at 218,925 English square miles, which is about 8195 miles more extensive than that of France and Belgium together. Except where the Andes are intersected by ravines, which frequently change into vales or plains fit for cultivation, these mountains, with their parallel ranges and spurs, occupy a great part of its area. South of the Cuesta de Chacabuco there are extensive plains, broken only by a few ridges of hills; but the highlands are almost continuous from north to south along the coast of the Pacific.

Chili is rich in almost every class of metals; but the silver mines of late years have yielded enormous quantities of ore. The metals at present discovered are gold, silver, copper, lead, antimony, cobalt, zinc, nickel, bismuth, iron, molybdenum, and quicksilver; but the only ores which are worked are gold, silver, copper, and occasionally quicksilver. The latter will now be abandoned in consequence of the low price of mercury, caused by the quantity produced in California. The metals are found in all the series of rocks between granite and trachyte, in veins which generally run from north and northwest to south and southeast; in some places, however, their course is irregular, or they extend east and west. The auriferous veins run nearly parallel to the grain or imperfect cleavage of the surrounding granite rocks. Gold is found most abundantly in the beds of detritus, derived from the degradation of the upper portion of the rocks. Copper ores, containing a small quantity of gold, are generally associated with micaceous specular iron. In the hills of Altrac, about four leagues from Rincagua, in the province of Santiago, are the only gold mines worked with any spirit, excepting some new mines near Copiapo, and they are remarkable for the variety of minerals mixed with the gold, such as galena, blende, copper and iron pyrites, and peroxyl of iron. The substances are found disseminated in quartz veins, running nearly north and south. Near Hlajel are

some very poor gold mines, in the beds of the gypseous formation, in altered felspathic clay-stone, which alternate with purple porphyritic conglomerate.

Until 1832, the only silver mines in Chili were those of Deheaa, San Francisco, San Lorenzo, Sema and San Pedro Nolasco, in the province of Santiago, and Arqueros mineral district, about 17 leagues from Coquimbo; but these mines now produce very little silver, and are nearly abandoned for the rich silver mines in the province of Atacama, near to Copiapo. Within a circuit of 25 leagues from Copiapo, there are 19 silver mineral districts; the richest are Chafareillo and Tres Puntas. In Chafareillo the upper part of the mines produces native silver, iodid, and bromid, associated with chlorid of silver and carbonate of lead. In the "Colorado" mine of Chafareillo, embolite with native silver is occasionally found. In the mine of San Antonio, in the same district, is found bismuthic silver ore, combined with native silver, copper, and arsenic. As the mines become deeper, the silver ores are changing principally into what the natives call "metales frios" (cold ores); these contain different proportions of antimony, sulphur, and one sort a little arsenic. The dark-red silver ore is a pyrrargite, containing sulphuret of silver and antimony, with sometimes a little arsenic. The gray ore contains silver, arsenic, and antimony. Of these two sorts upward of 5000 tons were exported to England during 1852, as the natives are unable to extract the silver by the usual plan of amalgamation adopted with the other ores. The export of the "metales frios" to England will in a great measure cease, as an English establishment is forming at Caldero, the port of Copiapo, to treat them on an improved plan. Some of the mines in Chafareillo yield nearly pure silver; the most productive are in the hands of four or five large capitalists. The ground near some of the richest mines is sometimes sold at enormous prices, the price being in some regulated by the probability of the rich veins of metal running into it. In Copiapo a regular traffic is carried on in buying and selling "barras" (a 24th part) in different mines.

A railroad runs from Caldera to Copiapo, a distance of 54 miles, which is to be continued on to Chafareillo, about 50 miles from the city; and a tram-road is projected to the rich mineral district of Tres Puntas (8400 feet above the sea), which, when completed, will enable the miners to send down the poor silver ores which they now throw away. The commerce of Chili has vastly increased since the time when the country lay torpid under the yoke of Spain. As soon as it had recovered from the unsettled condition caused by the revolution, business of all kinds acquired new energy, and the trade, freed from its oppressive restrictions, extended to the larger ports of the United States and Europe. A few years were sufficient to show a large increase in its export and import trade, and Valparaiso soon became a flourishing port.

The precious metals are the most valuable exports from Chili. While obtaining annually from her mines metal to the amount of £1,500,000, she exported in the year 1851 gold to the value of £50,950, silver to the value of £709,167, and copper to the value of £414,503. Flour, wheat, barley, and bisnits figure largely in her exports, but with considerable variations in amount. In 1850 there were shipped more than 68,000,000 lbs. of flour; in 1851, 44,000,000; and in 1852 only 41,000,000. Above 62,000 quarters of wheat were exported in 1850; in 1851 the quantity was 26,470; and in 1852, 55,570 quarters. In barley, however, there has been a considerable increase. From 37,750 quarters in 1850, it rose to 96,190 quarters in 1852. The increased export of wheat and flour in 1850 arises from the extensive shipments made in that year to California.

In the latter half of 1852 the exports of wool amounted in value to £22,330, pulse to £26,898, coal to £13,970, hides and skins to £3762, guano to £5562, and charqui

or jerked beef to £6393. Among the minor articles of export are figs, dried peaches, walnuts, Cayenne pepper, wine, brandy, bones, horns, hoofs, leather, ham, fat, cheese, butter, rugs, and timber.

In return for her various exports Chili receives from England cotton goods, from France silks and various articles of luxury, and from other countries a variety of articles for domestic use. Chili has reciprocal treaties of commerce with Austria, Brazil, Belgium, Bremen, Sardinia, Denmark, France, Great Britain, Prussia, Sweden, Norway, Tuscany, Hamburg, Lubeck, Oldenburg, the United States, Peru, Ecuador, and the Sandwich Islands. Her commercial relations are most extensive with Great Britain and the British colonies, the imports into Chili amounting in 1852 to £1,159,613, and the exports to £1,093,772. Next in importance is the trade with France, the United States and California. With the other republics of South America her commercial transactions, which were once considerable, appear to be on the decline.

In 1851 several important restrictions were removed from the customs code of Chili, which had been only partially modified in 1834. The exportation of national produce was then declared free in principle, but a small duty was to be maintained for a short time upon a very few articles. All imports, with the exception of iron, steel, zinc, cotton, mercury, coal, agricultural tools, surgical instruments, and books, are liable to a moderate duty. Jewelry pays 2 per cent.; horses, mules, and dried fruit, 6 per cent.; shoes, linen stuffs, furniture, and articles used only by the wealthy, 30 per cent. The duty on white wine is reduced to 10 reals per dozeau, and on red to 8 reals. Teas pay 2 reals the pound. Grain of all kinds is subject to a movable tariff. As long as the price in the home market does not exceed 16s. 8d. the fanega of 150 lbs., foreign grain pays an import duty of 12 reals the fanega; but if the price rises to 20 shillings, the duty falls to 8 reals, and if it exceeds 25 shillings the import duty ceases altogether. Many of the merchants of Valparaiso are desirous of the complete abolition of all restrictive duties; but government will probably delay any further steps in this direction until the advantage of the reform already made has been tested by further experience. The effect of this legislation, introduced under the administration of General Bulnes, has hitherto been to increase the revenue.

The weights and measures of Chili are the same as those used in Spain; but according to the decree of January, 1848, those of France are to be substituted in January, 1858. The largest dry measure of capacity is the fanega, which is subdivided into twelve almuds, and contains 5,430,626 cubic inches. The usual corn measure is the half fanega, which is a long parallelepipedon having one of its narrow sides trapezoidal. The imperial bushel contains 2,218,274 cubic inches, so that the fanega of Chili is to the former as 2.448 to 1. The average weight of a fanega of wheat is 157 lbs.

The old talbo of long measure is divided into lineas, palgadas, ples, varas, and cuadradas, or lines, inches, feet, yards, and cuadradas. Corresponding exactly in value to Troy weight there are the Spanish granos, onzas, and libras—or grains, ounces, and pounds; and to avoirdupois weight, onzas, libras, and quintales, or cwt. In liquid measure the English quart is equal to 1.022 Spanish cuartillo, and the imperial gallon to 4.069 cuartillos. Gold is bought by the castellano or marco. Its relative fineness is expressed by quillates or carats, four granos or grains making one quillate. The weight of the marco is equal to 4800 Spanish grains, or to 7 oz. 7 dwt. and 22 gr. English Troy weight. The standard fineness of gold is 21 quillates. The relative fineness of silver is expressed by dineros, the dinero being equal to 24 granos; and the standard fineness of that metal is 10 dineros and 20 granos. The old gold coins are the ounce, equal to 17 dollars 2 reals,

£23 9s. sterling money; the half ounce, equal to 8 dollars 5 reals, £1 14s. 6d.; the quarter ounce, equal to 4 dollars 2½ reals, 17s. 3d.; and the escudito, equal to 2 dollars 1¼ real, 8s. 7½d. Among the silver coins, besides the real, whose value is 6d., there are now pieces representing various values, expressed in centavos, a copper coin, of which one hundred make a dollar. There are silver pieces of 5, 10, and 20 centavos. One of 50 centavos is equal to half a dollar, or 2s. English money. The new gold and silver coins contain nine-tenths of pure metal, and one-tenth of alloy. The copper coins are quite pure, containing no alloy. Their names, value, and weight may be most conveniently represented by means of the following table:

	£ s. d.	Spanish Granos.	French Grammes.

The communication between the several towns of Chili is now greatly facilitated by roads, railways, and steam-vessels. The excellent road from Santiago to Valparaiso was constructed at a great cost by General O'Higgins, when President of the republic. A road, generally kept in good repair, connects the towns of Atacama and Concepcion. By far the most pleasant for the traveler is that by which Santiago and Talca are united. A railroad has been already established between Copiapo and Caldera; and in 1852 the President, M. Montt, laid the first stone on the line (about 90 miles in length) between Santiago and Valparaiso, and it is now rapidly advancing to completion. When finished it will be the most extensive work of the kind in South America. Proposals for railways from Serena to the sea, from Copiapo to Tres Puntas, and from Concepcion to Talcahuano, have also been laid before Congress. A line of electric telegraph has also been established between Valparaiso and Santiago.

The revenue of Chili is in a very prosperous condition, exhibiting a surplus of receipts over expenditure in the returns of several years. In 1845 the revenue amounted to £1,083,169 13s., leaving, after the necessary outlay, a surplus of £410,215. In 1849 the revenue, including the surplus from 1848, was £1,352,210. The surplus of 1849 was £57,048, which, together with the receipts of 1851, amounting to £385,881 8s., were entirely swallowed up during the revolution of the latter year. With the restoration of peace in 1852, the revenue rose to £1,096,096, which, with the sum of £21,000 paid by Peru as interest for its debt, gives an increase of £234,714 12s. over the income of the preceding year.

TABLE OF REVENUE FOR 1852.

	£1,120,996 0 0

The catastro is a duty of 5 per cent. levied upon the sale of lands. The alcabala is a duty of 4 per cent. on the sale and exchange of immovable property, and of 2 per cent. on the sale of mines. Peaje consists of tolls and pontages, and is levied on cattle, mules, vehicles, &c.—E. H.

In 1835, the exclusive right of steam navigation between the ports of the republic was granted to a

company, which commenced its operations in 1840. A similar privilege was afterward extended to the same company by the governments of Peru, Ecuador, and New Granada. The communication between England and Chili is maintained by way of the Isthmus of Panama. Steamers sail between England and Chagres,

from which by traveling across the Isthmus the Pacific is reached in about four hours, and the remainder of the journey continued in steam-vessels. The voyage from England to Chili by this route occupies about forty or fifty days; while the voyage from the United States to Chili requires about thirty days.

* 6 months to June 30.

† 1 year to June 30.

Chillies (Hind. *Gas Murridge*; Javan. *Lombok*; Malay *Chaba*), the pods or fruit of the *Capsicum annum*, or Guinea pepper. This is one of the hardiest and most productive plants found in tropical climates; growing luxuriantly in almost all dry soils, however indifferant. In the wild state the pods are small, and so pungent and acrid as to blister the tongue; but when raised on rich soils, they are large and comparatively mild. The plant is said to be a native of both Indies. It is very extensively cultivated; and, with the exception of salt, it is far more extensively used than any other condiment. In tropical countries, the pods are frequently made use of when unripe and green; when ripe, they become of a deep red color; and in that state they are exported dry and entire, or reduced to powder.—See CAYENNE PEPPER.

China. The continous empires of Russia and China occupy between them about one-fifth part of the habitable globe, in pretty nearly equal portions; but the population of the latter is about four times greater than that of the former, even after including its recent annexation of Poland. We can easily trace the boundaries and mark the extreme limits of these two great empires, by parallels of latitude and meridional lines of longitude; but when we come to reduce them to square miles, or speak of their contents in acres, the mind is bewildered by the magnitude of the numbers required to express them, and forms but an indistinct idea of their superficial extent.

No country in the world is better adapted, from situation, climate, and products, for extensive commerce, than China; yet no civilized country has profited less by these advantages. The happy equality of its numerous rivers, aided by artificial canals, affords an almost uninterrupted water communication from the

northern to the southern, and from the western to the eastern extremities of this grand empire; and thus a facility is given for the interchange of the products of one province with those of another, unknown in any other country, and unequalled even in Great Britain. The multitudes of barges of different sorts and sizes, which vary in their construction an almost every river, are incredible. The Chinese are rarely to be trusted where numbers are concerned; but they are probably not far amiss in stating that the number of imperial barges employed in the grand canal and its lateral branches, for the purpose of collecting and distributing among the public granaries the rice and grain paid in kind as taxes, amounts to 10,000, or, as they express it, where they mean to be correct, to 9999. A vast number of vessels are also employed in conveying the copper currency from place to place, wherever it may be wanted; others in collecting the silks, cottons, and various articles of taxes, paid in kind, and depositing them in the public magazines; and the salt barges alone are probably not less numerous than those which carry grain. It was calculated that the deposit of salt accumulated at Tien-sing for the use of the capital and the northern provinces was sufficient for a year's consumption for thirty millions of people. This was all brought up in the course of the summer, from the sea-coast of Tche-kiang and Fokien, in sea-going vessels. Cakes of coal-dust and turf, for fuel, and cakes made up of various ingredients for garden manure, employ a multitude of barges; and when to these are added the various kinds of vessels employed in general commerce, in the conveyance of passengers, and in the fisheries of the interior, we may be sure that the number of persons who constantly reside upon the water amounts to many millions.

* 6 months to June 30.

† 1 year to June 30.

All foreign commerce is systematically discouraged. The extent, fertility, and variety of their soil and climate, happily situated between the extremes of heat and cold, partaking of the advantages of both, without experiencing the inconveniences of either, supply the Chinese with the productions of almost all the world besides, whether to minister to the necessities, the comforts, or the luxuries of their numerous population; and leave this great empire, as a nation, almost independent of foreign supplies through the medium of commerce. Satisfied, or affecting to be satisfied, with the prodigal bounty of nature, jealous of strangers, and governed by a gradation of arbitrary despots, the Chinese long considered it as a favor bestowed on foreigners to open any of their ports for the interchange of commodities. The revenue derived from this limited intercourse was of little or no importance at the chief seat of government.

A very extensive intercourse is carried on by them with Japan, the Philippine Islands, Java, Sumatra, Timor, Gelolo, and the great Island of Borneo, in all of which are found multitudes of Chinese, living in habits of peaceful industry, in the midst of the more idle and less civilized natives, conducting the concerns of trade, cultivating the ground, and exercising all the various branches of the mechanical arts; in no place, however, varying in the smallest degree their original character. But though the Chinese spread themselves over every part of the Asiatic, and into many of the Polynesian islands, there seems to be no reciprocity of commerce by the vessels of those countries visiting the ports of China, excepting some ten or twelve junks that annually visit the southern ports of Fokien from Japan, and perhaps as many from Cochin China. "From Canton," says Lord Macartney, "to Ten-chou-foo, at the entrance of the Gulf of Pe-tche-lee (to say nothing of the country within the Gulf itself), is an extent of coast of near two thousand miles, indented with innumerable harbors, many of

them capable of admitting the largest European ships, and all of them safe and sufficiently deep for the vessels of the country. Every creek or haven has a town or city upon it; the inhabitants, who abound beyond credibility, are mostly of a trafficking mercantile cast, and a great part of them, from their necessary employment in the fishery, which supplies them with a principal article of their subsistence, are accustomed to the sea, and the management of shipping." From Java alone they import birds' nests to the value of half a million dollars annually; the sea-slug or bicho-de-mer (*holothuria*), from the coast of New Holland, Timor, and adjoining islands, to a still greater extent; sharks' fins from the same quarter; copper from Japan, and tin from Bantam; pepper, areca-nut, spices of different kinds, ebony, sandal-wood, red-wood for dyeing, tortoise-shell, pearl-shell, coral, camphor, wax, and a variety of articles, generally produced or collected by their own countrymen resident in the Islands of the East.

The Chinese levy no specific duties on the articles imported, nor *ad valorem* duties on the cargoes; the only impost is on the ship itself, and is estimated by a rule as absurd as it is partial and unequal. They measure the length from the centre of the foremast to the centre of the mizen-mast, and the breadth is taken close abaft the mainmast. The length is then multiplied by the breadth, and the product, divided by ten, gives the measurement of the ship. All ships, according to this measurement, are classed under first, second, or third rates; all other vessels, however small, are classed as third-rates. By this rule a ship of a hundred tons would pay from \$1000 to \$5000, and a ship of a thousand not above double that sum.

Revenue.—To ascertain exactly or even approximately the revenue of the Chinese Empire is almost impossible. In 1587, Trigault, a French missionary, stated it at 20,000,000 taels—the tael being equal to about 5s. 6d. English, or \$1 25 United States currency.

In 1655, Nieuhoff estimated it at 108,000,000 taels. Twelve years later, Magelhaens reckoned it at about £4,000,000 sterling. In 1721, it was calculated to have risen to £10,000,000 or £14,000,000 sterling. Toward the close of the eighteenth century it was given by Sir George Staunton at £66,000,000; of which sum, however, little more than a fifth was transmitted to Pekin. According to the Chinese constitution each province is obliged to support itself, and to transmit a certain surplussage for the maintenance of the Emperor and his court. The manner in which the items of the revenue are divided are thus stated by De Guignes, the last authority on this subject:

	Taels.
Income in money.....	27,907,000
Equal revenue in kind from grain.....	27,967,000
Tax on the second crop in the southern provinces.....	21,800,000
Gabel, coal, transit duties.....	6,479,400
Customs at Canton.....	800,000
Revenue from silk, porcelain, etc.....	7,000,000
Taxes, licences, tonnage duties.....	4,000,000
Total.....	89,713,400

Till within a few years ago, Canton was the principal mart for foreign commerce, and was in fact the only port open to foreigners. In virtue of the treaties, however, concluded at the termination of the war with England, four additional ports have been thrown open, viz., Shanghai, Ningpo, Foo-chow, and Amoy. Under the respective heads of these articles will be found detailed accounts of the exports and imports of the districts in which they are respectively situated. The foreign commerce of China, as more fully detailed below, may be roughly estimated at between 20 and 25 millions sterling. This, however, bears a very small proportion to the inland trade. It has been asserted that there is a greater amount of tonnage belonging to the Chinese than to all the other nations of the world combined; and from the length and number of the canals, and the myriads of boats necessary for carrying on the enormous inland trade of the empire, it is believed that this statement is not very wide of the truth.

The mode of conducting the trade is fully described in the *Chinese Commercial Guide*, where the forms of custom-house blanks are given both in English and Chinese. The foreigners themselves employ clerks called *linguists* to transact their business, and these linguists act also in many transactions as brokers. Every Chinese who intends to engage in trade in this capacity, or as a trader, previously learns to speak English by studying manuscript vocabularies in which the English sounds of words and phrases are written underneath in the Chinese character, the student obtaining the assistance of more advanced scholars to correct his pronunciation. The idioms of the English learned in this *prima voce* manner are chiefly Chinese, which explains the inverted arrangement of sentences in the Canton English, as this jargon is called, and the utter disregard paid to gender, number, person, time, and other properties considered of importance in most languages. The whole trade is conducted in this meagre gibberish, which the natives, however, suppose to be as copious and correct as foreigners themselves speak, but which hardly serves even the common purposes of trade and household need, much less enables the two parties to exchange ideas upon recondite subjects. Much of the misunderstanding and trouble experienced in daily intercourse with the Chinese is doubtless owing to this imperfect medium, for they seldom take the trouble to ascertain if their idea of what is told them is the correct one; and mutual vexation and ill-will arise, when one party finds his orders to have been heedlessly performed, and the other that his efforts to please have only earned maledictions instead of commendation. These petty annoyances have also had more serious results in strengthening the national dislikes, and still farther separating those who originally intended, perhaps, to endure each other only so long as they could make gain thereby.

The total amount of the exports and imports of the five towns now open to foreign commerce is given in the subjoined table for 1845:

Canton	{ Imports in vessels of all nations ..	£3,046,043
	{ Exports in vessels of all nations ..	6,822,726
Amoy	{ Imports in British vessels.....	147,494
	{ Exports in British vessels.....	154,731
Ningpo	{ Imports.....	18,000
	{ Exports.....	19,000
Foo-chow	{ Imports.....	100,000
	{ Exports.....	55,000
Shanghai	{ Imports.....	1,223,980
	{ Exports.....	1,547,069

The contraband trade in opium is estimated to amount to upward of 40,000 chests, at a sale price of nearly £5,000,000 sterling, which with the pearls, gold and silver ware, precious stones, and other articles smuggled, will swell the total of the foreign trade to about £21,000,000 sterling annually, exclusive of the Russian trade at Kiakha. The consumption of tea in England is about 60,000,000 of pounds annually; in the United States it is about 20,000,000; in the Netherlands, 2,000,000; in Russia, 5,000,000; in Germany, 3,000,000; in New South Wales, 4,000,000; in Spain and France, 3,000,000. The aggregate consumption of tea in China itself has been estimated, though not on very good authority, at about 700,000,000 of pounds. The prospects of the rapid extension of the foreign trade with China are not very promising, except in a few articles. The raw produce furnished from that country is very trifling, silk and alum being the chief, and there is in the mean time little prospect of any great increase in the exportation of her manufactured articles, except tea and silk goods. The opium trade has been for many years between three and four millions sterling in excess of the regular exchange of commodities, and the drainage of the country for this balance will probably go on as long as the taste for this pernicious narcotic continues, or there is any specie to pay for it. To legalize the opium trade would make no material difference in the exportation of specie, as long as the balance of imports so greatly exceeds the exports. England may make every effort to supply China with her manufactures, but so long as the Chinese furnish so little that she wants beyond a supply of tea, it is difficult to perceive with what they are to pay for all the cottons and woolens they may be expected to buy.

The Chinese appear to have no regular established system of credit among themselves, and the only circulating medium in the shape of coin is a small piece of base metal (copper, tin, or lead mixed), of the value of the one-thousandth part of six shillings and eightpence, of little more intrinsic value, in fact, than a cowrie-shell, which the Chinese, as well as the Hindus, would seem once to have used; as the same character in their language which signifies a *shell* signifies also money and wealth, and it enters into the composition of characters which represent *buying, selling, paying, etc.* Silver in small ingots is used in commerce, but they have no determinate value, the price fluctuating with the demand, as in other articles of commerce. The high rate of interest operates as a discouragement to mercantile speculations, and the rigor of corporal punishment is added, with the view, as it would appear, of deterring the most hardy speculator. The law says, "whoever shall lend either money or goods, shall only receive three parts in the hundred per month," and that "how much soever may be suffered to accumulate, the capital shall remain the same." It is lent from month to month, and if the lender should complain of the interest not being punctually paid, the borrower is subject to the punishment of ten stripes of the bamboo the first month, twenty the second, and so on. The legal rate of interest, however, is seldom paid, and in large transactions among business men it is from 12 to 15 per cent. per annum. The borrower makes a special agreement with the lender for a rate of interest varying between these two sums.

On the 31st of August 1845, Sir Henry Pottinger, by Ke-ying, Emperor of the treaty y the two em dollars dur the ports of Shanghai, and our office side at the and export and publish in perpetual successors terms of pe government signified h the 31st of government changed at sion of by erment ap The aim considerable in the coun China from Prussia, Si interviews to court. sent embas but neither ying havin purpose, a United States of the to with Eng of hospital for permis coasts of C leges to al were exch embassade into negot between t United St Their n antiquity, in fact, m from the foreig in same kin at the por were fou hundred y descriptio which the anchors or boats and cation ar cially the them suit and the v spective n navigate, supersede common in barges for sleepi victuals, name, is pation is be wante An Engl of China, NE3, etc.

On the 20th August, 1842, a treaty of peace was signed before Nankin, on board of the *Cornwallis*, by Sir Henry Pottinger on the part of Great Britain, and by Ke-ying, Elepeo, and Niu-kien, on the part of the Emperor of China. The most important provisions of the treaty were, lasting peace and friendship between the two empires; China to pay twenty-one millions of dollars during that and the three succeeding years; the ports of Canton, Amoy, Foo-chow, Ningpo, and Shanghai, to be thrown open to foreign trade; consular officers to be appointed by foreign powers to reside at these places; regular and just tariffs of import and export and inland transit dues to be established and published; the Island of Hong Kong to be ceded in perpetuity to her Britannic majesty, her heirs, and successors; and correspondence to be conducted on terms of perfect equality between the officers of both governments. To this important treaty the emperor signified his assent on the 8th of September, and on the 31st of December it was ratified by the British government. In June, 1843, the ratifications were exchanged at Hong Kong, which was then taken possession of by proclamation, and the functionaries of government appointed.

The announcement of the treaty of Nankin excited considerable sensation in Europe and America, chiefly in the commercial circles; and agents were sent to China from the governments of Belgium, Holland, Prussia, Spain, and Portugal, and most of them had interviews with Ke-ying at Canton before he returned to court. France and the United States of America sent ambassadors extraordinary to the court of Peking, but neither of them went farther than Canton. Ke-ying having been reappointed commissioner for the purpose, a treaty was signed between China and the United States, embodying all the important stipulations of the treaties and commercial regulations agreed to with England, and providing further for the erection of hospitals, chapels, and cemeteries at the five ports; for permission to ships of war to visit any part of the coasts of China; and for the extension of these privileges to all nations. The ratifications of this treaty were exchanged on 31st December, 1845. The French ambassador having also arrived at Canton, and entered into negotiation with Ke-ying, a treaty was concluded between them at Whampoa on the basis of that of the United States.

Their naval architecture wears the stamp of great antiquity, and is exceedingly grotesque. They have, in fact, made little progress in maritime navigation, from the inveterate dislike of the government to all foreign intercourse, and to all innovation. The very same kind of vessels as those described by Marco Polo at the port near at to Peking, in the thirteenth century, were found without variation by Lord Macartney, five hundred years afterward, and accurate to the Italian's description, even to the number of compartments into which the hold of each vessel was divided. They had anchors of wood, and ropes and sails of bamboo. The boats and barges for internal commerce and communication are very varied, generally commodious, especially the passage-boats on the grand canal, and all of them suited to the depth and velocity of the stream, and the width of the locks and flood-gates of the respective canals and rivers which are intended to navigate. These vessels are so numerous as almost to supersede the necessity of land-carriage; and the most common and convenient mode of traveling in China is in barges, which are generally provided with cabins for sleeping, and a kitchen and utensils for cooking victuals. Their military navy is unworthy of the name. It consists of a flotilla, whose principal occupation is that of conveying soldiers where they may be wanted, and looking after pirates and smugglers. An English frigate would beat the whole naval force of China.—GROZIER, DU HALLÉ, BARROW, DE GUIGNÉ, etc.

The principal articles of export from China are tea and raw silk; and of these the following quantities have been exported during the ten years ending 1st July, 1858:

TEA EXPORTED FROM CHINA TO THE UNITED KINGDOM.

Year ending June.	Pounds.	Year ending June.	Pounds.
1844	50,618,000	1851	64,020,000
1845	53,670,200	1852	65,137,000
1846	57,934,600	1853	73,900,000
1847	53,365,000	1854	77,217,000
1848	47,004,300	1855	60,500,000
1849	47,242,600	1856	61,025,000
1850	53,961,000		

Thus, in the last seven years, the quantity of tea shipped from China to the United Kingdom has become nearly doubled, and even compared with 1852, is nearly one half more. But, as we have already intimated, it is as important a question, as regards the exchanges with China, what progress has been made in the shipments to the United States. These have been as follows:

TEA EXPORTED FROM CHINA TO THE UNITED STATES.

Year ending June.	Pounds.	Year ending June.	Pounds.
1850	15,072,000	1855	40,974,000
1851	31,757,000	1854	27,807,000
1852	28,700,000	1855	31,515,000
1853	34,334,000	1856	40,246,000

From these two tables it appears that since 1843, only seven years ago, the quantity of tea exported from China to the United Kingdom and the United States has increased from 65,814,000 lbs. to 131,280,000 lbs. Since 1852 the increase has been from 99,471,000 lbs. to 131,282,000 lbs. Then as to silk: the entire exports from China to the United Kingdom, eleven years ago, amounted only to 10,727 bales. In the year ending June, 1848, there were 17,229 bales, since which time, particularly during the last four years, they have very rapidly increased. The following table shows the export in each year:

SILKS EXPORTED TO THE UNITED KINGDOM FROM CHINA.

Year ending June 30.	Bales.	Year ending June 30.	Bales.
1849	17,229	1854	25,571
1850	16,134	1855	31,943
1851	22,143	1856	51,486
1852	23,040	1857	55,459

China Porcelain. This manufacture is first mentioned in history in 1531: it was introduced into England in the sixteenth century. Porcelain was made at Dresden in 1706; the ware in England, at Chelsea, 1752; at Bow in 1758; in various other parts of England, about 1769; and by the ingenious Josiah Wedgwood, who much improved the British manufacture, in Staffordshire, 1762 *et seq.*—HAYDN. See PORCELAIN.
China-root (Ger. *Chinwurzel*; Du. *Chinawortel*, Fr. *Squiné*, *Esquiné*; Sp. *Raíz China*, *Coccolera*; Arab.

Rhubarb), the root of a species of climber (*Smilax China*, Linn.). It comes from the West Indies, as well as from China; but that from the latter is best. It is oblong and thick-jointed, full of irregular knots, of a reddish-brown color on the outside, and a pale red within; while new, it will snap short, and look glittering within; if old, the dust flies from it when broken, and it is light and kecky. It should be chosen large, sound, heavy, and of a pale red color internally. It is of no value if the worm be in it.—MILNOR's *Oriental Commerce*.

Chints, or Chintz (Fr. *Indiennes*; Ger. *Zitze*; It. *Indiane*; Rus. *Siz*; Sp. *Chiles*, *Zaraza*), a peculiar pattern upon printed calicoes, in which flowers and other devices are printed in five or six different colors, upon white and colored grounds. A good chintz pattern in fact colors is one of the most surprising and difficult efforts of the art. It was first manufactured in the East Indies, but is now largely manufactured in Europe, particularly in Great Britain.—See CALICO.

Chocolate (Du. *Chocolade*; Fr. *Chocolat*; Germ. *Schokolade*; It. *Chocolata*; Port. *Chocolat*; Rus. *Schokolad*; Sp. *Chocolate*), a kind of cake or confection, prepared principally from the cacao-nut. The nuts are first roasted like coffee; and being reduced to powder and mixed with water, the paste is put into the moulds of the desired shape, in which it speedily hardens, being, when taken out and wrapped in paper, fit for the market. Besides cacao, the Spanish use vanilla, sugar, maize, etc., in the preparation of chocolate. Chocolate was first introduced into Europe from Mexico about A.D. 1520. It was sold in the London coffee-houses soon after their establishment in 1650.—*Tatler*.

"Alike easy to convey and employ as an aliment, it contains a large quantity of nutritive and stimulating particles in a small compass. It has been said with truth that, in Africa, rice, gum, and shea butter, assist man in crossing the deserts. In the New World, chocolate and the flour of maize have rendered accessible to him the table-lands of the Andes, and vast uninhabited forests."—LITTON'S *Personal Narrative*, vol. iv. p. 284, Engl. transl.

Christiana, the capital of Norway, situated at the bottom of a fiord or gulf, in the province of Agderhus; in lat. 59° 55' N., long. 10° 48' E. Population in 1845, 26,141. Christiania is about 60 miles from the open sea; the gulf is in some places very narrow, and its navigation somewhat difficult; but it is sufficiently deep for the largest vessels, having 6 or 7 fathoms water close to the quay. It is compulsory on all ships to take a pilot on board at the mouth of the bay. The trade of the town is considerable. The principal exports are timber and deals, which are largely imported into England; glass, particularly bottles; iron and nails, bones, smalts, oak bark, etc. Salted and pickled fish, one of the staple products of Norway, is principally exported from Bergen. The deals of Christiania have always been in the highest estimation—a consequence of the excellence of the timber, and of the care with which the sap-wood and other defective parts are cut away; and not, as Mr. Coxo seems to have supposed, of the skillful sawing of the plank. The saw-mills were formerly licensed to cut a certain quantity only, and the proprietors were bound to make oath that it was not exceeded.—COXE'S *Travels in the North of Europe*, 5th edition, vol. iv. p. 28. This absurd regulation no longer exists. There are far fewer restrictions on industry and commerce in Norway than in Sweden. In the former, manufactured goods are admitted on moderate duties, and are very generally made use of. The principal articles of import are colonial produce; iron and hardware; machinery; woolen, linen, and cotton goods; coals, butter, wine, brandy, etc.; corn is sometimes extensively imported.

Customs Regulations.—Within 24 hours after a vessel has got to her moorings, the master should deliver to the collector his general report as to ship and cargo,

or present the requisite documents for having such report made out with the assistance of a ship-broker, whose services masters of foreign vessels can not entirely dispense with. On making this general report, the measuring bill is to be exhibited, and payment of the tonnage and other dues inward is to be made. If the ship have not been previously measured in Norway, and is, consequently, not provided with a Norwegian measuring bill, she is to be measured, to ascertain her burden in Norwegian commercial laats, for the calculation of the tonnage duty. The general report having been made, the custom-house officers in charge of the vessel are furnished with the books for delivery, and the discharge of the cargo commences under their inspection; and the consignees may make their special reports under their responsibility and signature. If they are without precise information as to the contents of any or all of the packages or bales to their address, these bales or packages may, at their request, be opened in the presence of the officers before report is made. If a consignee omits availing himself of this permission, his pretending thereafter that more or other goods than he had ordered or been advised of have been sent to his address, will not be attended to. In the reports or entries is to be stated whether it is intended to pay the duties forthwith, whether the goods are intended for exportation, or whether they are to be landed. Prior to commencing loading outward, the master is to give verbal notice of his intention at the custom-house. If he has no Norwegian measuring bill, the vessel is to be measured. This being done, the shipper or shippers of the outward-bound cargo are each of them to make their special entries as to the quality, weight, and measure of the goods they mean to load. A copy of such entries is to be deposited at the custom-house, and the loading commences under the control of the officers. This applies to all mixed cargoes; but if the outward-bound cargo consist exclusively of wood, the shipper or shippers are only to notify that they intend loading wood, without specifying quantity, measure, etc., as the export duty on wood is charged according to the burden of the vessel. When the master clears outward, he produces the proper documents for showing the burden of his vessel, and to what port she belongs, and he is then, on proper application being made, provided with a pilot, who takes his vessel to sea.

Warehousing.—In Norway goods brought from abroad may be bonded or warehoused, with a view to their being again exported at some future period. Goods entered for home consumption may also be bonded for a certain period, in order to facilitate the payment of the duties. The former is called "*transit oplug*;" that is, depositing or warehousing goods for exportation, subject to transit duties only. The latter is called "*cred-it oplug*;" that is, warehousing or bonding on credit.

Transit Oplug.—Under this system goods from abroad may be warehoused for exportation free of import duty, paying on exportation a transit duty, which in most cases is 1-10th of what they would pay if entered for home consumption. If the goods are deposited in the custom-house warehouses, they lie free of rent or dues during 14 days, and if in private warehouses, under the key and seal of the customs, during six months. If they remain long, viz., beyond 14 days in the one, and beyond six months in the other case, they pay rent or dues equal to $\frac{1}{4}$ of the transit duty per month, which, after the lapse of three months, as regards goods in the custom-house warehouses, is increased to $\frac{1}{2}$ of the transit duty per month.

Credit Oplug.—This system allows most goods imported from abroad to be placed in the owner's or importer's own warehouses, under his own lock, free of duty, for a given time, on his reporting to the customs, every three months, how much he has sold, otherwise consumed, or exported, and then paying the duty on such amount; the custom-house officers, who are bound quar-

terly to examine, to ascertain the quantity received on credit on the from the time

By way of which the credit themselves, 1. question. 2. goods, and effects trader availing property is not erty for the cus they shall decer tery inspection view of ascert value for the of this, full right, being offered, or as much as death or failure with the whole retain as much dies; and in ca the remainder ruff, as the ca allowance is m houses. Shipping Ch nature payabic tering the port board, unloading and clearing out

1. **Charges Inve** month of Ch take a pilot. 1/31 of health, the master, Tomkars fees, Brokers' fees.

2. **Charges Outw** Castle dues. Master's bill of lading. Pale or stake Measuring bill Charity chest Tonnage dues Highm Hght Privilege to Fy Brokers' fees

F. B.—There is ships in Norway is, the ships of co

terly to examine the goods, concurring themselves by ocular demonstration that no more is missing than the quantity reported to have been taken away. This credit on the duties in no case to exceed two years from the time the goods were imported.

By way of security for payment of the duties on which the credit is granted, government reserve to themselves, 1. Priority of mortgage on all the goods in question. 2. Priority, or first right, in the property, goods, and effects of every description belonging to the trader availing himself of this credit, in as far as such property is not previously legally mortgaged. 3. Liberty for the custom-house officers, when and as often as they shall deem it expedient, between the stated quarterly inspections, to look over the stock on hand, with a view of ascertaining whether there remains sufficient value for the duties; and if they see reason to doubt this, full right, in default of other satisfactory security being offered, to seize the stock, and to sell the whole, or as much as shall cover the duties. 4. In case of death or failure of the party, an equal right to sell forthwith the whole of his stock at public auction, and to retain as much of the proceeds as shall cover the duties; and in case of deficiency, an established claim for the remainder on the estate of the deceased or bankrupt, as the case may be. In charging the duties no allowance is made for waste or damage in the warehouses. The warehouse rent charged on goods bonded under the transit system, in the custom-house warehouses, is as follows:

On a quarter of wheat for the first 3 months	0 0-5533 per month
Afterward	0 1-1076 "
On a ton of raw sugar for the first 3 months	0 11-5384 per month
Afterward	1 11-0765 "

Money, Weights, and Measures.—In Norway there are no gold coins. The principal silver coin, called a species dollar, is divided into 120 skilling. There are also half species, or 60 skilling pieces; 1-5th species, or 24 skilling pieces; 1-15th species, or 8 skilling pieces; and what is denominated skillingmynt, or small change—that is, 4 and 2 skilling pieces. The species dollar contains 390-58 English grains of pure silver, and is consequently worth 4s. 6½d. sterling, the par of exchange being four species dollars 42 6-17 skillings=£1. All Norway coins, except the small change, are alloyed with 1-7th copper, so that the species dollar weighs 448-38 English grains, and its divisions in proportion. Small change coins are alloyed with three times their weight of copper. There are one and two skilling pieces of copper.

Weights and Measures, same as at COPENHAGEN; which see.

Shipping Charges.—The various charges of a public nature payable by a ship of about 300 tons burden, entering the port of Christiania with a mixed cargo on board, unloading there, taking on board another cargo, and clearing out, are as follows:

	£	s.	d.
1. Charges Inward. —Pilotage from Farder, at the mouth of Christiania Bay, where all ships must take a pilot on board	2	2	2
Bill of health, assuming that the crew, including the master, consists of 14 persons	0	17	0
Tonnage dues and light money	9	16	0
Brokers' fees	1	5	4
	£14	2	0
2. Charges Outward. —Pilotage	0	9	2
Cattle dues	0	1	7
Muster-roll of crew	1	0	5
Pale or stake money	0	3	2
Measuring bill	2	1	5
Charity chest	0	1	7
Tonnage dues and light money	10	11	1
Higholm light	0	0	9
Pilotage to Farder	1	16	8
Brokers' fees	1	18	11
	£15	6	11

N.B.—There is no difference between the charges on native ships in Norwegian ports and privileged foreign ships, that is, the ships of countries having reciprocity treaties with Nor-

way; nor in the duties on goods imported by native ships and such privileged foreign ships. Great Britain is a privileged country.

The shipping of Norway has declined considerably of late years; a proof, if any such were wanting, of the groundlessness of the clamors kept up in Great Britain as to the supposed pernicious influence of reciprocity treaties on shipping.

Banking.—There are no private banking establishments in Norway; but there is a public bank, having its principal office at Drontheim, with branches at Christiania, Bergen, and Christiansand. It was established by a compulsory assessment in 1816. Its capital consists of 2,000,000 species dollars, in transferable shares, divided among those who were forced to contribute to its formation. These shares are now at a premium of 30 per cent. Its managers are appointed by, and are accountable to, the Storting or Norwegian Parliament. It issues notes for 100, 50, 10, and so low as 1 species dollar. These notes should be payable in specie on demand; but they are at a discount of 35 per cent., and are paid by the bank at that rate. It discounts bills at two and three months date at 6 per cent. per annum; advances money on mortgage at 4 per cent.; and transacts the ordinary banking business of individuals. It does not allow interest on deposits.

Credit.—Goods are sold partly for ready money, and partly on credit, but principally the former.

Commission, etc.—The number of brokers in Christiania is limited to four. Commission on the sale of goods, 2 per cent., or, *del credere* included, 3 per cent. Brokerage is fixed by law at 5-6ths per cent., which, in practice, is paid by the sellers.

Insurance.—All houses situated in Norwegian market towns must be insured in the General Insurance Company at Christiania, which is guaranteed by the state. The premium is moderate, being, on buildage situated in towns, ¼th, and on those situated in the country, ¼th per cent. Sometimes, however, when very destructive fires occur, it is raised.

Provisions, etc.—Christiania is not a favorable place for canning and repairing ships; but supplies of beef, bread, water, and other sea-stores, may be had as cheap or cheaper than in any other port of Norway; but its distance from the sea is too great to allow of its being visited by ships desirous merely of victualing.—We have derived these details from various sources, but principally from Consular Returns.

Timber.—A standard Christiania deal is 11 feet long, 1½ inch thick, and 9 inches broad; and 51-2 such deals make a load. Freight of deals from Norway to England is calculated at the rate of single deals, the standard measure of which for Christiania and all the southern ports of Norway, except Dram (a small town on the Drammen, about 20 miles southwest of Christiania), is 11 feet long and 1½ in thickness. A single deal from Dram is reckoned 10 feet long and 1½ inch thick.

Battens.—Three battens make 2 deals, retaining their own length and thickness. Half deals are only counted as deal ends, if they run under 6 feet; but if they run 6 or 7 feet long, then two half deals are counted a deal, retaining their own thickness.

Ends of Deals.—Four ends of deals, although 5 feet long, make but a deal 11 feet long, retaining their thickness; but as the freighters of ships seldom wish to have this assortment, which commonly run from 3 to 5 feet, and are taken on board as stowage, consequently for the advantage of the ship and not the freighter, the ship ought to bear the burden.

Ends of Battens, called Larvick Pudings.—No less than six ought to be counted a single deal, 11 feet long and 1½ inch thick.

Pale-boards, when they have their proper length, are 7 feet long; three pale-boards are counted a single deal.

Staves for hogsheds take up much room; in consequence of which more than ten can not be computed a single deal.

Christopher (St.), or St. Kitt's, one of the British West India islands, Leeward group. Lat. (Fort Smith) 17° 17' 7" N., long. 60° 42' 2" W., 46 miles west-northwest from Antigua. Length, northwest to southeast, 20 miles, breadth 5 miles, except at its southeastern extremity, where a narrow tongue of land extends toward the island of Nevis. Area, 68 square miles. Population in 1848, 23,127, of whom about 2000 are whites. The island is an irregular oblong, traversed in the centre from north to south by a mountain ridge of volcanic origin, in the middle of which rises the perpendicular craggy summit of Mt. Misery, elevation 3711 feet, and overhanging the crater of an extinct volcano: from this central ridge the land gradually and uniformly slopes to the sea, every portion of which is a rich fertile soil, and highly cultivated; pasture and woodlands ascending almost to the mountain summits. Four rivers water this country, and in the northeast there are several salt ponds, producing abundance of salt. Soil composed of loam, clay, and volcanic ashes, in some places with a depth of 75 feet, resting on gravel. Brimstone-hill consists of granite, limestone, and primary schists. Sulphur is found in the central range, and some indication of silver ore. The climate is dry and healthy; mean annual temperature of coast 80°, but the mornings and evenings are cooled by sea-breezes. The coldest month is February, the warmest August. Prevailing winds, northeast and southeast; rains frequent, but not in excess; hurricanes occur occasionally, and a terrific and fatal one nearly destroyed the island in 1722. The scenery, especially the vale of Basseterre, is rich and beautiful. The soil is particularly adapted for sugar plantations. Chief towns, Basseterre, the capital, and Sandy Point. Besides the parish churches, there are three Methodist congregations, and several schools. This island was discovered by Columbus in 1493, and was then densely peopled by Caribs. In 1625 it was simultaneously taken possession of by colonies of English and French, and divided into upper and lower portions. From that period it became the scene of frequent and bloody contests between the two nations, till at last it was finally ceded to the British in 1783.

Chronometer (Greek *χρονος*, time, and *μετρον*, measure), a watch of peculiar construction, and great perfection of workmanship, used for determining geographical longitudes, or other purposes where time must be measured with extreme accuracy. The chronometer differs from the ordinary watch in the principle of its escapement, which is so constructed that the balance is entirely free from the wheels during the greater part of its vibration; and also in having the balance compensated for variations of temperature. Marine chronometers generally beat half seconds, and are hung in gimbals, in boxes about six or eight inches square. The pocket chronometer does not differ in appearance from the ordinary watch, excepting that it is generally a little larger. Chronometers are of immense utility in navigation; and ships going on distant voyages are usually furnished with several, for the purpose of checking one another, and also to guard against the effects of accidental derangement in any single one. The accuracy with which some of the better sort of chronometers have been found to perform is truly astonishing; the error in a two months' voyage not exceeding two or three seconds.—See DENT on the Construction and Management of Chronometers.

Chunam, the name given in India to lime. The best, obtained by the calcination of shells, is employed in the mastication of betel (which see), to prevent, it is said, its injuring the stomach.

Cider or **Cyder**, a vinous liquor made from the expressed and fermented juice of the apple. In England, the counties of Devon and Hereford are noted as the cider counties; but good cider is also produced in the counties of Gloucester, Monmouth, Worcester, Dorset, Somerset, and Cornwall. Normandy has long

been known for the excellence of its cider; and considerable quantities are manufactured in other districts of France, and also in Belgium, Germany, and in North America.

In England the manufacture of cider is almost entirely in the hands of the common farmer, so that little or nothing has been done either to improve the machinery or bring science to bear on the processes which are followed. Hence much of the cider is of inferior quality, and much waste ensues in the manufacture. The apples for cider should only be gathered when fully ripe, as it is only then that they contain their full proportion of saccharine matter. As the apples are gathered they are laid in heaps, and are allowed to lie thus from 15 to 30 days, in order to become fully ripe or mellow. They are then thrown into a stone trough, round which a heavy circular stone is turned by means of one or two horses. When the apples are thoroughly ground, the pulp is carried in pulps to the serew-press and poured into square pieces of hair-cloth, the edges of the hair-cloth being so folded over the pulp as to prevent any escaping. The pulp is then subjected to pressure, when the juice escapes, leaving a solid cake. The juice is now transferred to casks, where it rapidly undergoes a process of fermentation, without requiring any addition; and in three or four days the process is completed, when it is drawn off into casks. The best cider is almost always that in which the process of fermentation has been most slowly conducted. When the fermentation has been rapid the cider is apt to run to acidity.

In France several manufacturers of cider have lately employed improved apparatus for mashing their apples, somewhat similar to that used for mashing the beet-root in the manufacture of sugar; and have also given special attention to the management of the process of fermentation. The quality of the cider is said to have been thereby greatly improved. The cake after its first pressure is sometimes broken up with water, and subjected to a second pressure, and the juice it then yields furnishes, on fermentation, an inferior cider, which must be soon used, as it will not keep. Cider is not fit to be drunk till about three months after it is made. Good cider yields about 6 per cent. of alcohol on distillation, and thus contains nearly the same amount of alcohol as the ordinary bitter Indian ales; but the inferior kinds do not contain above half that proportion. Cider appears to be a refreshing and healthful drink; and the natives of the counties in which it forms the ordinary drink are remarked to be nearly exempt from stone and from gravel complaints.—E. B.

Cigars. See **Tobacco**.

Cincinnati, the metropolis of Ohio, capital of Hamilton county, and the largest and most commercial place west of the Alleghany Mountains. It is situated on the right bank of the Ohio River, 455 miles below Pittsburg, and 1548 miles above New Orleans, and 502 miles from Washington. It is the largest city of the Mississippi Valley north of New Orleans, and the fifth in population in the United States. Population in 1800, 750; in 1810, 2540; in 1820, 24,831; in 1840, 46,338; in 1845, 65,000; in 1850, 115,438; in 1853, 160,141. The suburbs have 25,000 inhabitants additional.

This city is near the eastern extremity of a valley, about twelve miles in circumference, surrounded by a series of hills, which rise to the height of 300 feet by gentle and varying slopes, and are partly covered with the native forest trees. From the summit of these hills is presented a beautiful and picturesque view of the city and valley. It is built on two table lands, the one elevated from 40 to 60 feet above the other. Low-water mark in the river, which is 108 feet below the upper part of the city, is 432 feet above tide-water at Albany, and 133 feet below the level of Lake Erie. Fulton and the adjacent parts of Mill Creek township on the north, are but suburbs of Cincinnati, and if added to the above population would extend it to 185,000. The shore of the Ohio at the landing is substantially paved to low-water mark, and is supplied with floating wharves, adapted to the great rise and fall of the river, which renders the landing and shipping of goods at all times convenient.

The Ohio River at Cincinnati is 1800 feet, or about one-third of a mile wide, and its mean annual range from low to high water is about 50 feet; the extreme range may be about 10 feet more. The greatest depressions are generally in August, September, and October, and the greatest rise in December, March, May, and June. The upward navigation is in winter very rarely suspended by floating ice, and in some winters not at all. Its current at its mean height is about three miles an hour; when higher or rising, it is more; and when very low, it does not exceed two miles

The commercial returns for the year 1856 show that Cincinnati has participated in the general prosperity of the W. t. The total value of principal imports for the year ending September 1, 1856, was \$75,235,000, against \$67,501,000 the previous year; and of exports \$50,744,000, against \$38,777,000 the previous year, showing an increase in the value of imports of \$7,794,000, and in the value of our exports \$11,967,000; these figures do not represent the total value of imports and exports at Cincinnati. To the value of the imports 10 per cent. may be added, and to the exports 25 per cent., to embrace those articles not included in them. The figures then would stand thus:

Value of imports.....\$82,828,000
Value of exports..... 63,430,000

No record being kept of imports by the Cincinnati custom-house officers, except those which come under custom-house bond, the Chamber of Commerce, at its own expense, keeps a record of the imports and exports.

Cinnabar (Germ. *Zinnober*; Du. *Cinaber*, *Vermilieu*; Fr. *Cinnabre*; It. *Cinabro*; Sp. *Cinabrio*; Russ. *Kiunwar*; Lat. *Cinnabrium*).

Native Cinnabar—a mineral substance, red, heavy, and brilliant. It is found in various places, chiefly in quicksilver mines, being one of the ores of that metal. The cinnabar of the Philippine Islands is said to be of the highest color; but that of Almaden, in Spain, is the richest. The best native cinnabar is of a high color, brilliant, and free from earthy or stony matter.

Artificial Cinnabar.—"When two parts of mercury and one of sulphur are triturated together in a mortar, the mercury gradually disappears, and the whole assumes the form of a black powder, formerly called *Ethiops mineral*. When this mineral is heated red hot,

it sublimes; and if a proper vessel be placed to receive it, a cuke is obtained of a fine red color. This cuke was formerly called *cinnabar*; and, when reduced to a fine powder, is well known in commerce under the name of *vermilion*."—*TILSON'S Chemistry*.

Cinnamon (Du. *Kaneel*; Fr. *Cannelle*; Ger. *Zimmet*, *Kanehl*; It. *Canella*; Lat. *Cinnamomum*, *Canella*; Port. *Canella*; Sp. *Canela*; Pers. and Hind. *Darchinie*; Arab. *Darsini*; Malay *Kainanis*; Greek *Kivaqov*), the bark of the cinnamon-tree (*Laurus cinnamomum*), a native of Ceylon, where it grows in great abundance, Cochin China, and perhaps of some other countries. It is brought home in bags or bales weighing 2½ lbs. each; and, in stewing it, black pepper is mixed with the bales to preserve the cinnamon. The best cinnamon is thin and rather pliable; it ought to be about the substance of royal paper, or somewhat thicker; is of a light yellow color, approaching nearly to that of Venetian gold; it is smooth and shining; fractures splintery; has an agreeable, warm, aromatic flavor, and a mild, sweetish taste; when chewed, the pieces become soft, and seem to melt in the mouth; it is not so pungent but that it may be borne on the tongue without pain, and is not succeeded by any after taste. Whatever is hard, thick as a half-crown piece, dark-colored or brown, or so hot that it can not be borne, should be rejected. Particular care should be taken that it be not false packed, or mixed with cinnamon of an inferior sort.—*MILBURN'S Oriental Commerce*; *MARSHALL'S Essay*.

The cinnamon of Cochin China grows in the dry sandy districts lying northwest of the town of Faifo, between the 15th and 16th degrees of north latitude.

It is referred in China to the cinnamon of Ceylon. The annual imports into Canton and other ports vary from 250,000 to 300,000 lbs. There are no fewer than ten varieties of this species in the market. It is not cured, like that of Ceylon, by freeing it from the epidermis.—*CRAWFORD'S Embassy to Siam*, etc., p. 475.

Cinnamon Monopoly.—Down to 1833, the cultivation of cinnamon in Ceylon was restricted to a few gardens in the neighborhood of Colombo, the production and sale of the article being wholly monopolized by government. Upon the transference of the Island from the East India Company to the king's government, the former agreed to pay £60,000 a year for 400,000 lbs. or 434½ bales of cinnamon; it being stipulated that if the quantity collected exceeded this amount the surplus was to be burned! But this agreement was afterward broken off; and the cinnamon was sent to England by government, and sold on its account at quarterly sales. The net revenue derived from the cinnamon monopoly, in 1831, is said to have amounted to £127,961. As the monopoly could not be enforced, except by confining the culture of cinnamon to certain districts, it necessarily led to the most oppressive interferences with the rights of individuals, to the creation of numberless imaginary offenses, and the multiplication of punishments forming a heavy drawback upon the prosperity of the island. A sense of these disadvantages led at length to the abolition of the monopoly system in 1833, when England ceased to be amenable to the charge of upholding, without improving, the worst part of the Dutch policy, and restored to the natives their right to cultivate cinnamon anywhere and in any way they think fit.

Cinque Ports (i. e. the five ports), five havens on the southeastern coast of England, opposite France, and thus called by way of eminence, on account of their importance as safeguards against invasion. These comprise Hastings, Romney, Hythe, Dover, and Sandwich; to which were afterward added the two ancient towns of Winchelsea and Rye. These places were anciently deemed of so much importance in the defense of the kingdom against invasion, that they received royal grants of particular privileges, on condition of providing during war a certain number of ships at their own expense. They are governed by a warden with the title of Lord Warden of the Cinque Ports, and each had the privilege formerly of returning to Parliament two members under the title of Barons of the Cinque Ports; but since 1831 this privilege has been confined to Hastings, Dover, and Sandwich. We are told by Camden that William the Conqueror appointed the first warden of the Cinque Ports; but their charters are traced to the time of Edward the Confessor. The salary of the Lord Warden is £3000 a year. E. B.—See *CHITTY'S Commercial Law*.

Circumnavigators. Among the greatest and most daring of human enterprises was the circumnavigation of the earth at the period when it was first attempted, A. D. 1519. The first ship that sailed round the earth, and hence determined its being globular, was Magellan's, or Magellan's; he was a native of Portugal, in the service of Spain, and by keeping a westerly course he returned to the same place he had set out from in 1519. The voyage was completed in three years and twenty-nine days; but Magellan was killed on his homeward passage, at the Philippines, in 1521.—*BUTLER*. The following are the most renowned of this illustrious class of men: their voyages were undertaken at the dates annexed to their names.—See *NAVIGATORS*.

	A. D.
Magellan, a Portuguese, the first who entered the Pacific Ocean	1519
Grosvia, a Spanish navigator	1527
Avallardi, a Spaniard	1527
Mendana, a Spaniard	1547
Sir Francis Drake, first English	1577
Cavendish, his first voyage	1584
Le Maire, a Dutchman	1616

Tasman, Dutch	1642
Doutie, British	1683
Dampier, an Englishman	1689
Cooke, an Englishman	1783
Gilbertson, British	1719
Rogerswain, Dutch	1721
Anson (afterward Lord)	1740
Byron (grandfather of Lord Byron)	1764
Wallis, British	1766
Carteret, an Englishman	1766
Cook, the illustrious captain	1768
On the death of Captain Cook, his last voyage was continued by King	1779
Bougainville, French	1776
Porlocke, British	1788
Wilkes, American	1837
D'Urville, French	1837

Several voyages have been since undertaken, and, among other nations, by the Russians.—*HAYN*.

Cities. The word *city* has been in use in England only since the Conquest, at which time even London was called *Londonburgh*, as the capital of Scotland is still called *Edinburgh*. The English cities were very inconsiderable in the twelfth century. Cities were first incorporated A. D. 1079. The institution of cities has aided much in introducing regular governments, police, manners, and arts.—*ROBERTSON*.

Citron (Ger. *Succade*; Da. *Sukkat*; It. *Confetti di cedro*; Sp. *Acitron verde*; Fr. *Citron vert*), an agreeable fruit, resembling a lemon in color, smell, and taste. The principal difference lies in the juice of the citron being somewhat less acid, and the yellow rind being somewhat hotter, and accompanied with a considerable bitterness.—*LEWIS'S Mat. Med.* It is imported, preserved and candied, from Madeira, of the finest quality.

Civet (Germ. *Zibeth*; Du. *Civet*; Fr. *Cirette*; It. *Zibetto*; Sp. *Algalia*), a perfume taken from the civet cat: it is offensive unless extremely diluted, and then, in combination with other perfumes, it adds to their energy. It is brought from the Brazils, Guinea, and the interior of Africa.

Civita Vecchia, a fortified sea-port town of the papal dominions, on the Mediterranean, lat. 42° 4' 38" N., long. 11° 44' 52" E. Population 7000. The port of Civita Vecchia is artificial, and is formed by three large moles. Two of them projecting from the main land, inclined one to the north and the other to the south, form the sides of the harbor; while a third mole, or breakwater, constructed opposite to the gap between the other two, serves to protect the harbor from the heavy sea that would otherwise be thrown in by the westerly gales. A light-house, carrying the lantern elevated seventy-four feet above the level of the sea, is erected on the southern extremity of the outward mole; the distance from its extremities to the extremities of the lateral moles, on which there are towers, being about ninety fathoms. Vessels may enter either by the south or north end of the outer mole, but the southern channel is the deepest, having from eight to six and four fathoms. Ships may anchor within the port, in from sixteen to eighteen feet of water; or between it and the outer mole, where the water is deeper. Within the port there is a dock and an arsenal.—*Plan of Civita Vecchia*.

Imports and Exports.—Though the wealth and population of the country round Civita Vecchia be much fallen off in modern times compared with antiquity, it still continues to be the *entrepôt* of Rome, and engrosses almost the entire trade of the papal dominions on the side of the Mediterranean. The imports consist principally of cotton, woolen, silk, and linen stuffs; coffee, sugar, cocoa, and other colonial products; salt and salted fish, wines, jewelry, glass and earthen ware, &c. The exports consist of staves and timber, corn, coal, wood, cheese, potash, pumice-stone, alum, from Tolfa, in the vicinity, and other articles. The total value of the imports may be reckoned at from £350,000 to £700,000, and it may be fairly presumed that the real value of the exports is not much inferior. *Marseilles*

and Genoa have the largest share of the foreign trade of Civita Vecchia, and next to them, England.

Duties.—Civita Vecchia is a free port; that is, a port into which produce may be imported, and either consumed or re-exported, free of duty.

Quarantine regulations are strictly enforced, no vessel with a foul bill of health being permitted to enter any of the papal ports.—*Annuaire du Commerce Maritime*, tom. li. p. 366, etc.

Claret, one of the best French wines. It is derived from the Latin *Claretum*, from *Claree*, to be clear.—*See the articles BORDEAUX and WINE.*

Clarification, the act of clearing; particularly the clearing or fining of liquids from feculent matter by the separation of the insoluble particles. This is performed by decantation, filtration, or coagulation. The substances usually employed for clarifying liquors are the albumen of eggs, blood, and isinglass. The first two are used for such liquors as are clarified while boiling hot; the last for those which are clarified in the cold state, as wines, etc. The whites of eggs are beaten up into a froth and mixed with the liquor, when they unite with and entangle the impure matters that float in it; and, presently coagulating by the heat, carry these impurities up to the surface in the form of scum. Blood operates in the same manner. Isinglass is much employed for fining wines. For this purpose, about a quarter of an ounce may be thrown into the cask, or the isinglass may be previously dissolved and boiled down to a slimy consistence. It is then mixed with the liquor by rolling the cask about; after which it is allowed to settle.

Clearing, among London bankers, is a method adopted for exchanging the drafts on each other's houses, and settling the differences. Thus, at half-past three o'clock, a clerk from each bank attends at the clearing-house, where he brings all the drafts on the other bankers which have been paid into his house that day, and deposits them in their proper drawers (a drawer being allotted to each banker); he then credits their accounts separately with the articles which they have against him, as found in the drawer. Balances are then struck from all the accounts, and the claims transferred from one to another, until they are so wound up and canceled that each clerk has only to settle with two or three others, and their balances are immediately paid.

Clearing-house, the place where the operation termed clearing is carried on. The London clearing-house was established some years since, for the convenience of bankers and joint-stock banks in the metropolis by facilitating the transfer, liquidation, or exchange of bank checks and bills. This object is fully accomplished by each party, or some one representing it, meeting at a fixed place, at a fixed hour per day, to deliver checks on each other, and receiving in return checks on themselves, or cash to balance. It follows, necessarily, that the payments and receipts daily must exactly counterbalance each other. The utility of this arrangement, its economy of time and labor, and avoidance of risk, may be estimated from the fact that the annual clearings for one year (1839) amounted to £54,000,000 sterling, or over \$15,000,000 each business day. In the year 1810, the average payments or clearings were \$1,700,000 daily, on an average.

The New York clearing-house was established in 1853, and a constitution adopted in September of that year, when fifty-two of the banks of the city were represented and became members. Operations were commenced the second week in October, 1853, and have been carried on regularly ever since.

The hour for making exchanges at the clearing-house is 10 o'clock A.M., when all the checks or bills of each bank are delivered by a clerk, and distributed by the manager or his assistant to the clerk or representative of the banks respectively. At 1 o'clock P.M., the debtor banks pay to the manager the balances against them, either in coin or in bank certificates—the latter representing coin and used only by and among the banks, to avoid the carrying of specie to and from the clearing-house. At the same hour the creditor banks receive from the manager, at the same place, the respective balances due to them. The manager receives a salary of \$3000, and has two clerks under him. The expenses of the clearing-house are borne by a tax upon the city banks who are members, now fifty-three in all. Banks having a capital less than \$1,000 pay \$100 each, annually; less than \$1,000,000 pay \$260, and those over \$1,000,000 pay \$300 each, annually.

The Boston clearing-house was organized in that city September 26, A.D. 1855, and commenced business March 29, A.D. 1856. All the banks in the city (thirty-five in number) are connected with the institution, representing a capital of \$31,960,000. The executive committee consists of five gentlemen, all of which are presidents of banks. The total transactions from its commencement to November 30th, 1856, amounted to \$1,060,390,841. The Merchants' Bank is the depository bank for the special deposit of coin from the several banks connected with the association.

Cleveland, city, port of entry, and the capital of Cuyahoga county, Ohio, on the south shore of Lake Erie. Lat. 41° 30' N., long. 81° 47' W. The population in 1799 consisted of one family; in 1825 about 500 inhabitants; in 1830, 1000; in 1834, 4300; in 1840, 6071;

in 1850, 17,034; and in 1854, about 25,000; and with the addition of Ohio City, 7000 more, making a total of 32,000. Cleveland is the emporium of Northern Ohio, and, next to Cincinnati, the most important town in the State; possesses a commanding situation on Lake Erie, at the mouth of the Cuyahoga River, and the northern termination of the Ohio Canal, by which it is connected with the Ohio River, and by railroad to New York, to Buffalo, to Philadelphia via Pittsburg, to Cincinnati, to Chicago. It is 150 miles north-west from Pittsburg, 146 northeast from Columbus, 200 by water from Buffalo, 180 from Detroit, and 359 from Washington. The value of imports in 1851 amounted to \$22,804,159; exports same year amounted to \$12,026,497. The licensed and enrolled tonnage of the district for 1851 was 36,070 tons; 11,355 steam, and 24,615 sail. The harbor of Cleveland is formed by the mouth of the Cuyahoga River, and improved by a pier on each side, extending 425 yards into the lake, 200 feet apart, and faced with substantial stone masonry. Cleveland has a ready communication with New York via railroad and the Erie Canal, with Philadelphia by railroad and canal, with Cincinnati by railroad, and with the Ohio River by the Ohio Canal, and it exports much by the way of the Welland Canal to Canada.—See Ohio.

Clock, Clocks (Ger. *Uhren, Grosse Uhren, Wanduhrke; Du. Uuren, Uurwerken, Horologien; Fr. Horloges; It. Orologgi, Orioli; Sp. Relojes; Russ. Tschasi*), a kind of machine put in motion by a gravitating body, and so constructed as to divide, measure, and indicate the successive portions of time with very great accuracy. Most clocks mark the hour by striking or chiming. It is a highly useful instrument, and is extensively employed for domestic and philosophical purposes. Clocks are made of an endless variety of materials and models, so as to suit the different uses to which they are to be applied, and the different tastes of their purchasers. The Germans, Dutch, and Americans are particularly celebrated for their skill in the manufacture of clocks; while the English, French, and Genevese, especially the former, have carried the art of making metallic clocks, so as to keep time with the greatest precision, to a high degree of perfection. The history of the invention, introduction, and successive improvements in the manufacture of clocks, has been carefully investigated by some very learned and industrious antiquaries (see BECKMANN'S *Hist. of Inventions*, vol. i. p. 419-462, English ed.; and REES' *Cyclopaedia*); but, notwithstanding these researches, the subject is still involved in considerable obscurity. It seems, however, that the middle of the fourteenth century may be regarded as the epoch when clocks, having weights suspended as a moving power and a regulator began to be introduced. The period when, and the individual by whom, the pendulum was first applied to clock-work, have been subjects of much contention. Galileo and Huygens have disputed the honor of the discovery. "But whoever may have been the inventor, it is certain that the invention never flourished till it came into the hands of Huygens, who insists that if ever Galileo thought of such a thing, he never brought it to any degree of perfection. The first pendulum clock made in England was in the year 1662, by one Fromantel, a Dutchman."—MUTTON'S *Math. Dictionary*.

The origin of clock-work is involved in great obscurity. Notwithstanding the statements by many writers that clocks, *horologia*, were in use so early as the ninth century, and that they were then invented by an archdeacon of Verona, named Pacificus, there appears to be no clear evidence that they were machines at all resembling these which have been in use for the last five or six centuries. But it is certain that for that period at least clocks have been made depending on the action of a weight on a train of wheels, as distinguished from the water-clocks, *clepsydra*, which are well known to have been used many

centuries before. We will refer the reader who is curious about it to the articles on clocks, etc., in the *Encyclopaedia Britannica* and the various works there given. We will only add to the information there cited, that it appears from a communication of Captain Smith to the Antiquarian Society in 1851, that there is still a clock in existence at Dover Castle bearing the date 1348, earlier by thirty years than that of the clock made by De Vick for the palace of the Emperor Charles V., which has generally been described as the earliest clock of which the actual construction is known. Mr. Denison also, in his *Tridimentary Treatise on Clocks* (of which we have largely availed ourselves throughout this article, and also of various papers by him in the Cambridge Philosophical Transactions, and the Journal of the Society of Arts), mentions a clock in Peterborough Cathedral, still in use as to the striking part, of which the construction is more like that of the Dover Castle clock than that of De Vick; and Lord Chief Justice Coke tells us that a clock was set up in Westminster Hall in the thirteenth century out of a fine levered on one of his predecessors in that seat, from which, perhaps, the appropriate inscription *Iscite justitiam monti* was copied on to the sundial on a house now facing the hall.

The clock called the clepsydra, or water-clock, was introduced at Rome 138 b.c. by Scipio Nasica. Toothed wheels were applied to them by Ctesibius, about 140 n.c. Said to have been found by Caesar on invading Britain, 55 n.c. The only clock supposed to be then in the world was sent by Pope Paul I. to Pepin, king of France, A.D. 760. Pacificus, archdeacon of Verona, invented one in the ninth century. Originally the wheels were three feet in diameter. The earliest complete clock of which there is any certain record was made by a Saracen mechanic, in the thirteenth century.

The segment, ascribed to Gerbert, A.D.	1600
A clock constructed by Richard, abbot of St. Albans, about	1226
A striking clock in Westminster	1268
A perfect one made at Paris by Vick	1270
The first portable one made	1620
His pendulum clock some time previously to	1656
at Hampton Court (maker's billata, N. O.)	1540
Richard Harris (who erected a clock in the church of St. Paul's, Covent Garden) and the younger Galileo constructed the pendulum	1641
Christian Huygens contested this discovery, and made his pendulum clock some time previously to	1656
Fromantel, a Dutchman, improved the pendulum, about 1673	
Repeating clocks and watches invented by Barlow, about 1670	
The dead beat, and horizontal escapements, by Graham, about	1700

The subsequent improvements were the spiral balance spring suggested, and the duplex segment invented by Dr. Hooke; pivot holes jeweled by Facio; the detached segment invented by Mudge, and improved by Berthoud, Arnold, Earnshaw, and others.—HAYDEN.

Clocks imported into the United States pay a duty of 30 per cent.; watches, 10 per cent. Of clocks, the value imported in the fiscal year 1854-'55 was \$69,258; watches, \$3,651,187.

Olive-oil is most commonly used in lubricating clock machinery and preventing too great wear. We believe, however, that animal oil is better than any of the vegetable oils, as some of them are too thin, while others soon get thick and viscid. For turret clocks and common house clocks, good sperm oil is fine enough, and is probably the best. For finer work the oil requires some purification. Even common neat-foot oil may be made extremely fine and clear by the following method: mix it with about the same quantity of water, and shake it in a large bottle, not full, until it becomes like a white soup; then let it stand till fine oil appears at the top, which may be skimmed off; it will take several months before it has all separated into water at the bottom, dirt in the middle, and fine oil at the top. And it should not be done in hot weather, because heat makes some oil come out as due

which in middle, after will be oils sold some for hildition, have no i to it, and would be cent. in use of spe quiring c

which in cold would remain among the dirty oil in the middle, and in cold weather that fine oil of hot weather will become muddy. There are various vegetable oils sold at tool-shops as oil for watches, including some for which a prize medal was awarded in the Exhibition, but not by any of the mechanical juries; we have no information as to the test which was applied to it, and none but actual use for a considerable time would be of much value. We have heard of 5 per cent. in power being saved in a manufactory by the use of sperm instead of sweet oil to small spindles requiring constant lubrication.—E. B.

Cloze-hauled; that is, the tacks close down, the sheets aft, the yards braced sharp up, and the bowlines hauled, the ship making her progress as near the direction of the wind as she can.

Cloth. Both woolen and linen cloths were known in very early times. Coarse wooleens were introduced into England A. D. 1191; and seventy families of cloth-workers from the Netherlands settled in England by Edward III.'s invitation, and the art of weaving was thereby introduced, 1331.—*Румянъ's Vœderez.* Wooleens were first made at Kendal in 1390. Medleys were manufactured 1614. The fine English broad-cloths were yet sent to Holland to be dyed, 1654. Dyed and dressed in England by one Brewer, from the Low Countries, 1667. The manufacture was discouraged in Ireland and that of linen countenanced, at the request of both Houses of Parliament, 1698.—*HAYDN.* See WOOL.

Clover (Ger. *Klee*; Du. *Klaver*; Fr. *Troisfe, Luzerne*, It. *Trifoglio*; Sp. *Trebol*; Russ. *Трлѣстник*; Lat. *Trifolium*), a very important species of grass. Some of the species in cultivation are annual, others biennial or triennial, and others perennial. The seed used formerly to be principally imported from Holland; but that which is raised in England is now said to be of a superior quality. Culture for seed is, however, very precarious, and of uncertain profit. For crops of hay and grass seeds (including clover) raised in the United States, see art. *HAY.*

Cloves (Ger. *Nigeln, Gewurznelken*; Du. *Kruidnagelen*; Fr. *Clous de girofle, Girofle*; It. *Chiovi di garofana, Garofana, Garoffoli*; Sp. *Clavos de especia, Clavillos*, Russ. *Гвоздика*; Arab. *Kerafaul*; Malay, *Chanker*), the fruit, or rather cup of the unopened flowers of the clove-tree, or *Caryophyllus aromaticus*. The clove-tree is a native of the Moluccas, where it was originally found; but plants have since been carried to Cayenne and other places, where they succeed tolerably well. Cloves are shaped like a nail, whence the name, from the French *clou*, nail. They are imported from the Dutch settlements; the best in chests, and an inferior kind in bags. The best variety of the Amboyna cloves is smaller and blacker than the other varieties, very scarce, and, as a mark of pre-eminence, is termed the royal clove. Good cloves have a strong, fragrant, aromatic odor; and a hot, acrid, aromatic taste, which is very permanent. They should be chosen large sized, perfect in all parts; the color should be a dark brown, almost approaching to black; and, when handled, should leave an oily moisture upon the fingers. Good cloves are sometimes adulterated by mixing them with those from which oil has been drawn; but these are weaker than the rest, and of a paler color; and whenever they look shriveled, having lost the knob at the top, and are light and broken, with but little smell or taste, they should be rejected. As cloves readily absorb moisture, it is not uncommon, when a quantity is ordered, to keep them beside a vessel of water, by which means a considerable addition is made to their weight.—*Thomson's Dispensatory*; *MILNIN's Oriental Commerce.*

Policy of the Dutch as to the Trade in Cloves.—From the expulsion of the English from Amboyna, in 1623, the Dutch have, a few short intervals only excepted, enjoyed the exclusive possession of the Moluccas, or Clove Islands. In their conduct as to the clove trade,

they have exhibited a degree of short-sighted rapacity, which has been, we believe, seldom equaled even in the annals of monopoly. Their object has not been to encourage the growth and trade of cloves, but to confine both within the narrowest limits. They have preferred deriving a large profit from a stunted and petty trade to a moderate profit from a trade that might have afforded employment for a very large amount of capital; and to prevent their narrow and selfish projects from being counteracted by the operations of the natives, they have subjected them to the most revolting tyranny. "That they might," says Mr. Crawford, "regulate and control production and price just as they thought proper, the clove-trees were extirpated everywhere but in Amboyna, the seat of their power; and the surrounding princes were bribed by annual stipends to league with them for the destruction of their subjects' property and birth-right. This plan was begun about the year 1531. The contractors are still in force, and an annual fleet visits the surrounding islands to suppress the growth of cloves, which in their native country, spring up with a luxuriance which these measures of Satanic rigor, and of sacrilege toward bountiful nature, can scarce repress. By the plan on which the clove trade is now conducted—a plan carried into effect through so much iniquity and bloodshed—the country of spices is rendered a petty farm, of which the natural owners are reduced to the worst condition of predial slavery; and the great monopolizer and oppressor is that government, whose duty it should have been to insure freedom and afford protection. Human ingenuity could hardly devise a plan more destructive of industry, more hostile to the growth of public wealth, or injurious to morals, than this system framed in a barbarous age; and it reflects disgrace upon the character of a civilized people to persevere in it. It is curious to remark how the monopolizers, in carrying the details of this system into effect, at once impose upon the natives and deceive themselves. The nominal price paid to the natives is actually above the natural price of the commodity, but they are cheated in the details. The cultivator brings his produce to the public stores, where it is subjected at once to a deduction of one-fifth for payment of the salaries of the civil and military officers. The price of the remainder is fixed at the rate of 9-6 Spanish dollars the picul; but before payment is made, another deduction of one-fifth is made; one-half of which is for the chiefs or *rajas*, and the other for the native *elders*, who are overseers of the forced culture. The real price, therefore, paid to the grower is 8 Spanish dollars per picul, or 11d. per pound avoirdupois, instead of 11 52-100 Spanish dollars per picul, or 13d., which is pretended to be given. When cloves have been sold on the spot, the price usually exacted has been about 61 Spanish dollars the picul, or eight times the price paid to the cultivator. The average price in Holland, previously to the war of the French Revolution, may be taken at 6s. per pound, or 177 78-100 Spanish dollars per picul, being 212 2 per cent. advance on the real cost of the commodity in the place of its growth. When brought direct to England, they have cost at an average 3s. 8d. the pound, making 108 64-100 Spanish dollars per picul, an advance on the natural export price of 1258 per cent."—*Eastern Archipelago*, vol. iii. p. 388-390.

Oil of Cloves is procured from cloves by distillation. When new, it is of a pale reddish brown color, which becomes darker by age. It is extremely hot and fiery, and sinks in water. The kind generally imported from India contains nearly half its weight of an insipid expressed oil, which is discovered by dropping a little into spirits of wine; and on shaking it, the genuine oil mixes with the spirit, and the insipid separating, the fraud is discovered.—*MILNIN.*

Clyde, one of the largest and most important rivers in Scotland. It takes its rise from numerous streams flowing from the mountain range in the south-

ern part of Lanarkshire and borders of Dumfriesshire; the chief summits of which are the Lowthers, Leadhills, Queensbury Hill, and Rodger Law, with elevation approaching 8000 feet. Its course is through rich and fertile valleys to Glasgow. From this city it expands into a river navigable for ships of 300 to 400 tons, and flows northwest, dividing the county of Renfrew on the west, from Dumbarton on the northeast, receiving the tributaries of the Kelvin, Cart, and Leven. After passing Dumbarton, it opens up into a noble estuary four miles in width, spreading northward into Loch Long, and southward into the Firth of Clyde, with the islands of Bute and Cumbræ, situated at the mouth of the estuary. Here the Clyde expands into a firth averaging about 82 miles in width, and at the distance of 48 miles becomes identified with the North Channel. The length of the river from its source to Glasgow, including windings, is about 75 miles. From Glasgow to the south point of Bute Island about 40 miles. In the Clyde was launched the first steamboat constructed in Britain, 1812. *Clydesdale* is the district forming the valley of the Clyde, and is celebrated for its orchards, coal and iron mines, and horses.

Coaches, vehicles for commodious traveling. They have sometimes two, and sometimes four wheels. The body of the coach is generally suspended, by means of springs, upon the frame-work to which the wheels are attached. They are usually drawn by horses, but recently have been impelled by steam. The forms and varieties of coaches are almost innumerable.

Historical Notice.—Bekmann has investigated the early history of coaches with his usual care and learning. It is certain that a species of coaches was used at Rome; but whether they were hung on springs, like those now made use of, is not certain. After the subversion of the Roman power, horseback was almost the only mode of traveling. About the end of the fifteenth century, however, covered carriages began to be employed by persons of distinction on great occasions. In 1550, there were at Paris only three coaches; one of which belonged to the queen; another to the celebrated Diana of Poitiers; and the third to a corpulent, unwieldy nobleman, René de Laval, lord of Bois-Dauphin. Coaches were seen for the first time in Spain in 1546. They began to be used in England about 1580; and were in common use among the nobility in the beginning of the seventeenth century.—*History of Inventions*, vol. i. p. 111, 127, English translation.

According to HAYDN'S *Dictionary of Dates*, the coach is of French invention. Under Francis I., who was a contemporary with Henry VIII., there were but two in Paris, one of which belonged to the queen, and the other to Diana, the natural daughter of Henry II. There were but three in Paris in 1560; and one only IV. had one, but without straps or springs. The first courtier who set up this equipage was John de Laval de Bois-Dauphin, who could not travel otherwise on account of his enormous bulk. Previously to the use of coaches the kings of France traveled on horseback, the princesses were carried in litters, and ladies rode behind their squires. The first coach seen in England was in the reign of Mary, about 1553.—PRIESTLEY'S *Lectures*. They were introduced much earlier.—ANDERSON'S *History of Great Britain*. They were introduced by Fitz-Allen, earl of Arundel, in 1580.—STOWE. And in some years afterward the art of making them.—ANDERSON'S *History of Commerce*. A bill was brought into Parliament to prevent the effeminacy of men riding in coaches, 43 Eliz. 1601.—HAYDN.

Stage-coaches, Travelling by.—Owing to the improvement in the breed of horses and the building of carriages, but above all, to the extraordinary improvements that were effected within the last half century in the laying out, construction, and keeping of roads, the ordinary rate of traveling by stage-coaches, previously to their all but total extinction by railways, was seldom under 9 or 10 miles an hour, stoppages included, and

on some roads was as much as 11 or 12. The stages having been shortened, this speed was not found to be materially more injurious to the horses than the slower rate at which they previously traveled. The surface of the roads being perfectly smooth, and most sharp turns or rapid descents having been got rid of, traveling even at this rate was comparatively safe; and it was surprising, considering the number of coaches, how few accidents occurred. They were occasioned, for the most part, by the misconduct of the drivers; and principally by their endeavoring to make up by increased speed for time lost at stoppages, or by their attempting to pass each other. It is, perhaps, needless to add that, since the opening of railways between all the principal places of the country, traveling by stage-coaches in England no longer exists, except in a few remote districts, and has now become almost a matter of history.

Coal (Du. *Steenkoolen*; Fr. *Charbon de terre*; Ger. *Steinkohlen*; It. *Carboni fossili*; Lat. *Lithanthrax*; Port. *Carvoes de terra, ou de pedra*; Russ. *Ugoli, Kamennoe*; Sp. *Carbones de tierra, Carbones de piedra*; Swed. *Stenkol*). This highly important combustible mineral is divided by mineralogists into the three great families of black coal, unflammable coal, and brown coal; each of these being again divided into many subordinate species.

It is contended, with much seeming truth, that coals, although they are not mentioned by the Romans in their notices of Britain, were yet in use by the ancient Britons.—BRANDT. They were first discovered at Newcastle-upon-Tyne in 1234; some say earlier, and others in 1239. Sea-coal was prohibited from being used in and near London, as being "prejudicial to human health;" and even smiths were obliged to burn wood, 1273.—STOWE. Coals were first made an article of trade from Newcastle to London, 4 Rich. II., 1381.—RYMER'S *Fœdera*.

This mineral will be considered under the general heads of—I. Origin of Coal; II. Coal Statistics of Great Britain; III. Areas of Coal-beds in the World, and a Comparison of their Extent; IV. Comparison of the Coal Trade of the United States and Europe; V. Statistics of the Coal Trade in the United States.

I. *Origin of Coal. Phenomena of Combustion, etc.*—Coal beds, or strata, lie among those of gravel, sand, chalk, clay, etc., which form great part of the present surface of the earth, and have been evidently accumulated during remote ages by the agency of "moving water"—similar to accumulations now in process of formation at the mouths of all great rivers, and in the bottoms of lakes and seas. When these strata had, by long contact and pressure, been solidified into a rocky crust to the earth, this crust, by subsequent convulsions of nature, of which innumerable other proofs remain, has been in various parts broken and heaved up above the level of the sea, so as to form the greater part of our dry or habitable land; in some places appearing as lofty mountains, in others as extended plains. In many situations, the fracture of the crust exhibits the edges of the various distinct strata found in a given thickness of it. When the fracture has the form of a precipitous cliff, these edges appear one above another, like the edges of piled planks or books; but often also they are met with in horizontal succession along a plain, as the edges of a pile of books laid down upon a table; or they may be seen surrounding hills of granite, which protrude through them. Coal, and other precious minerals, were first discovered at the fractures of the strata above described, and by the continued digging of the strata or veins the vast excavations called mines have been gradually formed. When it was at last discovered that the mineral strata occur every where in nearly the same order or succession, so that the exposure of a portion of one stratum is a good indication of the other strata being near, the operations of the miner became of much surer result, and expensive boring through superior strata might be

prudently desired but seen.

Before of cheap n used as fu pally emp purposes, fact, the t in their u both have stance call other ingr when seps hydrogen either coal when it is used to li remains o called cok ed, the p the pure carb nes. prudently undertaken, even where no specimen of the desired but more deeply buried substance had yet been seen.

Before the discovery of coal mines, or the invention of cheap means of working them, wood was generally used as fuel; and in many countries where the arts have not much flourished, it continues to be principally employed as such. Coal, however, for many purposes, answers much better than wood; and, in fact, the two, although in appearance so different, are in their ultimate composition very nearly allied. They both have for their basis or chief ingredient the substance called by the chemists *carbon*, and for their chief other ingredient the substance called *hydrogen*, which, when separated, exists in the form of air or gas. The hydrogen is easily driven away or volatilized from either coal or wood, by heating in a close place; and when it is caught and preserved, it forms the gas now used to light our streets and public buildings. What remains of coal, after being so treated, is the substance called *coke*; and what remains of wood, similarly treated, is the substance called *charcoal*—both being nearly pure carbon, but differing as to the states of compactness. This kindred nature of coal and wood does not surprise when the fact is known that much of our coal is really transformed wood; many coal mines being evidently the remains of antediluvian forests, swept together in the course of the terrestrial changes alluded to, and afterward solidified to the state now seen. In these mines the species of the plants or trees which formed them are still quite evident in abundant specimens, mixed often with the remnants of the animals which inhabited the earth at the same time. The extensive peat-mosses now existing on the surface of the earth consist chiefly of vegetable remains at an early stage of the kind of change which terminates in the formation of coal.

A substance which, like coal or wood, cheaply answers the purpose of producing great heat and light is called fuel, and the phenomenon of that production is called combustion. Now modern discovery has ascertained that, in every instance, combustion is merely an appearance which accompanies the mutual action, when very intense, of two substances in the act of forming an intimate or chemical union. Where that act is less energetic, the heat produced is less intense, and there is no light. Thus, water and sulphuric acid, when mixed, produce great heat, but no light. Water and quick-lime produce still greater heat; sufficient, it is known, to set fire to a ship in which the mixture unfortunately occurs. It is an occurrence of the same kind when heat is evolved from an acid dissolving a metal; and it is still of the same kind when a mass of coal or wood in a fire-grate is, with the appearance of combustion, undergoing solution in the oxygen of the atmosphere. In this last case, however, the temperature of the fuel is, by the very intense action, raised so much that the fuel becomes incandescent or luminous; an appearance assumed by every substance, whether burning or not—of a stone, for instance, or piece of metal—when heated beyond the temperature indicated by 800° of Fahrenheit's thermometer. The inferior degrees of such incandescence are called *red heat*; the superior degrees *whites heat*. The reason why our strongly heated body throws out light, we can not yet explain. When a quantity of wood or coal has been burned to ash in a confined portion of air, the whole of the fuel, vanished from view, is held in solution by the air, as salt is held in water, and is again recoverable by the art of the chemist. The phenomenon of common fire, or combustion, then, is merely the fuel being chemically dissolved in the air of the atmosphere. If the fuel has nothing volatile in it, as is true of pure carbon, and nearly true of coke and charcoal, it burns with the appearance of red-hot stones; but if there be an ingredient, as hydrogen, which, on being heated, readily assumes the form of air, that in-

gradient dilates before burning, and in the act produces the more bulky incandescence called flame.

Varieties of Coal.—There is a curious chain of links which connect living wood with dead coal. First, there is *peat*, consisting of various kinds of plants and moss, imbedded and pressed together into a mass, and exposed to the action of air or water, or both, and perhaps heat, for unnumbered centuries. Then there is *lignite*, formed in nearly the same way from trunks of trees, and accumulated in layers of vast thickness in Germany and other parts of Europe; it has not hitherto been much used as fuel, but there are indications that it will so be ere long. Next comes *jet*, which appears to be a peculiar variety of vegetable matter brought almost to a bituminous state. Then we have *cannel coal*, which not only yields the best and most abundant gas for street-lighting, but has often such a hardness, blackness, and polish, as to enable it to be worked up into very beautiful ornaments. One peculiar kind of cannel coal, called the Breckinridge coal, was lately discovered in Kentucky, from which a burning oil has been manufactured, which by experiment has proved quite equal to sperm whale oil, if not superior, and can be manufactured for one-half the cost of sperm oil. The United States government have under consideration a contract to use it in the light-house system. Next is the *caking*, or common bituminous coal, which combines so many useful qualities for household purposes. Somewhat different from this is the *stratified coal* of the midland counties of England, which is obtained in very long pieces, and has less bituminous or caking quality. A still less gaseous coal is that which, from the purpose to which it is now found to be admirably adapted, is called *steam coal*; it is obtained chiefly from Wales, and burns with intense heat, and little flame or smoke. Last on the list is *anthracite*, so nearly without gas as to consist almost entirely of carbon; its intense heat and freedom from sulphur render it invaluable for iron-smelting and other manufacturing processes.

The two great purposes which combustion serves to man are to give light and heat. By the former he may be said to lengthen considerably the duration of his natural existence; for he converts the dismal and almost useless night into what, for many ends, serves him as well as day; and by the latter, besides converting winter into any climate which he desires, he is enabled to effect most important mutations in many of the substances which nature offers for his use; and, since the invention of the steam-engine, he makes heat perform a great proportion of the work of society. From these considerations may be perceived the importance of having fire at command; and, as the cheapest means of commanding fire, of having abundance of coal.

II. Coal in Great Britain.—As respects the supply of coal, Great Britain is singularly favored, a large portion of the surface of the country having under it continuous and thick beds of this valuable mineral—vastly more precious than would have been mines of the precious metals, like those of Peru and Mexico; for coal, since it has been applied to the steam-engine, is really hoarded power, applicable to almost every purpose which human labor directed by ingenuity can accomplish. It is the possession of her coal mines which has rendered Great Britain, in relation to the whole world, what a city is to the rural district which surrounds it—the producer and dispenser of the various products of art and industry. Calling her coal mines the coal-cellars of the great city, there is in them a supply which, at the present rate of expenditure, will last for 2000 years at least; and, therefore, a provision which, as coming improvements in the arts of life will naturally effect economy of fuel, or substitution of other means to effect similar purposes, may be regarded as inexhaustible.

The kinds or differences of coal depend on their

comparative proportions of carbon and hydrogen, and of earthy impurities totally incombustible. While some species of coal contain nearly a third of their weight of hydrogen, others have not a fiftieth part. The former kinds are flaming coal, pleasing in parlor fires, and fit for the manufacture of gas. The other kinds—some of the Welsh stone coal, for instance—will only burn when in large heaps, or when mixed with more inflammable coal; they have no flame. When flaming coal is burned where a sufficiency of oxygen can not pass through or enter above the fire, to combine with and consume the hydrogen as fast as it rises, a dense smoke is given out, consisting of hydrogen and carbon combined in the proportions which form a pitchy substance. The Welsh coal above mentioned can as little give out smoke as flame, and hence is now much used in great breweries, and in the steam-engine furnaces of towns, where smoke is a serious nuisance. The foliated or culd coal, and slate coal, are chiefly used as fuel in private houses; the caking coals, for smithy forges; the slate coal, from its keeping open, answers best for giving great heats in a wind furnace, as in distillation on a large scale; and glance coal, found in Staffordshire, is used for drying grain and malt. The coals of South Wales contain less volatile matter than either the English or the Scotch; and hence, when employed in smelting the ore, produce a greater quantity of iron. It is supposed that three parts of good Newcastle coal are equivalent, as fuel, to four parts of good Scotch coal.

Consumption of Coal. Number of Persons engaged in the Trade. Supply of Coal.—The great repositories of coal in England are in Northumberland and Durham, whence London and most parts of the south of England are at present supplied; in Cumberland, whence large quantities of coal are exported to Ireland; and in Staffordshire, Derbyshire, Lancashire, Yorkshire, Leicestershire, Warwickshire, South Wales, &c. In Scotland, coal is found in the Lothians, Lanarkshire, Renfrewshire, Ayrshire, and other counties. In Ireland, coal is both deficient in quantity and inferior in quality to that of Great Britain; and turf forms the great article of fuel.

The importance of coal as a necessary of life, and the degree in which superiority in arts and manufactures are dependent upon obtaining supplies of it at a cheap rate, has naturally attracted a good deal of attention to the question as to the period when the exhaustion of the coal mines may be anticipated. But the investigations hitherto made as to the magnitude and thickness of the different coal-beds, and the extent to which they may be wrought, are too vague and unsatisfactory to afford grounds for forming any thing like a tolerably near approximation to a solution of this question. But such as they are, they are sufficient to show that many centuries must elapse before posterity can feel any serious difficulties from a diminished supply of coal. According to an estimate prepared by Mr. Taylor, an intelligent coal engineer, in 1829, the coal-fields of Durham and Northumberland are adequate to furnish the present annual supply for a very long period. We subjoin Mr. Taylor's estimate.

ESTIMATE OF THE EXTENT AND PRODUCE OF THE DURHAM AND NORTHUMBERLAND COAL-FIELDS.

	Durham.	Sq. Miles.
From South Shields southward to Castle Eden, 21 miles; thence westward to West Auckland, 32 miles; northward from West Auckland to Etringham, 35 miles; and then to Shields, 22 miles; being an extent or area of.....		504
<i>Northumberland.</i>		
From Shields northward 27 miles, by an average breadth of 9 miles.....	243	507
<i>Portion excavated.</i>		
In Durham, on Tyne, say.....	30	
on Wear.....	40	
	70	
In Northumberland, say 13 miles by 2.....	26	105
		732

	Tons.
Estimating the workable coal strata at an average thickness of 12 feet, the contents of one square mile will be 12,500,000 tons, and of 732 square miles.....	9,060,430,000
Deduct one-third part for loss by small coal, interceptions by dikes, and other interruptions.....	3,023,160,000
Remainder.....	6,046,270,000

This remainder is adequate to supply the present vend from Newcastle, Sunderland, Hartley, Blyth, and Stockton, of 3,500,000 tons, for a period of 1727 years.

It will be understood that this estimate of the quantity of coal in Durham and Northumberland can only be an approximation, especially as the northeastern coal district of Durham is yet almost wholly unexplored; but the attempt is made, in the hope of satisfying your lordships that no apprehension need be entertained of this valuable mineral being exhausted for many future generations.

There is also a considerable extent of coal-field in the northern and southwestern districts of Northumberland, but the foregoing comprises that which is continuous, and most suitable and available for exportation. It is, however, to be observed that the shipments of coal from the ports mentioned by Mr. Taylor has been largely increased during the last dozen years; so that, supposing the estimate to be in other respects accurate, it must now be modified accordingly.—*Lords' Report, 1829, p. 124.*

Dr. Buckland, the celebrated geologist, considers Mr. Taylor's estimate as greatly exaggerated; but in his examination before the committee of the House of Commons in 1829, he quoted with approbation a passage of Bakewell's *Geology*, in which it is stated that the coal-beds in South Wales were alone sufficient to supply the then demand of England for coal for 2000 years. The passage is as follows:

"Fortunately we have in South Wales, adjoining to the Bristol Channel, an almost exhaustless supply of coal and iron-stone, which are yet nearly unwrought. It has been stated that the coal-field extends over about 1200 square miles; and that there are 23 beds of workable coal, the total average thickness of which is 95 feet; and the quantity contained in each acre is 100,000 tons, or 65,000,000 tons per square mile. If from this we deduct one half for waste, and for the minor extent of the upper beds, we shall have a clear supply of coal equal to 32,000,000 tons per square mile. Now if we admit that 5,000,000 tons from the Northumberland and Durham mines is equal to nearly one-third of the total consumption of coal in England, each square mile of the Welsh coal-field would yield coal for two years' consumption; and as there are from 1000 to 1200 square miles in this coal-field, it would supply England with fuel for 2000 years, after all the English coal mines are worked out!"

But supposing this supply to last only 1000 years, that carries us so far into futurity, that it appears to be quite idle either to prohibit or impose heavy duties on the exportation of coal, on the ground of its accelerating the exhaustion of the mines.

Profits of Coal Mining. Coal Owners' Monopoly, &c.—Instead of the business of coal mining being, generally speaking, an advantageous one, it is distinctly the reverse. Sometimes, no doubt, large fortunes have been made by individuals and associations engaged in this business; but these are rare instances. The opening of a mine is a very expensive and hazardous operation, and of very uncertain result. Collieries are exposed to an infinite number of accidents, against which no caution can guard. The chances of explosion have, it is true, been a good deal lessened by the introduction of Sir Humphry Davy's lamp; and some mines are now wrought that, but for the invention of this admirable instrument, must have been entirely abandoned. But besides explosions, which are still every now and then occurring, from the carelessness of the workmen, and other contingencies, mines are very liable to be destroyed by creeps, or by the sinking of the roof, and by drowning, or the irruption of water from old workings, through fissures which can not be seen, and consequently can not be guarded against. So great, indeed, is the hazard attending this sort of

property, that it has never been possible to effect an insurance on a coal-work against fire, water, or any other accident.

Coal Trade.—It is estimated that not less than forty million tons of coals are raised annually from the various mines in the United Kingdom. Of these the greater part is either used in the immediate neighborhood of the mines, or sent by inland navigation or land carriage to different parts of the kingdom. In 1852, 12,709,771 tons of coals, cinders, and culm were shipped from ports in the United Kingdom; of these, 9,068,577 tons were sent coastwise to other ports of the kingdom; being, coals 8,605,934 tons, cinders 43,376 tons, culm 220,267 tons. The quantities of coals, cinders, and culm shipped coastwise from the different ports of the United Kingdom in 1851 and 1852, were:

In 1852 the exports from the United Kingdom to foreign countries, including British settlements, were as follows: Coals 3,479,282 tons, of the value of £1,287,626; cinders 159,040 tons, of the value of £83,832; culm 1872 tons, of the value of £656; total, 3,610,194 tons, of the declared value of £1,372,114.

The principal foreign countries to which coals, cinders, and culm were exported from the United Kingdom in 1851 and 1852, were the following:

Countries.	Quantities Exported.	
	Tons.	
	1851.	1852.
Russia.....	215,221	188,041
Denmark.....	206,163	210,689

British West Indies.....	82,144	95,440
United States, North America.....	83,546	122,285

The quantities of coal brought coastwise and by inland navigation into the port of London were:

Years.	Tons.		
	Coastwise.	Inland Navigation and Land Carriage.	Total.
1851.....	3,236,542	254,421	3,490,963
1852.....	3,090,428	414,017	3,504,445

During the six months ending 30th June, 1852, 179,886 tons of coal were imported into London by railway, and 19,637 tons by canal: for the corresponding period of 1853 the imports by railway were 296,361 tons, and by canal 10,322, showing a decrease by canal, but a very considerable increase by railway.

The coal trade was long subjected to very heavy and oppressive duties. A duty of 17s. per chaldron on large, and 4s. 6d. per chaldron on small coals, was levied on all coal exported to foreign countries. In 1831 these duties were considerably modified, and in 1835 they were repealed, with the exception of an *ad valorem* duty of 10s. per cent. on coal exported in British vessels, or in those of foreign countries entitled to the privileges conferred by treaties of reciprocity, while in other foreign vessels it was subject to a duty of 4s. a ton. These duties were, in 1840, altered to 10s. 6d. per cent., and 4s. 2s. 7d. per ton respectively. In 1842, duties of 2s. per ton on large, and 1s. per ton on small coal and culm were imposed, and on all coal exported in foreign vessels not entitled to the privileges conferred by treaties of reciprocity a duty of 4s. per ton. The two former were abolished on 12th March, 1845, but the last continued in force till 14th August, 1850.

In the reign of William III., a duty of 5s. per chaldron was laid upon coal carried coastwise from one part of the kingdom to another. During the last war with France this was raised to 9s. 4d., but in 1824 it was reduced to 6s., and in 1831 was repealed. This tax pressed unequally on different parts of the empire, for while it amounted to 6s. a chaldron, or 4s. a ton in the metropolis, and all the south of England, it was only 1s. 7½d. a ton on coal carried by sea to Ireland, and 1s. 8d. on that to Wales; while Scotland was for many years entirely exempted from this duty.

Though these duties are now abolished, the coal trade is still in some places burdened with heavy local duties. Thus a duty of 1s. 1d. per ton is chargeable upon all coal brought into the port of London. By act 1st and 2d William IV., cap. 76, several oppressive acts were repealed, and the duties payable to the corporation of the city of London were commuted for a duty of 1s. 1d. per ton; and by 8th and 9th Viet., cap. 101, a like duty was imposed on coal brought into London by railway, canal, or other inland carriage. Of this duty 8d. per ton is carried to the London Bridge Approaches Fund, for effecting street improvements in the metropolis; 4d. per ton is the property of the corporation of the city of London, and after defraying certain charges is carried to the general account of the corporation; 1d. per ton is payable to her majesty's commissioners of works, to be applied by them in effecting public improvements in the metropolis, authorized by several acts of Parliament. The produce of these duties, with the drawbacks allowed upon coal exported, was, in 1852,

	Gross Du. s.	Drawback.	Net Duty.
8d. per ton to 5th January, 1853.....	£128,657	£10,098	£118,559
4d. per ton to 31st December, 1852.....	62,640	5,040	57,601
1d. per ton to 31st December, 1852.....	15,560	1,262	14,298
Total.....	£206,857	£16,400	£188,458

In 1851 the gross amount of duty was, on sea-borne coal, £175,840; on coal brought landwise, £12,151. The 4d. per ton duty, in 1851, amounted to £54,104, of which £215 were salaries in relation to collection; £3009 drawback allowed upon coal exported; £7607 retiring allowances paid to deputy sea-coal meters and others, upon the abolition of their offices in consequence of act 1st and 2d Will. IV., cap. 76, and which had gradually decreased from £16,820 in 1836; and £20,000 an annual charge for making a new street in the line of Canon Street, and other improvements. The attention of government is at present directed to these unjust local imposts, by which our home trade is unnecessarily burdened, and the merchant and ship-

owner made to pay for improvements which ought properly to be charged against the landlords or inhabitants; and it is expected that they will speedily be abolished.—E. B.

III. *Areas of Coal-beds in the World, and a Comparison of their Extent.*—From the elaborate work, "Statistics of Coal," by R. C. Taylor, we extract a comparison of the proportionate areas of coal land in Europe and America:

The following table shows the relative magnitude of the principal coal-producing countries, and their respective areas of coal land, together with the proportions which they severally bear to each other. Those of France and Spain are considerably less than the actual amount. Coal occurs in almost every principal subdivision of Spain, but we have only included the Asturias region.

Countries.	Entire Area of each Country.	Area of Coal Lands.	Proportion of Coal to their whole Areas.	Proportions, Relative Parts of 1000, of Coal Areas.
	Square Miles.	Square Miles.		
Great Britain.....	120,290	11,850	1-10	64
Spain (Asturias region).....	177,731	3,408	1-52	18
France (area of fixed concession) in 1845.....	208,736	1,719	1-118	9
Belgium conceded lands.....	11,579	848	1-22	3
Pennsylvania, United States.....	43,580	15,437	1-3	84
British Provinces, North America.....	81,113	18,000	1-4½	95
Persian dominions.....	107,537
Austrian Provinces containing coal or lignite.....	150,000
United States.....	2,280,000	1-17	..
Twelve principal coal-producing States.....	665,533	133,129	1-4	724
Total.....	154,073	..	1000

We assume these, in round numbers, as correct; and here we perceive at a glance the vast resources of the United States in their coal-producing regions, when compared with Europe. It must be recollected, too, that several of our States have not had geological surveys; and it would not be surprising if other States than those enumerated were found hereafter to possess coal in abundant quantities.

The whole coal region of Europe is by Mr. Taylor shown to be only 50,941 square miles, being somewhat less than that of the Western States of Illinois and Indiana; while England has only 8139 miles, and Ireland 3720 miles, the aggregate being somewhat less than that of the State of Ohio. But Great Britain produces annually upward of 34,000,000 tons of coal; while that of Pennsylvania is about 10,000,000 tons.

IV. *Comparison of the Coal Trade of the United States and Europe.*—The consumption of coal in Europe and the United States was estimated as follows in 1845, showing also the square miles of coal formation, the relative proportions, and the value in dollars:

Countries.	Square Miles.	Production.	Proportion.	Value.
		1845.		
Great Britain.....	11,850	31,500,000	642	\$45,738,000
Belgium.....	518	4,960,000	101	7,680,000
United States.....	133,132	4,430,000	99	6,650,000
France.....	1,719	4,141,000	84	7,665,000
Prussian States.....	undefined.	3,500,000	70	4,122,000
Austrian States.....	undefined.	630,000	14	800,000
Total.....	40,160,000	1000	\$72,662,000

The quantities of coal imported into the United States from England and the British provinces were, in 1850, 180,439 tons; and in the year 1853, 231,508 tons. From a letter of Mr. E. K. Collins, we learn that the Collins line of steam vessels had used the Cumberland coal, but had relinquished it, and afterward tried the anthracite, which was used for three years. In January, 1854, they thought of using the Cumberland coal again.

Mr. Cunard states that for his line they use the Welsh or Ss on the voyage from Liverpool, and the Cumberland coal on the return trip.

"We have in the United States more iron ore and more coal, with the usual fluxes, in convenient connection and of cheaper access, than all the other civilized nations of the world, and have the necessary capital, skill, and labor to pro-

Hence, as regards European countries, Great Britain takes the first rank; Belgium, as regards territorial proportion, occupies the second rank, although in relative coal area she is the least of the four. Pennsylvania, in respect to territorial proportion, is higher than any of these, being relatively one-third; but in absolute area of coal formation, the four eastern colonies of British America united exceed them all, being larger than that of Great Britain, France, Belgium, and Spain conjoined. This table is not strictly perfect, since we possess the areas of the concessions only in France; and in Spain, only of the single coal region of Asturias. We add the coal areas of Prussia and Austria, but can not state the proportions of coal formation therein. The American area of coal is nearly three-fourths of the whole amount in our table.

duce all the iron and steel, and manufactures of iron and steel, required for our consumption, or that may be required for our consumption, for centuries to come, and also to enable us to supply the markets of other countries in fair competition with the iron and steel of other nations. Our production of iron and steel, and manufactures of iron and steel, was greater in proportion to population in 1850 than it was in 1840, and that it was greater in 1855 than it was in 1850, giving us the right to assume that, influenced by the same causes, it will be greater in 1860 than it now is, and in time will be sufficient for our own consumption, and then give us a surplus for export.

But taking into consideration our present population and accumulated capital, with the amount of capital annually drawn from other countries in the course of emigration, and the great cost of carriage to the interior of our country, with the late improvements in the modes of production and manufacture of iron and steel, it would not be rash to expect a full supply for our own consumption between this and the returns of the census of 1870."—*United States Treasury Report, 1856.*

The question of duty on coal attracts considerable attention, and it is well to understand certain facts which have a direct bearing upon its decision.

In the year 1815, when the duty on foreign coal was \$3 60, the price in New York was \$23 the chaldron of 36 bushels.

From 1816 to 1823 the duty was \$1 80, and the average price was \$11.

From 1824 to 1834 the duty was \$2 10, and the average price was \$14.

In 1842 the duty was \$1 75 per ton, and the market price was \$7 16; and in 1844, with a duty of \$1, the price was \$5 56. In the year 1846 the duty was altered to an *ad valorem* one of 30 per cent., or about 45 cents per ton, and the market price since has ranged from \$6 50 to \$7 50.

V. *Statistics of the Coal Trade of the United States.*—Pennsylvania is rich in its coal product. This article is one of the great sources of wealth to that State, and its importance may be seen from the single fact that about 6,000,000 tons are carried over or through the various railroads and canals of that State eastwardly. We refer only to the anthracite region, which mines seem to be inexhaustible, and we leave out of view the immense production in Western Pennsylvania. The latter portion of the State owes its growth mainly to its coal-beds, in conjunction with its iron and glass manufactures.

Total	7,000,000

If we may judge by the increase of the last two or three years, the quantity of coal required by the above conveyances will be 7,500,000 tons for the coming year, and between eight and nine millions for the year 1856. We have received from London the special Report of Professor Wilson on the New York Industrial Exhibition, in which document we find a variety of useful information in reference to the manufactures, minerals, mining, and metallurgy of the United States. His remarks on the iron, lead, copper, and zinc products and manufactures will be a valuable addition to the information already in possession, and will be acceptable as well to the legislator as to the manufacturer and merchant.

Virginia takes the lead among the Eastern (or Atlantic) States as the owner of coal-fields, and is, in fact, one of the prominent States of the whole Union as the possessor of this valuable mineral.

AREA OF THE SEVERAL STATES WHERE COAL IS FOUND, AND THE COAL AREA OF EACH, AND THE PROPORTION OF COAL.

States.	Area.		Proportion of Coal.
	Square Miles.	Square Miles.

Total	585,283	153,182	Nearly 4th

North Carolina is reputed to hold about as much coal land as Georgia. Iowa is one of the richest coal States, and has a coal area almost equal to Ohio.

From this valuable reference-table it will be seen that Illinois takes the lead, having within her own borders one-third of the entire coal region of the United States. Next in importance is Pennsylvania, producing both anthracite and bituminous coals. Of these immense fields Professor Wilson says:

"These comprise the three anthracite coal-fields of Eastern Pennsylvania, known as the Southern Schuylkill, the Middle of Shamokin, and the Northern or Wyoming, and the Frostburg or Cumberland coal-field (semi-bituminous), in the State of Maryland. Besides these beds, a small outlying bed exists in Pennsylvania of semi-bituminous coals, known as the Broadtop, which, however, owing to its insulated position, being without any means of access, is only available for local purposes; and some deposits of considerable area in Virginia, whose importance is being daily recognized, and whose produce is gradually finding its way into the markets. The demand at present, however, is confined chiefly to gas-making purposes.

"Of the three anthracite beds of Pennsylvania, the Southern is, both by situation and magnitude, the most important, and furnishes a large proportion of the entire supply. It presents great facilities of access, which have been made advantageous use of by two Canal Companies, the Lehigh and the Schuylkill, and by the Reading Railroad, which penetrate far into the interior, and form the great outlets for its produce. Other railways are now in progress, which will not only afford additional facilities of transfer to the Atlantic cities, but also open a communication to the latter, and through them to the Western markets."

The third in importance is Ohio, having nearly one-third of its area in coal. The returns as to production

are not copious; but Charles Lyell, who made critical inquiries on the subject, reported the following as the yield for 1851-'52:

	Bushels.	Tons.
Western Pennsylvania	85,000,000	1,170,000
Virginia	15,000,000	600,000
Eastern Ohio	10,000,000	635,000
Total	66,000,000	3,205,000

At the Exhibition were produced samples of coal from Valley Falls, Rhode Island, but the product is of inferior quality.

Of the Virginia coal, twelve miles west of Richmond, and extending fifty miles, the seams are 800 feet in thickness, being the deepest mines known in America. In Belgium some of the mines are known to be from 1140 to 1476 feet in depth. In England, 1000 to 1794 feet—with an average in Lancashire of 750 feet.

IMPORTED COAL.—The only countries from which coal ever finds its way into the United States are Great Britain and British America, and the contributions from them appear to be annually diminishing. For a time there was an increasing foreign importation; viz., from 22,123 tons in 1821, to 181,561 tons in 1839. By the operation of the American tariff this advance was not only checked, but a retrograde movement was produced, so as in 1843 to amount to only 41,103 tons, by the United States returns. By the last annual return, that for 1847, the entry of foreign coals, whether from Europe or from British America, was 148,021 tons; of which from 12,000 to 15,000 tons were re-exported for the service of the English steamships. In 1850, 180,439 tons were imported into the United States; in 1853, 231,508 tons; showing an increase.

INCREASED PRODUCTION OF COAL. Anthracite Coal.—The production of anthracite may be said to be entirely confined to Pennsylvania, which possesses a numerous and interesting group of coal basins of various sizes and character.

Our returns show that the consumption of anthracite, in other words, the coal trade, commenced with 365 tons in the year 1820; that the production reached 48,017 tons in 1827; that it had increased to 881,026 tons in 1837, and advanced to 3,000,000 tons in 1847, without including much that is consumed on the spot, in the mining districts, or interior of the country.

The increased production, therefore, was, in the first ten years, viz., from 1827 to 1837, 1735 per cent.; in the second ten years, viz., from 1837 to 1847, 240 per cent.; and in the twenty years previous to 1848, that is, from 1827 to 1847, 6100 per cent.

We introduce another view of the subject, which exhibits this accelerated increase in the consumption of anthracite, perhaps, with yet greater perspicuity. The amount which was periodically forwarded to market, exclusive of the consumption in or near the places of production, and which has not been estimated, is as follows:

	Tons.
Aggregate in the 21 years, from 1820 to 1840, inclusive	6,847,179
In the succeeding 7 years, to 1847, inclusive	12,374,061
Total	19,221,240
From 1847 to 1853, inclusive	23,841,858
Total	43,063,098

We add the statistics from the various regions for the year 1855.

Bituminous Coal.—We have given, in the first part of this article, data by which the approximate increase of this description of fuel can be determined, and give here all the statistics that can be collected.

	SEMI-ANTHRACITE OR BITUMINOUS.					
	1854.		1855.		Increase.	Decrease.
	Tons.	Tons.	Tons.	Tons.		
Lykens' Valley Co.	57,500	66,721	9,221
Short Mountain Co.	60,000	60,000	500
Dauphin Co.	63,000	1,000	62,000
Cumberland Region	648,299	664,304	16,005
Foreign coal	202,505	287,405	84,543
Total	1,071,664	1,069,933	60,260
Decrease in 1855	1,069,933	60,260
	1,731	1,731

The increase of semi-anthracite or bituminous coal in 1854 including foreign, over the previous year, was 218,167 tons. This year (1855) there is a decrease of 1731 tons, making the total increase of all kinds in 1855 684,001 tons, against 952,857 tons in 1854.

Almost as interesting as the statistics of the areas and production of the coal countries, is the consideration of the means of transportation and the facilities needed to give us fuel in abundance and at a low price. It is of great importance to the consumer, and an extract from a private letter will be of interest, throwing some light on the ways and means, the cost and contingencies in the transit to market:

"Ily canal, besides the distance and cost of the structure, there are so many contingencies, arising from too much or too little water, as to weaken the dependance; and on the railroads, the grades and the adaptation to the business are alone the objects by which the price can be regulated. If the grades be level or descending, the capacity of the engine is not only increased, but the expense is so much reduced as to determine its value, and it is only upon a road so graded and so constructed as to endure the burden that the price can be

fixed or defined. On the down-hill grade the momentum keeps up the speed, and relieves the engine, while on the up-hill grade the speed is depressed, the power is reduced, the strain is increased, and the expense augmented.

"On the Reading Railroad, in operation since 1811, these facts are so illustrated and defined as to establish their existence beyond a question. On the stem as upon the laterals, the descent is from 22 feet to a mile to a level of 36,000 feet, and as the maximum is but four miles in length, the balance descends to the level without the slightest rise to interfere with the speed. On this descent and over the level, a single engine can take as many cars loaded as it can bring empty to the place of starting. This difference, from the weight of the descending and ascending trains, is ascertained to be equal to two and three-quarters engines, or 175 per cent. more than on the downward grade—consequently a reversion of the trade; or upon a road where the grade is equal to twenty-two feet to the mile against the trade, the expense for engines, fuel, and wages, would be more for the same distance than the profits derived from the coal in market.

"But as these are the questions for railroad-makers, we will next consider the extent of the trade, and arrive at our object by the expenditure made to accommodate it. On the Lehigh, we have an expenditure on the part of the Lehigh Coal and Navigation Company of \$2,441,405, and on the part of some fourteen or fifteen companies passing over their works about five millions more, making together \$13,441,405. From the commencement of the company in 1820 until the close of the season in 1855, the production of the region is 12,278,012—equal to 353,725 tons per annum. But if we take the amount sent to market during the year just closed, 1,274,983 tons, and admit a clear profit of 75 cents per ton, which it did not give to the several parties concerned, the income would be less than 7 per cent. on the money expended. In the region it is also understood the mining operations are above water-level, and that until recently they were conducted on the principle of a quarry, and that the expenses, together with the transit, prevented a dividend to the stockholders until the outside operators came in to their relief.

"On the Lackawanna, the Delaware and Hudson Company, and the Pennsylvania Coal Company, with capitals amounting to \$11,626,761, brought to market during 1855, 1,092,000 tons, and during the period they have been in existence the average is equal to 332,000 tons per annum. The production of 1855, at 75 cents per ton clear profit, gives, however, but 7 per cent.

"On the Schuylkill, the operations are more extensive, and the expenditure, including the

Reading Railroad, east	\$18,464,114 64
Schuylkill Canal east	10,550,431 41
400 miles Lateral Roads to the Collieries	4,000,000 00
Total	\$33,014,566 05

Besides this expenditure for reaching the trade, there is a population depending upon it of 60,717 in 1850, which is divided into 10,927 families and 10,670 houses. In the region there are also 800 stationary engines, equal to 10,000 horse power, used in mining. In 1855, the production was 3,318,340 tons, and during the existence of the works (the Navigation Company thirty-four years, and the Reading fifteen years), the product has been 28,508,944 tons, equal to 838,495 tons per annum. At 75 cents on the product of the year just closed, clear profit, the percentage on \$36,031,516, including the improvements at the mines, would be between 7 and 8 per cent.

"Altogether the cost for improving and reaching the three regions in operation, including the eastern division of the Pennsylvania works, is \$62,272,808. The product during 1855 amounted to 5,262,189 tons, which, at 75 cents profit, would be equal to 74 per cent. profit."—See articles INOX and UNITED STATES.

Coasting-trade, the trade or intercourse carried on by sea between two or more ports or places of the same country. It has been customary in most countries to exclude foreigners from all participation in the coasting-trade. This policy began in England in the reign of Elizabeth (5 Eliz. c. 5), or perhaps at a more remote era; and it was perfected by the acts of navigation passed in 1651 and 1660. This policy is now entirely abrogated in Great Britain.—See GREAT BRITAIN.

Of Vessels which may engage in the Domestic Trade of the United States.—Vessels of twenty tons and upward, enrolled, and having a license in force, and vessels of less than twenty tons, not enrolled, but having a license in force, and no others, shall be deemed vessels of the United States, entitled to the privileges of vessels employed in the coasting-trade and fisheries. Every vessel of twenty tons or upward (other than such as are registered) trading between district and district, or between different places in the same district, or carrying on the fishery, without being enrolled and licensed, or if of less than twenty tons, and not less than five tons, without a license, if laden with goods the growth or manufacture of the United States only (distilled spirits only excepted), shall pay the same fees and tonnage in every port at which she may arrive as are payable by vessels not belonging to a citizen of the United States; and if she have on board any articles of foreign growth or manufacture, or distilled spirits, other than sea-stores, she, together with her tackle, apparel, and furniture, and lading, found on board, shall be forfeited. But if such vessel be at sea at the expiration of the time for which the license was given, and the master shall swear that such was the case, and shall also, within forty-eight hours after his arrival, deliver to the collector of the district in which he shall first arrive the license which shall have expired, she shall not be forfeited, nor shall be liable to pay such fees and tonnage. No goods shall be imported, under penalty of forfeiture thereof, from one to another port of the United States, in a vessel belonging wholly, or in part, to a subject of any foreign power; but such vessel may sail from one to another such ports, carrying such goods only as were imported in her from some foreign port, and which shall not have been unladen.

Of the Enrollment and License of Vessels.—The like qualifications and requisites are necessary for the enrollment as for the registry and record of vessels, and the same duties are imposed on, and authority given to, all officers respectively, in relation to such enrollments, and the same proceedings shall be had in similar cases touching such enrollments; and vessels so enrolled, with their masters or owners, shall be subject to the same requisites as are in these respects provided for registered vessels. The record of such enrollment shall be made, and an abstract or copy thereof granted, as nearly as may be, in the form directed by law. Enrolled and licensed vessels may be registered upon the registry being given up; and registered vessels may be enrolled, upon surrendering up the enrollment and license. And when any vessel shall be in any other district than that to which she belongs, the collector, on application of the master, and on his making oath that, to the best of his knowledge and belief, the property remains as expressed in the register or enrollment, proposed to be given up, and upon his giving the bonds required for granting register, shall make such exchanges; and such collector shall transmit the register or enrollment given up to the register of the treasury. The register or enrollment and license granted in lieu thereof, shall, within ten days after the arrival of the vessel within the district to which she belongs, be delivered up to the collector of such district, and be by him canceled. And if the master shall neglect to deliver such register or enrollment and license within the time specified, he shall forfeit one hundred dollars. In order to the licensing of any vessel for carrying on the coasting-trade

or fisheries, the husband, together with the master, with one or more sureties, to the satisfaction of the collector, shall become bound to pay to the United States, if she be of the burden of five tons and less than twenty tons, the sum of one hundred dollars; and if twenty tons, and not exceeding thirty tons, the sum of two hundred dollars; and if above thirty tons, and not exceeding sixty tons, the sum of five hundred dollars; and if above sixty tons, the sum of one thousand dollars, in case it shall appear, within two years from the date of the bond, that she has been employed in any trade whereby the revenue of the United States has been defrauded, during the time her license remained in force; and the master of such vessel shall also swear that he is a citizen of the United States, and that such license shall not be used for any other vessel, or any other employment, than that for which it is specially granted, or in any trade whereby the revenue may be defrauded; and if such vessel be less than twenty tons burden, her husband shall swear that she is wholly the property of a citizen or citizens of the United States; whereupon the collector of the district whereto such vessel may belong (the duty of six cents per ton being first paid) shall grant a license, in the form directed by law, for carrying on the coasting-trade, whale fishery, cod fishery, or mackerel fishery. A steam-vessel, intended to be employed only in a river or bay of the United States, owned wholly or in part by an alien, resident within the United States, shall be enrolled and licensed as if she belonged to a citizen of the United States, except that no oath shall be required that she belongs to a citizen or citizens of the United States. The owner of such steam-vessel, upon application for enrollment or license, shall give bond to the collector of the district, to and for the use of the United States, in the penalty of one thousand dollars, with sufficient surety, conditioned that she shall not be employed in other waters than the rivers and bays of the United States. When the master of any licensed vessel, ferry-boats excepted, shall be changed, the new master, or, in case of his absence, an owner, shall report such change to the collector residing at the port where the same may happen, if there be one, otherwise to the collector residing at any port where such vessel may next arrive, who, upon the oath of such new master, or in case of his absence, of an owner, that he is a citizen of the United States, and that she shall not, while such license continues in force, be employed in any manner whereby the revenue may be defrauded, shall indorse such change on the license, with the name of the new master; and when any change shall so happen, and shall not be reported, and the indorsement so made, such vessel, found carrying on the coasting-trade or fisheries, shall be subject to pay the same fees and tonnage as a vessel of the United States having a register, and the new master shall forfeit and pay the sum of ten dollars. Before any vessel, of the burden of five tons, and less than twenty tons, shall be licensed, the same admeasurement shall be made, and the same provisions observed relative thereto, as are to be observed in case of admeasuring vessels to be registered; but in all cases where such vessel, or any other licensed vessel, shall have been once admeasured, it shall not be necessary to measure her anew for the purpose of obtaining another enrollment or license, except she shall have undergone some alteration as to her burden subsequent to the time of her former license. Every licensed vessel shall have her name, and the port to which she belongs, painted on her stern, as is directed for registered vessels, and if found without such painting, the owner shall pay twenty dollars. No collector shall grant to any vessel, whose enrollment or license for carrying on the coasting-trade has expired, a new enrollment or license, before the master shall have rendered a true account of the number of seamen, and the time they have severally been employed on board such vessel during the continuance of the expired license,

and shall have paid to the collector twenty cents per month, for every month such seamen have been so severally employed, which sum the master may detain from the wages of such seamen. If the master shall render a false account of the number of men, and the length of time they have severally been employed, he shall forfeit and pay one hundred dollars. Any boat, sloop, or other vessel of the United States, navigating the waters on our northern, northeastern, and northwestern frontiers, otherwise than by sea, shall be enrolled and licensed in such form as may be prescribed by the Secretary of the Treasury; which enrollment and license shall authorize any such boat, sloop, or other vessel, to be employed either in the coasting or foreign trade; and no certificate of registry shall be required for vessels so employed on said frontiers: *Provided*, That such boat, sloop, or vessel, shall be, in every other respect, liable to the rules, regulations, and penalties, now in force, relating to registered vessels on our northern, northeastern, and northwestern frontiers.—*Laws of the United States.*

TONNAGE EMPLOYED IN THE COASTING-TRADE OF THE U. S.

1830.....	816,978	1851.....	1,854,817
1831.....	859,723	1852.....	2,008,021
1832.....	649,627	1853.....	2,134,266
1833.....	744,198	1854.....	2,273,900
1834.....	738,618	1855.....	2,491,108
1835.....	792,301	1856.....	2,211,935

From this table we see that our coasting-trade has increased 12 per cent. on an average for forty years, and has doubled in the past ten years—from 1845 to 1855. The total tonnage has increased from 435,066 tons in 1815 to 2,491,108 tons in 1855, giving an increase of 10 per cent. per annum; showing that we have at this time a larger tonnage than any other nation.

"The coasting-trade of the United States has, from the beginning, been strictly reserved for vessels built within the United States, and owned by citizens of the United States, to the exclusion of foreign-built and foreign-owned vessels. The American tonnage engaged in foreign trade and in the coasting-trade has been American built, and has had the absolute protection of our laws, and the licensed tonnage absolute protection, in the carrying-trade on our coast, and in our own waters. The protection given to our foreign-commercial and to our coasting-commercial marine has

secured a large and efficient body of skillful officers and sailors, at all times ready for the defense of our cities and coast, for repelling aggression on our commerce, and for manning our ships of war. In the protection given to our shipping interest, for the purpose of having at all times the power to repel foreign aggression, and protect our coast and trade, there appears to have been but little division of sentiment, from the earliest time to the present, while the yearly increase of our tonnage proves the wisdom of our laws in this particular. We have no data to ascertain the annual number of persons, or the annual tons of freight carried, in our coasting-trade, nor the value thereof. Each person must make his own estimate of the tonnage employed, and the average number of trips the vessels can make, combined with the facts that capital constantly tends to that business, and the growth of our enrolled and licensed tonnage keeps pace with our increasing population and wealth. The amount of coasting-tonnage, and the annual number of tons of freight transported on our railroads, with an estimate of that carried by other modes of transfer, exhibit the magnitude of the means required for our internal trade."—*U. S. Treasury Report*, December, 1856.

Coast Line. The following statement of the river navigation and shore line of the United States was prepared by Colonel Abert, of the Topographical Engineers, at the request of the Treasury Department, December 7th, 1845. It has since been completed to date. The head of tide-water is assumed as the limit of steam navigation, as impeding falls or rapids are encountered at that point, above which many rivers are adapted to steam navigation, but to what extent is not sufficiently known. The shore line of rivers to head of tide-water, from

Mato to Texas, la.....	10,501 miles.
Rivers of Texas.....	1,210 "
Lower Mississippi, islands and bayous.....	6,372 "
Upper Mississippi and tributaries.....	2,736 "
Big Black, Yazoo, and bayous.....	1,190 "
Red River and tributaries.....	4,924 "
Arkansas River and tributaries.....	3,250 "
Missouri River and tributaries.....	7,830 "
Ohio river and tributaries.....	7,942 "
Total.....	47,355 "
Add rivers on the Pacific—Sacramento.....	600
San Joaquin.....	600
Oregon.....	459
Umpqua.....	60
Total.....	1,710

Total river shore line to the United States in 1854, including both banks..... 49,065 miles.

Shore line of northern lakes, including bays, sounds, and islands (American)..... 3,620 "

Total river and lake shore line..... 52,785 "

A calculation made at the office of the Coast Survey in 1853 gives for the total main shore line of the United States (exclusive of bays, sounds, islands, etc.) 12,609 statute miles. If all of these be followed, and the rivers entered to the head of tide-water, the total shore line will be swelled to 33,069 miles.

SHORE LINE OF THE UNITED STATES IN STATUTE MILES.

The main shore line of the Atlantic, including bays, etc., is twice that of the Gulf, three times that of the Pacific, and more than equal to that of the Pacific and Gulf combined. The Southern States have three times as much sea-coast as the Northern.

Europe, in extent of shore line, is more favored than any other portion of the earth, and North America next; the former having, according to Guyot, only 156 miles, and the latter 228 miles of surface to one mile of coast (the United States having 241); while South Africa has 376, Africa 623, and Asia 459 miles.

The following table furnishes three measurements:

- The coast line, i. e. sea-coast, bays, islands, etc., of the Atlantic coast.....** 12,859 miles.
- The rivers to head of tide, both shores.....** 6,655 "
- For the Gulf of Mexico, the coast line to.....** 5,744 "
- Length of rivers to head of tide.....** 5,546 "
- Coast line, exclusive of islands and rivers to head of tide—for the Atlantic.....** 6,017 "
- " Gulf.....** 3,851 "
- Coast line, exclusive of bays, islands, etc., except Massachusetts Bay—Atlantic.....** 2,163 "
- Gulf.....** 1,704 "

THE RESULTS OF MEASUREMENTS OF COAST AND SHORE LINE OF THE UNITED STATES AS REQUIRED BY THE SUPERINTENDENT OF THE CENSUS BUREAU FROM THE COAST SURVEY OF JULY 12, 1854, ARE AS FOLLOWS, IN STATUTE MILES:

States.	Shore Line, including Bays, Islands, and all Irregularities.	Shore Line, except Islands.	Coastline Line; viz.: Shore Line, except Islands, Bays, etc.	Remarks.
Maine	2,496	794	278	Measurements taken on heat maps of the Coast Survey Archives.
New Hampshire ...	40	41	18	Measured on Greenleaf's map of Maine, as correct as possible, but the great Irregularities of coast prevent a correct result.
Massachusetts	686	622	296	Measured on Garrigan's map of N. H., generally correct as compared with Smith's map.
Rhode Island	320	245	45	Measured on Borden's map of Mass., generally correct as compared with Smith's map.
Connecticut	202	240	104	Measured on Coast Survey off shore charts.
New York	690	50	none.	Measured on Coast Survey off shore charts.
New Jersey	540	800	120	Measured on Coast Survey off shore charts.
Delaware	113	106	23	Measured on F. Lucas's map of Md., Ches. Bay, and C. S. Sketches and Charts.
Maryland	509	411	83	Measured on F. Lucas's map of Md., Ches. Bay, and C. S. Sketches and Charts.
Northern Atlantic	6,150	2790	907	From northeast boundary to State line between Md. and Va.
Virginia	654	348	116	Measured on F. Lucas's map of Md. and C. S. maps.
North Carolina	1,641	1089	320	Measured on Brazier's map of N. C., and compared with Smith's.
South Carolina	756	267	220	Measured on Smith's map, and compared with Mitchell's.
Georgia	684	480	123	Measured on Smith's map, and compared with Mitchell's.
Florida, East Coast.	2,474	1034	472	Measured on map of Topographical Engineers.
Southern Atlantic	6,269	3218	1256	From State line between Md. and Va. to S. extremity of Florida.
Total Atlantic ...	12,869	6017	2163	
Florida, West Coast	1,592	883	674	Measured on map of Topographical Engineers.
Alabama	816	247	88	Measured on Smith's map, and compared with Mitchell's.
Mississippi	287	226	88	Measured on Smith's map, and compared with Mitchell's.
Louisiana	2,250	1256	562	Measured on Gerdes's Reconnoissances and Smith's map.
Texas	1,330	940	392	Measured on Blunt's and Smith's map.
Total Gulf	5,744	3551	1764	
Total South Atlantic and Gulf	11,063	6769	3020	
Total Pacific, from boundary of San Diego to mouth of Frazer's River...	3,251	2533	1343	Measured on Alden's Reconnoissances.

Coast Survey of the United States. It was to be expected that a people devoted to the pursuits of commerce, and depending in some degree on the sea as a means of communication between distant parts of the national territory, should demand, at an early period of their history, a competent survey of their coasts and inland waters.

But a short time previous to the separation of the colonies, charts had been constructed of the shores and harbors of North America, under the direction of F. W. Des Barres, his majesty's Surveyor General for the Colonies. The progress of his labors was interrupted by the Revolution. The surveys made under the personal superintendence of Des Barres still bear testimony to his skill and fidelity, and present a generally correct view of those parts of New England and the British possessions which, being rocky, are but little liable to change. They continue to form the principal basis of the charts of the northeastern coast of this continent. In the Southern and Middle States, however, they have been rendered worse than useless by the inconstant character of the bottoms, and the unequal merit of the originals. The surveys of Des Barres, covering a vast extent of coast, were originally deficient in minuteness of detail, and in hydrographical information; and these defects have been increased by the rapid and extensive changes in the direction, means, and wants of navigation caused by the growth of the country.

The project of a complete survey, conducted upon a uniform system and extending over the whole coast, was first proposed by the late Professor Patterson, in 1806. It combined three objects, the astronomical determination of prominent points, a triangulation to connect those points, and a hydrographic survey based upon this triangulation. Mr. Gallatin, then Secretary of the Treasury, encouraged the project, and obtained in writing the opinions of learned men as to the best mode of executing it. He selected the plan of operations recommended by Mr. Hassler, the first superintendent of the Coast Survey. This gentleman, a na-

tive of Switzerland, had been employed in the triangulation of the Canton of Berne, and had studied the science of geodesy under the most distinguished masters. It was exceedingly fortunate that his presence and advice here secured the early adoption of the only method of conducting a comprehensive trigonometrical survey that science approves—the only one of which the results have a certain and permanent value.

It is only, however, since the year 1832 that the survey of the coast has been in steady and active operation. During this long interval of neglect on the part of the government, the coasting trade and foreign commerce of the country have been chiefly indebted to the indefatigable labors of those distinguished hydrographers, the Messrs. Blunt of New York (both father and son), for the means of safe navigation.

The history of its fortunes, or rather misfortunes, during the preceding twenty-five years, may be recited in a few words. A law authorizing a survey of the coast was passed in 1807, but nothing was done under the law until 1811, when Mr. Hassler was sent to Europe to procure the instruments specified in his plan. They had all to be constructed. The war of 1812, and the failure of remittances, prevented Mr. Hassler's return before 1816, and in August of that year he was appointed to the office of superintendent. In 1818 Mr. Hassler's connection with the work was broken off by the repeal of that part of the law of 1807 which authorized the employment of citizens. During the ten years that followed, the coast survey seems to have been forgotten by the public and by Congress. In 1827 Mr. Southard, the Secretary of the Navy, a name never to be mentioned without an expression of the high respect which ability, patriotism, and long, faithful, and valuable services must always command in the republic, took occasion in his annual report to say that perfect surveys and charts of our harbors could not be made without the aid of the means contemplated by the act of 1807; and in February, 1828, the House directed the Committee on Naval Affairs to inquire into the expe-

diency of carrying into effect the provisions of that act. Finally, in 1832, the act of 1807 was revised, and an appropriation made for carrying it into execution, and since that period regular annual appropriations have been made, varying in amount, but generally such as have been called for by the estimates of the superintendent.

In 1843 there was added to the appropriation a proviso stipulating that a board, consisting of scientific persons in the service of the government, should be empowered to reorganize the work, and the plan presented by them, when approved by the president, was to be, and is now, the law regulating the operations of the survey. The scientific methods pursued by Mr. Hassler were continued, and it was directed that the topography should be carried so far inland as might be necessary for a proper delineation of the shore, and for purposes either of commerce or defense.

It is now understood that the aim of the coast survey is to furnish with the utmost attainable accuracy, and in a connected and uniform manner, all the geographical, topographical, and hydrographical data that can be made in any way useful to the navigation and defense of the coast. And it is also supposed that, in collecting these data, information will be accumulated that may become serviceable in suggesting and directing local and general improvements; such as the placing and constructing of light-houses, beacons, buoys, etc., the means of improving channels, the effect of contemplated constructions upon harbors and tidal deposits, the suitability of a submerged soil for building, etc. And, lastly, it is presumed that those States through which the survey passes will, sooner or later, avail themselves of the base it is able to supply, to form a correct geographical map of their own territory, under circumstances very favorable to economy and accuracy. These are the practical benefits, either direct or incidental, conferred by the coast survey.

In abstract science it has also its mission, equally useful and distinguished. It is to contribute a part of the means by which the irregularly elliptical form of the earth may be satisfactorily determined, the variations in local gravitation, their causes, and thence the internal structure of the earth, be made known, and the phenomena of terrestrial magnetism be explained. It will illustrate the astronomical problem of the tides. Its numerous meteorological records will also contribute to a better knowledge of the climates of the United States, and of the nature and action of meteoric storms, and thus be of service to the farmer as well as the navigator.

The science of geodesics prescribes the principles upon which a survey of an extended region should be conducted. In the ordinary operations of land-surveying, the surveyor is permitted to regard his field of work as a plane surface; but the engineer who is to construct a map of a whole country, or of a long line of continuous sea-coast, must take into consideration the spheroidal figure of the earth, and present an exact delineation of that part of the spheroid upon which he is employed. This necessity controls the processes used in computation, and the plan of projection upon which the detailed results are given, whether it be called a map or chart. Both the projection and the formulae for computation involve the higher mathematics, and require an acquaintance with the most advanced state of the mathematico-physical sciences.

The system of projection introduced by Mr. Hassler originated with Flamsteed. It is the development of a part of the earth's surface upon a cone, either a tangent to a certain latitude, or cutting two given parallels and two meridians equidistant from the middle meridian, and extended on both sides of the meridian and in latitude only so far as to admit of no deviation from the real magnitudes, such as would be sensible in the detail surveys. In this method of reducing the curved surface of the earth to a plane, the radii of curvature

of the parallels and meridians, depending upon the value given to the expression for the ellipticity, and the assumed form of the globe, are important terms. For practical use, tables have been computed in the office of the coast survey, showing the length in metres of every minute and second of the arcs of the meridians and parallels comprehended in the maps. It has been found necessary to recalculate these tables since 1844, on account of the new value of the ellipticity announced by Bessel, and adopted by the present superintendent. There will be occasion to recur to this subject.

The practical operations of the coast survey are classified under the general heads of triangulation, astronomical and magnetic observations, topography, and hydrography. The fundamental basis of the survey is a network of great triangles, the sides of which, varying from ten to one hundred and ten miles, are the longest that the limits of vision or the nature of the country will allow, and hence a mountainous region is much the most favorable for a first or *primary triangulation*. The starting line, or first side of the first triangle, called the *base line*, is measured by mechanical means, and this is a labor demanding, as much as any other on the survey, accuracy, a philosophical regard to minute details, and long previous preparation. Observing, in passing, that several kinds of measuring-rods have been heretofore used, as wood and glass, and that the apparatus of Mr. Hassler consisted of an assemblage of four iron bars, each of them two metres in length, with which he obtained excellent results. In 1817 the preliminary measurement of two base lines was made by Mr. Hassler, and in 1834 the length of the same lines was determined by computation, carried from the new base on Tin Island beach. The difference between the measured and computed lengths of these lines was in one case less than a foot, and in the other about four inches; the bases themselves were 5.9 and 4.8 miles long.

It will, perhaps, best serve to convey an idea of the difficulty of measuring a base-line if some account be given of Professor Bache's base-apparatus. The measuring bars are upon the compensating system, first used by Colonel Colby in Great Britain, and by Mr. Borden in the trigonometrical survey of the State of Massachusetts; but a principle not before applied was introduced in reference to the dimensions of the bars, which is thus stated. Bars of brass and iron (the materials employed), of the same dimensions will not, owing to their different conducting powers and specific heats, heat equally in equal times, and therefore, during changes of temperature, the system ceases to be compensating. This Mr. Bache corrected by giving a coating to the bars that made them absorb equally, and by proportioning the sections to each other, so that both would have the same temperature during variable temperatures of the atmosphere. In order to do this satisfactorily, it was necessary to make direct experiments upon the materials of the bars themselves, after having first arranged them approximately by means of the numbers taken from the books. The contact between two sets of bars is made by a blunt knife-edge and a plane of agate, and a lever of contact at the ends of the bars is corrected by a level so delicate that several of its divisions make up a quantity entirely insignificant in the measurement. The bars are covered with a double coat of tin, to keep the fluctuations of the temperature within moderate limits, and the bases on which they are supported are covered with several thicknesses of imperfectly conducting material for the same purpose. The length of the apparatus is compared, before and after final measurement, with a standard iron bar that had been compared in the coast-survey office by means of Mr. Saxton's reflecting pyrometer. By this instrument, a change of the one hundred thousandth part of an inch in the length of the standard bar is perceptible.

To the preceding description it should be added that

the bars (regulated in size by the relative specific heats of the two metals) were heated above the possible temperature to which they could be exposed in use, in order to give them a set. This precaution was at first overlooked in the compensation base-apparatus of the British ordnance survey, and it was afterward found necessary to resort to it. Those who are at all familiar with the subject will perceive that Professor Bache's application of the lever of contact and level (first used by Hessel in standards of measure) has not only greatly increased the delicacy of the instrument and lessened its complexity, but also removed several sources of error. By optical contact, and the employment of a microscopic apparatus to determine the distance between the compensation points, the measures are repeated in two different terms, each having its peculiar standard. Such was the case in the British and Indian surveys, and Colonel Everest complains of the consequent liability to error, and the burdensome accumulation of petty corrections. The remeasurement of a base of seven and a half miles, in India, differed, however, only 2.4 inches from the first length. In a base of seven miles, Professor Bache found that the same difference might be about 0.5 inch, if all the errors were supposed to fall on the same side, which is most improbable. The probable error in remeasuring one hundred and twelve yards was less than five thousandths of an inch, and the actual resulting error in remeasuring one-third of a mile was nothing.

This may appear like refining too much, but it must be known that the lines measured by the same bar in winter and summer might differ materially in nominal length. This difference in the original use of the coast survey might be about twenty feet, and, at a rough estimate, an error of twenty feet in this place would amount, in one of the large triangles, of which the sides are between fifty and sixty miles, to about one-tenth of a mile. The source of error and its correction being recognized, there is no other limit to accuracy than the possible.

We return now to the great triangles of the survey, which, as has been said, form its fundamental basis. The points of the primary triangulation are selected with scrupulous regard to all those conditions which make triangles, in the technical acceptance, good. Scattered at distant intervals over the vast field of work, they are certain guides by which the more detailed operations are conducted and controlled. Within them the space is subdivided into smaller triangles, constituting the *secondary* and *tertiary triangulations*. They bring down the work to the minute details of topography and hydrography, and these subsidiary triangulations and details, circumscribed as they are by the primary points, are restrained and corrected by them in their deviations. As an additional explanation of the necessity for this first net of great triangles, it may be well to inform the general reader that there is no instrument, however delicate in construction, that is not liable to very small errors, which the most studious attention to every disturbing influence, whether mechanical or meteorological, can not altogether remove. Now this primary triangulation, which in a mountainous region spans the surface with giant strides, has fewer of these unaccountable errors, simply because it has fewer triangles. It is hardly necessary to add that better instruments also are used in it. The two and a half feet theodolite, made by Simms (after Troughton's death), under Mr. Hassler's supervision, and used by him and by Professor Bache in the primary triangulation, is still regarded in this country and in Europe as a master-piece of invention and mechanism. It reads to seconds.

Magnetic and astronomical observations accompany the primary triangulation. The latter are for latitude, longitude, and azimuth, or angular direction from the meridian.

Following the secondary triangulation in order comes

the *Topography*, the duty of which is to delineate faithfully the features of the ground. It exhibits the height and contour of elevations, the shape and extent of plains, the courses of streams, all the constructions of man, and the waving and indented outline of the shores. It distinguishes the tilled land from the pasture, and the grove from the orchard, and designates the character of the wood-land. It speaks a universal language, and observes strict fidelity to nature.

Depending upon the secondary triangulation and the topography for its means of progress, follows the *Hydrography*. In this term is included all that concerns local navigation, as the depths and character of the bottom, the direction and strength of the currents, the ebb and flow of the tides, and the information, coming under the head of sailing directions and nautical instruction, which make up the valuable knowledge of the local or general pilot. This branch enjoys the honor of announcing the nautical discoveries of the coast survey, which, though resulting from the combined operations of all, are yet brought out by its means.

In the preceding pages the plan of the survey is presented, and the general distribution of its labors is stated; it remains now to speak of the execution of the various details, and of the benefits that have been conferred by the coast survey upon science, and upon the local and general commerce of the country and of the world. In doing this it will be most convenient to keep to its actual state at this day.

It would not be just, however, to leave its past history without a tribute of respect to the memory and services of the man by whose enlightened efforts a right direction was given to the views of the government in founding the survey, who was faithful to it through thirty-five years of checkered fortunes, and who literally died in the performance of its duties, having written the last few lines of his final report after he felt that he had been touched by the hand of death. Educated in the best European schools of theory and practice, and devoted to the pursuits of science, for which he was eminently qualified by natural endowments, Professor Hassler always brought to the task before him that zeal and tenacity of purpose which give spirit to enterprises of great moment, and gain for them the name of action. He is honorably known for his mathematical and astronomical writings, and his papers in the *American Philosophical Transactions*, containing an account of the methods employed by him on the coast survey, will always be regarded as a valuable contribution to geodetical knowledge. Those who knew him intimately praise the ardor of his friendship and the generosity of his disposition, while the labors of his life, and the manner in which they were performed, bear ample witness to his industry and integrity. That he had some defects of character it is hardly necessary to say, for this is the inevitable lot of humanity; but they were not such as it requires the exercise of magnanimity to forget, and time, which is rapidly drawing over them the veil of perfect obscurity, will endear his name and his virtues to the reverent and affectionate respect of all true lovers of American science.

On the death of Mr. Hassler, in 1843, the appointment of his successor was regarded with deep interest by the learned men of the country. The office of superintendent of the coast survey is recognized as one of the central positions of American science, and the incumbent is expected not only to be able to fulfill its prescribed duties, but to be qualified to direct his powers to the advancement of knowledge in every department of the work. How far the present superintendent, Professor Bache, is suited to answer these expectations, to sustain the national reputation, and to promote the cause of science, may be estimated from the fact that his appointment was solicited by gentlemen in all parts of the country engaged in the pursuits of learning. He was educated at West Point, and since graduating there he has, in connection with the Franklin Institute

and the University of Pennsylvania, followed a course of physical science that has made him well known in this country and in Europe. While traveling as the President of Girard College, he received from the principal European academies distinguished marks of consideration. It is but justice to Professor Bache to say that there is no branch of the work into which he has not been able to introduce improvements, either owing to the discoveries of the day, as in the use of the magnetic telegraph for meridian differences, or owing (still oftener) to his own great and eminent scientific attainments. This must appear in the course of these remarks, but it is quite as creditable to his administration to state, as may be done with strict accuracy, that the amount of results now obtained is double that under the former plan, for an increase of 50 per cent. in the cost.

The points of the *primary triangulation* are selected by means of a preliminary reconnaissance. The reconnaissancees therefore precede the triangulations and are indispensable, and require great judgment. The object of the general reconnaissance is to make known the facilities and difficulties of the work, and to discover the best plan for its execution. A particular reconnaissance decides the position of the stations, and presents a general sketch of the triangles in any section. As they constitute the authority to which the rest is subordinate, and by which it is controlled, it is of the greatest consequence to know the circumstances under which a satisfactory result may be secured with the least delay. The rule generally followed (and adopted by the former superintendent) is to observe on those days only that appear entirely unobjectionable. This rule is attended with a serious loss of time. Mr. Bache has increased the rapidity of the work, and improved rather than diminished its value, by applying the mathematical test of the least probable error to observations made under such conditions as are ordinarily favorable and of frequent occurrence. The number of observations made under these conditions, which will reduce the probable error to what is attributable to the unavoidable errors of instrument and observer, is ascertained and taken as a governing rule. Six triangles measured by Mr. Bache in 1841 gave for the greatest difference from 180° , after allowing for the spherical excess, $0''\cdot2$ (of space) for each angle; from this the difference descended to nothing.

Allusion has been made to the necessity of recomputing the first tables of projection, in consequence of the adoption of Bessel's latest determination of the ellipticity. The tables for computing the triangles have also been affected by this change, and the formulae have been revised, and undoubtedly greatly improved in convenience and accuracy. The tables have undergone a further modification by substituting the *legal* ratio of the metre to the toise in the place of the arbitrary standard resulting from the ingenious, but (as Bessel has said) "not allowable," comparisons of Mr. Hassler.

This is the proper place to advert to the mode of operations pursued on the Southern coast. It was perceived, in the early progress of the work, that the inaptitude of this level region for a comprehensive triangulation was to be overcome, either by great expense, or by resources not yet developed. The most apparent expedient was that employed in the northern section of the great meridional arc of India, where it crosses the flat territory of the Doab. Costly edifices of masonry, with walls five feet thick at the base and two at the summit, are erected at each of the principal stations, and their height, about fifty feet, is sufficient to command a view above the vegetation. And this expedient was, if contemplated, in accordance with the former progress of the American survey, which, advancing in two directions from a central base, was necessarily slow.

In 1845, however, the present superintendent exhib-

ited in his annual report a plan for the more rapid execution of the survey, which consisted in dividing the whole of our extended sea-board, including the Gulf of Mexico, into nine sections, comprising a nearly equal extent of shore line, and in prosecuting the work separately and simultaneously in as many of these sections as the appropriations would allow. The work of each section is commenced by the measurement of a baseline, and, as the triangulation is extended, this base serves as the verification-base of an adjoining section. The rapidity of this plan is made apparent by considering that all the different processes of the survey (in their necessary order) may be conducted at the same time in every section, and thus, if the appropriations were sufficient, the whole coast might be completed in the time required for a single division of it. But this plan accommodates itself more easily to the character of the ground than one in which the direction and progress are derived from previous connections. Indeed, every latitude is allowed for the selection of sites for bases, and for the most favorable disposition of the triangles, because each section is for the time a distinct undertaking. The combination of all will unite the extended coast of the United States into one comprehensive scheme of triangulation.

The value of permanent and conspicuous structures of masonry to designate points of primary triangulation is not, however, underrated. While temporary means of elevation are employed, such as the high tripods, with independent stands for the instruments, first used in Delaware Bay by the senior assistant of the survey, Mr. Edward Blunt, of New York, it must be remembered that the coast survey is enabled to avail itself of the light-houses, and other lofty structures along the coast. And it may be safely concluded that the governments of the Southern States will raise appropriate edifices at those points of the primary triangulation of the coast survey which limit the bases of their local operations.

Accompanying the primary triangulation, as an essential part of it, are the *astronomical and magnetic observations*. The former are for azimuth, latitude, and longitude. For the determination of azimuths, Mr. Bache has employed for the first time on the work the elongations of Polaris in its eastern and western directions. At the time of elongation, when the change in altitude is most rapid, the movement in azimuth is nothing; and thus the opportunity is enjoyed of making careful and deliberate observations. This method is independent of local time. By using several circumelongation observations, a mean of a number of results is substituted for a single one. In this reduction a very simple formula, first investigated by Mr. Nulty, of Philadelphia, has been applied, and the practice is simplified by the use of tables for the computations of latitude, subjected to a slight trigonometrical change. It is proper to state that this method has been in use on the survey since 1845, as one similar to it, if not identical with it, has recently been communicated to the Royal Astronomical Society of London.

The superintendent has adopted the suggestion of the astronomer royal at Greenwich, who proposed referring the points of greatest elongation of circumpolar stars to marks in the horizon, by perpendicular lines denoted by means of an altitude and azimuth circle. Elongation signals are established about two miles distant, consisting of a delicate wand by day and a lamp by night, the latter seen through a perforated board.

The determinations of the latitude (as well as of the azimuths) are frequent. Since 1844 fourteen stations have been occupied for latitude, and seven for azimuth, in Sections I., II., and III. of the survey. A comparison of the latitudes deduced geodetically from a central point with astronomical determinations led the superintendent, in 1844, to the discovery of certain variations in the level, which could only be attributed to changes in form and density of the material compos-

ing the those of the late escaped element the future structure been more for-generated by Chambers of France certain served, spanning will be the irreg-

But th

ing the earth's crust. These variations are *similar* to those caused by the proximity of mountains; but while the latter have been well understood, the former had escaped notice. The numerous determinations of this element will, therefore, occupy an important place in the future discussions of the general form and internal structure of the earth. A similar discovery has since been made in the ordnance survey of Ireland by Major-general Colby, and appears to have been anticipated by Laplace in the opinion given by him in the Chamber of Peers, in 1817, upon the topographical map of France: "If the latitudes of the extreme points (of certain lines) and of several intermediate points are observed, and the length of the seconds pendulum corresponding to these points measured, a great deal of light will be thrown upon the figure of the earth, and upon the irregularities of its degrees and of gravity."

It is very interesting, in this respect, to know that latitudes observed at the extremities of the side of a triangle, and forward and backward azimuths on the same line, have differed by several seconds, and that these deviations in the plumb-line have occurred where the want of uniformity (whether arising from differences in density, or the want of homogeneity of structure) was not apparent as a topographical feature of the country. After the computations from which the preceding conclusions are derived were verified, the results were confirmed by the introduction of new instruments on the work. During the last year a zenith telescope has been used for obtaining the latitude, by a method invented by Captain Talcott, which consists in observing the differences of zenith distances of stars culminating within a short distance of each other, and at nearly the same altitudes, on different sides of the zenith. The circummeridian altitudes by the repeating circle, the prime vertical transits, and the absolute measurement of zenith distances by the zenith sector, are still used.

Observations for the comparison of these instruments and methods have been made by the superintendent, and by Captain T. J. Lee, of the United States Topographical Engineers, an assistant in the coast survey, whose valuable labors have been chiefly devoted to the astronomical and magnetic observations. Of the *magnetic observations* it will be sufficient to say, as an indication of their character, that they are made with the new instruments invented by Dr. Lloyd and Mr. Weber. The portable declinometer of Mr. Weber (perfected by Lieutenant Riddle, and manipulated according to his instructions) measures inclination, and, by a subsidiary apparatus, the horizontal force, by the method of Gauss. Fox's dip circle, with the use of the deflecting magnet, has given very satisfactory results. By means of these instruments, the *declination*, *inclination*, and *intensity* (horizontal and vertical) are determined in a manner that supplies all that is practically necessary, and contributes valuable additions to general magnetic researches.

Longitudes have been determined by occultations, eclipses, moon-culminations, and the frequent transportation of chronometers. Mr. Bond, the director of the observatory at Cambridge, Massachusetts, communicates the meridian differences by chronometers between the British observatories and Boston. All determinations of this element are referred to a principal port on the sea-coast, and are connected in the aggregate with differences obtained from Europe by chronometric and astronomical comparisons. The security against error afforded by employing persons to compute who are disconnected with the duties of the field or the observatory, is well understood. Gentlemen in private life are engaged to repeat the important calculations of the survey, and this system, which enlarges the sphere of labor in a way not less commendable for its economy than for its other advantages, receives universal sanction.

But the discoveries of Professor Henry (secretary

of the Smithsonian Institute), resulting in the invention of the magnetic telegraph, have provided a new and more precise method of arriving at the difference between the times of two places, or their difference of longitude expressed in time. The details of these observations were consigned to Mr. S. C. Walker. The following concise account of the manner of transmitting the signals, of the possible errors of observation, and of the real value of the results, is from the pen of Dr. Baehé: "The signals are given at one of the stations by pressing a key, which causes the closing of the circuit. This closing, it is intended, shall be simultaneous with the ticking of a clock or chronometer at the station. The circuit being closed, if the electrical wave or current takes a sensible time to propagate itself, or to pass from one station to another, the absolute time at which the signal reaches the second or receiving station is sensibly different from that of making the signal at the first or giving station. A coil about the poles of a horse-shoe magnet of soft iron forms part of the circuit through which the electrical effect is transmitted. Under its influence the soft iron becomes magnetic, attracting the soft iron bar (armature or keeper) delicately poised at a determined distance from the poles of the magnet; the movement of this keeper sets in action a local battery, which gives sufficient power to make the dots and lines constituting the Morse telegraphic signals. The click of the keeper of this temporary magnet is compared, at the receiving station, with that of a clock or chronometer, thus marking the time at which the signal made at a known time at the giving station is received. From this explanation, it appears that there is liability to error."

Dr. Baehé then proceeds to enumerate five possible errors, numbered in order, and shows that the numerical values can be in each case assigned to two (viz. 1 and 5), and that one (viz. 2) is insensible. A comparison of the observations proves that the errors denoted by 3 and 4 are canceled by a very small residual quantity having the opposite sign, and "the interesting consequences follow, that 'the telegraphic method of comparing clocks, distant two hundred miles from each other, is free from error when the method of coincidence of beats is employed; and that the probable error of the longitude, from this method, is the same as the mean result of the computed relative correction of the clocks for the nights of observation.' An investigation of the probable value of such error shows that, under favorable astronomical circumstances, and with due care in the use of the transit instrument, 'the astronomical difference of longitude between any two stations of a trigonometrical survey may be determined by telegraphic signals, with a degree of precision of the same order as that of difference of latitude,' the inaccuracy depending upon the same causes as the deviation of the plumb-line." Before concluding with the primary triangulation, it must be observed that Dr. Baehé uses reciprocal vertical angles for determining differences of heights at the primary stations. These angles may be measured at a time of day when it is impracticable to observe horizontal angles, and the effect of refraction near the surface is investigated by a long series of observations. The space circumscribed by the terrestrial angles of the first order, and defined by the celestial observations that accompany them, is subdivided into a minute net-work of smaller triangles, constituting the *secondary* and *tertiary triangulations*, the points of which embrace and determine headlands, light-houses, beacons, churches, hills, and all conspicuous objects along the coast, that can be made useful in its navigation. They also bring down the work to the details of the topography and hydrography, and supply the bases for these branches of the survey.

It has been already mentioned that the topography is minutely and exactly descriptive of the ground, both in form and character. The Lehman system of topographical drawing has been adopted, but with such

modifications as the nature of this country exacted, in order to preserve the beauty of the maps. The slopes are represented by hachures, the strength and distance apart of which indicates the degree of inclination. In the original maps, the horizontal curves limiting the different slopes are drawn in red ink, as the draughtsman progresses in his sheet.

The scale of the original sheet is $\frac{1}{10000}$, or about 6½ inches English to the mile. Plans are frequently executed in the field, and furnished from the office, when wanted for local improvement, on twice this scale. But the charts designed for navigators are necessarily reduced in dimension. The harbor charts are published on the scale of $\frac{1}{5000}$, or about 3½ inches English, and the more general charts on that of $\frac{1}{10000}$, or about three-fourths of an inch to the mile; which last is the scale of the great topographical map of France. In all the maps, the topographical details are faithfully preserved, including height, contour, &c.

It appears from the report of the council of the Royal Astronomical Society to the twenty-seventh annual general meeting, that a similar scale of execution, and an equal fidelity of representation in the topographical details, have been finally attained in the ordinance maps of England and Ireland. In both the American and English maps, the subdivisions of the meridians and parallels are so minute, that parts of a second of space can be estimated.

As the first object of the coast survey is the knowledge of our own shores and inland waters, and the general improvement of the navigation, both external and internal, of the coast, so the large class of facts and researches embraced in the general term *hydrography* are regarded as being of paramount importance. It is to the hydrography that the friends of the coast survey direct the public attention for the evidences of its great practical utility, and the discoveries in this department have been so numerous and valuable as to secure for it a high degree of public favor. The first popular inquiry concerning the coast survey is as to the progress it has made, and this inquiry is satisfied by learning the extent of the shore line over which the hydrographer has passed. But before estimating its performance in this way, it is necessary to say, that, as the operations of the triangulations, &c., must precede the hydrography, this leads to an unfair estimate. The hydrography can only be laid down when the trigonometrical points on which its operations are based have been established; thus two-thirds of the work may be completed when the hydrographical labors commence. In 1844, the first year of Dr. Baile's superintendence, nine States on the Atlantic sea-board shared in the benefits conferred by the coast survey; in 1845, thirteen States; in 1846, fifteen; and in 1847, eighteen States. The estimates for the present year include all the States on the Atlantic and the Gulf of Mexico, and it may be inferred at once from this statement that, if sufficient appropriations are supplied by Congress, a definite and not distant period can be assigned for the completion of the whole work.

Having premised this statement, which was necessary to give a correct idea of the progress of the work, it may be added that the nautical parts of the survey have extended generally from Nantucket Sound to Hampton Roads nearly, including the Vineyard Sound, Block Island and Long Island Sounds, with all their harbors, great and small, New York Bay and harbor, Delaware Bay and river, a large part of Chesapeake Bay, together with most of the rivers emptying into it north of the Potomac, and all the external sea-coast, from the southern coast of Massachusetts to the Capes of the Delaware. In this broad field a little remains to be done, but very little in comparison with the whole. In addition to the above, something has been accomplished in the hydrography of Albemarle and Mississippi Sounds, and in the latter especially great benefits have already resulted to its local commerce.

It will give, perhaps, the best idea of the value of the hydrographical work to enumerate some of those discoveries and corrections which, in different places, have signalized the progress of the coast survey. The first of these in order and in merit is the discovery of a new channel, straighter and deeper than the channels before known, over the outer bars of New York harbor. Such a gift as this to the first commercial city of the continent, where it was very much needed, ought to gain permanent favor for the enterprise by which it has been made. Important changes in the main ship-channel near Sandy Hook were first noticed by Major Bache, of the Topographical Engineers, by a comparison of his own limits with those of the coast survey in 1842, and this discovery has since been confirmed by the latter. So rapid has been the accumulation upon the extreme point of the Hook, that the high-water mark now stands where there was a depth of 40 feet in 1836. The Chamber of Commerce of New York has gratefully acknowledged the communication of this important fact by the present superintendent. In Delaware Bay a new and straight channel was discovered, lying parallel to the main ship-channel, more narrow than the latter, but likely to prove serviceable in scant winds, and better sheltered from floating ice. Three channels were opened through the ridges of Cape May, and a passage made known through the "Cove-falls." The future changes in the latter, which may prove to be the germ of a new pass to the ocean, will be watched with interest. The result of the survey in Delaware Bay has been wisely to change the form of the bottom, as it stood on the old charts. Some shoals have been erased altogether, a new one near the deep water of the channel-way has been added, and the limits, shape, depth, and direction of every shoal in the bay have been altered.

In Long Island Sound, Buzzard's Bay, Massachusetts Bay, and Chesapeake Bay, so much has been added to the safety of navigation by laying down positions correctly, and by good sailing directions, but chiefly by the actual discovery of useful channels or of hidden and unknown dangers, that a list of these additions alone would occupy too much space. In Long Island Sound, a rock having only 13½ feet of water on it, on the Cerberus Shoal, was discovered and determined by the brig Washington, in September, 1845; and in the same year three rocks were found in the most frequented part of Buzzard's Bay by the Gallatin. Changes of the highest importance, which, owing to natural causes, had taken place in the channel-way of the entrance to Mobile Bay, were found out by the Phoenix in 1847.

In the off-shore work, the most valuable discoveries have been made by the hydrographical party employed on the Nantucket Shoals. They deeply concern the navigation, foreign and domestic, of the whole coast; especially the European trade from New York and the West India trade from the Eastern States. The insurance offices of New York and Boston have publicly acknowledged their obligation for these discoveries.

To this part of the hydrography belongs the *exploration of the Gulf Stream*, an enterprise that originated with the present superintendent. This is a work of difficulty and time. It was commenced by the hydrographical assistant in command of the brig Washington, in 1845, who obtained bottom near the inner edge of the stream at the depth of 7800 feet, and the marked and rapid change of temperature at this place gave reason to hope that a curve of similar depths might be traced, corresponding to the inner line of direction of the Gulf Stream, of which any point would be known when crossing, from the characteristic changes of temperature. The latitude (the most easy of the two co-ordinates to ascertain correctly) being given, the ship's longitude would result sufficiently near the truth to be of essential service in approaching the coast. The deep-sea and surface temperatures were both taken in 1845.

Lieutenant Bache succeeded to the charge of this duty in 1846. Professor Henry has thus spoken of his merits and success: "In the last report, an account was given of a series of observations on the Gulf Stream, made by Lieutenant George M. Bache, whose life fell a sacrifice to his zeal in the discharge of his duty, and whose loss science was called upon to mourn just as he was commencing, with his accustomed ardor, the investigation of one of the most interesting phenomena of our globe. The results he obtained will be given to the world in another publication, and it will be sufficient to state in this place that he examined three entire sections across the stream. His researches exhibit the remarkable fact that the whole current of warm water, to the depth of at least 480 fathoms, divides itself into two principal branches, separated by a portion of cold water, and that the transition from the cold water, along and next to the coast, is almost instantaneous, as if the two were separated by a nearly perpendicular wall, slightly inclining to the east at the top."

The subject of the tides is now receiving for the first time, in this country, proper attention. The tide-tables on the charts contain all the information as to times, heights, and durations, that is required in practice. Corrected establishments are deduced from the means of the luni-tidal intervals combined for each half-hour of transit. The astronomical problem of the tides is worked out for prominent points where the observations have sufficiently accumulated.

The mean curves of semi-menstrual inequality of time and height, corrected for the mean annual parallax and declination, are compared with the curves of observation (freed from the diurnal inequality) at each semi-lunation, and the variations in the times and heights of high water, due to changes in the moon's declination and distance from the earth, are tabulated for the future improvement of the tide-tables.

By the continuance of careful and constant observations, the means will be supplied of adding to the knowledge of the diurnal and solar inequalities, and of studying all other phenomena of the tides. The residual errors that appear in the semi-menstrual curves, after eliminating the effects of parallax and declination, are caused by atmospheric changes. The local influence, therefore, of particular winds, and the general effect of changes in the pressure of the atmosphere, are to be investigated, and enough is already known to prove that the seaman will derive great profit from this part of the labors of the coast survey. The direction and velocity of tidal currents are now carefully determined for the normal condition of the tides, and for their disturbance by winds and storms, and a knowledge of the courses and conflicts of the tides in the harbors and inland waters of the United States (as Long Island and Vineyard Sounds) will also result from the comparison of numerous records, kept with a special view to their investigation.

To the preceding account of the operations of the coast survey it must be added, that the reduction of the maps to the scale of publication, the engraving and printing of them, are entirely executed in the office at Washington. An exception is made in the engraving of the smaller harbor maps, particularly of the harbors of refuge. They are sometimes placed in the hands of private artists, which serves the double object of an earlier publication and of encouraging the art of map-engraving in this country. The propriety of publishing to the world the important results of the coast survey as soon as obtained was immediately recognized by Professor Bache. In the case of a discovery affecting the general navigation of the coast, like that of the "New South Shoal," a "preliminary sketch," anticipating the complete chart, has been freely distributed. In other cases, information has been disseminated through the press, or furnished by authority, to chart-sellers. The office at Washington contains also workshops, at which the various instruments of the survey

are repaired and made. All the details of the office duties, whether relating to the verification and engraving of maps, or the occupation of the workmen, in the absence of the superintendent, are under the direction of Captain A. A. Humphreys, of the Topographical Engineers, an assistant. As the operations of the coast survey are numerous and various, and its duties very multiplied in detail and complicated in their connection, it will be readily believed that the direction and adjustment of them—the instructions, the reports, and communications arising from them—make the office of superintendent one of increasing labor and responsibility. Besides personal attention to these duties, Dr. Bache occupies the station of the primary triangulation at the north, and the observations, whether geodetic or astronomical, or magnetic, are either made by himself or under his immediate supervision. In the same manner he has also measured a base line for Section VIII., on Dauphin Island, and carried the main triangulation across from the Chesapeake to Washington. In a work of such magnitude and extent, occasional indirect contributions to knowledge may be expected, and there is every disposition to make them.

A point of interest to the geologist, developed by the operations of the coast survey, is the changes that are constantly occurring in different parts of the coast. In this respect its present accurate determinations will furnish in future the means of interesting comparisons. It must be remarked here, also, that too much importance can not be assigned to this view of the results of the coast survey. With regard to most harbors of consequence, the question is repeatedly asked whether they have undergone any change; and this question can rarely be satisfactorily answered, for the want of a correct standard of comparison. The charts of the coast survey will enable the future hydrographer to point out the changes, if any, and the future engineer, in his endeavors to improve or to preserve the channels of navigation, will, by a careful study of these changes, be able to guard against the causes of obstruction, and to co-operate intelligently with natural laws, instead of blindly opposing their effects. The manner in which harbors are affected by the matter held in suspension by the rivers emptying into them, that is, the place and form in which this matter is deposited, will receive such elucidation from the inquiries of the coast survey as will assist the counsels of the constructing engineer.

The charts of the coast survey exhibit, as far as they go, a view of the topographical formation of the bottom of the sea. Specimens are collected, and preserved in the office, of the bottom in all its varieties, and it was the intention of the late Lieutenant Bache to form a geological map, on which the materials thus collected should appear, in the natural order of their formation. Besides serving as useful indications to the navigator and pilot, they prove to be, when placed under the microscope, highly interesting to the naturalist. The deep-sea soundings have been examined by Professor I. W. Bailey, of West Point, and have been found to be filled with organisms, particularly those of the calcareous polythalamia, to an amount that is really amazing, hundreds of millions existing in every cubic inch. "One specimen, from the depth of ninety fathoms, is crowded with remains, most of them large enough to be recognized by a practiced eye without the aid of a magnifier." And it is not impossible that, in similar cases, science may supply the mariner with another mode of recognizing the character of the bottom. In 1847, Professor L. Agassiz, of Cant. ridge, accompanied one of the hydrographical parties engaged in the off-shore work, by the invitation of its commander, and enjoyed an opportunity of examining the animals inhabiting depths that are rarely accessible. It proved to be a rich field of discovery. Not only many new species, but several new genera, were added to the known lists; the subject of embryology received fresh illustrations, and a new light was thrown upon the

laws of the geographical distribution of animals, showing that in the different depths of the sea, as in the elevations of the land, distinct families have each their assigned and native dwelling-places.

It would lead to but a partial estimate of the value of the coast survey to omit these examples of its incidental benefits to knowledge. There are others upon which there is not room to dwell. The friends of this work have reason to be satisfied with its progress, and it is confidently believed that they may lay aside all

apprehensions for its future prosperity. It rests upon the firm support of a controlling public opinion in the government and among the people. Working, as it does, in a field that is useful and honorable, and being conducted in all its branches with zeal and efficiency, it can not fail to add every year to the consideration with which it is now regarded, not only at home, but in every country where science and its application to the arts of life are justly appreciated.—*American Almanac for 1849.*

General List of Coast Survey Discoveries and Developments to 1853 inclusive, compiled by Lieutenant E. B. Hunt.—As the operations of the survey advance along the coast, important facts before unknown are constantly brought to light. Many facilities for, and dangers to, navigation are thus discovered, which had been before wholly unknown, and those before but imperfectly known are developed by accurate surveys. Many such developments and discoveries occur in the geodetic and topographical operations, some of which are of no slight value; but those which are embraced in the hydrographic work are often of vital importance to commerce and navigation. The following list presents some of the most important items of this nature,

and may collectively be regarded as exhibiting one of the most valuable results of the survey. In fact, each sheet which gives shore line and hydrography with increased accuracy has somewhat of discovery or development to claim; but in this list only those cases are included in which a specific benefit has been conferred on navigation, either by unfolding some new facility, disclosing some serious danger, or indicating some important change of configuration. The arrangement is geographical, and in the order of sections.

1. A rock not on any chart, in the inner harbor of Gloucester, Massachusetts—discovered in 1853.
2. A bank 90 miles eastward of Boston, with about 36 fathoms water—probably a knoll connected with

Cashe's ledge, but with deep water between it and the ledge—1852.

3. Boston harbor: Broad Sound channel thoroughly surveyed, and marks recommended—1848.

4. Nantucket Shoals: Davis's New South Shoal, discovered in 1846, six miles south of the old Nantucket South Shoals, in the track of all vessels between New York and Europe, or running along the coast from the Eastern to the Southern States, or South America.

5. Ditto: Two new shoals north and east of Nantucket—discovered in 1847.

6. Ditto: Six new shoals near Nantucket, the outermost one 14½ miles from land, and with only ten feet water—discovered in 1848.

7. Ditto: McBlair's Shoals, off Nantucket—discovered in 1849.

8. Ditto: Davis's Bank—discovered in 1848, and survey finished in 1851.

9. Ditto: Fishing Rip, a large shoal extending north and south about 10 miles to the eastward of Davis's Bank and 30 from Nantucket, with 4½ fathoms—surveyed in 1852.

10. Ditto: A ridge connecting Davis's New South Shoal and Davis's Bank—found in 1853.

11. Ditto: A small bank or knoll, with but five fathoms on it, about five miles east of Great Rip, with 12 fathoms between it and Davis's Bank and Fishing Rip, the water gradually deepening outside of it to the northward and eastward, beyond the limits of the series of shoals.

12. Contracture of the inlet at the north end of Monomoy Island, and opening of new entrance to Chatham harbor—1853.

12 bis. Miskeget Channel—surveyed by Lieutenant C. H. Davis in 1848, and Lieutenant C. H. McBlair in 1850.

13. Numerous rocks in Martha's Vineyard Sound, Long Island Sound, and the various bays and harbors connected with them.

14. Gedney's Channel into New York Bay, having two feet more water than the old channels. Had the true depth of this channel (which is seen, by comparing old and new charts, to have then probably existed) been known in 1778, the French fleet under Count D'Estaing would have passed into the bay and taken the assembled British vessels.

15. Sandy Hook: its remarkable increase out across the main ship-channel has been traced from the surveys of the topographical engineers and others, and by several successive special surveys.

15 bis. Increase of depth in Huttermilk Channel, ascertained and made known in 1848, by survey of Lieutenant. D. D. Porter.

16. Delaware Bay: Illake's Channel at the entrance discovered in 1844—open when the eastern channel is closed by the ice. This discovery has served to develop strikingly the resources of that portion of Delaware.

17. Blunt's Channel in Delaware Bay.

18. Changes in the Delaware near the Pea Patch.

19. The true extent and position of the dangerous shoals near Chincoteague Inlet, Virginia—1852.

20. Metompin Inlet, Virginia, shoaling from 11 to 8 feet in the channel during 1852.

21. Two channels into Wachapreague Inlet, Virginia—one from the northward and the other from the eastward—both with seven feet water at low tide—1852.

22. A shoal half a mile in extent, not put down on any chart, 5½ miles east from the north end of Paramore's Island, Virginia: it has but four fathoms water on it, and has nine fathoms around it—1852.

23. Great Machipungo Inlet, Virginia: found to have a fine wide channel, with 11 feet water on the bar at low tide and 14 at high; good anchorage inside in from two to eight fathoms: the best harbor between the Chesapeake and Delaware entrances—1852.

24. Two shoals near the entrance to the Chesapeake—one 4½ nautical miles southeast by east from Smith's Island light-house, with 17 feet upon it; and the other east by south nearly, 7½ miles from the same light, with 19½ feet upon it—1859.

25. Only three feet water upon the "Inner Middle," the shoal part of the Middle Ground west of the "North Channel," at the Chesapeake entrance—1852.

26. A 25 fathom hole 2½ miles west-southwest from Tazewell triangulation point, eastern shore of the Chesapeake; all other charts give not more than 16 fathoms in this vicinity.

27. A shoal at the mouth of the Great and Little Choptank, in Chesapeake Bay—1848.

28. Deeper water found on Diamond Shoal, and a dangerous nine-foot shoal off Cape Hatteras—1850.

29. A new channel, with 14 feet water, into Hatteras Inlet, formed during the year 1852, which is better and straighter than the old channel.

30. The well-ascertained influence of prevailing winds in the movement of the bars at Cape Fear and New Inlet entrances, and the gradual shoaling of the main bar; the latter fact being of great importance to the extensive commerce seeking this harbor—1853.

31. Frying-pan Shoals, off Cape Fear, North Carolina. A channel of 2½ fathoms, upward of a mile wide, distant 11 nautical miles from Bald Head light-house, across the Frying-pan Shoals. A channel extending from 3 to 4 miles from the point of Cape Fear to 8 to 8½ miles from it, with sufficient water at low tide to allow vessels drawing nine or ten feet water to cross safely. A channel at the distance of 14 nautical miles from Bald Head light-house, one mile wide, with 8½ to 7 fathoms water on it. The Frying-pan Shoals extend 20 nautical miles from Bald Head light-house, and 16, 17, and 18 feet water is found 17 and 18 nautical miles out from the light—1851.

32. Shoaling of Cape Fear River bar thoroughly examined for purposes of improvement—1852.

33. Changes at the entrance of Winyah Bay, Georgetown harbor, and the washing away of Light-house Point, at the same entrance—1853.

34. Maffitt's new channel, Charleston harbor, with the same depth of water as the ship-channel—1850.

35. Changes in the channels at the entrance of Charleston harbor—1852.

36. The remarkable discovery of continuous deep-sea soundings off Charleston, and of soundings in the depth of between 400 and 500 fathoms beyond the Gulf Stream—1853.

37. The discovery of cold water at the bottom of the sea below the Gulf Stream, along the coasts of North and South Carolina, Georgia, and Florida—1853.

38. The discovery of the cold wall, alternate warm and cold bands, and various other features of the Gulf Stream, especially such as concern its superficial and deep temperatures on sections, and its distribution relative to the shore and bottom.

39. Various facts relative to the distribution of minute shells on the ocean-bottom, of probable use to navigators for recognizing their positions.

40. Netzel Shoal, off Cape Canaveral, Florida—1850.

41. A new passage, with three fathoms water, through Florida Reef to Legard harbor, under Triumph Reef (lat. 25° 30' N., long. 80° 03' W.), which, if properly buoyed, will be valuable as a harbor of refuge.

42. A new channel into Key West harbor—1850.

43. Isaac Shoal, near Rebecca Shoal, Florida Reef; not laid down on any chart—1852.

44. Channel, No. 4, a northwest entrance into Cedar-Keys Bay—1852.

45. Mobile Bay Entrance Bar; in 1822 only 17 feet at low water could be carried over it; in 1811 it was 19 feet; and in 1847 it was 20½ feet, as shown by successive surveys—1847.

46. The diminution, almost closing, of the passage

from
ing of
reef.

between Dauphine and Pelican Islands, at the entrance of Mobile Bay—1853.

47. Horn Island Channel, on the Coast of Mississippi.

48. The removal of the East Spit of Petit Bois Island in the hurricanes of 1852, opening a new communication between the Gulf and Mississippi Sound, and the rendering of Horn Island Pass more easy of access by the removal of knolls—1853.

49. The accurate determination of Ship Shoal, off the coast of Louisiana, in connection with the site for a light-house—1853.

50. The changes at Aransas Pass, Texas, as bearing on the question of a light-house site—1853.

51. The determination of the position and soundings on Cortez Bank, near the island of San Clemente, coast of California—1855.

52. A shoal inside of Ballast Point, San Diego Bay, with 12½ feet of water; not laid down on any chart—1852.

53. Changes in the channels of entrance of Humboldt Bay or harbor, California—1852 and 1853.

54. The depth of water on the bars at the entrance of Rogue River and Umquah River, Oregon—1853.

55. South Channel, Columbia River, surveyed and made available to commerce—1851. Changes of channels, their southward tendency, and a new three-fathom channel from Point Hancock, due west to open water, Columbia entrance—1852. Further changes—1853.

56. Various surveys and charts of small harbors on the Pacific, and a continuous reconnaissance of the entire western coast and islands adjacent, a great part of which was very imperfectly known.

Additional List for 1854.

57. Determination of the dimensions of Alden's Rock, near Cape Elizabeth, Maine.

58. A bank (Stellwagen's Bank), with 10½ to 14½ fathoms of water on it, at the entrance to Massachusetts Bay, and serving as an important mark for approaching Boston and other harbors.

59. A dangerous sunken ledge (Davis's Ledge) to the eastward, and in the neighborhood of Minot's Ledge.

60. Several rocks in the fair channel-way in Boston harbor entrance.

61. The tidal currents of Nantucket Shoals and the approaches.

62. The tidal currents of Long Island Sound.

63. The changes in New York harbor, near the city, between 1845 and 1854.

64. The general permanence of the Bodkin Channel and shoals in its vicinity, at the entrance of the Patuxco River—between 1844 and 1854.

65. A shoal (Now Point Shoal) in Chesapeake Bay, with 16 feet water on it, southeast from New Point Comfort light-house, off Moltjock Bay.

66. A reconnaissance of the Wimple Shoals near Nag's Head, coast of North Carolina.

67. The general permanence in depth on the bar of Beaufort, North Carolina, with the change of position of the channel.

68. The changes in Maffitt's Channel, Charleston harbor, South Carolina, from 1852 to 1854.

69. A harbor of refuge (Turtle harbor) to the northward and westward of Carysfort light-house, Florida Reef, with a depth of water of 26 feet at the entrance.

70. A safe rule for crossing the Florida Reef near Indian Key.

71. Co-tidal lines for the Atlantic coast of the United States.

72. An increase of depth of water on the bar at Pass Fourchon, Louisiana.

73. A shoal at the entrance to the Straits of Rosario, Washington Territory, giving good holding ground in 33 feet.

74. Belle Rock, in the middle of Rosario Strait,

Washington Territory, visible only at extreme low tides.

75. Entrance Rock, at the entrance of Rosario Strait.

76. Unit Rock, in the Canal de Haro, Washington Territory.

77. A five-fathom shoal in the Strait of Juan de Fuca, between Canal de Haro and Rosario Strait.

78. The non-existence of two islands at the northern entrance of Canal de Haro, laid down on charts.

79. The non-existence of San Juan Island, usually laid among the Santa Barbara group.

80. Tides of San Diego, San Francisco, and Astoria.—*Coast Survey Report for 1854.*

Cobalt (Ger. *Kobalt*; Du. *Kobal*; Swed. *Cobolt*; Fr. *Cobalt*; It. *Cobalto*; Russ. *Kobolt*; Lat. *Cobaltum*), a mineral of a gray color, with a shade of red, and by no means brilliant. It has scarcely any taste or smell; is rather soft; specific gravity about 8.6. Sometimes it is composed of plates, sometimes of grains, and sometimes of small fibres adhering to each other. Its oxides are principally employed.—See SMALTS, or SMALTZ. They form the most permanent blue with which we are acquainted. The coloring power of oxide of cobalt on vitrifiable mixtures is greater, perhaps, than that of any other metal. One grain gives a full blue to 240 grains of glass.—THOMSON'S *Chemistry* and URE'S *Dictionary*.

Cocculus Indicus, or Indian Berry (Sansc. *Kakumari*; Malay, *Tubabidi*), the fruit of the *Menispermum Cocculus*, a large tree of the Malabar coast, Ceylon, etc. It is a small kidney-shaped berry, having a white kernel inside of a most unpleasant taste. It is of a poisonous and intoxicating quality, and has been employed to adulterate ale and beer.

Cochineal (Ger. *Koschenille*; Du. *Conchenille*; Fr. *Cochenille*; It. *Cocciniglia*; Sp. *Cochinilla*, *Grana*; Port. *Cochenilha*; Russ. *Kosnened*), an insect (*Coccus cacti*) found in Mexico, Georgia, South Carolina, and some of the West India islands; recently, also, it has been introduced into Java, and promises to become an important product of that rapidly improving colony. Formerly it was in Mexico only that it was reared with care, and formed a valuable article of commerce; but its culture is now more or less attended to in various parts of the West Indies and of the United States. It is a small insect, seldom exceeding the size of a grain of barley; and was generally believed, for a considerable time after it began to be imported into Europe, to be a sort of vegetable grain or seed. There are two sorts or varieties of cochineal: the best or domesticated, which the Spaniards called *grana fina*, or fine grain; and the wild, which they call *grana sylvestra*. The former is nearly twice as large as the latter, probably because its size has been improved by the favorable effects of human care, and of a more copious and suitable nourishment, derived solely from the *Cactus cochinitifer*, during many generations. Wild cochineal is collected six times in the year, but that which is cultivated is only collected thrice during the same period. The insects, of which there are about 70,000 in a pound, being detached from the plants on which they feed by a blunt knife, are put into bags, and dipped in boiling water to kill them, after which they are dried in the sun. It is principally used in the dyeing of scarlet, crimson, and other esteemed colors. The watery infusion is of a violet crimson; the alcoholic, of a deep crimson; and the alkaline, of a deep purple, or rather violet hue. It is imported in bags, each containing about two hundred pounds; and has the appearance of small, dry, shriveled, rugose berries or seeds, of a deep brown, purple, or mulberry color, with a white matter between the wrinkles. In this state they suffer no change from length of keeping. Dr. Bancroft says that that cochineal is the best which is "large, plump, dry, and of a silver-white color on the surface."

The species of cochineal called *granilla*, or dust, is supposed by Dr. Bancroft to be principally formed of

grana sylvestra. The insects of which it consists are smaller than those composing the fine cochineal, and it does not yield more than a third part of the coloring matter that is yielded by the latter. The cochineal insect was introduced into India in 1795; but a very inferior sort only is produced. It has also been introduced into Java and Spain, but with what success remains to be seen.—THOMSON'S *Dispensatory*; BANCROFT on *Colours*, etc.

The cochineal plant (*Cactus cochinillifer*), or some of its congeners, is found in varying abundance throughout the torrid zone, as well as in several warm and temperate countries without the tropics. But much doubt still exists as to what particular species nourishes the cochineal insect, as it is believed that the plant which was named by Linnaeus, and which has been almost universally called *Cactus cochinillifer*, is not the one that produces the best Mexican cochineal; nor is it positively known in what part of America it was originally a native. Linnaeus speaks of it as indigenous to Jamaica, and the warmer parts of the New World; but others assert that it was brought from South America by a Spanish priest.

Cochin China. This extensive kingdom is situated in the southern extremity of Asia, and forms part of the peninsula between China and Hindostan. It is not separated, however, by any distinct boundary from the neighboring countries; and its limits have been greatly extended by conquest beyond those of Cochin China proper, which is merely a strip of land between the China Sea and the mountains, and is not above sixty or seventy miles broad. The empire of Cochin China, which took its present form in the beginning of the present century, comprehends Cochin China proper, Tonquin, the principal part of Cambodia, and the little state of Chianpa. This state, as it has been aggrandized by conquest, extends from the point of Cambodia, in about 8° 30' N. lat., to the northern confines of Tonquin, which reach within a very few miles of the tropic of Cancer, and from the longitude of 102° to about 109° E. It is bounded on the north by the Chinese Quangsí or Kiangsí and Yunan; on the west by the Kingdoms of Laos and Siam; while the Gulfs of Siam, Tonquin, and the China Sea bound it on the southwest, east, and northeast. Its area is estimated at about 98,000 square miles, and its population at from 12,000,000 to 16,000,000. This great country is divided by long ranges of mountains, which run nearly north and south, and in almost parallel chains, forming it into separate provinces, divided by physical boundaries, and inhabited by distinct tribes and nations, although subject to the same sovereign. By these mountainous ridges Tonquin and Cochin China proper are separated from Laetho, Laos, and Cambodia. Another chain separates the three latter states from Siam and China, and gradually diminishes in height as it approaches the south, terminating at the southern extremity of Cambodia.

The soil in Cochin China, especially in the low lands, is fertile, and its products are very valuable. Of these rice, as being the general food of the people, is the staple commodity; and after supplying the wants of the people, about 100,000 piculs remain annually for exportation. The cultivation of the sugar-cane, as well as the preparation of sugar, has of late years much increased; and the annual exportation of sugar is considered to be not less than 70,000 piculs. Cotton of the best quality is produced on the coast; and of this probably about 60,000 piculs are exported. Though raw silk is produced, it is principally for home consumption. Cinnamon ranks high among its productions, and has always been celebrated in China. In the southern parts the cocoa-nut grows very luxuriantly, and hence there is a large exportation of oil. Pepper of a good quality, but in small quantity and of a high price, is produced in the central provinces of Cochin China; but the quantity is inadequate to the de-

mand which the Chinese trade creates for its exportation. It grows among the central mountains of Cochin China, whence it is exported to Cambodia and Tonquin, but principally to China, where it is much more highly valued than any other quality of this aromatic. Another exclusive product of the central parts of the kingdom, which is extensively cultivated and sent to the neighboring provinces, is tea, which is very coarse and only used by the poorer classes. The other productions of the country are, gamboge, gum, cardamoms, eagle-wood, areca-palm, betel-nut, ivory, stick-lac; hides, consisting of deer-skins, buffalo, elephants', and rhinoceros hides; peltry, consisting of tiger, leopard, otter, and cat skins; feathers, salt fish, horns and bones, dye-woods, and woods for ship-building and for domestic purposes. Valuable timber is only found in Cambodia, and a small quantity of teak-wood is found in the forests; also ebony cedars, mimosa, walnuts, iron-wood, and poon, and most of the other trees found in the woods of India. The wood used for ship-building and for domestic purposes is strong and durable, and is carried to the capital in large quantities. There is a hard, black wood extensively used in cabinet-work, and of large dimensions, which takes a fine polish, and might form an article of exportation. Cambodia also produces the Portuguese rose-wood, which the Chinese export as they do from Siam; also sandal-wood and other scented woods. Among the products of Tonquin is a species of vegetable root, a cheap material, which forms the dead-weight of all the Chinese cargoes exported from Tonquin, and is used extensively both throughout Cochin China and the adjacent countries, and also in China, as the material of a red dye. Edible birds'-nests, the sea-slug usually called biche-de-mer, or *Sipunculus edulis*, and various marine productions of a gelatinous quality, form standing articles of trade with China, and are always in demand.

The geological formation of Cochin China is primitive; the mountains are chiefly composed of granite and sienite. Mica slates and primary limestone here and there occur, while several hills consist of quartz rock. Among the mountains of Tonquin is the only portion of the Cochin Chinese empire which produces iron, gold, and silver. The iron received from these mines, which is as cheap as that from Siam, supplies the whole kingdom, with the exception of Saigun, which is furnished from the latter country. Gold dust is found in many of the rivers; and there are immense rocks of marble situated on the banks of the River Faifo, on a kind of sandy plain, of which large quantities have been exported. This remarkable range of limestone rocks rises almost perpendicularly from the low sand hills, to a height of from 300 to 400 feet, without a hill or mountain near them.

The foreign trade of the Cochin Chinese is almost exclusively with China; the trade carried on with Siam being inconsiderable, and that with European nations still smaller. But there is no indisposition to trade, though among the European nations the notion has been propagated by travelers that the resort of European traders is in a great measure interdicted in this kingdom, on the same principle as in Japan and China. In 1818, a new tariff was imposed on foreign vessels, by which the high duties imposed on all foreign vessels prior to 1818 were repealed, and equal duties substituted in their stead. By this regulation all vessels pay a rated measurement duty, moderate in its amount, and are exempted from all import duties payable previous to 1818. Vessels that are driven into the ports of Cochin China by stress of weather, or that visit them for the purpose of commercial inquiries, are free from all charges. Besides the exports above mentioned are cardamoms, hotel-nut, eagle-wood, dye-woods, stick-lac, gamboge, ivory, elephants' hides and bones, and rhinoceros bones. The imports are silk goods of various kinds, the coarser kinds of teas, coarse china-ware, paper, cotton and woolen stuffs, iron, opl-

um, cutlery, etc. Of the internal trade of the country, though considerable, little is known. The trade with China is chiefly conducted with Cashao in Tonquin, Saigun in Cambodia, and Falfo and Huó in Cochín China. There is also some inconsiderable intercourse with other parts of the empire.

Cochín China, from its central situation, its navigable rivers, and its many excellent harbors, possesses extraordinary advantages for commerce. Few countries are so amply provided with harbors, there being within the 64° of latitude which intervene between Cape St. James and the Bay of Turon no less than nine of the finest harbors in the world, accessible in every wind, quite safe to approach, and affording the most complete protection. The Bay of Turon, situated in lat. 16° 7' N., is equaled by few in the Eastern World, and surpassed by none for the security and convenience which it affords.—E. B.

Cocket, in *Commerce*, a scroll of parchment, signed and delivered by the officers of the custom-house to merchants upon entering their goods, to certify that their merchandise is customed and may be discharged.

Cock-pit, of a ship of war, the apartment of the surgeon and his mates appropriated to the use of the wounded in time of action. It is situated under the lower deck, below the water-line.

Cockswain (pronounced *coose*), an officer on board of a man-of-war, who has the care of a boat or sloop, and who must be always ready with his gang or crew. He sits in the stern of the boat, which he steers, and has a whistle to summon his men.

Cocoa, or, more properly, **Cacao** (Fr. and Sp. *Cacao*; Ger. *Kakao*), the seed or nuts of the cocoa-tree (*Theobroma cacao*), growing in the West Indies, and in many parts of South America. It is said, by Mr. Bryan Edwards, to bear some resemblance, both in size and shape, to a young *black-heart cherry*. The nuts are contained in pods, much like a cucumber, that proceed immediately from all parts of the body and larger branches; each pod contains from ten to thirty nuts, of the size of large almonds, very compactly set. The shell of the nut is of a dark brown color, brittle and thin; the kernel is, both internally and externally, brownish, divided into several unequal portions, adbering together, but separating without much difficulty; it has a light agreeable smell, and an unctuous, bitterish, rather rough and peculiar, but not ungrateful taste. The nuts should be chosen full, plump, and shining, without any mustiness, and not worm-eaten. They yield, by expression, a great deal of oil; but they are cultivated only that they may be employed in the preparation of the excellent beverage cocoa, and the manufacture of chocolate, of which they form the principal ingredient. The finest cocoa is said to be that of Socomuseo. The principal importations were formerly derived from the Caraccas and Guayaquil, particularly the former, the cocoa of which is also the more valuable. The exports from Venezuela amounted in 1851 to 8,159,905 pounds, worth \$1,299,631. M. Humboldt estimated the consumption of cocoa in Europe in 1806 at 23,000,000 pounds, of which from 6,000,000 to 9,000,000 were supposed to be consumed in Spain. The production of cocoa was languishing in the Caraccas for several years previously to the commencement of the disturbances in South America; and latterly the cultivation of coffee seems to have been in most parts gaining the ascendancy.—HUMBOLDT, *Pers. Narrative*, vol. iv. p. 236-247, Engl. transl. In 1851 the exports of coffee from Venezuela amounted to 37,968,081 pounds.

Coco Coker, or, more properly, **Cocca-nuts** (Ger. *Kokosnüsse*; Du. *Kokosnoten*; Fr. and Sp. *Cocos*; It. *Cocchi*; Russ. *Kokos*; Sans. *Narikela*), the fruit of a species of palm-tree (*Cocos nucifera*, Linn.). This tree is common almost every where within the tropics, and is extremely valuable; being to the palmivorous inhabitants of many parts of Ceylon, Brazil, and other intertropical regions, not merely their principal wealth,

but almost their entire dependence. Every part of the tree is appropriated to some peculiar purpose; and an Indian with a garden containing twelve cocoa-nut trees and two jack-trees is said to be comparatively independent! But we may observe that this facility of obtaining subsistence is not an advantage, but the reverse; indolence and a want of civilization being its invariable accompaniment. The tree grows to the height of from 50 to 90 feet; it has no branches, but the leaves are from 12 to 14 feet in length, with a very strong middle rib. The fruit is nearly as large as a man's head; the external rind is thin, tough, and of a brownish-red color. Beneath this there is a quantity of very tough fibrous matter, which is used in the manufacture of cordage and coarse sail-cloth. It is buoyant and extremely well suited for ropes of large diameter; and until the introduction of chain cables a majority of the ships which navigated the Indian seas were supplied with cables of this material. Within the fibrous coating is the shell of the nut, which is nearly globular, very hard, susceptible of a high polish, and used for many domestic purposes; the kernel is white, its taste and firmness resembling that of a hazel-nut; it is hollow in the interior, the hollow being filled with a milky fluid. While the nut is green, the whole hollow of the shell is filled with fluid, which is refreshing, agreeable, and pleasant to the taste. The solid part of the ripe kernel is extremely nutritious, but rather indigestible. The kernels yield by expression a great deal of oil, which, when recent, is equal to that of sweet almonds; but it soon becomes rancid, and is then employed by painters. A tree generally yields about 100 nuts, in clusters, near the top, of about a dozen each. The wood of the tree is made into boats, rafts, the frames of houses, and gutters to convey water. The leaves are used for thatching buildings; and are wrought into mats, baskets, and many other things for which osiers are employed in Europe; so that every part of it is applied to some useful end.

If the body of the tree be bored, there exudes from the wound a white liquor, called palm wine or toddy. It is very sweet when fresh; kept a few hours, it becomes more poignant and agreeable; but next day it begins to grow sour, and in the space of 24 hours is changed into vinegar. When distilled, it produces the best species of Indian arrack; it also yields a great deal of sugar. Toddy is obtained from several species of palms, but that of the *Cocos nucifera* is the best.—See MARSHALL *on the Cocoa-nut Tree*; ARNSHEIM'S *Materia Medica*. An improvement effected in the preparation of cocoa-oil has made it of much importance in the arts, by rendering it available in the manufacture of candles and soap, and for various purposes to which it was not previously applicable. The palm-oil met with in the market is not obtained from the *Cocos nucifera*, but from another species of palm. It is chiefly imported from the coast of Guinea.—See PALM-OIL.

Cocoa-nuts are produced in immense quantities in Ceylon, forming, with their products, oil, arrack, and coir—the principal articles of export from that island. They are also very abundant in the Maldiv Islands, Siam, and on several places of the coast of Brazil. Cocor oil is in very extensive use all over India, and large quantities are manufactured in the lower provinces of Bengal. This latter is said to be superior to that imported from Ceylon. At an average of the three years ending with 1850, 481,071 gallons of cocor oil were exported from Ceylon.

Cod (Ger. *Cabjau*, *Bakalau*; Du. *Cabjauwe*, *Baukaelja*; Dan. *Cabjau*, *Skrat*; Fr. *Bakelau*; Sw. *Cabjau*, *Bakelau*; Fr. *Morus*, *Cabillaud*; It. *Bacca*, *Baccare*; Sp. *Bacalao*; Port. *B calhão*; Lat. *Gadus*), a species of fish too well known to require any description. "It is amazingly prolific. Leewenhook counted 9,381,000 eggs in a cod-fish of a middling size—a number that will baffle all the efforts of man to exterminate. In the British seas they begin to spawn in January, and

deposit their eggs in rough ground, among rocks. Some continue in roe till the beginning of April. The cod is only found in the Northern parts of the world; it is an ocean fish, and never met with in the Mediterranean. The great rendezvous of the codfish is on the Banks of Newfoundland, and the other sand banks that lie off the coasts of Cape Breton, Nova Scotia, and New England. They prefer those situations, by reason of the quantity of worms produced in these sandy bottoms, which tempt them to resort there for food. But another cause of the particular attachment the fish have to these spots is their vicinity to the polar seas, where they return to spawn: there they deposit their roes in full security; but want of food forces them, as soon as the more southern seas are open, to repair thither for subsistence. Few are taken to the north of Iceland, but they abound on its south and west coasts. They swarm on the coasts of Norway, in the Baltic, and off the Orkney and Western Isles; after which their numbers decrease in proportion as they advance toward the south, when they seem quite to cease before they reach the mouth of the Straits of Gibraltar. Before the discovery of Newfoundland, the greater fisheries of cod were on the seas of Iceland, and off the Western Isles, which were the grand resort of ships from all the commercial nations; but the greatest plenty was met with near Iceland. The English resorted thither before the year 1415; for we find that Henry V. was disposed to give satisfaction to the King of Denmark for certain irregularities committed by his subjects on those seas. In the reign of Edward IV. the English were excluded from the fishery by treaty. In latter times, we find Queen Elizabeth condescending to ask permission to fish in those seas from Christian IV. of Denmark. In the reign of her successor, however, no fewer than 150 English ships were employed in the Iceland fishery; which indulgence might arise from the marriage of James with a princess of Denmark.—*PENNANT'S British Zoology.* Cod is prepared in two different ways; it is either gutted, salted, and then barreled—in which state it is denominated green or pickled cod; or it is dried and cured—in which state it is called dried cod. Ready access to the shore is indispensable to the prosecution of the latter species of fishery.

Distant Cod Fishery.—The great Bank of Newfoundland, discovered by John or Sebastian Cabot in 1497, was long, and perhaps still is, the principal seat of the distant cod fishery. The extraordinary abundance of codfish on its banks having been speedily ascertained, the French, Portuguese, and Spaniards soon after engaged in the fishery. The English were later in coming into the field. In 1578 France had on the Banks of Newfoundland 150 vessels, Spain 120 or 130, Portugal 50, and England from 30 to 50. During the first half of last century, the fishery was principally carried on by the English, including the Anglo-Americans and the French; but the capture of Cape Breton, and of their other possessions in America, gave a severe blow to the fishery of the latter. The American war divided the British fishery; that portion of it which had previously been carried on from New England being thereafter merged in that of the United States. During the last war, the French being excluded from the fisheries, those of England attained to an extraordinary degree of prosperity; the total value of the produce of the Newfoundland fishery in 1814 having exceeded £2,800,000. But since the peace, the British fishery on the Newfoundland banks has rapidly declined; and can hardly, indeed, be said, at this moment, to exist. It is now carried on almost entirely by the French and the Americans; the facilities enjoyed by the latter for its prosecution being greater than those of any other people, and the former being tempted to engage in it by the extraordinary encouragements offered by government. At present, the British fishery carried on by the inhabitants of Newfoundland is confined entirely to the shore or boat fishery. But this, though probably

not so good a nursery of sailors as the bank fishery, is admitted to be "the most productive of merchantable fish and oil."—*M'GREGOR'S Brit. Amer.*, 2d ed. vol. 1.

American Cod Fishery.—The Americans have at all times prosecuted the cod fishery with great vigor and success. Their fishermen are remarkable for their activity and enterprise, sobriety and frugality; and their proximity to the fishing-grounds, and the other facilities they possess for carrying on the fishery, give them advantages with which it is very difficult to contend. In 1795 the Americans employed in the cod fishery about 31,000 tons of shipping; in 1807 they are said to have employed 70,306 tons; but it subsequently declined for several years, and was almost entirely suspended during the late war. According to the official returns (laid before Congress the 1st of January, 1853), the Americans had, in the year ending the 30th of June, 1852, 102,659 tons shipping engaged in the cod fishery. During the same year they exported 134,732 quintals of dried, and 19,379 barrels of pickled cod; their aggregate value being \$453,610. "The Americans follow two or more modes of fixing out for the fisheries. The first is accomplished by six or seven farmers, or their sons, building a schooner during winter, which they man themselves (as all the Americans on the sea-coast are more or less seamen as well as farmers), and after fitting the vessel with necessary stores, they proceed to the banks, Gulf of St. Lawrence, or Labrador; and, loading their vessel with fish, make a voyage between spring and harvest. The proceeds they divide, after paying any balance they may owe for outfit. They remain at home to assist in gathering their crops, and proceed again for another cargo, which is salted down, and not afterward dried: this is termed mud-fish, and kept for home consumption. The other plan is, when a merchant or any other, owning a vessel, lets her to 10 or 15 men on shares. He finds the vessel and nets. The men pay for all the provisions, hooks and lines, and for the salt necessary to cure their proportion of the fish. One of the number is acknowledged master; but he has to catch fish as well as the others, and receives only about 20s. per month for navigating the vessel; the crew have five-eighths of the fish caught, and the owners three-eighths of the whole. The first spring voyage is made to the banks; the second either to the banks, Gulf of St. Lawrence, or the coast of Labrador; the third or fall voyage is again to the banks; and a fourth, or second fall voyage, is also made, sometimes, to the banks."—*M'GREGOR*, vol. i. p. 220. It is stipulated in the first article of a convention between Great Britain and the United States, signed at London, 20th of October, 1818, that the citizens of the United States shall have liberty to take all sorts of fish "on that part of the coast of Newfoundland from Cape Ray to the Rameau Islands, on the western and northern coasts of Newfoundland from Cape Ray to the Quirpon Islands, on the Magdalen Islands, and also on the coasts, bays, harbors, and creeks, from Mount Joly, on the southern coast of Labrador, to and through the Straits of Belleisle, and thence northward indefinitely along the coast, without prejudice, however, to any of the exclusive rights of the Hudson's Bay Company; and that the American fishermen shall also have liberty forever to dry and cure fish in any of the unsettled bays, harbors, and creeks of the southern parts of the coast of Newfoundland here above described, and of the coast of Labrador; but so soon as the same, or any portion thereof, shall be settled, it shall not be lawful for the said fishermen to dry or cure fish without previous agreement for such purpose with the inhabitants, proprietors, or possessors of the ground. And the United States hereby renounce forever any liberty heretofore enjoyed or claimed by the inhabitants thereof, to take, dry, or cure fish on or within three marine miles of any of the coasts, bays, creeks, or harbors of his Britannic majesty's dominions in

The American fisherman are, however, admitted into all bays, etc., for the purpose of shelter, of repairing damages, of purchasing wood, and of obtaining water, and for no other purpose whatever; and when there, they are to be placed under such restric-

tions as may be necessary to prevent their abusing the privileges hereby reserved to them.—See FISHERIES. *French Cod Fishery.*—France has always enjoyed a considerable share of the cod fishery. The following table shows the extent to which she has carried it since the peace:

ACCOUNT OF THE NUMBER OF SHIPS, WITH THEIR TONNAGE, CREWS, AND CARGOES, THAT HAVE ENTERED THE DIFFERENT PORTS OF FRANCE FROM THE COD FISHERY DURING THE UNDER-MENTIONED YEARS.

Years.	Shipping.			Imports.		
	Ships.	Tons.	Men.	Codfish, green.	Codfish, dry.	Oil.

The quantities of oil are exclusive of draches (hulles non epurés); there are also sounds, etc. Marsailles, Granville, Dunkirk, Bordeaux, La Rochelle, and Nantes are the principal ports whence ships are fitted out for the fishery.

But notwithstanding the apparent prosperity of this branch of industry, it may be doubted whether it be really so beneficial to France as would at first sight appear. It depends more upon artificial regulations than upon any thing else. Foreign cod is excluded from the French markets by the oppressive duty with which it is loaded; and the comparatively great demand for dried fish in Catholic countries renders this a very great boon to the French fishermen. But it is admitted that this would not be enough to sustain the fishery; and high bounties are paid to those engaged in it. These, however, have been reduced of late years; and they will probably in no long time undergo still further alterations. St. Pierre and Miquelon, small islands on the coast of Newfoundland, belong to the French. Their right of fishing upon the shores of that island, and upon the great bank, was replaced in 1814, upon the footing on which it stood in 1792. This concession has been much objected to by Mr. McGregor and others: we believe, however, that they have materially overrated its influence.—For further information, see FISHERIES and FRANCE.

Cod-liver Oil. Pure cod-liver oil is obtained from the livers of codfish; and is best prepared when the liver is in a state most nearly approaching that in which it exists when alive, and is best adapted for medicinal use. The finest oil is devoid of color, taste, and smell, three physical characters that are more valuable than any chemical tests. The success which has attended the use of this oil in pulmonary complaints has led to the introduction of a spurious oil, chiefly prepared of bleached whale oil, etc., which does not possess the valuable medicinal properties of pure cod-liver oil.

Shark-liver Oil is an oil that has been lately imported from the coast of Africa. It gives the usual liver-oil reactions with sulphuric acid; its peculiar interest, however, comes from its low specific gravity. Until now, sperm oil, which has a specific gravity of .875, was the lightest oil known; but the specific gravity of this oil is only .866. It is prepared, as its name implies, from shark's liver.

Coffee (Ger. *Koffee*, *Kaffeebohnen*; Dn. *Koffy*, *Koffieboenen*; Da. *Kaffe*, *Kaffebønner*; Swed. *Kaffe*; Fr. *Il*, and Port. *Caffe*; Sp. *Café*; Russ. *Kafé*; Pol. *Kawa*; Lat. *Coffea*, *Caffen*; Arab. *Bun*; Malay, *Kawa*; Pers. *Tochem*, *Kwech*; Turk. *Chawbe*). The coffee-tree is a native of Ethiopia and Abyssinia; but it was in Arabia that it first became an object of interest and importance to the civilized world. The plant is an evergreen, and is accurately described by La Roque as follows: "The coffee-tree is from six to twelve feet high; the stem ten, twelve, and fifteen inches in circumference. When it is full grown, it much resembles in figure our apple-trees of eight or ten years' standing. The lower branches ordinarily bend when the tree begins to grow old, and extend themselves into a round form, somewhat like an umbrella; and the wood is so very limber and pliable, that the ends of the longest

branches may be bent down within two or three feet of the earth. The bark is whitish, and somewhat rough; its leaf is much like that of the citron-tree. It continues green all the year, and the tree is never without leaves, which are ranged almost opposite on each side of the bough, and at small distances from each other. Nothing is more singular in its kind than its productions; for almost in all seasons of the year blossoms, and green and ripe fruit, may be seen on the same tree at the same time. When the blossom falls off, there remains in its room, or rather springs from each blossom, a small fruit, green at first, but which becomes red as it ripens, and is not unlike a large cherry, and is very good to eat. Under the flesh of this cherry, instead of the stone, is found the bean or berry we call coffee, wrapped round in a fine thin skin. The berry is then very soft, and of a disagreeable taste; but as the cherry ripens, the berry in the inside grows harder, and the dried-up fruit, being the flesh or pulp of it, which was before eatable, becomes a shell or pod of a deep brown color. The berry is now solid, and of a clear transparent green. Each shell contains one berry, which splits into two equal parts. When the fruit is sufficiently ripe to be shaken from the tree, the husks are separated from the berries, and are used in Arabia by the natives; while the berries are exported for the European markets."

From Arabia the plant was taken by the Dutch about the year 1690 to Java, whence its culture spread slowly among the islands of the Indian Archipelago. In the early part of the eighteenth century it found its way to the West India Islands. The plant is now common in every botanical garden of Europe, and there are few private conservatories without good specimens of the tree. When cultivated with a view to trade, it is most productive on hills and mountains, where its root is almost always dry, and its head frequently watered with gentle showers. It prefers a westerly exposure and a loose gravelly soil, but freed from weeds and grass. The plants are inserted at distances of six or eight feet asunder, and in holes from twelve to eighteen inches deep.

If left to themselves they would rise to the height of sixteen or eighteen feet; but in extensive plantations the trees are topped and stunted to about five feet, for the convenience of having the fruit within reach of the gatherer. Thus dwarfed, they extend their branches until they cover the whole spot round about them. They begin to yield fruit the third year. By the fifth, sixth, or seventh year, according to the nature of the soil, they are at full bearing, and continue to bear for upward of twenty years.

It has but recently come to the knowledge of Europeans that the leaves of the coffee-plant contain the same essential principle for which the berries are so much valued, and that in the Dutch island of Sumatra, in the Indian Archipelago, the natives scarcely use any thing else, and greatly prefer a beverage made from the leaf to the berry itself. ness of curing similar to tea, and they possess all the virtues of either tea or coffee. This may be looked upon as the introduction of a new element among the innocent and beneficial necessaries of life; for while the culture of the coffee plant for the sake of its fruit is limited to particular soils and high temperatures, the tree produces leaves in abundance any where within the tropics where the soil is sufficiently fertile. This extensive habitat, added to its nutritive qualities and freedom from any deleterious principle, points out the coffee plant as the best adapted for general consumption of all the productions affording caffeine.

The coffee berry (for which the plant has hitherto been chiefly cultivated), when ripe, is cured in the West Indies, in Java, Ceylon, the East Indies, and South America, by a process called pulping and washing. In Arabia, Persia, etc., it is neither pulped nor washed, but cured in the ancient fashion by the labor of the hands and the action of the sun. The pulping process is performed by machinery, which greatly expedites the work; but practical experienced West India planters admit that this process is in some important respects inferior to the Oriental mode. "A manifest preference," says one, "is given in the leading European markets to coffee which has gone through the pulping and washing process; but, strange to say, the consumers of this beverage are totally ignorant of the fact that the produce which is cured in the pulp furnishes a stronger decoction than an equal quantity of the same coffee which has undergone the other process. The mucilaginous substance which is washed off by the pulping process is absorbed by the bean when cured in the pulp. This gives strength to the produce, and enhances its aromatic flavor." Before the berry is available for use, it undergoes a process called roasting. The valuable properties of coffee depend very much on the manner in which this process is performed. For the most recent and intelligent dissertation on this point, consult Dr. Ure's *Dictionary of Arts, Manufactures, and Mines*, last edition, vol. i. p. 456.

Species of Coffee. Roasting, etc.—The coffees of Jamaica, Ceylon, and Mocha are generally esteemed the best; then follow the coffees of Costa Rica, Dominica, Berbice, Demerara, Bourbon, Java, Martinique, and Hayti. Arabian or Mocha coffee is produced in a very dry climate, the best being raised upon mountainous slopes and sandy soils. The most fertile soils are not suitable for the growth of very fine coffee. Mr. Bryan Edwards observes, that "a rich deep soil, frequently ameliorated by showers, will produce a luxuriant tree and a great crop; but the beans, which are large, and of a dingy green, prove for many years rank and vapid." And the same remark is made by Mr. Crawford with respect to the coffee of Java.—*East Indian Archipelago*, vol. i. p. 487. Coffee is improved by being kept; it then becomes of a paler color. Mocha, or, as it is commonly called, Turkey coffee, should be chosen of a greenish light olive hue, fresh and new, free from any mustiness, the berries of a middling size, clean, plump, and without any intermixture of sticks or other impurities. Particular care should be taken that it be not false packed. Good West India coffee should be of a greenish color, fresh, free from any unpleasant smell, the berries small and unbroken. Coffee berries readily imbibe exhalations from other bodies, and thereby acquire an adventitious and disagreeable flavor. Sugar placed near coffee will, in a short time, so impregnate the berries and injure their flavor, as to lower its value 10 or 20 per cent. Dr. Mosely mentions that a few bags of pepper on board a ship from India spoiled a whole cargo of coffee.

"The roasting of the berry to a proper degree requires great nicety: the virtue and agreeableness of the drink depend upon it; and both are often injured by the ordinary method. Bernier says, when he was at Cairo, where coffee is so much used, he was assured by the best judges that there were only two people in

that great city who understood how to prepare it in perfection. If it be underdone, its virtues will not be imparted, and in use it will load and oppress the stomach; if it be overdone, it will yield a flat, burned, and bitter taste, its virtues will be destroyed, and in use it will heat the body, and act as an astringent."

Coffee also denotes the drink which is made from the coffee berries. This beverage has been familiar in Europe for the last two hundred years. The first human beings who appear to have used the coffee berries were the half savage tribes of the higher Ethiopia. According to Bruce, the berries were first parched like any other grain, bruised into powder, and mixed up with any sort of grease into paste rolled into little balls. The same authority declares that two or three of these balls were sufficient to support a man for a whole day in a marauding excursion, or in active war against some neighboring tribe. They merely preferred the coffee berry to other grain, because it fed them as well, and cheered them more.

From Ethiopia, both the coffee plant and the use of its fruit were introduced into Persia and Arabia, and it is to the Arabs that we are indebted both for the first written account of it and for the manner of using it in a liquid state. But though we derive the only authentic account of coffee from the Arabs, they admit that they were taught by the Persians; and it was in the city of Aden, in Arabia, about the middle of the fifteenth century, that the drinking of coffee first became general. The mufti of that city introduced the custom from Persia; his authority gave reputation to the practice—lawyers began to drink it—those who loved reading followed their example—artisans who were obliged to work in the night did the same thing, as well as travelers who journeyed in the night to avoid the heat of the day. In short, says M. Galland, "the whole inhabitants of Aden soon became drinkers of coffee, and not only at night to keep them awake, but even in the daytime for its other virtues."

From Aden the taste for coffee found its way to Mecca, from Mecca to Cairo, from Cairo to Damascus, from Damascus to Aleppo and from Aleppo to Constantinople; but it was not until 1615 that the use of coffee found its way from Constantinople to Venice.

In 1644 it was introduced to Marseilles, in 1652 to London, and in 1669 to Paris.

The first English author who mentioned coffee was Burton, in his *Anatomy of Melancholy* (vol. i. p. 130), published in 1621, thirty years before the introduction of the drink into London. "The Turks," says he, "have a drink called coffee (for they use no wine), so named of a berry as black as soot and as bitter, which they sip up as warm as they can suffer, because they find by experience that that kind of drink so used helpeth digestion and procureth alacrity."

It would be an error to infer that the mode of making coffee in Europe and Asia is the same. In Europe, an infusion or a decoction of the roasted berry is all that is consumed; but this is a refinement in cookery not appreciated in Asia; there the custom is now, and always has been, different.

A highly trustworthy traveler, Lamartine, in describing the ordinary klan in Palestine; and Syria, says, "a charcoal fire is constantly burning on the hearth, and one or two copper coffee-pots are always full of thick farinaceous coffee, the habitual refreshment and only want of the Turks and Arabs."—*Travels in Syria and the East*, vol. i. p. 292. A cup of well-made coffee exhilarates, arouses, and keeps awake. It allays hunger, to a certain extent, gives to the weary increased strength and vigor, and imparts a feeling of comfort and repose. Its physiological effects upon the system, so far as they have been scientifically investigated, appear to be that, while it makes the brain more active, it soothes the body generally, makes the change and waste of matter much slower than usual, and the demand for food in consequence proportionately less.

All these effects are produced by the conjoined action of three ingredients, either identical with, or similar to, those contained in tea. There is a volatile oil produced during the roasting; a variety of tannic acid, which is also altered in some degree during the roasting; and the substance called thein or caffeine, which is common to both tea and coffee, and is found in the leaves of *Guarana officinalis* and *Ilex paraguensis*, both used by the aborigines of South America, as tea is in the Old Continent, a remarkable result of chemical investigation. The chemical constitution of caffeine is $C_8H_{10}N_4O_2$.

Coffee-trade. The extent to which the cultivation of coffee has been carried in the British possessions, the vast amount of capital embarked in plantations suited to its growth, the multitude of hands engaged in its culture, and the shipping necessarily employed in connection with that trade, invest the article, in a commercial point of view, with great importance; while as a beverage, the tendency of which is to wean the community from indulgence in intoxicating liquors, it is second to no commodity in the British tariff. The history of the coffee-trade prior to 1850 is only valuable now as an example of a commodity for which there is a universal craving among mankind, struggling successfully, and at last triumphantly, over fiscal restrictions, high duties, differential duties, and an endless mass of antiquated obstructions. In common with other important necessities of life, it has now attained to the natural state of unrestricted competition, though it still pays a customs duty of three-pence per pound.—E. B.

The cultivation of coffee met with great success in St. Domingo, and for many years that was the source whence Europe derived its chief supplies, having exported at one time about 88,000 tons, or about seventy-six million pounds; and it was supposed that, had not the revolution broken out in 1792, it would in that year have exported 42,000 tons, or about eighty-four million pounds. The devastation by that event caused almost a total cessation in the supplies. Being driven from St. Domingo, its culture was greatly augmented in Cuba, Jamaica, Surinam, and Java, and was subsequently introduced with great success into Brazil. As the culture advanced in Brazil, it declined in Cuba, the growth of sugar having been found capable of more rapid extension and being more profitable. It was some time after coffee was first planted in Brazil before it became an article of export to any great extent.

In 1774 a Franciscan friar, named Villasor, cultivated a single tree in the garden of the Convent of St. Antonio. Brazil was then governed by the Marquis de Lavradio as viceroy. The first fruits of the tree were presented to the marquis, who distributed them among the most respectable planters, explaining to them the advantages of adding another valuable article to the produce of the country; but being strong in their prejudices in favor of sugar and indigo, few took pains to cultivate it, and hence its progress was very slow. In 1808 Don Joas VI. fled from Portugal to Rio Janeiro, and soon after opened the port to foreign trade. The annual crop of coffee then did not exceed 30,000 bags of 160 pounds each, or 8,000,000 pounds. Although the revolution in St. Domingo had overthrown its culture there, Cuba and Jamaica continued, to some extent, to supply the trader. In 1820 its increase in Brazil had swelled to 100,000 bags. The decrease of supply, by the desolation of St. Domingo, caused it to reach the enormous price of 148s. per cwt., or nearly 37½ cents per pound, in London, in the years 1817 and 1821. This great price stimulated the production in Brazil. The fall of St. Domingo had caused the culture of indigo to be transferred to British India, and its culture was abandoned in Brazil, with sugar, for coffee. Hence emancipation in St. Domingo gave the monopoly of the cultivation and supply of indigo to British India, where it has remained ever since.

In 1789, just previous to the revolution, Hayti exported 76,835,219 pounds of coffee; in 1818 we find the exports fell to about 26,000,000 pounds, and at this time they do not probably exceed thirty or thirty-five millions. The export of sugars in 1789, just before the revolution, reached 140,000,000 pounds. It has now ceased, and the population actually import supplies from Cuba and Porto Rico. In 1834, the year in which the Emancipation Act went into effect, Jamaica exported to England,

	1834.	1835.
Sugar, cwt.	1,350,758	708,072
Coffee, pounds.	13,268,859	0,423,197

We thus find that the exports of coffee fell off the first five years after emancipation about one-half, and sugar nearly in an equal ratio. In August, 1834, the negroes were emancipated by the English government in Jamaica, which struck a death-blow at its culture there, while sugar had measurably superseded its growth in Cuba. These causes combined, with the unrestricted supply of African slave labor, to give its culture a powerful impulse in Brazil. Hence we find by the year 1830 its crop had increased to 400,000 bags, or 64,000,000 pounds. The slave-trade, by convention with England, was to cease in February, 1830. This produced an enormous import of slaves, which could only be disposed of at low prices and on long credits. This, again, stimulated the planting of new estates, and the crop rapidly increased, so that in 1840 it actually reached 1,060,898 bags, or about 168,600,000 pounds. The cultivation being found profitable, the demand for slaves continued, and notwithstanding the attempts of the British government to put a stop to it, the slave-trade has been continually carried on clandestinely ever since, the importations from Africa having amounted to from 80,000 to 50,000 annually, the vessels supplied for which having been chiefly built and fitted out in the Northern cities of the United States, and sailing under whatever colors best answered their purpose.

The increase in the crop since 1840 has been very rapid, and in 1847 reached about 1,804,568 bags, about 288,333,000 pounds. The low prices in 1848 and 1849 had a tendency to check production. The difficulties of importing slaves, under a new treaty made with England in 1845, cut off the supply so far that those which were secretly introduced barely supplied the annual loss, which was 10 per cent., and sometimes more; and should the trade be stopped altogether, as aimed at by England, it will cease the cultivation of coffee to decrease in Brazil, to become augmented in the East Indies, and especially in British India; and should negro slavery be overthrown, coffee would to a great extent follow the course of indigo, and become to some extent an article of British production and control. The climate of Brazil is highly favorable to the cultivation of coffee, the trees yielding nearly double those of the West Indies.

The growth of Brazil, by 1854, reached the astonishing quantity of 400,000,000 pounds, while the production in the British West India Islands has rapidly declined since the emancipation of the slaves in 1834, as will be seen from the following table:

In the year 1848 the British West India Islands yielded	10,000,000 lbs.
In the years 1853, '54, and '55, they yielded only	5,000,000 lbs.
Jamaica alone, in 1834, the year the Emancipation Act was declared in the Islands, amounted to	15,268,183 lbs.

We see by this the same result as that which followed emancipation in St. Domingo. Coffee, with other tropical products, has fluctuated with the supply, and cheapness, and reliability of African slave-labor. If coolies can be brought in under a voluntary apprenticeship, why can not Africans be allowed to come in by the same method, placed under proper regulations and guarantees on the coast of Africa?

The coffee-growing districts of Brazil are divided into the Serra Abaixo (or below the mountains) and Serra Acima (above the mountains). The produce of the former is about one-sixth part of the whole crop in good years, but is much more uncertain than the Serra Acima, being more liable to injury from drought, which is said of late years to have been frequent. The quality is also inferior, and seldom shipped to the United States. The trees usually flower three times each year, generally in August, September, and October, and are ready for picking, in favorable seasons, in March, April, and May, with considerable variation according to situation. In April small quantities of poor new coffee appear in market. In May and June the quantity is greater, but never abundant until July and August. The trees of Serra Acima bloom later, but the crop is more uniform, enabling planters to gather a crop at a single picking, which is a great saving of labor. Entire cargoes are not generally obtained from the Serra Acima district until August and September. Usually the supplies remaining over of the old crop are first sent to the market before planters clean out the new, and hence it is often as late as October and November before the bulk of the new crop is in market.

The cost of transporting the coffee to market is said to average the planter about two cents per pound, owing to imperfect facilities. The actual cost of production is said to be not much under 4½ cents per pound, and as negroes are decimated by cholera and other diseases, without new importations are required to supply their places, negroes must advance in value and enhance the cost of production.

The first import of Brazil coffee into the United

States was made in 1803, which consisted of 1809 bags, landed at Salem, by the ship *Marquis de Someriville*. Hence, within the brief period of forty-seven years, the exports from Brazil have increased to the large amount of 400,000,000 pounds in 1854, and 820,000,000 in 1858. From 1809 to 1849, or in a period of forty years, the imports of coffee from Brazil into the United States increased from 1809 bags to over 100,000,000 pounds.

For the fiscal year ending the 30th of June, 1855, the United States imported from Brazil 185,869,863 pounds of coffee, of the value of \$11,815,818; other Brazilian products, including some sugars, amounted to \$3,408,117. Total imports..... \$15,218,935
Total exports to Brazil..... 4,261,978
Balance of trade against the United States... \$10,957,669

The imports of coffee alone from Brazil in 1854-55 exceeded the exports of the United States to that country by \$7,558,546.

The total importation of coffee into the United States for the year ending June 30th, 1855, amounted to 190,764,259 pounds, valued at \$10,764,259. For the year ending June, 1856, the quantity has been much larger, and as prices have ruled high, the value has been much greater.

The consumption of coffee has rapidly increased within the past twenty-five years, the greatest augmentation having been in the United States, where it has averaged 7½ per cent. per annum, while in Europe it has been 2½ per cent. per annum, or at the rate of 4 per cent. per annum for the world.

We submit the following table, showing the production and consumption of coffee for the world at different periods:

COMPARATIVE STATEMENT OF THE PRODUCTION OF COFFEE IN THE WORLD AT DIFFERENT PERIODS. (THE PRODUCTION OF ONE YEAR ENTERS INTO THE CONSUMPTION OF THE SUCCEEDING YEAR.)

	1848.	1850.	1854.	1855.
	Pounds.	Pounds.	Pounds.	Pounds.
Brazil.....	270,000,000	280,000,000	400,000,000	320,000,000
Java.....	110,000,000	115,000,000	140,000,000	180,000,000
S. Domingo.....	40,000,000	25,000,000	40,000,000	35,000,000
Cuba and Porto Rico.....	40,000,000	80,000,000	25,000,000	20,000,000
British West India.....	10,000,000	5,000,000	5,000,000	5,000,000
Sumatra.....	10,000,000	15,000,000	15,000,000	15,000,000
Mocha, etc.....	5,000,000	5,000,000	5,000,000	5,000,000
Ceylon, India.....	25,000,000	35,000,000	40,000,000	50,000,000
Venezuela.....	20,000,000	25,000,000	25,000,000	20,000,000
Costa Rica.....	5,000,000	7,000,000	8,000,000	9,000,000
Total.....	640,000,000	665,000,000	716,000,000	607,000,000

It will be seen from this table that the greatest increase in 1855 was in Ceylon, a British East India possession, where its future growth is to be most largely augmented should slavery be overthrown in Brazil; with regard to which attempts have already been made by a member of the Legislature. A bill was introduced for gradual emancipation, but it, of course, did not pass. The question arises, if negro slavery in Brazil should be overthrown, where will the cultivation of coffee next take refuge? Java can not materially augment the supplies. There are but two other points, viz., British India and the west coast of Africa. The tree is a native of the latter locality. The consumption of the world in time of peace, and increased wealth from the influx of gold, has overtaken the labor of production. The future consumption in England and in the United States is expected to be materially augmented.

France.—In France, also, owing to the failure of the vintage for several years, the consumption of coffee is likely to be increased. The annexed statement shows the present estimated consumption of the world:

	Pounds.
United States and British provinces.....	210,000,000
German Zollverein.....	110,000,000
Austria, and other German states.....	75,000,000
Holland and Belgium.....	90,000,000
France, Switzerland, and Southern Europe.....	125,000,000
Great Britain.....	40,000,000
Denmark, Sweden, and Norway.....	30,000,000
Russia.....	15,000,000
Cape of Good Hope, Australia, and California.....	15,000,000
Total.....	710,000,000

The question of labor in the cultivation of this and other tropical productions which have become commercial necessities to the populations of the temperate northern latitudes, which embrace the largest civilized portions of the human race, is becoming one of great importance. The growing deficiency must not only continue, but in time greatly enhance the prices of these products, which have become necessities of life, and tend to drain the money from Northern nations, in order to secure them, or, in other words, place them under heavy tribute for articles which are, from habit, necessary to their comfort and well-being. England, through her East India possessions, is, no doubt, anxious to secure as large a share of this tribute as possible, and may, to a certain extent, succeed with indigo, sugar, and coffee; but she has failed, and will continue to fail, in the production of cotton. The United States have secured, and are likely to keep, and, if necessary, by the aid of England to back the South in securing this indispensable production to her prosperity, as well as the prosperity of Europe and the Northern States of this Union. The value of slaves in Brazil—the only South American state which has made any great progress, and that through African labor—has for several years steadily increased. Prior to 1830, when the slave-trade was legal, slaves were sold at 120ll, or \$60. From 1830 to 1850, when the trade was, under treaties with England, prohibited, and had to be conducted clandestinely, they advanced to 400ll, or \$20. Since 1850, the trade having been almost

entirely suppressed, they have gradually advanced, aided by the declination of 5 per cent. per annum, to 11000, or \$605, in 1856. Since then, 10 per cent., it is estimated, have died from cholera, as appears by a recent statement of the Minister of the Empire, and they are now stated to be worth 15000, or \$825 each. It was the low price of slaves prior to 1830 which stimulated the production of coffee, and caused prices to rule so low, which were in 1835 to 1840 not much over half the present prices.

It takes four to five years to mature coffee-trees after planting them before they will yield a crop of berries; hence the sudden rise or fall in prices can not so suddenly influence production, as is the case with annual crops from new plantations of sugar and cotton. At the present time, owing to the high prices of slaves, no new estates can be formed, and none have been for several years; and it is stated that there are not hands enough left in the country to pick out a full crop.

It may be remarked that the rise and fall of tropical productions have fluctuated with the supply of the only labor suitable for their production beneath a tropical sun, and that is African.

ESTIMATED SUPPLIES OF COFFEE FOR EUROPE AND THE UNITED STATES.

From	1851.			1852.			1853.		
	Tons.	Tons.	Tons.	Tons.	Tons.	Tons.	Tons.	Tons.

Coffee-houses. The first in England was kept by a Jew, named Jacobs, in Oxford, 1650. In that year, Mr. Edwards, an English Turkey merchant, brought home with him a Greek servant named Pasquet, who kept the first house for making coffee in London, which he opened in George-yard, Lombard Street, in 1652. Pasquet afterward went to Holland, and opened the first house in that country.—ANDERSON. The Rainbow Coffee-house, near Temple-bar, was represented as a nuisance to the neighborhood, 1657. Coffee-houses were suppressed by proclamation, 26 Charles II., 1675. The proclamation was afterward suspended on the petition of the traders in tea and coffee.—HAYDN.

Coffer-dam. In architecture and bridge-building, a case of piling, water-tight, fixed in the bed of a river for the purpose of laying the bottom dry for a space large enough to build the pier on. Coffer-dams are formed in various ways, either by a single inclosure or a double one, with clay or chalk rammed in between the two to prevent the water from coming through the sides. They are also made either with piles only, driven close together, and sometimes notched or dovetailed into one another; or, if the water is not very deep, by piles driven at a distance of five or six feet from each other, and grooved in the sides, with boards let down between them by the grooves. In order to build in coffer-dams a very good natural bottom of solid earth or clay is required; for though the sides be made water-tight, if the bed of the river be of a loose consistence, the water will ooze up through it in too great a quantity to permit the operations to be carried on. It is almost needless to remark that the sides must be very strong, and well braced in the inside to resist the pressure of the ambient water.—HUTTON'S *Tracts*, vol. 1.

Coffins. The Athenian heroes were buried in coffins of the cedar-tree, owing to its aromatic and incorruptible qualities.—THUCYDIDES. Coffins of marble and stone were used by the Romans. Alexander is said to have been buried in one of gold; and glass coffins have been found in England.—GOTTG. The earliest record of wooden coffins in England is that of the burial of King Arthur, who was buried in an entire trunk of oak, hollowed, A.D. 542.—ASSEN. The patent coffins were invented in 1796.—HAYDN.

Cognac (Cognac), a commune and town of France, capital of arrondissement, department of Charente, 21 miles west from Angoulême, on the left bank of the Charente. Population 4148. It has an old castle, in which Francis I. was born. It is the entrepôt of the brandy of the Charente, to which it gives its name, and which forms the object of a very extensive commerce. Manufactures, earthen-ware and paper.

Coins, pieces of metal, most commonly gold, silver, or copper, impressed with a public stamp, and frequently made legal tender in payment of debts, either to a limited or an unlimited extent. When the precious metals first began to be used as money, or as standards by which to measure the value of different articles, and the equivalents for which they were most commonly exchanged, they were in an unfashioned state, in bars or ingots. The parties having agreed upon the quantity of metal to be given for a commodity, the exact amount was then ascertained by weight. But it is obvious that a practice of this sort must have been attended with a great deal of trouble and inconvenience. There can, however, be little doubt that the greatest obstacle to the use of unfashioned metals as money would be found in the difficulty of determining their quality, or the degree of their purity, with sufficient precision. The operation of assaying is one of great nicety and difficulty; and could not be performed in the early ages otherwise than in a clumsy, tedious and inaccurate manner. It is, indeed, most probable that when the precious metals were first used as money their quality would be appreciated only by

their weight and color. A very short experience would, however, be sufficient to show the extreme inexactness of conclusions derived from such loose and unsatisfactory criteria; and the devising of some method by which the fineness of the metal might be easily and correctly ascertained would very soon be felt as indispensable to the general use of gold and silver as money. Such a method was not long in presenting itself: it was early discovered that, to ascertain the purity of the metal, and also to avoid the trouble and expense of weighing it, no more was necessary than to mark each piece with a stamp declaring its weight and fineness. This invention was made at a very early period. According to Herodotus, the Lydians were the first who coined money.—*Lib. l. c. 94.* Other ancient authors say that the art of coining was invented during the period when Saturn and Janus reigned in Italy; that is, in a period antecedent to authentic history.—GOUVER, *De l'Origine des Loix*, etc. tome 1. p. 267.

Metal used in the Manufacture of Coins.—Before the art of metallurgy was well understood, the baser metals were frequently used as money. Iron was the primitive money of the Lacedæmonians, and copper of the Romans. But both iron and copper deteriorate by being kept; and besides this defect, the rapid improvement of the arts, by lowering their price, rendered their bulk too great in proportion to their value to permit of their continuing to be used as money. Copper, indeed, is still used, in the form of tokens convertible into silver, in very small payments. In England, copper pence and halfpence are rated at about 72 per cent. above their real value; but as their issue is exclusively in the hands of government, and as they are only legal tender to the extent of one shilling in any one payment, this over-valuation is not productive of any bad effect. The use of copper in other countries is limited in much the same way; gold and silver being every where the only metals made use of in the manufacture of the coins used in considerable payments.

Standard of Coins.—By the standard of a coin is meant the degree of its purity and its weight; that is, the fineness of the metal of which it is made and the quantity of metal contained in it. **Silver Coins.**—A pound Troy, or 12 ounces, of the metal of which English silver coins are made, contains 11 oz. 2 dwts. pure silver, and 18 dwts. alloy. This pound is coined into 66 shillings; so that each shilling contains 80-727 grains fine silver, and 87-27 grains standard silver; and the money pound, consisting of 20 shillings, contains 1614-545 grains pure silver, and 1745-454 grains standard silver. From 1600 down to 1816, the pound weight of standard silver bullion was coined into 62 shillings. All the English silver coins have been coined out of silver of 11 oz. 2 dwts. fine, from the Conquest to this moment, except for the short period of 16 years, from the 31st Henry VIII. to the 2d Elizabeth. **Gold Coins.**—The purity of gold is not estimated by the weights commonly in use, but by an Abyssinian weight called a *carat*. The carats are subdivided into four parts, called grains, and these again into quarters; so that a *carat grain*, with respect to the common divisions of a pound Troy, is equivalent to 2½ dwts. Gold of the highest degree of fineness, or pure, is said to be 24 carats fine. When gold coins were first made at the English Mint, the standard of the gold put in them was of 23 carats ½ grains fine and ½ grain alloy; and so it continued, without any variation to the 18th of Henry VIII., who in that year first introduced a new standard of gold of 22 carats fine, and 2 carats alloy. The first of these standards was called the old, and the second the new standard, or crown gold; because crowns, or pieces of the value of 5s., were first coined of this new standard. Henry VIII. made his gold coins of both these standards under different denominations; and this practice was continued by his successors until 1633. From that

period to the present, the gold of which the coins of England have been made has been invariably of the new standard, or crown gold; though some of the coins made of the old standard, previously to 1633, continued to circulate till 1732, when they were forbidden to be any longer current.

Variations of the Standard.—The value of all sorts of property being estimated, and the stipulations in almost all contracts for its purchase, sale, or hire, being made in money or coins, it is plain that no change can take place in the value of such money or coins without virtually subverting these estimates and contracts, and enriching the debtor portion of society at the expense of the creditor portion, or *vice versa*. As the cost of producing all commodities is liable to vary, from improvements in the arts, the exhaustion of the present, or the discovery of new sources of supply, none can be selected to serve as money or coin that may not vary in its real value. It is believed, however, that the precious metals vary less than any material that could be suggested. And with the exception of the extraordinary fall in their value caused by the discovery of the American mines, it seems to have been remarkably constant at other periods. But in addition to the fluctuations naturally inherent in the value of coins, arising from variations in the cost of the metal of which they are made, their standard has been repeatedly changed. Notwithstanding that money or coin, from its being universally used as a scale by which to compute the value of all commodities, and as the equivalent for which they are commonly exchanged, is by far the most important of all measures used in society, and should, consequently, be preserved as invariable as possible, there is none that has been so frequently altered. The necessities or extravagance of governments have forced them to borrow; and to relieve themselves of the incumbrances thus contracted, they have almost universally had recourse to the disgraceful expedient of degrading the coin; that is, of cheating those who lent them money, to the extent of the degradation, and of enabling every other debtor in their dominions to do the same.

The ignorance of the public in remote ages facilitated this species of fraud. Had the names of the coins been changed when the quantity of metal contained in them was diminished, there would have been no room for misapprehension. But although the weight of the coins was undergoing perpetual, and their purity occasional, reductions, their ancient denominations were almost uniformly preserved; and the people, who saw the same names still remaining after the substance was diminished—who saw coins of a certain weight and fineness circulate under the names of florins, livres, dollars, and pounds; and who saw them continue to circulate as such, after both their weight and the degree of their fineness had been lessened—began to think that they derived their value more from the stamp affixed to them by the authority of government than from the quantity of precious metals they contained. This was long a very prevalent opinion. But the rise of prices which invariably followed every reduction of the standard, and the derangement that was thereby occasioned in every pecuniary transaction, undeceived the public, and taught them and their rulers the expediency of preserving the standard of money inviolate.

The standard may be reduced by simply raising the denomination of the coin; by ordering, for example, that a half-sovereign should pass for a sovereign, and the latter for a double sovereign, etc. If injustice be resolved upon, this is the least mischievous way in which it can be perpetrated, inasmuch as it saves all the trouble and expense of a recoupage. But as it renders the fraud obvious and glaring, it has rarely been resorted to; and most reductions have been effected either by diminishing the weight of the coins, or by increasing the proportion of alloy in the metal of

which they are made, or both. Originally the coins of all countries seem to have had the same denomination as the weights commonly used in them, and contained the exact quantity of the precious metals indicated by their name. Thus the *talent* was a weight used in the earliest period of the Greeks, the *as* or *pondo* by the Romans, the *livre* by the French, and the *pound* by the English and Scotch; and the coins originally in use in Greece, Italy, France, and England, bore the same names, and weighed precisely a talent, a pondo, a livre, and a pound. The standard has not, however, been preserved inviolate, either in modern or ancient times. It has been less degraded in England than any where else; but even there the quantity of silver in a pound sterling is less than the *third* part of a pound weight—the quantity it contained in 1300. In France, the *livre* current in 1789 contained less than *one sixtieth* part of the silver implied in its name, and which it had actually contained previous to 1103. In Spain, and some other countries, the degradation has been carried still farther. From 1206 to 1355, the coins of England and Scotland were of the same weight and purity; but at the last-mentioned epoch the standard of Scotch money was for the first time sunk below that of England; and by successive degradations, the value of Scotch money, at the union of the crowns in 1600, was only a *twelfth* part of the value of the English money of the same denomination. It remained at this point till the union of the kingdoms canceled the separate coinage of Scotland. The gold and silver coins of Ireland have been for a considerable period the same as those of Great Britain; but, until 1825, they were nominally rated 84 per cent. higher. This difference of valuation, which was attended with considerable inconveniences, was put an end to by the act 6 Geo. IV. c. 79, which assimilated the currency throughout the empire. The tables annexed to this article contain all the information that can be desired by mercantile men with respect to the weight, fineness, etc., of English and Scotch gold and silver coins, from the earliest periods to the present moment.

Mint, or Government Valuation of Gold and Silver Coins.—If both gold and silver coins be made legal tenders, it is obviously indispensable that their value with respect to each other should be fixed by authority; or that it should be declared that individuals shall be entitled to discharge the claims upon them by payment, either of gold or silver coins, according to some regulated proportion. The practice of making both metals legal tenders was long adopted in England. From 1257 to 1664, the value of gold coins was regulated by proclamation; or, which is the same thing, it was ordered that the gold coins then current should be taken as equivalent to certain specified sums of silver. From 1664 down to 1717, the relation of gold to silver was not fixed by authority; and silver being then the only legal tender, the value of gold coins fluctuated, according to the fluctuations in the relative worth of the metals in the market. But in 1717 the ancient practice was again reverted to; and it was fixed that the guinea should be taken as the equivalent of 21s., and conversely. But the value of each of the precious metals is liable to perpetual change. And hence, how accurately soever their proportional value, as fixed by the Mint regulations, may correspond with the proportion which they actually bear to each other in the market when the regulation is made, the chances are ten to one that it will speedily cease to express their relation to each other. But the moment that such a change takes place, it becomes the obvious interest of every one who has a payment to make to make it in the *overvalued* metal; which, consequently, becomes the sole, or nearly the sole, currency of the country. Hence the reason why the coins of some countries are almost wholly of silver, and others almost wholly of gold. It is estimated, for example, that when it was

fixed, in 1717, that the guinea should exchange for 21s., gold was overvalued as compared with silver to the extent of 1 13-31 per cent.; and as the real value of silver with respect to gold continued to increase during the greater part of last century, the advantage of paying in gold in preference to silver became more decided, and ultimately led to the universal use of gold in all large payments, and to the fusion or exportation of all silver coins of full weight.

In France, a different valuation of the metals has had a different effect. Previous to the recoinage in 1785, the *Louis d'or* was rated in the Mint proportion at only 24 livres, when it was really worth 25 livres 10 sols. Those, therefore, who should have discharged the obligations they had contracted by payments of gold coin instead of silver would probably have lost 1 livre 10 sols on every sum of 24 livres. In consequence very few such payments were made; gold was almost entirely banished from circulation, and silver became almost the only species of metallic money used in France. In 1816, however, a new system was adopted in Great Britain; it being then enacted (56 Geo. III. c. 68) that *gold coins only should be legal tender in all payments of more than forty shillings*. The pound of silver bullion, that had previously been coined into sixty-two shillings, was then also coined into sixty-six shillings, the additional four shillings being retained by the government as a *seignorage* or duty (amounting to 6 14-31 per cent.) upon the coinage. To prevent the silver coins from becoming redundant, government has retained the power to issue them in its own hands. Under these regulations, silver has ceased to be a standard of value, and forms merely a subordinate or subsidiary species of currency or change, occupying the same place in relation to gold that copper occupies in relation to itself. This system has been found to answer exceedingly well. A good deal of difference of opinion has existed as to whether gold or silver coins are best fitted for being made legal tender. It does not seem that the one possesses any very striking advantage over the other; none, certainly, that would justify a change after a selection had been made and acted upon for any considerable period. Down to 1626, a seignorage or duty upon the coinage was usually charged upon the gold and silver coins issued by the Mint; and it may be easily shown that the imposition of such a duty, when it is not carried to an undue height, is advantageous. A coin is more useful than a piece of uncoined bullion of the same weight and purity; the coinage fitting it for being used as money, while it does not unfit it for being used for any other purpose. When, therefore, a duty or seignorage is laid upon coin equal to the expense of coinage, it circulates at its real value; but when this charge is defrayed by the public, it circulates at less than its real value, and is consequently either melted down or exported whenever there is any demand for bullion in the arts, or any fall in the exchange. It is, indeed, true, that were a seignorage to be laid on gold coins, it would be necessary, to prevent an enhancement of the value of the currency, that their weight should be proportionally reduced; and it is on this account better, perhaps, to let them remain on the present footing. But when a seignorage was laid on the silver coins in 1816, it was not necessary to take the circumstance now alluded to into consideration; for as they were made subordinate to gold, and were intended to serve as change merely, its imposition had no tendency to raise the value of the currency, at the same time that it was calculated effectually to prevent the fusion of the coins and to yield a small revenue to government.

Current Coin; loss by wear.—From very careful investigations made by the officers of the British Mint towards the close of the last century, it was found that 78 1-liver shillings, taken as a fair average from all those then in circulation, wore required to make 1 lb. Troy; whereas 62 is the number when new. Eleven

years afterward another fair average was taken, and another examination made, when it was found that 82 9-40 shillings were required to make a pound. But this diminution of weight is excessive, and is not likely to be exhibited by the less-worn and more frequently renewed silver coinage of the present day. Still it is unquestionable that the gold and silver coins are exposed to daily wear and diminution. The British government requested Mr. Cavendish and Mr. Hatchett, two distinguished fellows of the Royal Society, to make an extensive investigation respecting the power of metals to resist friction; and their results are highly curious. They made various alloys of silver, copper, platinum, iron, tin, lead, bismuth, manganese, nickel, cobalt, zinc, antimony, and arsenic, with gold; they rubbed plates of different kinds of metal over each other half a million times, to determine which resist friction best; and they rotated similar pieces among each other in a barrel. The effects were such as to reflect no little credit on those, whoever they were, who established the standard of English gold coin; for the English standard (22 gold to 2 alloy) and the quality of the alloy (silver and copper combined) were found about the best of all the combinations subjected to experiment. In 1807 the Mint officers, wishing to ascertain how much the current coin had actually lost by wear, selected at random one thousand good guineas from a broker, and found that they had lost on an average 19s. per cent. in value. A hundred guineas from a shop-keeper's till had lost 22s. per cent. Two hundred half-guineas exhibited a loss of 42s. per cent.—the smaller coins being subjected to more severe wear than the larger. Mr. Jacob, a great authority on the subject of precious metals, stated it as his opinion that, taking the average of all the gold coins in this country, and an average of all the hard usage to which the coins are exposed, each one bears an annual loss of about 1-900 by friction, which is a little more than a farthing in the pound. In silver coins the loss is supposed to be five or six times greater, owing to the more unceasing circulation of silver than gold, and to the less fitness of the metal to bear friction. The matter may be stated thus: put 900 new sovereigns and 900 new shillings into average ordinary circulation; in twelve months' time the former will be worth about 89s. and the latter about 89s.

Recent Coins of the World.—A coin, once set in circulation, retains its place and use longer than any other part of the machinery of life, and is extremely slow in going out of fashion; so that the information respecting it which the dealer, the collector, and the public at large require, does not soon become obsolete. "Pieces are current among us a full century old; and all that space of time is included in the history of coinage, contained in our large manual. But new coins, or modifications of old ones, are continually appearing; and in the latter case, it often happens that the holder finds he has become, if we may so speak, an unconscious sufferer. Old names are retained, but essential properties are altered; and a new progeny of doubloons, dollars, francs, or shillings, is found by an assayer's acuteness to be something different, most likely inferior, to the older stock. Keeping a steady watch on these, as it is impliedly our duty, we have collected a number of items which, as in our former publication, will be set forth in alphabetical order, and as briefly as possible."—*Manual of Coins*, by ECKFELDT and DU ROIE.

The weight is expressed in grains, and the fineness in thousandths parts.

Belgium.—Gold coin, 25 francs; a new denomination: 1848 is the earliest date noticed. It expresses on its reverse the intended standards, 7-915 grammes (equal to 122-12 Troy grains), 900 fine. The value of twenty pieces tried is 121-9, fineness 899; value $\$4$ 72. This is a slight depreciation; it ought to be $\$4$ 79, to compare with the former series of Belgian gold coin, or $\$4$ 81, to be equivalent with the French.

We notice also, in silver, a piece of 2½ francs, 1849, weighing 192 grains; fineness (of a single specimen) 901; value 46¢ cents.

Bolivia.—The dollars from 1841 to 1846, tried in parcels, vary in fineness from 896 to 901; a very large lot gave 897; showing some tendency downward. Weight, varying from 411 to 421, averages 416½; value on a general average, 100¢ cents.

Britain.—The new *sovereign*, or two-shilling piece, being one-tenth of a pound sterling, is understood to be an advance toward a decimal system. A considerable number have been coined, and the piece is fairly in circulation; but, like other silver coins of that country, it seldom makes its way out of the realm.

California.—See *Coins of United States*, p. 844.

Central America.—It is not easy to keep pace with the fluctuations in the coinage of this country, any more than with its political history. Nine years ago, we averaged the doubloon at \$14 96, and the dollar at \$1 00 1. The country now seems to be divided (we judge by the coins) into two distinct republics, Central America and Costa Rica.

Of the recent *gold* coinage of Central America, we have had opportunities of examining the quarter-doubloon, the eighth or escudo, and the sixteenth. The first, 1860, weighed 97 grains, fineness 863, value \$3 60. The second, 1844 to 1849, 48 grains, 809 fine, value \$1 67. The third, 1825 to 1849, 24 grains, 809 fine, value 83½ cents. In *silver*, the dollar of 1847 is found to vary from 880 to 820 thousandths in fineness; those of 1840 to 1842 averaged 887. It would, therefore, not be safe to give more than 92 cents for a single piece, or 95 by the quantity; the laws of wholesale and retail, in the coin market, being directly opposite to those in other branches of trade.

The coins of Costa Rica, the seceding state, are in several respects quite remarkable; and in this particularly, that the gold pieces are among the handsomest that are current in the world, while the silver are beyond comparison the rudest; at least the samples that we have seen. The specimens assayed here lately are the half-doubloon, weighing 208 grains, 851 fine, value \$7 62; and the quarter-doubloon, 97 grains, 845 fine, value \$3 53. The silver piece is the *real* (apparently shaped with hammer and chisel), 1846, 29 to 45 grains, 550 to 637 fine; average value 57½ cents.

Chili.—In the dollar of 1848 we find a variation of weight from 415 to 419; fineness 901½, which is lower than former *dracmas*; but the average value is 101 cents.

Until lately we had no opportunity of testing the fractional coins. The quarter-dollar, 1843 to 1845, weighs only 92, but is 903 fine; the eighth, or *real*, is strictly proportional. Value, respectively, 22½ and 11½ cents; making a profit to government, and a loss to holders, of about 31 per cent.

The newspapers of the day contain the following statement, concerning which we have no other information:

"The Chilian Congress, now in session, has passed a new coinage law, article first of which states that three classes of gold are to be coined, of the standard of nine-tenths fine, to be denominated, respectively, condor, doubloon (doblon), and escudo.

"1. The condor to weigh three hundred and five ¹⁰⁰/₁₀₀₀ grains, and to correspond in value with ten silver dollars.

"2. The doubloon to weigh one hundred and fifty-two ¹⁰⁰/₁₀₀₀ grains, and to correspond in value with five silver dollars.

"3. The escudo to weigh sixty-one ¹⁰⁰/₁₀₀₀ grains, and be of the value of two silver dollars.

"Art. 2. There shall be five classes of silver money, also of the standard of nine-tenths fine; viz.:

"A dollar, weighing five hundred ¹⁰⁰/₁₀₀₀ grains, and divided into hundredth parts or cents.

"A piece of fifty cents, containing two hundred and fifty ¹⁰⁰/₁₀₀₀ grains.

"One of twenty cents, with one hundred ¹⁰⁰/₁₀₀₀ grains.

"One of ten cents, with fifty ¹⁰⁰/₁₀₀₀ grains.

"One of five cents, with twenty-five ¹⁰⁰/₁₀₀₀ grains.

"Art. 3d establishes two classes of copper coinage, to be termed cents and half cents, to be composed of pure copper without any alloy."

China.—The trashy coin of this great empire deserves notice only by way of recreation. In 1842 we quoted the *cash* (long-taien) at 800 to the Spanish dollar; in 1847 their equivalent varied from 1200 to 1300—so hard is it to fasten a value upon that which is valueless. A carpenter or tailor, we are told, receives 160 of them (say thirteen cents) for a day's work, of which sixty are required for his daily bread. The coin is extremely convenient for alms-giving, a single piece being the usual quietus for a beggar.

Ecuador.—The quarter-dollar, or two-real piece, 1847, weighs 104, and is only 675 fine; value 18½ cents. This depreciation corresponds with what prevails in some of the fractional coins of Peru.

France.—The twenty and five-franc pieces of the republic, although entirely changed in face, are the same for weight and fineness as before.

Germany.—Here there is no change of standards, but we observe the denomination of double gulden, not in general circulation, value 79 cents. The whole German issue of the gulden series gives an average of 900 fine by actual assay.

Since the adoption of the new rate of charges at this Mint, the thaler of Northern Germany, 750 fine, yields a return of 67½ to 68½ cents, according to wear; the crown, 875 fine, 106 to 107 cents.

Hayti.—Large quantities of Haytian coins have been received here. They are so variable in weight and fineness that it is not easy to put a definite valuation upon them. They should, however, yield 76 to 78 cents per ounce, taken promiscuously and unwashed. The piece of 100 centimes, dignified with the name of dollar, bearing the head of President Boyer, is worth about 25 cents upon an average; while that of 25 centimes, both of Petion and Boyer, averages 7½ cents. In a large promiscuous deposit of all sizes, we found the average net value of the "dollar" to be 25 7/8 cents. The coins range from 600 to 625 fine, if free from counterfeits—a baser quality than is to be found in any other coinage on this side of the Atlantic. But since August, 1849, there has been a new order of things; and coin collectors and assayers are looking with impatience for the head of Faustin the First.

Mexico.—In 1842, we averaged recent dollars at 416½ grains, 898 fine, value 100 6/8 cents. The average fineness has since improved to 899, and value 100 7/8 cents.

The coins of two new Mints have recently been tried. The doubloon of Guadalupe y Calvo, in the state of Durango, 1847, varies in weight from 417 to 420; fineness 869 to 873; average value \$15 69. The dollar of the same Mint, 1844 to 1847, averages in weight 420½, in fineness 908, and therefore in value as high as 102 8/8 cents. The Mint began operations in 1844; its distinctive mark is G. C., in the usual place in the legend.

The dollar of Culiacan, in Sinaloa, 1846 to 1848, averages 415½ grains, with a pretty wide variation in individual pieces; fineness 903; value 101 cents. The Mint-mark is the letter C.

Mexican dollars are not flowing so abundantly in this direction as in former years, although they are yielding a better return.

Milan.—The revolution of 1848 produced a new gold coin in Lombardy; it bears on the obverse a female figure with the legend, ITALIA LIBERA, DIO LO VUOLE.

"Italy free, God wills it;" and on the reverse, a wreath, within which is the denomination, 20 LIRE ITALIANE—"20 Italian Livres;" and outside of it the legend, GOVERNO PROVVISORIO IN LOMBARIA. It weighs the same as the twenty-franc piece of France, and was evidently meant as a return to the Milanese

standard of 1805. The coin is more rare than could be wished; only a single specimen has reached us. Coin-collectors will consider it as a prize for its singular beauty and its scarcity, and as the monument of a great event in history.

Netherlands.—The new 2½-guilders piece was announced in our Manual as having been decreed, but had not then been received. The legal standards are, 25 grammes (385·8 grains) in weight, 945 thousandths in fineness. The actual results of dates 1842 to 1845 are, 386 grains, 944 fine; value 98·2 cents. The coin often appears here in mixed deposits. It is remarkable for its high grade of fineness; yet is really a depreciated issue, since, to be equal to the former guilder series, it ought to be worth 100·2 cents.

New Granada.—This country continues to send a large supply of doubloons to our market, and this makes it the more important to notice a very recent and considerable reduction in the value of the coin. Within a few months a new piece has appeared, with new devices and standards; the latter being expressed on the face of the coin by "LEI 0,900—Peso 25,8064 G." That is, *fineness*, 900 thousandths; *weight*, so many *grammes*—a long-drawn fraction, corresponding to 998·31 Troy grains. At those rates, the piece would be worth \$15 43·8, and would avowedly fall below the previous value of the doubloon; but upon actual trial it is still worse, as will be shown directly. This change must have taken place since the beginning of 1840, as we notice pieces of the old style bearing that date.

But as the doubloons of New Granada are alloyed almost entirely with silver, which is now profitably parted at this Mint, it is necessary to restate the Mint value of the old piece, as well as to give information respecting the new. The silver extracted makes a sensible addition to the values of both kinds; that is, if they are offered in sufficient quantities to meet the requirement that the net product of a parting must be not less than five dollars; below that limit the operation is not performed. The following terms must therefore be noticed. The doubloon of the old style, down to the early part of 1840, weighs on an average 416½ grains, and contains 870 thousandths gold, and about 120 silver; if presented in a quantity less than 58 ounces, its net Mint value will be \$15 61; in a larger quantity than that, it will be \$15 66. The new doubloon, beginning with 1840, weighs 398 grains, and contains in parcels 893½ to 895 thousandths gold, say 894, and of silver about 100; net Mint value, in any quantity less than 93 ounces, \$15 31; in a larger quantity, \$15 36.

Norway.—The immigration from this country brings us considerable parcels of Norwegian and Swedish silver coins. The *dalers* of these two realms, which have the same monarch, were stated in the Manual to be interchangeable as to value, although very different as to their standards. Under our new Mint charges there is some variation of value, since those of Sweden are of so much lower fineness, and are subjected to a greater charge for refining. They will be noticed in place. The daler, and half, of Norway, average 878 fine (the law calling for only 875, or seven-eighths), and their weights, unworn, are respectively 446 and 223 grains; net Mint value of the daler, 105 cents; the half, 52½. This valuation is down to 1848, the latest date we have seen.

Peru.—A new half-dollar, with the word *Pasco* in the legend, 1844, gives an average weight of 203 (variation 200 to 210), fineness 906; value 49½ cents.

Prussia.—The years 1848 and 1849, in other respects unsettled, show no change in the gold coinage. It still maintains its superiority to the other classes of ten and five-thaler pieces. The double-Frederick, or ten-thaler, is 903 fine, weighs 200 grains, and is worth \$8 01; practically, an even eight-dollar piece for us.

Russia.—Five-rouble pieces of 1848 and 1849 show the fineness of 910½; a proof that the assaying and al-

loying are conducted with admirable exactness, the standard being 916½. The coin is worth \$3 96·7. As the Russian Mint depends, no doubt, upon the Russian mines, and not upon foreign coins, for its material, we felt an interest in examining as to what proportion of silver was left in the alloy of the coin, and found only 6½ thousandths. Hitherto we have found no gold coins so nearly desilvered.

Siam.—We were not sufficiently acquainted with the silver bullets of Siam to take account of them in the Manual. Some specimens of this curious money have since been examined. They are of different calibres, and tolerably well proportioned to each other. The *tical* weighs, without much variation, 235 grains, and is 928 fine; value 58·7 cents. The *salung*, 61 grains, 929 fine, 15·2 cents. The *prang*, 30 grains, 907 fine, 7·8 cents. Below this we have, as a present to the Mint collection, three varieties, weighing 10, 4, and 1½ grains; the last being worth about three-eighths of a cent, and very good silver withal. A sight of it would reconcile our people to the gold dollar. Siam may claim the merit of originality in the shape of her coin, which will not admit of faking, and scarcely of lying still—the lively emblem of a true circulating medium.

Sweden.—The specie daler of Osean, 1847 and 1848, is 750 fine, weighs 525 grains, and yields 104·2 cents after Mint charges.

Turkey.—There was a new system of coinage promulgated in 1840, which did not prevail long; there is a still newer, beginning with 1845. The gold coins are evidently designed to be 22 carats (916·6) fine, as in the neighboring empire of Russia. By actual assay they are 915 fine; the piece of 100 piastres weighs 111 grains, and is worth \$4 37·4; the piece of 50 piastres, 55½ grains, worth \$2 18·7. In respect to value they compare with the former series of 20, 10, and 5 piastres, though entirely of different standards.

The silver coins are greatly improved in quality, and apparently based upon the Austrian standard of five-sixths (833½) fine. They are the piece of 20 piastres, 371½ grains, 828 fine, net value 82 cents; 10 piastres, 186 grains, 826 fine, 41 cents; and 5 piastres, 92½ grains, 824 fine, 20½ cents. These coins are well adjusted in their weight, and altogether show in their way a great advance in the progress of Turkish civilization. The piastre of commerce seems to be based upon the gold; the exchange in 1845, when these coins were received, rated the piastre at 4·3 cents.

United States.—By the law of March 3, 1849, two new gold coins, the double-eagle and the dollar, were added to the list; the former weighing 516 grains, or 21½ pennyweights, the latter 25½ grains; and both of the fineness of nine-tenths, as the other coinage. A very large number in both denominations have been issued.

The new postago law of March 3, 1851, provided for the coinage of a three-cent piece, composed of three-fourths silver and one-fourth copper, and weighing 12½ grains.

There are several classes of gold coin which are not of the United States, but which are struck within the national boundaries, and which ought to be noticed in this place. These are the *BECHTLER'S* coins of *North Carolina*, and the various *California* coins. In the same connection, it will be proper to give some details respecting several varieties of stamped ingots.

The coins of C. Bechtler are fully described in the Manual (p. 160); but since the date of that publication, the mint has passed into the hands of A. Bechtler, as appears on the face of the coin; and there is a marked difference of value between the C and A. The five-dollar pieces of the former were deficient from 1 to 6 per cent. upon the alleged value, averaging 3 per cent., or \$4 85; the one-dollar pieces were worth 95½ to 97 cents. The five-dollar pieces of the latter vary, from the full alleged value, to a deficit of 1½ per cent. There are no dates on the coins to enable us to mark

the difference; but the pieces assayed in 1843 were better than those (apparently fresh) assayed in 1849. The last and newest lot gave $\$4.94$ to the five-dollar piece. It is to be borne in mind, that as Bechtler's pieces are alloyed with silver, they will produce about a half of one per cent. more if offered in sufficient quantity. The dollars, as far as tried, are 2 per cent. below their nominal value. The coin appears to be considerable in amount, but it is not current in the Middle and Northern States; it is frequently brought to the Mint for recoinage.

The number of private Mints which have been in operation in California, as indicated by specimens received here, is fourteen. Some of these have issued but a single denomination of coin, others two, and one (the Mormon) four. Besides these, there are the stamped ingots of Moffatt & Co., and of F. D. Kohler, State Assayer; and lastly, the coin of Augustus Humbert, a United States assayer under a legal provision of 1850.

1. The coin of "N. G. & N." does not profess the same degree of accuracy as Bechtler's as to fineness. Its claim to be FULL WEIGHT OF HALF EAGLE is proved by a number of trials, the variation not exceeding one grain in any case; but the legend on the reverse, CALIFORNIA GOLD WITHOUT ALLOY, allows a pretty wide range. As far as our assays go, the truth of this stamp is proved; there is no alloy other than that already introduced by the hand of nature, and which is generally more than sufficient. Three pieces gave severally the fineness of 870, 880, and 892 thousandths; all were within the scope of "California gold." They consequently are worth $\$4.88$, $\$4.89$, and $\$4.95\frac{1}{2}$ respectively, without the silver; and including that, 2 $\frac{1}{2}$ cents more.

The coin is neatly executed, and besides the two legends above quoted, bears an eagle, a circle of stars, the date 1849, and the name SAN FRANCISCO. It wears the somewhat brassy tint which belongs to gold alloyed with silver only.

2. The Mint of the "Oregon Exchange Company" issues two denominations, 10 and 5 dollars. They respectively profess 260 and 130 grains weight of "native gold." One five-dollar piece was found to weigh 127 $\frac{1}{2}$ grains, was 878 fine, and contained only the natural alloy; resulting value, $\$4.82$; with the silver (in sufficiently large lots), 22 cents more.

The coin is not well struck, but is pleasantly distinguished by the picture of a beaver, a good emblem of mining industry and of Western life.

3. Next is the mintage of the "Miners' Bank, San Francisco;" a ten-dollar piece, of plain appearance.

The average weight is 263 $\frac{1}{2}$ grains, the fineness about 865 thousandths, part of the alloy being copper. Average value $\$9.87$, with a risk of having it as low as $\$9.75$.

4. Coinage of Moffatt & Co., 1849, 1850; pieces of 10 and 5 dollars, in imitation of the national coinage. Several of the coining establishments, as will be seen, have adopted the same device, but evidently without evil intent, as most of their coins are worth what is professed, and some even more. The fineness, however, is in every case inferior to the standard of the Mint, and this is likely to prove a source of discredit from European assayers, who will not take the trouble to assort. A large promiscuous lot of both kinds of Moffatt & Co.'s coins, dates 1849, 1850, shows an average of 897; average weight, to the ten-dollar piece, 258 $\frac{1}{2}$ grains; average value, $\$9.97$.

The S. M. V. on this and other coins is said to mean "Standard Mint Value."

5. Ten-dollar piece of J. S. O. (said to be Dr. Ormsby, of Pennsylvania); one piece assayed gave 842 fine; weight 268 $\frac{1}{2}$ grains; value $\$9.37$. Very few have come to hand.

6. Twenty-five dollar and ten-dollar pieces of Templeton Reid; weight respectively 649 and 260 grains. Being the only two specimens received, they have not

been cut for assay, but appear to be of California gold without artificial alloy. Assuming this, the values would be about $\$24.50$ for the first, and $\$9.75$ for the second.

7. Ten-dollar and five-dollar pieces of the "Cincinnati Mining and Trading Company," 1849. These also have not been cut on account of their rarity, but appear to be of native gold, and, at the weights of 268 and 132 grains, may be rated at $\$9.70$ and $\$4.95$ respectively.

8. Ten and five-dollar pieces of the "Pacific Company," 1849; very irregular in weight, and debased in fineness; a ten-dollar piece weighed 229 grains, a five-dollar, 130; assay of a third, 797 thousandths. At those rates, the larger piece would be worth $\$7.86$, the smaller $\$4.48$; but the valuation is altogether uncertain.

9. Five-dollar piece of the "Massachusetts and California Company," 1849; a very pretty coin, but apparently debased with copper. Only one specimen has been noticed here; it weighs 115 $\frac{1}{2}$ grains; has not been assayed.

10. Coins of Baldwin & Co., four varieties; 1. A ten-dollar piece, 1850, distinguished by a horse and his rider, with a lasso; 2. Twenty-dollar piece; 3. Ten-dollar, 1851; 4. Five-dollar, 1850; the last two in imitation of United States coinage. Of the first, one piece tried weighed 263 grains, fineness 880, value $\$9.96$. Of the second, four pieces tried varied from 511 to 523 grains; but one hundred pieces averaged 517; the fineness varied from 861 to 871; average fineness 868 $\frac{1}{2}$, average value $\$19.38$. Of the third, ten pieces averaged 259 $\frac{1}{2}$ grains; average fineness 870; average value $\$9.72$. Of the fourth, average value $\$4.92$. The Baldwin coins contain some copper; about 20 thousandths.

11. Ten and five-dollar pieces of Duboseg & Co., 1850, also in imitation of the national coinage. The larger piece averages 262 grains, and three specimens gave the fineness of 899 $\frac{1}{2}$, which is a mere shade below standard; consequent value, $\$10.15$. A single five-dollar piece weighed $\$4.92$. But a mixed parcel containing $\$1000$, gave the fineness of 887, and the close value of $\$1000.20$. Consequently the pieces may be averaged at par.

12. Five-dollar piece of Shultz & Co., 1851. Average weight, 128 $\frac{1}{2}$ grains; fineness of three pieces, 879; value, $\$4.97$. The devices are in imitation of United States coin.

13. The Mormon coinage, although executed in the Territory of Utah, is without impropriety classed among California coins, on account of neighborhood, and the source whence the material is derived. These are the four denominations of twenty, ten, five, and two and a half dollars. Although there is much irregularity both in weight and fineness, the denominations are tolerably in proportion to each other. A parcel made up of all sizes, and counting $\$569.60$, yielded at the Mint $\$479.20$; say $\$85.20$ to the ten-dollar piece. The fineness was 886.

14. Five-dollar piece of Dunbar & Co., in imitation of United States coin. A lot of 111 pieces averages 131 grains weight, 883 fineness, value $\$4.98$.

15. Fifty-dollar piece of the United States Assay-Office at San Francisco, established by act of Congress of 1850. It first appeared here in April, 1851. The coin is prepared and issued by Messrs. Moffatt & Co. as contractors, and bears the stamp of Augustus Humbert, assayer. The two professed rates of fineness, 880 and 887 thousandths, are found upon assay here to be duly maintained, whether in single pieces or in large quantities. But some irregularity in the weight of so heavy a piece, alloyed with silver only, and offering eight corners to wear is to be expected. When presented in quantities sufficient to allow for parting the silver, say 70 ounces, the average Mint value is about $\$60.10$; in less quantities, the silver not being allowed for, the average value is about $\$49.00$. But even with-

out the silver they occasionally come up fully to the alleged value. This colnage is understood to have put a stop to all private issues in California.

The foregoing comprehend all the varieties of coin that have been brought to this Mint. There have been, besides, two sorts of stamped bars or ingots, evidently intended for currency.

1. The ingots of Moffatt & Co., of various sizes, from about \$70 to \$260. It may be stated, in general, that some were found to be rated too high, and others too low. The sixteen-dollar ingot yields about \$15 75, but is irregular.

2. The issue of bars by F. D. Koller, Assayer of the State of California, commenced in May, 1850. They are of various sizes, from \$40 to \$150. We find a slight undervaluing in his basis of calculation, and generally an error of assay in the same direction; so that on the average his bars are worth at the mint 1 per cent., perhaps 1½, more than the value stamped upon them.

Recapitulation of the net Mint Value of Gold and Silver Coins issued within twenty-five Years past.—Inquiry has been frequently made at the Mint for a compend of the values of foreign coins, without a due consideration of the difficulty of putting in a small space such a statement as would be satisfactory. The quarto volume, now entirely out of print, was not found too large for its purpose, which was to supply such information as dealers, amateurs, and legislators would from time to time be likely to require. Still, a condensed table of the coins more usually seen, and within a contracted range of date, would certainly be useful to dealers and others, and especially with the modifications occasioned by the new Mint tariff of charges. We therefore offer the following, inserting values only, and leaving the details of legal weight and fineness, and of actual weight and fineness, to be sought for elsewhere; as also the particulars concerning coinage of older date than just specified.

1551-5 Edward VI. The coinage of debased silver money, in the 5th year of Edward VI., of 3 oz. fine, ought more properly to be considered as Tokens. The sum of £120,000 only was so coined.—See James's Essay, chapter iv.

1527—Henry VIII. The Saxon or Tower pound was used at the Mint up to this time, when the pound Troy was substituted in its stead. The Tower pound was but 11 oz. 5 dwts., Troy; so that, from the Conquest to the 23rd of Edward I., 20 shillings in this were exactly a pound in weight.

1666-13 Charles II. The seigniorage on the coinage was at this time given up, and the gold bullion brought to the Mint has ever since been coined free of expense. A seigniorage of 6 1/4 per cent. was imposed on the coinage of silver by 66 Geo. III.

The London Assays in this Table were made by Robert Bingley, Esq., F.R.S., the Assay Master of the Royal Mint, and those at Paris by Pierre Frédéric Bonnevillie, Essayeur du Commerce, as published in his elaborate work on the coins of all nations. Specimens of all the foreign coins brought to London for commercial purposes have been supplied for this Table from the Bullion-office, Bank of England, by order of the Bank Directors, and have been selected by Philip Humber, Esq., the chief clerk of that office, who also examined the Tables in their progress. It may likewise be added, that the Mint Reports of these commercial coins are chief; for average assays; and that all the computations have been carefully verified by different calculators.—Note by Dr. Knapp, to second edition of the *Cambist*, published in 1821.

"By one of the articles of the Zollverein, or Customs-union of Germany, it was stipulated that the settlements for the duties should be made either in Prussian dollars or in forins, at the rate of 7 forins for four Prussian dollars. There were, however, no forins in existence exactly of this value; but as the nearest approach to it was a valuation called the 24 guldenfuss, or forin-foot, these Zollverein forins were nominally reckoned to be in this rate, though the difference amounts to more than 2 per cent. The term 24 guldenfuss implies that the mark weight of fine silver is rated at 24 gulden or forins. It was formed by giving to the coins minted or valued in 20 guldenfuss an increased value of one-fifth, as rating the 20-kreutzer piece at 24 kreutzers. At 60d. per ounce standard, the value of this mark of fine silver is worth 40s. 7 1/2d. sterling, from which the value of the different German monetary integers is readily obtained; as reckoning 2 1/2 marks banco or 3 1/4 marks current of Hamburg, 14 dollars of Prussia, 2 1/4 forins of South Germany, 20 forins of Austria, and also 60 lire of Austriacho of Lombardy, to be of this amount. In order, therefore, to prevent the loss or inconvenience which would attend their adhering to this mode of valuation, a money convention was entered into on the 25th of August, 1837, among the states forming the union, by which it was agreed upon that a new basis of valuation should be adopted for their coins, under the term of Suddentscher Wahrung, or South German valuation, at the rate of 24 gulden or forins from the mark's weight of fine silver. Bavaria, Wirtemberg, Baden, and Saxony have since issued their coins at this rate, and the other states of the confederation are doing or preparing to do the same. Among them Frankfurt, in 1840, began the mintage of coins of this value; and by a regulation of the Chamber of Commerce of this free city, all the rates of exchange, as well as the values of bullion and foreign coins, were ordered to be expressed in this Suddentscher Wahrung from the commencement of the year (1843). One of these new and very exactly-minted forins was assayed by Messrs. Johnson and Cook, of Hatton Garden, who reported it to be, full weight, 6 dwts, 19 1/2 grains, worse 6 dwts., gold under 2 grains; from which the value, at 60d. per ounce standard, is very exactly 19 1/2d. sterling, making the par of exchange with London 120 1/2 forins in S. D. W. for £10

sterling. I have been thus particular in these explanations, partly because several persons imagine that the late alteration in the rate of exchange with Frankfurt was made in compliance with the wishes, or to suit the convenience, of one or more of our leading houses in exchange negotiations, but more particularly because it is maintained by many that the valuation of this rate is not merely nominally, but really, in 24 guldenfuss. This is a point of no small importance to the commercial world, for had it been so, the par of exchange with London would have been only 118 forins for £10 sterling, and the difference between this and the present price of eight bills on Frankfurt would have exceeded 2 1/2 per cent.; a variation which every practical cambist well knows could not exist, except under very extraordinary circumstances, and with nearly corresponding differences in the other rates of exchange; neither of which causes is now in operation."—*Letter of William Tate, Esq., cambist to the Times.*

Sterling silver remained in high repute all over the Continent, because it was superior to any other currency; and even in England the words conveyed for centuries the ideas of goodness and purity. And we may remark here that the gold coins of England, from the reign of Henry III., when they were generally introduced, to the reign of Henry VIII., who debased their purity, were made of fine gold. This is a remarkable circumstance, because as gold in its native state is rarely discovered so pure, the existence for a long period of a coinage fabricated of that metal in a state of purity necessarily implies the knowledge of the art of refining, which must have been practiced at a very early period. Pliny, indeed, says that in his time gold was refined by mercury, which mingled with it, but rejected all alloy, and the gold was freed from the mercury by squeezing both in skins, in which operation the mercury ran through and left the gold in a pure state. Some of the Greek gold coins were also of great purity, as those of Phillip of Macedon, and his son Alexander the Great, rivaled by those of the other princes and cities which immediately followed. Those of the successors of Alexander in Egypt were 23 carats 3 grains fine, and 1 carat grain alloy, which we give on the authority of Jacob in his book on the "Precious Metals." The Greek silver coins were inferior to ours; as also the Roman of the earliest period.—E. B.

* The Prussian coins, having been debased at different periods, vary in their reports.

† This is the coin which is universally circulated under the name of the Spanish dollar.

‡ The American dollars, and inferior silver pieces of late coinage, vary in fineness from W. 4 dwts. to W. 9½ dwts.

The sterling value of the foreign coins, in the foregoing tables, has been computed from the assays as follows: Let it be required to assign the value, in sterling, of a French double Louis d'or coined since 1786, the assay master's report being as follows: "Weight, 9 dwts. 20 grs.; assay W. 1 1/2 grs.," that is, 0 car. 1 1/2 grs. worth than the English standard. We proceed as under:

From 22 car. 0 gr. the fineness of English standard gold, take 0 car. 1 1/2 gr., there remains 21 car. 2 1/2 gr. Then, as 22 car. : 21 car. 2 1/2 grs. :: 9 dwts. 20 grs. : 9 dwts. 16 grs., the standard gold contained in the Louis d'or; and hence, as 1 oz. : £3 17s. 10 1/2d. :: 9 dwts. 16 grs. : £1 17s. 7 1/2d., the value of the Louis in sterling money, and so for any of the other coins.

Ancient Coins.—We subjoin, for the convenience of each of our readers as may at any time have occasion to consult works in which reference is made to ancient coins, the following tables of those that were principally current among the Jews and Greeks. They were calculated by Dr. Arbuthnot (*Tables of Ancient Coins, Weights, etc.*, 4to ed., Lond., 1754), and do not differ materially from the tables of Faunton, whose *Mitologie* (4to Paris, 1780) is the most complete and elaborate work that has ever been published with respect to ancient moneys, weights, and measures. At the same time we confess we should not be disposed to place much reliance on these tables, and we have elsewhere stated our reasons for holding this opinion.—*Encyc. Britannica*, art. MONEY.

The currency of France consists chiefly of gold and silver, in which larger payments are effected, and of copper coins for the smaller sums.

It appears that from 1803 to 1814 there were coined, with the effigy of Napoleon, at the different mints, of which there are thirteen in France, in gold to the value of £22,001,018, and in silver to the value of £36,992,502. From 1814 to 1828, the amount of the coinage was £17,081,635 in gold, of twenty and forty franc pieces; and in silver the amount in pieces of five francs down to five sous was £39,996,560 bearing the effigy of Louis XVIII. and Charles X. On the above data, the amount of circulating specie in the kingdom was estimated, on the 1st of January, 1828, at 2,713,731,183 francs, equal in value to £119,072,132 sterling. The gold and silver currency, prior to the Revolution in 1789, was estimated at £87,500,000 sterling. We can scarcely, however, draw any positive inference from the quantity of gold and silver coined in France, respecting the amount of specie actually circulating, as within the last twenty-seven years the exportation of coin has been freely permitted. The coinage of France has accordingly become an article of trade; and bullion and coin have been freely exported or imported,

according to the necessities of commerce. For the ten years preceding 1830, the quantity of bullion imported exceeded the quantity exported by £39,089,607.

The amount of the gold and silver coinage in France for 1853, with the value in francs and in sterling money, was:

	Coinage.		Value.	
	Number.	Francs.	£	Value in Sterling.

Coinage of the United States.—The Annual Report of the Director of the Mint, for the year 1855, shows clearly the operation of the parent Mint and all the branches, as well as of the Assay Office at New York, for the whole year of 1855. It appears that the total coinage for the year was over \$56,000,000; and that the aggregate coinage of the Mint and all its branches (including gold bars), from the year 1793, has been \$498,866,565 82. The portions executed at the parent Mint, and at each branch, have been as follows:

Mints.	Commenced Business.	Coinage, 1855.	Total Coinage, 1793 to end of 1855.
Mint, United States, Philadelphia.....	1793	\$12,046,562 98	\$377,388,808 87
Branch, New Orleans.....	1838	2,368,500 00	57,336,665 00
Branch, Dahlonega.....	1838	116,778 60	5,630,286 00
Branch, Charlotte, North Carolina.....	1838	217,005 60	4,222,626 60
Branch, San Francisco.....	1854	21,121,752 43	30,863,320 64
Assay Office, New York.....	1854	20,441,813 03	20,320,872 81
Total.....		\$56,312,732 99	\$498,866,565 82

The domestic production of gold, so far as is indicated by the deposits at the Mint, amounts to more than three hundred and twenty-two millions of dollars from the year 1793 to 1855, both inclusive. Of this large sum, the gross product to the end of the year 1848 was little more than thirteen millions of dollars, as is shown by the annexed table. To this aggregate of three hundred and twenty-two millions of dollars should be added several millions as the export from California, via Panama, to Southampton, and also the export to China and elsewhere.

STATEMENT OF GOLD AND SILVER, OF DOMESTIC PRODUCTION, DEPOSITED AT THE MINT AND BRANCHES AND ASSAY OFFICE AT NEW YORK, FROM 1804 TO THE END OF 1855.

Years.	Gold.	Silver.
1804-1827.....	\$110,000 00
1828-1837.....	5,065,500 00

South Carolina.....	1,154,305 44
Alabama.....	192,205 92
Tennessee.....	80,193 00
New Mexico.....	45,037 00
Other sources.....	64,851 00
Total.....	\$381,002,371 54
Deduct re-deposits of 1854.....	8,041,187 00
Net product of the States.....	\$372,961,184 54

The gold mines of North Carolina are still in working order, with a large outlay of capital for their prosecution; but the average results may be considered as not very profitable to the shareholders.

The reduced coinage at Philadelphia for 1855 is accounted for by the unavoidable delays in the repairs at the Mint, authorized by an appropriation made by Congress for this purpose in 1855. These repairs and alterations were commenced 19th July last, and occupied six months.

The total value of the coinage of the United States, from the year 1793 to 1855, both inclusive, has been within a fraction of five hundred millions, namely:

Mints.	Gold.	Silver.	Copper.	Total.
Philadelphia.....	\$205,371,682 66	\$30,440,020 90	\$1,572,196 31	\$377,388,808 87
San Francisco Branch, 1854.....	30,689,251 01	164,075 00	30,853,326 04
New Orleans.....	37,830,865 00	19,556,900 00	57,386,665 00
Charlotte.....	1838-1855.....	4,222,626 60	4,222,626 60
Dahlonega.....	1838-1855.....	5,630,286 00	5,630,286 00
Assay Office, New York, 1854.....	20,320,872 81	20,320,872 81
Total.....	\$377,134,464 61	\$100,159,904 90	\$1,672,196 31	\$498,866,565 82

For the year 1855, the aggregate coinage, including fine bars, was \$56,312,732 99, namely:

Mints.	Gold.	Silver.	Copper.	Total.
Philadelphia.....	\$10,610,752 14	\$1,419,170	\$16,030 72	\$12,046,952 93
San Francisco.....	20,157,077 43	164,075	21,121,752 43
New Orleans.....	400,500 00	1,018,000	2,308,500 00
Charlotte.....	217,935 60	217,935 60
Dahlonega.....	116,778 60	116,778 60
Assay Office.....	20,441,813 03	20,441,813 03
Total.....	\$22,795,457 20	\$3,501,245	\$16,030 72	\$26,312,732 99

It will appear from this tabular view that the branch Mints at New Orleans, Dahlonega, and Charlotte could be advantageously dispensed with. The gold coinage last year at New Orleans was only \$450,500, and the silver, \$1,918,000. All this could have been done at Philadelphia; and now that the parent Mint is provided with new and improved machinery, all the silver coinage may as well be done at that point.

It appears that the annual coinage at the Georgia and North Carolina branches is less than the years 1818-1853—having declined from \$900,000 in 1852, to \$383,000 in 1855. According to a report made by Mr. J. Phillips Phenix, of the Committee on Commerce, to the House of Representatives, in September, 1850, when the coinage at these two branches was double what it is now, the expense of coinage was estimated as follows:

At Philadelphia	2-23 per cent.
At New Orleans	6-63 "
At Charlotte	9-00 "
At Dahlonega	9-97 "

At this time, the percentage at the branch Mints must be greater, as the work is less. Every dollar coined at the Charlotte and Dahlonega, probably costs ten cents; whereas the raw material could be transported, at a small cost, to Philadelphia or New York. The annual expense of thirty or forty thousand dollars for the maintenance of these two Mints could well be dispensed with, and the coinage executed at Philadelphia and New York. In fact, the heavy expense incurred by the government for the support of the Mint at New Orleans is entirely superfluous. The receipts of gold at that quarter are now too small to require the further working of a Mint there.

The Director of the Mint, in his report recently made, alludes to recent improvements in machinery which are calculated to facilitate coinage operations, and to produce more highly finished pieces, namely: "In the coinage of half eagles particularly, we shall be materially aided by a very remarkable machine lately invented. * * * This machine was manufactured at Paris, and has been introduced into the Mint there, and one of similar powers is also employed in the Mint of England. The one imported for the United States Mint is adapted to the half eagle only. It is justly regarded as a triumph of mechanism."

The largely increased production of gold in Australia and California, of late years, has, of course, stimulated the workings of the Mints of foreign countries. The coinage may be fairly estimated at about two hundred millions of dollars annually in gold, fifty millions in silver, and nearly one million in copper. We find

the annexed summary of foreign coinage for the year 1853, the latest, to which we add that of the United States for the same year, all reduced to sterling:

SUMMARY OF THE COINAGE OF VARIOUS MINTS THROUGHOUT THE WORLD IN THE YEAR 1853.

Countries.	Gold.	Silver.	Copper.	Total.
Great Britain.....	\$11,002,391	\$701,544	\$9,273,212	\$21,677,147

India.....	128,000	4,240,000	63,600
Totals.....	\$27,400,700	\$29,594,863	\$166,051,247	\$130,650

The act of Congress to create new silver coins and to reduce the weight of the old denominations, has had a good effect in providing the country with an abundance of the small coins, and the new act passed by Congress in February, 1857, and now in force, will have the effect to drive out of circulation the old and depreciated Spanish coins that have for many years been in use.

The Act of Congress of February, 1857, in reference to the Coinage, will produce a very desirable reform in our currency of silver and copper coins. The new act authorizes the creation and distribution of a new cent, which relieves us of a hitherto ponderous coin—the comparative weights being as follows: Act of January 18, 1837, 168 grains; Act of February, 1857, 72 grains; difference, 96 grains. The former acts of Congress did not make copper coins a legal tender; and it has been disputed as to what amount they were receivable for debts; nor does the new act make them legal tenders for any sum. The new cent may be readily distinguished in the dark from the current silver coin. It presents about the same surface as the ten-cent piece, but is about double the thickness with a smooth edge; whereas the ten-cent piece has a milled edge.

With the aid of the twenty millions of dollars in small silver coins executed since the act of March 3, 1853, and the coinage of two or three millions more annually, for the next few years, the country will be liberally provided with small silver coins, that will not only enter into general circulation and effect the purposes intended, but they will not be liable to be used for the arts and manufactures, their legal value being about ten per cent. beyond that of their intrinsic value as metal.

According to a careful table prepared for the Augsburg Allgemeine Zeitung, published April 16, 1856, the following table will show the amount of gold and silver that has been extracted during various periods from the birth of Christ down to the year 1855:

Year.	Gold.		Silver.		Value.	
	Kilo.	Kilo.	Francs.	Dollars.		
From A. D. to 1492.....	6,122,711	13,622,107	23,400,000,000	4,691,800,000		
" 1492 to 1810.....	9,854,487	137,000,830	40,023,000,000	8,104,600,000		
" 1810 to 1825.....	270,100	6,237,414	2,288,000,000	457,600,000		
" 1825 to 1848.....	663,514	16,715,923	6,698,000,000	1,319,600,000

GOLD, SILVER, AND COPPER COINS OF THE UNITED STATES.

Table with 4 columns: Coins, Fineness, Standard Weight, Value. Lists various gold and silver coins from 1837 to 1857.

COINAGE OF THE UNITED STATES.

GOLD AND SILVER COINAGE AT THE MINT OF THE UNITED STATES IN THE SEVERAL YEARS FROM ITS ESTABLISHMENT, IN 1792, AND INCLUDING THE COINAGE OF THE BRANCH MINTS AND THE ASSAY OFFICE (NEW YORK), FROM THEIR ORGANIZATION TO SEPTEMBER 30, 1857.

Large table with 4 columns: Years, Gold, Silver, Aggregate. Shows the amount of gold, silver, and aggregate coinage from 1793 to 1857.

By an act of Congress, the Old Spanish coins are receivable at the Treasury of the United States and several offices, at the Post-offices and Land-offices, at the following rates:

- Quarter-dollar 20 cents.
Eighth-dollar 10 cents.
Sixteenth-dollar 5 cents.

[But by the sixth section, they will be receivable at 26, 12 1/2, and 6 1/2 cents, respectively, in exchange for the new cents.]

2. Such old coins "shall not again be paid out or put in circulation, but shall be recoined at the Mint" for distribution.

3. All former acts authorizing the currency of foreign gold or silver coins, and declaring the same a legal tender in payment for debts, are repealed; but it shall be the duty of the Director of the Mint to cause assays to be made, from time to time, of such foreign coins as may be known to our commerce, to determine their average weight, fineness, and value, and to embrace in his annual report a statement of the results thereof.

4. The standard weight of the cent shall be seventy-two grains; composed of 88 per cent. of copper and 12 per cent. of nickel; and the coinage of the half-cent shall be discontinued.

5. Authorizes the Treasurer of the Mint to purchase the materials necessary for the coinage of the new cent.

6. It shall be lawful to pay out the said cent at the Mint in exchange for any of the gold and silver coins of the United States, and also in exchange for the former copper coins issued; and to transmit parcels of the said cents, from time to time, to the assistant treasurers and other officers for exchange; and it shall also be lawful for the space of two years from the passage of this act, and no longer, to pay out at the Mint the cents aforesaid for the fractional parts of the dollar herein before named at their nominal value of twenty-five, twenty and a half, and six and a quarter cents respectively.

7. Hereafter the Director of the Mint shall make his Annual Report up to the 30th June (instead of 31st December, as heretofore), so that the results of the year's operations may appear in the Annual Report of the Secretary of the Treasury.

In the Annual Report of the Director of the Mint of the United States for 1857, he says: "As my Report in January last presented a statement of the operations for the year 1856, this Report will embrace the operations since that time, namely, from the first day of January to the 30th of June, a period of six months.

"For the purpose of exhibiting in a condensed form the entire operations of the Mint and its branches, I present the annexed summary statement. It embraces the amount of gold and silver billion operated upon from the time of their respective organizations to the 30th of June, 1857:

Table showing Mint of the United States established 1809, Branch Mint at New Orleans, Branch Mint at Dahlonega, Branch Mint at Charlotte, Branch Mint at San Francisco, Assay Office at New York.

"Of this amount there has been received since the 1st of January, 1849, of native gold, the production of the United States, the sum of four hundred and two millions of dollars. If, in addition to this sum, we add the gold produced from Australia and other foreign countries during the same period, which may be stated to be about five hundred millions of dollars, and the production of silver bullion from all sources, which is at the rate of about forty millions per annum, it will be seen that within this comparatively brief period the world's supply of the precious metals has been increased to the extent of twelve hundred and forty-two millions of dollars."

Adams); Hunt's Merchants Magazine, v. 379, vi. 27, iv. 434; De Bow's Review, li. 281; Bankers Magazine, vol. x. (Professor De Morgan); Manual of Coins, by Eckfeldt and Du Bois, of United States Mint.

as they think fit, and may from time to time revoke, alter, or vary the same. 3. All regulations made in pursuance of this section shall be published in the London Gazette, and shall come into operation on a day to be named in the Gazette in which they are published, and the Admiralty shall cause all such regulations to be printed, and shall furnish a copy thereof to any owner or master of a ship who applies for the same, and production of the Gazette containing such regulations shall be sufficient evidence of the due making and purport thereof. 4. All owners and masters shall be bound to take notice of the same, and shall, so long as the same continue in force, exhibit such lights, and use such fog signals, at such times, within such places, in such manner, and under such circumstances as are enjoined by such regulations, and shall not exhibit any other lights or use any other fog signals, and in case of default the master, or the owner of the ship, if it appears that he was in fault, shall for each occasion upon which such regulations are infringed incur a penalty not exceeding £20.

Rule as to Ships meeting each other.—Whenever any ship, whether a steam or sailing ship, proceeding in one direction, meets another ship, whether a steam or sailing ship, proceeding in another direction, so that if both ships were to continue their respective courses they would pass so near as to involve any risk of a collision, the helms of both ships shall be put to starboard so as to pass on the port side of each other; and this rule shall be observed by all steamships and by all sailing ships, whether on the port or starboard tack, and whether close-hauled or not, unless the circumstances of the case are such as to render a departure from the rule necessary in order to avoid immediate danger, and subject also to the proviso that due regard shall be had to the dangers of navigation, and, as regards sailing ships on the starboard tack close-hauled, to the keeping of such ships under command. **Rule for Steamers in narrow Channels.**—Every steamship, when navigating any narrow channel, shall, whenever it is safe and practicable, keep to that side of the fair way or mid-channel which lies on the starboard side of such steamship. *If Collision ensues from Breach of the above Rules, Owner not to be entitled to recover.*

—If in any case of collision it appears to the court before which the case is tried that such collision was occasioned by the non-observance of any rule for the exhibition of lights or the use of fog signals issued in pursuance of the powers before contained, or of the foregoing rules as to the passing of steam and sailing ships, the owner of the ship by which such rule has been infringed shall not be entitled to recover any recompense whatever for any damage sustained by such ship in such collision, unless it is shown to the satisfaction of the court that the circumstances of the case made a departure from the rule necessary.

Breach of such Rules to imply willful Default.—In case any damage to property arises from the non-observance by any ship of any of the said rules, such damage shall be deemed to have been occasioned by the willful default of the person in charge of the deck of such ship at the time, unless it is shown to the satisfaction of the court that the circumstances of the case made a departure from the rule necessary.

An authority similar to that given to the Lords of the Admiralty by the clause of the Mercantile Shipping Act now quoted had been already given to them, and under that authority they issued the following regulations, which are now (1855) in force:

Steam Vessels.—All British sea-going steam vessels (whether propelled by paddles or screw) shall, within all seas, gulfs, channels, straits, bays, creeks, roads, roadsteads, harbours, havens, ports, and rivers, and under all circumstances, between sunset and sunrise, exhibit lights of such description, and in such manner as hereinafter mentioned; viz., when under steam: A bright white light at the foremast head; a green light on the starboard side; a red light on the port side. 1. The mast-head light is to be visible at a distance of at least five miles in a dark night, with a clear atmosphere, and the lantern is to be so constructed as to show a uniform and unbroken light over an arc of the horizon of twenty points of the compass, being ten points on each side of the ship, viz., from right ahead to two points abaft the beam on either side. 2. The green light on the starboard side is to be visible at a distance of at least two miles in a dark night, with a clear atmosphere; and the lantern is to be so constructed as to show a uniform and unbroken light over an arc of the horizon of ten points of the compass, viz., from right ahead to two points abaft the beam on the starboard side. 3. The red light on the port side is likewise to be fitted so as to throw its light the same distance on that side. 4. The side lights are, moreover, to be fitted with screens, on the inboard side, of at least three feet long, to prevent the lights from being seen across the bow. **When at anchor:** A common bright light.

Sailing Vessels.—We hereby require that all sailing vessels when under sail, or being towed, approaching or being approached by another vessel, shall be bound to show between sunset and sunrise a bright light in such a position as can be best seen by such vessel or vessels, and in sufficient time to avoid collision. All sailing vessels at anchor in roads, creeks, or fair ways shall be also bound to exhibit, between sunset and sunrise, a constant bright light at the mast-head, except within harbours or other places where regulations for other lights for ships are legally established. The lantern to be used when at anchor, both by steam vessels and sailing vessels, is to be so constructed as to show a clear good light all round the horizon. We hereby revoke all regulations heretofore made by us relating to steam vessels exhibiting or carrying lights, and we require that the preceding regulations be strictly carried into effect after the 1st day of August, 1852.

Directions for Fitting the Lights.—The manner of fitting the colored lights is to be particularly attended to. They should be fitted each with a screen of wood on the inboard side, in order to prevent both being seen at the same moment from any direction but that of right ahead. This is important, for without the screens (a principle first introduced with this plan) any plan of bow-lights would be ineffective as a means of indicating the direction of steering. This will be readily understood by a reference to the illustrations, which will appear evident that in any situation in which two vessels may approach each other in the dark, the colored lights will instantly indicate to both the relative course of each; that is, each will know whether the other is approaching directly or crossing the bows, either to starboard or to port. This intimation is all that is required to enable vessels to pass each other in the darkest night, with almost equal safety as in broad day, and for the want of which so many lamentable accidents have occurred. Patterns of the lanterns to be carried, and of the mode in which the screens are to be fitted, may be seen at the custom-houses of the principal commercial ports in the United Kingdom. The system of night lights laid down in the above regulations has been adopted in her majesty's service, and by the governments of the principal foreign maritime nations.

Every master of a ship is bound, as well by the duty he owes to his employers and to those on board his ship, as by positive rule, to keep a proper watch at sea, especially in channels much frequented by shipping, and to use every precaution to avoid coming into contact with other vessels. In order still better to provide against danger, and to obviate disputes, the Trinity House promulgated, on the 80th of October, 1840, the following Rule of Navigation:

Rule of Navigation issued by the Trinity House.—The attention of this Corporation having been directed to the numerous severe, and in some instances fatal, accidents which have resulted from the collision of vessels navigated by steam, and it appearing to be indispensably necessary, in order to guard against the recurrence of similar calamities, that a regulation should be established for the guidance and government of persons intrusted with the charge of such vessels; and whereas, 1. The recognized rule for sailing vessels is, that those having the wind fair shall give way to those on a wind; that when both are going by the wind, the vessel on the starboard tack shall keep her wind, and the one on the larboard tack bear up strongly, passing each other on the larboard hand; that when both vessels have the wind larboard or abeam, and meet, they shall pass each other in the same way on the larboard hand, to effect which two last-mentioned objects the helm must be put to port; and as steam vessels may be considered in the light of vessels navigating with a fair wind, and should give way to sailing vessels on a wind of either tack, it becomes only necessary to provide a rule for their observance when meeting other steamers, or sailing vessels going large.

Under these considerations, and with the object before stated, this Board has deemed it right to frame and promulgate the following rule, which, on communication with the Lords Commissioners of the Admiralty, the Elder Brethren find has been already adopted in respect of steam vessels in her majesty's service; and they desire earnestly to press upon the minds of all persons having charge of steam vessels the propriety and urgent necessity of a strict adherence thereto; viz., 1. **Rule for Steam Vessels on different Courses.**—When such vessels meet (whether or not necessarily cross so near that, by continuing their respective courses, there would be a risk of their coming in collision, each vessel shall put her helm to port, so as always to pass on the larboard side of each other. A steam vessel passing another in a narrow channel must always leave the vessel she is passing on the larboard hand. **By order,**

J. HENREY, Secretary.

TRINITY HOUSE, London, 30th October, 1840.

It may, however, be proper to state that neither this nor any rule of the sort is to be regarded as inflexible, or to be followed at all hazards. The safety of the ship is the paramount consideration, and no master is justified in abiding by a rule, when by doing so he plainly incurs danger. A. may be in his proper course, but if by pursuing it he will run a great risk of coming into collision with B., who is upon a wrong course, he is bound to alter his course so as to avoid a collision. The fact of one master being ignorant, careless, or in fault, is no reason why another should not use every means in his power to provide for the safety of his ship, and, consequently, of the lives and property intrusted to his care.

The conditions under which cases of collision take place differ extremely. Thus, 1st. It may be merely accidental, or be occasioned by circumstances beyond the power of control, as by the violence of the wind or waves dashing or impelling the ships together, without blame being imputable to either party; or, 2d. It may be owing to the culpable negligence or misconduct of one party; or, 3d. Both parties may be to blame. In adjudicating upon losses growing out of collisions that have taken place under such different circumstances, the conclusions must also be very different.

With respect to the first class of cases there is little apparent difficulty: wherever a loss is occasioned by a storm, a fog, or other accidental circumstance without any blame being ascribable to either party it would appear to be equitable that it should be borne by the sufferer. And this principle having been embodied in the Roman law, was subsequently ingrafted into that of England.—MARSHALL on Insurance, cap. 17, § 2. But other authorities, to whom the greatest deference is due, contend that the loss arising from accidental collisions, however it may affect the parties, should be equally divided between them; and this is the rule followed in most maritime states.—Ordinance of 1681, lib. iii. tit. xii. art. 10, with the observations of Valin. It also is the rule sanctioned by the law of England in cases where both parties are to blame, but where the blame can not be discriminated. Those cases in which the blame is clearly ascribable to either party present no difficulty.

The leading doctrines of the law of England with regard to collisions have been clearly and succinctly stated by Lord Stowell. "In the first place," says his lordship, "a collision may happen without blame being imputable to either party, as when the loss is occasioned by a storm or any other *vis major*. In that case the misfortune must be borne by the party on whom it happens to light; the other not being responsible to him in any degree. Secondly, a misfortune of this kind may arise where both parties are to blame, where there has been a want of due diligence or of skill on both sides; in such a case the rule of law is, that the loss must be apportioned between them, as having been occasioned by the fault of both of them. Thirdly, it may happen by the misconduct of the suffering party only; and then the rule is, that the sufferer must bear his own burden. Lastly, it may have been the fault of the ship which ran the other down, and in this case the innocent party would be entitled to an entire compensation from the other."—2 DUNSON'S Admiralty Reports, 83.

We may add that the rule of the equal division of the damage where both vessels are to blame has been, since Lord Stowell's time, fully recognized and finally established by a decision of the House of Lords, on an appeal from Scotland.

Various authorities have spoken disparagingly of the rule now referred to, and have called it a *judicium rusticorum*; and it would, no doubt, be very desirable in cases of collision where both parties are to blame, that the neglect or culpability of each should be accurately determined, and the damages assessed accordingly. But from the obscurity in which such cases are

almost always involved, and the conflicting testimony brought forward by the different parties, the difficulties in the way of this being done are usually quite insuperable; and it is better to adopt a rule which, though perhaps less equitable in principle, is fair in its application than any other that could be adopted. Of its expediency there can, indeed, be no reasonable doubt. The observations of Valin are, in this respect, quite conclusive. "C'estoit," says he, "le moyen le plus propre à rendre les capitaines ou maîtres des navires extrêmement attentifs à éviter tout abordage, surtout ceux des bâtimens foibles et plus susceptibles d'être incommodés par le moindre choc, en leur rendant toujours présent la crainte de supporter la moitié du dommage qu'ils en pourroient recevoir. Et si l'on dit qu'il auroit été plus simple et plus court de laisser pour le compte particulier d'un chacun le dommage qu'il auroit reçu, comme provenant d'un cas fortuit; la réponse est qu'alors les capitaines des gros navires n'auroient plus craint de heurter les bâtimens d'un beaucoup moindre force que les leurs: rien de plus juste que la contribution par moitié."—*Commentaire sur l'Ordonnance de 1681*, li. 179, ed. 1776.

In apportioning the damage in cases where both parties have been in fault, the question occurs, whether the damage done to the cargo shall be taken into account or left out in the estimate on which the apportionment is to be made. This knotty point has been differently decided in different countries. But the rule which limits the liability of owners to the value of the ship and freight applies to cases of damage by collision. For further observations on this curious and important subject, in addition to Valin and the other authorities already referred to, the reader may consult the chapter on collision added by Mr. Serjeant Shee to his edition of Lord Tenterden's work on the Law of Shipping, and the chapter on the same subject in Maude and Pollock's Treatise on the Law of Merchant Shipping.

Number of Collisions at Sea.—A statement has been prepared by Mr. John A. Rucker, underwriter, giving a classification of the number of collisions at sea reported in Lloyd's lists during the five years from 1845 to 1849 inclusive. It thence appears that the annual numbers were 608, 564, 699, 633, and 565; so that there was a decrease in 1849, notwithstanding the increased traffic of that year. The total collisions of the five years amounted to 3064. Of these 279 were cases in which a vessel was sunk, run down, or abandoned; 189 were cases in which there was serious damage; 686 in which the damage, although less, was still considerable; and 1910 in which it was only slight. The average of steamers in contact with steamers during each year is about 11; of steamers in contact with sailing vessels about 37; of sailing vessels in contact with steamers 36; and of sailing vessels in contact with sailing vessels 593. Since that time the number of collisions has been increasing; and in the years 1855 and 1856 they have been particularly large in number; and attended with great loss of life, especially in the cases of the *Arcité*, the *Pacific*, and the *Lynnaia*.

Colchicum Autumnale (*Meadow Saffron*, or *Autumn Crocus*), a plant of the natural order *Melantheraceæ*, is largely collected for medicinal use in England. Its infusion is well known as a powerful remedy for gout, and has long been celebrated in France under the name of *Eau Médicinale*. The cornus or bulb, and also the seeds, are used in medicine, and have a strong, persistent, bitter taste. Its medicinal virtues appear to be derived from a peculiar alkaloid, which has been termed *colchicina*. The best preparation is the wine of colchicum, prepared by digesting eight ounces of the seeds in forty ounces of sherry for about a week, shaking the vessel daily, and pressing out the liquor. The usual dose is from ten to fifty drops taken in water. It possesses intense activity as a poison. The plant derives its name from Colchia, in Armenia, where it is

Colocynthis, Coloquintida, or Bitter Cucumber (Germ. *Koloquinten*; Du. *Bitter-appelen*; Fr. *Coloquintes*; It. *Coloquintida*; Sp. *Coloquintidas*; Arab. and Pers. *Hunzil*), the produce of an annual plant (*Cucumis colocynthis*, Linn.), growing in Turkey, Nubia, India, and other places, much resembling the cucumber in herbage. When ripe, the fruit is peeled and dried in a stove, and in this state is brought to England. It is an exceedingly powerful drastic cathartic. When it is larger than a St. Michael's orange, and has black acute-pointed ends, it is not good.—AINSLIE's *Materia Medica*.

Cologne (Ger. *Köln*; ancient *Agrippina colonia*), a fortified city of Western Germany, formerly capital of electorates, now capital of Rhenish Prussia, on the left bank of the Rhine, across which a bridge of boats connects it with its suburb, Deutz, 45 miles north-west of Coblenz. Lat. of cathedral 50° 56' 29" N., long. 6° 57' 52" E. Population 78,500. It communicates by railroad with Hamm, Bonn, Aix-la-Chapelle, Mechin, and has extensive passage traffic with steam-packets on the Rhine. It has manufactures of cotton-yarn and stuffs, silk fabrics, velvets, woolen cloths, hosiery, lace, cordage, tobacco, hats, wax-lights, starch, needles, clocks, gold and silver articles, viuegar, sealing-wax, earthen and lacquered wares, and twenty-four factories of *Eau de Cologne*. Its position gives it an extensive and increasing trade between Germany and the Netherlands, and under the French it was the capital *dépot* of Roër. Population of arrondissement in 1849, 437,390.

Colonies; Colony Trade. *Colonies* are establishments founded in foreign countries by individuals who either voluntarily emigrate from, or are forcibly sent abroad by, their mother country. The *colony trade* is the trade carried on between colonies and their parent states.

1. ESTABLISHMENT OF COLONIES. *Greek Colonies.*—Various motives have, in different countries and ages, led to the formation of colonies. The Greek colonies of antiquity seem to have been chiefly founded by citizens whom the violence and fury of contending factions forced to leave their native land; but they were sometimes formed for the purpose of relieving the mother country of a redundant population, and sometimes also for the purpose of extending the sphere of commercial transactions, or of providing for their security. The relations between the mother country and the colony depended, in a great measure, on the motives which led to the establishment of the latter. When a colony was founded by fugitives forcibly expelled from their ancient homes; or when it was founded, as was frequently the case, by bodies of voluntary emigrants, who received no assistance from, and were in no respect controlled by, the parent state, it was from the first independent; and even in those rarer cases in which the emigration was conducted under the superintendence of the parent city, and when the colony was protected by her power and influence, the dependence was mostly far from being absolute and complete. The great bulk of the Greek colonies were really independent states; and though they commonly regarded the land of their forefathers with filial respect, though they yielded to its citizens the place of distinction at public games and religious solemnities, and were expected to assist them in time of war, they did so as allies only, on fair and equal terms, and never as subjects. Owing to the freedom of their institutions, and their superiority in the arts of civilized life to the native inhabitants of the countries among whom they were generally placed, these colonies rose in a comparatively short period to a high pitch of opulence and refinement; and many among them, as Miletus and Ephesus in Asia Minor, Syracuse and Agrigentum in

Sicily, and Tarentum and Locri in Italy, not only equaled, but greatly surpassed, their mother cities in wealth and power.

Roman Colonies.—The Roman colonies were for the most part founded by and under the authority of government; being intended to serve both as outlets for poor and discontented citizens and as military stations or garrisons, to secure the subjection of the conquered provinces over which they were scattered. The most intimate political union was always maintained between them and the mother city. Their internal government was modeled on that of Rome; and, while their superior officers were mostly sent from the capital, they were made to contribute their full quota of troops and taxes, to assist in carrying on the contests in which the Republic was almost constantly engaged.

Spanish Colonies.—The early colonies of most modern nations were founded by private adventurers, influenced either by the hope of gain or by a desire to escape from religious persecution, without any wish to relieve the mother country of a surplus population or to bridle subjugated provinces. On their first institution, therefore, the modern colonies approached, though with some essential variations, more nearly to the Grecian than the Roman model; but the period of their freedom was of very limited duration. They were very soon subjected to laws and regulations framed in the metropolis, and calculated, as was to be supposed, rather to promote its interests than those of the colony. At a somewhat later period the foundation of colonial establishments was eagerly patronized by most European governments, in the view of extending commerce and of enriching the mother country, by securing to her the exclusive possession of the market of distant countries; and where, from the thinness of the aboriginal population, or their inferiority in the arts of civilized life, the colonists were enabled to reap success fortunes with comparative rapidity. The Spaniards who first resorted to America after its discovery had no intention of settling in the country, or of colonizing it. The idea that gold and silver alone constituted wealth was then universally prevalent; and the bold and enterprising companions and followers of Columbus, instead of engaging in industrious undertakings, which they neither understood nor relished, sought only to enrich themselves by plundering the feeble and defenseless natives of the gold and silver in their possession, and of the abundance of which the most exaggerated accounts were immediately spread throughout Europe. When new adventurers arrived on an unknown coast, their single inquiry was, whether it abounded in gold. If it did, they remained, for some time at least, in the country; if not, they immediately set sail for some other quarter. *Auri rabida sitis a cultura Hispanos divertit*, is the expressive statement of a contemporary writer (Petrus Martyrus, in the *Novus Orbis* of Grynaeus, p. 511). The slow progress of the Spanish colonies after their first discovery must principally be ascribed to this cause. The gold and silver accumulated by the natives were very soon exhausted; and the skill and energy of the successive swarms of adventurers, who continued to pour into the country, were principally directed to the unproductive and generally ruinous trade of mining. The few large fortunes that were made in this way, like the large prizes in a lottery, inflamed the cupidity of the multitude, and gave an appearance of credibility to the fabulous accounts of the excessive productiveness of the mines. After the gambling spirit which had exclusively actuated the early adventurers had begun to subside, the colonists gradually betook themselves to agricultural and commercial pursuits; and the vast variety of valuable productions with which Mexico and the other Spanish colonies abounded, the extreme richness of the soil, and their advantageous situation, would, had they been only tolerably well governed, have occasioned their rapid increase in wealth and civilization. But

a blind and intolerant despotism paralyzed their energies, and fettered and retarded their progress. All the abuses and defects of the government of Old Spain were transferred to, and multiplied in, the colonies. The whole property of those vast regions was considered as vested in the crown of Spain; and every law or regulation, whether of a local or general nature, affecting their government, emanated from the council of the Indies, in which it was supposed the king was always present. We can not stop to describe the sort of regulations to which the colonists were subjected with any degree of minuteness; but we may notice a few of them, to furnish the means of judging of their general spirit and probable effect. It was, for example, made a capital offense to carry on any intercourse with foreigners; and the inhabitants of the different colonies were even forbidden any intercourse with each other, unless under the strictest and most vexatious regulations. There were several articles, such as flax, hemp, and wine, which they were not permitted to cultivate; at the same time that the crown reserved to itself the monopoly of salt, tobacco, gunpowder, and some other less important articles. The alcavala, and other oppressive imposts, which had proved destructive of industry in Old Spain, were rigorously levied as well on the exports as on the imports of the colonies. No situation of power or ennoblement could be filled except by a native of Old Spain. The Catholic religion was established, to the exclusion of every other; and bishops, tithes, and the Inquisition followed in its train: while, in order still better to consolidate and strengthen the foundations of this monstrous despotism, the government endeavored to make the colonists insensible of their degradation, by proscribing every species of instruction, and watchfully opposing the introduction and progress of all useful knowledge. Under such circumstances, we can not be surprised that the continental colonists, among whom the monopoly system was maintained in its greatest purity, should have languished for above two centuries in a state of sluggish inactivity. Though surrounded by all the means of producing wealth, they were not generally wealthy. Oppression rendered them indolent; and went far to deprive them not only of the power, but also of the wish, to emerge from poverty. The progress of the colonists who occupied the West India Islands was not quite so slow. It is certain, however, that, down to the middle of last century, Spain reaped no greater advantage from the possession of Cuba, Hispaniola, and Porto Rico, than England or France from the smallest of its dependencies. In proof of this we may mention that the noble island of Cuba, which could without difficulty supply all Europe with sugar, did not, in 1750, produce a sufficient quantity even for the consumption of Old Spain. But the combined influence of an arbitrary and intolerant government, and of a degrading superstition, could not balance the means of improvement which the fertility of the soil, and the command thence arising over most of the necessaries and many of the conveniences of life, gave to the colonists. Owing also to the total incapacity of Old Spain to furnish her transatlantic provinces with a sufficient supply of the articles she had forced them to import from Europe, and the consequent extension of the contraband trade carried on with them by the other European nations, she had been compelled gradually to relax the severity of her commercial monopoly. A new impulse was thus given to the spirit of industry. The colonists began to be more sensible of the natural advantages of their situation, and less inclined to submit to the blind and bigoted policy of the Spanish court. In 1781, a rebellion broke out in Peru, in consequence of an attempt made by the government to establish a new monopoly in that province, which threatened to end in the total dissolution of the connection between Spain and South America, and was not quelled without great difficulty and much blood-

shed. But the spirit of liberty, when once excited, could not be suppressed. It continued to gain ground progressively, until the commencement of the last contest between France and Spain interrupted the communication with the mother country, and gave the colonists an opportunity of proclaiming that independence which, after a lengthened and bloody struggle, they happily succeeded in achieving.

British Colonies.—The English, who, like all the other nations of Europe, had been impressed with mingled feelings of admiration and envy by the extent and importance of the acquisitions made by the Spaniards in the New World, speedily entered with enthusiasm and ardor into the career of discovery. Owing, however, to the bull which Ferdinand and Isabella had obtained from the Pope, conveying to them the ample donation of all the countries inhabited by Infidels that the Spaniards had discovered or might discover, the English, to avoid encroaching on the dominions of their rivals, directed their efforts farther to the north. Several attempts to found colonies on the coast of America were made in the reign of Elizabeth by Sir Humphrey Gilbert, Sir Richard Grenville, Sir Walter Raleigh, and others. But in consequence of their ignorance of the country, the deficiency of their supplies of provisions, the loss of time in fruitless searches after gold, and the various difficulties incident to the first settlement of a colony, none of these attempts proved successful; and it was not until 1607 that a small body of adventurers founded the first permanent establishment of the English in America, at Jamestown, in Virginia. Letters patent were granted in 1609 by King James to the principal persons resident in London, by whom the expense attending the formation of the colony was to be defrayed, incorporating them into a company, and establishing a council in England for the direction of their proceedings, the members of which were to be chosen by, and removable at the pleasure of, the majority of the partners of the company; permitting whatever was necessary for the support and sustenance of the colony for the first seven years to be exported free of duty; declaring that the colonists and their descendants were to be secured in all the rights and privileges of Englishmen, the same as if they had remained at home or been born in England; and reserving only, as the stipulated price of these concessions, and in imitation of the policy of the Spaniards, one-fifth part of the gold and silver ore to be found in the colonies, which was to be paid to his Majesty and his successors in all time to come. In virtue of these powers, the company issued, in 1621, a charter or ordinance, which gave a legal and permanent form to the constitution of the colony. By this charter the supreme legislative authority was lodged, partly in the governor, who held the place of the sovereign, partly in a council of state named by the company, and partly in a general council or assembly composed of the representatives of the people, in which were vested powers and privileges similar to those of the House of Commons. It was not long, however, before the king and the company quarrelled. The latter were in consequence divested of all their rights, partly by open violence, and partly under color of law, without compensation, after having expended upward of £150,000 in founding the colony; and a governor and council of state appointed by the king succeeded to the powers of those appointed by the committee.—ROBERTSON'S *History of America*, book ix. *passim*; JEFFERSON'S *Notes on Virginia*, p. 179.

The founders of the colony in Virginia had been actuated solely by the hopes of gain; but the colonies that were soon after established in New England were chiefly planted by men who fled from religious and political persecution. The form of government in the New England colonies, though at first modified a good deal by the peculiar religious opinions entertained by the colonists, was in its leading principles essentially free. For a considerable period the colonists elected

their most whole and their lower glundling as vorities of the Mary, the W of governists thusing to quite internic colonies represent shall I lantly their ce guarde ginia, M the sun that the lie of N populat the hist colonies of the K ed value of to al It is example America under s colonists and scie ple. their own governors, coined money, and exercised most of the rights of sovereignty; while the English, wholly engrossed with the contest between freedom and prerogative at home, had no leisure to attend to their proceedings. Subsequently to the Restoration, however, the governments of most of the New England States were established nearly on the same footing as that of Virginia; which, indeed, became the favorite model, not only for the constitution of the colonies established on the continent, with the exception of the proprietary governments of Pennsylvania and Maryland, but also for those that were established in the West India Islands. But under every vicissitude of government and fortune, the New England colonists were distinguished by the same ardent and enthusiastic love of liberty that had first induced them to quit their native land. Every thing relating to the internal regulation and administration of the different colonies was determined, in the colonial assemblies, by representatives freely chosen by the settlers. The personal liberty of the citizens was well secured and vigilantly protected. And, if we except the restraints on their commerce, the monopoly of which was jealously guarded by the mother country, the inhabitants of Virginia, Pennsylvania, and New England enjoyed nearly the same degree of freedom when colonists of England that they now enjoy as citizens of the powerful republic of North America. Their progress in wealth and population was in consequence quite unprecedented in the history of the world. The white population of the colonies had increased in 1776, at the commencement of the Revolutionary war, to above 2,000,000, and the value of the exports from Great Britain to them amounted to about £1,300,000 a year!

It is not difficult to discover the causes of the unexampled prosperity and rapid growth of our North American colonies, and generally of all colonies placed under similar circumstances. The North American colonists carried with them a knowledge of the arts and sciences practised by a civilized and polished people. They had been trained from their infancy to habits of industry and subordination. They were practically acquainted with the best and wisest form of civil polity that had been established in Europe; and they were placed in a situation that enabled them, without difficulty, to remedy its defects, and to try every institution by the test of utility. But the thinness of the aboriginal population, and the consequent facility of obtaining inexhaustible supplies of fertile and unoccupied land, must certainly be placed at the head of all the causes which have promoted the rapid increase of wealth and population in the United States, and in all the other colonies both of North and South America. On the first foundation of a colony, and for long after, each colonist gets an ample supply of land of the *best quality*; and having no rent, and scarcely any taxes, to pay, his industry necessarily becomes exceedingly productive, and he has every means and every motive to amass capital. In consequence, he is eager to collect laborers from all quarters, and is both willing and able to reward them with high wages. But these high wages afford the means of accumulation, and, joined to the plenty and cheapness of the land, speedily change the more industrious laborers into proprietors, and enable them, in their turn, to become the employers of fresh laborers; so that every class participates in the general improvement, and capital and population advance with a rapidity hardly conceivable in old-settled and fully-peopled countries.

It has been frequently said that the establishment of the British American and West India colonies was a device of the supporters of the exclusive or mercantile system—that they founded them in the view of raising up a vast agricultural population, whose commerce should be confined entirely to an exchange of raw products for other manufactured goods. There is, however, no truth in these assertions. On the con-

trary, the charters granted to the founders of the settlement in Virginia distinctly empower the colonists to carry on a direct intercourse with foreign states. Nor were they slow to avail themselves of this permission; for they had, so early as 1620, established tobacco warehouses in Middleburg and Flushing; and the subsequent proceedings of the British government depriving them of this freedom of commerce, were the chief cause of those disputes which broke out in 1676, in an open rebellion of ominous and threatening import.—*Rosenkrantz's America*. It was not until the colonists had surmounted the difficulties and hardships incident to their first establishment, and had begun to increase rapidly in wealth, that their commerce became an object of importance, and that regulations were framed in the view of restricting its freedom, and of rendering it peculiarly advantageous to the mother country. The act of 1650, passed by the republican Parliament, laid the first foundations of the monopoly system, by confining the import and export trade of the colonies exclusively to British or colony built ships. But the famous Navigation Act of 1660 (12 Charles II. c. 18) went much farther. It enacted that certain specified articles, the produce of the colonies, and since well known in commerce by the name of *enumerated* articles, should not be exported directly from the colonies to any foreign country; but that they should first be sent to Britain, and there laden (the words of the act are, *laid upon the shore*) before they could be forwarded to their final destination. Sugar, molasses, ginger, fustic, tobacco, cotton, and indigo, were originally enumerated; and the list was subsequently enlarged by the addition of coffee, hides and skins, iron, corn, lumber, &c. In 1739, the monopoly system was so far relaxed that sugars were permitted to be carried directly from the British plantations to any port or place southward of Cape Finisterre; but the conditions under which this indulgence was granted continued so strict and numerous down to 1803, when they were a good deal simplified, as to render it in a great degree nugatory (*Edwards's West Indies*); and with this exception, the oppressive and vexatious restrictions on their direct exportations to foreign countries were maintained on most of the other *enumerated* commodities of any importance down to a late period.

But besides compelling the colonists to sell their produce exclusively in the English markets, it was next thought advisable to oblige them to buy such foreign articles as they might stand in need of entirely from the merchants and manufacturers of England. For this purpose it was enacted, in 1663, that "no commodity of the growth, production, or manufacture of Europe shall be imported into the British plantations but such as are laden and put on board in England, Wales, or Berwick-upon-Tweed, and in English-built shipping, whereof the master and three-fourths of the crew are English." The preamble to this statute, which effectually excluded the colonists from every market for European produce, except that of England, assigns the motive for this restriction to be, "the maintaining a greater correspondence and kindness between the subjects at home and those in the plantations; keeping the colonies in a firmer dependence on the mother country; making them yet more beneficial to it, in the further employment and increase of English shipping, and the vent of English manufactures and commodities; rendering the navigation to and from them more safe and cheap; and making that kingdom a staple, not only of the commodities of the plantations, but also of the commodities of other countries and places for their supply, it being the usage of other nations to keep their plantation trade exclusively to themselves." It was also a leading principle in the system of colonial policy, adopted as well by England as by the other European nations, to discourage all attempts to manufacture such articles in the colonies as could be provided for them by the mother country. At the beginning of the Revolution the Southern colonies had, therefore, 812,000 white inhabitants, and the Northern 1,491,000. Connecticut was the fourth State in rank. Massachusetts and Pennsylvania were each a third larger than New York, which was even exceeded by Connecticut.—United States Census Report, 1850.

II. MAGNITUDE OF THE BRITISH COLONIES.—Notwithstanding the loss of the United States, the colonies of Great Britain, exclusive of India, exceed in number, extent, and value, those of every other country. Previously, indeed, to the breaking out of the late contest, the colonial dominions of Spain far exceeded in extent and importance those of any other power. But Cuba, Porto Rico, and the Philippine Islands are now all that remain to her. These, indeed, are very valuable possessions, though inferior to those of England.

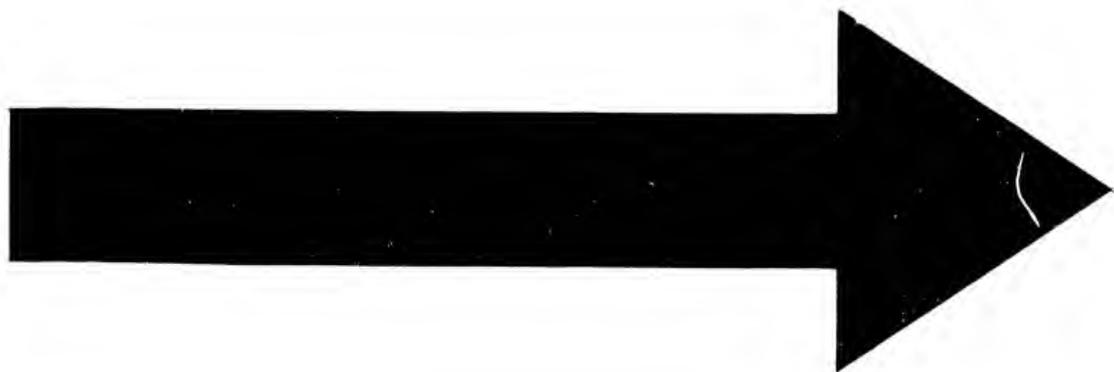

North American Colonies.—In North America, Great Britain possesses the provinces of Lower and Upper, or of East and West Canada, Nova Scotia, New Brunswick, Prince Edward's Island, and their dependencies. The situation and boundaries of these provinces will be more easily learned from the inspection of the map than they could be from any description. The shores of Nova Scotia and New Brunswick are washed by the Atlantic Ocean; and the noble River St. Lawrence, by its communication with the great American lakes, gives to Canada all the benefits of a most extensive inland navigation, and forms a natural outlet for her surplus produce, as well as for the surplus produce of that part of the United States which is washed by the lakes. There is every variety in the soil and climate of these regions. In Lower Canada the winter is very severe. The surface of the country is covered with snow for nearly half the year. From the beginning of December to the middle of April the St. Lawrence is frozen over, and affords a smooth and convenient passage for the sledges by which it is then covered. But though severe, the climate is far from being unhealthy or disagreeable. The weather is generally clear and bracing; and the labor of artisans, at their out-door employments, is rarely suspended for many days in succession. On the breaking up of the ice in the latter end of April or the beginning of May, the powers of vegetation almost immediately resume their activity, and bring on the fine season with a rapidity that is astonishing to a stranger. The highest temperature in Lower Canada varies from 96° to 102° of Fahrenheit; but the purity of the atmosphere alters the oppressive heat that is felt in most countries where the mercury ranges so high; and the weather is, on the whole, decidedly pleasant. That part of the province of Upper or West Canada which stretches from Lake Simcoe and the Rivers Trent and Severn, westward to Lake Huron and the St. Clair River, and southward to Lake Erie and part of Lake Ontario, has a soil of extraordinary fertility, capable of producing luxuriant crops of wheat and every sort of grain. "The climate," says Mr. Bonchette, late surveyor general of Lower Canada, "is so particularly salubrious, that epidemic diseases, either among men or cattle, are almost entirely unknown. Its influence on the fertility of the soil is more generally perceptible than it is in Lower

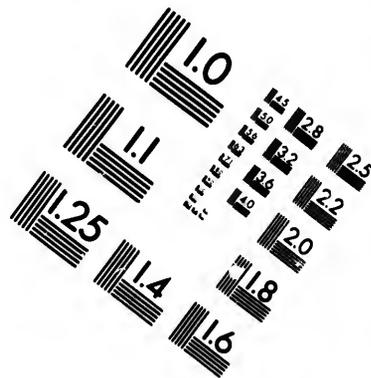

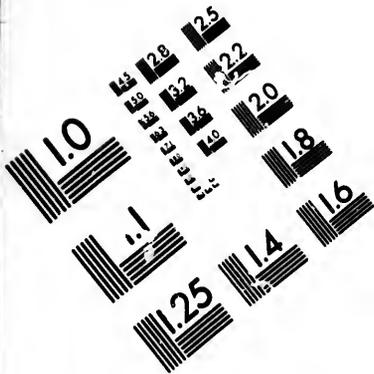

(Canada, and is supposed to be congenial to vegetation in a much superior degree. The winters are shorter, and not always marked with such rigor as in the latter. The duration of frost is always accompanied with a fine clear sky and a dry atmosphere. The spring opens, and the resumption of agricultural labors takes place, from six weeks to two months earlier than in the neighborhood of Quebec. The summer heats rarely prevail to excess, and the autumns are usually very friendly to the harvests, and favorable for securing all the late crops."—BOUCHETTE'S *Topographical Description of Canada*, p. 595. The ground on the shores of Lake Ontario and Lake Erie, as far west as the junction of the Thames with the St. Clair Lake, is laid out in townships, and partly settled. But the population is still very thin. To the north of the River Thames, along the banks of the St. Clair and the shores of Lake Huron, round to the River Severn, and thence to the river that joins Lake Nipissing and Lake Huron, is a boundless extent of country that is almost entirely unoccupied. The interior of this space has hitherto been but imperfectly explored; but the banks of the St. Clair and the shores of Lake Huron afford the finest situations for settlements. The soil is in many places of the greatest fertility, the river and lake teem with fish, and every variety of the best timber is found in the greatest profusion. The winters in the provinces of Nova Scotia, Prince Edward's Island, and New Brunswick are more severe than in Upper Canada, and they are a good deal infested with fogs and mists; but their proximity to England, and their favorable situation for the fishing business, give them considerable advantages. In addition to the above, Great Britain possesses the Hudson's Bay territory, a tract of vast extent, but situated in an inhospitable climate, and worth very little except as hunting-grounds. She also possesses the large islands of Newfoundland and Cape Breton, the latter being a dependency of Nova Scotia; but their soil is barren, and the climate severe and foggy; so that they are valuable principally as fishing stations. The following table exhibits the population of the different North American colonies at the under-mentioned epochs:

Colonies.	Population.	Date of Census.
Eastern (Lower) Canada.....	1,048,000	1854
Western (Upper) Canada.....	1,300,000	1854
New Brunswick.....	190,800	1851
Prince Edward's Is. and C. Breton.....	62,034	1849
Newfoundland.....	90,606	1845
Nova Scotia.....	270,117	1850

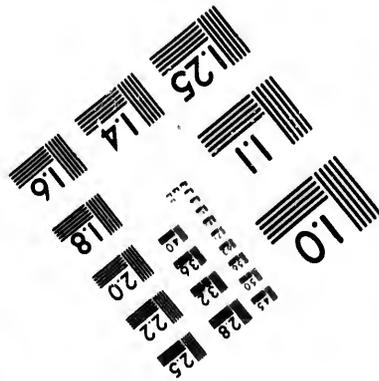

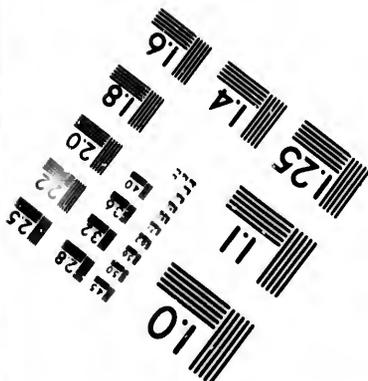

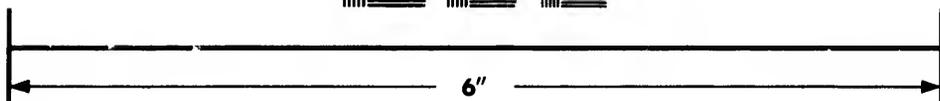

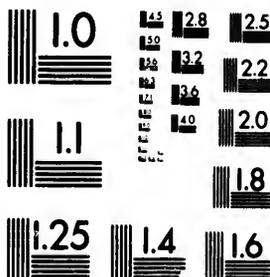

Of the inhabitants of Lower Canada in 1844, no fewer than 518,565 were of French extraction, forming what is called the *Nation Canadienne*. In Upper Canada, on the other hand, the population is almost wholly of British origin.

West India Colonies.—In the West Indies the English possess Jamaica, Barbadoes, St. Lucia, Antigua,

Grenada, Trinidad, and some other islands, besides Demerara and Berbice in South America. Jamaica, by far the largest and most valuable of her insular possessions, is about 120 miles in length and 40 miles in mean breadth, containing about 2,800,000 acres, of which from 1,100,000 to 1,200,000 are supposed to be in cultivation. Being situated within the tropic of Cancer, the heat in the West Indies is intense, but is moderated by the sea-breeze which blows regularly during the greater part of the day. The rains make the only distinction of seasons. They sometimes fall with prodigious impetuosity, giving birth to innumerable torrents, and laying all the low country under water: the trees are green the whole year round: they have no snow, no frost, and but rarely some hail. The climate is very humid; iron rusts and corrodes in a very short time; and it is this, perhaps, that renders the West Indies so unfriendly to European constitutions, and produces those malignant fevers that are so very fatal. The vegetable productions are numerous and valuable; but the sugar-cane and the coffee-plant are incomparably more important than the others, and constitute the natural riches of the islands.

The West Indies are occasionally assailed by the most dreadful hurricanes, which destroy in a moment the hopes and labors of the planters, and devastate entire islands. Whole fields of sugar-canes are sometimes torn up by the roots, houses are either thrown down or unroofed, and even the heavy copper boilers and stills in the works have, in numerous instances, been wrenched from the ground and battered to pieces. The rain pours down in torrents, sweeping before it every thing that comes in its way. The destruction caused by such dreadful scourges seldom fails to produce a very great scarcity, and not unfrequently famine; and we are grieved to have to add, that the severity of the distress has on several occasions been materially aggravated by a refusal on the part of the authorities to allow importation direct from the United States! This was the case at Dominica so late as 1817. "It is stated in a report by a committee of the Assembly of Jamaica, that 15,000 negroes perished between the latter end of 1780 and the beginning of 1787, through famine occasioned by hurricanes and the prohibition of importation from the United States."—Edwards's *West Indies*, vol. ii. p. 516.

Jamaica was discovered by Columbus in 1494, and continued in possession of the Spaniards till 1655, when it was wrested from them by the English. Although it had thus been for more than a century and a half under the power of Spain, such was the deadening influence of her colonial system, that it did not, when it was conquered, contain 1600 white inhabitants, and these were immersed in sloth and poverty. Of the many valuable articles which Jamaica soon after produced in such profusion, many were then altogether unknown; and of those that were known, such a supply only was cultivated as was required for the consumption of the inhabitants. "The Spanish settlers," says Mr. Bryan Edwards, "possessed none of the elegancies of life; nor were they acquainted even with many of those gratifications which, in civilized states, are considered necessary to its comfort and convenience. They were neither polished by social intercourse nor improved by education; but passed their days in gloomy languor, enfeebled by sloth and depressed by poverty. They had been for many years in a state of progressive degeneracy, and would probably in a short time have expiated the guilt of their ancestors by falling victims themselves to the vengeance of their slaves."—*History of the West Indies*, vol. i. p. 297, 8vo ed.

For a considerable number of years after England obtained possession of Jamaica, the chief exports were cocoa, hides, and indigo. Even so late as 1772, the exports of sugar amounted to only 11,000 hogsheads. In 1774 they had increased to 78,000 hogsheads of

sugar, 26,000 puncheons of rum, and 6547 bags of coffee. The American war was very injurious to the West India settlements; and they may, indeed, be said to be still suffering from its effects, as the independence of America led to the enactment of those restrictions to the importation of food, lumber, &c., that were so very hurtful to the planters. In 1780 Jamaica was visited by a most destructive hurricane, the devastation occasioned by which produced a dreadful famine; and other hurricanes followed in the immediately succeeding years. But in 1787 a new era of improvement began. The devastation of St. Domingo by the negro insurrection which broke out in 1792, first diminished, and in a few years almost entirely annihilated, the annual supply of 115,000 hogsheads of sugar, which France and the Continent had previously been accustomed to receive from that island. This diminution of supply, by causing a greatly increased demand for, and a consequent rise in the price of, sugar raised in the other islands, occasioned an extraordinary extension of cultivation. So powerful in this respect was its influence, that Jamaica, which at an average of the six years preceding 1790 had produced only 83,000 hogsheads, exported in 1801 and 1802 upward of 286,800 hogsheads, or 143,000 a year!

The same rise of price, which operated so powerfully in Jamaica, occasioned a similar though less rapid extension of cultivation in other islands, and in Cuba, Porto Rico, and the foreign colonies generally. The vacuum caused by the cessation of the supplies from St. Domingo being thus more than filled up, a reaction commenced. The price of sugar rapidly declined; and, notwithstanding a forced market was for a while opened to it, by substituting it for malt in the distillery, prices did not attain to their former elevation. On the opening of the Continental ports, in 1813 and 1814, they, indeed, rose, for a short time, to an extravagant height; but they very soon fell, involving in ruin many of the speculators upon an advance. Prices, however, continued at a pretty high level down to 1818; but they sustained a material fall in the course of the following year, and were comparatively low from that period down to 1836, when the extraordinary falling off in the supplies of sugar consequent to the measures connected with the emancipation of the slaves again occasioned a considerable rise of price. But, as already seen, this high price was entirely factitious, being wholly caused by our excluding foreign sugar from our market. Now that the sugar of Brazil, Cuba, and Java is admitted on paying reasonable duties, prices are comparatively low. And from the extraordinary facility with which sugar may be raised in the countries referred to and elsewhere, we have no idea, provided they adopt no rash or ill-advised measures in relation to slaves, that its price in their markets would be likely to sustain any material or permanent increase, even though the demand for it were doubled or more. The imports to England of sugar from her West Indian colonies, which amounted to 4,103,800 cwts. in 1801, sunk, in 1841, to 2,151,217 cwts. In 1852 they amounted to 3,408,627 cwts.

The devastation of St. Domingo gave the same powerful stimulus to the growth of coffee in the other West Indian colonies that it did to the growth of sugar; and owing to the extraordinary increase in the demand for coffee in England and other European countries, the supply went on increasing till it was checked by the influence of the measures relating to slavery. In 1752, for example, only 60,000 lbs. of coffee were exported from Jamaica; in 1775 the export amounted to 440,000 lbs.; in 1797 it had increased to 7,031,621 lbs.; and in 1832, when it had attained its maximum, the exports to England only amounted to 19,405,033 lbs. Such, however, and so rapid has been their subsequent decline, that in 1852 the exports to England from Jamaica amounted to only 3,787,790 lbs.!

We have already seen that when Jamaica was taken

from the Spaniards it only contained 1500 white inhabitants. In 1678 the population amounted to 7768 whites, and 9504 slaves. It would have been well for the island and the races continued to preserve this relation to each other; but, unfortunately, the black population has increased more than five times as rapidly as the white; the latter having only increased from 7768 to about 80,000, while the former has increased from 9504 to about 810,000, exclusive of persons of color. The real value of the exports to Jamaica amounts to about £700,000 a year, being about one-third part of the exports to the West Indian colonies. It was formerly much more; but then a large portion of the articles sent to Jamaica, and some of the other colonies, were only sent there as to an *entrepôt*; being subsequently exported to the Spanish main. During the ascendancy of the Spanish dominion in Mexico and South America, this trade, which was then contraband, was carried on to a great extent. It is now much fallen off, and is principally carried on from St. Thomas and Honduras.

Barbadoes was the earliest English possession in the West Indies. It is the most easterly of the Caribbean islands; Bridgetown, the capital, being in long. 59° 41' W. Barbadoes is by far the best cultivated of all the West Indian islands. It contains about 105,000 acres, having (in 1852) a population of about 13,000 whites, 15,000 people of color, and 110,000 blacks. Of late years it has exported from 500,000 to 740,000 cwts. of sugar. Barbadoes had attained the acme of its prosperity in the latter part of the seventeenth century, when the white population is said to have amounted to about 50,000, though this is probably an exaggeration. But it is only as compared with itself that it can be considered as having fallen off; for, compared with the other West Indian islands, its superiority is manifest. It raises nearly as much food as is adequate for its supply. The islands next in importance are St. Vincent, Grenada, Trinidad, Antigua, &c. It is unnecessary to enter into any special details with respect to them, their population and trade being exhibited in the annexed tables. During the late war Great Britain took from the Dutch the settlements of Demerara, Berbice, and Essequibo, in Guiana, which were definitively ceded to them in 1814. The soil of these settlements is naturally very rich; and they have, in this respect, a decided advantage over most of the West Indian islands. Their advance was for a while very great, but recently their progress has been checked, and their exports have declined most materially. This, however, is entirely in consequence of the want of labor; for in other respects these colonies have every facility of production. Various schemes have been suggested for supplying this want; but none of them, unless they involve the principle of compulsory service, will, we apprehend, be successful. The rum of Demerara enjoys a high reputation. The best samples of Berbice coffee are very superior, and it used to be extensively cultivated both in that colony and in Demerara. In 1831 the exports amounted, from both colonies, to 8,576,744 pounds; but they have since declined to next to nothing, having amounted in 1852 to only 84,890 pounds. Considerable quantities of cotton were formerly exported from Guiana; but the Americans having superior facilities for its production, its culture has nearly ceased. Cocoa, annatto, &c., are produced, but not abundantly.

Exclusive of the above, the English possess the settlement of Balize, on the Bay of Honduras. This is of importance as affording a means of obtaining abundant supplies of mahogany; but it is of more importance as an *entrepôt* for the supply of Guatemala and Central America with English manufactured goods.

The exports from England to the West Indian colonies consist of coarse cottons, linens, checks, hats, and other articles of negro clothing; iron and steel, wrought and unwrought; leather, including saddlery and harness; glass; beer and ale; soap and candles; station-

ery; hardware and earthen-ware; staves, hoops, coal, lime, paint, lead; Irish provisions, herrings, and other salt fish; along with furniture, wine, beer, medicines, and indeed almost every article which a great manufacturing country can supply to one situated in a tropical climate, which has very few mechanics and hardly any manufactures. Since the opening of the ports on the Spanish Main to ships from England, the exports to the West Indies have decreased both in quantity and value; this decrease being, however, more than balanced by the increased shipments to Mexico, Colombia, &c. The declared or real value of the exports amounted, in 1852, to £2,081,556.

Money.—What used to be called West India currency was an imaginary money, and had a different value in different colonies. The value it bore, as compared with sterling money, was supposed to represent the corresponding value of the coins in circulation in the different islands at the time the proportion was fixed: these coins being for the most part mutilated and otherwise worn and defaced, currency was in all cases less valuable than sterling. The following are the old values of £100 sterling, and of a dollar, in the currencies of the different islands:

	Sterl.	Curr.	Dol.	Curr.
Jamaica.....	£100 =	£140	1 =	6s. 8d.
Barbadoes	£100 =	£185	1 =	6s. 3d.
Windward Islands (except Barbadoes).....	£100 =	£175	1 =	6s. 3d.
Leeward Islands.....	£100 =	£200	1 =	9s. 0d.

But latterly these currencies have been in great measure superseded by the introduction of sterling money, current at the same rates as in England, and of the Spanish dollar.

By an order in council of the 23d of March, 1825, British silver money was made legal tender throughout all British colonial possessions at the same nominal value as in England; and bills for the same are given on the treasury of London, of £100 each bill for £108 such silver money. By this order, also, the value of the Spanish dollar was fixed at 4s. 4d. British silver money throughout all the colonies where it is current; but this value was further reduced on the 21st of September, 1838, to 4s. 2d. The value of the doubloon was then also fixed at 6s.

Australian Colonies.—This group of colonies, though founded in a very distant part of the world, and at a comparatively recent epoch, will probably, at no very distant epoch, far surpass the others in magnitude and importance. The countries in which they are situated, including the great Australian continent, formerly called New Holland, with Van Diemen's Land or Tasmania, New Zealand, &c., are of vast extent, and differ in many respects from each other. Hitherto, also, by far the larger portion of the continent is wholly unexplored; and even the islands are but very imperfectly known. Enough, however, has transpired to show that this great division of the globe differs in some most important respects from most or all countries with which we were previously acquainted; and that it is, in fact, full of anomalies. The interior of the continent has not been sufficiently explored to enable any distinct opinion to be formed as to the height of the mountain chains; but it appears to be pretty well established that it has no great rivers, or at least none that reach the sea. Indeed, it seems, speaking generally, to be a law in this new world that rivers are largest near their source; and that they gradually diminish as they proceed, and most commonly dwindle into insignificance, or lose themselves in marshes, before they reach the ocean. In consequence, perhaps, of this singular constitution of its river system, it is found that in Australia the best land is not at the mouths, but toward the sources of the rivers. There are, no doubt, exceptions to this rule; but it appears to hold in the greater number of instances. Generally, also, the extent of fine land appears to be comparatively limited; and in so far as the continental portion of the country has been ex-

plored, it appears to be much better adapted for pasturage than for tillage.

Gold Deposits.—The land, the pasturage, the sheep, the copper and other ordinary minerals, which are found in abundance in various parts of Australia, have all been rendered, for the present at least, of no importance compared with the gold deposits with which the continent is so largely endowed. These, which were discovered so late as 1851, are of the most extraordinary richness. They exceed in productiveness not only the gold fields of California, but every thing, indeed, of which any idea could previously have been entertained. Australia has, in consequence, become an object of earnest and universal attention. An almost unparalleled amount of emigration has been directed to her shores. Her population and her trade are both increasing with gigantic strides; and her gold is influencing the wages, the prices, and the industry of every civilized people.—See art. AUSTRALIA and GOLD.

It were idle to indulge in speculations regarding the period when the exhaustion of the Australian gold fields may be expected; there are no data on which to hazard even a conjecture on such a subject. But whether the supplies from them be destined to be of long or short duration, they have already been, and no doubt will continue to be, of great advantage. We do not mean by this to say or insinuate that the good resulting from the influx of gold from Australia and California has been unaccompanied by any drawbacks. The gambling and dissipation to which it has given rise are obvious. But these, though considerable, are but a trifling deduction from its many advantages; from the powerful stimulus it has given to industry and civilization, from the new channels it has opened to commerce, and from its greedily ameliorating the condition of the laboring classes in this and most other countries.

The northern portion of Australia, including, perhaps, about a third part of the entire continent, lies between the tropics; the other portion of the continent, with the adjacent islands of Van Diemen's Land and New Zealand, being in the south temperate zone. The climate of the different parts of the continent must, therefore, it is obvious, differ very widely. We, however, know but little of the climate of intertropical Australia, except that it is within the range of the Indian monsoon; that the temperature along the coast is rapidly raised by a wind from the south, which has been supposed to afford a strong presumption of the existence of sandy deserts in the interior; and that the air is so very moist that during the season of the monsoon iron implements are with the utmost difficulty preserved from rusting. It is commonly said that the climate of extra-tropical Australia, and especially of New South Wales, assimilates closely to that of Southern Italy. But this statement must be taken with considerable limitation; for, 1st. The atmosphere is very decidedly denser; 2d. The extremes of temperature are infinitely greater; 3d. The average heat is rather less; and, 4th. The temperature appears to decline more rapidly by increase of elevation. The grand defect in the climate of extra-tropical Australia appears to consist in the periodical recurrence of wet and dry seasons. Sometimes hardly a single drop of rain falls for an entire year or more; and though, happily, dews are in such seasons peculiarly abundant, they form no adequate substitute for rain. During long-continued droughts crops of all kinds are destroyed; and herbage, except in a few favored spots, suffers severely. Hence, as already stated, all the eastern parts of extra-tropical Australia, and perhaps also the southern, would seem to be much better fitted for pasturage than for husbandry. The droughts are exceedingly injurious to the latter, and they would necessarily involve any large population that depended principally on the indigenous products of the soil in extreme privations. Certainly, however, no country seems to be better fitted for graz-

ing, or rather for the growth of sheep and wool. A dry climate is especially suitable to the latter; and though the pastures be far from luxuriant, their boundless extent compensates for every other deficiency. Sheep are not native to the country, a small flock of twenty-nine head having been introduced for the first time by the original English settlers in 1788. For a while, however, their value was not appreciated; but the importance of sheep-farming, and its suitability to the country, having been demonstrated by John McArthur, Esq. (to whom the colony is under the greatest obligations), it has since increased with unprecedented rapidity. In proof of this, it may be stated that while the import of wool into Great Britain from Australia amounted, in 1822, to only 152,880 pounds, it had increased in 1825 to 411,600 pounds, in 1830 to 899,750 pounds, and in 1851 to the enormous amount of 41,810,187 pounds. Van Diemen's Land being less subject to droughts than New South Wales, husbandry is carried on in it to a greater extent, and with more advantage; but there also sheep-farming is the principal, and perhaps the most advantageous employment.—See VAN DIEMEN'S LAND.

New Zealand. New Zealand, which has only been resorted to by regular colonists since 1840, is better fitted for agriculture than either Australia or Van Diemen's Land, and its climate is more like that of England. The ground in it is, however, rather difficult to clear; the natives are also much formidable, and it is not so suitable for sheep-farming.

Population.—The European population of the Australian colonies is believed to have been, at the unmentioned dates, nearly as follows:

Colonies.	Years.	Population.
New South Wales.....	1851	197,168
Victoria, 31st December.....	1852	200,000
Van Diemen's Land.....	1850	70,000
South Australia.....	64,000
Western Australia.....	1850	7,000
New Zealand.....	1850	22,400
Total.....	560,568

Expenditure by Great Britain on the Australian Colonies.—England does not appear to spend any money in Victoria: the last parliamentary return on colonial expenditure does not mention that colony. The following table exhibits the amounts expended on four colonies in the years 1853-'54, and the purposes to which they were applied:

Colonies.	Military Charges.	Civil Charges.	Naval Charges.	Total.
South Australia.....	£10,848	£2	..	£10,250
New South Wales... ..	61,198	10,086	£88	71,313
Van Diemen's Land... ..	55,110	200,178	..	254,287
West Australia.....	85,711	98,128	..	183,839
Total.....	£192,867	£297,887	£88	£490,654

These totals do not really represent £479,985 spent by Great Britain on her Australian colonies; except South Australia, all are "penal settlements," or have been, and the large expenditure has mostly been incurred in guarding, disciplining, feeding, and clothing convicts. In fact, the Australian colonies cost her next to nothing, being but a small per cent. of what it would cost to keep convicts at home. Under the new constitution for the four free colonies, Western Australia has become a convict settlement by her own choice, and has the advantage of a large expenditure in consequence, the following sums having been reserved out of the revenue annually for the purposes indicated. The civil list includes the governor's salary, judicial salaries, and those of departments. The retiring allowances are for officials liable to removal on political grounds.

Colonies.	Civil List.	Retiring Allowances.	Public Works.
Victoria.....	£40,500	£4,000	£50,000
New South Wales.....	30,550	5,000	28,000
Van Diemen's Land.....	13,800	9,175	18,000
South Australia.....	16,000	1,750
Total.....	£100,650	£19,844	£96,000

III. OTHER COLONIES. Spanish Colonies.—Spain, whose colonial possessions extended a few years ago from the frontiers of the United States to the Straits of Magellan, is not at present possessed of a foot of ground in the whole American continent. Still, however, her colonial possessions are of great value and

importance. In the West Indies, she is mistress of Cuba and Porto Rico—the former by far the largest and finest of the West Indian islands, and the latter also a very valuable possession. In the East, Spain is mistress of the Philippine Islands, which, were they in the hands of an enterprising people, would speedily become of very great commercial importance.—See the articles HAVANA, MANILLA, PORTO RICO.

Dutch Colonies.—Java is the principal Dutch colonial possession, and it is one of which it is not easy to exaggerate the value and importance.—See BATAVIA. In the East, the Dutch also possess the Moluccas, Benccolen, on the coast of Sumatra, Macassar, and the eastern coast of Celebes, Banda, etc. They have several forts on the Gold Coast in Africa; and in the West Indies they possess the islands of Curaçoa and St. Eustatius, Saba, and part of St. Martin; and on the continent of South America they are masters of Dutch Surinam. Curaçoa and St. Eustatius are naturally barren, but they have been both highly improved. From its being very conveniently situated for maintaining a contraband traffic with the Caraccas and other districts in South America, Curaçoa was formerly a place of great trade, particularly during war. But since the independence of South America, Curaçoa has ceased in great measure to be an *entrepôt*; the goods destined for the continent being now for the most part forwarded direct to the place of their destination. That district of Surinam ceded to the British

in 1814, comprising the settlements of Demerara, Berbice, and Essequibo, formed the most valuable portion of Surinam, or Dutch Guiana. The district which still belongs to the Dutch lies to the south of Berbice. It contains about 38,000 square miles, and a population of about 65,000. It is daily becoming of more value and importance. The exports of sugar may amount to about 25,000,000 pounds, and those of coffee to about 4,000,000 pounds.

French Colonies.—Previously to the negro insurrection that broke out in 1792, St. Domingo was by far the most valuable colony in the West Indies. But this disastrous event, having first devastated the island, terminated in the establishment of the independent black republic of Hayti.—See PORT AU PRINCE. Having also sold Louisiana to the Americans, and ceded the Mauritius to the English, without making any new acquisition, the colonial dominions of France (for Algiers can not be reckoned among them) are at this moment of very limited extent. They consist of Guadeloupe and Martinique, and the small islands of Marie-Galante and Desceada, in the West Indies; Cayenne, in South America; Senegal and Goree, in Africa; the Isle de Bourbon, in the Eastern Ocean; St. Marie, in Madagascar; and Pondicherry and Chandernagor, with a very small surrounding territory, in the East Indies. The annexed tabular statements show the population, trade, etc., of the French colonies.

But it would appear from the following account of the exports from Martinique and Guadeloupe, in 1851, that the emancipation of the slaves has had much the same influence over production in the French colonies that it has had in the British colonies, without being, we believe, in any degree more advantageous to the blacks.

Danish Colonies.—In the West Indies, these consist of the islands of St. Croix, St. Thomas, and St. John. St. Croix contains about 100 square miles, and has about 24,000 inhabitants. The soil is fertile, and it is well cultivated. The principal productions are sugar, rum, and coffee, the exports of sugar having formerly amounted to about 25,000,000 pounds a year. Probably, however, they have been diminished in consequence of the emancipation of the slaves in 1848. St. Thomas, which has about 14,000 inhabitants, has long been, and still continues to be, one of the principal emporiums in the West Indies. It owes this distinction partly to its convenient situation, partly to its spacious and safe harbor at St. Thomas, on the south side of the island, and partly and principally to the moderation of the import duties, which vary from 1 to 1½ per cent. St. Thomas has in consequence become, as it were, a *dépôt* for the supply of the neighboring islands, goods being sent to it to be warehoused till opportunity offers for conveying them to their final destination. The great articles of importation are, manufactured goods, principally from England, but partly

bique. It is not cultivated, but grows naturally in great abundance. It is imported in circular pieces from $\frac{1}{2}$ to 3 inches in diameter, generally from $\frac{1}{2}$ to $\frac{3}{4}$ of an inch thick; the bark is wrinkled and thick, of a brownish color without, and a brightish yellow within; the pith is spongy, yellowish, and slightly striped: when fresh, its smell is rather aromatic; it is disagreeably bitter, and slightly pungent to the taste, somewhat resembling mustard that has been too long kept. Choose the largest pieces, fresh, and of a good color, as free from worms as possible, rejecting that which is small and broken. The freight is calculated at 16 cwt. to a ton.—MILBURN'S *Oriental Commerce*.

Columbus, Christopher, the celebrated navigator and discoverer of the Western World, was born in Genoa about the year 1446. Although several illustrious families have contended for his alliance to them, his father Domenico, and his ancestors, appear to have followed the trade of wool-combers or carders, and were of humble, though reputable origin. Columbus received his education at the university of Padua, and, having evinced an early passion for the sea, entered into nautical life at the age of fourteen. The first voyage in which we have any authentic accounts of his being engaged was a warlike expedition fitted out at Genoa in 1469, when, associated with hardy and daring adventurers, he acquired so much distinction as to be intrusted with a separate command. After this, it is supposed, he was employed in various commercial, pious, and predatory expeditions against the Mohamedans and Venetians, in company with a famous corsair of his own name and family, and acquired reputation and experience in his profession. His son Fernando relates that, in an engagement off the coast of Portugal with four Venetian galleys, returning richly laden from Flanders, the vessel on board which he served, and one of the Venetian ships to which it was grappled, took fire. Columbus threw himself into the sea, seized an oar which was floating near him, and by this means, and his dexterity in swimming, reached the shore, although two leagues distant. Proceeding thenceforward to Lisbon, he was induced to take up his residence in that capital.

Columbus became acquainted in Lisbon with the most eminent men in science and maritime art, whom the encouragement of Prince Henry of Portugal had attracted around him. At this period (anno 1470) he was in the vigor of manhood, of engaging appearance, grave, courteous, and affable in his deportment, moderate and simple in his diet and apparel, eloquent in discourse, possessing high magnanimity, and a temper which, though irritable, was under the control of a gentle and enthusiastic piety. Here he married Dona Felipa, daughter of Bartolomeo Mons de Palestrello, an Italian cavalier lately deceased, and a distinguished navigator, who had discovered and colonized the island of Porto Santo. Having obtained possession of the journals and charts of this sea captain, and also hearing accounts of his voyages from his widow, Columbus was seized with an irresistible desire of visiting unknown regions. In order to indulge it, he made a voyage to Madeira, and continued during several years to trade with that island, the Canaries, Azores, the settlements in Guinea, and the other places which the Portuguese had discovered on the continent of Africa. By the experience acquired in such a number of voyages, Columbus became one of the most skillful navigators in Europe.

His eminent biographer, Washington Irving, relates that "he divided the circumference from east to west at the equator, according to Ptolemy, into twenty-four hours, of fifteen degrees each, making three hundred and sixty degrees. Of these he imagined, comparing the globe of Ptolemy with the earlier map of Marinus of Tyre, that fifteen hours had been known to the ancients, extending from the Canary or Fortunata Islands, to the city of Thine, in Asia, the western and

eastern extremities of the known world. The Portuguese had advanced the western frontier one hour more by the discovery of the Azores and Cape de Verd Islands; still about eight hours, or one-third of the circumference of the earth, remained to be explored. This space he imagined to be occupied in a great measure by the eastern regions of Asia, which might extend so far as to approach the western shores of Europe and Africa. A navigator, therefore, by pursuing a direct course from east to west, must arrive at the extremity of Asia, or discover any intervening land. The great obstacle to be apprehended was from the tract of ocean that might intervene; but this could not be very wide, if the opinion of Alfraganus the Arabian were admitted, who, by diminishing the size of the degrees, gave to the earth a smaller circumference than was assigned to it by other cosmographers—a theory to which Columbus seems generally to have given much faith. He was fortified also by the opinion of Aristotle, Seneca, Pliny, and Strabo, who considered the ocean as but of moderate breadth, so that one might pass from Cadiz westward to the Indies in a few days."

On these grounds Columbus formed the vast and daring enterprise which was destined to hand down his name to posterity with unfading honor; and firmly established in a belief of the successful result of his projects, "he never," says Irving, "spoke in doubt or hesitation, but with as much certainty as if his eyes had beheld the promised land. A deep religious sentiment also mingled with his thoughts, and gave them at times a tinge of superstition, but of a sublime and lofty kind. He looked upon himself as standing in the hand of Heaven, chosen from among men for the accomplishment of its high purpose; he read, as he supposed, his contemplated discovery told in Holy Writ, and shadowed forth darkly in the prophecies. The ends of the earth were to be brought together, and all nations, and tongues, and languages, united under the banners of the Redeemer." The disturbed state of Portugal under Alfonso retarded the progress of discovery. The compass, though in general use, had not gained that reliance which induced mariners fearlessly to brave the dangers of the deep; and the project of a voyage through boundless wastes appeared extravagant and impracticable. Nothing daunted, however, by these disheartening symptoms, Columbus pursued his favorite schemes with ardor, and longed to put them into execution. So perilous an adventure was not, however, to be attempted without the patronage of some sovereign power; and John II., of Portugal, having at this juncture ascended the throne, and being favorably inclined to the cause of discovery, Columbus made his proposals, which were graciously received by the monarch, and referred to a learned junta. The result of their conference therefore was, that they recommended the king to fit out a caravel privately, and attempt the proposed discovery by the designated route, which they ascertained from charts and details craftily obtained from Columbus. John, in an evil hour, had the weakness to adopt this perfidious counsel. The caravel departed, but the pilots had neither the genius nor fortune of Columbus; their courage failed, and putting back to the Cape de Verd Islands, they returned from thence to Lisbon, execrating the project as extravagant and irrational.

Columbus next carried his proposition to Venice, where he was equally unsuccessful. He also sent his brother Bartholomew to lay his plans before Henry VII. of England, leaving in the mean time sailed himself for Spain, where he arrived after having spent all his means. Columbus, in this state of abject poverty, set out for the Castilian court at Cordova in the spring of 1486. The moment was unpropitious for such a proposition, the Spanish sovereign being at the time engaged in military preparations against the Moorish kings. At length, through the intercession of Cardinal Gonzalez, he obtained an interview, and submitted

his project to Ferdinand. Worn out with a series of disappointments and delays, and supporting himself by making maps and charts, Columbus, despairing of the Spanish patronage, began to look to other courts, in hopes of meeting more encouragement. He had already made preparations for this purpose, and taken measures for the disposal of his children during his absence, when Juan Perez solicited him to defer his journey, making application at the same time to Isabella the result of which was a gracious invitation of Columbus back to court, accompanied with the present of a small sum to equip him for the journey. The monarchs were now pledged to attend to his proposals, and negotiations were set on foot to carry them into execution. He proposed that a small fleet should be fitted out under his command to attempt the discovery, and stipulating that he should be invested with the titles and privileges of admiral and viceroy of all the seas and lands he should discover, with one-tenth of all gains, either by trade or commerce. He further offered to furnish an eighth of the cost, on condition of enjoying an eighth of the profits. His terms were, however, deemed inadmissible; the negotiation broke off, and Columbus, in indignation, mounting his mule, was already on the road to Cordova, with the intention of immediately proceeding to France, when he was overtaken by a messenger from the queen, who had been prevailed upon by the arguments of Quintanilla and St. Angel, two of Columbus' patrons, to favor his undertakings. The negotiations were now completed, and the capitulations were signed by Ferdinand and Isabella at Santa Fé, on the 17th of April, 1492. The articles of agreement were to the following effect: That Columbus should be constituted high admiral in all the seas, islands, and continents he should discover, with similar honors and prerogatives to those enjoyed by the high admiral of Castile in his district. He was also nominated viceroy and governor general over all the said lands and continents; and a tenth of all free profits arising from the merchandise and productions of the countries within his admiralty was granted to him forever. Columbus, or his lieutenant, was to be sole judge of all causes and disputes arising out of traffic between those countries and Spain. He was further permitted to contribute an eighth part of the expense of expeditions to the countries he expected to discover, and was entitled in return to an eighth part of the profits. A principal object of Columbus in this undertaking was the propagation of the Christian faith, to which he was a zealous devotee. Expecting to arrive at the extremity of Asia, he hoped to spread the light of the Gospel among the barbarian nations of the East; and so confident was his anticipations that letters were actually given him by the sovereigns for the Grand Khan of Tartary. Although the royal documents were signed both by Ferdinand and Isabella, her separate crown of Castile defrayed all the expense; and the queen in consequence reserved for her subjects of that kingdom an exclusive right to all the benefits which might accrue from the success of the expedition.

The arrangement being finally completed, Columbus set sail on the 3d of August, 1492, in three small vessels, only one of which (commanded by himself) was completely decked. The two others were commanded by Martin Alonso Pinzon and Vincente Yañez Pinzon. The expedition had sailed nearly 200 leagues to the westward, when Columbus perceived that the needle of the compass, when night set in, had varied; a circumstance which filled the pilots with consternation. For this phenomenon he was obliged to invent a reason, which, though it did not satisfy himself, yet served to dispel their fears. As the squadron advanced, various indications of land, such as birds flying from the west, the water becoming less salt, and occasionally covered with weeds, animated and supported the courage of the crew; but at length murmurs and fears began to prevail among them. They had sailed for eleven days,

wafted by a most propitious breeze, over a tranquil sea, without lowering or shifting a sail. The rude seamen began to be alarmed that no other winds blew but easterly, and that it would therefore be impossible for them ever to return home. A few light breezes from the west allayed for a time their apprehensions, and several small singing birds came in the morning and flew away at night. But the sailors lost all patience, and became so mutinous and refractory that it required the utmost address of Columbus to maintain his authority. The appearances of land, though frequent, were in many instances deceiving; and at last the seamen broke forth into loud clamors, and insisted upon abandoning the voyage. Fortunately, however, on the following day the manifestations of land were such as no longer to admit of doubt. In the evening Columbus perceived a light glimmering at a distance, and the next morning land was clearly seen about two leagues distant. The sailors now burst forth into the most extravagant transports. They threw themselves at the feet of Columbus, implored his pardon, and pronounced him to be a person inspired by Heaven with more than human sagacity and fortitude, to accomplish a design so far beyond the ideas and conceptions of all former ages. At daybreak, says his biographer Spertorno, on the 12th of October, the hero landed, "*e di grando forma il nuovo mondo imprimo*" (and with his great footsteps impressed the New World). Columbus and his followers threw themselves on their knees; and rising, the admiral drew his sword, planted the cross, hoisted the royal standard, and in the presence of the astonished natives, who imagined that the Spaniards had dropped from heaven, took possession of these new countries in the names of the Castilian sovereigns, giving the island the name of San Salvador. Having visited several of the West India islands, and settled a colony in Hispaniola, he again set sail for Spain. On the voyage he fell in with the Pinta, which had separated from him for a long time through the wickedness of the captain, who had gone in search of gold. After encountering several violent tempests, Columbus arrived in the Tagus, near Lisbon, on the 4th of March, 1493. He was treated with the most honorable attentions by the court of Portugal, and finally reached the port of Palos on the 15th of March.

The triumphant return of Columbus excited the most unbounded transport. Wherever he went the air rang with acclamations, and he received such honors as are paid to sovereigns. The court was then at Barcelona, and Columbus took care immediately to acquaint the king and queen of his arrival. They were no less delighted than astonished with this unexpected event. The admiral was conducted into the city with all imaginable pomp. The sovereigns received him seated in state under a rich canopy of brocade of gold, surrounded by their principal nobility. When he approached they stood up, and, raising him up, he knelt to kiss their hands, ordered him to be seated in their presence, and give a circumstantial account of his voyage. When he had finished his oration, which he delivered with much modesty and simplicity, the king and queen, kneeling down, offered up solemn thanks to God for the discovery. Every possible mark of honor that could be suggested by gratitude or admiration was conferred on Columbus; the former capitulation was confirmed, his family was ennobled, and a fleet ordered to be equipped to enable the navigator to go in quest of those more opulent countries which he still confidently expected to find.

The successful attainment of the splendid discovery of Columbus, great and manifold as were its advantages to mankind, was the prelude to the dark and troubled epoch of his life. By his second voyage to the Western World he no doubt in part realized his expectations, extended his discoveries, and came back to Spain with substantial proofs of success; but the ostensible purpose of his return was to obtain reparation

of injurious imputations which had been heaped upon him, and generally to have his privileges confirmed and enlarged so as to enable him to exercise his authority over the colonists, who had become refractory and unmanageable. But his third voyage only accelerated his disastrous fate. The newly-discovered possessions were distracted with the horrors of rebellion. The verdant and blooming isles, the expected abodes of peace and happiness, were converted into theatres of sanguinary conflicts and misery; and Columbus found himself an object of fear and execration. It was during this voyage that he landed on the coast of Paria, in South America. Meanwhile his enemies in the Old World were not idle. An investigation into his conduct was instituted under the control of Francisco Bovadilla, who was empowered, should he find the charges of maladministration proved, to supersede Columbus, and assume the government of Hispaniola. The result was, that he and his brothers Diego and Bartolomeo, after having been treated with the greatest indignities, were sent to Spain in chains. From these disgraceful bonds he was immediately on his arrival released by the Spanish monarchs; but his complaints were tardily acknowledged; he again sank into obscurity, and was reduced to such straitened circumstances that, according to his own account, "he had no place to repair to except an Inn, and very frequently had not wherewithal to pay his reckoning."

At length he was again employed upon a fourth voyage, with restricted powers; but the result was unpropitious, and he returned to Spain dejected in mind and worn out with bodily infirmities. Death at last relieved him from his earthly afflictions. He expired on the 24th of May, 1506, commending, with his latest breath, his spirit to God. A marble tomb was reared over his dust, bearing the inscription,

A Castilla y a Leon,
Nuevo mundo dio Colon.

Columbus was a man of great and original genius, energetic in his conduct, and possessed of lofty, daring, but nobis ambition. "The magnanimity of his nature," says Irving, "shone forth through all the troubles of his stormy career. Though continually outraged in his dignity, braved in his authority, foiled in his plans, and endangered in his person, by the seditions of turbulent and worthless men, and that too at times when suffering under anguish of body and anxiety of mind enough to exasperate the most patient, yet he restrained his valiant and indignant spirit, and brought himself to forbear, and reason, and even to supplicate." His piety, though tinged with superstition, was genuine and fervent. If on certain occasions his religion displayed itself in harshness and severity, the spirit of the age he lived in must be adverted to in palliation of his conduct. His temperament was deeply imbued with poetic enthusiasm. "It presided," remarks Irving, "a golden and glorious world around him, and tinged every thing with its own gorgeous colors. It betrayed him into visionary speculations, which subjected him to the sneers and cavils of men of cooler and safer, but more groveling minds. It filled his mind with solemn and visionary meditations on mystic passages of the Scriptures, and on the shadowy portents of the prophecies." "His soul," observes a Spanish writer, "was superior to the age in which he lived. For him was reserved the great enterprise of traversing a sea which had given rise to so many fables, and of deciphering the mystery of his age." "With all the visionary fervor of his imagination," adds Washington Irving, "his fondest dreams fell short of the reality. He died in ignorance of the real grandeur of his discovery. Until his last breath he entertained the idea that he had merely opened a new way to the old resorts of opulent commerce, and had discovered some of the wild regions of the East. He supposed Hispaniola to be the ancient Ophir which had been visited by the ships of King Solomon, and that

Cuba and Terra Firma were but remote parts of Asia. What visions of glory would have broken upon his mind could he have known that he had indeed discovered a new continent, equal to the Old World in magnitude, and separated by two vast oceans from all the earth hitherto known by civilized man! and how would his magnanimous spirit have been consoled, amid the afflictions of age and the cares of penury, the neglect of a fickle public and the injustice of an ungrateful king, could he have anticipated the splendid empire which would arise in the beautiful world he had discovered, and the nations, and tongues, and languages which were to fill its lands with his renown, and to revere and bless his name to the latest posterity!" It will be remarked that Mr. Irving, in accordance with the generally entertained belief of all his biographers, alludes to Columbus as being the first discoverer of the American continent, which is emphatically so, as far as the commercial world is concerned. It is, however, certain that the continent was visited by the Icelanders in the end of the tenth and the beginning of the eleventh centuries; and Sebastian Cabot discovered Newfoundland and Labrador in June, 1497, nearly a year previous to the visit of Columbus on the coast of Paria. It also seems more than probable that Columbus was aware of Cabot's discovery.

Several controversies have arisen bearing upon the claims of Columbus to the discovery of the Western World; but such disputes, in so far as they affect the discovery of the *Columbian Archipelago*, are proved to be idle and futile, as no doubt now remains of Columbus having been the first navigator of the Old World who reached the island of San Salvador, and the first who visited the shores of the South American continent. One of the most current slanders on our navigator's fair fame, as related by Inca Garcilaso, was that Alonso Sanchez, sailing to the Canaries in 1484, reached the island of St. Domingo, and communicated his voyage and route to Columbus. Some other Spanish writers notice the event without giving the name of the author of the discovery. Oviedo considers these relations as mere vulgar fables. We are, however, told by Columbus himself that he took advantage of such accounts as were transmitted to him by Spanish and Portuguese mariners, some of whom had sailed westward so far as to perceive what they considered to be indications of land. Gallo and Giustiniani, authors contemporaneous with Columbus, assert that Bartolomeo Columbus first conceived the idea of western discovery, and communicated it to his brother; but Columbus has been triumphantly vindicated from these ungenerous aspersions by the unanimous testimony of the Spanish writers, among whom Las Casas, who knew both brothers, and preserved many papers belonging to Columbus, merits especial credence. But if any doubts remained, they are completely removed by the written declaration of Ferdinand and Isabella, who, in a communication dated the 4th of August, 1494, write thus to the admiral: "One of the principal reasons for which your discovery (the first) has caused so much joy to us is, that it is to be ascribed to your genius (por ser inventada), and that it has been commenced and terminated by your own individual endeavors, by your courage, your perseverance, and industry."—E. B.

The discoveries of Columbus were followed, in 1497, by those of Cabot on the northeast coast of America; in 1500 by Cabral, a Portuguese, who visited the coast of Brazil and the mouth of the Amazon; in 1508 by Pinzon, who is said to have entered the Rio de la Plata. In 1511 Diego Columbus conquered the island of Cuba. In 1518 Balboa crossed the Isthmus of Darien. In 1519 Cortez landed in Mexico. In 1581 Peru was invaded and conquered by Pizarro.

Colza, Oil of. The oil expressed from the seed of the *Brassica oleracea*, a species of cabbage. Colza oil is much used in France and Belgium for burning in lamps and other purposes.

Commerce. Commerce, in its most general sense; is the exchange of articles of any kind for money or other articles. The earliest form of such exchanges is by barter, because the use of gold and silver is not adopted until society has made a certain progress. "The armor of Diomed," says Homer, "was plain, and paid for by nine oxen; while the splendid armor of Glaucus cost a hundred." Barter being now disused in all improved countries, commerce is almost always understood to denote the exchange of commodities for money. In France and the south of Europe the words used to designate commerce are derived from the Latin; in Holland, Germany, and other northern countries, a vernacular word is more frequent; but all are alike in meaning, being applied equally to home and foreign trade.

We propose in the present essay to treat of, I. The principles of commerce, and the evils of interfering with the free course of trade; II. The history of Commerce, particularly in Great Britain, Holland, and America; III. Prominent commercial changes of the nineteenth century.

I. PRINCIPLES OF COMMERCE.—By "principles of commerce," we understand conclusions of two kinds; those deduced from the practice of merchants, and applicable to the management of trade by individuals; and those of a more comprehensive character, which, resulting from the course of productive industry generally, are entitled to the attention of a minister, or officer, of the Department engaged in the task of devising regulations for trade. Most of those conclusions seem so plain as to admit of little question; but it is a fact that several of them have been the result of long, and, in some cases, of dearly bought experience. As a specimen we give the following:

1. *Mercantile Axioms; example of them.*—Short credits and quick returns, however small the commission or profit, are eventually better than long credits and a large commission or charge.

2. The greatest mercantile profit arises from intercourse with populous and long-settled countries, such as Holland, because the inhabitants are in general possessed of capital, and punctual in their payments.

3. Recently-settled countries, like the United States of America, the West Indies, Spanish and Portuguese America, are always bare of capital. There is a perpetual tendency in them to draw it from Europe; and mercantile transactions with these countries, profitable in the outset, often become otherwise, from delays of payment, and ultimate insolvency.

4. Trade should be left as much as possible to its natural course, interference being almost always hurtful. Governments ought merely to remove obstacles and grant facilities. Privileges and monopolies were formerly very general; but these, if necessary in an early age, when individual capital was too scanty for distant undertakings, should be withdrawn as soon as such capital becomes sufficient.

5. Division and subdivision of employment can be carried to only a limited extent in agriculture. In manufactures they may be carried very far, and are productive of the greatest advantage. They afford employment to persons of every age, and they conduce greatly to the finished execution of work. Hence the superiority of towns, in particular of the larger towns.

Rules or observations like these are very seldom met with, either in printed works or in personal intercourse; and the reason is, that while few departments of industry have been followed in practice to so great an extent as commerce, hardly any other has been less an object of study in regard to its principles. There are hardly any books or written compositions for the purpose of instructing the merchant in the practical management of his business, and not many containing statistical or other information connected with trade. To no profession are written precepts considered to be so little applicable; in none is proficiency

thought to depend so exclusively on practice. Hence an unacquaintance with principles or general rules, and the commission of grievous errors, as well by merchants in the pursuit of business, as by the government in the enactment of commercial regulations. Of the former we may take as examples the repeated glutting of foreign markets with goods, and the injudicious extension of sugar cultivation in the West Indies; of the latter, the fetters imposed upon the banking system, without stability being given to the system by the control and interest which should be taken by the general government.

The belief that it is for the advantage of a nation to manufacture almost every article it consumes has been the cause of the most serious inconvenience and loss. It is thus that in France the making of sugar from beetroots, and the more serious error of erecting blast-furnaces for making iron in districts unprovided with coal fuel, have placed a large amount of capital in a situation whence it can not be withdrawn without heavy loss. In like manner, the privileges so long conferred by act of parliament on the silk manufacture in England, frequently tended to produce embarrassment, because they interfered with the natural course of trade. No branch of industry can be of permanent advantage to a nation, unless it can support itself without indirect or artificial aid. Were merchants and manufacturers left to themselves, the natural course of things would point out the branches of productive industry likely to succeed or not in a particular country; and capital would not then be advanced on an insecure foundation. Plain as this appears, it is quite at variance with the creed of our ancestors; a creed which, under the name of "mercantile system," long retained an influence over our traders, and, in some degree, over members of the Legislature.

The Mercantile System explained.—The basis of that system was, that "wealth consisted in the precious metals; that what is gained in trade by one nation must be lost by another; and that our great object in receiving returns for our exports should be to get money instead of merchandises." It followed from such notions, that of all possessions, a mining country, such as Mexico and Peru, was the most desirable; and hence in a great measure the rupture of England with Spain in 1740, which led to the unfortunate British expedition to Carthage, involved her in a contest with France, and caused her in the course of eight years an immense waste of blood and treasure. The return to a state of peace in 1748 obliged her to desist from attempts on Spanish America, but the influence of the mercantile system continued, and was singularly favored by the annual custom-house returns. These returns exhibit an apparent excess of exports above imports, and give rise to the notion that the balance is sent to this country in the shape of money. Supposing the exports of England to the Continent of Europe to amount for any given year to £20,000,000, and the imports to £14,000,000; the difference, or £6,000,000, is, according to this absurd notion, the amount of profit paid in money. It is clear, however, that the custom-house returns take no notice of some very important items, such as the export of public money for foreign garrisons, the transmission of bills of exchange to foreign merchants, or the import of smuggled goods. Besides, if the quantum of circulating medium remain, as it probably does, very nearly on a par, what becomes of the supposed importation of money? Were England in possession of all the annual balances which the advocates for this system suppose her to have received in money during the last century, her metallic stock would not be below £400,000,000 sterling; that is, ten times its actual amount!

Wealth supposed to consist in Gold and Silver.—When a merchant exports goods, the sale, of course, takes place abroad, and a remittance is made, either by bill or by the return of other merchandises. It hardly ever enters into the contemplation of the exporter that he

would find an advantage by obtaining a return in coin or bullion. Money owes the reputation it has acquired, as an object of national interchange, to its convenience in other respects; to its being the commodity with which we regularly go to market, and to its fitness for the smallest purchases, by the minuteness of its subdivisions. But this recommendation, however important in private business, should have no weight in the intercourse of nations; merchants can be at no loss to dispose of a remittance made in the shape of goods, nor is it any object with them to multiply the means of petty purchases.

Capital defined.—The interest of a commercial country is not to increase the amount of its currency, but to quicken its circulation; the same sum performing double and triple duty when passed expeditiously from hand to hand. Now nothing but notes circulation so much as exemption from arbitrary interferences, were the effect nothing more than the general preservation of credit. In France, the monstrous abuse made of the paper system in the beginning of the Revolution has long prevented the use of any other circulating medium than coin; the result is an annual loss of three millions sterling to the public, such being the difference between the cost of paper and the precious metals, even after making an allowance for the retention of a portion of the latter sufficient for the purpose of banking. Some people, however, imagine that to increase the amount of the circulating medium is to increase the capital of a country. These persons should recollect that capital is by no means limited to money, but embraces all that mass of property which is devoted to reproductive consumption. When we wish to lend capital, or to employ it in business, we begin by selling the various articles at our disposal: the amount is then in our hand in the shape of money; but this is very transient; the money disappears as soon as we make payment for the new purchases. The public not having time to enter into all this reasoning, judge from first impressions, and take for granted that money is capital, because its agency is required to put capital in motion. Governments, however, might have saved themselves much trouble in providing supplies of metallic currency, since the natural course of business will invariably provide them for itself. The plenty or scarcity of the precious metals depends on considerations altogether different from the imagined balance of trade. Specie was so scarce in England in 1809 that the government was not a little embarrassed to find £200,000 for the Walcheren expedition; yet in that year her custom-house returns presented an apparent balance of above £7,000,000 in her favor.

Losses to England from the Mercantile System.—No country has suffered so much from the errors of the mercantile system as England; partly on account of the influence of traders and manufacturers in her legislature; partly from the temporizing policy of the ministers, who have seldom scrupled to buy the consent of any great body of the community to a new tax, by the grant of some injurious preference. Hence a variety of pernicious regulations in favor of the landed, the shipping, and the manufacturing interests; hence, also, a number of unfortunate measures in the foreign policy.

The 17th and 18th Centuries.—Our English ancestors laid it down as a fundamental rule, that there could be no profit on the one hand, without a corresponding loss on the other. They considered trade as a game of mere transfer, and had no idea how a country could derive wealth by an intercourse between its own inhabitants. Charles II. entered on the war of 1672 with high hopes, imagining that, by destroying the commerce of Holland, England would not only increase her own, but in a manner absorb that of the world. Political reasons led England afterward into close alliance with Holland, and prevented the ebullitions of jealousy in that direction; but the alarming power of Louis XIV. and the prospect of his acquiring the crown of Spain, led her to a closer connection with Portugal, and particularly to

the well-known Methven treaty, concluded in 1703, the object of which was to favor the consumption of port wine, in return for a similar preference to her manufactures. The result has been, that she has not scrupled, for more than a century, to import injurious commodities for the sake of an imaginary political advantage; we say imaginary, because France could evidently have agreed to take English manufactures in return for her produce; and if the increase of French trade had, on one hand, the effect of augmenting, to a certain extent, her national power, it would, on the other, have increased her dependence on England, and have rendered a war extremely impolitic and unpopular.

English attachment to Portugal arose, in a great measure, from her not being a manufacturing country, and likely, in the opinion of the calculators of the day, to be so much the more advantageous in the capacity of a customer. This notion has prevailed to a very recent period; the administration of 1808 and 1809 not scrupling to give encouragement to the export of merchandises, on a large scale, to the unproductive occupants of Brazil and Spanish America. Now, the fact is, that the means of extending trade, and consequently profits, with a foreign country, are to be estimated by a quite opposite rule; they depend on the productive power of that country, on its means of affording equivalents for our commodities; in other words, on its capability of paying for that which it suits us to sell to it. Now, what country was ever wealthy without industry? The mines of Mexico and Peru, the richest the world ever saw, fall, in point of annual produce, far short of the annual value of the cotton, the tobacco, the flour, and other less tempting products of the United States. In like manner, the cochineal, the cocoa, the barilla, and even the indigo of Spanish America, form a small amount when put in competition with the exchangeable commodities possessed by the industrious nations, such as France, the Netherlands, or the north of Germany.

Mercantile Policy of other Countries.—If from England's favorite policy we turn our attention to that of Continental states, we find Holland steering a course of impartiality, and guarded from an imitation of these trespasses, not indeed by superior knowledge, but by the characteristic moderation of her government. The northern kingdoms deserve comparatively little attention, their rulers having in general given their thoughts much more to war than to discussions of internal policy. The same thing was long true of a country where the commercial interest has at no time been very considerable; the personal will of the sovereign, and the influence of the noblesse, having afforded the grand *raison determinantes* for public measures. Still the history of France is not without traces of the effects of mercantile prejudices. Among other regulations of the kind, there formerly existed several for the purpose of favoring linen manufactures instead of cotton, because flax was a home product, while the purchase of cotton carried money out of the country.

France.—At last it was found out by some Frenchmen of greater sagacity than the rest, that cotton might be safely admitted to entry, the money required to buy it proceeding necessarily from the employment of French industry in some shape or other. But the extent of popular prejudice was most singularly exemplified at the time when it was proposed to permit the unrestrained use of *toiles peintes*, or printed calicoes; every town that had a chamber of commerce remonstrated against it. A deputation sent from Rouen affirmed, that "the proposed measure would throw its inhabitants into despair, and make a desert of the surrounding country;" Lyons, the centre of the silk manufacture, declared that "the news had spread terror into all its workshops;" Tours "foresaw a commotion likely to cause a convulsion in the body politic;" Amiens asserted "that the proposed act would become the tomb of the manufacturing industry of France;" and Paris declared, "that

her merchants came forward that they might bathe the throne with their tears." The government, however, stood firm; the duty on printed calico was withdrawn, and the inspector-general of manufactures ventured some time afterward to challenge the authors of those elegant effusions to compare their predictions with the result. "Will any of you," he said, "deny that the manufacture of printed calico has been the cause of giving a vast extension to the industry of the country, by employing a number of hands in spinning, weaving, bleaching, and printing? Look only to the branch of dyeing, and say whether this change has not done more for it in a few years than other manufactures would have accomplished in a century."

Commerce of Austria.—In some countries government go much farther, and still act in a commercial or manufacturing capacity, notwithstanding all the admonitions of political economists, or the more home-felt lessons of experience. The Austrian government conducts the gold and silver mines of Hungary to so little account, that the profit realized from these splendid establishments does not exceed a few thousands a year. In the year 1817 the French government, desirous of laying in a stock of corn for Paris, obtained a loan of money, with which they made purchases in various markets both in and out of the kingdom. The result was most distressing; the price of corn rose from 80s. to 120s. per quarter. The people in the provincial towns became apprehensive of a scarcity, and, though in general submissive to a fault, attempted at Rouen and other places to impede the course of the market, and to prescribe a limit to the price of corn. The alarm, once given, extended through great part of Europe, and gave occasion to a sudden rise, as may be seen by reference to the corn prices at the time in London, Amsterdam, and Hamburg. Nothing is, therefore, more impolitic than the interference of the public treasury with markets, however good the motive; a truth which has been so thoroughly felt in England as to prevent any thing of the kind during the last sixty years, government having confined itself in seasons of scarcity, as 1800, 1810, 1816, to permitting the free import of corn.

Modified State of the Mercantile System.—We are next to advert to the mercantile system in its most limited sense, in the shape which it now bears, after all the modifications of the experience of a century and a half. The predilection for the importation of "hard dollars" has disappeared among a portion of the public, particularly since making the discovery that bank paper can be made to answer the purpose of gold and silver. But even these persons are far from admitting the doctrines of political economists in all their extent; they still cling to the notion that we should discourage the import of a foreign article whenever a corresponding commodity can be raised at home; that we should impede, or even prohibit, all foreign manufactures; and that we should not scruple to encourage certain fabrics of our own by bounties. Such was formerly the creed of the majority of the merchants and manufacturers; such was, forty years ago, the creed of ministers and presidents of boards of trade. It proceeds on the plausible idea, that there can be no overdone provided too much employment, and that our people would be in danger of falling short of work, were we to purchase finished articles at the hands of foreigners. But there is not in the natural course of things any such deficiency of labor as to make it necessary, or even expedient, for us to turn things out of their regular order for the sake of giving employment to our population. Providence has evidently ordained that industry should be at no loss for objects; the interruptions to its peaceful course arise from our own wayward policy; from our restraints, prohibitions, and, above all, from our sudden changes from war to peace, and from peace to war.

Equally erroneous is the notion that it is more for our interest to send abroad manufactures than raw produce or money. If you grant a bounty on an export,

you do nothing more or less than bribe a foreigner to make a purchase from you; you withdraw from its natural destination a portion of your capital and labor; for the sake of extending one branch of business, you weaken your means of competition to others. Mr. Hume has justly remarked, that in a question of personal right, the perception of a half-educated man may be sufficiently sound; but that the case is different in regard to matters of general policy, where the real is often different from the apparent result. Now this state of half knowledge has been the origin of almost all mercantile miscalculations; we have listened to first impressions, and have not scrupled to give them a practical operation by acts of government, without ever considering that the remote consequences would be injurious to ourselves.

The true Principles of Commerce.—We may safely discharge from our minds all that has been said, and all that has been written, in regard to the greater relative advantage attendant in trading in this or that particular commodity; we may feel satisfied that profits are much more on an equality than is commonly supposed; that no one would long be a dealer in that which did not afford him advantage, or remain a stranger to that which was throwing an extra gain into the pockets of his neighbor. The same rule is applicable in a national sense, the traffic in one commodity being either directly or indirectly as productive of profit as in another. Even foreign articles of luxury should not be discouraged, since the money required to pay for them must be previously raised by the employment of industry in some useful manner. This affords a new proof of the fallacy of first impressions, and lends to the grand practical conclusion of allowing people to "buy commodities wherever they can be got cheapest, without seeking to favor home produce above colonial, or colonial above foreign."

Merchants should possess unrestricted freedom, not only in regard to the articles they deal in, but in respect to the time of keeping them back or bringing them to market; and this not only from the general title which every one has to the management of his own property, but from a conviction that whatever benefits the individual will be productive of corresponding benefit to the public. This is a point of the last importance, as reconciling the lower orders to a variety of unpopular employments of capital, such as buying up goods to be warehoused, and not brought to market till prices are advanced. Take, for instance, the capitalist who buys a thousand hogsheads of sugar on its arrival from the West Indies in August, for the purpose of selling it in the succeeding March or April. Such a transaction is of use to all parties, affording, in the first instance, a customer for the planter or planter's correspondent; a depository for the public during the season that the article ought in great part to be stored up; and finally a seller, at a time when, without such demand, and such forthcoming of supply, the price might have become exorbitant, and might have continued so until the arrival of the next year's crop.

The more we study the natural progress of commerce, the more we shall be satisfied of the expediency of leaving all its various agents to their uncontrolled management. Business then divides itself, particularly in a large city, into a variety of separate branches, each of which may be carried on to a surprising extent by separate establishments. The commission charged by such persons is small, their dispatch extraordinary; capital does not remain locked up in their hands, and goods find their way to the market whenever prices are encouraging, that is, whenever the consumers are in want of them; they are withheld only when the market is glutted, and when to force sales would be productive of eventual injury to the buyers themselves. The doctrine of the happy medium is nowhere more applicable than in commerce; if you reduce prices for one season below what is necessary to

indemnify the next, and so forth.

The division merce and of in that among ind appropriated to e particular kind tent in one con yet only begin men, for it has to establish, in

indemnify the producer, you discourage production for the next, and you expose yourself to the hazard of a dearth.

Monopolies.—Monopoly is now generally admitted to be highly impolitic. No new grants of the kind have been issued in Great Britain for many years, and every renewal of the charter of the East India Company has been marked by a diminution of its restrictive character, till in 1834 its monopoly was abolished. In the United States monopolies have never been permitted, the government having early seen their injurious effects. The public are now aware that a privileged company can not make its purchases abroad on better terms than individuals, and that the chief operation of the privilege is to enhance the sale prices, or, in other words, to put money into the hands of a few at the expense of the nation. They are further aware that the concerns of a large corporation can not be managed with the minute economy and vigilance of the private merchant, and that its grand advantage lies in the intelligence and dexterity acquired by the transaction of business to a large extent by one establishment; an advantage of great importance, but which has nothing to do with the possession of exclusive privileges.

The final conclusions to be drawn from the principles of commerce are of the most comprehensive and beneficent nature. They teach us that every nation finds its account in the prosperity of its neighbors; that it would experience a corresponding suffering from their decline; that to aim at engrossing more trade than *naturally falls to our share*, is sooner or later injurious to ourselves; and that war, even when successful, is attended with the most serious losses. War turns to waste a large portion of our productive means; it leaves us oppressed with a ruinous burden in peace; it impedes the future extension of our exports, for the injury done to our neighbors recoils on ourselves; in short, it is so replete with evil to the public and individuals, as to be justifiable only in an extreme case, such as the defense of national independence, or the overthrow of a tyrannical usurper.

Division of Employment; its manifold Advantages.—Division and subdivision of employment form the great distinction between a backward and an improved state of productive industry. It increases the efficiency of the mechanic or manufacturer to an extent of which no one who has not studied the subject can have an adequate conception. Now, the degree to which employment is subdivided depends mainly on the size of a city or town; and in estimating the state of civilization in a particular country, we can not have a better guide than the proportion of the inhabitants of towns to those of the open country. Flanders and Holland were long the most improved part of the north of Europe, and had the greatest number of towns on a given extent of territory. This they still have, with the exception of the counties (Lancashire and the West Riding of York, England) which are the chief seats of English manufactures. After the Netherlands in town population come the north of Italy and northeast of France, along with the western part of Germany. Prussia and Austria have each a comparatively small number of towns; Poland has still fewer, and Russia is the most deficient of any country in Europe. In England the increase of town population has been progressive during the last eighty or ninety years, and bids fair to go on in an equal or greater ratio.

The division of employment is the result of commerce and of increased population. It is of two kinds; that among individuals, by which a specific task is appropriated to each, and that among nations, by which particular kinds of products are raised to a greater extent in one country than in another. The latter is as yet only beginning to claim the attention of public men, for it has been a frequent error with government to establish, in their respective territories, a variety

of manufactures, without sufficiently weighing the local obstacles or disadvantages. Of this France furnishes some striking examples, particularly in the case of iron. The abundance of coal in England, and the ease in conveying it, and other bulky goods, by canals, give to their manufactures of iron and hardware an advantage which France in vain endeavors to equal. Her true policy would be to repeal the very heavy duties on the import of foreign manufactures, and to trust to her means of supplying the world with wine, brandy, and the other natural products of her country to an equal or greater amount.

Principles of Commerce; how far understood.—In point of knowledge of the great doctrines of political economy, Germany, or, to speak more properly, the Protestant part of Germany, particularly Saxony, may be said to take the lead of other countries on the Continent. The Dutch, however exemplary in their practical legislation, have little turn for speculative reasoning; the French have not patience to follow through its various links a chain of philosophical deductions; but their admiration of whatever is humane or liberal makes them wonderfully delighted with the brilliant conclusions of the science. They have the advantage of possessing, in the work of the late J. B. Say, the best arranged general treatise that has hitherto appeared on the subject; and they are by no means ill prepared for a very extensive application of political improvements, such as the abolition of privateering, the repeal of all heavy duties on foreign goods, and the substitution of inland taxes for those custom-house imposts which impede the free communication of nations. The rest of Europe is so much in the dark in regard to the great truths of political science as to see merely through the medium of local governments. Such is the case likewise in Italy, although that country can boast individuals of some note among the writers on the principles of commerce, and the reflecting turn of the people is favorable to such investigations; and even in Britain a large party is still adverse to the unrestricted application of these simple and beneficent principles, but this party is daily diminishing. The happy effects of the free-trade principles, which have been for some time in operation, as proved by the periodical returns of the English Board of Trade, are facts which can not be withstood; and we may safely calculate that a few years will convert the remaining advocates of protection to the free-trade faith.

Speculation in Trade.—Among men of business this expression is applied to incurring extensive hazards in the hope of extensive emolument; in short, to whatever is foreign to the proper business of the individual, or beyond the control of common rules. It is to such undertakings that vulgar credulity ascribes extraordinary profits; and even well-informed men are apt to give way to the assertions so confidently made, of swift occasional gains in this line of business. Dr. Smith himself, after remarking (*Wealth of Nations*, book 1. chap. 10) that to make a fortune in a regular line commonly requires a long life of industry and frugality, adds, no doubt on the faith of repeated assurances from mercantile friends, that there are many examples of fortunes realized by speculators in the course of a few years. Now, the men who embark in speculation are, in general, very loose accountants; their estimate of profits applies to the gross, never to the net return; besides, they are almost always adventurers, and adventurers are seldom noted for the observance of truth. Their favorite season of activity is a time like that of 1808, when the sudden stoppage of ordinary intercourse caused a rapid fluctuation in the price of commodities, and when the regular merchants withdrew from the scene. Now, what sober estimate can be formed of loss or gain in such a chaos? Add to this, that these men trade almost always on credit, are in need of all the support which flattering representations, and rumors of sudden profit, can give them. All these rea-

sons seem to justify a deliberate inquirer in doing what is seldom done on such occasions, we mean in withholding his belief from the confident allegations of speculators, so long as they are not supported by collateral evidence.

Frequency of Disappointment.—Our opinion is, that instead of the large profits commonly ascribed to this course of trade, the individuals concerned in it experience little else than disappointments, and maintain a perpetual struggle to keep up a fair appearance to the world. This opinion is founded partly on a knowledge of the actual career and circumstances of speculators, but more on the well-known fact that almost every line of business is in the hands of established merchants, who, of course, are too vigilant to overlook the opportunity of emolument, and who have much better means of information than temporary interlopers. Still, should there remain doubts as to the accuracy of our opinion, the question may be brought to a point by reference to the account-books of any given number of celebrated speculators; their affairs end almost always in bankruptcy; their papers continue open to access for years in the hands of their solicitors or assignees; and we are much mistaken if an inspection of them would show, in one case out of ten, that the parties had at any period succeeded in realizing their boasted profits.

Pernicious Effects of Speculation.—We have been induced to dwell the more on the boasts of speculators, because they are productive of great mischief in unsettling persons in business, particularly young men, and in making them look on their proper line with comparative indifference. It would be endless to attempt an enumeration of the various ways in which the rage for speculation has brought misfortune on merchants and manufacturers. The opening of a new country, such as Buenos Ayres, Brazil, or Caracas, led to the export not only of a prodigious overstock of merchandise fitted for the country, but of many articles totally unsuited to the climate and habits of the people. Again, in 1814, when the war with France was drawing to a close, goods, both colonial and manufactured, were poured into the Continent of Europe, as if the compass of the markets was unbounded, and as if the calamities of war had produced no decrease of capital.

Holland; its instructive Example.—The country in which trade shone forth in all its splendor; where it was cultivated without the support of arms or prohibitory regulations; where, in short, it developed its beneficial tendency in all its extent, was Holland. If we look to the early enterprises of the Dutch, we find them enabled, by the power of their productive industry, to assert their independence at home, and to assail their enemies in the remotest part of their empire. The Portuguese in the East, and the Spaniards in the West, were each found unequal to the task of resisting these republicans. A proud stand was made by them against the navy of England, and they did not fall into despair even when assailed by English forces in conjunction with those of France. Afterward, when restored to an alliance with England, and when they co-operated with her in the great struggle against Louis XIV., it is surprising how large a proportion both of troops and subsidies was furnished by this apparently inconsiderable state. "No country," says Sir William Temple, "can be found where so vast a trade has been managed, yet the inhabitants have no native commodities toward building vessels, and hardly any that are considerable for traffic with their neighbors. Holland is grown rich by force of industry, by improvement and manufacture of foreign growths." Proceeding to specify more particularly the causes of this mercantile prosperity, Sir William enumerates "the easy communication of water, particularly by the Rhine and Maese; the security of property; the undisturbed liberty of conscience, and the progressive influx of people persecuted for their religious opinions in Flanders, England,

France, and Germany." Such were the original causes; those of subsequent operation were the "general habit of industry and economy; the formation of canals; the institution of banks; the low interest of money; the appropriation of particular towns to particular branches of business; application to the fisheries, and, what he regrets much should not exist in England, the practice of keeping an official register of all purchases of land or houses;" a practice introduced into Holland and Flanders in the reign of Charles V., and which at present exists in Scotland, to the incalculable convenience and security of money transactions.

Effects of Trade upon Individuals.—We are now to say a few words on a different topic, namely, the effects of trade in forming the character of individuals; a matter of no little importance in a country like ours, where merchants both constitute so large a portion of the community, and exercise such influence on the proceedings of government. The mercantile character has a number of good points, being exempt from the vacuity and indecision so frequent in fashionable life, as well as from the various vices consequent on idleness, and which are so strikingly exemplified in the gambling and libertinism of the French metropolis. Whatever good is produced by continued activity, and by a pointed attention to the specific objects of one's occupation, may be confidently looked for among commercial men; with the further advantage, in large concerns, of an exemption from petty jealousies and invidious interferences. In such cities as London and Amsterdam, merchants are aware that the field is ample for all; that the prosperity of one is very far from impeding that of others; and that when disappointment and failure occur, their origin will be found in a very different cause than competition. Here, however, we must close our encomium, and, in the spirit of impartiality, proceed to exhibit the opposite side of the picture. The merchant's knowledge is particular, not general; he obtains a habit of understanding individual character, and a dexterity in managing his own affairs; but he has not, and can not, from his course of occupation, acquire the power of reasoning comprehensively on the interests of trade. If he observe in war a tendency to raise prices, or to invigorate particular lines of trade, such as ship-owning or insurance, he will probably be led to the general inference that to a maritime country war is advantageous. The contests of Great Britain from 1770 to 1810 having been attended with the undisputed command of the ocean, nothing more was required to satisfy the majority of traders that her mercantile marine was in a state of equal ascendancy. They took *an pied de la lettre* the custom-house reports of annual exports, without observing how much was to be deducted on account of the depreciation of bank paper, or how surely they were laying the foundation of future distress by submitting to enormous taxation. Again, when in 1807 the long continuance of war had given a serious wound to her trade and navigation, a majority of the merchants ascribed it, not to the true cause, but to the undermining competition of the United States. Their range of reflection was not such as to enable them to perceive that, by overturning the prosperity of the latter, they would sap the foundation of their own; and that every million which they prevented us from adding to our capital was so much withdrawn from a fund devoted to the increase of the productive industry of Britain. Hence the unfortunate orders in council, the main cause of the overthrow of her exchanges with the Continent, of the increase of expenses in Spain and Germany, of her war with the United States; in short, of the long continuance of her sufferings since the peace.

Bad Effect of long Credits.—Nothing would, in our opinion, conduce more to the prosperity of trade than the adoption of the plan of doing all wholesale business for ready money, and the relinquishment of that habit

of long credit which prompts to unguarded enterprises, and has for so many years been the principal cause of crowding the columns of the gazettes.

To show the results of long credit, it is necessary to go to some length into practical illustration, and to apprise our readers of the real situation of the majority of our manufacturers and export merchants. A manufacturer on the present footing receives orders in the course of the year from twenty or thirty mercantile houses; the goods to be exported probably to the West Indies, the Spanish Main, or Brazil; the understood term of credit twelve months. The manufacturer does not receive the orders from abroad; he has an intermediate guarantee, that of the exporting merchant. Still the risk is considerable; but he naturally hopes for the best, and is unwilling to decline an order when it comes to him from a quarter of respectability. Now by mercantile respectability our readers are to understand integrity, and the intention of acting up to engagements; but the power of doing so, especially at a remote date, is a very different question, and is, in general, possessed in a much smaller degree than the public imagine. The trader whose capital is large will not scruple to ship goods to the value of 50 per cent. greater than his capital, first in the hope, so general among merchants, of realizing a handsome profit, and next in confidence that, should the foreign market be dull, and should delays occur in obtaining returns within the given time, his credit will procure him indulgence for several months, at the end of which the expected remittances can hardly fail to arrive. No may, and in general does go on for several years without much embarrassment, receiving, indeed, less than he sends out, but informed that all has been well sold, and can not fail to be soon realized. If this goes on pleasing himself at every balance of his books with the seeming profit, and only regretting that hitherto that profit has not been tangible, since it exists in the shape of a debt due by his correspondents. He continues, however, under a favorable expectation of their making up for past deficiencies, and flatters himself that the delay has resulted from partial or temporary causes. He begins to find himself straitened for funds, but has as yet little difficulty in obtaining relief from a moneyed friend, or a prolonged credit from the manufacturers. His correspondents continue to write in a strain of confidence, and to call for more goods, which if he be of a confident character, will lead him to extend the annual amount of his shipments; but at all events he is obliged to continue a certain supply for the sake of keeping up the assortment of stock. Still he finds that year after year a larger portion of his capital remains with his correspondents, and that they, however decisions (for we by no means put an extreme case), are unable to prevent an accumulation of debt, because they are in like manner left unpaid by the inhabitants of the country. To go to law would be of no avail, since it is the policy of almost every government in a recently-settled country to favor the debtor, and to give him the means of retaining capital in his hands. Affairs now begin to be serious with the exporter; the manufacturer and other creditors can not or will not give further time, and demand an explanation of his circumstances. This explanation takes place, and serves to show that their debtor is a man of honor, with more assets than debts, but the latter are certain, while the former are at a distance of 3000 miles. The consequence is a grant of time, an allowance to the debtor of two, three, or four years, to act under letter of license. In the hope of accomplishing that which it is evident can not be performed sooner. This is, in general, both the wisest and most liberal course; still it is not often found to succeed, because the foreign debts can seldom be realized in climates where life is held by so uncertain a tenure, where respectable agents are so rarely found, where buyers of goods have so little capital, and, above all, where the law allows them

such a length of time for payment. A few of the promised installments are probably made good, but in general the merchant recognizes the impracticability of fulfilling the remainder, and finds it eventually necessary to submit to bankruptcy.

Holland a Country of short Credit.—In Holland we find that in its better days bargains were almost always made for ready money, or for so short a date as six weeks or two months; profits were small in their ratio, but the quickness of returns made them eventually large; failures were rare, even in so distressing an era as the occupation of their country by the French, which began in 1795, and involved from the outset a stoppage of maritime intercourse with all their possessions in India and America. The consequence of this stoppage was a decay of trade, a suspension of various undertakings, a scarcity of work, a miserable dullness in the sale of goods; all leading, in the first instance, to diminished income, and eventually to encroachment on capital; but, amid this distress, the failures were surprisingly few. Another example, equally replete with instruction, was the state of France after the double invasion of 1814 and 1815. These prevailed at that time a general discouragement among the upper ranks, and a great deal of wretchedness among the lower, trade being at a stand, and stocks of goods lying unsold in shops or warehouses for years; still bankruptcy was exceedingly rare. All this shows what a satisfactory prospect we may anticipate when we adopt the plan of transacting the greater part of our business for ready money. Yet we are far from recommending any law or measure to enforce that object; the evident advantage of the plan will not fail to secure its adoption.

II. HISTORY OF COMMERCE. *Origin of Commerce.*—It has been an object with many writers to ascertain in what nation of antiquity commerce was first carried to a considerable extent; but as that extent implies a previous population, the more simple inquiry would be, in what country population first acquired density, particularly in towns. The answer is, that mankind first increased their numbers in warm latitudes, especially in situations where irrigation, whether effected by the overflowing of rivers, by the descent of streams from a range of mountains, or by any other means, was so extensive as to counteract the parching effect of heat, and give to vegetation a luxuriance unknown in colder regions. It was thus that the Nile gave fertility to Egypt, the Euphrates to Chaldea, and the Ganges, in the lower part of its course, to Bengal.

The earliest written notice of commercial intercourse is in Scripture, where we read of Joseph being sold by his brethren to a company of Ishmaelites or Arabs, who were going to Egypt with spices, balm, and myrrh, conveyed on the backs of camels. These itinerant traders probably brought back corn, Egypt being, even at that remote period, an occasional granary for Syria and other adjacent countries. The conveying of goods on the backs of animals ought to be remarked as indicative of a primitive state of commercial intercourse—of that which is carried on before the forming of roads or the use of wheel-carriages. Such was the case in England two centuries ago; such at present is the case in Spanish America, and, in some degree, in Old Spain, the mountainous nature of that country making it a matter of some difficulty to form roads.

Phœnicia, Sidon, and Tyre.—But whatever might be the inland traffic of the Arabians, Chaldeans, or Egyptians, they made very little progress in navigation; that was the province of the Phœnicians, who acted as naval carriers to the neighboring nations, in the same way as the Dutch did during the sixteenth and seventeenth centuries to the rest of Europe. This almost exclusive possession of navigation may seem strange in the present age, but the cause was the same in both cases—namely, the difficulty in a rude age of finding men capable of conducting vessels in the open sea.

Seamanship, now so familiar to the inhabitants of almost every port in Europe, was in those days understood by only a limited number, and was carried on with a degree of caution and slowness hardly credible to a modern reader. Thus the seaman of ancient times made it a rule to keep within sight of land, as if trusting for protection to a situation which the mariners of our days look on as attended with considerable risk. This arose from the great difference in the mode of propelling vessels, for which the moderns trust chiefly to the wind, and navigate with comparatively few hands. The small barks of the ancients were fitted out with oars; a method which required a great sacrifice of manual labor, but was attended with the advantage of finding a ready shelter in a bay or creek whenever the sky portended tempestuous weather.

What, it may be asked, was the chief cause of the extension of the navigation of Phœnicia? The vicinity of Egypt, and the quantity of provisions and merchandise exported from that fertile country. The navigation of the Red Sea, also, was conducted chiefly by Phœnicians. History is not sufficiently explicit in regard to the commodities forming the object of traffic along the Red Sea, nor have we any certain knowledge of the era at which the trade with India by that channel commenced. Bouaparte, when meditating his expedition to Egypt, was led, in his sanguine estimate of its advantages, to consider the Red Sea as the fittest line of communication with India, and to ascribe the wealth of Thebes, in Egypt, one of the earliest of commercial cities, to intercourse with the coast of Malabar. But whether the navigators of the Red Sea proceeded at that early date as far as the shores of India, it is evident that an extensive traffic was carried on with Cosseir, or a sea-port on the Red Sea which communicated with Thebes. The epoch at which Homer celebrated the wealth of that city is nearly the same as that at which Phœnician mariners navigated the Red Sea on account of the Jewish government in the reign of Solomon; but no historical investigator has been able to fix with certainty the situation of Ophir and Tarshish, the ports with which these vessels traded. Some confident calculators have considered them to have been in India; but, judging from the limited skill of navigators in that early age, it seems more likely that these harbors were near the eastern or more remote parts of the Red Sea, a part from which there probably was a direct communication with India.

Greece.—Such was the traffic of the Phœnicians with the south and east; it extended also to countries less peopled and in a still more primitive state in the west. The island of Crete seems to have owed to them its early civilization; and after Crete came Attica, Bœotia, the Peloponnesus, in all of which tradition recorded the early introduction of the arts by settlers arriving from Phœnicia or Egypt. These arrivals seem to have taken place about a thousand years before the Christian era, and half of that time elapsed in the gradual attainment of that state of civilization to which Greece had arrived at the period of her political celebrity—the invasion of her territory by the Persians under Darius and Xerxes. Greece is in several respects well fitted for foreign commerce. Her coast is greatly indented by the sea, and presents a number of inlets hardly inferior to the well-known gulfs of Argos and Corinth. Hence an early familiarity with the use of shipping, and the practice of sending out colonies at so early a date as a century after the Trojan war. These colonies proceeded in various directions, to Asia Minor in the east, to Thrace and the Euxine in the north, to Sicily and Italy in the west. The progress made by the inhabitants of these colonial settlements was rapid, particularly at Syracuse, whose capacious harbor soon acquired its extensive commerce and a numerous population. Agrigentum, Messina, Tarentum, were likewise places of considerable importance. It was the custom of these and other colonies to maintain an al-

liance and mercantile connection with the parent states, such as Athens, Corinth, Argos; and a number of characters eminent in literature and the arts appeared in the colonies at a time when their establishment might have been considered as too recent to afford more than the necessaries of life. But in a newly-settled country, such as the United States of America, various circumstances occur to increase the number and improve the condition of the inhabitants; provisions are abundant, in consequence of the extent of unoccupied land; the connection with the mother country insures a certain extent of trade; while the monopolies and other abuses natural to a long-settled community are in a manner unknown.

Athens.—On the other hand, the inland territory of Greece was not well fitted for commercial intercourse. It is traversed by no navigable river; and being mountainous and rugged, it could not, even in the days of its prosperity, boast of roads, merchandise being in those days, as at present, conveyed, not in carriages, but on the backs of horses and oxen. This deficiency of communication by land was one cause of the different states of Greece so long maintaining their independence, and of the limited ascendancy attained by Lacedæmon, which, in extent of military means, was so superior to the other states of the Peloponnesus. Sparta and Thebes being inland towns, and Corinth comparatively a small state, Athens was the chief commercial city of ancient Greece. Her distance from the sea, five miles, was such as to afford her security against a sudden descent from an invading armament, while it was sufficiently near to her harbor, the Piræus, for the easy transmission of merchandise. The trade and shipping of Athens, however small it might appear to a modern reader, was such as to give it an ascendancy over the different islands to the eastward of Greece, and to enable it to maintain, in the Peloponnesian war, a long struggle against a strong confederacy. When overcome at last, in consequence of what may be termed an accidental cause, the capture of its fleet by Lysander, its political depression was of short duration; the activity and industry of its inhabitants revived its trade, so that Athens continued for ages the most populous and commercial place in Greece.

Tyre.—Tyre, though at no time a town of great extent, remained long in the enjoyment of considerable trade. From the reign of Solomon, when its commercial activity is described in Scripture, to its capture and destruction by Alexander the Great, there elapsed a period of seven centuries. The formidable resistance it made to the Macedonian arms impressed Alexander with a strong sense of the value of commerce, and of its effect in increasing the sources of national power. Though known to the world chiefly as a warrior, Alexander had considerable claims to the character of a politician. He adopted, and caused his followers to adopt, to a certain extent, the manners of the nations they conquered; and by the expedition of Neuchrus from the mouth of the Indus to the Persian Gulf, he discovered a commendable zeal for maritime discovery. Equal judgment was evinced by him in founding his new city of Alexandria in a position such as to command an extensive range of intercourse. The Nile brought it to on one hand the valuable products of Egypt, and afforded on the other a ready inlet to the merchandise imported from Europe. To India, also, the route by Alexandria and the Red Sea was preferable to that of the Persian Gulf, which involved the necessity of a considerable journey by land.

Carthage.—Contemporary with the decline of Athens and the rise of Alexandria, but superior to either in commercial activity, was Carthage, the destruction of which forms one of the foulest blot in the history of the Romans. The situation of Carthage was well adapted for trade; its harbor was good, its range of navigation extensive, both to east and west. Founded by a colony from Tyre, it maintained a friendly intercourse

with Phœnicia, in Sicily, with no commerce, time uncivilly indebted to the gent settlers, ages which received from the harbors of Carthage sort of shipping, calling on the north of Europe confidence at fallen, from been the meagre part of several centuries.

Rome.—The Pacific, was tendency to a In navigation, ble. Pisa.—Nex merce came P at a distance o trade was chi Sardinia, Cors ance was pri though it neve tion, nor in declined from Leghorn, whic being better a Genoa.—Ge 1000 until its latter half of

with Phœnicia; while in the west of the Mediterranean, in Sicily, Spain, and the south of France, it met with no commercial rival. These countries, at that time uncivilized, and almost uncultivated, were greatly indebted to Carthage for the introduction of intelligent settlers, and derived from her the same advantages which Greece, several centuries before, had received from Phœnicia and Egypt. In Spain the fine harbors of Carthage and Cadix were rendered the resort of shipping by the Carthaginians; and without calling on our readers to believe the traditional assertions of the extent of their navigation, either to the north of Europe or the south of Africa, we may with confidence affirm that, had not this state unhappily fallen, from the jealousy of the Romans, it would have been the means of diffusing industrious habits over a great part of the west of Europe, and of advancing by several centuries the progress of the useful arts.

Rome.—The policy of Carthage, though not uniformly pacific, was far less pernicious than the perpetual tendency to aggression of a military state like Rome. In navigation the Romans were at no time remarkable. During their conflicts with the Carthaginians they sustained repeated losses, chiefly from the unskillfulness of their seamen, and their inability to cope with the fury of the elements. After they had triumphed over the Carthaginians, and extended their conquests to Macedonia and Greece, the Romans were no longer under the necessity of equipping fleets, because no maritime power dared to dispute their supremacy. But the extension of the Roman power was favorable, in several respects, to commerce; piracy was suppressed, and merchant vessels had free access to almost every part of the Mediterranean. Hence a gradual increase in the length of mercantile voyages, which now extended on one hand to the north of France and Germany, on the other to the Indian Ocean, to which it became easy, from the progressive improvement of navigation, to proceed either by the Red Sea or the Persian Gulf. The mariners' compass was still unknown, but the uniform direction of the wind in certain seasons enabled the navigators to and from India to complete their voyages with little difficulty.

The Middle Ages.—It was toward the middle of the fifth century, about a hundred years after the removal of the seat of empire to Constantinople, that the Romans became unable to defend their frontier against the uncivilized tribes who pressed on them from the north and east. The consequence was that the country along the Rhine, the inland provinces of Gaul, and, some time afterward, Spain and the north of Italy, were overrun by these rude assailants. The increase in the population of towns was checked, many places being plundered, others subjected to heavy contributions, and property in general rendered unsafe. There was no longer a central or general government; the territory of the empire was divided into a number of separate states, the rulers of which had no just idea of the importance of commerce. These uneducated governors, accustomed to appeal on almost all occasions to the sword, were not sufficiently enlightened to forego the temptation of a present seizure for the sake of the lasting advantage of mercantile intercourse.

Pisa.—Next to Venice in the history of modern commerce came Pisa, a town built on the banks of the Arno, at a distance of nearly three leagues from the sea. Its trade was chiefly with the western coast of Italy, with Sardinia, Corsica, and Sicily. Its commercial importance was prior by two centuries to that of Genoa, although it never equalled the latter in extent of navigation, nor in the number of distant settlements. Pisa declined from its commercial rank in consequence of Leghorn, which was situated immediately on the coast, being better adapted to foreign intercourse.

Genoa.—Genoa continued flourishing from the year 1000 until its ill-judged hostilities with Venice in the latter half of the fourteenth century. These were in-

jurious to both, yet both recovered from the effects so as to hold, during several centuries, a distinguished rank in trade. They were remarkable also, particularly Venice, for a variety of the finer manufactures. Neither could boast of a supply of the raw materials of almost any manufacture in their respective territories; but their numerous merchant vessels brought a variety of products from a distance, and the amount of the population of either city was such as to render practicable that division of employment which is the soul of manufacture, and which was at that time almost unknown in other parts of Europe.

Constantinople.—Constantinople had the good fortune to remain untouched by the enemies of the empire until the middle of the fifteenth century, a time when civilization had made progress in the west of Europe, and literature was on the eve of receiving a great extension by the discovery of the art of printing. To this fortunate coincidence of the revival of the arts in the west, at a time when the east of Europe was sinking under the pressure of barbarism, we owe the preservation of much that was valuable in the ancient world; and, among other things, that of certain manufactures and branches of commerce. Constantinople had all along maintained a commercial intercourse with Venice and other ports in Italy, and, in general, with Alexandria. The same had been the case in regard to India; for when the occupancy of Egypt by the Saracens prevented the trade to India by the Red Sea, it was kept up by the Caspian and Euxine. But by far the shortest course from the east of Europe to India is by the Euphrates and the Persian Gulf. It was to the extent of intercourse carried on by this channel, some time after the Christian era, that we are to ascribe the wealth and grandeur of Palmyra, a city erected in the midst of deserts. This would have continued one of the chief routes of communication between Europe and India during the Middle Ages, had not the caravans been in perpetual danger from the Arabs after the decline of the civilized governments in this part of Asia.

Venice.—The apprehension engendered by the approach of barbarians from the north and east, led a number of traders and manufacturers settled in the north of Italy to fix their families in the small islands near the mouth of the Po. There the surrounding waters afforded them a degree of protection against invaders, who, however formidable by land, had no means of carrying on hostilities by sea. Such was the origin of Venice, a city situated in the midst of the waters, and destined to acquire extensive trade from the security attendant on her position, and to take a lead amid the mercantile states of the Middle Ages.

The growing trade between Europe and India, though of considerable value, was not extensive enough to be productive of the wealth ascribed to it by Dr. Robertson and other historians, who, unacquainted practically with commerce and its limited gains, are ready to lend an ear to the sanguine statements of early writers. Thus the wealth of Venice, commonly ascribed to its trade with Alexandria and India, was the consequence of a variety of causes, no one being of particular importance, because several centuries were passed in the gradual increase of its population and capital. Venice afforded a secure resort in ages when other countries were in danger of invasion and plunder. It had also a prudent government in times when, in most parts of Europe, there was little idea of a free constitution, or of a regular administration of justice. Venice was in this state when, in the twelfth and thirteenth centuries, the increase of traffic, arising from conveying the crusaders, with their military stores, and the readiness of those zealous combatants to extend the sway of a Christian state, enabled that commercial republic to increase her foreign territories. In general, the foreign policy of Venice was pacific, but she found it difficult to avoid hostilities with the Turks, or to escape from taking a part in the repeated contests which took

place between France and Austria for the territory of the Milanese. Those who take an interest in tracing the gradual extension of industry will find in Venice the origin of several important commercial institutions. In that city was established the first public bank, and there also was first introduced a funded debt transferable from hand to hand. The same thing held in regard to lesser matters connected with the details of mercantile business. Bills of exchange, if not invented by Venetian merchants, were first carried by them to a great extent; and the principles of book-keeping by double entry were there first understood and applied in practice. However familiar those principles may be to merchants of the present day, they were too refined for the rude and primitive state of most parts of Europe in the Middle Ages.

Spain.—Here it may be well to point out the fallacy of a notion general in Spain, and not uncommon in other parts of Europe, namely, that in the Middle Ages Spain was a flourishing country, and possessed, in Taragona, Tortosa, and Zaragoza, great population and wealth, each of these towns being said to have contained several hundred thousand inhabitants. This singular opinion was widely spread, in consequence of the prominent figures made by Spain in the politics of Europe, in the reigns of Charles V. and Philip II. The public did not take into account the great addition of power conferred on Spain by her possessions in Italy and the Low Countries; nor were there in these days statisticians capable of explaining the very slow manner in which either cultivation or commerce can acquire extension in a country so mountainous, and with so few means of transport, as Spain. Of roads she can boast only the few that are required for the purposes of government, the cross-roads being little more than bridle paths, and the traffic of the country being in general carried on by mules. All this indicates a scanty population and backward state of society, as has been the case in Spain in every age; for there is no truth in the traditionary opinion that her population was greatly thinned by emigration to America. The number of persons who proceeded annually from Spain to America never exceeded the tenth part of those who at present go annually from Ireland to Canada. The truth is, that the power of Charles V. and Philip II. was great only because the power of the other princes of Europe was very limited. The military establishments of that age were quite insignificant compared to those of the present times.

The Hanse Towns.—One of the chief features in mercantile history during the Middle Ages was the association of towns in the north of Europe for the purpose of giving security to mercantile property. At that time the different countries of Europe were very imperfectly governed; there were then no regular posts and very few roads, so that the means of redressing grievances, or of making communications from one part to another, were very imperfect. Too much has been said of the political power exercised by the Hanse Towns, but the association was of great use in protecting individual property. It dated from the middle of the thirteenth century, and originated at Lubeck, a sea-port, which had not in those days more population or wealth than at present, but possessed much more comparative importance, because very few places in Europe could at that time boast of 30,000 or 40,000 inhabitants. The trade between the Baltic and the west of Germany centered in the harbor of Lubeck, in ages when navigators were not sufficiently skilled to proceed to or come from the Baltic by the circuitous route of the Sound. The association of the Hanse Towns consisted first of Lubeck, Hamburg, and Brunswick, but soon extended to other places—to Amsterdam, Dordt, Cologne, on the one side, to Dantzic, Königsberg, Riga, on the other. These and many smaller towns, to the number of sixty and upward, became members of this protecting body, which continued in a state of union during three cen-

turies. At the end of that time it was gradually dissolved, not by any violence or exercise of authority, but by the continued progress of civilization; the different governments in the north of Europe having by that time acquired the power of protecting their mercantile subjects. It is now about two centuries since the association of the Hanse Towns ceased to exist in a comprehensive sense; and for a considerable time the name has been confined to Hamburg, Lubeck, and Bremen. Hamburg took the lead of other trading towns of the north of Germany, by means chiefly of the extent of its river, and the consequent easy communication with the sea on the one hand, and the interior of Germany on the other. It gained also by the improvement of navigation in the fifteenth and sixteenth centuries, when vessels from the south of Europe found it no longer necessary to suspend their voyage at Bruges, but found it practicable, and even easy, to proceed at once as far as the Elbe.

The Netherlands.—The wealth and possession of the Netherlands belong, like the early opulence of Tyre, and the magnitude of the trade of Carthage, to the remarkable phenomena of mercantile history. To judge from the physical aspect of Holland, the general marshiness of the soil, the indifferent climate, and the total absence of mineral products, we should be inclined to consider it among the least favored countries of Europe; but all these advantages were balanced, and more than balanced, by the possession of extensive water communication. No part of Europe equals Flanders and Holland in extent of inlets from the sea, in the breadth of navigable rivers, or in the ease with which canals may be excavated. To these advantages, much more than to civil institutions, we are to ascribe the early prosperity of the Netherlands; for these apparently unpromising countries took a lead in civilization almost as remarkable as the more favored regions of the north of Italy. That they were not so early in the career of improvement, was owing to the comparative barbarism of the countries in the north of Europe with which they held intercourse; while Italy had communication on one hand with Constantinople and the Eastern empire, on the other hand with the south of France, the west of Italy, and various sea-ports which still preserved a portion of ancient civilization.

Flanders; Holland.—The soil of Flanders, without being naturally fertile, was more easily cultivated than the comparatively marshy districts of Holland. Hence the early superiority of the Flemings in agriculture and manufactures. It was in the fourteenth century that the art of weaving the finer woolens was introduced from Flanders into England, and in the sixteenth that we derived from the same quarter many useful imports in agriculture and gardening. The progress of the Dutch in navigation was equally remarkable. The Maek and Rhine enabled them to bring down the bulky produce of the interior, such as timber, corn or cattle, to their own coast, as well as to carry up these rivers to the inland provinces the various articles of merchandise imported from the south of Europe. Hence the increase of Dordt at Rotterdam. The rise of Amsterdam was owing to a different cause; to the extent of the Zuyder Zee; to the easy access which that expanse of water afforded to vessels from the Elbe, the Weser, and the Baltic.

Bruges.—Bruges owed its increase to its adoption as an intermediate port for vessels from the north and south of Europe. A voyage from the Mediterranean to the Baltic was in those days a formidable undertaking; sea-faring men accounted it too long to be performed out and home in one season, and gladly embraced the opportunity afforded by the warehouses of Bruges for landing their cargo from the south, and taking on board another from the north, without the delay of a passage through the Sound. This plan of dividing the voyages to the north continued during the thirteenth and fourteenth centuries; in the fifteenth it in a great

measure ceased, because the improvements in seamanship made it easy for vessels to proceed directly to Hamourg, Copenhagen, and other northern parts.

Antwerp.—Antwerp succeeded Bruges as the station authorized by the Hanse Towns; but its prosperity was mainly owing to the width and depth of the Scheldt, which may be said to surpass any of the maritime inlets in the north of Europe. The time of the chief prosperity of Antwerp was in the sixteenth century; its population and wealth had attained a great height for so unimproved an age, and would have continued to increase, had not the tyranny of Philip II. provoked the inhabitants to insurrection, and exposed them to all the evils of a siege and capture by a military force. The consequence of this misfortune, and of the continued intolerance of the Spanish government, was the removal to Amsterdam of many of the inhabitants, and of a great share of the mercantile business of Antwerp. In the next century the Dutch acquired great political weight, and took advantage of it to prevent the navigation of the Scheldt, that Amsterdam and Rotterdam might possess exclusively the trade with the interior provinces. This singular prohibition, unexampled in the history of commerce, remained in force 150 years; for the Scheldt was not opened to merchant vessels until 1794, when the Netherlands fell under the dominion of France. During all that time Antwerp was deprived of the benefit of foreign trade; its population ceased to increase, and remained stationary at the number, on an average, of 50,000.

Maritime Route to India.—The great object of navigators in the fifteenth century was to reach India by the ocean, and to carry on what was accounted a lucrative traffic without interruption from the Turks or Arabs. The discoveries required for this purpose were made by the Portuguese, who, in situation, were nearer than other Europeans to the western coast of Africa, the line necessarily followed by those who aimed at reaching India by a new course. The Portuguese had in these days more than one prince of the blood disposed to patronize maritime discovery; but their seamen were very unskillful, so that in following their awkward efforts at discovery, we find season after season passed in tracing the unknown part of the coast of Africa to a distance of only fifty or sixty leagues. This inconceivable slowness marked the navigation of the Portuguese in their progress toward the equator, until, in 1481, they ventured to forsake the coast, stood out to the open ocean, and penetrated 1500 miles to the south of the line. From that time a bolder course was taken by these adventurers, and at last the discovery of the route to India by the Cape of Good Hope was accomplished in 1497.

Discovery of America.—The discovery of America was effected in a very different manner. Though accomplished by Spanish vessels, the honor of the enterprise belonged more properly to Italy; for it was only in a country accustomed to navigation, and possessing well-educated mariners, that so distant a voyage could have been accounted practicable. Many years were passed, as is well known, by Columbus in forming his plan, and soliciting the aid required to carry it into effect; but, once embarked in the attempt, the success was speedy, because the mind of the conductor was sufficiently enlightened to persevere in the voyage, instead of returning, as would probably have been done by an inferior navigator before traversing the half of the Atlantic.

We now come to the sixteenth century, the time when the productive industry of Europe received a considerable impulse from the influx of the precious metals from America. At that time the chief trading towns of Europe were in Italy, the Netherlands, and, in a much less degree, in France, England, and Germany. In the latter countries the towns were very small, not being peopled to the extent of one third of their present numbers. Nothing shows more clearly the back-

wardness of manufactures in that age, the imperfect division of employment, or the limited communication between one province and another. There were in those days few lines of intercourse entitled to the name of roads, or fit for conveying corn or merchandise by wheel carriages. Even in countries comparatively level, such as the south of England, the north of France, the north of Germany, there were no carriage roads, and goods were conveyed on the backs of mules and horses, in the same manner as over the mountainous regions of the Alps. Nor were there in that time post-office establishments for the service of either governments or merchants.

An increase in town population is the best evidence of improvement in agriculture, as in commerce. In a rude state of cultivation, the labor of seventy or eighty persons is required to raise provisions for a hundred; so that three fourths of the inhabitants are obliged to live in country districts, for the mere purpose of raising subsistence. But as machinery and implements become improved, and the art of husbandry is better understood, the farmer can render more effectual the labor of himself and his assistants; there remains a greater surplus of provisions for the support of the inhabitants of towns; and somewhat more of the population are enabled to attach themselves to employments distinct from agriculture, namely, those of mechanics and manufactures. To this improved condition Europe was slowly advancing, when the discovery of the silver mines of America had the effect of materially quickening its progress. This renders it proper to make a few remarks on the supply of gold and silver in early ages.

The precious Metals.—It is somewhat singular that Egypt, a country never remarkable for mines in its own territory, should have been among the first to give an example of mining on a large scale. But the Egyptians had extended their conquests to the southward, where, in the mountains of Nubia, there were extensive mining districts. In these, as in the mines of other parts of the world, masses of ore contained only particles of silver, and the task of raising the ore to the surface was very laborious. This was performed in the Nubian mines with little aid from machinery, and chiefly by manual labor, as is still the case in many parts of Spanish and Portuguese America. The next accounts of mining in ancient history relate to Greece, where, from the mountainous nature of the country, the mines were numerous, though not particularly productive. They were wrought in Attica, Thrace, and several of the islands. The laborers were paid partly in money, partly in provisions; and the accounts handed down to us by Greek writers show that mining, like agriculture, afforded a fair return for the capital and labor employed, but no remarkable profit. Spain in those times, as at present, was remarkable for extensive mining; as were in a less degree Sardinia, Corsica, and the small island of Elba.

Such undertakings were long carried on for the public account; but toward the fifth century of the Christian era, the Roman government withdrew from most of its mining establishments, allowing individuals to carry them on for their own account. The quantity of gold and silver in circulation appears to have subsequently decreased; but we are greatly at a loss for correct information in regard either to the state of mines or the prices of commodities, as represented in money, during the Middle Ages.

Influx of Silver from America.—It is now three centuries since the importation of silver from America, in particular from Mexico and Peru, amounted at first to half a million annually, and increased to one, and afterward to two millions. This sum was such as to affect the prices of corn, labor, and merchandise generally. It caused a gradual rise of prices, carried to the greatest length in maritime districts, in parts connected with each other by navigation. The published works of the sixteenth century contain many notices

of the rise in the price of commodities, and of the inconvenience resulting to the consumers from such rise: the advantages to agriculturists and producers generally were not so clearly perceived, or the humble classes enjoying them had not equal means of stating them to the public. The supplies of gold and silver from America to Europe continued during the seventeenth and eighteenth centuries, and on a much larger scale than during the sixteenth; yet their effect was not so great for several reasons. First, the number of persons among whom silver now circulated was far greater than formerly. Gold also had become more common, and began to form the chief, or almost the sole medium for large payments; and, lastly, the use of silver for plate, jewelry, watches, and other ornamental purposes, increased greatly in consequence of the improved circumstances of the middle and upper classes. There remained thus less silver to add to the coin in circulation.

Bank-notes.—It was in the eighteenth century, particularly after 1750, that the use of bank-notes became general in England, and subsequently in the United States of America. This may be compared in its effect on prices to an additional supply of gold from the mine, because its tendency to raise prices is considerable, though not so great as is vulgarly supposed; because bank paper payable in cash on demand, of which alone we speak, can never be unduly extended. Bank-notes have as yet obtained little currency on the Continent of Europe; but in Great Britain, Ireland, and North America, their effect on prices may be said to have been similar to that of the importation of the precious metals from America. In either case, the consequence was a rise in the money price of corn, and commodities generally. To comprehend the benefit of such rise, we should consider society as divided into two great parts; the producing and the non-producing classes. The latter consist of capitalists, landlords, or fixed annuitants; the former of farmers, especially tenants on lease, manufacturers, merchants, and, in general, all persons who carry on business with borrowed capital. If a tenant on lease continue to pay during twenty-one years the same rent, while the market price of his crops experiences a progressive rise, it follows that his circumstances will improve. Thus, on the augmented importation of silver from America to Great Britain, which began three centuries ago, there took place a slow but steady rise in prices, the effect of which was of great advantage to agriculturists, in particular to those who held land on lease. The yeoman who was cautious and persevering thus laid the foundation of a little property, the next generation added to it, and the third rose from the condition of cottagers to that of farmers. This, or something like this, was the course of circumstances in England, during the chief part of the sixteenth, seventeenth, and eighteenth centuries. If the effect was at no time very great, it was continued and progressive; for we can trace no great or general decline in the price of agricultural produce until the general peace of 1814.

Trade of Great Britain.—The trade and navigation of Great Britain, great as it now is in extent, did not by any means make an early figure in the commercial history of Europe. Of this the principal cause was the thinness of her population compared to that of the north of Italy or the Netherlands, and the consequent insignificance of her towns. The slow progress in trade is also to be ascribed to political causes, to the civil troubles originating with the great barons, the frequent wars with France, and still more to the long and sanguinary contests in the fifteenth century, respecting the rival claims of the houses of York and Lancaster. It was not till the reign of Henry VII., little more than three centuries ago, that the advantages arising from the extent of coast and abundance of fuel began to be brought into active operation. During the reign of his successor, the progress of improvement received lit-

tle patronage from the court, but a most efficient indirect aid from the introduction of Protestantism. The advantages resulting from that happy change, and the development of national industry, were strongly displayed during the long reign of Elizabeth, under the wise administration of Cecil. At that time, also, was felt the benefit arising to the productive classes, from the augmented import of gold and silver from America.

Exports to North America.—A striking feature in the trade of England, compared to that of France, Germany, and other Continental countries, is the magnitude of its exports to distant parts, such as India, North America, and the West Indies. These different branches of trade employ a number of seamen, and make a conspicuous figure in the list of yearly exports. They are considered as the pillars of commercial prosperity; but those who estimate them so highly have no idea of the large sums of capital that have been withdrawn by each of these countries from England. The United States of America consumed English manufactures largely for nearly a century, but in no one year did we remit back to Great Britain the full value of the articles which we imported. The amount due from the United States to England has exceeded the general estimate, and is known only to the merchants, who feel the deduction thus made from their pecuniary means. A similar drain has long been made by her West India colonies, but in a less degree, until within these fifty years, since which the capital drawn from England has amounted to many millions. With India commercial intercourse was more limited; and the exports, confined to the East India Company and to a few mercantile houses in London, were on a comparatively small scale until the present age, during which the extension of the private trade from Liverpool, and the advance of capital on indigo plantations, made the India business assume a considerable resemblance to that with North America and the West Indies. The real and substantial benefit arising from commerce takes place at home, and shows itself in the extension of manufactures, the increase of towns, the improvement of roads, canals, and harbors.

Of the course of trade in Great Britain during the last half century, the following is a brief summary. After the peace with the United States of America in 1783, her trade suffered for some time by the transition from war to peace, but gradually improved; and in the years 1789, 1790, 1791, 1792, was decidedly prosperous. After this came the war with France, which was at first injurious to trade, but after the abundance of money consequent on the extended circulation of bank paper in 1797, assumed a very different appearance, and seemed to bring a yearly addition to the national wealth. This ostensible increase of profits was kept up during the chief part of the war, but at the peace the state of circumstances underwent a complete change; the transition was great beyond example; prices fell in every department of business, and the year 1816 was among the most gloomy in the commercial history. A revival of trade took place in 1817 and 1818, but it was succeeded by a long depression. In 1823 trade revived once more; in 1824 it became prosperous, and in 1825 afforded a striking example of the abuse of mercantile prosperity; at the end of that year a general fall of prices, and afterward the heavy calls to meet the expenses of the late gigantic railway undertakings, aggravated by the failure of the potato crop of 1846, occasioned the greatest difficulty in procuring pecuniary accommodation, and led to the crisis of 1847.

Effect of War Expenditure.—From the case with which money was borrowed by the government of Great Britain during the eighteenth century, the war carried on were both of frequent occurrence and on a scale of great expense. The result was a continued increase of debt and taxation; but the burden did not appear beyond her means, until the unprecedented length to which it was carried by the wars of 1793 and 1803.

Both took place the extreme to which was the most long experience of his coming into state of the trade measures, such as and the commerce entitled to great not now entertain and it was in an to be diverted fro of the aristocrac against the French atrocities of these parts, and, above checked issue of to an unprecedented

Both took place under the ministry of Mr. Pitt, and the extreme to which he allowed expenditure to be carried was the more remarkable when we consider his long experience in finance, and that from the time of his coming into office his attention was given to the state of the trade and revenue. Several of his early measures, such as the commutation of the duty on tea, and the commercial treaty with France in 1786, were entitled to great commendation. A similar opinion is not now entertained of his revival of the sinking fund; and it was in an evil hour that he allowed himself to be diverted from his pacific course by the urgency of the aristocracy and his sovereign to take up arms against the French revolutionists. Unfortunately the atrocities of these men, the endless usurpations of Bonaparte, and, above all, the facilities afforded by the uncheckered issue of bank paper, carried the expenditure to an unprecedented height.

In the midst of this hazardous career, the death of Mr. Pitt, and the removal from office of his immediate successors, transferred the management of British finances to the hands of men wholly unequal to the task: of men unconscious of the precarious nature of paper currency, and of the danger of such measures as a stoppage of neutral navigation, or a war with the United States of America. The consequence was a depreciation of the bank paper during five years, an enormous waste of the public money, and a burden on the country of unparalleled amount. A state of war is attended by a great demand for the service of individuals, as well in the army and navy as in the public offices. A great number of persons are thus withdrawn from productive employment, and the consequence is an increase of the wages and incomes of those who remain so employed, as well as bringing into activity a number of persons who in a season of peace would hardly have been accounted worthy of employment. A rise in the price of corn and other produce is another consequence of a state of war; this leads to a rise of rent; a rise of rent to increased expenditure on the part of the landlord; and that to a general activity and continued employment of working classes. Such was the condition of Great Britain during the twenty years from 1794 to 1814, while in the twenty years that followed the peace there was a corresponding decline, and then a gradual return to higher prices. The fall in the price of produce lowered rents, and greatly lessened the income of the upper classes; hence a contracted expenditure, and a want of employment for the lower orders. All this exemplifies the precarious nature of such a rise of prices as took place in the late wars, and will, more than any other argument, confirm the public in an adherence to peace.

Decrease of the precious Metals.—The supply of gold and silver from America to Europe continued regularly to increase until the year 1810, since which the disorders in Spanish America, particularly in Mexico, shortened the supply from that quarter by at least one-half. Mr. Jacob, in his work on the precious metals, calculated the reduction in the quantity of circulating coin, during the twenty years that succeeded the peace of 1814, at not less than 20 per cent. This decrease in the supply of the precious metals must have had some effect in lowering the prices of commodities, but to what extent it is not possible, with our imperfect data, to form an opinion. But the discovery of gold in California in 1848, and in Australia in 1851, has not only made up for any deficiency in the supplies from other quarters, but from these two countries alone there has been furnished more than twice the amount of the entire annual produce of the precious metals from all parts of the world in the most productive periods of their working. The effect of this has been to raise wages and prices very largely both in Europe and America, and to give a great stimulus to emigration from Britain, and especially from Ireland, and to some extent from Germany.—See EMIGRATION.

Free Trade.—In 1845 Sir Robert Peel abolished the customs duties on 420 different articles. This measure was a virtual abandonment of the system of protection, which was shortly after followed by the total repeal of the corn laws.

Progress of American Commerce.—The sixteenth century introduced the leading European powers to a minute acquaintance with the continent of America. Adventurous navigation had rescued a world from savage dominion, and there were adventurous spirits enough to people that world, and identify thenceforward their destinies with it. A hundred years after, and civilization planted her abodes through all this waste. Peculiar, indeed, is the feeling with which these infant days of our country are regarded, so like an illusion does it seem—so like a dream of glowing imagery. We look back as to a classic era, and the romance of Pocahontas, and of Raleigh, of Fernando de Soto, and Juan Ponce de Leon, do they thrill us less than the beatific visions of the Greek, recurring to ages long ago, when Iliad resisted the shock of Agamemnon's heroes, and the Argo sailed away to distant Colchis? The dim antiquity seems gathered around both of them alike. But let it pass, all—the romance of our history. They imagined not, the men of that day imagined not the stupendous results which have occurred so soon. They saw not the benign and regenerating influences of a virgin land, preserved for countless ages uncorrupted by tyranny, and ignorant of oppression. Could such a soil have nurtured else than freemen? They saw it not, and do we—even we—see other than darkly yet the great consummation, the mighty destinies of the regions which, three centuries ago, were proclaimed from the mast-head of a crazy ocean bark, a speck upon the distant heaven?

The development of American character is replete with instruction, and solves one of the most remarkable problems in the history of mankind. The untried scenes of a new world, cut off by trackless oceans from contact and communion with the civilization of unnumbered generations, were sufficient to introduce, what might have been predicted of them, results new, striking, and without a precedent. The indomitable will, the stern endurance, the inflexible and hardy spirit of independence, the high daring, the lofty patriotism, the adventurous, unlimited enterprise, the genius resolute, active, intrepid; inexhaustible in resources, elastic in vigor and in freshness, buoyant ever and hoping on, and executing amid every trying scene, every danger, and difficulty, and disaster—triumphing every where and in all things. Philosophy could have argued this complexion for the men whose fathers braved so much beyond the ocean, and would philosophy have won less than the fame of prophecy by her judgment?

But we pause not here to lament the causes which have counteracted these genial influences, and left whole regions of America stagnated, as it were, in the very elements of vitality and yet living hopelessly on. Should we refer to Mexico and the South American States? What is there here of progress to chronicle, and how much of humiliation? Regions blessed by Heaven in every thing but in men. Changing ever their dynasties and their despots in revolution and in blood. In motion always, without progress. In arms, without valor. Loving change rather than halting oppressors. Proclaiming civilization and annihilating its advances. The bitterness of Voltaire's sneer has no cruelty or injustice in its application to many of them, "*en passant les cheveaux de leurs maîtres ils se donnent le titre d'électeurs des rois et de destructeurs des tyrans!*" Under Heaven, as it was the destiny of the savage aboriginal, incapable of civilization, and with no law of progress ingrafted upon his nature, to fade away before the steady advances of European arms and policy, so the Anglo-Saxon element of America, by its flexibility and its power, by the new elements which it has taken to itself in the trying, yet triumphant scenes through

which it has passed, will and must, in the inevitable course of events, preside over the destinies of the continent of America, aiding and directing them, adding life and vitality, rousing dormant and sleeping energies, and developing, upon the theatre of the world, movements in comparison with which all that history can furnish before the deluge, before the era of Christ, and since, shall dwindle into insignificance! It needs no ardent temperament to draw a stronger picture.

American Commerce in the seventeenth Century.—The early colonists were exposed for a fearful probation to the most extraordinary vicissitudes and necessities. With the axe in one hand they reduced the sturdy forests into the farm-yard, and with the knife in the other they resisted the approaches of the stealthy and sanguinary savage. A meagre subsistence rewarded the toils that knew no rest, and the charities of the mother country were invoked for men whose determined wills grew stronger as they suffered. This period had its different limits. Fifteen years after the landing of William Sale, we find the proprietary government in England complaining to the Carolinas, "we must be silly indeed to maintain idle men." Thirty-three years after the landing of Bienville in Louisiana, the Western Company threw up their charter in utter hopelessness and despair.

New England's rugged soil yielded a too reluctant tribute to the industry of her sons. They went out early upon the ocean by which they were girt in search of bread that the plow yielded not. To this hardy and daring people the boons of Nature were to be found in her apparent denial of them all.

The seventeenth century affords us, however, but a few particulars of the trade which had been started in the colonies. That it was limited can be readily imagined; that it should be worthy of any regard at all, is the only source of surprise. The materials of this portion of our history are meagre. It is sufficient that, in 1647, a trade had been opened from the Northern ports to Barbadoes and others of the West Indies; that a collector of the customs was appointed at Charleston in 1685, and that the hardy enterprises of the Nantucket whalers received their first impulse in 1690.

American Commerce from 1700 to the Revolution.—In the year 1731 we find a petition read in Parliament from the American colonies that the African trade be thenceforward laid open to them. In the same Parliament it was conceded that the whole gain of the mother country from the trade of Virginia and Maryland alone amounted annually to £180,000. The Pennsylvanians were exporting corn to Spain and to Portugal, and with the proceeds of their ships and cargoes selecting out merchandise in the English markets. To the Dutch alone they sold 5000 pistoles annually in liquor and provisions. They had their invoices to Surinam, and Hispaniola, the West Indies, Canaries, Newfoundland, and the other colonies, and £150,000 from the proceeds to traffic in Britain. "New York," says a chronicle of this epoch, "sends fewer ships to England than some other colonies do, but those they do send are richer, as dealing more in furs and skins with the Indians, and they are at least of equal advantage to England with those of Pennsylvania. The soil of New England is not unlike that of Britain. It employs about 40,000 tons of shipping, and about 600 sail of ships, sloops, etc., about half which shipping sails to Europe." Now began the parent's jealousy of her offspring. Nothing, it was said in Parliament, nothing is more prejudicial, and in prospect more dangerous to any mother kingdom than the increase of shipping in her colonies. The only use of colonies, added Lord Sheffield, is the monopoly of their consumption and the carriage of their produce. In 1730 the Commons of England struck an ineffectual blow at the American trade with the French and Dutch colonies, it having been represented to them as greatly detrimental to England and her colonies.

In 1782 a writer gravely announced that the con-

venience of the Americans from the plenty of beavers, hare, coney wool, and many other furs, gave them such advantages that, unless restrained, they would soon supply all the world with hats. The Board of Trade of the same year report that there are more trades carried on and manufactures set up in the provinces on the continent of America, northward of Virginia, prejudicial to the trade and manufactures of Great Britain than in any other of the British colonies. In 1750 the Americans were forbidden to work in iron, and Lord Chat-ham declared not long after in Parliament that the colonies of North America had not even the right of manufacturing a nail. So stringent had become the protective policy.

In 1764 was imposed an onerous burden upon American commerce by the mother country, grown jealous of its too great extension. This commerce had greatly enriched the home as well as the colonial government, but the former was too much blinded by erroneous policy to perceive it. She heeded not the annual purchases made in her markets with the avails of lumber, beef, fish, pork, butter, horses, poultry, livestock, tobacco, corn, flour, bread, cider, apples, cabbages, onions, etc., disposed of by our traders to the eager West India planters; and Lord Sheffield, in his observations on the commerce of the American States, tells us that at this time the Carolinians, of their exports to Kingston, Jamaica, took back one-half in the produce of that country, the middle provinces one-fourth, New England one-tenth, and the balance in specie dollars. The trade of Britain with the American colonies employed in 1769, 1078 ships, and 28,910 seamen. The value of her imports from them for that year amounted to £3,370,000, and of their imports from her to £3,724,606, showing a large difference in favor of the parent country.

In 1770 the imports of Carolina were £585,714, those of New England £564,034, of Maryland and Virginia £351,140, the exports of Virginia at the same time being double the value of those of either of the others named. Mr. Burke triumphantly announced in the House of Commons, "Our trade with America is scarcely less than that we carried on at the beginning of the century with the whole world! In the six years ending with 1774 there was an average import from the colonies into England of £1,752,142, and an average export to them in turn of £2,732,056. Crippled as our energies were, they could not be repressed. It was a vain effort to confine the enterprises of a people whose views embraced the world itself, into the narrow compass afforded by English ports, and by portions of Europe southward of Cape Finisterre. When the day of reckoning came, as it did at last, for these reckless abuses of power, and they were proclaimed in the bill of rights, not the least of the usurpations for which retribution was demanded is to be found in the clause: 'She has cut off our trade with all parts of the world.'"

In the article COLONIES a table will be found compiled from the most authentic sources, which exhibits the trade of the mother country during the whole of the periods we have been considering; the table is of great interest, embracing as it does in one view almost the entire commerce of America for seventy-six years.

From these statistics we learn the relative commercial position of the different provinces. Dividing the whole time embraced into periods of twenty-five years each, we observe in the first period that Virginia, Maryland, and Carolina furnish almost the entire exports, and import much more largely than New England and New York. In the second period New York greatly increases her imports, which still fall short of those of New England, or Virginia and Maryland, while her exports are enhanced but little. The whole exports of New York, Pennsylvania, and New England combined did not reach the amount of those of Carolina singly. In the third period Pennsylvania imports more

largely than the Southern Carolina, Maryland, and plantation, traffic a few

largely than New York, but less than New England; the Southern provinces retain their rank as exporters, Carolina being still greater than New York, New England, and Pennsylvania together; and Georgia, a new plantation, equals New York. Truly is the empire of trade a sickle and inconstant one.

Commerce of the United States under the Articles of Federation.—During the Revolution all foreign enterprise was of necessity suspended, and in struggling for liberty men taught themselves to forget and despise every mere physical want. Leagued together for common defense, the states were able to resist every device of power, and sustain a long and bloody contest. But when that contest ended and liberty won, the confederation exhibited at once its nervelessness for peace, and for the arts, and policy, and duties of peace. The fabric which could resist the storm crumbled away when the sunshine succeeded. So true is it that the necessities of men are the only durable bond of their union, and that without this union there is no strength.

From the close of the war until the adoption of the Constitution there may be considered to have been no great regulating head in America. No uniformity or system prevailed among the states, and their commerce was consequently exposed to the utmost uncertainty, fluctuation, and loss. Tonnage duties were levied in different ports, as it suited the caprices of the several governments, and as they were more or less desirous of encouraging particular branches of navigation and trade at the expense of others. By a policy more astute than that of her neighbors, New York managed in this way soon to increase largely her foreign trade, and laid the foundation of the empire she now maintains. From 1784 to 1790 our commerce exhibited the most remarkable results. For seven years consecutively the imports into American cities from Britain were never otherwise than twice the amount of the exports to her, and for several years were three and even five times their value. A drain of specie is said to have been the consequence, a very natural, though not necessary one, and great commercial embarrassment and distress.

The following table made up from records of the English custom-house will be found of interest:

Year.	Exports, America to Britain.	Imports, America from Britain.
1784	2,749,545	23,079,467
1785	309,694	2,308,023
1786	443,119	1,608,465
1787	899,637	2,009,111
1788	1,023,754	1,886,142
1789	1,000,118	2,625,298
1790	1,101,071	3,431,773

Commerce of the United States under the Constitution and until 1812.—In this crisis the attention of thinking men and patriots in all parts of the nation was aroused, and there was perhaps nothing which contributed so much in urging the States into a general convention, and into the adoption of a constitutional government and union, calculated to preserve their liberties, their fortunes, and their glory in all the future. One of the first grants of power conceded to Congress under this Constitution was that of "regulating commerce with foreign nations, among the several states, and with the Indians." Referring to the state of things which existed under the articles of federation, an able writer observes, "Interfering regulations of trade and interfering claims of territory were dissolving the attachments and the sense of the common interest which had cemented and sustained the Union during the arduous struggles of the Revolution. Symptoms of distress and marks of humiliation were rapidly accumulating. The finances of the nation were annihilated. In short, to use the language of the authors of the Federalist, each state, yielding to the voice of immediate interest or convenience, successively withdrew its support from the confederation, till the frail and tottering edifice was ready to fall upon our heads, and to crush us beneath its ruins. Most of the federal constitutions of the world

have degenerated in the same way, and by the same means."—KENT, vol. 1. p. 217.

No more, said a memorial from Charleston, on the adoption of this Constitution—no more shall we lament our trade, almost wholly in the possession of foreigners, our vessels excluded from the ports of some nations and fettered with restrictions in others; our materials, the produce of our own country, which should be retained for our own use, exported and increasing the maritime consequence of other powers. With this memorial before them, and others of a similar character, Congress at its first session appointed a committee to report upon "the expediency of increasing the duty upon foreign tonnage carrying American produce to places in America not admitting American vessels; and to frame a bill placing the same restraint upon the commerce of foreign American states that they place upon us."

By the report of Alexander Hamilton in 1790, it appears that the total tonnage of the United States at that time was as follows:

American vessels in foreign trade	363,093 tons.
Coasters above twenty tons	113,181 "
In the fisheries	26,259 " —502,533 tons.
Total foreign tonnage	302,913 "
United States and British	312 "
United States and other foreign	338 "
Total	766,089 "

The tariff of 1789 was specific and *ad valorem*, and discriminated 10 per cent. in favor of the trade conducted by our own shipping. In this we but imitated the navigation acts of European states, by means of which it has been supposed the enormous maritime consequence of some of them was principally secured. We shall not pause to argue a point in political economy so long mooted among writers of the greatest ability. The jealousies of nations have gone and still go very far. Even the philosopher Voltaire thought that their gain could not other wise accrue than with each other's loss. England long imposed the most onerous restrictions upon all other commerce than her own, and her advances in consequence, or notwithstanding, have been unprecedented. Her tonnage when she commenced this system was less than that of the United States at the adoption of the Constitution.

There was one department of our maritime industry which demanded the earliest attention of government, and we think its general interest will be sufficient apology for any space we may allot to its consideration—THE FISHERIES. Mr. Jefferson, in 1791, then Secretary of State, furnished an admirable report upon the subject, which we proceed to analyze. As early as 1520 there were fifty ships upon the Newfoundland coasts at a time for cod. In 1577 the French had 150 vessels there, the Spaniards 100, Portuguese 50, and English 15. The French fisheries began early to decline. In 1768 the Americans took but little less than the English, and the French took least of all. In 1789 England obtained double the quantity of America and France together. During the Revolution the American fisheries were almost entirely abandoned, and Mr. Jefferson left it to the wisdom of Congress to decide whether they should not be restored, by opposing prohibitions to prohibitions and high duties to high duties, on the fish of other nations.

The whale fishery was prosecuted by the Biscayans as early as the fifteenth century. The British began its encouragement in 1672 by bounties. The Americans opened their enterprises in 1715. They succeeded early in the discovery in the Southern Seas of the sperm-cet whale, which they attacked instead of the Greenland hitherto known to navigators. In 1771 we had 204 whalers. During the war England held out the largest bounties to the trade, and so irresistible were these in the depressed condition of our fishermen, that it is said many of them were on the eve of removing to Halifax, to prosecute the business there, and were only deterred by a letter from Lafayette declaring that

France would abate her duties upon oil. The little island of Nantucket is the great heart of these fisheries. A sand-bar, said Mr. Jefferson, fifteen miles long and three broad, capable by its agriculture of maintaining twenty families, employed in these fisheries, before the Revolution, between 5 and 6000 men and boys, and contained in its only harbor 140 vessels. In agriculture, then, they have no resources, and if that of their fisheries can not be pursued from their own habitations, it is natural they should seek others from which it can be followed, and principally those where they will find a sameness of language, religion, laws, habits, and kindred.

In 1808 Mr. Huger stated to Congress in his report, that it would seem the cod fisheries had gained ground since the Revolution, but that the whale fisheries, on the contrary, had been for some time past on the decline. The war of 1812 was most disastrous to the fishermen, but they soon afterward recovered their prosperity, and on the first of January, 1844, we had 644 vessels engaged at sea, of the value, including catchings, of \$27,784,000. On the first of January, 1846, there were 680 ships, 84 brigs, 21 schooners, and 1 altop; tonnage 233,149; manned by about 20,000 seamen and officers, consuming over three million dollars annually of American produce. Proceeds of whale fisheries \$9,000,000 per annum, of which only \$2,000,000 are re-exported.

In 1844, Mr. Grinnell stated in Congress:

"This fleet of whaling ships is larger than ever pursued the business before. Commercial history furnishes no account of any parallel. The voyages of those engaged in the sperm fishery average three and a half years; they search every sea, and often cruise three or four months with a man at each mast-head on the look-out, without the cheering sight of a whale. They are hardy, honest and patriotic, and will, as they did in the last war, stand by their country when in danger; they will man our ships, and fight our battles on the ocean."

Mr. Clayton remarked in February, 1846:

"We have at this time a commerce of 2,417,000 tons of shipping, England has 2,490,000 tons; so that we are nearly, nay, it is my opinion, we are completely on a par with her. I doubt, sir, whether England has a greater commercial navy or greater interests to protect. We have more than 700 whale ships in the Pacific, an extensive Indian commerce and a great and daily growing commerce with China."—Baow's *Whaling Cruise and History of the Whaling Fishery*, 1846, p. 680.

At the close of the last century there were many causes which tended to add a vast importance to the commerce of the United States. For several years this commerce enjoyed unparalleled and almost unmeasured prosperity. Scarcely admitted into the family of nations, we found the whole civilized world engaged in the fiercest and most sanguinary conflict. A wise and indeed "masterly" neutrality was of course the true policy of the nation. The carrying trade of the world fell at once into our hands. We supplied the mother countries with the products of their own colonies. The East and West Indies alike were opened to our shipping. Their rich products filled our warehouses, supplying consumption and re-export. Prosperity such as this, however, was fated to be brief. The conflicting powers sacrificed every thing to their mutual hatred, and minded little the rights of a nation they had not even learned to respect. Protestation ended in war, and the rights of our sailors were established on every sea. With the return of peace in Europe, the carrying trade departed rapidly from us.

In 1791 the king and council of England admitted American unmanufactured goods, except fish, oil, blubber, whale fins, certain naval stores, etc., into Britain at the same duties as British American produce. The treaty of commerce of 1794 between the two governments was a reciprocity one, both parties binding themselves to impose no greater restrictions upon each other than they imposed upon others. This treaty regu-

lated our East India commerce, then newly opened and promising a great extension.

From 1790 until 1797 Pennsylvania continued largely the greatest exporter in the Union. In 1791 South Carolina occupied the third rank. In 1797 New York for the first time took a leading position, which she has ever after maintained. The first exports of Tennessee and Mississippi date from 1801, those of Kentucky and Indiana from 1802, of Michigan 1803, Orleans Territory 1804, and Ohio 1804. This we shall see more particularly hereafter. It is sufficient now to indulge the reflections which the facts before us so naturally awaken. Mysterious have been the changes. Old age and premature decay have fallen upon cities once famous for their trade; and the quays, where the flags of all nations floated, have come at last to be comparatively deserted. We look around, and there have started up others like mature creations, full of vigor and stalwart even in their infancy. How hardly can reason realize that these wondrous changes are not all the pictures of a fertile imagination. Where is placed Virginia now, that mother of states, who in 1769 exported to foreign lands four times as much as New York? and where is Carolina, whose exports at the same time doubled those of New York and Pennsylvania together, and were equal to five times those of all New England? If trade grow to colossal stature, its proud empire, hastens also to swift decay.

The difficulties which beset our commerce in the early part of the present century, when the rival hostile powers of Europe, jealous of our prosperous neutrality, strained every nerve to involve us in their disputes, will be called to mind by every one familiar with history. We were made the victims of the policy and arts of these nations, and even as early as 1795 their depredations upon our commerce were considerable. In five months alone of that year it was stated in the House of Peers, that six hundred American vessels were seized or detained in British ports for alleged violations of orders and decrees claimed as principles under the law of nations. These aggressions upon our rights were long and extensively practiced, as the following table will exhibit:

SEIZURES OF AMERICAN VESSELS FROM 1803 TO 1812.	
By the British.....	917
By the French.....	558
By the Neapolitan.....	47
By the Danish tribunals.....	70
Total vessels.....	1592

And this at a time when we were at peace with all the nations on earth! Indemnity for these spoliations has been the subject of numerous treaties; among others, that of England in 1794, France 1803, and Spain in the Florida treaty of 1819. But this whole period, so interesting in our annals, deserves a minute survey.

On the conquest of Prussia in 1806, Bonaparte conceived the idea of crushing the maritime power of Britain, by prohibiting all the world, in his famous *Berlin Decree*, from conducting any trade with her or her numerous dependencies. The retaliatory British orders in Council followed at once, and all countries in the world connected in any way with France, or opposed to England, were declared to be under precisely the same restraints as if actually invested in strict blockade by British forces. Incensed by so unexpected and ruinous a measure, Napoleon issued the memorable *Milan Decree*, making lawful prize of all vessels submitting at any time or in any way to British search or taxation. It was natural that these illegal and unauthorized proceedings should excite the utmost interest and concern in the United States so materially and even vitally affected by them. We protested in vain. The administration recommended as the sole remaining alternative of peace an embargo, which Congress adopted in 1807. This measure the commercial interests warmly opposed as ruinous to them, and memorials were forwarded from many quarters praying for its repeal. To

these it was teaching commerce and nation to privilege for to supply matter, however, who to France, glish communication, would be the just ground.

In 1800, was substituted or regarded if her in American.

these it was replied by government, "The embargo, by teaching foreign nations the value of American commerce and productions, will inspire them with a disposition to practice justice. They depend upon this country for articles of first necessity, and for raw materials to supply their manufactures." Such a view of the matter, however, did not occur to the mind of Napoleon, who regarded the embargo as greatly favorable to France, and aiding him in his warfare against English commerce. "To submit," said he to Mr. Livingston, "to pay England the tribute she demands, would be for America to aid her against him, and a just ground of war."

In 1800, a non-intercourse with Britain and France was substituted for the embargo, which the latter power regarded as such an evidence of hostility as to justify her in proceeding at once to condemn millions of American property as lawful prize.

The Congress of 1810 determined upon the admission of the commercial vessels of the powers above-named, if the act were preceded by a revocation of their hostile and arrogant decrees. The French government pretended to close in at once with the proposal, but it was nearly one year later before her repealing ordinance was officially promulgated, evidencing a disposition on the part of Napoleon to play with us in bad faith, and to turn the game at any time to his advantage—so humiliating to our pride are the events of this entire era. With England it was long doubtful what relationship we might expect to sustain. Hostile and peaceable alternately, according to her caprices or her interests, she had provoked in American minds a resentment too deep to be subdued, and forbearance longer was regarded a crime. The Orders of Council remaining in force, and the aggressions increasing daily, a non-intercourse act of sixty days was resorted to, the prelude only to a solemn declaration of war. Then was the hour of severe retribution, and then was the national honor and dignity of America triumphantly vindicated!

Commerce of the United States since 1812.—This has been an era of prosperity and rapid advance, and the great powers of the civilized world seem to have realized for once the rich benefits of a prolonged armistice, or, if another expression be preferred, a protracted, and we hope permanent peace. In commercial rank, the United States of America, subordinate to Britain only, and having outstripped all the world else, is prepared to share a divided sceptre, until that sceptre can be wielded alone by her hand, and the empire of the seas be transferred to her keeping.

The history of our trade for the last thirty years has material enough for many more pages than we can allot to it, even with the greatest condensation. The period has been celebrated by an approach to a more liberal *eternality*, and a *reciprocity* something else than in *ama*. The progress in the last year or two has been most strongly marked toward that *ultimatum*, in the minds of every lover of truth and of human advancement, perceived first by Lord Bacon, and ably, though imperfectly, presented by his followers—*commerce unfettered as the winds that waft it*—free religion, free government, free press, free traffic—freedom every where, and in every righteous thing throughout all the world! When shall nations sacrifice their foolish jealousies, and meet each other on this high, broad and Christian ground? We are no partisan here, but a cosmopolite. We advocate a policy as wide as the earth, and as generous. No single nation can afford to set alone—the movement, if made at all, must be *universal*.

The condition of Europe now, however, argues little for the early triumph of those principles to which we have been referring. The latest British, French, and Austrian tariffs have been restrictive, though in the case of the first-named nation her policy would appear about to be radically changed, as in the late repeal of the corn-laws. The German states maintain the exclusive policy, as do also the Spaniards and Portuguese. Russia was

latest in adopting the restrictive system, but we see by her last tariff some evidences of improvement, which neither Sweden nor Denmark furnishes. The duties of the Italian states have been generally moderate, except for Rome and Naples, and we recognize a great improvement in these in the late tariff of his Holiness the Pope. The commercial system of Holland is the most liberal in all Europe, but the South American states appear to be governed by the same spirit as that which dictated the policy of Spain.

In 1824, Great Britain seemed desirous of removing in some degree her restrictions upon the navigation of other powers. She entered into reciprocity treaties with many of them, and in this was soon after imitated by the United States, in the treaties of 1825—6—8—9 with Central America, Denmark, Sweden, Hanse Towns, Prussia, Brazil, Austria, Hungary and Bohemia, Mexico, Russia, Venezuela, Greece, Sardinia, Netherlands, Hanover, and Portugal. We also entered into similar but limited reciprocity treaties with France in 1822, continued afterward, and with England in 1821, 1825, and 1833, and a full reciprocity treaty with Canada in 1854. These treaties were arranged by Mr. Kennedy, Chairman of the Committee of Commerce, into three classes.

1. Those securing mutual privileges of export and import of produce, the growth, produce, or manufacture of the stipulating powers, transported in their own vessels, without discrimination on tonnage.
2. Those providing for a levy of duties not less favorable upon the tonnage of either than are levied upon the tonnage of other powers.
3. Those requiring equality of port charges.

For statistics of the commerce of the United States, see article UNITED STATES.

Commercial Policy of the United States.—The United States have, since the very commencement of their existence as an independent government, ever been willing and ready to reciprocate, to the fullest extent and in the most liberal spirit, all privileges and favors, whether of navigation or commerce, extended to their flag by foreign nations. To this end, and in order to anticipate the usually dilatory process of treaty negotiations, the President of the United States is vested, by act of Congress, with authority to issue his proclamation granting to the vessels of foreign nations equal and similar privileges and favors to those extended to the vessels of the United States in the ports of such foreign nations, on receiving official notice thereof from the accredited agents of such governments.

Vessels belonging to the following nations are admitted, under the provisions of law, treaties of commerce and navigation, or conventions, into the ports of the United States on the same terms as American vessels, with the produce or manufactures of their own or any other country: Argentine Confederation, Austria, Belgium, Brazil, Chili, Denmark,* Ecuador, Great Britain, Greece, New Granada, Guatemala, Hanover, Hanse Towns (Hamburg, Bremen, and Luebeck), Mecklenburg-Schwerin, Netherlands, Oldenburg, Peru, Prussia, Russia, San Salvador, Sardinia, Sweden and Norway, Tuscany, Two Sicilies,† Venezuela.

Vessels belonging to the following nations, with which the United States have reciprocal treaties on the footing of the "most favored nations," or with whom reciprocity exists, are admitted into the ports of the United States on the same terms, as respects *tonnage or navigation duties*, as vessels of the United States, with the produce or manufactures of their own or any other country: Bolivia, Costa Rica, Mexico, Muscat, Ottoman Empire, Portugal, and Uruguay.

* The treaty between the United States and Denmark expired on the 14th day of April, 1856.

† By decree of December 18, 1854, equality with the national flag is offered by the government of the Two Sicilies to the vessels of such nations as reciprocate the favor. This equality applies to the direct and indirect trade.

LEADING EVENTS OF A COMMERCIAL CHARACTER IN THE 16TH, 17TH, 18TH, AND 19TH CENTURIES.

Sixteenth Century.—1503. The Portuguese commander Albuquerque, on his way to India, discovered Zanzibar.—1504. Death of Isabella, Queen of Spain, and friend of Columbus, November 26, æ. 53. Columbus returned from his fourth and last voyage. The Venetians, jealous of the new Indian trade of the Portuguese, incite the manacles of Egypt to commence hostilities against them.—1505. Francisco de Almeida, Portuguese viceroy, established factories along the coast of Malabar, and his fleets interrupted the commerce of Egyptians and Venetians.—1506. The sugar-cane brought to Hispaniola from the Canaries. The *Great Harry*, the first ship of the English navy, built.—1507. Margaret of Savoy, governess of the Netherlands, concluded a commercial treaty with England. Portuguese settlements formed on Ormus by Albuquerque, and on Ceylon by Almeida. Madagascar visited by Tristan d'Acanha.—1509. The Venetians recover Padua, and rise again in power. Diego Columbus (son of Christopher) governor of Spanish America.

1510-1520.—The Portuguese established themselves at Malacca (1511), which becomes the centre of their trade with the neighboring islands and with China.—1513. Vasco Nunez de Balboa crosses the Isthmus of Darien, and reaches the Pacific.—1515. The Rio de la Plata discovered by Juan Diaz de Sotis.—1516. Death of Ferdinand of Spain, January 23, æ. 61.—1517. The Portuguese trade with China at Macao. Negro slaves brought to Hispaniola. The sweating sickness (cold plague) raged in London.—1518. Silveira opens the Portuguese trade with Bengal.—1519. Fernando Cortez attacked Mexico. Fernando de Magelhaens sailed on his expedition to the Pacific, and having passed through the Straits now bearing his name, discovered the Ladrones and Philippines, and was murdered by the natives.—1520. Cortez took the City of Mexico.

1521-1530.—After the death of Magelhaens (1521), Cano conducted the squadron to the Moluccas, and (in 1522) returned to Seville, via Cape of Good Hope; having concluded the first circumnavigation of the globe, in 151 days.—1521. First discovery of Peru, by Pizarro and Almagro.

1531-1540.—Porto Bello and Cartagena (Spanish Main) founded in 1532.—Mines of Zacatecas discovered.—1533. Cortez conquered Cuzco and Quito, the capitals of Peru.—1534. The Sun opened to the Netherland merchants. Canada discovered by Cartier.—1535. The use of tobacco first known in Europe.—1536. Final subjugation of Peru; discovery of California by Cortez.—1537. Conquest of New Granada.—1540. Cherry-trees brought from Flanders and planted in Kent, England.

1541-1550.—The Portuguese admitted (1542) to trade with Japan.—1543. Death of Copernicus: he deferred until his last days the publication of his great work, *De Orbium Cælestium Revolutionibus*.—1545. Discovery of the mines of Potosi.—1546. Rate of interest in England fixed at 10 per cent. (37 Henry VIII.).—1548. Introduction of the orange-tree from China into Portugal.

1551-1560.—The London Steelyard Company (the first commercial company established in England, 1232) deprived (1531) of their privileges.—1552. All loans at usury declared illegal, and subject to forfeiture in England. The King of France (Henry II.) prohibits the export of money.—1558. The Salters' Company, London, established.—1560. Ordinary rate of interest at Antwerp, 12 per cent.; and fixed at the same rate in Germany, Flanders, and Spain, by Charles V. Course established at Antwerp.

1561-1570.—Merchant Tailors' School, London (1561), instituted.—1561. The Manillas, ceded by Portugal to Spain, received the name of the Philippines.—1567. The Royal Exchange, London, founded by Sir Thomas Gresham, September 7. Caracas, in Venezuela, built

by the Spaniards.—1568. Some ships, conveying money from Spain to the Duke of Alva, are detained by Queen Elizabeth at Southampton and Plymouth.—1569. Luis de Atalbe revives the waning power of Portugal in India. Drawing of the first English lottery.—1570. The Royal Exchange, London, opened by Queen Elizabeth.

1571-1580.—Rate of interest limited in England to 10 per cent.—1571. Large accumulations of gold from America. Manilla built (1573), and made the seat of a Spanish viceroy.—1576. The plague devastated Italy, 70,000 died at Venice. Martin Frobisher sailed, June 11, to seek a northwest passage; failed, and returned.—1577. Drake commenced his voyage round the world, November 15.—1578. The Norwegians attempted to interrupt the English commerce with Archangel. California explored by Drake. First colony planted in Virginia, by Gilbert. Tulips introduced into England.—1579. Queen Elizabeth entered into a treaty of commerce with the Sultan, and established the Turkey Company.—1580. Drake returned from his voyage, November 3; the order of knighthood conferred upon him.

1581-1590.—Correction of the Calendar by Gregory III. (1582); October 5th made the 15th.—1583. Queen Elizabeth claimed the sovereignty of Newfoundland, and fortified St. John's.—1584. Raleigh conducted a second colony to Virginia.—1585. Drake and Frobisher, with a powerful fleet, attacked the Spanish settlements in the West Indies. Davis explored the northeast coast of America. Coaches first used in England.—1586. Success of Drake in Hispaniola, San Domingo, and Florida. Potatoes and tobacco introduced into England. Cavendish sailed on his expedition.—1587. The Scottish Parliament (James VI.) adopted 10 per cent. as the maximum rate of interest.—1588. The Spanish armada sailed from Lisbon May 29, entered the English channel July 19, and was defeated. Lord Burleigh established the first newspaper, *The English Mercury*.—1589. Cavendish returned with great wealth, taken from the Spanish settlements during his voyage round the world. The stocking frame invented by Rev. William Lee, of Cambridge.—1590. The first paper-mill in England established by John Spillman, at Dartford, in Kent.

1591-1600.—English ships pursued the whale-fishery (1591) at Cape Breton. Telescopes improved and brought into general notice by Jansen, of Middleburg.—1593. Whalebone first used in England.—1594. The Falkland Islands discovered by Hawkins.—1595. Oranges first known in England.—1598. Whale-fishery commenced at Spitzbergen.—1600. The English East India Company established.

Seventeenth Century.—1601-1610.—Debate on monopolies (1601), defended by Francis Bacon—abolished by Queen Elizabeth. The first English factories established on the Malabar coast.—1601. The rate of interest in France (Henry IV. and Sully) fixed at 6½ per cent.—1602. Artichokes introduced into England from Holland; Asparagus from Asia; Cauliflower from Cyprus.—1604. The plague raged violently in London.—1606. English companies chartered for settlements in Virginia. The French established themselves in Canada. New Holland discovered by the Dutch.—1608. Hudson explores the bay now known as Hudson's Bay. Quebec built.—1609. Many Puritans left England for Virginia, with Sir Thomas Gates and Sir G. Somers—the latter driven to the Bermudas (or Somers' Islands). The Dutch, by levying heavy tolls at the mouth of the Scheldt, transfer the commerce of Antwerp to Amsterdam and Rotterdam. Copper coin first issued by the Mint, London. Armistice of twelve years concluded between Spain and the United Provinces.—1610. Batavia settled by the Dutch on the island of Java. The invention of the thermometer ascribed to Fra Paolo, to Sanctorio, and to Drebbel of Alkmaar.

1611-1620.—from the Turk in the Levant at Surat, in the Gulf. The bay to which age of the Dutch bar. Patent last and water engine.—1622 Plymouth col.—1621-1630.—First pemance by the Dutch, led by the Sgland reduced Scotland in 16 in Virginia.—Guyana.—162 in Brazil: Es

1611-1620.—The United Provinces obtained (1612) from the Turks advantageous terms in their commerce in the Levant.—1613. English factories established at Surat, in India, and at Gombroon, on the Persian Gulf. The buccaners noted on the coasts of America.—1614. Logarithms invented by Lord Napier.—1615. Coffee in use at Venice.—1616. Baffin explored the bay to which his name was given.—1618. First voyage of the Danes to India, and settlement at Tranquebar. Patent granted for a fire-engine for raising ballast and water, nearly on the principle of the steam-engine.—1620. Silk first manufactured in England. Plymouth colony settled.

1621-1630.—The conquests of the Dutch commenced. First permanent settlement on Manhattan Island (1621) by the Dutch. The colony at Nova Scotia (1622) settled by the Scotch.—1624. The rate of interest in England reduced to 8 per cent. (21 James I.), and in Scotland in 1632.—1625. The culture of silk commenced in Virginia.—1626. French settlements at Senegal and Guyana.—1627. Success of the Dutch admiral, Heun, in Brazil: Essequibo, in Guyana, founded by him.

1631-1640.—Charles I. revived monopolies, sold patents and privileges to new companies, and imposed a stamp on cards.—1632. A colony of Catholics, under Lord Baltimore, settled in Maryland. The Dutch acquired the island of St. Eustatia.—1634. Writ for levying ship-money in England. The Dutch took Curacao.—1635. Proclamation in England against hackney-coaches standing in the streets. Guadaloupe and Martinique appropriated by France.—1637. The levy of ship-money unpopular.—1640. Ship-money voted to be illegal.

1641-1650.—Tasman discovered Van Diemen's Land (1642), and named it in honor of the Dutch governor of Batavia.—1643. Cayenne colonized by the French. Van Diemen sent De Vries and Schaeap to explore the ocean north of Japan.—1645. The greater part of Candia conquered by the Turks.—1647. Huygens invented and applied the pendulum to clocks.—1650. The Dutch took possession of the Cape of Good Hope.

1651-1660.—Quarrel between the English and the Dutch (1651) about the right of fishing; the massacre at Amboyna; and colonial encroachments. Rate of interest reduced by the Rump Parliament to 6 per cent.—1660. Tea used in London.

1661-1670.—Bombay and Tangier ceded to England (1662), and free trade with Brazil.—1663. The profits of the English Post-office and wine licenses, granted to the Duke of York. The finances, manufactures, commerce, marine and colonial system of France, improved under Colbert.—1665. London afflicted by the plague, April 28.—1666. Great fire in London, from September 2 till September 6; property destroyed valued at £8,000,000.—1667. A tax of twelve-pence levied on every ton of coal brought into London, January 18, to aid the rebuilding of London. The first stone of the new Royal Exchange laid (August 23) by Charles II.

1671-1680.—The money in the Exchequer (12th January, 1672) seized by Charles II. Great confusion and commercial distress followed.—1680. The publication of newspapers and pamphlets without a license declared (May 16) to be illegal in England.

1681-1690.—A penny-post first established in London (1683) by a private individual named Murray.—1685. The Pope of Rome, by compulsory process, reduced the rate of interest on the public debt from 4 to 3 per cent.—1688. The Venetians made further progress in Dalmatia.

1691-1700.—Origin of the Bank of England (1694, 25th April), under William III. Stamp duties in England commenced, 28th June.—1695. Commissioners appointed for building Greenwich Hospital.—1697. Charter of Bank of England renewed till 12 months' notice.—1698. Address of the English House of Commons to William III., for the discouragement of the woollen manufacture and the promotion of the linen, 10th June.

—1699. Czar Peter introduced the computation of time in Russia by the Christian era, but adhered to the old style. Dampier explored the northwest coast of New Holland.

Eighteenth Century.—1704. The *Boston News Letter* published—the first newspaper in the American colonies.—1708. Bank of England charter renewed, and again in 1713.—1709. Copyright act in England, 8 Anne.—1710. The South Sea Company originated, 6th May.

1711-1720.—A capital of £4,000,000 raised (1711) for the South Sea Company.—1711. Rio Janeiro taken by the French admiral, Duguay Trouin.—1712. The first stamp duty on newspapers levied in England.—1718. The *Clarendon Press* established at Oxford, by the profits of the History of the Rebellion.—1714. The rate of interest in England reduced from 6 to 5 per cent., and all contracts at a higher rate declared void.—1716. John Law originated his banking and Mississippi schemes.—1717. First project of a sinking fund for the liquidation of the English national debt. Law obtained extended privileges for his bank.—1718. Law's Company declared to be the Royal Bank.—1720. The South Sea Company Act, passed 7th April. South Sea stock rose to 800, June 2. Rage for speculative schemes. Seventeen petitions for joint-stock patents refused. South Sea bubble burst, 30th September.

1721-1730.—The directors of the South Sea Company (1721) taken into custody, 24th January. Aislabie, and other members of Parliament implicated, expelled. Walpole, Lord Treasurer and Chancellor of the Exchequer, 2d April. The estates of directors of South Sea Company, amounting to two millions sterling, forfeited.—1723. Act passed to prohibit English subscriptions to the Ostend Company.—1725. Tumults at Glasgow, 25th June, on account of the Malt tax.—1726. Cotton a staple product of Hispaniola.—1729. Fire at Constantinople; 12,000 houses and 7000 people perished. John Law died at Venice, 21st March, *x.* 58.—1730. Charter of the East India Company renewed.

1731-1740.—Culture of silk commenced (1732) in Georgia. Parliamentary grant to Sir Thomas Lambe (1732, April 3) for having introduced the silk-engine.—1733. The English government refused to join the Dutch in stopping the East India commerce of the Danes and Swedes.—1733. The Excise law proposed in England, and abandoned by Walpole.—1734. English act passed against stock-jobbing. The new Bank of England building opened 6th June, in Thread-needle Street.—1736. High tide in the Thames. Westminster Hall flooded. Parliamentary debates published in the *Gentleman's Magazine*.—1740. The first circulating library in London established at 132 Strand. Parliamentary debates prepared by Dr. Johnson.

1741-1750.—Charter of Bank of England (1742) renewed. Lord Anson returned (1744) from his voyage round the world, with £1,250,000 in treasure.—1750. A riot at Tiverton against the introduction of Irish worsted yarns, 16th January. Bounties granted, and a company formed, to encourage the British and white herring and cod fisheries.

1751-1760.—An act of Parliament (1751, 24 Geo. II.) orders the Gregorian (or new) style to be used in Great Britain.—1753. Two thousand bales of cotton exported by Jamaica.—1754. Commencement of war between England and France, and military operations under Washington in Virginia, etc.—1759. The Bank of England issued £15 and £10 notes, 31st March.—1760. Culture of silk commenced in Connecticut.

1761-1770.—Opening of the Duke of Bridgewater's Canal (1761) between Manchester and Liverpool.—1762. The island of Cuba surrendered to Lord Albemarle and Admiral Pococke. Martinique, St. Lucia, St. Vincent, and other islands taken from the French.—1764. First improvement of the steam-engine by Watt. Bank of England charter renewed.—1765. Stamp Act for America passed by the British Parliament, March.—1767.

The House of Commons resolved to impose duties on various articles imported into America.

1771-1780.—Arkwright's second patent (1771) for his improvement in cotton spinning. Culture of silk commenced in Pennsylvania.—1772. Commercial panic in London, caused by the failure of Neal, Forlyce, & Company, bankers.—1778. Tea destroyed in Boston harbor, 16th November. The Governor of Bengal made governor of all the British settlements in India.—1774. The petition of the Massachusetts Assembly to Parliament presented (January) to Dr. Franklin, who was then removed from office of deputy postmaster-general for the colonies. Burko's celebrated speech on the tea tax, April 19.—1774. Watt, in partnership with Boulton, founds his steam-engine establishment at Soho.—1776. Captain Cook sailed on his third voyage.—1780. Charter of the first Bank of North America, approved by Congress 26th May.

1781-1790.—Bank of England charter renewed, on making further advances to government of £3,000,000. Necker published his financial statement for France 1781, and retired from office.—1782. National Bank of Ireland established.—1783. Charter granted to the Bank of Ireland.—1784. The Bank of New York chartered, 9th June.—1786. British treaty of commerce with France.—1787. "Pennsylvania Society for the encouragement of Manufactures and the useful Arts" formed. Cotton exported by West India Islands.—1789. Issue of assignats in France, 17th December.

1791-1800.—Vancouver's voyage of discovery (1791). The buckle-makers of Birmingham petitioned Parliament against the use of shoe-strings. Numerous riots at Birmingham.—1793. The first ambassador from Turkey arrived in London, December 20. Whitney's cotton-gin invented and first used.—1795. Embargo on all Dutch ships in English ports, 26th January. Warren Hastings acquitted, 23d April.—1797. Suspension of the Bank of England, 26th February. Notes of £1 and £2 first issued, March 11.—1798. Silver tokens issued by the Bank of England, 1st January.—1799. Sugar first extracted from beet-root, by the Prussian chemist Achard.—1800. General distress and riots in England, caused by the high price of bread, January. Dispute respecting the close of the century. Lalande decided that 31st December, 1800, is the last day of the 18th century. Union of Great Britain and Ireland, 2d July. Bank of England charter renewed until 1833.

Nineteenth Century.—1801-1810.—Embargo laid (January, 1801) on all Russian, Danish, and Swedish vessels in English ports.—1802. Santee Canal, South Carolina, completed.—1803. Louisiana sold by France to the United States for \$15,000,000. The first printing-press in New South Wales established at Sydney. Caledonia Canal opened for travel. Trial of steamboat on the Seine by Fulton, 9th August. The first bank in Ohio chartered.—1804. Wilberforce's slave-trade bill rejected by the House of Lords. The Code Napoleon adopted. Ice first exported from the United States to the West Indies.—1805. The Gregorian calendar again adopted in France.—1806. The Cape of Good Hope surrendered to the English. Abolition of the slave-trade by English Parliament, 10th June. The loom invented by Jacquard, a mechanic of Lyons. East India docks opened at London, 4th August.—1807. Milan decrees against English commerce, 11th November. Fulton's first voyage on the Hudson. The Bank of Kentucky chartered. First manufactory of woolen cloths in the United States established at Pittsfield, Massachusetts. Middlesex Canal, Massachusetts, completed.—1808. Manufacturing districts of Manchester, etc., petitioned for peace.—1810. Deaths, by suicide, of Abraham Goldschmidt, Francis Baring, and other English merchants.

1811-1820.—English guineas publicly sold for a pound note and seven shillings.—1811. Mr. Horner's proposition for resumption of cash payments in England

rejected. First steamboat built at Pittsburgh.—1812. Serious riots in the manufacturing districts of Lancashire and Yorkshire. Declaration of war by the United States against England, 18th June.—1814. London *Times* first printed by steam, 29th November.—1815. Veto of the United States bank bill by President Madison. Bank rechartered for 20 years.—1816. The new Russian tariff prohibited the importation of nearly all British goods. Bank of England advanced £3,000,000 further to government, making a total of £14,000,000.—1817. Paris first lighted by gas. First steamboat from New Orleans to Louisville.—1818. First Polar expedition of Captain John Franklin left England. Steamboats built on Lake Erie.—1819. Emigration to Cape of Good Hope encouraged by the British government. The steamship *Sarannah* arrived at Liverpool from the United States, 15th July. Commencement of the suspension bridge over the Menai by Telford. The first bank in Illinois chartered.—1820. Florida ceded to the United States by Spain. Suspension bridge over the Tweed. First steamer ascended the Arkansas River.

1821-1830.—Captain Parry's and Lyon's expedition to the Arctic Ocean left England 30th March, 1821. Bank of England resumed specie payments.—1822. Funeral of Coutts, the London banker, 4th March. The first cotton-mill in Lowell erected.—1823. Revival of business in the English factories.—1824. Advance in the prices of agricultural produce in England. Act passed for the Thames Tunnel, 24th June. Fauntleroy, banker, hung for forgery, 30th November. Champlain Canal, New York, completed.—1825. Panic in the English money market (December). Failure of numerous country banks. Erie Canal completed.—1826. Mr. Huskisson's free-trade policy advocated in House of Commons by vote of 223 to 40. Coin in Bank of England reduced to £2,460,000, 28th February.—1827. Commercial confidence restored in England, and employment for the poor. "Society for the Diffusion of useful Knowledge," established at the instance of Lord Brougham. Union Canal, Pennsylvania, completed. Quincy Railroad completed.—1828. Delaware and Hudson Canal, Syracuse and Oswego Canal, New York, completed. India rubber goods manufactured in Connecticut.—1829. Increase of silk manufactures in England and reduction of duty on raw silk. Prize awarded to Mr. Stephenson for his locomotive engine on the Liverpool and Manchester Railway. Subscription by Congress to the Chesapeake and Ohio Canal, May 3. Departure of Captain Ross on his voyage of discovery. Chesapeake and Delaware Canal opened, 17th October.—1830. Opening of the Liverpool and Manchester Railway, 15th September. Free navigation of the Black Sea opened to the United States by treaty, 7th May. Charles X. fled from Paris, 31st July. West India trade with the United States opened to British vessels. Independence of Belgium acknowledged. Pennsylvania State Canal finished.

1831-1840.—Parliamentary reform bill introduced in 1831 by Lord John Russell; rejected by the House of Lords, 8th October. Free trade convention at Philadelphia, October 1. Stephen Girard died 26th December, x. 81. Insurrection in Jamaica, 28th December.—1832. Veto of United States Bank bill by President Jackson, 10th July. New tariff act passed by Congress, July. Ohio State Canal finished. Albany and Schenectady Railroad, Columbia Railroad, Pennsylvania Railroad, Newcastle and Frenchtown Railroad, completed.—1833. Ice first exported to the East Indies from the United States, 18th May. Opening of the China trade to the English. East India Company charter renewed; ceased to be a commercial body. Bank of England charter renewed. Usury restrictions removed in England from all commercial paper having less than three months to mature. Mr. Clay's tariff bill passed by Congress. Removal of the deposits from the United States Bank, September.—1834. The Chinese suspend intercourse with the English at Canton. The

United States Exploring expedition, under Captain Wilkes, left Hampton Roads, 1st August. Imprisonment for debt abolished in England.—1839. British trade with China stopped, December. Second suspension of the banks at Philadelphia (9th September), followed by bank failures in the South and West. Western Railroad, Worcester to Springfield, opened 1st October. Union Bank, London, commenced business.—1840. Penny postage adopted in England. Antarctic continent discovered by Wilkes, 19th January. First steam vessel at Boston arrived from England, 3d June. First Cunard steamer, (the *Britannia*) arrived at Boston 18th July; and the *Acadia*, 17th August. Fiscal Bank bill vetoed by President Tyler, 16th August. Bankrupt law passed by Congress, 18th August. Bill for distribution of public lands passed by Congress, 23d August. Fiscal corporation bill vetoed by President Tyler, 9th September. Loan of \$12,000,000 authorized by Congress. 1841-1850.—The island and harbor of Hong Kong ceded (1841) by the Chinese to England. Pennsylvania United States Bank failed third time, 5th February, and made an assignment 4th September. Union of Upper and Lower Canada, 10th February. Foreign trade of Canton suspended, and hostilities with the English renewed, 21st May. Canton taken 27th. American cloaks exported to England.—1842. Anti-corn-law movement in Parliament by Sir R. Peel. Captain Wilkes returned from his exploring expedition, 11th June. Ashburton treaty ratified by the Senate, 20th August. British treaty with China (29th August), by which it was agreed to open five free ports.—1843. Return of Captain Ross from the South Pole, 6th September. Treaty of commerce by Sir H. Pottinger with China.—1841. Treaty of annexation of Texas to the United States rejected by the United States Senate, 8th June. Anti-rent riots in New York, August. Re-charter of Bank of England. Magnetic telegraph between Baltimore and Washington. Cheap postage act of United States went into operation July 1.—1845. Treaty between United States and China ratified by United States Senate, 16th January. Sir John Franklin left England 25th May on his Arctic expedition. Anti-corn-law league at Manchester. Steamship *Great Britain* arrived at New York, 10th August. Treaty of

annexation of Texas ratified by United States Senate, 1st March. Loss of \$6,000,000 by fire in New York city, 19th July. Peel ministry resigned, 11th December.—1846. Oregon treaty between England and the United States signed in London, 17th July. Second failure of the potato crop in Ireland. Steamship *Great Britain* stranded in Dundrum Bay, 22d October. Declaration of war with Mexico by the United States, 12th May. New tariff bill passed by Congress, 28th July. Veto of French spoliation bill by President Polk, 8th August.—1847. Gold in California discovered. United States ship *Jamestown* left Boston 28th March, and frigate *Macedonian*, 18th July, with provisions for relief of the Irish. Great commercial distress throughout Great Britain, Sept.-Nov.—1848. The State of Maryland resumed payment of interest 1st January. Treaty of peace between Mexico and United States, signed 30th May. Suspension bridge at Niagara Falls, completed 29th July. Edict to incorporate Bank of France with nine branches, 27th April. India rubber life-preservers invented.—1849. Penny postage adopted in Prussia. First experiment of a submarine telegraph at Folkestone.—1850. Lopez invasion of Cuba. £20,000 reward offered by Parliament for discovery of Sir John Franklin, 8th March. Collins line of steamers to Liverpool commenced operations. Steamer *Atlantic* left New York, 27th April. The celebrated Koh-i-noor diamond, valued at \$2,000,000, brought to England, July.

1851-1858.—The London exhibition opened 1851, May 1. Contract of Pacha of Egypt with Mr. Stephenson for a railway from Alexandria to Cairo. Railways completed between St. Petersburg and Moscow, Dublin and Galway. Collins steamer *Pacific* arrived in Liverpool, May. Yacht *America* won the race at Cowes, 22d August. Hudson River Railroad opened to Albany, 8th October. Dr. Kane returned from the Grinnell expedition, October.—1852. Construction of French Crystal Palace ordered, February. Expedition of United States naval forces to Japan, March. Dr. Kane returned from his search for Sir John Franklin, February. Ship *Prince Albert* returned from search for Sir John Franklin, 7th October.—1853. Trial trip of the calorific steamship *Ericsson* from New York to the Potomac, 11th January. Second Arctic expedition left New York, 31st May. American expedition arrived at Japan, 8th July. Loss of the steamship *Humboldt*, 5th December.—1854. Combined fleets of England and France entered the Black Sea, 11th January. Loss of the steamer *San Francisco*, 5th January. Steamer *City of Glasgow* lost, March. Declaration of war by England against Russia in behalf of Turkey, 28th March. Commercial treaty between United States and Japan. French loan of 250,000,000 francs, announced March 11, and Turkish loan of £2,727,400. London joint-stock bankers admitted to the clearing-house, June 7. Crystal Palace at Sydenham, opened 10th June. Bombardment of San Juan by ship *Cycane*, 13th July. Loss of steamer *Arctic*, 27th September. Captain McClure returns from Arctic discovery, 28th September.—1855. Discovery of Captain Franklin's remains. £10,000 awarded Captain McClure by Parliament. Paris exhibition opened 15th May. Submarine telegraph wire laid in Black Sea. Resistance by United States to payment of Sound dues. First railroad train crossed suspension bridge at Niagara, 14th March. French loan of 500,000,000 francs taken, 18th January. Suspension of Page, Hacon, & Company, Adams & Company, San Francisco, 22d February. English loan of £10,000,000 taken by Rothschilds, 20th April. Ships *Arctic* and *Rescue*, Captain Hartstene, left New York for relief of Dr. Kane and party.—1856. The Arctic discovery-ship, *Resolute*, was delivered to the British authorities at Portsmouth, 30th December.—1857. Trial trip of the United States frigate *Niagara*, 22d April. Suspension of Ohio Life and Trust Company, New York, 24th August. Suspension of the banks at Philadelphia, 25th September; Baltimore, etc., 26th; New York, 14th October.

Commerce, Code de. This was a part of the Code Napoleon known as *Les Cinq Codes* and afterward as *Les Six Codes*. The Code de Commerce was promulgated in January, 1808. It was founded in some measure upon the ordinances of 1673-'81 of Louis XIV. On account of the many modifications which the code of 1805 had undergone, a new text of the code was promulgated in January, 1841. The Code de Commerce is considered the best part of French legislation. The institution of the commercial tribunals has been of great advantage to France, and has been adopted in other countries. These courts, of which there are 213, consist of a president and two or more judges, all chosen by the merchants among themselves, and for a limited time: they are not paid for their services, but the *greffier* or registrar receives a salary. The *Code de Commerce* consists of four books: the first treats of commerce in general; of the various descriptions of commercial men; of the keeping of books; of companies and partnerships; of brokers, commissioners, carriers, etc. The second treats of maritime commerce; shipping; insurances; bankruptcy, etc. The third concerns bankruptcies; and the fourth treats of the commercial tribunals, their jurisdiction, and proceedings. By a law of April, 1838, appeals in matters above 1500 francs (formerly 1000 francs) are carried to the Cour Royale of the district.—BOIN'S *Cyclopaedia*.

The French code is retained in Rhenish Prussia; in the kingdom of Naples with some few modifications; in the Canton of Geneva, in Switzerland, and in Belgium; and formed the basis of the code of Louisiana, suggested or prepared by the late Edward Livingston.

Commercial Treaties. The first treaty of commerce made by England with any foreign nation, was entered into with the Flenings, 1 Edward I., 1272. The second was with Portugal and Spain, 2 Edward II., 1308.—See TREATIES.

Commodore, a general officer in the navy, invested with the command of a detachment of ships of war destined on any particular enterprise, and his ship is distinguished from the rest of his squadron by a broad pendant tapering toward the outer end, and sometimes forked. The word is corrupted from the Spanish *comendador*, which signifies both the superior of a monastery and a knight who holds a commandery. Commodore is also a name given to the convoy or leading ship in a fleet of merchantmen, which carries a light in her top to guide the other ships.—E. B. See Convoy.

Companies. In commerce or the arts a company is a number of persons associated for the purpose of carrying on some commercial or industrial undertaking. When there are only a few individuals associated, it is most commonly called a *copartnership*; the term company being usually applied to large associations, like the East India Company, the Bank of England, etc., who conduct their operations by means of agents acting under the orders of a board of directors. Companies have generally been divided into two great classes—exclusive or joint-stock companies, and open and regulated companies.

1. *Exclusive or Joint-stock Companies.*—By an institution of this sort is meant a company having a certain amount of capital, divided into a greater or smaller number of transferable shares, managed for the common advantage of the shareholders by a body of directors chosen by and responsible to them. After the stock of a company of this sort has been subscribed, no one can enter it without previously purchasing one or more shares belonging to some of the existing members. The partners do nothing individually; all their resolutions are taken in common, and are carried into effect by the directors and those whom they employ. According to the common law, all the partners in a joint-stock company are jointly and individually liable, to the whole extent of their fortunes, for the debts of the company. They may make arrangements among

themselves, limiting their obligations with respect to each other; but unless established by an authority competent to set aside the general rule, they are all indefinitely responsible to the public.

"In a private copartnership, no partner, without the consent of the company, can transfer his share to another person, or introduce a new member into the company. Each member, however, may, upon proper warning, withdraw from the copartnership, and demand payment from them of his share of the common stock. In a joint-stock company, on the contrary, no member can demand payment of his share from the company; but each member may, without their consent, transfer his share to another person, and thereby introduce a new member. The value of a share in a joint stock is always the price which it will bring in the market; and this may be either greater or less, in any proportion, than the sum which its owner stands credited for in the stock of the company."—*Wealth of Nations*, p. 333.

2. *Utility of Joint-stock Companies.*—Whenever the capital required to carry on any undertaking exceeds what may be furnished by an individual, it is indispensable, in order to the prosecution of the undertaking, that an association should be formed. In all these cases, too, in which the chances of success are doubtful, or where a lengthened period must necessarily elapse before an undertaking can be completed, an individual, though ready enough to contribute a small sum in connection with others, would, generally speaking, be very little inclined, even if he had the means, to encounter the whole responsibility of such enterprises. Hence the necessity and advantage of companies or associations. It is to them that we are indebted for those canals and railways by which every part of the country is intersected, for the formation of so many noble docks and warehouses, for the institution of our principal banks and insurance offices, and for many other establishments of great public utility carried on by the combined capital and energies of large bodies and individuals.

3. *Branches of Industry, for the Prosecution of which Joint-stock Companies may be advantageously established.*—In order to insure a rational prospect of success to a company, the undertaking should admit of being carried on according to a regular systematic plan. The reason of this is sufficiently obvious. The business of a great association must be conducted by factors or agents; and unless it be of such a nature as to admit of their duties being clearly pointed out and defined, the association would cease to have any effectual control over them, and would be, in a great measure, at their mercy. An individual who manages his own affairs reaps all the advantage derivable from superior skill, industry, and economy; but the agents, and even directors of joint-stock companies labor, in most cases, entirely or principally for the advantage of others; and can not therefore, however conscientious, have the same powerful motives to act with energy, prudence, and economy. "Like," says Dr. Smith, "the stewards of a rich man, they are apt to consider attention to small matters as not for their master's honor, and very easily give themselves a dispensation from having it. Negligence and profusion therefore must always prevail more or less in the management of the affairs of such a company." It also not infrequently happens that they suffer from the bad faith, as well as the carelessness and extravagance of their servants; the latter having in many instances endeavored to advance their own interests at the expense of their employers. Hence the different success of companies whose business may be conducted according to a nearly uniform system—such as dock, canal, and insurance companies, railroad companies, etc.—and those whose business does not admit of being reduced to any regular plan, and where much must always be left to the sagacity and enterprise of those employed. All purely commercial companies, trading upon a joint stock, belong to the latter class.

Not one of them has been able to withstand the competition of private adventurers; they can not subject the agents they employ to buy and sell commodities in distant countries to any effectual responsibility; and from this circumstance, and the abuses that usually insinuate themselves into every department of their management, no such company has ever succeeded, unless when it has attained some exclusive privilege, or been protected from competition.

The Abbé Morellet has given, in a tract published in 1769 (*Examen de la Réponse de M. A.*, p. 35-38), a list of 15 joint-stock companies, for the prosecution of various branches of foreign trade, established in different parts of Europe since 1600, every one of which had failed, though most of them had exclusive privileges. Most of those that have been established since the publication of the Abbé Morellet's tract have had a similar fate. But notwithstanding both principle and experience concur in showing how very ill fitted a large association is for the purpose of prosecuting commercial undertakings, there are cases in which they can not be prosecuted except by associations of this sort, and when it may be expedient to grant them certain peculiar privileges. When, owing either to the disinclination or inability of government to afford protection to those engaged in any particular department of trade, they are obliged to provide for their own defense and security, it is obviously necessary that they should have the power to exclude such individuals as may refuse to submit to the measures, or to bear their due share of the expense, required for the common protection of all. The Russian Company, the East India Company, the Levant or Turkey Company, and most of the other great trading companies that have existed, seem principally to have grown out of a real or supposed necessity of this sort. It was not believed that any safe or advantageous intercourse could be carried on with barbarous countries without the aid of ships of war, factories, interpreters, etc., and as government was not able or willing to afford this assistance, the traders were formed into companies or associations, and vested with such peculiar privileges as appeared to be necessary for enabling them to prosecute the trade without any extrinsic support. "When," says Dr. Smith, "a company of merchants undertake, at their own risk and expense, to establish a new trade with some remote and barbarous nation, it may not be unreasonable to incorporate them into a joint-stock company, and to grant them, in case of success, a monopoly of the trade for a certain number of years. It is the easiest and most natural way in which the state can recompense them for hazarding a dangerous and expensive experiment, of which the public is afterward to reap the benefit. A temporary monopoly of this kind may be vindicated upon the same principles upon which a like monopoly of a new machine is granted to its inventor, and that of a new book to its author. But upon the expiration of the term, the monopoly ought certainly to determine; the forts and garrisons, if it was found necessary to establish any, to be taken into the hands of the government, their value to be paid to the company, and the trade to be laid open to all the subjects of the state."—*Wealth of Nations*, p. 333. It may be doubted, however, whether it be really necessary, even in such a case as that now mentioned, to establish a joint-stock company with peculiar privileges, and whether the same thing might not be more advantageously effected by the establishment of an open or regulated company.

4. *Open or Regulated Companies.*—The affairs of such companies or associations are managed by directors appointed by the members. They do not, however, possess a common or joint stock. Each individual pays a fine upon entering into the company, and most commonly an annual contribution: a duty applicable to the business of the company is also sometimes charged upon the goods imported and exported from and to the

countries with which they trade. The sums so collected are applied by the directors to fit out ambassadors, consuls, and such public functionaries as may be required to facilitate commercial dealings, or to build factories, maintain cruisers, etc. The members of such companies trade upon their own stock, and at their own risk; so that when the fine, or the sum payable on admission into a regulated company, is moderate, it is impossible for its members to form any combination that would have the effect of raising their profits above the common level; and there is the same keen and close competition among them that there is among other classes of traders. A regulated company is, in fact, a device for making those engaged in a particular branch of trade bear the public or political expenses incident to it, at the same time that it leaves them to conduct their own business with their own capital, and in their own way. Should, therefore, government at any time refuse, or be unable to afford, that protection to those engaged in any branch of trade which is necessary to enable them to carry it on, their formation into a regulated company would seem to be the most judicious measure that could be adopted, inasmuch as it would obtain for them that protection which is indispensable, without encroaching on the freedom of individual enterprise. The African and the Levant companies in Great Britain, and some other branches of trade, were for a long time conducted by open or regulated companies. These, however, have been recently abolished: the African Company, by the act 1 and 2 Geo. IV. c. 28; and the Levant Company, by the act 6 Geo. IV. c. 33. The Russia Company still exists.—*See RUSSIA COMPANY.*

In so far as relates to protection, it may perhaps be thought, for the reasons given by Dr. Smith, that a joint-stock company is better calculated to afford it than a regulated company. The directors of the latter having, Dr. Smith alleges, no particular interest in the prosperity of the general trade of the company, for behoof of which, ships of war, factories, or forts have to be maintained, are apt to neglect them, and to apply their whole energies to the care of their own private concerns. But the interests of the directors of a joint-stock company are, he contends, in a great measure identified with those of the association. They have no private capital employed in the trade; their profits must depend upon the prudent and profitable management of the common stock; and it may therefore, it is argued, be fairly presumed that they will be more disposed to attend carefully to all the means by which the prosperity of the association may be best secured. On the other hand, however, it is seldom that the directors of joint-stock companies stop at the proper point; having almost invariably attempted to extend their commercial dealings by force, and to become not only merchants but sovereigns. Nor is this any thing but what might have been expected, seeing that the consideration and extensive patronage accruing from such measures to the directors is generally of far more importance to them than a moderate increase of the dividends on their stock. Whenever they have been able, they have seldom scrupled to employ arms to advance their projects; and instead of contenting themselves with shops and factories, have constructed fortifications, embodied armies, and engaged in war. But such has not been the case with regulated companies. The businesses under their control have uniformly been conducted in a comparatively frugal and parsimonious manner; their establishments have been, for the most part, confined to factories; and they have rarely, if ever, allowed themselves to be seduced by schemes of conquest and dominion.

And hence, considering them as *commercial machines*, it does not really seem that there can be any doubt as to the superiority of a regulated over a joint-stock company. The latter has the defect, for which nothing almost can compensate, of *entirely excluding individual*

enterprises and competition.—When such a company enjoys any peculiar privilege, it naturally, in pursuing its own interest, endeavors to profit by it; how injurious soever it may be to the public. If it have a monopoly of the trade with any particular country, or of any particular commodity, it rarely fails, by understocking the home and foreign markets, to sell the goods which it imports and exports at an artificially enhanced price. It is not its object to employ a comparatively large capital, but to make a large profit on a comparatively small capital. The conduct of the Dutch East India Company, in burning spices, that their price might not be lowered by larger importations, is an example of the mode in which such associations uniformly, and, indeed, almost necessarily act. All individuals are desirous of obtaining the highest possible price for what they have to sell: and if they are protected by a monopoly, or an exclusive privilege, from the risk of being undersold by others, they never hesitate about raising the price of their products to the highest elevation that the competition of the buyers will allow them; and thus frequently realize the most exorbitant profits. And yet, notwithstanding these advantages, such is the negligence, profusion, and peculation inseparable from the management of great commercial companies, that even those that have had the monopoly of the most advantageous branches of commerce have rarely been able to keep out of debt. It will be shown in the article EAST INDIA COMPANY, that that association has lost by its trade; and that, had it not been for the all derived from the revenues of India, it must long since have ceased to exist. To buy in one market; to sell with profit in another; to watch over the perpetually occurring variations in the prices and in the supply and demand of commodities; to suit with dexterity and judgment the quantity and quality of goods to the wants of each market, and to conduct each operation in the best and cheapest manner, requires a degree of unremitting vigilance and attention, which it would be visionary to expect from the directors or servants of a great joint-stock association. Hence it has happened, over and over again, that branches of commerce which proved ruinous to companies have become exceedingly profitable when carried on by individuals.

6. *Constitution of Companies.*—When application is made for an act to incorporate a number of individuals into a joint-stock company for the prosecution of any useful undertaking, care should be taken not to concede to them any privileges that may be rendered injurious to the public. If a company be formed for the construction of a dock, a road, or a canal, it may be necessary, in order to stimulate individuals to engage in the undertaking, to give them some peculiar privileges for a certain number of years. But if other persons were to be permanently hindered from constructing new docks, or opening new lines of communication, a lasting injury might be done to the public. It may be highly expedient to incorporate a company for the purpose of bringing water into a city; but, supposing there were no springs in the vicinity other than those to which this company had acquired a right, they might, unless restrained by the act incorporating them, raise the price of water to an exorbitant height, and make large profits for themselves at the expense and to the injury of the public. In all cases of this sort, and in the case, indeed, of all joint-stock companies established for the formation of canals, railroads, etc., it would be sound policy to limit the rates charged for their services, or on account of the water, ships, goods, etc., conveyed by their means, and also to limit the dividends, or to fix a *maximum* beyond which they should not be augmented: enacting, that if the rates charged by the company produce more than sufficient to pay the maximum rate of dividend, and to defray the wear and tear of the aqueduct, canal, etc., they shall be allowed to reduce them till they only yield this much;

and, in the event of their declining to do so, that the whole surplus above paying the dividend shall be applied to purchase up the stock of the association, so that ultimately the charges on account of dividends may be entirely abolished.

6. *Companies en Commandite.*—In France there is a sort of companies denominated *sociétés en commandite*. A society of this description consists of one or more partners, liable, without limitation, for the debts of the company; and one or more partners, or *commanditaires*, liable only to the extent of the funds they have subscribed. A *commanditaire* must not, however, take any part in the business of the company; if he do this, he loses his inviolability, and makes himself responsible for the debts of the association. The names of the partners in such societies must be published, and the amount of the sums contributed by the *commanditaires*. It has been proposed to introduce partnerships of this sort into this country; but it seems very doubtful whether any thing would be gained by such a measure. Partnerships *en commandite* may be very easily abused, or rendered a means of defrauding the public. It is quite visionary to imagine that the *commanditaires* can be prevented from indirectly influencing the other partners; and supposing a collusion to exist among them, it might be possible for them to divide large sums as profits, when perhaps they had really sustained a loss; and to have the books of the association so contrived that it might be very difficult to detect the fraud. This, it is alleged, is by no means a rare occurrence in France.

7. *Civis Compania, or Corporations.*—Exclusive of the companies previously mentioned, a number of ancient companies or corporations exist in most European countries, the members of which enjoy certain political as well as commercial privileges. When the feudal system began to be subverted by the establishment of good order and regular government in the towns, the inhabitants were divided into certain trades or corporations, by which the magistrates and other functionaries were chosen. The members of those trades, or corporations, partly to enhance the value of their privileges, and partly to provide a resource, in case of adversity, for themselves, acquired or usurped the power of enacting by-laws regulating the admission of new members, and at the same time set about providing a fund for the support of such as accident or misfortune might reduce to a state of indigence. Hence the origin of apprenticeships, the refusal to allow any one not a member of a corporation to carry on any business within the precincts of any town corporate, and the various regulations that had to be submitted to, and the fees that had to be paid by the claimants for enrollment in corporations. For a lengthened period these privileges and regulations were very oppressive. Within the last century, however, their influence has been progressively diminishing. In France, where the abuses inseparable from the system had attained to a very great height, it was entirely swept off by the Revolution; and though corporations still exist in Great Britain, they have been stripped of several of their peculiar franchises; and should now, for the most part, be regarded more perhaps in the light of charitable than of political institutions. It would be well, however, were they reduced entirely to the former character, and were the few political and commercial privileges which they still enjoy communicated to the rest of the citizens. At their first institution, and for some time after, corporations, considered as political bodies, were probably useful: but such is no longer the case; and in so far as they now possess any special immunities, they tend to obstruct that free competition that is so advantageous.

advantages resulting from the unrestricted freedom of industry in a very striking point of view. "No cause," says he, "has, perhaps, more promoted in every respect the general improvement of the United States, than the absence of those systems of internal restrictions and monopoly which continue to disfigure the state of society in other countries. No laws exist here, directly or indirectly, confining men to a particular occupation or place, or excluding any citizen from any branch he may, at any time think proper to pursue. Industry is, in every respect, free and unfettered; every species of trade, commerce, and profession, and manufacture, being equally open to all, without requiring any regular apprenticeship, admission, or license. Hence the improvement of America has not been confined to the improvement of her agriculture, and to the rapid formation and settlement of new states in the wilderness; but her citizens have extended their commerce to every part of the globe, and carry on with complete success even those branches for which a monopoly had heretofore been considered essentially necessary."

There is in REES' *Cyclopaedia*, art. COMPANY, a list of the different civic companies belonging to the city of London, in which the periods of their incorporation, and various other important particulars with respect to several of them, are specified.

Among the earliest commercial companies in England may be named the Steel-yard Society, established A. D. 1232. The second company was the merchants of St. Thomas à Becket, in 1248.—STOWE. The third was the Merchant Adventurers incorporated by Elizabeth, 1564. There are ninety-one city companies in London; the first twelve are,

Companies, Bubble. Ruinous speculations conjoined under this name have been formed, commonly by designing persons. Law's Bubble, in 1720-'21, was perhaps the most extraordinary of its kind, and the South Sea Bubble, in the same year, was scarcely less memorable for its ruin of thousands of families. Many companies were established in Great Britain in 1824 and 1825, and most of them turned out to be bubbles; and owing to the rage for taking shares in each scheme as it was projected, immense losses were incurred by individuals, and the families of thousands of speculators were totally ruined.—See LAW'S BUBBLE and BANKRUPTS.

Compass (Germ. *Ein Kompass*; Fr. *Zeekompass*; Da. *Nielskompass*; Sw. *Sjökompass*; It. *Boussole*, *Compass de mer*; It. *Bussola*; Sp. *Aguja de marear*; Port. *Compasso de marear*; Russ. *Kompass korabelnyi*), or mariner's compass, an instrument composed of a needle and card, by which the ship's course is directed. The needle, with little variation, always points to the north; and hence the mode of steering by the compass.

The common opinion is that the compass was invented by Flavio Gioia, a citizen of the once famous republic of Amalphi, very near the beginning of the fourteenth century. Dr. Robertson has adopted this opinion, and regrets that contemporary historians furnish no details as to the life of a man to whose genius society is so deeply indebted.—*History of America*, vol. i. p. 47, 8vo ed. But though Gioia may have made improvements on the compass, it has been shown that he has no claim to be considered as its discoverer. Passages have been produced from writers who flourished more than a century before Gioia, in which the polar-

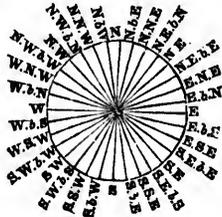

ity of the needle, when touched by the magnet, is distinctly pointed out.—Not only, however, had this singular property been discovered, but also its application to the purposes of navigation, long previously to the fourteenth century. Old French writers have been quoted (MACHENSON'S *Annals of Commerce*, anno 1200; REES' *Cyclopaedia*), that seem fully to establish this fact. But whatever doubts may exist with respect to them can not affect the passages which the learned Spanish antiquary, Don Antonio de Capmany (*Questiones Criticas*, p. 78-132), has given from a work of the famous Raymond Lully (*De Contemplatione*) published in 1272. In one place Lully says, "as the needle, when touched by the magnet, naturally turns to the north" (*sicut acus per naturam veritatis ad septentrionem dum sit tacta à magnete*). This is conclusive as to the author's acquaintance with the polarity of the needle; and the following passage from the same work—"as the nautical needle directs mariners in their navigation" (*sicut acus nautica dirigit marinarios in sua navigatione*, etc.), is no less conclusive as to its being used by sailors in regulating their course. There are no means of ascertaining the mode in which the needle Raymond Lully had in view was made use of. It has been sufficiently established (see the authorities already referred to, and AZUNI, *Dissertation sur l'Origine de la Boussole*) that it was usual to float the needle, by means of a straw, on the surface of a basin of water; and Capmany contends that we are indebted to Gioia for the card and the method now followed of suspending the needle; improvements which have given to the compass all its convenience, and a very large portion of its utility. But this part of his *Dissertation*, though equally learned and ingenious, is by no means so satisfactory as the other. It is difficult to conceive how mariners at sea could have availed themselves of a floating needle; but, however this may be, it seems most probable that Gioia had considerably improved the construction of the compass; and that, the Amalphi-tans having been the first to introduce it to general use, he was, with excusable partiality, represented by them, and subsequently regarded by others, as its inventor.

The reader will not consider these details out of place in a work on commerce, which the compass has done so much to extend. "Its discovery," to borrow the language of Mr. Macpherson, "has given birth to a new era in the history of commerce and navigation. The former it has extended to every shore of the globe, and increased and multiplied its operations and beneficial effects in a degree which was not conceivable by those who lived in the earlier ages. The latter it has rendered expeditious, and comparatively safe, by enabling the navigator to launch out upon the ocean free from the danger of rocks and shoals. By the use of this noble instrument, the whole world has become one vast commercial commonwealth, the most distant inhabitants of the earth are brought together for their mutual advantage, ancient prejudices are obliterated, and mankind are civilized and enlightened."

According to the purposes to which the instrument is chiefly applied, it becomes the *mariner's compass*, the *azimuth compass*, the *variation compass*, each particular application requiring some peculiarity of construction; but whatever modifications it may receive, the essential parts are the same in all cases. These are a magnetized bar of steel, called the *needle*, having fitted to it at its centre a cap, which is supported on an upright pivot made sharp at the point in order to diminish the friction as much as possible and allow the needle to turn with the slightest force. The *mariner's compass* has a circular card attached to its needle, which turns with it, and on the circumference of which are marked the degrees, and also the thirty-two *points* or *rhumbs*, likewise divided into half and quarter points. The pivot rises from the centre of the bottom of a circular box, called the *compass-box*, which contains the needle

and its card, and which is covered with a glass top to prevent the needle from being disturbed by the agitation of the air. The compass-box is suspended within a large box by means of two concentric brass circles or gimbals; the outer one being fixed by horizontal pivots, both to the inner circle which carries the compass-box, and also the outer box, the two sets of axes being at right angles to each other. By means of this arrangement, the inner circle, with the compass-box, needle, and card, always retain a horizontal position, notwithstanding the rolling of the ship.

The notation of the mariner's compass is as follows: The circumference being divided into the four quadrants by two diameters at right angles, the extremities of these diameters are the four cardinal points (cardo, a hinge), marked N., S., E., W. (north, south, east, west). Bisection each of the quadrants, the several points of bisection are denoted by placing the two letters at the extremities of the quadrant in juxtaposition. Thus N.E. (northeast) denotes the point which is half way between north and east; and so with N.W.,

S.E., S.W. (northwest, southeast, southwest). Let the octants next be bisected; the points of division are denoted by prefixing to each of the above combinations first the one and then the other of the two cardinal points of which it is formed. Thus N.E. gives N.N.E. and E.N.E. (north-northeast and east-northeast); and so in respect of the others. Sixteen points have thus been named. Let the distances be again bisected, then each of the points so found is expressed by that one of the preceding points already named to which it is nearest, followed by the name of the cardinal point toward which its departure from the nearest point leads it, the two being separated by the letter *b* (by). Thus this point half way between N. and N.N.E. is N. by E. (north-by-east); that which is half way between N.N.E. and N.E. is N.E. by N. (northeast-by-north), etc. The whole of the thirty-two points are thus distinguished in the figure.

The principal requisites of a compass are intensity of directive force, and susceptibility. The first of these is obtained by constructing the needle of the material and form best suited to receive and retain the magnetic virtue. A number of experiments on this subject were made by Comlomo, and more recently by Captain Kater, an account of which is given in the *Phil. Trans.* for 1821. Captain Kater found that the kind of steel capable of receiving the greatest magnetic force is shear steel; and that the best form is that of a lozenge or rhomboid, cut out in the middle, so as to diminish the extent of surface in proportion to the mass, it being found that the directive force of the needle, when magnetized to saturation, depends not on the extent of surface, but on the mass. Beyond a certain limit (about five inches) no additional power is gained by increasing the length of the needle; and needles exceeding a very moderate length are apt to have several consecutive poles, the effect of which is to produce a great diminution of directive force. On this account short needles, made very hard, are to be preferred.—BRANDE'S *Encyclopedia of Arts*.

Like many other of the most valuable arts of life, the origin of the compass is entirely unknown. By some

writers it is ascribed to Flavio Giola, who lived in the thirteenth century; yet Guyot de Provence, who lived a century earlier, speaks of the loadstone, to which he gives the name of *marinetti*, or mariner's stone, as useful to navigation. Others pretend that it was invented in France; but there seems to be no other reason for this supposition than the fact that from time immemorial the north point of the compass card has been distinguished and ornamented with a *fleur de lis*. For a reason of a different kind, but perhaps of the same degree of weight, Dr. Wallis and others have supposed the invention to belong to England, the name *compass*, which is given to the instrument by most European countries, being used in England to signify a circle. The term *bus-sola* in Italian and *boussole* in French, has also been supposed to be derived from our term *box*, by which the compass is frequently designated. Gilbert, in his celebrated work *De Magnete*, affirms that Marco Polo brought the invention to Europe from China, about the year 1260. It appears very probable that the Chinese were acquainted with the directive property of the loadstone at an early period.

The *azimuth compass*, being intended to show the bearing of objects in respect of the magnetic meridian, has its circle divided merely into degrees, instead of the rhumbs used in navigation, and is provided with sights to allow the angles to be taken more accurately.

The *variation compass* is designed to exhibit the diurnal changes in the deviation of the magnetic from the true meridian; and the needle is generally made much greater length than the mariner's compass, in order to render minute variations more sensible.

Compass Variations.—In a recent publication on the danger to which vessels are exposed from compass variations, there was suggested a plan of much importance to commerce: that in all large ports at least, where vessels are equipped, a competent person ought to be appointed, whose duties should be to select in every ship an advantageous position for a standard compass, combining the two requisites in such selection of a manageable local attraction, and of convenient access for navigating the ship—to determine experimentally the local deviations of the standard compass in different azimuths, to instruct the master how to repeat the same on future occasions, and to see that he rightly and thoroughly understands the deduction of the true magnetic courses from those of the standard compass, and of the course by the standard compass corresponding to the true course which he desires to steer.

Self-registering Compass.—The self-registering compass, by M. Delull, is designed to register the changes of direction in a vessel for every three minutes during the twenty-four hours. The marking is made upon a compass card. It consists of a clock movement placed at the centre of the apparatus for causing the point or pivot carrying the needles to move up and down at regular intervals—of an endless screw, furnished with a nut carrying the point, for piercing the paper—and of the compass card, made of three needles fixed to a sheet of mica. The mica is covered with a disk of velvet, and whose tissue has been saturated with a kind of glue that is soft when cold. When the needle is fixed toward the north, the axis or diametral line of the compass card is placed in the line of the axis of the ship, and the punctures made every three minutes indicate the deviation of this axis.

Composition, in Commerce, commonly implies the dividend or sum paid by an insolvent debtor to his creditors, and accepted by them in payment for their debts.

Consey Wool (Ger. *Kaninchenvolle*; Du. *Konyn-hair*; Fr. *Poil de lapin*; It. *Pelo di Coniglio*; Sp. *Consejuna*), the fur of rabbits. This article is extensively used in the hat manufacture; and besides the large supplies raised at home, a great deal is imported. The imports usually range from about 300,000 to about 500,000 skins a year.

Congreve Rockets. Invented by General Sir William Congreve in 1808. The Congreve rockets, first used against Boulogne in 1806, are of various dimensions, and differently armed, as they are intended for the field or for bombardment. Those of the former class carry shells or case-shot; those of the latter are armed with a very combustible material contained in a strong metallic cylindrical case with a conical head. When once inflamed, this substance is unextinguishable, it scatters its burning particles in every direction, and when spent, the ball explodes like a grenade. The rocket is projected horizontally, and makes a loud whizzing noise in its passage through the air. The ammunition used varies from 6 to 42 lbs. and upward. These rockets were certainly a very important invention; but from their liability to deflection and other defects, they are now regarded as less advantageous than the ordinary red-hot shot and bombs. The secret of their composition also is not so great as to defy imitation by foreign artillerymen. *Sir William Congreve, Bart.* (1772-1828), inventor of the rocket called by his name, was a general of artillery, and co-operated with the Duke of York in reforming the British army. He wrote an *Elementary Treatise on the Mounting of Naval Ordnance* (Lond. 1812); and a *Description of the Hydro-pneumatic Lock* (Lond. 1815). He died at Toulouse in 1828.—E. D.

Connecticut, the southernmost of the New England States, is situated between $1^{\circ} 41'$ and $42^{\circ} 2' N.$, and long. $71^{\circ} 20'$ and $73^{\circ} 15' W.$, and between $3^{\circ} 46' 24''$ and $5^{\circ} 41' 24'' E.$ long. from Washington. It is bounded north by Massachusetts, east by Rhode Island, south by Long Island Sound, and west by New York. It contains 4750 square miles, or 3,040,000 acres. Its population in 1790, was 297,946; in 1800, 251,002; in 1810, 261,942; in 1820, 275,248; in 1830, 297,711; in 1840, 300,015; in 1850, 370,792. The capitals are, Hartford, on the right bank of the Connecticut, at the head of steamboat navigation, 50 miles from its entrance into Long Island Sound, and New Haven, at the head of a bay which sets up 4 miles from the sound. It contained, in 1850, eight counties.

The beautiful river from which the State of Connecticut derives its name was first discovered (in the year 1613) by the Dutch Captain Adrian Block, who sailed into it as far up as the present site of Hartford, and who named it "*De Versche Rivier*" (the Fresh River), probably from the fresh appearance of its waters and green valleys. The Dutch from New Amsterdam made some attempts at settlement along this river. But the English colonists and explorers from Plymouth and Boston, on their way to the west, reached it about the year 1630, and became soon the exclusive proprietors of the river and its valley. They adopted for it the original name of the aborigines, which, in its true Indian shape, is said to have been "*Quonehtuck*." The meaning of this word is said to be "*The Long River*," and it appears to be a designation which the Indians applied often as a river name. Among others, we find also in Long Island a Connecticut River. The name was at first written in different ways. We find, for instance, on one map of the year 1635, the orthography "*R. Conokteook*." At last the orthography "*Connecticut*" prevailed. The English colonists applied the name of the river for the first time to a territory in the year 1631, when they claimed a tract of land around the present site of Hartford, and intended to erect there a colony, to which the name of "*Colony of Connecticut*" was given. This was an inland country, sometimes also called "*the Colony of Hartford*." In the year 1662 King Charles II. united with this colony that of New Haven, which was planted on the shores of Long Island Sound, and which had existed for some time separately under a particular name. The king named both united colonies "*The Province of Connecticut*," and in this way this name was extended to the sea-coast. It included then also a great part of Long Island,

which had been settled and was claimed by planters and emigrants from the Connecticut valleys. But soon after the conquest of New Netherland by the English (1664) the Duke of York claimed the whole of Long Island, which now was separated from the colony of Connecticut and became a part of the province of New York. In compensation for this loss the boundaries of Connecticut were extended to the west as far as Marmaronek or Byram's River, within thirty miles from New York, so that now the name Connecticut covered nearly the whole of the northern shore of Long Island Sound. These boundaries along the sea-coast have, upon the whole, remained unchanged ever since.—J. G. KONZ.

Though generally hilly and broken, no part of the surface rises to a great height above the sea. The greatest elevation is a range of mountains commencing at a bluff called East Rock, near New Haven, and continuing northward through the state. The hills are generally of moderate size, and occur in quick succession in ranges trending northward, presenting to the traveler an ever-varying aspect. The soil is generally fertile, but better adapted to grazing than tillage. There were in this state, in 1850, 1,768,178 acres of land improved, and 615,701 of unimproved land in farms. Cash value of farms \$72,726,422; and the value of implements and machinery, \$1,892,543; live-stock: horses, 20,879; asses and mules, 49; milch cows, 85,461; working oxen, 46,988; other cattle, 80,226; sheep, 174,181; swine, 76,472; value of live-stock, \$7,467,490.

Manufactures.—There were in the state, in 1850, 106 cotton factories, with a capital invested of \$4,012,600, employing 2665 males, and 8313 females, producing 54,370,527 yards of sheeting, etc., and 950,000 pounds of yarn, valued at \$4,122,952; 149 woolen factories, with a capital of \$2,583,742, employing 1693 males, and 1665 females, producing 8,950,372 yards of cloth, valued at \$4,921,152; 12 establishments making pig iron, with a capital of \$207,600, employing 120 persons, producing 13,020 tons of pig-iron, etc.; the entire value of products, \$879,600; 60 establishments, with a capital of \$580,800, employing 949 persons, and making 11,210 tons of castings, etc., valued at \$981,400; 18 establishments, with a capital of \$529,600, employing 874 persons manufacturing 6325 tons of wrought iron, etc., valued at \$667,500; 117 flouring mills, 115 tanneries, with a capital of \$360,500, employing 407 persons; value of products, \$731,006. Capital invested in manufactures, \$23,890,348; value of manufactured articles, \$41,897,848.

The state is watered by numerous rivers and streams. Few of the rivers are navigable for more than a short distance from their mouths. The principal is the Connecticut, which rises on the northern border of New Hampshire, and after a course of about 400 miles falls into Long Island Sound between Saybrook and Lyme. Its general direction is south-by-west, separating New Hampshire from Vermont, and afterward passing through the western part of Massachusetts and the central part of Connecticut. Below Middletown it turns to the south-southeast, and continues in that direction to its mouth. It is navigable to Middletown, 80 miles from the sea, for vessels drawing 10 feet, and to Hartford, 20 miles higher, for vessels drawing 8 feet of water. The canals and other improvements recently made to overcome the rapids and falls, have rendered it navigable for small boats as far as Wells River, 250 miles above Hartford. The principal tributary of the Connecticut in this state is the Tuxnis or Farmington, which rises in the eastern slope of the Green Mountains in Massachusetts, and flows southward to Farmington, where it abruptly changes its course to the northward. On breaking through the trap range of the Talcott Mountains, it again takes a southerly direction, and falls into the Connecticut opposite East Windsor. The Housatonic rises in the western part of Massachusetts and enters this state near its northwest corner, after which it

has a south and southeast course to the Sound. Its entrance is obstructed by a bar, but there is a sloop navigation for 12 miles. The Thames, formed by the junction of the Quinebaug, Shetucket, and Yantic Rivers near Norwich, falls into the Sound at New London. The mineral wealth of Connecticut is considerable. Iron ore of excellent quality is found abundantly in various parts. The copper mines of Bristol and Plymouth are said to be the most profitable in the United States. According to Professor Silliman, the Bristol vein extends in a southerly direction for more than 30 miles, and is fully worked is capable of affording employment to 30,000 miners. The Plymouth mines are considered to be equally rich. Copper is also found at Granby. Fine marbles of different kinds are abundant, and extensive quarries of freestone exist in the mountain regions, and furnish an excellent

building material. Zinc, cobalt, manganese, and plumbago are also found; and the mineral waters of Stamford have long been celebrated.

Connecticut has a larger productive school fund, in proportion to its population, than any other state, amounting to \$2,049,492. This originated chiefly from the sale of the Western Reserve, constituting a large part of the northern portion of the State of Ohio included in its original charter, and ceded to it by the United States by way of compromise. In 1852 there were in the state 53 banks, with a capital of \$12,509,808. It has no state debt. There is a state prison at Wethersfield, erected in 1826.

The following synopsis of the length, cost, capital, earnings, etc., of the Connecticut railroads, is from the Official Report of the Railroad Commissioners of that state for 1856:

* Nine months to June 30, and fiscal year begins July 1, 1843.

Consolidated Fund. Down to 1816 the exchequers of Great Britain and Ireland were kept separate, certain portions of the public revenue arising in each kingdom being especially appropriated to the discharge of the interest of its own debts, and other peculiar purposes. But on January 5th, 1816, the separate exchequers were consolidated into one; and an

act was at the same time passed consolidating certain portions of the joint revenue of Great Britain and Ireland into one fund, hence called the Consolidated Fund, and providing for its indiscriminate application to the payment of the public debts, civil lists, and other specified expenses of both kingdoms. Some portions of revenue are not included in this fund; but it embraces

Reference to the direct

and driven on Scraglio Point. It may be worth while, however, to remark that, notwithstanding this inconvenience, the current has been of signal service to the city, by scouring the harbor, and carrying away the filth and ballast by which it must otherwise have been long since choked up. The distance across from Scraglio Point to the opposite suburb of Scutari, on the Asiatic coast, is rather more than an English mile. Within less than a quarter of a mile of the latter is a rocky islet, upon which is a tower and light-house, known by the name of the Tower of Leander. Foreigners reside in Galata, Pera, and the suburbs, on the eastern side of the harbor; and it is there, consequently, that the principal trade of the place is carried on. The quays are good, and ships lie close alongside.

The Bosphorus, or channel of Constantinople, runs in a northeast by north direction about 16 miles, varying in breadth from 12 to $\frac{1}{2}$ a mile. It is swept by a rapid current, which it requires a brisk gale to stem, and has throughout a great depth of water. The Hellespont, or Strait of the Dardanelles, leading from the Archipelago to the Sea of Marmora, is about 18 leagues in length. Its direction is nearly northeast. Where narrowest, it is little more than a mile across. It also is swept by a strong current, and has deep water throughout.

The subjoined plan of part of Constantinople and its port is copied, without reduction, from the beautiful plan of the city and Bosphorus, drawn and engraved by M. Merzoff Robert of Munich, and published by Mr. Wilde of London.

Nothing can be more imposing than the appearance of the city when seen from the sea, but on landing the illusion vanishes. The streets are narrow, dark, ill-paved, and irregular. Owing to the want of any effective system of police, and of the most ordinary attention to cleanliness, they are extremely filthy; and are infested with herds of dogs, and also with rats, which perform the functions of scavengers. The houses are mostly built of wood, and fires are frequent. Most of these happen designly; the burning of a few hundred houses being deemed the readiest and most effectual means of making the government aware of the public dissatisfaction, and of procuring a redress of grievances.

Money.—Accounts are kept in piastres of 40 paras, or 120 aspers. The Turkish coin has been so much degraded, that the piastre, which a few years ago was worth 2s. sterling, is now worth little more than 4d. A bag of silver (*kefer*) = 500 piastres, and a bag of gold (*kitze*) = 30,000 piastres.

Weights and Measures.—The commercial weights are: 176 drams = 1 rottolo; 2·272 rottoli = 1 oke; 6 okes = 1 batman; $7\frac{1}{2}$ batmans = 1 quintal or cantaro = 124·457 (124 $\frac{1}{2}$ very nearly) lbs. avoirdupois = 56·437 kilogrammes = 116·527 lbs. of Hamburg. The quintal of cotton is 45 okes = 127·2 lbs. avoirdupois.

The pik or pike is of two sorts, the greater and the lesser. The greater, called *habebi* or *arschim*, used in the measurement of silks and woolsens, is very near 28 inches (27·9). The lesser, called *endese*, used in the measuring of cottons, carpets, &c. = 27 inches. Hence 100 long pikes = 77·498 English yards, and 100 short pikes = 75·154 English yards. But in ordinary commercial affairs the pik is estimated at $\frac{1}{4}$ ths of an English yard.

Corn is measured by the *kisloz* or *killow* = 0·941 of a Winchester bushel $8\frac{1}{4}$ kisloz = 1 quarter. The *fortin* = 4 kisloz.

Oil and other liquids are sold by the *atma* or *meter* = 1 gallon 3 pints, English wine measure. The *atma* of oil should weigh 8 okes.—NICKERMEYER and Dr. KELLY.

The Port charges on account of English vessels in the harbors of the Ottoman empire are fixed by treaty at 800 aspers, neither more nor less.

Trade, &c.—Owing to the vicious institutions of the

Turks, and the disorganized state of the empire, the trade of Constantinople is very far from being so extensive as might be supposed from its situation and population. The imports consist of corn, iron, timber, tallow, and furs, principally from the Black Sea; and of cotton stuffs and yarn, coal, tin, tin plates, woolsens, silks, cutlery, watches and jewelry, paper, glass, furniture, indigo, cochineal, &c., from England and other European countries. Corn and coffee are imported from Alexandria; but considerable quantities of Brazil and West India coffee are also imported, particularly in British and American bottoms. Sugar is partly imported from the East, but principally from the West Indies. The exports consist of silk, which is by far the most important article, carpets, hides, wool, Angola goats' hair, yellow berries, boxwood, opium, galls, bullions and diamonds, and a few other articles. But the exports are always very much less than the imports; and ships carrying goods to Constantinople either return in ballast, or get return cargoes at Smyrna, Odessa, Salonica, &c., on which places they frequently procure bills at Constantinople. By far the largest proportion of the trade of the city, and of the Levant generally, is in the hands of Greek merchants, who by their superior skill, industry, and knowledge of those with whom they have to deal, have completely distanced their English, French, and other European competitors (denominated Franks). The Armenians only have been able to withstand the competition of the Greeks. Bargains are negotiated by Jew brokers, some of whom are rich.

Constantinople was known as the Stanboul of the Greeks, or Istanbul of the Turks. An attempt was made to change this latter name into Islamabad, that is, the town of Islam or Mohammedanism, and coins were even struck bearing the new name; but the attempt failed, and the coinage again bears the impression "struck at Istanbul." The entire civil and ecclesiastical authority of the Turkish empire is concentrated in the city, where reside the chief pashas, muftis, and ulemas; the patriarch and synod of the Greek Church; an Armenian and a Catholic archbishop. That part of it which is now occupied by the seraglio, and which is separated from the rest by a wall, is understood to have been the Byzantium of the ancients.

Commercial Policy.—It is singular that, as respects commerce, the policy of the Turkish government, whether originating in design or carelessness, is entitled to the highest praise. "No restrictions," says Mr. Thornton, "are laid on commerce, except in the instance of a general prohibition of exporting the articles necessary for the support of human life to foreign countries, especially from the capital, where alone it is rigorously enforced; and this impolitic restraint will no doubt be removed when the Turkish government shall become sensible that what is intended as the means of securing abundance is, in fact, the sole cause of that scarcity which is sometimes experienced. With this one exception, commerce is perfectly free and unfettered. Every article of foreign or domestic growth or manufacture is conveyed into every port, and over every province, without any interference on the part of the magistrates, after payment of the duties. On this subject I speak from actual experience, and may appeal to every foreign or native merchant in Turkey for its general truth."—*Present State of Turkey*, vol. i. p. 82.

The duties, too, are extremely moderate, being only five per cent. on imports, viz., three per cent. on goods when landed, and two per cent. on their being admitted to consumption (*Ubiqini*, l. 281), and about three per cent. on most articles of export. Hence, in almost all that relates to her commercial regulations, Turkey is entitled to read a lesson to the most civilized European powers; and this she did in a very able manner, in an official paper published in the *Moniteur Ottoman*, in September, 1832. We extract a few paragraphs from this interesting document.

"Good sense, tolerance, and hospitality have long ago done for the Ottoman empire what the other states of Europe are endeavoring to effect by more or less happy political combinations. Since the throne of the sultans has been elevated at Constantinople, commercial prohibitions have been unknown; they opened all the ports of their empire to the commerce, to the manufactures, to the territorial produce of the Occident, or, to say better, of the whole world. Liberty of commerce has reigned here without limits, as large, as extended as it was possible to be.

"Here every object of exchange is admitted, and circulates without meeting any obstacle other than the payment of an infinitely small portion of the value to the custom-house. The chimeras of a balance of trade never entered into heads sensible enough not to dream of calculating whether there was most profit in buying or selling. Thus the markets of Turkey, supplied from all countries, refusing to objects which mercantile spirit puts in circulation, and imposing no charge on the vessels that transport them, are seldom or never the scenes of those disordered movements occasioned by the sudden deficiency of such or such merchandise, which, exorbitantly raising prices, are the scourges of the lower orders, by smothering their habits, and by igniting privations. From the system of restrictions and prohibitions arise those devouring tides and ebbs which sweep away in a day the labor of years, and convert commerce into a career of alarms and perpetual dangers. In Turkey, where this system does not exist, these disastrous effects are unknown.

"The extreme moderation of the duties is the complement of this regime of commercial liberty; and in no portion of the globe are the officers charged with the collection of more consulting facility for the vendition, and of so decidedly conciliatory a spirit in every transaction regarding commerce.

"Away with the supposition that these facilities granted to strangers are concessions extorted from weakness! The dates of the contracts termed capitulations, which establish the rights actually enjoyed by foreign merchants, recall periods at which the Mussulman power was altogether predominant in Europe. The first capitulation which France obtained was in 1535, from Soliman the Canotat (the Magnificent). The dispositions of these contracts have become antiquated, the fundamental principles remain. Thus, 800 years ago, the sultans, by an act of munificence and of reason, anticipated the most ardent desires of civilized Europe, and proclaimed unlimited freedom of commerce."

Did the policy of Turkey in other respects harmonize with this, she would be one of the most civilized and powerful of nations, instead of being one of the most sordid and degraded. Unfortunately, however, this is very far from being the case. Tyranny and insecurity universally prevail. "The cultivator of the soil," says one of her eulogists, "is ever a helpless prey to injustice and oppression. The government agents have to suffer in their turn from the cruelty and rapacity of which they themselves have been guilty; and the manufacturer has to bear his full share of the common insecurity; he is fixed to the spot, and can not escape the grasp of the local governor. The raw material monopolized by a bey or ayan, may be forced upon him at a higher price than he could purchase it himself, and perhaps of inferior quality; thence may be imposed upon him, he may be taken for forced labor, or troops may be quartered on his workshop."—URQUHART on Turkey and its Resources, p. 139.

Some vigorous efforts have been made of late years by the Turkish government to reform abuses; but with little or no practical effect. There is, in truth, neither public virtue nor principle in the country to second these efforts. Corruption of every kind is as prevalent as ever; and the rayas continue to be exposed to every sort of oppression. There are no roads in any part of the empire; and agriculture is everywhere in the most sordid condition. Indeed, vast tracts of the most fertile (and of old the most flourishing) districts of Asia Minor are wholly waste and unoccupied; and the evil, instead of diminishing, is continually increasing. The greater density of population in European Turkey, and the little industry found in it, are due to the energies of the Christian population. And when the latter have been emancipated from the slavery in which they have been long held, by the expulsion of their barbarian task-masters from Europe,

the beautiful provinces in which they have been so long permitted to encamp will again become the favorite seats of industry and civilization. But the degradation in which the native inhabitants are involved would have been still more complete, but for the freedom of commerce they have always enjoyed. This has tended to keep alive the seeds of industry, and to counteract to some small extent the destructive influence of oppression and insecurity. Had their intercourse with foreigners been either prohibited or placed under oppressive restrictions, the barbarism of Turkey would have been completed, and it is difficult to suppose that there could have been any thing like wealth or industry in the empire.

"As the Turks do not allow a census to be taken, all statements of the number of inhabitants in their dominions must be doubtful and conjectural. Eton calculates the population of Constantinople at no more than 300,000; while General Androskey calculated it, without including Scutari, at 597,600; his calculation being founded on the daily consumption of bread. The number of houses is about 88,100. According to Androskey, the division of the inhabitants is as follows: 300,000 Turks, Tatars, and other Mussulmans; 200,000 Greeks; 50,000 Armenians; 30,000 Jews; and the remainder of the various Frank nations. In 1851, the census of the resident British gave only 200. The mortality is said to be greater than in any other city in Europe; but the recruits that arrive from all parts of the Turkish dominions, and especially the slaves brought for sale, fill up the numbers faster than they fall away by death. Of late years, too, the rayas seek refuge from the exactions of the provincial pashas in the neighborhood of the seat of government, where the Tanzimat or new constitution is better observed. Although the public slave-market has been shut for a few years, the trade in slaves is still carried on with all its episodes of horror and abomination. The closely latticed windows of the harems of the rich, the prison-like aspect of the better streets, and the caravan of gaunt, shoeless Nubian girls in their cotton wrappers, are part and parcel of the odious system.

"The trade of Constantinople consists chiefly in the supply of the wants of the state officers, and of the military and naval persons who are attracted to the capital; but it is chiefly by foreigners that the handicraft operations are performed. The principal manufactures are those of cotton and silk goods. The Armenians are the chief jewelers and silversmiths. The Jews are perfumers, druggists, and brokers; the Franks are the principal mechanics; and the chief business is transacted at the several bazars.

"The foreign trade of Constantinople is favored by its excellent harbor, capable of containing 1200 ships. It is the medium of intercourse between that part of Asia whence laden camels arrive, and the different divisions of Europe, collecting the drugs and silks of the one, and distributing them among the others. It would require much space to collect and enumerate the ramifications of such a trade as is carried on in minute articles to and from the city of Constantinople. The city is distant 1680 miles from London."—E. B. See TURKEY.

Consuls. We propose to divide this article into three parts: I. Consuls, their Origin, and Laws respecting them; II. Duties of Consuls; III. Diplomatic and Consular Law of the United States.

Consul (*ὄναρος*), the highest ordinary magistrate of the Roman republic. It is probable that the word is compounded of *con* and *salvo*, and is formed like *exsul* and *presul*, so that *consules* signifies those who go together. They were anciently called *pretiores*, *imperatores*, or *judices*.

I. CONSULS, THEIR ORIGIN, AND LAWS RESPECTING THEM.—Consuls, in the nineteenth century, are commercial agents, appointed to reside in the sea-ports of foreign countries, with a commission to watch over the

commercial rights and privileges of the nation deputing them. The establishment of consuls is one of the most useful of modern commercial institutions. They were appointed about the twelfth century in the opulent states of Italy, such as Pisa, Lucca, Genoa, and Venice, and their origin has been ascribed to the necessity for extraordinary assistance in those branches of commerce formerly carried on with barbarous and uncivilized nations. The utility of such a mercantile officer has been perceived and felt by all trading nations, and the Mediterranean trade in particular stands highly in need of such accredited persons. Consuls have been multiplied and sent to every part of the world where navigation and commerce can successfully penetrate; and their duties and privileges are now generally limited and defined by treaties of commerce, or by the statute regulations of the country which they represent. In some places they have been invested with judicial powers over disputes between their own merchants in foreign ports; but in the commercial treaties made by Great Britain there is rarely any stipulation for clothing them with judicial authority, except in treaties with the Barbary powers; and in England it has been held that a consul is not strictly a judicial officer, and they have there no judicial power. It has been urged by some writers, as a matter highly expedient, to establish rules requiring merchants abroad to submit their disputes to the judicial authority of their own consuls, particularly with reference to shipping concerns. But no government can invest its consuls with judicial power over their own subjects in a foreign country, without the consent of the government of the foreign country, founded on treaty; and there is no instance in any nation of Europe, of the admission of criminal jurisdiction in foreign consuls. The laws of the United States, on the subject of consuls and vice-consuls, especially authorize them to receive the protests of masters and others in relation to American commerce, and they declare that consular certificates under seal, shall receive credit in the courts of the United States. It is likewise made their duty, where the laws of the country permit, to administer the personal estates of American citizens dying within their consulates, and leaving no legal representative; and to take charge of and secure the effects of stranded American vessels in the absence of the master, owner, or consignee; and they are bound to provide for destitute seamen within their consulates, and to send them at the public expense to the United States. It is made the duty of American consuls and commercial agents to reclaim deserters, and to discountenance insubordination, and to lend their aid to the local authorities for that purpose, and to discharge the seamen cruelly treated. It is also made the duty of masters of American vessels on arrival at a foreign port, to deposit their registers, sea-letters, and passports, with the consul, vice-consul, or commercial agent, if any, at the port. These particular powers and duties are similar to those prescribed to British consuls, and to consuls under the consular convention between the United States and France, in 1788; and they are in accordance with the usages of nations, and are not to be construed to the exclusion of others, resulting from the nature of the consular appointment. The consular convention between France and this country in 1778, allowed consuls to exercise police over all vessels of their respective nations, "within the interior of the vessels," and to exercise a species of civil jurisdiction by determining disputes concerning wages, and between the masters and crews of vessels belonging to their own country. The jurisdiction claimed under the consular convention with France, was merely voluntary, and altogether exclusive of any coercive authority; and we have no treaty at present which concedes even such consular functions. The doctrine of our courts is, that a foreign consul, duly recognized by our government, may assert and defend, as a compe-

tent party, the rights of property of the individuals of his nation in the courts of the United States, and may institute suits for that purpose without any special authority from that party for whose benefit he acts. But the courts, in that case, said that they could not go so far as to recognize a right in a vice-consul to receive actual restitution of the property, or its proceeds, without showing some specific power for the purpose from the party in interest. No nation is bound to receive a foreign consul unless it has agreed to do so by treaty, and the refusal is no violation of the peace and amity between the nations. Consuls are to be approved and admitted in the usual form; and if any consul be guilty of illegal or improper conduct, he is liable to have his *exequatur* (a written recognition of his character) revoked, and to be punished according to the laws of the country in which he is consul; or he may be sent back* to his own country, at the discretion of the government which he has offended. The French and American consuls are forbidden to be concerned in commerce, but British consuls are generally allowed to be concerned in trade; and in such cases the character of consul does not give any protection to that merchant, when these characters are united in the same person. Though the functions of a consul would seem to require that he should not be a subject of the state in which he resides, yet the practice of the maritime powers is quite lax on this point; and it is useful, and thought most convenient, to appoint subjects of the foreign country to be consuls at its ports.

A consul is not such a public minister as to be entitled to the privileges appertaining to that character, nor is he under the special protection of the law of nations. He is entitled to privileges to a certain extent, such as for safe conduct; but he is not entitled to the *ius gentium*. Vattel thinks that his functions require that he should be independent of the ordinary criminal jurisdiction of the country, and that he ought not to be molested unless he violates the law of nations by some enormous crime, and that if guilty of any crime he ought to be sent home to be punished. But no such immunities have been conferred on consuls by the modern practice of nations; and it may be considered as settled law that consuls do not enjoy the protection of the law of nations, any more than other persons who enter the country under a safe-conduct. In civil and criminal cases they are equally subject to the laws of the country in which they reside. The same doctrine, declared by the public jurists, has been frequently laid down in the English and American courts of justice. It seems, however, from some decisions in France, mentioned by Mr. Warden, that foreign consuls can not be prosecuted before a French tribunal for acts done by them in France by order of their government, and with the authorization of the French government, and that in general a consul can not be prosecuted without the previous consent of his government.

Consular privileges are much less extensive in Christian than in Mohammedan countries. In the latter, they can not be imprisoned for any cause whatever, except by demanding justice against them of the Porte, and they partake very considerably of the character of resident ministers. They are diplomatic agents under the name of consuls, and enjoy the rights and privileges which the Ottoman Porte recognizes in relation to the foreign ministers resident at Constantinople. By treaty an entire immunity is usually given to the persons, domestics, and effects of the resident consuls, and no consuls reside with the Barbary States but under the protection of treaties.

Considering the importance of the consular functions, and the activity which is required of them in all great maritime ports, and the approach which consuls

* As was the case with the British consuls at New York, Philadelphia, and Cincinnati, in the year 1856. The official *exequatur* of these gentlemen was withdrawn by President Pierce, and their official functions ceased.

make to the efficacy and dignity of diplomatic characters, it was a wise provision in the Constitution of the United States, which gave to the Supreme Court original jurisdiction in all cases affecting consuls as well as ambassadors and other public ministers; and the federal jurisdiction is understood to be exclusive of the state courts.—*KENT'S Comm.*, Lect. II.

In the treaty between Sweden and the United States of America, ratified on the 24th of July, 1818, it is stipulated that the consuls appointed by either government to reside within the dominions of the other, or their substitutes, "shall, as such, have the right of acting as judges or arbiters in all cases of differences which may arise between the captains and crews of the vessels of the nation whose affairs are intrusted to their care. The respective governments shall have no right to interfere in this sort of affairs, except in the case of the conduct of the crews disturbing public order and tranquillity in the country in which the vessel may happen to be, or in which the consul of the place may be obliged to call for the intervention and support of the executive power, in order to cause his decision to be respected; it being, however, well understood, that this sort of judgment or arbitration can not deprive the contending parties of their rights of appealing, on their return, to the judicial authorities of their country."

II. *Duties of Consuls.*—The duties of a consul, even in the confined sense in which they are commonly understood, are important and multifarious. It is his business to be always on the spot, to watch over the commercial interests of the subjects of the state whose agent he is; to be ready to assist them with advice on all doubtful occasions; to see that the conditions in commercial treaties are properly observed; that those he is appointed to protect are subjected to no unnecessary or unjustifiable demands in conducting their business; to represent their grievances to the authorities of the place where they reside, or to the ambassador of the sovereign appointing him at the court on which the consularship depends, or to the government at home; in a word, to exert himself to render the condition of the subjects of the country employing him, within the limits of his consularship, as comfortable, and their transactions as advantageous and secure as possible.

The following more detailed exposition of the general duties of a consul is taken from Mr. Chitty's work on *Commercial Law*: "A consul, in order to be properly qualified for his employment, should take care to make himself master of the language used by the court and the magistracy of the country where he resides, so as to converse with ease upon subjects relating to his duties. If the common people of the court use another, he must acquire that also, that he may be able to settle little differences without troubling the magistracy of the place for the interposition of their authority; such as accidents happening in the harbor, by the ships of his nation running foul and doing damage to each other. He is to make himself acquainted, if he be not already, with the law of nations and treaties, with the tariff or specification of duties on articles imported or exported, and with all the municipal ordinances and laws.

"He must take especial notice of all prohibitions to prevent the export or import of any articles, as well on the part of the state wherein he resides, as of the government employing him; so that he may admonish all his countrymen against carrying on an illicit commerce, to the detriment of the revenues, and in violation of the laws of either; and it is his duty to attend diligently to this part of his office, in order to prevent smuggling, and consequent hazard of confiscation or detention of ships, and imprisonment of the masters and mariners. It is also his duty to protect from insult or imposition his countrymen of every description within his jurisdiction. If redress for injury suffered is not obtained, he is to carry his complaint by memo-

rial to the minister residing at the court on which the consularship depends. If there be none, he is to address himself directly to the court; and if, in an important case, his complaint be not answered, he is to transmit the memorial to the secretary of state.—*BEAWE'S, WARDEN*, &c.

"When insult or outrage is offered by one from his country to a native of the place, and the magistrate thereof complains to the consul, he should summon, and in case of disobedience, may by armed force bring before him the offender, and order him to give immediate satisfaction; and if he refuse, he resigns him to the civil jurisdiction of the magistrate, or to the military law of the garrison; nevertheless *always acting as counselor or advocate at his trial*, when there is question of life or property. But if a subject be accused of an offense alleged to have been committed at sea, within the dominion or jurisdiction of his sovereign, it is then the duty of the consul to claim cognizance of the cause for his country, and to require the release of the parties, if detained in prison by the magistracy of the place on any such accusation brought before them, and that all judicial proceedings against them do instantly cease; and he may demand the aid of the power of the country, civil and military, to enable him to secure and put the accused parties on board such a ship as he shall think fit, that they may be conveyed home to be tried by their proper judges. If, contrary to this regulation, the magistrates of the country persist in proceeding to try the offense, the consul should then draw up and transmit a memorial to the minister at the court of that country; and if that court give an evasive answer, the consul should, if it be a sea offense, apply to the proper authorities, stating the case; and upon their representation, the secretary for the proper department will lay the matter before the king, who will cause the ambassador of the foreign state to write to his court abroad, desiring that orders may immediately be given by that government that all judicial proceedings against the prisoner be stayed, and that he be released.—*See Case of Horseman and his Crew*, *BEAWE'S*, vol. II. p. 422.

"The consul is not to permit a merchant ship to leave the port where he resides without his passport, which he is not to grant until the master and crew thereof have satisfied all just demands upon them; and for this purpose he ought to see the governor's pass of a garrisoned town, or the burgomaster's, unless the merchant or factor to whom the ship was consigned will make himself responsible.—*BEAWE'S, Lex. Merc.*, vol. II. p. 423. It is also his duty to claim and recover all wrecks, cables and anchors belonging to the ships of his country found at sea by fishermen or other persons, to pay the usual salvage, and to communicate a report thereof to authorities at home. The consuls and vice-consuls are, by express enactment (46 Geo. 3, c. 98, § 99), empowered to administer oaths in all cases respecting quarantine, in like manner as if they were magistrates of the several towns or places where they respectively reside. It is also laid down that a consul is to attend, if requested, all arbitrations where property is concerned between masters of ships and the freighters, being inhabitants of the place where he resides.—*CHITTY on Commercial Law*, vol. I. p. 68-61, and the numerous authorities there quoted.

Any individual, whether he be a subject of the state by which he is appointed, or of another, may be selected to fill the office of consul, provided he be approved and admitted by the government in whose territory he is to reside. In most instances, however, but not always, consuls are the subjects of the state appointing them. Much, however, of the peculiar duties of a consul must always depend on the nature of the intercourse with the country to which he is sent, and of the instructions given him. Consuls are regularly supplied with copies of all acts relating to trade and navigation, quarantine, slave-trade suppression, emigra-

tion, etc., and with the treaties between this and other countries, and must of course shape their conduct accordingly. They are strictly forbidden from corresponding with private parties on public matters. Under the *General Instructions for British Consuls*, "he will bear in mind that it is his principal duty to protect and promote the lawful trade and trading interests of his country by every fair and proper means, taking care to conform to the laws and regulations in question; and while he is supporting the lawful trade, he will take special notice of all prohibitions with respect to the export or import of specified articles as well on the part of the state in which he resides as of his government, so that he may caution all his countrymen against carrying on an illicit commerce to the detriment of the revenue, and in violation of the laws and regulations of either country; and he will not fail to give this Department immediate notice of any attempt to contravene those laws and regulations.

"The consul will give his best advice and assistance, when called upon, to his countrymen, quieting their differences, promoting peace, harmony, and good-will among them, and conciliating as much as possible the subjects of the two countries upon all points of difference which may fall under his cognizance. In the event of any attempt being made to injure his countrymen, either in their persons or property, he will uphold their rightful interests, and the privileges secured to them by treaty, by due representation in the proper official quarter. He will, at the same time, be careful to conduct himself with mildness and moderation in all his transactions with the public authorities, and he will not, upon any account, urge claims on behalf of his countrymen to which they are not justly and fairly entitled. If redress can not be obtained from the local administration, or if the matter of complaint be not within their jurisdiction, the consul will apply to the consul-general, or to his minister, if there be no consul-general in the country wherein he resides, in order that he may make a representation to the higher authorities, or take such other steps in the case as he may think proper; and the consul will pay strict attention to the instructions which he may receive from the minister or consul-general."—See *McCulloch's Dictionary of Commerce*; *KENT'S Commentaries*; *Encyclopædia Britannica*, 8th ed. published by Messrs. Little, Brown and Co., Boston; *Manual for United States Consuls*, 1857; *Tuson's British Consul's Manual*, London, 1856. The reader may with advantage refer to the articles on *Consuls* and *Consular Duties* contained in *DR. HOW'S Review*, vol. i. p. 56; *HUNT'S Merchants' Magazine*, vol. vi. p. 297, vol. xlii. p. 651, vol. x. p. 447, vol. xii. p. 211, vol. xvii. p. 43, vol. xviii. p. 60; *Foreign Quarterly Review*, vol. xli. p. 106.

Jurisdiction, Privileges, and Immunities of Consuls.—"The jurisdiction of a consul only extends over the subjects of the nation he is nominated by, either resident in, or arriving at, the place in which he has been appointed to reside. In countries where there are embassies as well as consulates the jurisdiction of the latter generally only extends over the sea-faring subjects of our nation, at the same time it watches over her commercial interests. That of a consul-general presides over the consul, and that of a consul, in most instances, over that of the vice-consul. The consular jurisdiction depends more entirely into what country the consul may be sent. Thus foreign consuls in England have no judicial authority whatever. British consuls, however, in most countries, have judicial power, and consequently their jurisdiction becomes either retrenched or extended, according to the nature of the stipulations of the ratified treaty.

"When the consul is appointed he is always provided with copies of the conventions with the country he is sent to. In regard to the privileges and immunities a consul enjoys, there have always existed doubts whether he may be considered exempt from the civil

jurisdiction of the state to which he is nominated; and although many others have laid down to the contrary, still it may be maintained, and in perfect conformity to the law of nations, that where the regular exequatur has been accorded to the consul, he ought to be exempt from the civil jurisdiction of the state to which he is accredited. By the exequatur the sovereign acknowledges him as the consular representative of his empire, bearing her appointment, and protected by her passport; and, as regards the nature of his mission, only resident for a short time at the state. Under these circumstances he ought to be exempt.

"In countries out of Europe, or where there is no embassy, the consul enjoys the same privileges as an ambassador, and is *de facto* the ambassador or representative of his sovereign, only under another name. He can perform all acts of a notary public, all deeds executed by him being held to be valid, and acknowledged in our courts of law. He can attend all levees of the sovereign after receiving his exequatur and either after having been presented to the sovereign by the ambassador, or, in his absence, by the minister of foreign affairs. The consulate is generally considered as the territory of the power by which it is tenanted, and all deeds, acts, and any other documents executed under the seal of the consul are valid in the country from which he has been sent. At the same time, it must be perfectly understood that all acts thus issued by the consul are, with a few exceptions, not valid in the country in which he resides, except there be a special convention to that effect. All documents, required to be valid before the tribunals of the country he is in, ought to be made out by the proper lawyers appointed for that purpose; for it can not be expected that where a consul is only authorized as judicial authority for his own country, that his acts should be acknowledged and received as legal instruments in the tribunals of the country he is accredited to, although his acts should be respected, as it might be possible that they could be grounded upon quite a different *lex mercatoria*, and could not, therefore, be taken in evidence against documents perhaps quite opposite in a legal point of view, and it would be unjust to allow them to be received."—*Tuson's British Consul's Manual*, 1856.

III. **Consular System of the United States.**—The establishment of a consular system in the United States was nearly coeval with that of the general government. In the second annual address of President Washington to the first Congress, he informed that body that "the patronage of our commerce, of our merchants, and seamen, called for the appointment of consuls in foreign countries; that it seemed expedient to regulate by law the exercise of that jurisdiction and those functions which are permitted either by express convention or by a friendly indulgence in the places of their residence." Prior to this period consuls were not allowed salaries, nor permitted to demand fees or receive perquisites.

In each branch of Congress this recommendation of the President was referred to the appropriate committee, and consular bills were reported in accordance therewith. They failed, however, to become laws, the House having stricken out the whole of the Senate bill with the exception of the first section.

In the early part of the second Congress substantially the same bill, probably drawn by Mr. Ellsworth (afterward Chief Justice), was reported to the Senate by a committee to whom the recommendation of the President had been referred; and, subsequently, after the adoption of several amendments, it passed both branches of Congress unanimously, and became, on the 14th of April, 1792, a law of the land.

From this period till the year 1855, with the exception of the act of July 20th, 1840, regulating the shipment and discharge of seamen and the duties of consuls, scarcely any change was made in the laws affecting the consular system.

In the year 1854, Mr. Perkins, of Louisiana, then a member of the House of Representatives from Louisiana, having devoted himself most assiduously to the study of the subject, prepared a bill to remodel the diplomatic and consular systems of the United States.

The bill was advocated in the House, and finally passed by a vote of 148 yeas to 88 nays.

In the Senate it passed unanimously, received the approval of the President on the 1st of March, 1855, and went into operation on the 1st of July, in the same year.

According to the recommendation of Mr. Marcy, Secretary of State, the subject was again brought forward in August, 1856, and a new act passed by a vote in the House of Representatives of 103 to 66, and passed the Senate unanimously on the 16th of that month.

It has rarely happened that a law so important as this has passed Congress with such unanimity—one involving many and important changes in the diplomatic and consular systems of the United States; creating new offices; increasing, reducing, or entirely abolishing the salaries of many consular officers; containing provisions affecting every American merchant and shipmaster engaged in foreign trade, and every American traveler in Europe; repealing provisions of existing laws; enacting others for the regulation of the agents of the government in foreign countries, and of civil officers in the United States; imposing heavy penalties for the violation of the provisions of the statute; and authorizing and requiring the performance of important duties by the highest executive officers of the government. The favor which the bill received in both branches of Congress was doubtless due, in part, to the fact that the near approach of the close of the session left little time for its discussion and amendment, and to the respect entertained by the House for the committee on foreign affairs, which reported the bill, whose chairman, it was understood, had devoted much time and care in its preparation. The law provides for the rate of compensation to be received by all diplomatic and consular officers, of whatever grade; fixes their compensation; permits the latter to transact business, or prohibits them from doing so, in certain places; prescribes the conditions of official bonds; imposes penalties for the violation of the provisions of the law, and indicates the manner in which actions for the recovery of penalties shall be tried; authorizes the appointment of consular pupils, of interpreters, and of additional secretaries of legations; fixes the period at which the compensation of the officers named in the act shall commence and terminate; provides for the filling of diplomatic and consular offices temporarily vacant, and the pay to be received by officers acting *ad interim*; forbids the exercise of diplomatic functions by unauthorized persons; authorizes the President to define the limits of the several consular and commercial agencies, to provide for the appointment of subordinate consular officers and their compensation, and likewise to fix the rate or tariff of fees for consular services, and designate what shall be regarded as official services; requires the consular tariff to be reported to Congress annually, and also the amount of fees received at the several consulates; directs the mode in which the payment of fees shall be made and accounted for, and the coin in which they shall be payable; imposes additional duties upon collectors and shipmasters in respect to consular services, receipts, and invoices; forbids diplomatic and consular officers to be absent from their posts, or to hold correspondence in regard to the public affairs of any foreign government with the press, or private persons, or otherwise than with the proper officers of the United States; forbids consular officers being pecuniarily interested in the receipt or disbursement of the wages of seamen, or in expenditures made for their relief or transportation; provides that no compensation shall be paid to diplomatic and consular officers, unless they shall be citizens of the United States; au-

thorizes the President to supply the legations and consulates of the United States with certain articles necessary for the transaction of the public business, and to prescribe such regulations, and make and issue such orders and instructions, not inconsistent with the Constitution or any law of the United States, in relation to the duties of all diplomatic and consular officers, the transaction of their business, the rendering of accounts and returns, the payment of compensation, the safekeeping of the archives and public property in the hands of all such officers, the communication of information, and the procurement and transmission of the products of the arts, sciences, manufactures, agriculture, and commerce, from time to time, as he may think conducive to the public interests; requires these officers to conform to such regulations, orders, and instructions; makes it the duty of the Secretary of State to publish official notifications, from time to time, of such commercial information communicated to him by the diplomatic and consular officers as he may deem important to the public interests, and to report to Congress, at least once in each year, a synopsis of so much of the information on all subjects, which shall be so communicated to him, as he may deem valuable for public information; authorizes the granting and issuing of passports, under certain conditions, and the performance of notarial duties by secretaries of legation and consular officers; enacts various provisions in regard to the desertion of seamen, the payment and the forfeiture of wages and extra wages in certain cases, and the settlement of seamen's accounts, and their discharge in foreign countries; provides for the accountability of consular officers for the extra wages of seamen; prescribes the kind of returns and reports to be made by consular officers, and requires all shipmasters to apply to consular officers for the transaction of consular business, and permits the detention of ships' papers till payment shall be made of all demands and wages on account of such ships and vessels; defines the duties of consular officers in respect to all citizens of the United States dying abroad, and the meaning to be affixed to the several titles by which consular officers are designated; imposes heavy penalties for all malfeasance, and for the violation of the provisions of the act; repeals all acts and parts of acts inconsistent with its provisions; and, finally, provides that the act shall take effect on the first of January, 1857. It will thus be seen that the law which now regulates the diplomatic and consular systems of the United States embraces a great number of subjects, and enters into much detail with respect to all matters pertaining to the consular office. Many of its provisions are eminently judicious; the expediency of others must be tested by time and their practical operation. The treaties and conventions of the United States with foreign nations contain many important provisions relating to the duties, rights, and privileges of consuls, especially those which have been negotiated with China and the Ottoman Porte.

But "the most complete consular conventions ever concluded," as remarks Mr. Tuson, the latest writer on the subject of the duties of consuls, "are those between France and the United States, and between the latter country and Holland; the former negotiated at Washington by Mr. Everett and M. Sartiges, and the latter at the Hague, under the instructions of Mr. Marcy. The rules laid down therein are very explicit, and ought to be taken as examples by all other nations. They will be of great utility to all consuls, in showing them what their present duties are, and what they are most likely to become. These conventions are such as are likely to be taken as precedents for future treaties on the same subject." Occurrences which have taken place in the United States and elsewhere, within the last few years, have shown how defective is the legislation of this country in respect to consuls. The subject attracted Mr. Webster's attention, while Secretary

of State; and, at his suggestion, the attention of Congress was called to it. He remarked that no country has a deeper interest in securing the protection of diplomatic and consular agents than the United States. Their commerce spreads over every sea, and visits every clime; and these agents are appointed to protect its interests, as well as to guard the peace of the country, and maintain the honor of its flag. While thus engaged in the discharge of important functions, they should be objects of especial respect and protection, each according to the rights belonging to his rank and station.

As much has been done during the last four years as at any former period in this country, by means of consular conventions, by legislation, and by circulars issued by the Secretary of State, not only to secure these objects, but to perfect the consular system, and to render it useful to the country. In obedience to the circulars issued by Mr. Marcy to consular officers on the 8th of October, 1853, the 16th of March, 1854, the 11th of July, 1855, and also the general and special instructions of the Department of State, a vast amount of information relating to ship-building, shipping, navigation, tonnage, seamen, foreign tariffs, commercial regulations, and other subjects, has been transmitted to the Department by the United States consuls. The matter thus collected is important and valuable; its preparation reflects great credit on the industry and intelligence of the consular corps, and affords a striking illustration of the importance of their services.

At the present time the consular corps of the United States consists of seven consuls-general, one hundred and seventeen consuls, and nine commercial agents, who receive for their compensation fixed salaries; ninety consuls, ten commercial agents, and eighty-five consular agents, who are authorized to retain for their compensation the official fees which they receive. Residing as these officers do in all the principal marts of traffic and commerce throughout the world, and having their duties carefully defined by law and the instructions of the Executive, it may reasonably be expected that all information affecting the commercial relations of the United States with foreign nations will be furnished by them to the Department of State, and published for the benefit of their fellow-citizens.

As an illustration of the value to be placed on the correspondence of consuls, it may be stated that in a debate which took place in 1842, in the House of Commons, Lord Palmerston remarked, that, during the time he had the honor of being at the head of the foreign department, he had read every report and every letter received from the consular officers abroad, from the most elaborate report of the highest consul-general down to the least-important letter of the lowest vice-consul. "Very laborious reading it was," he adds, "but, scattered through the voluminous papers that thus came under my eye, I found many important matters with which it was my duty to be acquainted; and it is quite a mistake to suppose that, because there is a superintendent of the consular department, the Secretary of State does not give the same minute attention to the consular as to the other duties of the office, though the consular correspondence amounts to one-half of the whole correspondence of the foreign office." The perfection to which the consular system has attained in France furnishes an illustration of what may be accomplished by a thoroughly organized consular establishment. The objects contemplated by such a system, as has been well remarked by a writer practically acquainted with the subject, are nothing less than the advancement of the prosperity and power of nations. Deputed to watch over the commercial rights and privileges of their respective countries, consular officers are intrusted with the care of the highest interests, and exercise a more important influence upon mercantile prosperity, the foundation of national greatness, than any other foreign agents of government.

Scattered throughout the whole world, occupying an eminent social position in all the mercantile cities of every nation, and performing duties which bring them more or less into collision with the people among whom they reside, they, by their conduct and manners, influence the judgment which is formed of the country they represent, and either add to its dignity or reflect dishonor on its national character.

1. *Nature and Duties of the Consular Office.*—The word "consul," as used in the Constitution of the United States, designates a class of public officers appointed by their government to reside in foreign countries, and especially in sea-ports and other places of commerce, to discharge administrative and sometimes judicial functions in regard to their countrymen who dwell or may be in the country where they reside; to aid in the authentication of documents abroad, and generally to perform such other duties as may be assigned to them by the laws and orders of their government.

2. *Classes of Consular Officers.*—Accordingly, by various laws of the United States, duties are imposed and rights conferred on this description of public officers, under the names of consuls-general, consuls, vice-consuls, deputy-consuls, commercial agents, vice-commercial agents, and consular agents. It is provided by the 31st section of the act of Congress approved August 18, 1856, that these official designations shall be deemed to have the respective meanings therein assigned to them, namely: "consul-general," "consul," and "commercial agent," shall be taken to denote full, principal, and permanent "consular officers," as distinguished from subordinates and substitutes; "deputy-consul" and "consular agent" to denote "consular officers" subordinate to such principals, exercising the powers and performing the duties within the limits of their consulates or commercial agencies respectively—the former at the same ports or places, and the latter at ports or places different from those at which such principals are located respectively; and "vice-consuls" and "vice-commercial agents" to denote "consular officers" who shall be substituted, temporarily, to fill the places of "consuls-general," "consuls," or "commercial agents," when they shall be temporarily absent or relieved from duty; and the term "consular officer" to include all such officers as are mentioned in the said section, and none others.

3. *Application of Acts of Congress.*—It is further provided by the same section that, in the construction and for the purposes of all other acts and parts of acts which shall remain in force after the act above mentioned shall take effect, defining any of the powers, declaring any of the rights, prescribing any of the duties, or imposing any penalty or punishment for any act of omission or commission of any consul, commercial agent, vice-consul, or vice-commercial agent, or allowing or enjoining the performance of any act, matter, or thing, with or before any such officer, all such acts and parts of acts shall in all these several respects, so far as may be consistent with the subject-matter and context of the same, and with the said act and the treaties of the United States, be deemed and taken to include and apply to all consular officers just as though all such officers were specifically named therein.

4. *Certain Consular Powers.*—The important act of 1792 contains a declaratory provision, which is to be understood as implied in all other acts of Congress, as follows:

"The specification of certain powers and duties, * * *, to be exercised or performed by the consuls and vice-consuls of the United States, shall not be construed to the exclusion of others resulting from the nature of their appointments, or any treaty or convention under which they may act.*"

So that the powers and duties of consuls, besides

being defined by acts of Congress, are indicated by general treaties and consular conventions entered into between the United States and other sovereign powers.

5. *International Law.*—Consuls possess, moreover, by the law of nations, many functions, rights, and privileges, other than such as are defined by convention, by legislative act, or by regulation.

6. *Consular Privileges.*—Their privileges necessarily arise from the character of their appointments; but they are not, like those of ambassadors and other public ministers, precisely defined by international law; and, consequently, they may be extended or limited among different nations, either by treaties or the legislative policy of those countries. Although the commissions which United States consuls receive from their government are expressed in the same terms and confer the same authority, yet, as the consular functions are to be exercised in a foreign country, and in accord with an exequatur issued by its sovereign, they may be more or less restricted. Whenever the immunities, rights, and duties of consuls are prescribed by mutual consular conventions, they are to be enjoyed or exercised in accordance with the stipulations of such conventions. In those countries with which the United States have entered into no consular convention, consular officers may discharge such duties as are allowed or are not forbidden by the laws of those countries, or which are allowed by common usage; and sometimes they are permitted to exercise such privileges as are granted to foreign consuls by the United States within its own territory.

7. *When Obstacles are interposed.*—If the authorities of the places where consuls reside oppose any obstacles to their enjoyment of the privileges which may have been accorded by consular conventions, or which, founded on usage or reciprocity, may have been claimed by themselves, they will refer the subject to the legation of the United States residing in the country, and report the facts, together with their own proceedings and a copy of all their correspondence in relation to the same, to the Department of State, and await its instructions. In no case will they strike the consular flag or abandon their post without the express permission of the Department.

8. *Personal Demeanor.*—One of the first duties of consular officers is to exhibit in their official conduct, and in their intercourse with the local authorities and with the people of the country, a proper respect for the supreme authority.

9. *Style of Official Communications.*—In their communications with official functionaries, they will be careful to set forth their views and opinions courteously but firmly, avoiding in all cases the use of violent or intemperate language. All discussions extending beyond the limits of a just moderation are injurious and defeat their own object.

10. *Influence of Personal Character.*—It is, above all, by their personal influence and character, by circumspect conduct and a conciliatory spirit, that consuls will best succeed in settling difficulties and in the accomplishment of important objects. Commercial intercourse is a common bond of interest among all countries and all men, and it is by arguments drawn from this source, rather than by unreasonable pretensions and disputes, that injurious restrictions can be removed.—DE CLENQ, tome ii. p. 32 *et seq.*

11. *Duties imposed by Laws.*—The laws of the United States on the subject of consuls and vice-consuls specially authorize them to receive the protests of masters and others relating to American commerce, and declare that consular certificates under seal shall receive faith and credit in the courts of the United States. It is likewise made the duty of consular officers, where the laws of the country permit, to collect and remit the assets of the personal estates of American citizens who may die within their consulates and leave no legal representative, and to take charge of and secure the

effects of stranded vessels, in the absence of the master, owner, or consignee; and they are bound to provide for destitute seamen within their consulates, and to send them, at the public expense, to the United States. It is their duty, likewise, to reclaim deserters, to discountenance insubordination and lend their aid to the local authorities for this purpose, to discharge seamen cruelly treated, and to receive from the masters of American vessels, on their arrival at a foreign port, and after the vessel shall have come to an entry, the registers, sea letters, and passports of such vessels. These duties, and some others which are prescribed by legal enactment, are in accordance with the usages of nations [KENT, vol. i. p. 42], and with special treaty stipulations with certain countries.

12. *Variety and Importance of Consular Duties.*—Many of the consular duties arise from peculiar circumstances: such as the character and habits of the nation in which the consul resides, its laws and customs, and the nature of its intercourse with the United States. In the most restricted sense, they are important and multifarious, are quite different from those of other officers employed in foreign affairs, and require for their proper performance an amount of practical information for which the consular officer needs a special training. Consuls are so situated as to exercise toward their countrymen within their consular jurisdiction the duties of judges, arbiters, and peace-makers; they are the registers of marriages, births, and deaths; they act as notaries, and sometimes as revenue officers; they watch over and verify the sanitary condition of their consulates; and, by their domestic relations, they can furnish a full and accurate idea of the commerce, navigation, and industry peculiar to the country of their residence.

13. *Commercial Regulations.*—The commercial interests of their own country are, in a measure, committed to their care. They are to see whether the stipulations in commercial treaties are observed, and report all changes in commercial regulations and municipal ordinances.

Every law, edict, or regulation of the government where they reside, in any way affecting the commerce of the United States, which comes to the knowledge of consular officers, must be immediately transmitted to the State Department; and, if it be a local regulation, operating only on a particular port, they must also give immediate notice thereof to the minister, if there be one in the country to which the district belongs.

14. *Suggestions.*—Consular officers are expected, in their correspondence, to note all events which bear upon the commerce between the country where they reside and the United States, the establishment of new branches of industry within the limits of their consular jurisdiction, and the increase and decline of such as have been before established. They should also make such suggestions as, in their opinion, may lead to an increase of trade, and point out any circumstances which may have produced a contrary effect, with the means that appear proper for avoiding such a result.

When new products of the arts, sciences, or manufactures appear to be valuable either for export or import, and this is not generally known, the fact should be communicated to the Department, and samples sent, if not too bulky, with the consular letters; but if too bulky they may be addressed to the collector of some one of our principal ports. Seeds of plants and grain suitable for cultivation in the United States should also be sent. In general, the duties of a consular officer require an attention to every thing that can promote the commerce and navigation of this country, and the interests of its citizens.

15. *Contentions to be avoided.*—Consular officers are particularly cautioned not to enter into any contentions which can be avoided, either with their countrymen or the authorities of the country in which they reside; referring questions of that nature to the min-

leter or to the Department; using every endeavor to settle in an amicable manner all disputes in which their countrymen may be concerned; and countenancing and protecting them before the authorities of the country in all cases in which they may be injured or oppressed, but withholding from them support when they have been willfully guilty of an infraction of the laws, particularly in any attempt to defraud the revenue. In this last case they will aid the proper officers in checking any such practices.

16. *Foreign Politics.*—All consular officers are forbidden to participate in any manner whatever, direct or indirect, in the political concerns of the countries by whose governments they are severally acknowledged and recognized in their public character; and they will be on their guard against the enlistment of their feelings upon the side of any of the political or sectional parties which may exist in these countries. In their letters upon such subjects, even to this Department, they will confine themselves to the communication of important or interesting public events, as they occur, in a clear and concise form, avoiding all unnecessary reflections or criticism upon the character or conduct of individuals or governments; and will not give publicity, through the press or otherwise, to opinions or speculations injurious to the public institutions of those countries, or the persons concerned in the administration of them; but it is, at the same time, no less their duty to report, freely and seasonably, to their own government, all important facts which may come to their knowledge, through authentic channels, touching the political condition of these countries, especially if their communications can be made subservient to, or may affect, the interest and well-being of their own.

17. *Prohibitions.*—All consular officers are prohibited by the 19th section of the act approved August 18, 1856, from corresponding in regard to the public affairs of any foreign government with any private person, newspaper, or other periodical, or otherwise than with the proper officers of the United States, and from recommending any person, at home or abroad, for any employment of trust or profit under the government of the country in which they are located; as well as from asking or accepting, for themselves or any other person or persons, any present, emolument, pecuniary favor, office, or title of any kind, from any such government.

18. *Diplomatic Functions.*—As consuls, excepting in Mohammedan states, are not invested with diplomatic powers, they are not entitled to communicate directly, except under special circumstances, with the government of the country in which they reside. Consular officers are forbidden by the 12th section of the act to exercise diplomatic functions, or hold any diplomatic correspondence or relation on the part of the United States, in, with, or to the government or country to which they shall be appointed, or any other country or government, when there shall be in such country any officer of the United States authorized to perform diplomatic functions therein, unless expressly authorized by the President.

19. *Made of addressing foreign Governments.*—Whenever application is to be made to such government, it must be done through the minister of the United States, if there be one; if not, and the case should require it, the consul may make the application to the proper department, but in respectful terms, stating the exigency of the case, and that an application to the subordinate officers could not be made, or that it had proved ineffectual.

20. *Privileges.*—A consul is not such a public minister as to be entitled to the privileges appertaining to that character, nor is he under the special protection of the law of nations. In civil and criminal cases, where not otherwise provided by treaty stipulations, he is subject to the laws of the country in which he resides.

21. *Treaties and Conventions.*—It is the duty of consuls to be conversant with all treaties, conventions, and consular conventions, also with the laws and commercial and other regulations relating to their consular functions.—*Manual for Consuls, issued by the Department of State, Washington, 1857.*

An Act to regulate the Diplomats and Consular System of the United States, passed August 10, 1856.—Be it enacted by the Senate and House of Representatives of the United States of America, in Congress assembled, that ambassadors, envoys extraordinary and ministers plenipotentiary, ministers resident, commissioners, chargés d'affaires, and secretaries of legation, appointed to the countries hereinafter named in schedule A, shall be entitled to compensation for their services, respectively, at the rates per annum hereinafter specified; that is to say, ambassadors and envoys extraordinary and ministers plenipotentiary, the full amounts specified therefor in said schedule A; ministers resident and commissioners, 75 per centum; chargés d'affaires, 50 per centum; and secretaries of legation, 15 per centum of the said amounts, respectively; Provided, that the compensation of the Secretary of the Legation to China, acting as Interpreter, shall be at the rate of \$5000, and if not acting as such, at the rate of \$3000; and that of the Secretary of Legation to Turkey, acting as dragoman, at the rate of \$3000, and if not acting as such, at the rate of \$2000 per annum.

Schedule A.—Great Britain, \$17,500; France, \$17,500; Russia, \$12,000; Spain, \$12,000; Austria, \$12,000; Prussia, \$12,000; Brazil, \$12,000; Mexico, \$12,000; China, \$12,000; all other countries, each \$10,000.

Sect. 2. And be it further enacted, that the President be, and he is hereby authorized to appoint for the legations at London and Paris, respectively, an assistant secretary of legation, who shall be entitled to compensation for their services respectively, at the rate of fifteen hundred dollars per annum; for the legation to China, an Interpreter, when the secretary of legation shall not be acting as such, who shall be entitled to compensation at the rate of \$3000; and for the legation to Turkey, a dragoman, when the secretary of legation shall not be acting as such, who shall be entitled to compensation at the rate of \$1000 per annum.

Sect. 3. And be it further enacted, that consuls-general, consuls, and commercial agents, appointed to the ports and places hereinafter specified in schedules B and C, shall be entitled to compensation for their services, respectively, at the rates per annum hereinafter specified in said schedules B and C; and if the President shall think proper to appoint a consul to any port or place named in the said schedules B and C, for a commercial agent, instead of such consular agent, or vice versa, and an appointment shall be made accordingly, the compensation for such consular officer shall be the same in any such case as that fixed for such port or place in the schedule embracing the same; and if he shall think the public interests will be subserved by appointing to any such port or place a consul-general, instead of a consul or commercial agent, and an appointment shall be made accordingly, the compensation for such consul-general shall be the same as that fixed for such port or place in the schedule embracing the same.

Sect. 4. And be it further enacted, that consuls-general, consuls, and commercial agents, not embraced in schedules B and C, shall be entitled, as compensation for their services, to such fees as they may collect in pursuance of the provisions of this act, respectively.

Sect. 5. And be it further enacted, that no consul-general, consul, or commercial agent, embraced in schedule B, shall, while he holds his office, be interested in or transact any business as a merchant, factor, broker, or other trader, or as a clerk or other agent for any such person, to, from, or within the port, place, or limits of his consulate or commercial agency, directly or indirectly, either in his own name, or in the name or through the agency of any other person; and if appointed after this act shall take effect, he shall, in his official bond, stipulate, as a condition thereof, not to violate this prohibition; and if appointed before, and retained in office after this act shall take effect, he shall, within such reasonable time as the President shall prescribe, enter into a new official bond, with such stipulation as a condition thereof; and if any such consul-general, consul, or commercial agent, shall violate such prohibition, he shall be liable to a penalty therefor, for the use of the United States, equal in amount to the annual compensation specified for him in said schedule B, which may be recovered in an action of debt at the suit of the United States, either directly for the penalty, as such, against such consul-general, consul, or commercial agent, or upon his official bond, as liquidated damages, for the breach of such condition, against such consul-general, consul, or

commercial them; and the United States shall every such applicable commorced as heretofore provided by law. Sect. 6. and is heretofore Chinese his hundred drent, and such consular think prop.

commercial agent and his sureties, or any one or more of them; and in every such case all such actions shall be open to the United States for the collection of such penalty till the same shall be collected in some one of such actions; and every such penalty, when collected, shall be paid into the treasury of the United States; and such prohibition shall be applicable to all consuls-general, but not to any consul or commercial agent not embraced in said schedule B, except as hereinafter authorized, unless otherwise expressly provided by law.

Sec. 6. And be it further enacted, that the President be, and is hereby authorized to appoint three interpreters of the Chinese language, who shall be entitled to compensation for their services, respectively, at a rate not to exceed fifteen hundred dollars per annum, to be determined by the President, and to assign such interpreters, from time to time, to such consulates in China, and with such duties as he may think proper.

Sec. 7. And be it further enacted, that the President be, and is hereby authorized, whenever he shall think the public good will be promoted thereby, to appoint consular pupils, not to exceed twenty-five in number at any one time, who shall be citizens of the United States, and entitled to compensation for their services, respectively, at a rate not to exceed one thousand dollars per annum, to be determined by the President; and to assign such pupils, from time to time, to such consulates, and with such duties as he may think proper; and before the appointment of any such pupil shall be made, satisfactory evidence, by examination or otherwise, shall be furnished of his qualifications and fitness for the office to the Secretary of State, and by him laid before the President.

Sec. 8. And be it further enacted, that no person appointed, after this act shall take effect, to any such office as is mentioned in the first, second, third, sixth, or seventh sections of this act, shall be entitled to compensation for his services therein, except from the time when he shall reach his post, and enter upon his official duties, to the time when he shall cease to hold such office, and for such time as shall be actually and necessarily occupied in receiving his instructions, not to exceed thirty days, and in making the transit between the place of his residence, when appointed, and his post of duty, at the commencement and termination of the period of his official service, for which he shall in all cases be allowed and paid, except as hereinafter mentioned, and no person shall be deemed to hold any such office after his successor shall be appointed and actually enter upon the duties of his office at his post of duty, nor after his official residence at such post shall have terminated, if not so relieved; but no such allowance or payment shall be made to any consul-general, consul, or commercial agent, contemplated by the fourth section of this act, or to any vice-consul, vice-commercial agent, deputy consul, or consular agent, for the time so occupied in receiving instructions, or in such transit as aforesaid; nor shall any such officer as is referred to in this section be allowed compensation for the time so occupied in such transit, at the termination of the period of his official service, if he shall have resigned, or been recalled therefrom, or for any malfeasance in his office.

Sec. 9. And be it further enacted, that, when to any diplomatic office held by any person there shall be superadded another, such person shall be allowed additional compensation for his services, in such superadded office, at the rate of fifty per centum of the amount allowed by this act for such superadded office; and such superadded office shall be deemed to continue during the time to which it is limited by the terms thereof, and for such time as shall be actually and necessarily occupied in making the transit between the two posts of duty, at the commencement and termination of the period of such superadded office so limited, and no longer.

Sec. 10. And be it further enacted, that for such time as any secretary of legation shall be lawfully authorized to act as chargé d'affaires *ad interim* at the post to which he shall have been appointed, he shall be entitled to receive compensation at the rate allowed by this act for a chargé d'affaires at such post; but he shall not be entitled to receive, for such time, the compensation allowed for his services as secretary of legation.

Sec. 11. And be it further enacted, that for such time as any consular officer shall be authorized, pursuant to the provisions of this act, to perform diplomatic functions in the absence of the regular diplomatic officer in the country to which he shall be appointed, he shall be entitled, in addition to his compensation as such consular officer, to receive compensation for his services while so authorized, at the rate allowed by this act for a secretary of legation in such country.

Sec. 12. And be it further enacted, that no consular officer shall exercise diplomatic functions, or hold any diplomatic correspondence or relation on the part of the United States, in

with, or to the government or the country to which he shall be appointed, or any other country or government, when there shall be in such country any officer of the United States authorized to perform diplomatic functions therein, nor in any case, unless expressly authorized by the President so to do.

Sec. 13. And be it further enacted, that every consul-general, consul, and commercial agent, appointed before, and retained in office after this act shall take effect, shall, without unnecessary delay, and every such officer appointed after this act shall take effect, shall, before he receives his commission or enters upon the duties of his office, enter into a bond with the United States with such sureties, who shall be permanent residents of the United States, as the Secretary of State shall approve, in a penal sum not less than one thousand nor more than ten thousand dollars, and in such form as the President shall prescribe, conditioned for the true and faithful accounting for, paying over, and delivering up of all fees, moneys, goods, effects, books, records, papers, and other property which shall come to his hands, or to the hands of any other person to his use as such consul-general, consul, or commercial agent, under any law now or hereafter enacted; and for the true and faithful performance of all other duties now or hereafter lawfully imposed upon him as such consul-general, consul, or commercial agent; and in the cases of consuls-general, consuls, and commercial agents embraced in schedule B, such bond shall contain, by way of further condition, the stipulation required by the fifth section of this act; and all such bonds shall be deposited with the Secretary of the Treasury, and in no case shall the penalty of such bond be less than the amount of compensation allowed to the officer entering into such bond; and the President shall be authorized to require a new or additional bond from any such consul-general, consul, or commercial agent, in like form and in such penalty, within the limits aforesaid, in amount, as he shall prescribe, whenever, in his opinion, the public good shall require it.

Sec. 14. And be it further enacted, that the President be, and he is hereby authorized to define the extent of country to be embraced within any consulate or commercial agency, and to provide for the appointment of vice-consuls, vice-commercial agents, deputy consuls, and consular agents therein, in such manner, and under such regulations as he shall deem proper; but no compensation shall be allowed for the services of any such vice-consul, or vice-commercial agent beyond nor except out of the allowance made by this act for the principal consular officer in whose place such appointment shall be made; and no vice-consul, vice-commercial agent, deputy consul, or consular agent, shall be appointed otherwise than in such manner and under such regulations as the President shall prescribe, pursuant to the provisions of this act.

Sec. 15. And be it further enacted, that every vice-consul and vice-commercial agent shall be entitled, as compensation for his services as such to the whole or so much of the compensation of the principal consular officer, in whose place he shall be appointed, as shall be determined by the President, and the residue, if any, shall be paid to such principal consular officer; and every consular agent shall be entitled, as compensation for his services, to such fees as he may collect in pursuance of the provisions of this act, or so much thereof as shall be determined by the President; and the principal officer of the consulates or commercial agency within the limits of which such consular agent shall be appointed, shall be entitled to the residue, if any, in addition to any other compensation allowed him by this act for his services therein; and the President shall have power to subject any consul or commercial agent contemplated by the fourth section of this act, and any vice-consul, vice-commercial agent, deputy consul, or consular agent, to the prohibition as to trade contained in the fifth section of this act, and to require from any of them such bond as is provided for by the thirteenth section of this act, whenever he shall think the public interests will be promoted thereby.

Sec. 16. And be it further enacted, that the President be, and is hereby authorized to prescribe, from time to time, the rates or tariffs of fees to be charged for official services, and to designate what shall be regarded as official services, besides such as are expressly declared by law, in the business of the several legations, consulates, and commercial agencies, and to adapt the same, by such differences as may be necessary or proper, to each legation, consulate, or commercial agency, and such rates or tariffs shall be reported annually to Congress; and it shall be the duty of all officers and persons connected with such legations, consulates, or commercial agencies to collect for such official services, such and only such fees as may be prescribed for their respective legations, consulates, and commercial agencies, and it shall be the duty of the collectors of the several districts, whenever any clearance is granted to any ship or vessel of the United States, duly registered as such, and bound on any foreign voyage, to

annex thereto, in every case, a copy of the rates or tariffs of fees which shall be allowed in pursuance of the provisions of this act, and then in force, and it shall be the duty of all consular officers at all times to keep up in their offices, respectively, a copy of such rates or tariffs as shall be in force, in a conspicuous place, and subject to the examination of all persons interested therein.

Sec. 17. And be it further enacted, that it shall be the duty of all consular officers to give receipts for all fees which shall be collected for their official services respectively, expressing the particular services for which the same were collected; and if any such consular officer shall collect, or knowingly allow to be collected, for any such services, any other or greater fees than such as shall be allowed pursuant to the provisions of this act for such services, he shall, besides his liability to refund the same, be liable to pay to the person by whom or in whose behalf the same shall be paid triple the amount of said unlawful charge so collected as a penalty therefor, to be recovered by such person in any proper form of action, to and for the use of such person, besides costs of suit; and in any such case the Secretary of the Treasury is hereby authorized to retain out of the compensation of such officer the amount of such overcharge and of such penalty, and charge the same to such officer in account, and thereupon to refund such unlawful charge, and pay such penalty to the person entitled to the same, if he shall think proper so to do.

Sec. 18. And be it further enacted, that all fees collected at any of the legations, or by the consuls-general, consuls, and commercial agents, in schedules B and C, and by vice-consuls and vice-commercial agents appointed to perform their duties, or by any other persons in their behalf, shall be accounted for to the Secretary of the Treasury, and held subject to his draft, or other directions; and all such consuls-general, consuls, commercial agents, and consular agents as are allowed for their compensation the whole or any part of the fees which they may collect pursuant to the provisions of this act, and all vice-consuls and vice-commercial agents appointed to perform the duties of said consuls-general, consuls, and commercial agents as are allowed for their compensation the whole or any part of such fees as aforesaid, shall make returns of all such fees as they or any other persons in their behalf shall so collect, in such manner as the Secretary of State shall prescribe; and all such fees as shall be so collected, accounted for, and reported, shall be reported annually to Congress, with the report of the rates or tariffs of fees required by the seventeenth section of this act, with a full list of all consular officers; and if any consul-general, consul, or commercial agent, mentioned in schedules B and C, or any vice-consul, or vice-commercial agent, appointed to perform the duty of any such officer mentioned in said schedules B and C, shall omit to collect any fees which he shall be entitled to charge, pursuant to the provisions of this act, for any official service, he shall be liable to the United States therefor, as though he had collected the same, unless, upon good cause shown therefor, the Secretary of the Treasury shall think proper to remit the same; and every consular officer shall number all receipts given by him for fees received for official services, in the order of their dates, beginning with number one at the commencement of the period of his service, and on the first day of January in every year thereafter; and he shall keep a book, in which he shall register all fees so received by him, in the order in which they shall be received, specifying in such register each item of service and the amount received therefor, from whom, and the dates when received, and if for any service connected with any ship or vessel, the name thereof, and indicating what items and amounts are embraced in each receipt given by him therefor, and numbering the same according to the number of the receipts respectively, so that the receipts and register shall correspond with each other; and he shall, in such register, specify the name of the person for whom, and the date when he shall grant, issue, or verify any passport, certify any invoice, or perform any other official service in the entry of the receipt of the fees therefor, and also number each consular act so receipted for, with the number of such receipt, and as shown by such register; and it shall be the duty of all owners, agents, consignees, masters, and commanders of ships and vessels to whom any receipt for fees shall be given by any consular officer, to furnish a copy thereof to the collector of the district in which such ships and vessels shall first arrive on their return to the United States; and it shall be the duty of every collector to forward to the Secretary of the Treasury all such copies of receipts as shall have been so furnished to him, and also a statement of all certified invoices which shall come to his office, giving the dates of the certificate and the names of the persons for whom, and of the consular officers by whom the same were certified; and every consular officer, in rendering his account or report of fees re-

ceived, shall furnish a full transcript of the register which he is hereby required to keep, under oath or affirmation that the same is true and correct, and that the same contains a full and accurate statement of all fees received by him, or for his use, for his official services as such consular officer, to the best of his knowledge, during the period for which the same shall purport to be rendered, and that such oath or affirmation may be taken before any person having authority to administer oaths and affirmations at the port or place where such consular officer is located; and if any such consular officer shall wilfully and corruptly commit perjury, in any such oath or affirmation, within the intent and meaning of any act of Congress now or hereafter made, he may be charged, proceeded against, tried, and convicted, and dealt with in the same manner, in all respects, as if such offense had been committed in the United States, before any officer duly authorized therein to administer or take such oath or affirmation, and shall be subject to the same punishments and disability therefor as are, or shall be prescribed by any such act for such offense.

Sec. 19. And be it further enacted, that no such officer as is mentioned in the first, second, third, fourth, sixth, or seventh sections of this act shall, nor shall any consular agent, be absent from his post, or the performance of his duties, for a longer period than ten days at any one time, without the permission previously obtained of the President; and no compensation shall be allowed for the time of any such absence in any case, except in cases of sickness; nor shall any diplomatic or consular officer correspond in regard to the affairs of any foreign government with any private person, newspaper, or other periodical, or otherwise than with the proper officers of the United States, nor recommend any person, at home or abroad, for any employment of trust or profit under the government of the country in which he is located; nor ask nor accept, for himself or any other person, any present, emolument, pecuniary favor, office, or title of any kind, from any such government.

Sec. 20. And be it further enacted, that the compensation provided by this act shall be in full for all the services and personal expenses which shall be rendered or incurred by the officers or persons respectively for whom such compensation is provided, of whatever nature or kind such services or personal expenses may be, or by whatever treaty, law, or instructions such services or personal expenses so rendered or incurred are or shall be required; and no allowance, other than such as is provided by this act, shall be made in any case for the outfit or return home of any such officer or person; and no consular officer shall, nor shall any person under any consular officer, make any charge or receive, directly or indirectly, any compensation, by way of commission or otherwise, for receiving or disbursing the wages or extra wages to which any seaman or mariner shall be entitled who shall be discharged in any foreign country, or for any money advanced to any such seaman or mariner who shall seek relief from any consular or commercial agency; nor shall any consular officer, or any person under any consular officer, be interested, directly or indirectly, in any profit derived from clothing, boarding, or otherwise supplying or sending home any such seaman or mariner: provided, that such prohibition as to profit shall not be construed to relieve or prevent any such officer who shall be the owner or otherwise interested in any ship or vessel of the United States, from transporting in such ship or vessel any such seaman or mariner, or from receiving or being interested in such reasonable allowance as may be made for such transportation, under and by virtue of the fourth section of the act entitled "An Act supplementary to the Act concerning Consuls and Vice-consuls, and for the further protection of American seamen," approved February 28, 1856.

Sec. 21. And be it further enacted, that no compensation provided by this act for any such officer as is mentioned in the first section of this act, or for any assistant secretary of legation, or for any such officer as is mentioned in schedules B and C of the third section of this act, or any appropriation therefor, shall be applicable to the payment of the compensation of any person appointed to or holding any such office after this act shall take effect, who shall not be a citizen of the United States; nor shall any other compensation be allowed in any such case.

Sec. 22. And be it further enacted, that the President be, and is hereby authorized to provide at the public expense all such stationery, blanks, record and other books, seals, presses, flags, and signs, as he shall think necessary for the several legations, consulates, and commercial agencies in the transaction of their business; and whenever he shall think there is sufficient reason therefor, to allow consuls-general, consuls, and commercial agents, who are not allowed to trade, actual expenses of office rent, not to exceed, in any case, ten

per centum of the amount of the annual compensation allowed to such officer, and to prescribe such regulations and make and issue such orders and instructions, not inconsistent with the Constitution or any law of the United States, in relation to the duties of all diplomatic and consular officers, in the transaction of their business, the rendering of accounts, and returns, the payment of compensation, the safe keeping of the archives and public property in the hands of all such officers, the communication of information, and the procurement and transmission of the products of the arts, sciences, manufactures, agriculture, and commerce, from time to time, as he may think conducive to the public interests; and it shall be the duty of all such officers to conform to such regulations, orders, and instructions. And it shall be the duty of the Secretary of State to publish official notifications, from time to time, of such commercial information communicated to him by such diplomatic and consular officers, as he may deem important to the public interest, in such newspapers, not to exceed three in number, as he may select, and report to Congress, at least once in each year, a synopsis of so much of the information on all subjects which shall be so communicated to him, as he may deem valuable for public information.

Sec. 23. And be it further enacted, that the Secretary of State shall be authorized to grant and issue passports, and cause passports to be granted, issued, and verified in foreign countries by such diplomatic or consular officers of the United States, and under such rules as the President shall designate and prescribe for and on behalf of the United States, and no other person shall grant, issue, or verify any such passport; nor shall any passport be granted or issued to, or verified for any other persons than citizens of the United States; nor shall any charge be made for granting, issuing, or verifying any passport except in a foreign country; and in any such case the fee allowed therefor shall not exceed the sum of one dollar, nor shall any such charge be made for more than one such verification in any foreign country; and if any person acting, or claiming to act, in any office or capacity under the United States, or any of the states of the United States, who shall not be lawfully authorized so to do, shall grant, issue, or verify any passport, or other instrument in the nature of a passport, to or for any citizen of the United States, or to or for any person claiming to be or designated as such in such passport or verification, or if any consular officer who shall be authorized to grant, issue, or verify passports, shall knowingly and willfully grant, issue, or verify any such passport to or for any person not a citizen of the United States, the person so offending shall be deemed and taken to be guilty of a misdemeanor, and, on conviction thereof, shall be imprisoned, not exceeding one year, or fined in a sum not to exceed five hundred dollars, or both, and may be charged, proceeded against, tried, convicted, and dealt with, therefore, in the district where he may be arrested or in custody; and it shall be the duty of all persons who shall be authorized, pursuant to the provisions of this act, to grant, issue, or verify passports, to make return of the same to the Secretary of State, in such manner and as often as he shall require; and such returns shall specify the names and all other particulars of the persons to whom the same shall be granted, issued, or verified, as embraced in such passport; provided, that in any country where a legation of the United States is established, no person other than the diplomatic representative of the United States at such place shall be permitted to grant or issue any passport, except in the absence thereof from such representative.

Sec. 24. And be it further enacted, that every secretary of legation and consular officer is hereby authorized, whenever he shall be required or may deem it necessary or proper so to do, at the post, port, place, or within the limits of his legation, consulate, or commercial agency, to administer to or take from any person an oath, affirmation, affidavit, or deposition, and also to perform any notarial act or acts such as any notary public is required or authorized by law to do or perform within the United States; and every such oath, affirmation, affidavit, deposition, and notarial act administered, sworn, affirmed, taken, had, or done, by or before any such officer, when certified under his hand and seal of office, shall be as good, valid, effectual and of like force and effect within the United States to all intents and purposes as if such oath, affirmation, affidavit, deposition, or notarial act had been administered, sworn, affirmed, taken, had, or done, by or before any other person within the United States duly authorized and competent thereto; and if any person shall willfully and corruptly commit perjury, or by any means procure any person to commit perjury, in any such oath, affirmation, affidavit, or deposition, within the intent and meaning of any act of Congress now or hereafter made, such offender may be charged, proceeded against, tried, convicted, and dealt with

in any district of the United States in the same manner, in all respects, as if such offense had been committed in the United States, before any officer duly authorized therein to administer or take such oath, affirmation, affidavit, or deposition, and shall be subject to the same punishment and disability therefor as are or shall be prescribed by any such act for such offense; and any document purporting to have affixed, impressed, or subscribed thereto or thereon the seal and signature of the officer administering or taking the same in testimony thereof, shall be admitted in evidence without proof of any such seal or signature being genuine or of the official character of such person; and if any person shall forge any such seal or signature, or shall tender in evidence any such document with a false or counterfeit seal or signature thereto, knowing the same to be false or counterfeit, he shall be deemed and taken to be guilty of a misdemeanor, and on conviction shall be imprisoned not exceeding three years, nor less than one year, and fined in a sum not to exceed three thousand dollars, and may be charged, proceeded against, tried, convicted, and dealt with, therefore, in the district where he may be arrested or in custody.

Sec. 25. And be it further enacted, that whenever any seaman or mariner of any vessel of the United States shall desert such vessel, the master or commander of such vessel shall note the fact and date of such desertion on the list of the crew, and the same shall be officially authenticated at the port or place of the consulate or commercial agency first visited by such vessel after such desertion, if such desertion shall have occurred in a foreign country; or if in such case such vessel shall not visit any place where there shall be any consulate or commercial agency before her return to the United States, or the desertion shall have occurred in this country, the fact and time of such desertion shall be officially authenticated before a notary public immediately at the first port or place where such vessel shall arrive after such desertion; and all wages that may be due to such seaman or mariner, and whatever interest he may have in the cargo of such vessel, shall be forfeited to and become the property of the United States, and paid over for their use to the collector of the port where the crew of such vessel are accounted for, as soon as the same can be ascertained; first deducting therefrom any expense which may necessarily have been incurred on account of such vessel in consequence of such desertion; and in settling the account of such wages or interest no allowance or deduction shall be made except for moneys actually paid or given at a fair price supplied, or expenses incurred to or for such seaman or mariner, any receipt or order, or arrangement with such seaman or mariner, to the contrary notwithstanding.

Sec. 26. And be it further enacted, that upon the application of any seaman or mariner for a discharge, if it shall appear to the consular officer that he is entitled to his discharge under any act of Congress, or according to the general principles or usages of maritime law, as recognized in the United States, he shall discharge such seaman or mariner, and shall require from the master or commander of the ship or vessel from which such discharge shall be made, the payment of three months' extra wages, as provided by the act hereinbefore mentioned, approved February 23, 1803; and it shall be the duty of such master or commander to pay the same, and no such payment or any part thereof shall be returned in any case, except such as are mentioned in the proviso of the ninth clause of the act entitled "An Act in addition to the several Acts regulating the Shipment and Discharge of Seamen and the Duties of Consuls," approved July 20, 1840, and as hereinafter provided, and the extra wages required to be paid by the said ninth clause of the last hereinbefore-mentioned act, and by this section, shall be applicable to the same purposes and in the same manner as is directed by the said act, approved February 23, 1803, in regard to the extra wages required to be paid thereby; and if any consular officer, when discharging any seaman or mariner, shall neglect to require the payment of, and collect the extra wages required to be paid in the case of the discharge of any seaman or mariner, by either of the said acts, as far as they shall remain in force under this act or by this act, he shall be accountable to the United States for the full amount of their share of such wages, and to such seaman or mariner to the full amount of his share thereof; and if any seaman or mariner shall, after his discharge, have incurred any expense for board or other necessities at the port or place of his discharge before shipping again, such expense shall be paid out of the share of the three months' wages to which he shall be entitled, which shall be retained for that purpose, and the balance only paid over to him; provided, however, that in cases of wrecked or stranded ships or vessels, or ships or vessels condemned as unfit for service, no payment or extra wages shall be required.

Consular Fees of the United States, prescribed by the President, in accordance with the provisions of the act of Congress approved August 18, 1856, regulating the diplomatic and consular systems of the United States:

DEPARTMENT OF STATE, November 10, 1856.

The following is the rate or tariff of fees prescribed by the President to be charged by all consular officers for the services herein specified, which shall be regarded as official services, and the fees therefor collected in American or Spanish silver dollars, or their equivalent.

At the expiration of each quarter the statement of fees must be rendered, in accordance with the printed instructions, by all consular officers entitled to salaries residing at sea-ports and at inland places, to the Secretary of the Treasury, and the amount thereof held subject to his draft or other direc-

tions. If the consular officer are not entitled to salaries, the returns must be made to the Secretary of State.

Receiving and delivering Ship's Papers.—For receiving and delivering ship's register and papers, including consular certificates, half a cent on every ton, registered measurement of the vessel for which the service is performed.

Discharging or shipping Seamen or Mariners.—For every seaman, from one to ten, who may be discharged or shipped, including certificates therefor attached to crew list and shipping articles, to be paid by the master of the vessel, 50 cents; but no additional charge shall be made for any number of seamen exceeding ten, who may be discharged from or shipped between the date of the arrival and departure of the vessel.

Protets, Passports, &c.

Recording Documents.

Calls of survey on vessel, hatches, cargo, provisions, and stores, or either; warrants and reports of ditto, ditto; estimates of repairs; certificates of consuls to advertisements for funds on bottomry, and of sale of vessel; inventories of vessel, cargo, provisions, and stores; letter of master to consul notifying sale of vessel, cargo, provisions, and stores, or either; letter of master to auctioneer, and account of sales of vessel, cargo, provisions, and stores, or either, for every 100 words.....	0 20
(As the original documents are required to be filed in the consulate, it will not be necessary to record them. Should it ever become necessary, however, to deliver up the originals, they must be recorded before delivery, the party receiving the same paying the record fee, as above mentioned.)	
Order and consul's certificates to pay seamen's wages or royalties, at home.....	0 25
Certificate given to master at his own request, when required.....	0 25
Appointment of new master.....	0 25
Application of a citizen of the United States for a sea letter.....	0 25
Sea letter, for every 100 words.....	0 20
Bill of sale, when required, for every 100 words.....	0 20
Consul's letter to captain of port, or authorities, in cases of sinking vessels.....	0 25
Consul's certificates to masters taking home destitute American seamen.....	no fee.
Protests of masters and others, other than marine protests, for every 100 words.....	0 20
Average bonds, when required, for every 100 words.....	0 20
Powers of attorney, when required, for every 100 words.....	0 20
Any other document or instrument of writing not herein named or enumerated, prepared in or out of the consulate, and required to be recorded, for every 100 words.....	0 20

Estate of deceased American Citizens.—For taking into possession the personal estate of any citizen who shall die within the limits of a consulate, inventoring, selling, and finally settling and preparing or transmitting, according to law, the balance due thereon, 5 per cent. on the gross amount of such estate. If part of such estate shall be delivered over before final settlement, 2½ per cent. to be charged on the part so delivered over as is not in money, and 5 per cent. on the gross amount of the residue. If among the effects of the deceased are found certificates of foreign stocks, loans, or other property, 2½ per cent. on the amount thereof. No charge will be made for placing the official seal upon the personal property or effects of such deceased citizen, or for breaking or removing the seals, when required by the person or persons referred to in section 79 of the act of August 18, 1866.

Miscellaneous Services.

For consul's seal and signatures to clearance from custom-house authorities.....	\$0 50
For administering oaths, not heretofore provided for.....	0 25
For consul's attendance at a shipwreck, or for the purpose of assisting a ship in distress, or of saving wrecked goods or property, over and above traveling expenses, a per diem of \$4, whenever the consul's interposition is required by the parties interested.....	4 00
For attending an appraisalment, where the goods or effects are under \$1000 in value.....	3 00
For attending valuation of goods of \$1000 and upward in value, for every day's attendance during which the valuation continues.....	5 00
For attending sale of goods, if the purchase-money be under \$1000.....	3 00
For attending sale of goods, if the purchase-money is \$1000 and upward, for every day during which the sale continues.....	5 00
For attending sale of vessel, when required.....	2 00

Fees for unofficial Services.—As the unofficial acts of a consular officer may be performed by a notary public, and as the compensation charged therefor is regarded as a prerequisite of his office, the rate of such compensation may be determined either by agreement or the custom of the place, subject, however, to future instructions.

Exterritorial and other Privileges of Consuls.—According to an elaborate opinion prepared by Mr. Cushing, Attorney-General of the United States, under date July 14, 1855, the United States may, with consent of the government of another country, superadd to the regular duties therein of consul any of those of a minister. There are two great classes of cases in which this fact exists, and might well be systematized, or at least more explicitly recognized, in consular stipulations with foreign governments.

Consular Privileges in Colonial or other Dependencies of Foreign States.—One is, that of the transmarine possessions of suzerity of the states of Europe. Here, many cogent reasons dictate that the concession should be granted to our consuls, by such states, of the right to address the colonial or provincial governor. There is nothing in the law of nations to prevent this; it is convenient for all parties; it is a consular right exercised by treaty in the great pashalics of the Turkish empire. The United States have recently made provision to the same effect in treaty with a Christian power, namely, the Netherlands; and that government having thus wisely relinquished its long-subsisting scruples on this point, we may reasonably expect similar liberality in future commercial negotiations with other countries of Europe.

Consular Duties where there is no Diplomatic Representative of the United States.—The other class of cases of this nature is that of a consul residing near a metropolitan government where there is no minister, either because of temporary cessation, or because inducements have not existed for the interchange of diplomatic representatives between such government and the United States. In this case it becomes the office, perhaps it may be said the right, of the consul to place himself, with the permission of his own government, in direct communication with the political authority of such government. Here, as in the other case, the fact occurs, and is of common convenience; it is not inconsistent with public law; and so far as regards the United States, it has example in treaties, for instance, in our last consular convention with France. It is a thing of manifest necessity as between the United States and some of the countries of Germany, with which our relations are entirely amicable, without calling for permanent diplomatic representation. The German Bund, though in some features resembling our own federal republic, yet differs essentially in this, that, in the former, the federal authority, in matters of peace and war, acts on states, not individuals, and of course each state retains the power of foreign representation and negotiation. Hence, if we do not see cause to interchange ministers, we may yet well reciprocally enlarge the consular functions, in our relations with such states as

Derivation of Privileges by Consuls.—Meanwhile, it would not in either of these classes of cases follow, because a consul of the United States in Bavaria, or one of Bavaria in the United States, may be admitted to address the government, that therefore he becomes a diplomatic personage, with international rights as such, and among them that of exterritoriality. If his commission be that of consul only, if his public recognition be an *exequatur*, the foreign consul is subject to the local law in the United States; and our own consul in the foreign country, if invested in any case with quasi-exterritorial rights, does not derive these from the law of nations, but only from the special concession, by general law or otherwise, of the particular foreign government. If, indeed, the United States see fit, in any case, to confer the function of chargé d'affaires on their consul, either with or without limitation of time, as they may lawfully do, that is, to superimpose the office of minister on that of consul, then he has a double political capacity, and, though invested with full diplomatic privilege, yet becomes so invested as chargé d'affaires, not as consul; and the fact of such casual duplication of function does not change the legal status of consuls, whether they be regarded through the eyes of the law of nations, or that of the United States.

Pagan and Mohammedan Countries.—It has been observed, that "in Egypt, Tunis, Tripoli, China, the islands of the Pacific, the consuls enjoy all the diplomatic privileges. The motive is not only in the difference of law and religion with ours, but also in the absence of other diplomatic representatives." This remark requires qualification. In the case of China and Turkey, for instance, our consuls have not, *quid* consuls, any "diplomatic privileges," except such as they might have in France during the absence of a minister; such exterritorial, not diplomatic, privileges, as they really enjoy, they enjoy, not because they are consuls, nor because of the absence of proper diplomatic representatives in those countries, for we have them, but because they are citizens of the United States. And the true explanation of the diplomatic rights appertaining to consuls in the Mohammedan states, whether independent ones, like Morocco and Muscat, or subject to the suzerainty of the Porte, like Tripoli, Tunis, and Egypt, and so of the Pacific or Indian islands, is, that they are not Christians, and are not admitted to a full community of international law, public or private, with us, the nations of Christendom.

Institution of the consular Office.—It might be demonstrated historically, what in this place it will suffice to affirm, that the institution of consuls, in their present capacity of international agents, originated in the mere fact of differences in law and religion at that period of modern Europe in which it was customary for distinct nationalities, coexisting under the same general political head, and even in the same city, to maintain each a distinct municipal government.

Consuls in the Levant.—Such municipal colonies, organized by the Latin Christians, and especially by those of the Italian republics in the Levant, were administered each by its consuls, that is, its proper municipal magistrates of the well-known municipal denomination of ancient Italy. Their commercial relation to the business of their countrymen was a mere incident of their general municipal authority. Such, also, at the outset, was the nature of their political relation to other coexisting nationalities around them in the same country, and to that country's own supreme political or military power.

In Countries not Christian.—The consuls of Christian states, in the countries not Christian, still retain unimpaired, and habitually exercise, their primitive functions of municipal magistrates for their countrymen, their commercial or international capacity in those

countries being but a part of their general capacity as the delegated administrative and judicial agents of their nations.

Origin of the Law of Nations.—This condition of things came to be permanent in the Levant, that is, Greek Europe and its dependencies, by reason of the tide of Arabic and Tartar conquest having overflowed so large a part of the Eastern empire, and established the Mohammedan religion there. But the result was different in Latin Europe, because the modern nations, formed in this quarter out of the broken fragments of the Western empire, being Christian, and thus deriving their religion and their civilization from the same fountain-head of Rome, settled into something of approximation to one great political community, under the influences, potential when combined, of the military power of the Frankish or Germanic emperors, and the moral power of the Papal See. Thus it was that the mass of legal ideas, which we now call the law of nations, came to exist and have authority. It is, in its origin at least, the system of public law of Latin or Western Europe.

Approximate Unity of Public Law.—This imperfect political unity of Western Europe was obstructed at first by the antagonism of the Celto-Romanic and the Germanic races, and was threatened with complete dissolution when that original antagonism reappeared in the separation of some of the Germanic populations from the Papal See, under the popularly assumed religious title of Protestants. But after thirty continuous years of reciprocal devastation and slaughter, the states of the old and new faith concluded a truce at least, if not a peace, and agreed, while acquiescing in the fact of religious difference, to maintain approximate unity of public law, and thus, by subordinating the religious idea to the legal one, to live together in some sort, as they have continued to do, with only occasional spasms of fanatical intolerance breaking out into civil or foreign war. At a late period, Russia, though of Greek faith, came into the European system of public law, with the less difficulty, indeed, for the reason that Latin Europe and Greek Europe alike nourished the legal traditions of the Roman empire, though these be derived in the former case from Rome, and in the latter from Constantinople.

Change in the Nature of the consular Office among Christian Nations.—Thus, by the combination of Romanic law and Christian faith it is that we have come to have a common public law, under whose gradual operation claims of private exterritoriality soon fell into desuetude among the governments of Christendom; Italians in England, and Englishmen in Italy, at length submitted to the local law; foreign colonial nationalities finally ceased to exist of right; their consuls proceeded to sink from the condition of municipal functionaries into that of mere commercial or semi-diplomatic ones; and thus, in process of time, by traditional usage, by positive provisions of local law, and by treaty stipulations, the existing legal character, with its limited rights, was fixed on the foreign consuls mutually accredited in the countries of Christian Europe and America.

In Mohammedan States.—In our relations with nations out of the pale of Christendom, we retain for our own citizens and consuls, though we can not concede to theirs, the rights of exterritoriality. Religion is the chief representative sign, and it is an element of the question of public law. But the critical fact is the difference of law. The legislation of Mohammed, for instance, is inseparable from his religion. We can not submit to one without also undergoing the other. The same legal incompatibility exists, for one reason or another, between us and the unchristian states not Mohammedan.

Institutes and Pandects.—Whereas Christendom, on the other hand, in all its subdivisions of race, nationality, and religion, is the common heir of the political

ideas, and especially the legislation, of the Roman empire; for the Institutes and Pandects themselves, though comprising the sum of the legal science of Rome, were compiled and promulgated at Constantinople, and constitute the broad foundation of the jurisprudence, public and private, of the whole of Christendom.

Unity in Christendom.—When the countries now Mohammedan shall be reabsorbed to the doctrines of the Roman law, then can they be admitted to the same reciprocal community of private rights with us, which prevails in Christian Europe and America. Until that event happens, Turkey, and other Moslem states in Africa or Asia, may, like China or Japan, enter into the sphere of our public law in the relation of government to government, but not in the relation of government to men. That full interchange of international rights is admissible only among the nations which have unity of legal thought, in being governed by, or constituted out of, the once discovered, but since then partially remitted, constituent of the Graeco-Roman empire.—*Manual for Consuls, United States, 1857.*

Contraband, in commerce, a commodity prohibited to be exported or imported, bought or sold. Contraband is also a term applied to designate that class of commodities which neutrals are not allowed to carry during war to a belligerent power. It is a recognized general principle of the law of nations, that ships may sail to and trade with all kingdoms, countries, and states in peace with the princes or authorities whose flags they bear; and that they are not to be molested by the ships of any other power at war with the country with which they are trading, unless they engage in the conveyance of *contraband* goods. But great difficulty has arisen in deciding as to the goods comprised under this term. The reason of the limitation suggests, however, the species of articles to which it principally applies. It is indispensable that those who profess to act upon a principle of neutrality, should carefully abstain from doing any thing that may discover a bias in favor of either party. But a nation who should furnish one of the belligerents with supplies of warlike stores, or with supplies of any article, without which that belligerent might not be able to carry on the contest, would obviously forfeit her neutral character; and the other belligerent would be warranted in preventing such succors from being sent, and confiscating them as lawful prize. All the best writers on international law admit this principle; which, besides being enforced during every contest, has been sanctioned by repeated treaties. In order to obviate all disputes as to what commodities should be deemed contraband, they have sometimes been specified in treaties or conventions. (See the references in LAMPERTI *Del Commercio de Popoli Neutrali*, § 9.) But this classification is not always respected during hostilities; and it is sufficiently evident that an article which might not be contraband at one time, or under certain circumstances, may become contraband at another time, or under different circumstances. It is admitted on all hands, even by M. Hubner, the great advocate for the freedom of neutral commerce (*De la Société des Bâtimens Neutres*, tom. i. p. 193), that every thing that may be made directly available for hostile purposes is contraband, as arms, ammunition, horses, timber for ship-building, and all sorts of naval stores. The greatest difficulty has occurred in deciding as to provisions, which are sometimes held to be contraband, and sometimes not. Lord Stowell has shown that the character of the port to which the provisions are destined, is the principal circumstance to be attended to in deciding whether they are to be looked upon as contraband. A cargo of provisions intended for an enemy's port, in which it was known that a warlike armament was in preparation, would be liable to arrest and confiscation; while, if the same cargo were intended for a port where none but merchantmen were

fitted out, the most that could be done would be to detain it, paying the neutral the same price for it he would have got from the enemy.

Contraband of War.—Questions of contraband were much discussed during the continuance of our neutral character, in the furious war between England and France, commencing in 1793, and the United States professed to be governed by the modern usage of nations on this point. The national convention of France, on the 9th of May, 1793, decreed, that neutral vessels laden with provisions, destined to an enemy's port, should be arrested and carried into France, and one of the earliest acts of England, in that war, was to detain all neutral vessels going to France, and laden with corn, meal, or flour. It was insisted, on the part of England, that, by the law of nations, all provisions were to be considered as contraband, in the case where the depriving of an enemy of those supplies was one of the means employed to reduce him to reasonable terms of peace; and that the actual situation of France was such as to lead to that mode of distressing her, inasmuch as she had armed almost the whole laboring class of her people, for the purpose of commencing and supporting hostilities against all the governments of Europe. This claim on the part of England was promptly and perseveringly resisted by the United States; and they contended that corn, flour, and meal, being the produce of the soil and labor of the country, were not contraband of war, unless carried to a place actually invested. The treaty of commerce with England, in 1794, in the list of contraband, stated, that whatever materials served directly to the building and equipment of vessels, with the exception of unwrought iron and fir planks, should be considered contraband, and liable to confiscation; but the treaty left the question of provisions open and unsettled, and neither power was understood to have relinquished the construction of the law of nations which it had assumed. The treaty admitted that provisions were not generally contraband, but might become so according to the existing law of nations, in certain cases, and those cases were not defined.

"It was only stipulated, by way of relaxation of the penalty of the law, that whenever provisions were contraband, the captors or their government should pay to the owner the full value of the articles, together with the freight and a reasonable profit. Our government has repeatedly admitted that, as far as that treaty enumerated contraband articles, it was declaratory of the law of nations, and that the treaty conceded nothing on the subject of contraband.

"The doctrine of the English admiralty on the subject of provisions being considered contraband, was laid down very fully and clearly in the case of the *Jonque Margaretha*. It was there observed, that the catalogue of contraband had varied much, and sometimes in such a manner as to make it difficult to assign the reasons of the variations, owing to particular circumstances, the history of which had not accompanied the history of the decisions. In 1673, certain articles of provisions, as *rum*, wine, and oil, were deemed contraband, according to the judgment of a person of great knowledge and experience in the practice of the admiralty; and, in much later times, many other sorts of provisions have been condemned as contraband. In 1747 and 1748, butter and salted fish and rice were condemned as contraband; and those cases show that articles of human food have been considered as contraband when it was probable they were intended for naval or military use. The modern established rule is, that provisions are not generally contraband, but may become so under circumstances arising out of the particular situation of the war, or the condition of the parties engaged in it. Among the circumstances which tend to preserve provisions from being liable to be treated as contraband, one is, that they are the growth of the country which exports them. Another circumstance

to which nations, if manufactured, or manufacture

These difficulties were essentially taken up by Congress in 1800, to whomsoever the necessities of the colonies, should they were Court of the and feel the party to a *con*, a neutral in the act of fish articles being neutral country, an military or observed, tions were become so on war, or on for the ordi were not ce for the arm military or were the gre for the con band, and he or navy we rect interpo

"This case Scott, and applied to pro voyage of t the infliction "It was t be contrabandments of wa in the remar from time to not indeed b in the appli to meet the are at once tion to the e the practice ing provision

to which some indulgence is shown by the practice of nations, is when the articles are in their native or unmanufactured state. Thus iron is treated with indulgence, though anchors and other instruments fabricated out of it are directly contraband. Hemp is more favorably considered than cordage, and wheat is not considered as so objectionable a commodity, when going to an enemy's country, as any of the final preparations of it for human use. The most important distinction is, whether the articles were intended for the ordinary use of life, or even for mercantile ship's use, or whether they were going with a highly probable destination to military use. The nature and quality of the port to which the articles are going is not an irrational test. If the port be a general commercial one, it is presumed the articles are going for civil use, though occasionally a ship of war may be constructed in that port. But if the great predominant character in that port, like Brest in France, or Portsmouth in England, be that of a port of naval military equipment, it will be presumed that the articles were going for military use, although it is possible that the articles might have been applied to civil consumption. As it is impossible to ascertain positively the final use of an article *incipit sensu*, it is not an injurious rule which deduces the final use from the immediate destination; and the presumption of a hostile use, founded on its destination to a military port, is very much inflated, if, at the time when the articles were going, a considerable armament was notoriously preparing, to which a supply of those articles would be eminently useful."

These doctrines of the English prize law were essentially the same with those adopted by the American Congress in 1775, for they declared, that all vessels, to whomsoever belonging, carrying provisions or other necessaries, to the British army or navy within the colonies, should be liable to seizure and confiscation. They were likewise fully adopted by the Supreme Court of the United States, when we came to know and feel the value of belligerent rights, by becoming a party to a maritime war. In the case of the *Commercen*, a neutral vessel, captured by one of our cruisers in the act of carrying provisions for the use of the British armies in Spain, the court held, that provisions, being neutral property, but the growth of the enemy's country, and destined for the supply of the enemy's military or naval force, were contraband. The court observed, that, by the modern law of nations, provisions were not generally contraband, but they might become so on account of the particular situation of the war, or on account of their destination. If destined for the ordinary use of life in the enemy's country they were not contraband, but it was otherwise if destined for the army or navy of the enemy, or for his ports of military or naval equipment. And if the provisions were the growth of the enemy's country, and destined for the enemy's use, they were to be treated as contraband, and liable to forfeiture, even though the army or navy were in a neutral port, for it would be a direct interposition in the war.

"This case followed the decisions of Sir William Scott, and carried the doctrine of contraband, as applied to provisions, to as great an extent. It held the voyage of the Swedish neutral so illegal as to deserve the infliction of the penalty of loss of freight.

"It was the *usua bellii* which determined an article to be contraband; and as articles come into use as implements of war which were before innocent, there is truth in the remark that as the means of war vary and shift from time to time, the law of nations shifts with them; not indeed by the change of principles, but by a change in the application of them to new cases, and in order to meet the varying inventions of war. When goods are at once clearly shown to be contraband, confiscation to the captor is the natural consequence. This is the practice in all cases, as to the article itself, excepting provisions; and as to them when they become con-

traband, the ancient and strict right of forfeiture is softened down to a right of pre-emption on reasonable terms. But, generally, to stop contraband goods would, as Vattel observes, prove an ineffectual relief, especially at sea. The penalty of confiscation is applied, in order that the fear of loss might operate as a check on the avidity for gain, and deter the neutral merchant from supplying the enemy with contraband articles. The ancient practice was, to seize the contraband goods, and keep them on paying the value. But the modern practice of confiscation is far more agreeable to the mutual duties of nations, and more adapted to the preservation of their rights. It is a general understanding, grounded on true principles, that the powers at war may seize and confiscate all contraband goods, without any complaint on the part of the neutral merchant, and without any imputation of a breach of neutrality in the neutral sovereign himself. It was contended on the part of the French nation in 1796, that neutral governments were bound to restrain their subjects from selling or exporting articles contraband of war to the belligerent powers. But it was successfully shown on the part of the United States, that neutrals may lawfully sell, at home, to a belligerent purchaser, or carry, themselves, to the belligerent powers, contraband articles subject to the right of seizure, *in transitu*. This right has since been explicitly declared by the judicial authorities of this country. The right of the neutral to transport, and of the hostile power to seize, are conflicting rights, and neither party can charge the other with a criminal act."—*KENT'S Commentaries*, Lect. VIII.

Contraband articles are said to be of an *infectious* nature, and they *contaminate* the whole cargo belonging to the same owners. By the ancient laws of Europe, the ship also was liable to condemnation when captured. But the modern view, since Grodus, is milder, and latterly the ship is liable to confiscation, and when fraud is detected, the innocent portions of the cargo are also liable.

By the ancient law of Europe, a ship conveying any contraband article was liable to confiscation as well as the articles. But in the modern practice of the courts of admiralty of this and other countries, a milder rule has been adopted, and the carriage of contraband articles is attended only with the loss of freight and expenses, unless when the ship belongs to the owner of the contraband cargo, or when the simple misconduct of conveying such a cargo has been connected with other malignant and aggravating circumstances. Of these a false destination and false papers are justly held to be the worst.—(5 *ROBINSON'S Admiralty Reports*, 275.) The right of visitation and search is a right inherent in all belligerents; for it would be absurd to allege that they had a right to prevent the conveyance of contraband goods to an enemy, and to deny them the use of the only means by which they can give effect to such right.—(VATTEL, book iii, c. 7, § 114.) The object of the search is two-fold; first, to ascertain whether the ship is neutral or an enemy, for the circumstance of its hoisting a neutral flag affords no security that it is really such; and, secondly, to ascertain whether it has contraband articles, or enemies' property, on board. All neutral ships that would navigate securely during war must, consequently, be provided with passports from their government, and with all the papers or documents necessary to prove the property of the ship and cargo; and they must carefully avoid taking any contraband articles or belligerent property on board; and hence, as Lamfredi has observed, a merchant ship which seeks to avoid a search . . . crowding sail, or by open force, may justly be captured and subjected to confiscation.

It has, indeed, been often contended that *free ships make free goods* (*cum le pavillon couvre la marchandise*), and that a belligerent is not warranted in seizing the property of an enemy in a neutral ship, unless it be

contraband. The discussion of this important question would lead us into details which do not properly come within the scope of this work. We may, however, shortly observe, that no such privileges could be conceded to neutrals, without taking from belligerents the right, inseparable from a state of war, of seizing an enemy's property if found in places where hostilities were lawfully carried on, as on the high seas. In fact, were the principle in question admitted, the commerce of a belligerent power with its colonies, or other countries beyond the sea, might be prosecuted in neutral ships, with as much security during war as in peace; so that neutrals would, in this way, be authorized to render a belligerent more important assistance than, perhaps, they could have done had they supplied him with troops and ammunition! But it is surely unnecessary to say, that to act in this way is a proceeding altogether at variance with the idea of neutrality. Neutrals are bound to conduct themselves in the spirit of impartiality, and must not afford such aid or assistance to one party as may be better enable him to make head against the other. It is their duty "*non interponere as bello, non hoste imminente hostem eripere.*" And yet it is manifest that the lending of neutral bottoms to carry on a belligerent's trade is in direct contradiction to this rule. The ships or cruisers of a particular power may have swept those of its enemy from the sea, and reduced him to a state of great difficulty, by putting a stop to his commerce with foreigners, or with his own colonies; but of what consequence would this be if neutrals might step in to rescue him from such difficulties, by carrying on that intercourse for him which he can no longer carry on for himself? It is natural enough that such a privilege should be coveted by neutrals; but, however advantageous to them, it is wholly subversive of the universally admitted rights of belligerent powers, as well as of the principles of neutrality; and can not, therefore, be truly said to be bottomed on any sound principle.

In the war of 1756, the rule was laid down by Great Britain, that neutrals are not to be allowed to carry on a trade during war that they were excluded from during peace; so that, supposing a nation at war with Great Britain had, while at peace, prohibited foreigners from engaging in her colonial or coasting trade, neutrals would not have been permitted to engage in it during war. This rule has been much complained of; but the principle on which it is founded seems a sound one, and it may in most cases be safely adopted. The claims of neutrals can not surely be carried farther than that they should be allowed to carry on their trade during war as they had been accustomed to carry it on during peace, except with places under blockade; but it is quite a different thing when they claim to be allowed to employ themselves during war in a trade in which they had not previously any right to engage. To grant them this, would not be to preserve to them their former rights, but to give them new ones which may be fairly withheld. Supposing, however, that either of the belligerent powers has force sufficient to prevent any intercourse between the other and its colonies, or any intercourse between different parts of the other, she might, in the exercise of the legitimate rights of a belligerent, exclude neutrals from such trade, even though it had formerly been open to them; because otherwise she would be deprived of the advantage of her superior force; and the neutrals would, in fact, when employed in this way, be acting as the most efficient allies of her enemy.

For a full discussion of this important and difficult question, and of the various distinctions to which it gives rise, see the work of Hubner (*De la Saisie des Bâtiments Neutres*, 2 tomes, 12mo, 1757), in which the different arguments in favor of the principle that "the flag covers the cargo," are stated with great perspicuity and talent. The opposite principle has been advocated by Lampredi, in his very able treatise *Del Com-*

mercio de' Popoli Neutrali, § 10; by Lord Liverpool, in his *Discourse on the Conduct of Great Britain in respect to Neutrals*, written in 1757; and, above all, by Lord Stowell, in his justly celebrated decisions in the Admiralty Court; and Hubner's *Commentaries*, Lect. III. Martens inclines to Hubner's opinion.—See *Précis du Droit des Gens*, liv. viii. c. 7.

Contracts. An executory contract is an agreement of two or more persons, upon sufficient consideration, to do or not to do a particular thing. The agreement is either under seal or not under seal. If under seal, it is denominated a speciality, and if not under a seal, an agreement by parol; and the latter includes equally verbal and written contracts not under seal. The agreement conveys an interest either in possession or in action. If, for instance, one person sells and delivers goods to another for a price paid, the agreement is executed, and becomes complete and absolute; but if the vendor agrees to sell and deliver at a future time, and for a stipulated price, and the other party to accept and pay, the contract is executory, and rests in action merely. There are also express and implied contracts. The former exists when the parties contract in express words, or by writing; and the latter are those contracts which the law raises or presumes, by reason of some value or service rendered, and because common justice requires it.

Every contract, valid in law, is made between parties having sufficient understanding and age and freedom of will, and of the exercise of it, for the given case. If the contract be entered into by means of violence offered to the will, or under the influence of undue constraint, the party may avoid it by the plea of duress; and it is requisite to the validity of every agreement, that it be the result of free and bona fide exercise of the will. Nor will a contract be valid if obtained by misrepresentation or concealment, or if it be founded in mistake as to the subject matter of the contract. A contract, valid by the law of the place where it is made, is generally speaking valid every where, *jure gentium*, and by tacit consent.

The *lex loci contractus* controls the nature, construction, and validity of the contract; and on this broad foundation the law of contracts, founded on necessity and commercial convenience, is said to have been originally established. If the rule were otherwise, the citizens of one country could not safely contract, or carry on commerce in the territories of another. The necessary intercourse of mankind requires that the acts of parties, valid where made, should be recognized in other countries, provided they be not contrary to good morals, nor repugnant to the policy and positive institutions of the state. Parties are presumed to contract in reference to the laws of the country in which the contract is made, and where it is to be paid, unless otherwise expressed. But if a contract be made under one government, and is to be performed under another, and the parties had in view the laws of such other country in reference to the execution of the contract, the general rule is, that the contract, in respect to its construction and force, is to be governed by the law of the country or state in which it is to be executed; the foreign law is in such cases adopted and effect given to it. Thus, the days of grace allowed upon bills of exchange are to be completed according to the usage of the place in which they are to be paid, and not of the place in which they are drawn, for that is presumed to have been the intention of the parties.

It is essential to the validity of a contract that it be founded on a sufficient consideration. It was an early principle of the common law, that a mere voluntary act of courtesy would not uphold an assumpsit, but a courtesy shown by a previous request would support it. There must be something given in exchange, something that is mutual, or something which is the inducement to the contract, and it must be a thing which is lawful and competent in value to sustain the

assumption to the valid and agreement bills of exchange between negotiable instruments are affected as to third paper in the original debt be alleged.

If the transfer of valuable goods to its validity of the contract practicing paper or potential and capable contract of a If the unjustly in the possession nevertheless one depends the article can be no to B, and it time, though contract is a

assumption. The rule, that a consideration is necessary to the validity of a contract, applies to all contracts and agreements not under seal, with the exception of bills of exchange and negotiable notes after they have been negotiated and passed into the hands of an innocent indorsee. The immediate parties to a bill or note are affected by the want of consideration, and it is only as to third persons, who come to the possession of the paper in the usual course of trade, without notice of the original defect, that the want of consideration can not be alleged.

Of the Contract of Sale.—A sale is a contract for the transfer of property from one person to another, for a valuable consideration; and three things are requisite to its validity, viz.: the thing sold, which is the object of the contract, the price, and the consent of the contracting parties. The thing sold must have an actual or potential existence, and be specific or identified, and capable of delivery, otherwise it is not strictly a contract of sale, but a special or executory agreement. If the subject matter be in existence, and only constructively in the possession of the seller, as by being in the possession of his agent or carrier abroad, it is nevertheless a sale, though a conditional or imperfect one depending on the future actual delivery. But if the article intended to be sold has no existence, there can be no contract of sale. Thus if A sells his horse to B, and it turns out that the horse was dead at the time, though the fact is unknown to the parties, the contract is nevertheless void.

The price is an essential ingredient in the contract of sale; and it must be real and not merely nominal, and fixed, or be susceptible of being ascertained in the mode prescribed by the contract, without further negotiation between the parties. Mutual consent is requisite to the creation of the contract; and it becomes binding when a proposition is made on one side and accepted on the other; and on the other hand, it is no contract if there be an error or mistake of a fact, or in circumstances going to the essence of it. In creating the contract the negotiation may be carried on by mail; and the contract is complete when the answer is sent with all due diligence after the receipt of proposal, and is out of the control of the party accepting.

In every sale of a chattel, if the possession be at the time in another, and there be no warranty of title, the party buys at his peril. But if the seller has possession, and he sells as his own and not as agent for another, and for a fair price, he is understood to warrant the title. With regard to the quality, the seller is not bound to answer unless he expressly warrants, or unless he has made a false representation or concealment. The common law requires the purchaser to attend to the qualities of the article he buys, which are supposed to be within the reach of his observation and judgment, and which it is equally his interest and duty to exert.

When the goods are discovered to be unsound the purchaser ought immediately to give notice or return them, and thereby rescind the contract. In the case of breach of warranty, he may sue upon it without returning the goods; but he must return them and rescind the contract before he can maintain an action to recover the price. He can not deal with the goods after discovery of fraud in a sale, without losing his right of action.

If there be intentional concealment or suppression of material facts in the making of a contract, in cases where both parties have not equal access for information, it will be deemed unfair dealing, and will vitiate the contract.

When the bargain is completed, by the terms of sale being agreed upon, the contract becomes binding between the parties and without actual delivery of goods, and the property is at the risk of the buyer; and he is entitled to the goods on payment of price when no conditions have been made. Special conditions may be made as to risk, time of delivery, credit, &c. In the

first instance to make the contract valid, there must be a delivery or tender of payment, or earnest given, or a memorandum in writing signed by the purchaser. When goods are to be delivered, delivery to an agent, carrier, or master of a vessel is equivalent to delivery to purchaser. The delivery to agent or carrier must be such as to create responsibility in that agent or carrier, and if insurance is the usage it ought to be done, and also the buyer informed, with diligence, of consignment and delivery. Symbolical delivery will, in many cases, be sufficient, such as transfer of key of warehouse from seller to buyer, or putting private mark by buyer upon the goods. Unless time and place are specified, the common rule is cash payment and place where they are at time of sale.—KENT'S Commentaries, Lect. XXXIX.

CONVOY, in navigation, the term applied to designate a ship or ships of war, appointed by government, or by the commander-in-chief on a particular station, to escort or protect the merchant ships proceeding to certain ports. Convoys are mostly appointed during war; but they are sometimes also appointed during peace, for the security of ships navigating seas infested with pirates.

Individuals have not always been left to themselves to judge as to the expediency of sailing with or without convoy. The governments of most maritime states have thought proper, when they were engaged in hostilities, to oblige their subjects to place themselves under an escort of this sort, that the enemy might not be enriched by their capture. Acts to this effect were passed in Great Britain during the American war and the last French war. The last of these acts (43 Geo. III. c. 57) enacted, that it should not be lawful for any ship belonging to any of his majesty's subjects (except as therein provided) to depart from any port or place whatever, unless under such convoy as should be appointed for that purpose. The master was required to use his utmost endeavors to continue with the convoy during the whole voyage, or such part thereof as it should be directed to accompany his ship; and not to separate therefrom without leave of the commander, under very heavy pecuniary penalties. And in case of any ship departing without convoy contrary to the act, or willfully separating therefrom, all insurances on the ship, cargo, or freight, belonging to the master, or to any other person directing or privy to such departure or separation, were rendered null and void. The customs officers were directed not to allow any ship that ought to sail with convoy to clear out from any place in the United Kingdom for foreign parts, without requiring from the master bond with one surety, with condition that the ship should not depart without convoy, nor afterward desert or willfully separate from it. The regulations of this act did not extend to ships not requiring to be registered, nor to those licensed to sail without convoy, nor to those engaged in the coasting trade, nor to those belonging to the East India Company, &c.

It is very common, during periods of war, to make sailing or departing with convoy a condition in policies of insurance. This, like other warranties in a policy, must be strictly performed. And if a ship warranted to sail with convoy, sail without it, the policy becomes void, whether this be imputable to any negligence on the part of the insured, or the refusal of government to appoint a convoy.

There are five things essential to sailing with convoy, viz.: first, it must be with a regular convoy under an officer appointed by government; secondly, it must be from the place of rendezvous appointed by government; thirdly, it must be a convoy for the voyage; fourthly, the master of the ship must have sailing instructions from the commanding officer of the convoy; and fifthly, the ship must depart and continue with the convoy till the end of the voyage, unless separated by necessity.

With respect to the third of these conditions we may observe, that a warranty to sail with convoy generally means a convoy *for the voyage*; and it is not necessary to add the words "for the voyage" to make it so. Neither will the adding of these words in some instances make the omission of them in any case the ground of a different construction. A warranty to sail with convoy does not, however, uniformly mean a convoy that is to accompany the ship insured the entire way from the port of departure to her port of destination; but such convoy as government may think fit to appoint as a sufficient protection for ships going the voyage insured, whether it be for the whole or only a part of the voyage.

Sailing instructions, referred to in the fourth condition, are written or printed directions delivered by the commanding officer of the convoy to the several masters of the ships under his care, that they may understand and answer signals, and know the place of rendezvous appointed for the fleet in case of dispersion by storm, or by an enemy, etc. Those sailing instructions are so very indispensable, that no vessel can have the full protection and benefit of the convoy without them; hence, when, through the negligence of the master, they are not obtained, the ship is not said to have sailed with convoy; and a warranty in a policy of insurance to that effect is held not to be complied with. If, however, the master do all in his power to obtain sailing instructions, but is prevented from obtaining them by any insuperable obstacle, as the badness of the weather, or if they be refused by the commander of the convoy, the warranty in the policy is held to be complied with.

For further information as to convoy, see *ANBON on the Law of Shipping*, part iii. c. 3; MARSHALL on *Insurance*, book i. c. 9 § 5.

Cook, Captain James. This celebrated navigator was born at Minton, near Stockton-on-Tees, October 27, 1728, and was originally apprenticed to a merchant in Yorkshire; but having a strong predilection for a sailor's life, he succeeded in obtaining his discharge, and immediately entered into new indentures with some coal shippers in the same county. In their employ he became a good seaman, and was promoted to mate, but subsequently entered the British navy as volunteer. In 1755 he was appointed to the mastership of a sloop, and joined the fleet operating against the French, in the St. Lawrence. His judgment, bravery, and great skill in conducting hydrographic surveys, gained for him a lasting reputation and increasing honors; and in 1764 he was appointed marine surveyor of Newfoundland and Labrador. In 1767, on the recommendation of the Royal Society, he was sent to the South Pacific to observe the approaching transit of Venus, and was accompanied by Messrs. Green, Solander, and King [afterward Sir Joseph] Banks. All the planets were successfully observed at Otaheite, June 3, 1769. Cook then sailed in quest of the supposed southern continent, circumnavigating New Zealand, and after other scientific observations he crossed to Batavia, and thence returned to England in the summer of 1771, and was promoted shortly after. In July, 1772, he commenced his second voyage, which lasted three years, when he was raised to a post-captaincy, with a lucrative appointment in Greenwich Hospital. In 1776 he volunteered to lead the scientific expedition to determine the problem of a northwest passage between the Atlantic and Pacific oceans, and running from the Cape to New Zealand, and thence through the Pacific, he discovered the Sandwich Islands, which he left for further observations, returning, however, to winter at Owyhee. An unfortunate misunderstanding between some of his people and the natives terminated in a fray, in which Cook was killed, after a desperate resistance, February 14, 1779.

Cooperage. This art must be coeval with the dawn of history, and seems to have been early known

in every country. The coopers of London were incorporated in 1501.

Copal, a resin which exudes spontaneously from two trees, the *Rhus copallinum*, and the *Elaeocarpus copalifer*, the first of which grows in America, and the second in the East India. A third species of copal-tree grows on the coasts of Guinea, especially on the banks of some rivers, among whose sands the resin is found. It occurs in lumps of various sizes and of various shades of color, from the palest greenish yellow to darkish brown. Its specific gravity is found to vary in different specimens from 1.059 to 1.071, being intermediate in density between its two kindred resins, animá and amber. Some rate its specific gravity so high as 1.139, which is probably one of the errors with which chemical compilations teem. Copal is too hard to be scratched by the nail, whence the excellence of its varnish. It has a conchoidal fracture, and is without smell or taste. When exposed to heat in a glass retort over a spirit lamp, it readily melts into a liquid, which being further heated boils with explosive jets. A viscid, oily-looking matter then distills over. After continuing the process for some time, no succinic acid is found in the receiver, but the copal blackens in the retort. Anhydrous alcohol boiled upon it causes it to swell, and transforms it by degrees into an elastic, viscid substance. It is not soluble in alcohol of 0.825 at the boiling point, according to experiment. Copal dissolves in ether, and this ethereal solution may be mixed with alcohol without decomposition. Caoutchoucine acts very slightly upon it by an experiment, even at the boiling temperature of this very volatile fluid; but a mixture of it with alcohol of 0.825, in equal parts, dissolves it very rapidly in the cold into a perfectly liquid varnish. Alcohol holding camphor in solution also dissolves it, but not nearly so well as the last solvent. According to Unverdorben, copal may be completely dissolved by digesting one part of it for 24 hours with one part and a half of alcohol (probably anhydrous), because that portion of copal which is insoluble in alcohol dissolves in a very concentrated solution of the soluble portion. Oil of petroleum and turpentine dissolve only one or two per cent. of raw copal. By particular management, indeed, oil of turpentine may be combined with copal.

Fused copal possesses different properties from the substance in its solid state; for it then may be made to combine both with alcohol and oil of turpentine. Unverdorben has extracted from the copal of Africa five different kinds of resin, none of which has, however, been applied to any use in the arts.

The ultimate constituents of copal by an analysis are, carbon 79.87, hydrogen 9.00, oxygen 11.1; being of hydrogen 7.6 in excess above the quantity necessary to form water with the oxygen.

Much information has been received from various sources concerning this somewhat ill-understood product of late years. It is now known that there are three different kinds of copal in commerce, but nothing is known of their distinguishing characteristics. We have East Indian and West Indian copal, and, under the latter name, two very different substances. The East Indian, called also African, is more colorless, soft, and transparent than the others; it forms a fine surface, and when heated emits an agreeable odor. It furnishes the finest varnish. Fresh essence of turpentine dissolves it completely, but not old. Essence digested upon sulphur will dissolve double its own weight, without letting any fall. Fresh rectified oil of rosemary will dissolve it in any proportion, but if the oil is thickened by age it serves only to swell this copal.

When cautiously melted, it may be then dissolved in good essence of turpentine in any proportion, producing a fine varnish, of little color.

A good varnish may be made by dissolving one part of copal, one of essence of rosemary, with from two to three of pure alcohol. This varnish should be

applied hot, durable.

The West lumps of a greenish color which are hard is usually yellow. Insects are very common in the Antilles, and dissolve in ether.

The third kind was formerly used in the water covering. It contains no aromatic odor, and is very solid varnish.

Copal varnish was long known applied to enamel. It preserves a color by reflecting light, and is not confounded with the former.

Besides the color, it is very distinct to the touch, and furnishes a use in this fluid, and copal is also used in softens in the

tionary, etc.

Weights and

applied hot, and when cold becomes very hard and durable.

The West India species, or American, comes, not in lumps of a globular form, but in small flat fragments, which are hard, rough, and without taste or smell. It is usually yellow, and never colorless like the other. Insects are very rarely found in it. It is also found in the Antilles, Mexico, and North America. It will not dissolve in essence of rosemary.

The third kind of copal, known also as West Indian, was formerly sold as a product of the East Indies. It is found in fragments of a concavo-convex form, the outer covering of which appears to have been removed. It contains many insects. When rubbed it emits an aromatic odor. It gives out much ethereous and empyrenematic oil when melted. It forms a soft varnish, which dries slowly.

Fusel oil, or amylic spirit, has been lately used as a solvent of the hard copal; but it does not dry into a very solid varnish.

Copal varnish was first discovered in France, and was long known by the name of *vernix martin*. It is applied to snuff-boxes, tea-boards, and other utensils. It preserves and gives lustre to paintings; and contributes to restore the decayed colors of old pictures, by filling up cracks, and rendering the surface capable of reflecting light more uniformly. Copal is liable to be confounded with *gum animé*, when the latter is very clear and good. But it is of importance to distinguish between them, as the animé, though valuable as a varnish, is much less so than the finest copal; the varnish with the former being darker colored, and not so hard. Besides the external appearance of each, which is pretty distinct to a practiced eye, the solubility in alcohol furnishes a useful test, the animé being readily soluble in this fluid, while the copal is hardly affected by it; copal is also brittle between the teeth, whereas animé softens in the mouth.—*REES' Cyclopaedia*; *URE'S Dictionary*, &c.

Copeck (kopeika), a Russian copper coin, so called from the impression of St. George bearing a lance. A hundred of them make one ruble. The value of the copper coin, compared with the assignation-ruble, varies in the different governments.

Copenhagen, the capital of Denmark, on the east coast of the island of Zealand, in the channel of the Baltic called the Sound; lat. 55° 41' 4" N., long. 12° 33' 46" E. Population, in 1845, 126,787. It is a well-built, handsome city. In going into Copenhagen, the course is between the buoy on the Stubben Bank to the left, and the buoy on the Middle-grounds, and those in advance of the three Crown batteries on the right, west-southwest by compass. From the three Crows to the roads the course is south-southwest. The water in the channel is from six to four fathoms deep; but it is narrow, and the navigation rather difficult. There is no obligation to take a pilot on board; but if a vessel wish for one, she may heave to abreast of the battery, when he will come to her. Vessels not intending to come into harbor bring up in the roads, at from a quarter to half a mile from shore, in about four fathoms, the town bearing south-southwest. In the harbor, within the boom, the water is from 17 to 18 feet deep. Vessels in harbor load and unload alongside the quay. The anchorage in the roads is good and safe.

Money.—Accounts are kept in rix dollars of 6 marcs, or 96 skillings; the rix dollar being formerly worth about 4s. 1d. sterling. But in 1813, a new monetary system was adopted, according to which the new or *Rigsbank* dollar is worth 2s. 3½d., being half the value of the old specie dollar, and ½ of the old current dollar. But the money generally used in commercial transactions is bank money, which is commonly at a heavy discount. The *par* of exchange, estimated by the *Rigsbank* dollar, would be 8 dollars 7-6 skillings per pound sterling.

Weights and Measures.—The commercial weights

are, 16 pounds = 1 *llspound*; 20 *llspound* = 1 *shilpound*; 100 lbs. = 11¼ lbs. *avoldrupis* = 134 lbs. *Troy* = 101 lbs. of Amsterdam = 108 lbs. of Hamburg.

The liquid measures are, 4 ankers = 1 *ahm* or *ohm*; 1½ *ahm* = 1 *hoghead*; 2 *hogheads* = 1 *pipe*; 2 *pipes* = 1 *quarter*. The anker = 10 (very nearly) English wine gallons. A *fuder* of wine = 930 pots; and 100 pots = 25½ wine gallons.

The dry measures are, 4 *viertels* = 1 *scheffel*; 8 *scheffels* = 1 *toende* or *ton*; 12 tons = 1 *last* = 47½ Winchester bushels. The last of oil, butter, harrings, and other oily substances should weigh 224 lbs. net.

The measure of length is the Rhineland foot = 12½ inches very nearly. The Danish ell = 2 feet; 100 ells = 68½ English yards.

Trade of Copenhagen.—The trade of Copenhagen has lately increased considerably, particularly the grain trade with England. At the commencement of 1852, 297 merchant vessels of about 35,000 tons burden belonged to the port. The harbor is large and commodious, capable of containing 600 merchant vessels besides the navy; and by the aid of canals, large vessels can come almost to the centre of the town. The entrance is commanded by the powerful batteries of *Trekroner* and *Sextus*. The principal imports are timber, pitch, and tar, chiefly from Norway and Sweden; flax, hemp, masts, sailcloth, and cordage, from Russia; tobacco from America; wines and brandy from France; coal, earthenware, iron, steel, and salt from England; and West India produce. The principal exports are corn, rape-seed, butter, cheese, beef, pork, horses, cattle, wool, hides, skins, bones, grain-spirits.

The manufactures of Copenhagen are not important, but are making considerable advances. There are extensive cloth and calico factories, foundries, and iron-works; also breweries, distilleries, tanneries, sugar-refineries, &c. Piano-fortes, clocks, watches, surgical and mathematical instruments, tobacco, chocolate, porcelain are among its other productions. The royal China factory is celebrated for its models of Thorwaldsen's works in biscuit China. The population of Copenhagen was in 1769, 92,571; in 1801, 100,975; in 1834, 119,292; in 1840, 120,819; in 1845, 126,787; and in 1855, 143,591; of which last about 67,000 were males, and over 76,000 females, including a Jewish population of 2500. The climate is damp, changeable, and unhealthy; which, added to the almost total want of sanitary regulations, renders the mortality greater here, it is said, than in any other town of Europe with the exception of Vienna.

The Port Charges at Copenhagen vary according as the vessel has come from this or the farther side of Cape Finisterre, or from the Indian seas; as she is wholly, or only partly loaded; and as she clears out with goods that have been in *transit*, and are for the most part free of duty, or has on board a cargo of native produce subject to duty. On a ship of 300 tons belonging to a privileged nation from this side Cape Finisterre, unloading and loading mixed cargoes in Copenhagen, the different public charges, including Sound dues, brokerage, &c., would exceed £60; and from the farther side of Cape Finisterre, the charges would be nearly £100. When a ship is not fully loaded, lastage money and light dues are only charged in proportion to the cargo on board. Lastage money is not charged on ships outward bound, laden with transit goods, as tar, pitch, iron, &c. But notwithstanding these deductions, it is obvious that port charges are very heavy, and there can be no doubt that they are a material obstacle to the extension of trade.

Citizenship.—To enable a foreigner to trade as a merchant in Denmark, he must become a burgher, which costs about £100, and it will require about £60 more to free him from the obligation of serving in the militia. The obstacles in the way of a foreigner establishing himself in Denmark as a manufacturer are much greater, on account of the exclusive privileges

enjoyed by the guilds or corporations into which the principal crafts or trades are divided.

Credit.—Goods imported into Copenhagen are commonly sold on credit; three months is the term generally allowed on most sorts of goods, and in a few instances six months. The discount for ready money is $\frac{1}{4}$ per cent. Bankruptcy is of rare occurrence.

Insurance.—Marine insurance is effected, on liberal terms, by a company established in 1746. Many Copenhagen risks are, however, insured at Amsterdam and Hamburg. Copenhagen has good building yards, and is in all respects an eligible place for the repair of ships, and for supplying them with provisions.

General Remarks.—On the whole, the commerce of Denmark used to be in a stationary state; a consequence partly of the peculiar circumstances under which the country is placed, and partly of the policy of government. The latter long exerted itself to bolster up a manufacturing interest, by laying oppressive duties on most species of manufactured articles. Even under the most favorable circumstances, such conduct, though it may benefit a few individuals, is sure to be productive of great national loss. But in the case of Denmark, the circumstances were such as to render the restrictive system peculiarly injurious. All, or nearly all, the branches of industry carried on in the kingdom were subject to the government of guilds or corporations; no person could engage in any line of business until he was authorized by its peculiar guild; and as the sanction of this body was rarely obtained without a considerable sacrifice, the real effect of the system was to fetter competition and improvement, and to perpetuate monopoly and routine. Even the Danish writers acknowledge that such was the influence of the late regulations. "Nos ouvrier," say they, "*sont chers, travaillent lentement, et souvent mal et sans goût; leur éducation est négligée. On ne les forme point à penser, et l'apprentif suit machinalement ce qu'il voit faire au maître.*"—CATTEAU, *Tableau des États Danois*, tome ii. p. 260. But within the last few years this system has been quite changed. Industry has been emancipated from many troublesome regulations, and moderate duties have been substituted for prohibitions. But, however favorably situated in other respects, it would be idle to expect that a country without waterfalls, and without coal, should be able to manufacture cottons, woollens, &c., at so cheap a rate as they may be imported from others enjoying greater natural facilities for their production. The staple business of Denmark, her agricultural and rural economy, has been most materially improved of late years; and, as already seen, her exports of raw produce are now of great value and important. The trade of the country suffers from the too great magnitude of the port dues and of the transit duties; and the Sound duties, being charged on native as well as foreign ships, operate as an inland duty on trade. Considerable improvements have, however, been effected in the commercial legislation of the country during the last dozen years, by the opening of the trade to the East and West Indies, and the abolition and reduction of other regulations and duties; and it may be fairly presumed that the benefits resulting from these measures will pave the way for the introduction of others of a similar character.—*See DENMARK.*

Copper (Germ. *Kupfer*; Du. *Koper*; Da. *Kobber*; Sw. *Kopper*; Fr. *Cuivre*; It. *Rame*; Sp. *Cobre*; Port. *Cobre*; Russ. *Медъ, Красной медъ*; Pol. *Miedz*; Lat. *Cyprum*; Arab. *Nehass*; Sans. *Tamra*), a well-known metal, so called from its having been first discovered, or at least, wrought to any extent, in the island of Cyprus. It is of a fine red color, and has a great deal of brilliancy. Its taste is styptic and nauseous; and the hands, when rubbed for some time on it, acquire a peculiar and disagreeable odor. It is harder than silver; its specific gravity varies according to its state, being, when quite pure, near 9.000. Its malleability is great; it may be hammered out into leaves so thin as to be

blown about by the slightest breeze. Its ductility is also considerable. Its tenacity is so great, that a copper wire 0.078 of an inch in diameter is capable of supporting 302.26 lbs. avoirdupois without breaking. Its liability to oxydation from exposure to air or damp is its greatest defect. The rust with which it is then covered is known by the name of verdigris, and is one of the most active poisons.—TOMSON'S *Chemistry*.

It is one of the six primitive metals; its discovery is said to have preceded that of iron. We read in the Scriptures of two vessels of fine copper, precious as gold.—*Ezra viii. 27*. The great divisibility of this metal almost exceeds belief; a grain of it dissolved in alkali, as pearl ashes, soda, &c., will give a sensible color to more than 500,000 times its weight in water; and when copper is in a state of fusion, if the least drop of water touch the melted ore, it will fly about like shot from a gun.—BOYLE. The mine of Faldun, in Sweden, is the most surprising artificial excavation in the world. In England, copper mines were discovered in 1561, and copper now forms an immense branch in the British trade.—HAYDN.

If we except gold and silver, copper seems to have been more early known than any other metal. In the first ages of the world, before the method of working iron was discovered, copper was the principal ingredient in all domestic utensils and instruments of war. Even now it is applied to so many purposes, as to rank next, in point of utility, to iron.

Alloys of Copper are numerous and of great value. Those of tin are of most importance. Tin added to copper makes it more fusible, less liable to rust, or to be corroded by the air and other common substances, harder, denser, and more sonorous. In these respects the alloy has a real advantage over unmixed copper; but this is in many cases more than counterbalanced by the great brittleness which even a moderate portion of tin imparts; and which is a singular circumstance, considering that both metals are separately very malleable.

In a pure state, copper is a very brilliant metal, and susceptible of a high polish. It is of a fine red color, differing in this respect from every other metal except titanium. Its specific gravity varies, according to its density, from 8.581 to 8.9.

Copper alloyed with from 1 to 5 per cent. of tin is rendered harder than before; its color is yellow, with a cast of red, and its fracture granular; it has considerable malleability. This appears to have been the usual composition of many of the ancient edged tools and weapons, before the method of working iron was brought to perfection. The χαλκος of the Greeks, and perhaps the *as* of the Romans, was nothing else. Even their copper coins contain a mixture of tin. The ancients did not, in fact, possess (as has been often contended) any peculiar process for hardening copper, except by adding a small quantity of tin. An alloy in which the tin is from 0.1 to one-eighth of the whole is hard, brittle, but still a little malleable, close grained, and yellowish white. When the tin is as much as one-sixth of the mass, it is entirely brittle; and continues so in every higher proportion. The yellowness of the alloy is not entirely lost till the tin amounts to 0.3 of the whole.

Copper (or sometimes copper with a little zinc), alloyed with as much tin as will make from about 0.1 to one-sixth of the whole, forms an alloy which is principally employed for bells, brass cannon, bronze statues, and various other purposes. Hence it is called *bronze* or *bell metal*; and is excellently fitted for the uses to which it is applied, by its hardness, density, sonorousness and fusibility. For cannon, a lower proportion of tin is commonly used. According to Dr. Watson, the metal employed at Woolwich consists of 100 parts of copper and from 8 to 12 of tin; hence it retains some little malleability, and, therefore, is tougher than it would be with a larger portion of tin. This alloy being more sonorous than iron, brass guns give a loud-

er report than iron guns. A common alloy for bell metal is 80 parts of copper and 20 of tin; some artists add to these ingredients zinc, antimony, and silver, in small proportions; all of which add to the sonorousness of the compound.—See BELL-METAL.

When in an alloy of copper and tin the latter metal amounts to about one-third of the mass, the result is a lustrous compound, very hard, of the color of steel, and susceptible of a very fine polish. It is well adapted for the reflection of light for optical purposes; and is therefore called *speculum metal*. Besides the above ingredients, it usually contains a little arsenic, zinc, or silver. The application of an alloy similar to the above to the construction of mirrors is of great antiquity, being mentioned by Pliny; who says, that formerly the best mirrors were reckoned those of Brundisium, of tin and copper mixed (*stanno et are mista*).—*Hist. Nat. lib. xxxlii. § 9.* See THOMSON'S *Chemistry*; REES' *Cyclopædia*; Dr. WATSON'S *Chemical Essays*, vol. iv., etc.

British Copper Trade.—Great Britain has various copper mines in Cornwall, Devonshire, Wales, etc., but particularly in the first. Though known long before, the Cornish copper mines were not wrought with much spirit till last century. From 1726 to 1735, they produced at an average about 700 tons a year of pure copper. During the ten years from 1766 to 1775, they produced at an average 2650 tons. In 1798, the produce exceeded 5000 tons; and it now amounts to from 11,000 to 12,500 tons, worth, at £100 a ton, from £1,100,000 to £1,250,000 sterling. In 1768, the famous mines in the Parys Mountains, near Anlwech, in Anglesea, were discovered. The supplies of ore furnished by them were for a long time abundant beyond all precedent; but for many years past the productiveness of the mine has been declining, and it is now almost exhausted. At present the mines of Anglesea, and other parts of Wales, do not furnish 200 tons of copper. These of Devonshire yield nearly 2000 tons; the quantity produced in the other parts of England being quite inconsiderable. The Irish mines produce about 960 tons. Those of Scotland never were productive, and have been almost entirely abandoned. The entire produce of the copper mines of the empire may, therefore, be estimated at present at from 15,000 to 16,000 tons. In consequence of the greatly increased supplies of copper that were thus obtained, England, instead of being, as formerly, dependent on foreigners for the greater part of her supplies of this valuable metal, became, previously to 1798, one of the principal markets for the supply of others; and notwithstanding the vastly increased demand for copper during the war for the sheathing of ships and other purposes, the exports continued to increase and the imports to diminish; the greater productiveness of the Cornish mines having sufficed not only to balance the increased demand, but also to make up for the falling off in the supplies from Anglesea. Owing to the want of coal in Cornwall, the ores are not smelted on the spot, but are all sent to Swansea; it being found cheaper to carry the ores to the coal than the contrary. The East Indies and China, France, the United States, and Italy, are the great markets for British copper. Thus, in 1851, of the total quantity exported from Great Britain, amounting to 17,555 tons, 3603 went to the East Indies and China, 3183 to

France; 3085 to the United States; 1396 to Italy; and 2113 to the Hanse towns and Holland.—*Parl. Paper*, No. 462; Session, 1852.

Foreign Copper.—Copper ores are abundant in Sweden, Russia, Japan, Australia, Cuba, Chili, Columbia, etc. Near Fahlun, in the province of Dalecarlia, in Sweden, is the celebrated copper mine of the same name, supposed to have been wrought nearly one thousand years. For a long time it was extremely productive, yielding, toward the beginning of the seventeenth century, an annual produce of about 8,000,000 pounds of pure metal; but it has since greatly declined; and it is most probable that at no distant period it will be wholly abandoned.—THOMSON'S *Travels in Sweden*, p. 221. There are copper mines in other parts of Sweden; but the entire produce of copper in that country does not at present exceed from 750 to 800 tons, of a quality inferior to that of England. The produce of the copper mines of Russia has been estimated at 290,000 pecks or 4661 tons (English) a year.—TEGONORSKI, *Forces Productives de la Russie*, l. 300. The copper mines of Japan are said to be among the richest in the world. The Dutch and Chinese export considerable quantities of their produce, which is spread all over the East, and is regularly quoted in the prices current of Canton, Calcutta, and Singapore. It is uniformly met with in the shape of bars or ingots; and when the copper of South America is worth in the Canton market from \$15 to \$16 per picul, that of Japan is worth from \$18 to \$20 per picul. Copper, the produce of the Persian mines, is imported into Bombay and Calcutta from Bushiro and Bussorah. But, in a commercial point of view, the copper mines of the United States, Cuba, Chili, and Australia are, after those of England, by far the most important. The working of the mines of Cuba, which had been abandoned for a lengthened period, was resumed a few years ago, principally by an English company, which has been eminently successful. Large quantities of Cuba ore are taken to Swansea to be smelted; and large quantities of Chili ore are also taken there for the same purpose. Of the total imports of copper ore in 1851, amounting (including *regulus*) to 42,131 tons, Cuba furnished 20,875 tons; Chili, 8051 tons; and Australia, 7219 tons; the rest being supplied by Spain, Peru, &c. There was a very extraordinary increase in the supplies of copper from Australia during the four or five years preceding the discovery of the gold fields. The produce of the Burra Burra Mine, for example, which in 1846 was 6359½ tons of ore, had swelled in 1850 to 18,692 tons. But since then some of the mines have been abandoned, and the progress of the others checked. Foreign copper imported into Great Britain, and the copper obtained from the smelting of foreign ore, were, previously to 1812, wholly, or almost wholly, re-exported; the duty in Great Britain on the copper ore when it was taken or smelted for home use being so very heavy as to make it be altogether exported in an unwrought state. But in 1812 that duty on copper ores and unwrought copper was very materially reduced; and it was repealed in the course of the year 1853. The presumption, therefore, is, that the imports into Great Britain of ore for smelting will increase, and that considerable quantities of copper derived from foreign ores will be brought into use.

Copper is in extensive demand all over India, being largely used in the dock-yards, in the manufacture of cooking utensils, in alloying spelter and tin, etc. The funeral of every Hindoo brings an accession to the demand, according to his station; the relatives of the deceased giving a brass cup to every Brahmin present at the ceremony: so that five, ten, fifty, one hundred, one thousand, and sometimes more than ten times this last number, are dispensed upon such occasions.—

BELL'S Commerce of Bengal.

A modern, and now a very extensive use of sheet-copper, is for the sheathing of ships. That part of the hull of a ship that is in the water is covered with sheet-copper. This covering preserves the wood from the attacks of the *teredo*, and thereby gives the ship the advantage of passing more rapidly through the water, as the copper bottom remains always smooth; for seaweed and shells will not take root and attach themselves to copper, as they do to bare planks, owing to the galvanic effect produced by the action of sea-water. As this action, however, produces a rapid decay of copper, it was proposed by Sir Humphry Davy to neutralize it by applying metallic protectors—an object which was accomplished; but as this also deprived the copper of its protective effect it was intended to produce, and allowed the molluscous tribes to attach themselves, the protecting process was abandoned.

Copper bolts are used for fastening the planks and the copper sheathing. This is a great improvement in ship-building. A copper-fastened ship or boat is preferable to one with iron fastenings, because the copper bolts remain unaltered by rust, and endure longer than the wood which they hold together, particularly when used in the state of alloy, which preserves it from waste by neutralizing the galvanic action. For the frames of delicate dipping needles and magnetic compasses, copper is employed, as it has been found that the brass generally used in philosophical instruments sometimes contains iron, which of course might affect the magnetic needle. Copper is drawn into wire, used for communication with the bells in houses, and for other purposes. Small pipes for conveying coal-gas from the level of the street to the aperture by which the gas issues were formerly made of copper or of brass, till superseded by tin. These pipes were fitted on an iron cylindrical mandril, and a cylindrical ring drawn over the outside. By this means copper and brass tubes are drawn out. The brass tubes for telescopes are drawn out in the same manner.

Copper may be plated; that is, its surface may be covered with a layer of silver, by rubbing the surface with a mixture of nitrate of silver, muriate of soda, and acidulous tartrate of potass (cream of tartar). But the method practiced at Birmingham is the most permanent and effectual. A plate of copper, with a plate of silver applied to it, and borax placed in the interstice, is heated to a particular degree, which it requires the skill of a workman to know—a degree of heat, in short, near that at which copper and silver melt. The two metals thus heated, and in contact, are then taken out of the furnace and passed through rollers. There is a fusion and combination of the adjacent surfaces; and their adhesion is perfected by the pressure of the rollers. Copper thus plated is manufactured at Birmingham into candlesticks, teapots, buttons, buckles, and a variety of other articles.

Standard silver coins contain a small proportion of copper, for the purpose of giving them hardness. This proportion is regulated by government in the several countries of Europe, and varies in different states. The combination of gold and copper in various proportions is used for making rings and other trinkets. Copper is gilded by applying on its surface an amalgam of gold with mercury. Bronze ornaments are gilded in the same way. Copper united with zinc forms brass; when alloyed with tin it forms bronze. This combination is hard and brittle if the proportion of tin be

great; but when the proportion of tin is small, the bronze is soft, and possesses tenacity so as not to be easily broken. The ancients employed hard bronze, containing much tin, in making sword blades, spear heads, hatchets, and cutting instruments. Bronze cramps are found in ancient buildings in Egypt. Statues and bas-reliefs, culinary vessels, and a variety of other articles of soft bronze, are to be seen in different collections of antiquities. In modern times soft bronze is used for casting cannon and statues.

Copper melted with a large proportion of tin constitutes bell-metal, which is hard and brittle. The metal of which the Chinese gongs are made is composed of the same ingredients; and it has the property of being in some degree malleable at a certain stage of its cooling, for their gongs are covered with marks of the hammer. The most common ore of copper, from which the chief supplies of that metal are derived, is the yellow copper ore, or copper pyrites, essentially a combination of copper with sulphur and iron. There are, however, numerous other ores of copper in which the metal is in combination with oxygen, carbonic acid, various other metals, etc. Copper in its varied artificial combinations, as in that of verdigris (acetate of copper), blue vitriol (sulphate of copper), Scheele's green (arsenite of copper), verditer (carbonate of copper), etc., is largely used in the arts of dyeing, painting, enamelling, glass and porcelain coloring, etc. The salts of copper are poisonous; and from the facility with which copper minerals become oxydized, their use should be as restricted as possible. One or two of the salts of copper are occasionally used in medicine: and the sulphate of copper has been found to be one of the most efficacious emetics in croup, checking the discharges, and preventing the effusion of the fibrinous matter into the trachea. This salt is also used as a lotion in the treatment of ulcers, etc.

American Copper.—Although the copper-mining interest in this country is, as yet, in its infancy, it has already produced results that give promise of its soon standing among the foremost of our mineral products, and of adding greatly to the already diversified resources of wealth and power of our people. Previous to 1810 we were, in common with the rest of the world, entirely dependent upon England for our supply of this useful material.

We are this year, 1856, producing about 5000 tons of it, equal to one-seventeenth of the whole amount required to meet the demand of the world. The copper mines of Cornwall, England, have been worked for centuries, while those of our Lake Superior region have only been opened a few years, and not successfully and systematically worked until within the last five years. The opening of the Sault St. Marie canal, by connecting the navigation of Lake Superior with that of the chain of lower lakes, has given an impetus to the business that will soon make it the great source of supply of copper to our own and foreign countries on account of its great purity and the inexhaustible beds of its ore. Eighteen new stamping mills have been erected the past year, and at least fifty more will be put into operation this year. The total shipments of the Lake Superior copper mines are thus stated:

	Tons.
Ontonagon District.....	2176
Porcupine Lake District.....	21
Keweenaw Point District.....	23
Total.....	2220

The value of the copper on the wharves on Lake Superior equals £110 a ton; total product, \$2,092,200. The increase of the year 1855 over 1854 was about 2000 tons, and it is estimated that in 1856-57, the increase will be 1500 tons over 1855. The government of France has had Mons. Rivot, of the School of Mines in France, examining the Lake Superior copper, in consequence of the supply from Russia being cut off; and the American copper has been tested and found equal, if not su-

perior to the Russian, and far superior to the English. The superior tenacity of the American copper is a strong recommendation.

Copper Busts and Statues.—These consist wholly of copper, in a thin sheet; and the whole of the metal has been reduced or precipitated from a liquid solution. We believe that the first example of this striking production was a bust of the late Dr. Dalton, made by Mr. Choverton about ten years ago; and the practicability being thus demonstrated, the art may be now followed to any extent. The processes are curious. The bust is first modeled in some kind of clay, which may afterward easily be broken away piecemeal; and on this a thick copper film is deposited by the electro process. The clay core or model being broken away, the copper remains as a hollow shell, the inside of which has ta'en the exact impress (though reversed) of the outside of the bust. This copper shell, on being properly prepared on the inner surface, is made the groundwork on which a second deposition takes place; it is used, in fact, as a mould, from which one or more busts may be procured.

Architects and sculptors are gradually availing themselves of this art in the furtherance of their professional labors. The late Bavarian sculptor, Pöglmayer, who was employed by King Ludwig on so many important works at Munich, devised a mode of coating colossal plaster statues with copper, by the electro process, in a remarkably expeditious way. But one of the most important applications of the art is that which is exhibited in the new and splendid cathedral of St. Isaacs, at St. Petersburg, on which the emperor has expended large sums. Certain parts have been ornamented in a remarkable way. The cathedral has seven very large doors, or rather door-ways, three of which are 44 feet wide by 30 high; they are formed of bronze, but all the adornments are produced by the electro process. These adornments are of a most elaborate nature; they comprise no less than 51 bas-reliefs, 63 statues, and 84 alto-relievo busts. It is not simply as a matter of economy that the electro process has been adopted, for the czar is not a man to entertain scruples on such a point; but there are certain advantages of an artistic character. By the electro process the sculptor is sure to have his model faithfully copied; and the lightness of the material enables him to impart bolder relief to his designs than if they were cast in bronze; while this lightness of weight also justifies him in suspending pendants or bosses from vaulting, of a larger size than would be safe if made otherwise.

Copperas, a term employed by the older chemists, and popularly as synonymous with vitriol. There are three sorts of copperas: the *green*, or sulphate of iron; the *blue*, or sulphate of copper; and the *white*, or sulphate of zinc. Of these, the first is the most important. Sulphate of iron is distinguished in common by a variety of names, as Martial vitriol, English vitriol, &c. When pure it is considerably transparent, of a fine bright, though not very deep, grass green color; and of a nauseous, astringent taste, accompanied with a kind of sweetness. Its specific gravity is 1.831. It uniformly reddens the vegetable blues. This salt was well known to the ancients, and is mentioned by Pliny (*Hist. Nat. lib. xxxiv. § 12*) under the names of *misgony*, and *colchicum*. It is not made in the direct way, because it can be obtained at less charge from the decomposition of pyrite, on a large scale in the neighborhood of collieries. It exists in two states, one containing oxyd of iron, with 0.22 of oxygen, which is of a pale green, not altered by gallic acid, and giving a white precipitate with prussiate of potass. The other, in which the iron is combined with 0.30 of oxygen, is red, not crystallizable, and gives a black precipitate with gallic acid, and a blue with prussiate of potass. In the common sulphate, these two are often mixed in various proportions.

Sulphate of iron is of great importance in the arts.

It is a principal ingredient in dyeing; in the manufacture of ink, and of prussian blue; it is also used in tanning, painting, medicine, &c. Sulphuric acid, or oil of vitriol, was formerly manufactured from sulphate of iron.—See ACIDS.

Sulphate of copper, or *blue vitriol*, commonly called Roman or Cyprian vitriol, is of an elegant sapphire blue color, hard, compact and semi-transparent; when perfectly crystallized, of a flatish, rhomboidal, decahedral figure; its taste is extremely nauseous, styptic, and acid; its specific gravity is 2.1943. It is used for various purposes in the arts, and also in medicine.

Sulphate of zinc, or *white vitriol*, is found native in the mines of Goslar and other places. Sometimes it is met with in transparent pieces, but more commonly in white efflorescences. These are dissolved in water, and crystallized into large irregular masses, somewhat resembling fine sugar, having a sweetish, nauseous, styptic taste. Its specific gravity, when crystallized, is 1.912; when in the state in which it commonly occurs in commerce, it is 1.3275. Sulphate of zinc is prepared in the large way from some varieties of the native sulphuret. The ore is roasted, wetted with water, and exposed to the air. The sulphur attracts oxygen, and is converted into sulphuric acid: and the metal, being at the same time oxydized, combines with the acid. After some time the sulphate is extracted by solution in water, and the solution being evaporated to dryness, the mass is run into moulds. Thus, the white vitriol of the shops generally contains a small portion of iron, and often of copper and lead.—Lewis's *Mat. Medica*; *UNE'S Dictionary*; REES' *Cyclopædia*.

Copper Money. The Romans, prior to the reign of Servius Tullius, used rude pieces of copper for money. In England, copper money is of extensive coinage. That proposed by Sir Robert Cotton was brought into use in 1609. Copper was extensively coined in 1665. It was again coined by the crown, 23 Car. II. 1672. Private traders had made them previously to this act. In Ireland, copper was coined as early as 1339; in Scotland in 1406; in France in 1580. Wood's coinage in Ireland commenced in 1723. Penny and two-penny pieces were extensively issued in 1797. The half-farthing was coined in 1843.—See CENT.

Copyright. See BOOKS.

Coracle, a small kind of boat, constructed of wicker, and covered with leather, or with cloth made water-proof with oil or tar. From its extreme lightness it may be transported on the shoulders from place to place. Coracles are common in Wales. A similar kind of boat has been used in the East from remote antiquity.

Coral (Germ. *Korallen*; Du. *Koraalen*; Fr. *Corail*; It. *Corale*; Sp. and Port. *Coral*; Russ. *Koralli*; Lat. *Coralium*; Arab. *Besed*; Pers. *Merjan*; Hind. *Moonyan*), a marine production, of which there are several varieties. It was well known to the ancients, but it was reserved for the moderns to discover its real nature. It is, in fact, the nidus or nest of a certain species of vermes, which has the same relation to coral that a snail has to its shell. As an ornament, black coral is most esteemed; but the red is also very highly prized. Coral is found in very great abundance in the Red Sea, the Persian Gulf, in various places in the Mediterranean, on the coast of Sumatra, &c. It grows on rocks, and on any solid submarine body; and it is necessary to its production that it should remain fixed to its place. It has generally a shrub-like appearance. In the Straits of Messina, where a great deal is fished up, it usually grows to nearly a foot in length, and its thickness is about that of the little finger. It requires eight or ten years to arrive at its greatest size. The depth at which it is obtained is various—from 10 to 100 fathoms or more; but it seems to be necessary to its production that the rays of the sun should readily penetrate to the place of its habitation. Its value depends upon its size, solidity, and the depth and bril-

hancy of its color, and is so very various, that while some of the Sicilian coral sells for eight or ten guineas an ounce, other descriptions of it will not fetch 1s. a pound. It is highly prized by opulent natives in India, as well as by the fair sex throughout Europe. The inferior or worn-eaten coral is used in some parts of the Madras coast, in the celebration of funeral rites. It is also used medicinally. Beside the fishery in the Straits of Messina already alluded to, there are valuable fisheries on the shores of Majorca and Minorca, and on the coast of Provence. A good deal of Mediterranean coral is exported to India, which, however, draws the largest portion of its supplies from the Persian Gulf. The produce of the fishery at Messina is stated by Spallanzani (*Travels in the Two Sicilies*, vol. iv.) to amount to 12 quintals of 250 lbs. each.

The manner of fishing coral is nearly the same everywhere. That which is most commonly practiced in the Mediterranean is as follows: seven or eight men go in a boat, commanded by the proprietor; the caster throws his net, if we may so call the machine which he uses to tear up the coral from the bottom of the sea; and the rest work the boat, and help to draw in the net. This is composed of two beams of wood tied crosswise, with leads fixed to them to sink them; to these beams is fastened a quantity of hemp, twisted loosely round, and intermingled with some loose netting. In this condition the machine is let down into the sea; and when the coral is pretty strongly entwined in the hemp and nets, they draw it up with a rope, which they unwind according to the depth, and which it sometimes requires half a dozen boats to draw. If this rope happens to break, the fishermen run the hazard of being lost. Before the fishers go to sea, they agree for the price of the coral: and the produce of the fishery is divided, at the end of the season, into thirteen parts; of which the proprietor has four, the caster two, and the other six men one each; the thirteenth belongs to the company for payment of boat-hire, etc. See *AINSLIE'S Materia Indica*; *REES'S Cyclopaedia*; *Encyclopaedia Metropolitana*; *BELL'S Commerce of Bengal*, etc.

Cordage (Germ. *Tauwerk*; Du. *Touwerk*; Fr. *Manœuvre, Cordage*; It. *Coilane*; Sp. *Jarcia, Cordaje*), a term used in general for all sorts of cord, whether small, middling, or great, made use of in the rigging of ships. The following table shows how many fathoms, feet, and inches, of a rope of any size, not exceeding 14 inches, make 1 cwt. At the top of the table, marked inches, fathoms, feet, inches, the first column is the circumference of a rope in inches and quarters; the second, the fathoms, feet, and inches that make up 1 cwt. of such a rope. One example will make it plain.

Suppose it is required how much of a 7-inch rope will make 1 cwt.; find 7 in the third column, under inches, or circumference of the rope, and immediately opposite to it you will find 9, 5, 6; which shows that in a rope of 7 inches there will be 9 fathoms 5 feet 6 inches required to make 1 cwt.

—See **CABLE**.

Cordwainers or **Cordiners**, the term by which *shoemakers* are designated in the statutes. The word is formed from the French *cordonnier*, which Ménago derives from *cordouan*, a kind of leather brought from Cordova, and used for the upper leather of shoes. Others derive it from *corde*, rope, because shoes were anciently made of cords; as, indeed, they still are in some parts of Spain, under the name of *alpargates*. But the former etymology is evidently more proper.

Corea, a large peninsula of Asia, formed on one side by the Yellow Sea, and on the other by the Sea of Japan. It is situated immediately to the east of China; and its length may be estimated at 400 miles, by 150 in average breadth. A great part of what was formerly supposed to be its western coast was found by Captains Hall and Maxwell to consist of an immense archipelago of small islands, which have since been subdivided into several groups, and are known as Amherst's Islands, the Corean, and Hall's Archipelago. The largest of these is the Island of Quelpaert, called by the natives *Musa*, in the centre of which there is a mountain peak about 6000 feet above the level of the sea. Though rocky and bare, these groups are for the most part inhabited. The peninsula itself is divided from the Japanese Island of Kjusiu by the Straits of Corea, and by a high mountain range called the Shanalin or Champshan, from the country of the Mantchoos. It embraces an area of about 95,000 miles, with a population of about eight millions. The interior of the country is rugged and mountainous, being intersected by a lofty branch of the northern range, which in turn sends off numerous offshoots to the sea. The principal valleys lie toward the western and southern coasts, and these districts alone enjoy a temperate climate. The eastern coast is bleak and precipitous, while the northern frontier is cold and desolate, and thus subserves the purposes of despotism by cutting off all friendly communication with the main land. The principal products of the country comprise wheat, millet, rice, ginseng, tobacco, silk, cotton, and hemp. The three last are exported both in the raw and manufactured state. Timber and cattle are plentifully supplied from the forests and pasture-grounds, as well as furs from the northern jungles. Its mineral wealth is said to include gold, silver, iron, rock-salt, and coal; and from the tribute sent to the Emperor of China—consisting both of bullion and manufactured articles—the precious metals seem to be wrought to a considerable extent. The Coreans resemble the Japanese and Chinese in dress, habits, and religion, but are said to be as inferior to either of these in mental vigor as they are superior in strength and stature. Their mode of writing is alphabetic, and they are said to possess an extensive literature; but as all ingress into the country is denied to Europeans, and all egress to natives, little is known of these particulars. They keep up considerable commercial intercourse with China and Japan, whence they import pepper, aromatic woods, alum, and goods of Dutch manufacture; but most of the trade is managed by a circuitous overland route, and being discouraged by the government, is carried on with secrecy and at considerable risk. The kingdom of Corea, although tributary to China, is governed at will by its own king—the Chinese emperor doing little more than formally ratifying his decrees. It is divided into eight provinces, and contains, according to Chinese accounts, 161 towns. The capital, King-ti-tao, stands on the river Kiang, a small stream which flows into the Yellow Sea. It is the residence of the king, and contains, among other things, an extensive library. In modern times a few French missionaries have penetrated into the country, but with little success.

Cork (Germ. *Kork*; Du. *Kork, Kurk, Vlothout*; Fr. *Liège*; It. *Sughero, Suvvero*; Sp. *Corcho*; Port. *Cortica (de Suervo)*; Russ. *Korkovos derewo*; Lat. *Suber*), the thick and spongy bark of a species of oak (*Quercus Su-*

ber, Linnaeus) abundant in dry mountainous districts in the south of France, and in Spain, Portugal, Italy, and Barbary. The tree grows to the height of thirty feet or more, has a striking resemblance to the *Quercus ilex*, or evergreen oak, and attains to a great age. After arriving at a certain state of maturity, it periodically sheds its bark; but this valuable product is found to be of a much better quality when it is artificially removed from the tree, which may be effected without any injury to the latter. After a tree has attained to the age of from twenty-six to thirty years, it may be barked; and the operation may be subsequently repeated once every eight or ten years, the quality of the cork improving with the increasing age of the tree. The bark is taken off in July and August; and trees that are regularly stripped are said to live for one hundred and fifty years or more.—FOUR, *Hist. Philosophique des Plantes*, tome vii. 419. Cork is light, porous, readily compressible, and wonderfully elastic. It may be cut into any sort of figure, and notwithstanding its porosity, is nearly impervious to any common liquor. These qualities make it superior to all other substances for stoppers for bottles, in the manufacture of which it is principally made use of. It is also employed as buoys to float nets, in the construction of life-boats, the making of water-proof shoes, and in various other ways. Before being manufactured into stoppers, the cork is charred on each side; this makes it contract, lessens its porosity, and consequently fits it the better for cutting off all communication between the external air and the liquid in the bottle. Spanish black is made of calcined cork. The cork tree, and the uses to which the bark may be applied, were known to the Greeks and Romans. Pliny mentions that the Romans employed it to stop all kinds of vessels; but the use of it for this purpose does not appear to have been common till glass bottles came into general use, which, according to Beckmann, was not till the fifteenth century. Other vegetable productions have been sometimes employed instead of cork; as, for instance, the *spodias lutea*, a tree which grows in South America, particularly in moist places, and which is there called *moulin* or *moulinin*. The roots of liquorice are applied to the same use, and on this account the plant is cultivated in Slavonia, and exported. A tree called *nyssa*, which grows in North America, has been found also to afford a substitute for cork.

Considering it in a politic as well as in an economical sense, reasonable measures should be taken to form in the United States plantations of this tree, sufficient for the future supply of cork, particularly for the increasing demands for that material which are likely to arise from the culture of the vine. As a further argument in showing the importance of fostering this branch of rural economy, it may be stated, that the amount of cork which is yearly imported into the United States, is valued at more than \$281,000.

Cork Jacket, an apparatus to buoy up the body in swimming. It consists of pieces of cork inclosed between two pieces of strong canvas, and is shaped so as to be worn like a jacket, but without arms. It is now almost quite superseded by the air belt made of waterproof cloth. The cork jacket appears to be a very old invention; for Plutarch, in his life of Cælius, mentions that the messenger sent by that general to his fellow-citizens when besieged in the capitol, made use of a cork jacket in swimming across the Tiber, the Gauls being in possession of the bridge.

Cork, a city, parliamentary borough, and river port of Ireland, capital of the county of Cork, and a county of itself, on the Lee, eleven miles above the entrance of Cork Harbor, and 137 miles southwest of Dublin. Area of city, 48,006 acres; of the municipality, 2683 acres. Population of county and city, or barony, 106,955; of municipal borough (1851), 84,114. The city proper is built on an island formed by the Lee. Principal manufactures are of leather, iron, and other

metallic goods, glass, gloves, and paper, and there are some extensive breweries and distilleries; the woolen and cotton manufactures, formerly extensive, are now all but extinct. The trade is extensive, the exports consist of corn, flour, butter, and other Irish produce; imports consist chiefly of manufactured goods from England; wines, fruits, and salt from Portugal and the Mediterranean; timber from the Baltic and North America. Cork communicates by steam-packets with London, Dublin, Bristol, Liverpool, and Glasgow. *Cork Harbor* is a fine land-locked basin, formed by the estuary of the Lee, which is navigable to 14 miles above Cork city. It is large and deep enough to contain the whole British navy, and has an entrance one mile across, within which its breadth varies to eight miles. It contains Spike and Haulbowline Islands, on which are artillery barracks and various ordnance works. Lat. 51° 50' 4" N., long. 8° 19' W. On its shores are the towns of Cove and Passage, with quays four miles in length, and which were erected at a cost of £100,000.

Corn (Saxon *Corn*), the grain or seeds of plants separated from the spike or ear, and used for making bread. According to the European interpretation there are several species of corn, such as wheat, rye, and barley, millet and rice, oats, maize, and lentils, peas, and a number of other kinds, each of which has its peculiar qualities and usefulness. Egypt was anciently the most fertile of all countries in corn. This appears both from sacred and profane history. It supplied a considerable part of the people subject to the Roman empire, and was called the *dry nurse of Rome and Italy*. Ceres has the credit of being the first who taught them the use of corn, on which account she was ranked by them as a deity. Some, however, attributed the honor to Triptolemus; while others award the honor to both alike, making Ceres the first discoverer, and Triptolemus the first planter and cultivator of corn. Diodorus Siculus ascribes the whole to Isis; in which, as Polydore Virgil observes, he does not differ from other authors—Isis and Ceres being in reality the same person. The Athenians pretended that it was among them the art of sowing corn took its rise; and the Cretans or Candiots, Sicilians, and Egyptians, also lay claim to the distinction. Some think the title of the Sicilians best supported, Sicily being the country of Ceres; and it is alleged that she did not teach the secret to the Athenians till she had first instructed her own compatriots. Others say that Ceres passed first into Attica, thence into Crete, and last of all into Sicily. Many scholars, however, maintain that it was in Egypt the art of cultivating corn first began; and it is certain that there was corn in Egypt and the East long before the time of Ceres.—E. B.

Maize, or Indian Corn.—Among the objects of culture in the United States, maize, or Indian corn, takes precedence in the scale of crops, as it is best adapted to the soil and climate, and furnishes the largest amount of nutritive food. Where due regard is paid to the selection of varieties, and cultivated in a proper soil, it may be accounted as a sure crop in almost every portion of the habitable globe between the 44th degree of north latitude and a corresponding parallel south. Besides its production in this country, its principal culture is limited to Mexico, the West Indies, most of the states of South America, France, Spain, Portugal, Lombardy, and southern and central Europe generally. It is also cultivated with success in northern, southern, and western Africa, India, China, Japan, Australia, and the Sandwich Islands, the groups of the Azores, the Madras, the Canaries, and numerous other oceanic isles.

Although there has been much written on the Eastern origin of this grain, it did not grow in that part of Asia watered by the Indus at the time of Alexander the Great's expedition, as it is not among the productions of that country mentioned by Nearchus, the commander of the fleet. Neither is it noticed by Arrian,

Diodorus, Columella, nor any other ancient author. And even as late as 1491, the year before Columbus discovered America, Joan di Cuba, in his "Ortus Sanitatis," makes no mention of it. It has never been found in any ancient tumulus, sarcophagus, or pyramid; nor has it ever been represented in any ancient painting, sculpture, or work of art, except in America. But in this country, according to Gardilaso de la Vega, one of the earliest Peruvian historians, the palace gardens of the Incas were ornamented with maize in gold and silver, with all the grains, spikes, stalks, and leaves; and in one instance, in the "Garden of Gold and Silver," there was an entire corn-field of considerable size, representing the maize in its exact and natural shape, a proof no less of the wealth of the Incas, than of their veneration for this important grain.

In further proof of the American origin of this plant, it may be stated that it is still found growing in a wild state, from the Rocky Mountains, in North America, to the humid forest of Paraguay, where, instead of having each grain naked, as is always the case after long cultivation, it is completely covered with glumes or husks. It is, moreover, a well-authenticated fact, that maize was found in a state of cultivation by the aborigines on the island of Cuba at the time of its discovery by Columbus, as well as in most other places in America first explored by Europeans.

The first successful attempt of the English in North America to cultivate this grain was made on James River, in Virginia, in 1608. The colonists sent over by the "London Company" adopted the mode then practiced by the Indians, which, with some modifications, has been pursued ever since. The yield at that time is represented to have been from two hundred to more than a thousand fold. The same increase was noticed by the early settlers in Illinois. The present yield, east of the Rocky Mountains, when judiciously cultivated, varies from twenty to one hundred and thirty-five bushels to an acre.

The varieties of Indian corn are very numerous, exhibiting many grades of size, color, and conformation. Among these are, the shrubby red that grows on the shores of Lake Superior; the gigantic stalks of the Ohio Valley; the tiny ears, with flat, close-clinging grains, of Canada; the brilliant, rounded little pearl; the bright-red grains and white cob of the eight-rowed hematite; and the awelling ear of the big white; and the yellow gourd-seed of the South.

From the flexibility of this plant, it may be acclimated, by gradual cultivation, from Texas to Maine, or from Canada to Brazil; but, in either case, its character is somewhat changed, and often new varieties are the results. The blades of the plant are of great value as food for stock, and form an article but rarely estimated sufficiently, when considering the agricultural products of the southern and south-western states especially.

The increase of production from 1840 to 1850 was 214,000,000 bushels, equal to 66 per cent. The production of New England has advanced from 6,993,000 to 10,377,000 bushels, showing an increase of 3,384,000 bushels—nearly 50 per cent. New York, New Jersey, Pennsylvania, Delaware, and Maryland increased 20,812,000 bushels—more than 50 per cent. In the production of this crop no state has retrograded. Ohio, which in 1840 occupied the fourth place as a corn-producing state, now ranks as the first; Kentucky, second; Illinois, third; Tennessee, fourth. The crop of Illinois has increased from 22,000,000 to 57,500,000 bushels, or at the rate of 60 per cent. in ten years.

Of the numerous varieties, some are best adapted to the southern states, while others are better suited for the northern and eastern. Those generally cultivated in the former are the Southern big and small yellow, the Southern big and small white-flint, the yellow Peruvian, and the Virginia white gourd-seed. In the more northerly and easterly states, they cultivate the

golden Sioux, or Northern yellow-flint, the King Philip, or eight-rowed yellow, the Canada early white, the Tuscarora, the white flour, and the Rhode Island white-flint flour.

The extended cultivation of this grain is chiefly confined to the eastern, middle, and western states, though much more successfully grown in the latter. The amount exported from South Carolina in 1748 was 39,908 bushels; from North Carolina, in 1753, 61,680 bushels; from Virginia, for several years preceding the Revolution, annually, 600,000 bushels; from Philadelphia, in 1762, 90,740 bushels; in 1767-'68, 60,205 bushels; in 1771, 259,441 bushels.

The total amount exported from this country in 1770 was 578,949 bushels; in 1791, 2,064,936 bushels, 851,695 of which were Indian meal; in 1800, 2,032,435 bushels, 338,108 of which were in meal; in 1810, 1,140,960 bushels, 80,744 of which were in meal. In 1820-'21, there were exported 607,277 bushels of corn and 181,669 barrels of Indian meal; in 1830-'31, 571,312 bushels of corn and 207,604 barrels of meal; in 1840-'41, 535,727 bushels of corn and 232,284 barrels of meal; in 1845-'46, 1,286,068 bushels of corn and 208,790 barrels of meal; in 1846-'47, 16,326,050 bushels of corn and 948,060 barrels of meal; in 1850-'51, 3,426,811 bushels of corn and 208,622 barrels of meal. More than 11,000,000 bushels of Indian corn were consumed in 1850 in the manufacture of malt and spirituous liquors.

According to the census of 1840, the corn crop of the United States was 377,531,875 bushels; of 1850, 592,326,512 bushels.

Corn Laws. An adequate supply of breadstuffs is evidently of the very first importance to every country, and should be as regular as is possible, since sudden fluctuations in an article of such universal necessity are injurious, and scarcity, with the consequent high prices, brings distress upon the poorer classes, and is a fruitful cause of discontent and convulsions. The best means of securing a sufficient and steady supply of this article is a subject of some diversity of opinion, and the practice of governments has varied much at different times. One theory, urged by Adam Smith, but questioned by Mr. Malthus and most others, is, that the government should do absolutely nothing in the matter, on the ground that the farmers and corn

merchants, if unchecked, will always form correct views of their own interest, and that their interest will coincide with that of the rest of the community. But broad, sweeping theories of this sort are rarely adopted in the practical administration of affairs; and a government, in making regulations on this subject, as on every other, looks at its internal condition, the character and pursuits of its population, and its foreign commercial relations; and though it may not judge correctly of the best means of securing a steady and sufficient supply, this does not prove that a total neglect of the subject would be the wisest and the safest policy in all countries and at all times. It is certain, however, that very unwise measures have often been resorted to, and sometimes such as tended rather to aggravate the evil than to provide a remedy. One way to guard against a scarcity is that adopted by the king of Egypt in the time of Joseph—the purchasing of corn by the government in time of plenty at home, or importing it from abroad, and storing it in public magazines, to be distributed as the public wants may demand. But this system is attended with great expense, and affords but an uncertain and inadequate provision. Most governments, accordingly, instead of making direct purchases, attempt to provide a remedy by the passage of laws. This subject of grain legislation is by no means entirely modern. The Athenians had laws prohibiting the exportation of corn, and requiring merchants who loaded their vessels with it in foreign ports to bring their cargoes to Athens. The public provision and distribution of corn was an important branch of administration at Rome, and very intimately connected with the public tranquillity. The regulation in the supply of corn, and the trade in the article, has been a fruitful subject of legislation in modern Europe. But it is to be observed, that the public solicitude and current of legislation take this direction only in populous countries, or at least those in which the population presses hard upon the means of domestic production of breadstuffs; for a country of which, like this, the staple exports are breadstuffs needs to take no measures for securing a supply; and, as flour and Indian meal are great articles of exportation in the United States, this country has had no occasion for laws to guard against a famine, since the ordinary course of industry and trade gives the greatest possible security, by producing a surplus in provisions, which a high price at home, in anticipation of any scarcity, will be sure to retain for the supply of domestic wants. In agricultural countries the object of solicitude is to supply the want of arts and manufactures, as in populous and highly improved countries it is to supply the want of food. But the laws directed to this object have been very various, and some of them contradictory; for as in Athens, so in England at one period, the laws prohibited the exportation of corn; whereas, at another period, and for a very long one in the latter country, a bounty was given on the exportation; and both these laws had the same object, viz., the adequate and steady supply of the article. For this purpose the bounty is the measure undoubtedly calculated to produce the effect intended, and the permanent prohibition of exportation must aggravate the scarcity which it is intended to prevent. Such a bounty tends to stimulate a surplus production, and so to give a country, by this factitious encouragement, the same security in respect to a supply as results from the spontaneous intercourse of industry and trade in Poland, the southern part of Russia, and the United States. But the objection to the bounty is its great expense, requiring, as it does, the imposition of a tax, and, at the same time, raising the price of the article to the domestic consumer. To secure the advantages and avoid some of the burdens of this law, Mr. Burke, in 1773, proposed the system of corn laws so long adhered to in Great Britain, according to which no bounty is paid, but the exportation of corn is permitted when it is sold under a certain

price in the home market. This price is determined by the average sales in certain specified places for a given time; and when it rises above a certain other fixed price, the importation is permitted. By Mr. Burke's bill, wheat might be exported when the price was under 4s. the quarter, and imported when it was over 48s. The home grower is, therefore, sure to be free from a foreign competition at any price under 48s., and this gives him confidence in pursuing this species of cultivation. The rates or prices at which exportation and importation have since been allowed, have varied from time to time very materially; but the principles of the laws and their effect are the same.—E. A.

Reform of the Corn Laws of England.—In 1843, a measure was adopted which made a wide breach in the corn laws. In 1842 the Legislature of Canada passed a law imposing a duty of 3s. a quarter on all wheat imported into the province, unless from the United Kingdom, stating, in the preamble to this act, that it was passed in the expectation and belief that a corresponding reduction would be made in the duties on wheat and wheat flour imported into the United Kingdom from Canada. And conformably to this anticipation, the act 6 & 7 Vict. c. 29, passed in 1843, reduced the duty on wheat imported from Canada to 1s. a quarter, and proportionately on wheat flour. This act met with much opposition from a part of the agricultural interest in England, who contended that it would lead to the introduction of unlimited supplies of corn from the United States, at a duty of only 4s. a quarter, or, allowing for smuggling, at perhaps only half that amount. But experience showed that these anticipations were not likely to be realized; for, though the imports from Canada were materially increased, the obstacles in the way of the importation of corn from the United States into Canada, and the danger and expense of the voyage from Montreal or Quebec to England, must necessarily have prevented the importation through this channel from ever becoming of much importance. Still, however, the measure was in so far an abandonment of the corn laws; and if Great Britain was justified in admitting the produce of the United States to her markets in this indirect way, it was not easy to discover satisfactory grounds on which to exclude the produce of other countries.

The success of the measures adopted in 1842 encouraged Sir Robert Peel to attempt still more considerable changes in 1845, when he abolished the customs' duties on about 420 articles, some of which were of very considerable importance. The measures then adopted were equivalent, in fact, to the virtual abandonment of the protective system; and, under such circumstances, it could not be expected that the corn laws, on which so serious an inroad had been made by the Canada act, would be able to maintain their place on the statute-book for any very lengthened period.

They might, however, have been continued for some time longer, had not the unsatisfactory corn harvest, and the failure of the potato crop of 1845, made it necessary to adopt measures for averting the anticipated deficiency in the supplies of food. Under the critical circumstances in which the population was then believed to be placed, the temporary suspension of the corn laws could hardly have been avoided; but, if once suspended, their re-enactment would have been all but impossible, and it was better, perhaps, by at once providing for their repeal, to make an end of the system, and of the dissatisfaction and agitation to which it had given birth, than to endeavor to continue it in any modified shape. Such was the view of the matter taken by Sir Robert Peel; and he fortunately succeeded, despite difficulties that none else could have overcome, in carrying the act 9 & 10 Vict. c. 22, for the immediate modification of the corn laws, and for their total repeal at the end of three years, or on the 1st February, 1849. From that date wheat and other corn were sub-

jected, on importation into Great Britain, to a fixed duty of *s.* a quarter; and flour and meal, of all sorts, to a fixed duty of 4*d.* a cwt.—E. B.

Cornucopia (Lat. *cornu*, a horn; and *copia*, plenty). In the fine arts, an ornament representing a horn, from which issues flowers, fruits, leaves, and the like. The origin of the cornucopia has been variously given. Some authors have traced it to the infant days of Jupiter, whose nurse, Amalthea, when one of her goats had broken off a horn against a tree, presented it to the god wreathed with flowers and filled with fruit. Hence it became the emblem of Plenty among the ancients, in which light it is regarded also by many modern nations. The cornucopia is found in the types of ancient coins, particularly upon those of Sicily.

Corporation is the term generally applied to a body of men by special law endowed with the power and means of acting collectively, with the distinctness and individuality of one man pursuing the dictates of his own will, while their existence is kept up by a perpetual succession, so that the collective body acts like an individual man with a perpetuated vitality. Though the corporation might be deemed, from the admiration bestowed on it by professional writers, to be the peculiar creation of English genius, there is little doubt that the system was derived from the *municipia*, *universitates*, and *collegia* of the Romans; and there is even reason to believe that there are corporations which date their history back to the institutions of the Western Empire. The adage, indeed, expressed by a Roman jurist—*tres faciunt collegium* (50 *Dig.* 16, 85)—shows a practical consciousness of the most effective means of strengthening the action of a small corporation, in an adjustment by which equal numbers with the chances of balanced divisions are to be avoided, and that number is selected which always affords a majority of two to one.—E. B. Corporations are stated by Livy to have been of very high antiquity among the Romans. They were introduced into other countries from Italy. These political bodies were first planned by Numa, in order to break the force of the two rival factions of Sabines and Romans, by instituting separate societies of every manual trade and profession.—PLUTARCH.

Corsair (It. *corsaro*). A term used in the south of Europe and some other parts for a pirate or his ship. The corsairs of Barbary were commissioned by their princes to attack the merchant ships of hostile countries.

Corvette, a sloop of war; according to some authorities, an advice-boat with fewer than twenty guns.

Cosmetic (*κοσμητικόν*, to adorn), any preparation to render the skin soft and white, or to beautify and improve the complexion. The word *cosmetic* among the Romans was used to denote a class of slaves whose business it was to dress and adorn their mistresses.—E. B. Preparations for improving beauty were known to the ancients, and some authorities refer them even to mythology, and others to the Grecian stage. The Roman ladies painted; and those of Italy excelled in heightening their charms artificially, by juices and colors, and by perfumes. Rouge has always been in disrepute among the virtuous and well-ordered women of England, though some simple cosmetics are regarded as innocent, and are in general use.—ASHLE. The females of France and Germany paint more highly than most other nations.—RICHARDSON. In Great Britain a stamp was laid on cosmetics, perfumery, and such medicines as really or suppositiously beautify the skin or perfume the person, and the vendors were obliged to take out licenses, 26 *Geo.* III. 1786.—HAYDN.

Costa Rica, a republic of Central America, bounded on the north by Nicaragua, from which it is separated on the northeast by the river San Juan, on the east and north by the Caribbean Sea, on the east by New Granada, from which it is separated by the river Chiriqué entering the Caribbean Sea, and the Chiriquí entering the Pacific, and on the south and west by the

Pacific; between lat. 8° and 11° N., and long. 81° 45' and 84° 40' W. Area, about 16,300 square miles. It is divided into six districts, viz.: San José, Cartago, Heredia, Alajuela, Guanacacote, and Punta Arenas, and estimated to contain 215,000 inhabitants, of whom 2500 are Indians. It is intersected diagonally by the primary range of the Isthmus, which throws off numerous spurs on either side, giving to the surface a continued alternation of abrupt heights and sudden depressions. The principal range has several lofty eminences, and also several volcanoes, both active and dormant, including those of Orosi, Votos, and Cartago; from the summit of the last of which both the Pacific and the Atlantic waters are distinctly visible. Costa Rica contains some exceedingly rich gold mines; hence the origin of its name. The mines, however, are now very little wrought. Silver and copper also exist. With the exception of the sea-coasts, the climate is mild and temperate, never subject to excessive heats or colds, and rarely experiencing any other vicissitudes than those from the dry to the rainy season. It is therefore extremely well adapted to agricultural purposes, and capable of bringing to maturity most of the plants peculiar to the tropics, and many exotics. The soil is remarkably fertile, especially the valleys and the tablelands. The productions are coffee, cacao, Indian corn, tobacco, sugar, and some wheat. The horses of Costa Rica are of an inferior description, but the mules are much esteemed; and cattle, sheep, goats, and hogs are reared in great numbers, and of excellent quality.

Among the principal rivers of Costa Rica are the Tempisque and Grande, falling into the Bay of Nicoya; the Ueus or Macho, which afterward takes the name of Reventason, and falls into the Caribbean Sea; the Matina, formed by the rivers Chirripo and Bahilla; the Escudo de Veragua, dividing Central from South America; the Banana, Tiribee, and Culabra, all falling into the Caribbean Sea; the Chirico Molu or Chiriquí, falling into the Bay of Chiriquí; the Costa Rica or San Carlos, and the Sarapiquí, into the San Juan. The *Baja* is a canal, believed by some to be natural, and by others to have been cut by the aborigines, commencing at the port of Molu or Salt Creek, and running parallel to the coast as far as Pearl Key Lagoon, a distance of 180 miles.

Costa Rica produces, in large quantities, mahogany, cedar, Brazil, and various other kinds of timber. On the sea-coast of Nicoya some pearls and large quantities of mother-of-pearl shells are found. Coffee, however, forms the most important product of the republic. Its cultivation, though only introduced about the year 1830, has increased so rapidly, that 3000 to 4000 tons are now exported annually. Tobacco, which is of excellent quality, is a government monopoly, and is exported in small quantities. The other exports are gold, sugar, Brazil wood, mother-of-pearl, ox and cow hides, horns, etc. The imports consist chiefly of manufactured goods. Total revenue in 1852, \$161,119; expenditure in the same year, \$415,207.

The commercial relations between the United States and Costa Rica are regulated by the treaty of July 10, 1851, and by the local legislation of the country. The treaty guarantees reciprocal freedom of commerce, and places the two countries, with respect to each other, on the footing of the most favored nations.

The local commercial legislation of Costa Rica is completely remodeled and materially modified in the year 1854. The decree by which this was effected bears date August 31, 1854.

The 1st article grants liberty of commerce to the vessels of all nations—specifying certain descriptions of merchandise monopolized by the government, and others prohibited; which are detailed in the tariff of Costa Rica.

The 2d article provides that, at the minor ports, the export of productions of the country only can be permitted, under proper regulations.

Art. 3. At the inland or frontier ports, custom-houses shall be established, under such regulations as the government may deem fit to adopt.

Art. 4. At such ports, inland and export commerce only shall be allowed, except in respect of such merchandise as shall be monopolized by the government or prohibited.

The second chapter of the law contains a specification of free goods, together with a list of prohibited articles; among the former being the personal effects of, or merchandise exported for the use of, diplomatic agents or their suite, but not those of consuls; and in the latter are included rum, fire-arms, and munitions of war, which can be imported only under special authority. The monopolized articles are tobacco (in leaf or manufactured), powder, and saltpetre; which can be admitted only on government account.

This law extends to sixteen chapters; and such parts as apply to navigation and commerce would be translated and inserted at length, were it not understood to have been materially modified by a recent decree, of which a summary is given, with the tariff of Costa Rica.

The United States consul at San José (Costa Rica) communicates the following changes, under date October 8, 1855:

"I have the honor to inclose herewith copies of three decrees issued by this government, numbered, respectively, 1, 2, and 3. No. 1, dated November 24, 1854, is merely prolonging the time fixed for the new tariff (a copy of which has been transmitted), to take effect from the 1st of December, 1854, to the 1st of July, 1855. No. 2, of the same date, requires, article 1st, previous to the landing of merchandise, in addition to the manifest heretofore presented by the master of any vessel arriving at the port of Punta Arenas, that permission to disembark be obtained from the collector of customs, and that in the document soliciting this permission must be expressed the quality, origin of the goods intended to be landed, and also their market value in the port. Article 2 requires, previous to the clearance of a vessel from any port of the republic, the presentation by the consignee of a manifest of the merchandise to be exported, and its value in the

port of shipment. Article 3, of the same, requires, in cases where a part only of a cargo has been landed, that the consignee, previous to a clearance, present another 'corrected manifest,' specifying the quality and value of the goods that have been landed. No. 3, dated July 24, 1855, orders that all distilled spirits landed in the port of Punta Arenas be deposited in the public stores, and exacts the payment of four cents per pound, gross weight, upon their removal from bond. No further changes have been made in the commercial system of this republic within the time specified."

For the last fifteen years the country has been rapidly progressing, owing to the peaceable and industrious character of the people, and the moderate course pursued by the government. Many internal improvements, principally in common roads, have been completed; and the productions of the country have increased so that the exports now amount to \$1,000,000 yearly, while fifteen years ago they amounted only to about \$100,000. In the same time the population has been doubled, and may now (1855) be estimated at 180,000 inhabitants. Some few emigrants, principally Germans, have gone into the country; but the difficulties met with on the route to Costa Rica will prevent much immigration. The two principal ports of Costa Rica are Punta Arenas, on the Gulf of Nicoya, and Matina, on the Caribbean Sea.

Money.—The money of account is the peso, or dollar, valued at the same as the United States dollar; but some are coined of base metal, which are worth only 75 cents. At Venezuela and Ecuador, the dollars are similar to those of New Granada. 1 dollar = 8 reales (100 cents); 1 real = 16 quartos = 32 maravedi, also 12 grani.—*Cor. P. J. of T.*

The values of imports and exports between the United States and Costa Rica can not be distinguished from those given for Central America generally. The following statement, exhibiting the general foreign navigation and trade of the principal port of the republic (Punta Arenas), furnishes a fair average annual statement. It may be observed, that the values are given from ships' registers, or invoices, and are, consequently, considerably below the market values.

STATEMENT EXHIBITING THE GENERAL FOREIGN NAVIGATION AND TRADE OF THE PORT OF PUNTA ARENAS, DURING THE YEAR ENDING DECEMBER 31, 1855.

Costume. Accounts of magnificent attire refer to very remote antiquity. The costume of the Grecian and Roman ladies was comely and graceful. The women of Cos, whose country was famous for the silk-worm, wore a manufacture of cotton and silk of so beautiful and delicate a texture, and their garments, which were always white, were so clear and thin that their bodies could be seen through them.—Ovid. As relates to costume worn on the stage, *Æschylus* the Athenian was, it is said, the first who erected a regular stage for his actors, and ordered their dresses to be suited to their characters, about 436 B. C.—*Parian Marble*. Excess in dress was restrained by a law in England, in the reign of Edward IV., 1465. And again in the reign of Elizabeth, 1574.—*Stow*. Sir Walter Raleigh, we are told, wore a white satin-pinked vest, close-sleeved to the wrist, and over the body a brown doublet finely flowered, and embroidered with pearls. In the feather of his hat, a large ruby and pearl drop

at the bottom of the sprig, in place of a button. His breeches, with his stockings and ribbon garters, fringed at the end, all white; and buff shoes, which on great court days, were so gorgeously covered with precious stones as to have exceeded the value of £6000; and he had a suit of armor of solid silver, with sword and belt blazing with diamonds, rubies, and pearls. King James's favorite, the duke of Buckingham, could afford to have his diamonds tacked so loosely on, that when he chose to shake a few off on the ground, he obtained all the fame he desired from the pickers-up, who were generally *les dames de la Cour*.—*HAYDN*.

Cott, or Cot, a particular sort of bed-frame, suspended from the beams of a ship, between decks, for the officers to sleep in. It consists of a large piece of canvas sewed into the form of a chest, about six feet long, one foot deep, and three feet wide, and is extended by a square wooden frame with a canvas bottom, and used principally in the ward-room of a man-of-war.

Cotton. This article will be considered under the general heads of I. Species and Places of Production. II. Cotton Climate: 1. Of the World; 2. Of the United States; 3. Nile; 4. Algeria; 5. Africa; 6. The Mediterranean; 7. British India. III. Cotton Trade of the United States: 1. History; 2. Statistics. IV. Cotton Trade of the United States with 1. Great Britain; 2. France; 3. Spain; 4. Haïssa Towns; 5. Belgium; 6. Sardinia; 7. Switzerland; 8. Russia; 9. Sweden; 10. Portugal; 11. Brazil; 12. Egypt; 13. Mexico. V. Capacity of the Cotton Bale.

COTTON MANUFACTURES will be treated under its proper head.

I. SPECIES AND PLACES OF PRODUCTION OF COTTON.—Cotton (*Gossypium*) is a vegetable down of exquisite softness, with beautifully fine fibres, and is an indigenous product of all intertropical regions. Linnaeus subdivided the cotton plant into five species: 1. *Gossypium herbaceum*; 2. *G. arboreum*; 3. *G. hirsutum*; 4. *G. religiosum*; 5. *G. Barbadosense*.

Other authorities have enumerated as many as ten species, but for all practical purposes the division into three classes will be sufficiently minute. The varieties are exceedingly numerous; yet of those most widely diffused, *herbaceous cotton*, *shrub cotton*, and *tree cotton* need only be especially referred to. The most useful cotton is the herbaceous, which is an annual plant, chiefly cultivated in the United States and in the East Indies. It grows from two to five feet in height, is rich in foliage, and its fibrous fruit is preceded by flowers of white or pale yellow color, like those of the convolvulus. As the flowers fade, a pod, or capsule is formed of the size of a small walnut, containing the fibres of cotton, and as the pod ripens it expands, and the snow-white fibres burst forth ready to be gathered.

1. *This Herbaceous Cotton.*—This plant grows to the height of eighteen to twenty-four inches, with leaves of dark green, blue-veined, and five-lobed. The flower is a pale yellow, one pistil, five petals or leaves, purple-spotted at the bottom. On the falling of the flower a pod of triangular shape and triple shell is developed. The pod, in course of ripening, bursts, discloses a snow-white or yellowish ball of down, in three locks, inclosing and tightly-adhering to the seeds, which resemble those of the grape, though of several times the size. The seed is planted in spring, and the cotton gathered at fall. The rows in the fields are five or six feet apart; the distance of the holes, in which several seeds are deposited, is about eighteen inches. Much care in weeding, thinning, and pruning, is required during the process of culture. This is the course pursued in the United States, which has the advantage over that pursued in India, by producing a cotton vastly more valuable. A field of cotton at the gathering, says Mr. Haines, when the globes of snowy wool are seen among the glossy dark leaves, is singularly beautiful; and in the hottest countries, where the yellow blossom or flower and the ripened fruit are seen at the same time, the beauty of the plantation is, of course, still more remarkable. The herbaceous cotton is grown to the greatest extent, and said to be cultivated in nearly every country congenial to the gossypium, existing even at Aleppo, in Upper Egypt, Arabia, and Senegal.

2. *The Hirsutum, or Shrub Cotton.*—It is said to grow wherever the herbaceous is found, and to vary according to climate, being biennial or triennial in the West Indies, lasting from six to ten years in India and Egypt, perennial in the hottest climates, and in the mildest cotton regions an annual. The shrub cotton is likened to a currant bush, and is of several varieties. The *hirsutum*, a low shrub already mentioned, the *Indicum*, attaining ten or twelve feet; the *vilfidium*, of the south of France and South America; the *religiosum*, of Surinam and India; the *lucifidum* of the West Indies; the *Barbadosense* of Barbadoes; and the *Persicum*. The pod of the shrub cotton differs from that of the herb in being egg-shaped. The Guiana and Brazil cotton is of

this kind, and is said to yield, in the hottest countries, two crops a year.

3. *The Arborecent, or Tree Cotton.*—This remarkable plant is of Indian, Chinese, Egyptian, and American growth. The height of the tree varies from fifteen to twenty feet. Marco Polo describes the tree at Guzerat six yards high, and bearing fruit for twenty years. There is a tree described in South America, Indian Isles, West Indies, and on the Guinea coast, of a hundred feet high, bearing a silky cotton, only useful for making quilting and beds. The justly-celebrated *American sea-island cotton* is derived from the *arboreum*. Its fibre is long, strong, silky, and of a yellowish tinge. The seed is black and of Persian origin, though originally introduced into this country from the Bahama Islands, where it had been introduced by the Board of Trade from Anguilla, an island of the Caribbean Sea. This cotton was raised first in Georgia in 1786, and the first bag exported by Alexander Bissel, of St. Simon's Island, two years after. The section of country capable of producing this staple is very limited, being confined to the low sandy islands along the coast of South Carolina and Georgia, from Charleston to Savannah. The quantity grown in 1806 and in 1832 was precisely the same.

In the United States the seed of the herbaceous cotton is sown generally in the months of March and April, and its marketable fruit is usually gathered in the period commencing with August and terminating with the year. Bowed and Orleans cottons constitute the great productions of the United States, and are recognized in the English and European markets as "American cotton." These cottons are chiefly cultivated in the great valley of the Mississippi, the fields of its growth now extending to Texas. The cultivation of cotton in the United States is most scientifically and industriously pursued, and is attended with highly profitable results, the value of the crop being little less than \$150,000,000. It is expected that in 1856 the entire crop will amount to 3½ millions of bags, of more than 400 lbs. each. But the skill of the American planter has been most conspicuous in the production of fine sea-island cotton. The seed of this cotton, which is also an annual and herbaceous plant, was obtained in 1780, in the Bahama Islands, where it had been introduced from the West Indies, and was first cultivated in Georgia. The small islands which extend along the American coast from Charleston to Savannah were found, from their sandy soil and contiguity to the sea, to be admirably adapted to the production of exquisitely fine, long, and strong-stapled cotton. This cotton soon acquired great and deserved celebrity. A great demand arose for it; but from the limited extent of the islands upon which it can be grown, and the expense attending its cultivation, it can only be supplied at a comparatively high price. Hence the production of this cotton was not susceptible of indefinite extension like the shorter-stapled cottons of the United States; and from the beginning to the middle of the present century the total yearly amount of the crop has not greatly varied, the annual yield averaging about ten millions of pounds weight. From the circumstance of the seed of this cotton having been first introduced into Georgia, it was consequently called Georgia cotton, though its cultivation had only been successful upon the sea-coast of that state. Its celebrity, however, caused it to be planted upon the high lands of Georgia, where it was found to degenerate; but still the quality, though shortened in staple, was found to be of a desirable class, and it acquired the name of uplands, or bowed Georgia cotton, while the same seed yielded the famed sea-island cotton. Here it may be observed that a humid atmosphere and a sandy soil seem most conducive to the production of good useful cotton; but for the growth of very fine and long stapled cotton an impregnation of salt, both in the soil and in the air, appears to be indispensable.

Without the energy of the American planter, it is difficult to conceive the possibility of the cotton trade of England and of the world attaining the extent and importance which it now possesses. As the colonies of Great Britain—the West Indies in particular—possessed all the natural advantages of soil and climate for producing cotton to an extent much beyond the probable consumption of the United Kingdom, it might reasonably have been inferred that the colonial interests alone would have stimulated the cultivation and production of cotton to supply the certain and increasing home demands of the constantly-enlarging manufactures. Whether the fatality of protection to the English colonies, maladministration of colonial affairs, or supineness on the part of the colonists themselves, produced the indifference which caused an article of increasing importance like cotton to be neglected among remunerative markets were opening for indefinite supplies of it, may be wisely inquired into, not to remedy the past, but for the purpose of ascertaining how far a new and profitable direction may be given for the future to colonial labors and efforts; for the stigma will remain, that while arts and inventions were being developed at home, which became the sources of great national wealth, the cultivation of the material on which to exercise the skill and labor of her working-classes had to be sought and obtained from a foreign source.

In the British East Indies the cultivation and manufacture of cotton have certainly existed longer than in any other country. For five centuries before the Christian era, cotton was largely used in the domestic manufactures of India, and the clothing of the Hindoos then consisted chiefly of garments made from that vegetable product. Earliest in possession of the herbaceous cotton plant, the natives of India were enabled to manipulate its fibres, and to establish a cotton-manufacturing industry which has remained almost unchanged to the present time. More than two thousand years before Europe or England conceived the idea of applying modern industry to the manufacture of cotton, India had matured a system of hand-spinning, weaving, and dyeing, which, during that vast period of time, received no recorded improvement. With a plant indigenous to the soil, and a people remarkable for intelligence when Europe was in a state of barbarism, it is wonderful that no approximation was made to the mechanical manufacturing operations of modern times, and still more strange that the agricultural production of cotton should not within that period have been improved and considerably enlarged. The cotton of India, during its known existence, can only be regarded as a material for manufacture greatly inferior to the like productions of other countries. India unquestionably possesses soil, climate, and all the requisite elements from nature for the cultivation of cotton to an almost boundless extent, and of a quality which might be most useful and acceptable in the manufactures of Europe, and even of America. During a series of years the weight of cotton grown in the East Indies and consumed in Great Britain may have been one-tenth of the whole, while the value can not be estimated at more than one-twentieth of the total cost of home-consumed raw cotton. The British West Indies supply only small portions of the cotton required by the manufacturers of the United Kingdom, though the quality of the cotton there produced is excellent; and would be very largely bought and consumed if it were largely supplied. For a considerable time the British colonies have not supplied more than one-twentieth part of the British consumption of cotton, and yet in the possession of Great Britain there exists a greater extent of land suited to the growth of cotton than in any other dominion. At Port Natal cotton of excellent quality might be grown to any reasonable extent; and in Australia, cotton equal to the finest of the fine might be produced to an almost indefinite amount.

The most remarkable fact is, that although cotton was cultivated in gardens from remote antiquity in China, yet this ingenious people never turned it into any account until the end of the thirteenth century, at which time its manufacture among them began.

The following passages from the narratives of those who have visited India, are replete with interesting information on the subject before us. Marco Polo found cotton in Guzerat in large quantities, taken from a tree about six yards high, and bearing for twenty years. The cotton from a tree of this age is adapted only to quilting, but that taken from trees of twelve years is suitable for muslins and other manufactures of extraordinary fineness. Sir John Maundeville, in the fifteenth century, later by fifty years than Polo, says, that in many places the seed of the cotton in India which we call tree wool, is sown every year, and there spring up from it copes of low shrubs on which the wool grows.

A luxuriant field, says another, exhibiting at the same time the expanding blossom, the bursting capsule, and the snowy flakes of ripe cotton, is one of the most beautiful objects in the agriculture of Hindoستان. Malto Brun is equally instructive on the point: "The cotton tree grows on all the Indian mountains, but its produce is coarse in quality; the herbaceous cotton prospers chiefly in Bengal and on the Coromandel Coast, and there the best cotton goods are manufactured. Next to these two provinces, Madure, Marwar, Poescaria, and the coast of Malabar produce the finest cotton. The plant is cultivated in every part of India; the finest grows in the light, rocky soil of Guzerat, Bengal, Oude, and Agra. The cultivation of this plant is very lucrative, an acre producing about nine quintals of cotton annually."

Brazil is an extensive cotton-growing country, and sends steady supplies of it to the European markets. The quality of its cotton is everywhere highly esteemed. Persia, Spain, Italy, Malta, and the adjacent countries, are all capable of producing excellent cotton; but in Africa there are probably greater undeveloped resources for the cultivation of cotton than can be found in any other portion of the globe. The example of Egypt is a great lesson for the governors of those countries whose agricultural resources remain undeveloped. In 1821, Mohemet Ali conceived the possibility of effectually cultivating cotton, and succeeded. From that year to the present time large supplies of that useful and now indispensable raw material have been obtained from Egypt, to the great convenience of the British manufacturer, who has found the quality second only to the sea-island cotton of the United States.

The herbaceous cotton plant unquestionably exhibits all the desirable qualities of cotton applicable to manufacture, as proved by the productions of the United States and of the East Indies. The cottons produced in the West Indies, in Brazil, and in Egypt, are from the shrub; and it is observed that the older the plant the coarser become the fibres. Tree cotton, as a marketable product, is almost unknown; but in Borneo, and in many other tropical regions, the plant on which it grows is found flourishing in a wild state. To insure economy of culture, and of gathering the cotton as it opens and ripens, it is evident that the plant and the shrub are most accessible, and that the tree can not always be either safely or conveniently climbed to obtain its downy fruit.

In Central Africa, cotton has also been a staple growth since the date of our earliest records. It is mentioned by travelers as abundant on the banks of the Senegal, the Gambia, and the Niger, at Timbuctoo, Sierra Leone, the Cape de Verd Islands, on the coast of Guinea, and in Abyssinia. In hot climates, also, says an authority, the cotton plant grows so abundantly, that this is the cheapest material of which cloth can be made. With such recommendations, it can not fail to continue the staple and universal manufacture of Africa.

In modern times, no material on which the industry of mankind is exerted can be compared with the vast importance of that beneficent gift of Providence, cotton. Millions of our fellow-creatures depend upon its cultivation and manipulation for support. Capitalists embark in its production and manufacture, as also in its trading and mercantile distribution. National resources are enlarged and benefited by it; and to Great Britain and the United States it has proved a fountain of wealth, from which streams of prosperity have flowed from the time of its first introduction as an agent of labor and traffic to the present moment.

The upland cotton is a different species from the sea-island, and is separated with such difficulty from the seed, that the expense of cleaning the wool must have put a stop to its further cultivation, had not a machine, by which the operation of cleaning is easily and successfully accomplished, been invented. This machine was invented in 1795 by Mr. Eli Whitney of Massachusetts. There are two qualities of the cotton—the one termed Upland Georgia, grown in the states of Georgia and South Carolina; and the other, of superior quality, raised upon the banks of the Mississippi, and distinguished in the market by the name of New Orleans cotton. A strong prejudice existed for some time against the upland wool, which was thought to be of inferior quality, and not to take a good color in dyeing; but being found suitable for different coarse fabrics, its cultivation was so rapidly extended, that in 1807, 55,918,449 lbs. of upland cotton were exported from the United States.

The cotton of the finest quality ever brought to the English market, or probably ever grown, was that formerly mentioned as having been raised in the island of Tobago, between the years 1789 and 1792, upon the estate of Mr. Robley. That gentleman carried the cultivation of this article to some extent; but the price of cotton falling very low, and the cultivation of sugar becoming extremely profitable in consequence of the destruction of the sugar plantations in the French islands, he was induced to convert his cotton grounds into a sugar plantation. The production of cotton of this very fine description has hardly ever been attempted by any other person, although it is believed that the price it would yield would amply repay its expense.

Until about the year 1815, it was thought that the cotton wool of India, from the shortness of its staple, could not be spun with advantage upon machinery; and, in consequence, the greater part of the Indian cotton was spun upon the common jenny, and used for the coarsest calicoes. It was discovered, however, that by mixing it with the longer stapled wools of other countries, it might be brought into a state fit for the mule and spinning frames.

The United States consul at Naples, in answer to the cotton circular issued by the Commissioner of Patents, says: "The cotton cultivated in the plains near Castellamari, Angri, Scafata, and Nocera, is similar to that of the United States. The plant is small and annual, and is cultivated with so much advantage that various projects by companies have been started to give extension to its cultivation; but without being carried into execution. It has been cultivated for more than ten years. Before the French occupation there was a very limited quantity, but during the Berlin and Milan decrees of Napoleon, the cultivation increased very rapidly, and the price reached a dollar a pound, though it had to be sent by land to Lombardy, Switzerland, and France. The quantity has since decreased. I have not been able to learn whether the French introduced seed, or sowed such as they found here; but the cotton fibre has not deteriorated either as to length, strength, or uniformity. On the contrary, the quality has improved.

"About two millions of pounds are produced here. In Sicily, to the south of the island, the cultivation is greater than in Naples. In past times, small quanti-

ties of cotton were shipped to Marseilles, but since manufactures have increased here, it is all consumed in the country. The most extensive manufacturers (Vonwiller & Co.) import annually from the United States two cargoes of cotton, of moderate size, besides quantities indirectly. Much twist is imported from England. Manufactures are improving, but are still far from reaching such perfection as to offer any inducement to export them.

"The price of ginned cotton is about 14 to 15 cents per pound. The cultivation is protected by a duty of \$8 per cantar of 196 lbs. English if introduced direct from the United States, and \$16 if indirect. It is ginned by the ordinary roller and by hand, as well as by the saw-gin; and 100 lbs of unginned will yield about one-third clear cotton. It is packed with hands and feet, and is not exported, nor is there any fixed number of pounds to the bale. The cost of producing one pound of cotton fibre, well ginned, is from 10 to 12 cents.

"An acre of ground will produce about 600 lbs. of unginned cotton. The value of an acre of cotton land is \$450, and the rent is \$20 to \$25 per annum; but you must take into consideration the annual land tax of from one-fifth to one-fourth of the rent, which must be paid by the owner of the land every two months in equal rates.

"If any causes operate injuriously to the cotton crop, they are to be ascribed more to the social condition of the inhabitants than to any thing else. The relations generally between the landowner and the cultivator are not of the best kind, the bad faith of the latter being characteristic, while the owner barely leaves him enough to miserably subsist on. In some seasons, too, worms do injury to the plants, as well as fogs and mists in July and August."

11. COTTON CLIMATES. 1. *The Cotton Districts of the Globe considered with reference to their Climates.*—On inquiring into the climate best suited to the cultivation of cotton, we must remember that we have to pay attention, not only to the air, but also to the vapor. These may be considered in some respects as forming two distinct atmospheres; the one uniform in quantity, and in the proportion of its ingredients, but ever-varying in temperature; while the vapor varies not only in this respect, but in the quantity in which it is present, and also in its point of deposition, when alone it becomes perceptible as moisture.

Cotton is cultivated in so many countries, that we can not but expect it to be capable of flourishing in considerable diversities of climate. Thus, the rich alluvial lands of the Mississippi differ not only in soil, but also in temperature and dryness, and the sandy fields of Georgia. In dryness, both must differ from the uniformity of moisture which prevails in the islands where sea-island cotton is produced. Some grow naturally in the warmer parts of Mexico, as well as in the countries situated along the east of the Andes; and much is cultivated in the moist parts of Guiana and Brazil. Humboldt has seen it at 900 feet of elevation in the equatorial Andes, and at 5500 feet in Mexico. But here different species may, perhaps, be included, as we know that which yields Pernambuco cotton is cultivated in many parts of South America. In the Old World, we find cotton growing in the interior, both of Africa and of India, where there must be considerable dryness of climate. It is cultivated with some success in Egypt, and also, of late, in Algeria, and near Port Natal, in South Africa; but, in the two former, only by the aid of artificial irrigation. It is produced in various islands of the Indian Ocean, in many parts of China, and in almost every part of continental India. Thence it may be said to extend into Persia, Asia Minor, and to the southern parts of Europe, including the islands of the Mediterranean, whence the English manufacturers received their earliest supplies of cotton.

Within forty degrees considerable mer in mean temperature of the amount continents, greater comparative increase even radiation w atmosphere. Barbadoense favorite climate mean annual heat, but in the same heat of 73° 46° or 48°.

Within these limits, extending from the equator to forty degrees of latitude, we know that there are considerable diversities of climate; but the heat of summer in many of these localities, does not differ so much as might be expected from their latitudes. The temperature of tropical regions is known to be modified by the amount of moisture, while that of the interior of continents, even in high latitudes, is increased by the greater clearness of sky, which is dependent on the comparative absence of moisture. This cause tends to increase even the cold of winter, from the more free radiation which takes place at night in a cloudless atmosphere. Humboldt has remarked that *Gossypium Barbadense*, *hirsutum*, and *religiosum*, have each their favorite climate, from 0° to 84° of latitude, where the mean annual temperature is from 82° to 88° Fahrenheit, but that *G. herbaceum* is successfully cultivated in the temperate zone, where, with a mean summer heat of 73° to 75°, the mean of winter is not less than 46° or 48°.

But, in taking a general survey of the localities where cotton is chiefly cultivated, we should observe that many of them are in islands, and others in the vicinity of the sea. This is certainly the case with the districts where the finest cottons are produced, and the largest returns to the acre obtained. It has frequently been stated that the beneficial effects of such localities are chiefly due to the presence of salt in the soil, or to its being carried up in the spray, which is transported by winds into the interior. Koster, in his "Travels in Brazil," states, on the contrary, that "the districts which are universally allowed to be the best adapted for the growth of cotton, are far removed from the sea-coast, arid, and oftentimes very scantily supplied with water; also, that the opinion is very general, that the cotton plant will not thrive in the neighborhood of the coast, and also that plantations were yearly receding farther into the interior, the soil preferred being a deep-red earth, which becomes extremely hard after a long interval without rain." Something, no doubt, must be owing to the species which is cultivated, and to the climate of the plantation being more or less moist. Thus, Spix and Martius, in their "Travels," state that "the cotton tree cultivated at Rio de Janeiro (*G. Barbadense*)—sometimes, but more rarely, the *G. herbaceum* thrives very well, but it is stated not to furnish such durable materials as that in the higher and dryer districts of Minas Novas."

Proximity to the sea has, however, other peculiarities besides the facility of affording saline ingredients to the soil or to the atmosphere. It participates, to a certain degree, in the peculiarities of an insular climate; that is, in greater uniformity of temperature than is found in places farther in the interior, and in the freer circulation of air from the usually alternating land and sea breezes. There is also greater equality of moisture; for air, passing over the surface of the sea, necessarily takes up a larger proportion of water. This it does not immediately deposit on the coast, unless it is backed by hills, because it usually becomes a little warmed by the heated land, and is then capable of taking up more moisture. But, as it reaches the coast in a comparatively moist state, it necessarily rather checks than favors excessive evaporation, and thus does not force the foliage, exposed to its influence, to give up an undue quantity of moisture. This, however, is necessarily the case whenever a dry current of air passes over the surface of the leaves. To the influence of moisture, therefore, we must ascribe the more luxuriant vegetation of some sea-coasts, and of many tropical islands.

Haron Humboldt and Professor Dove have pointed out that, while Europe has a true insular or sea climate, both in winter and summer, North America inclines to a continental one in winter, and, in many parts, to a sea climate in summer; that is, it has a cold winter, with a cool summer, with the exception of certain dis-

tricts, which are excessively hot. But Northern and Central Asia have a true continental climate, both in winter and summer, or a cold winter and a hot summer. Notwithstanding this, we must also recollect that, though each locality may participate in the characteristic climate of its continent, all places near the coast will have more or less of an insular climate, while those in the interior have such as are of a continental nature, though in varying degrees.

The different varieties of cotton cultivated in the United States are believed to belong to one species; that is, that the "Georgian," or "short-staple," is the sea-island, carried into the interior; and that the "sea-island" itself was originally introduced from the Bahamas, or, more remotely, from Anguilla, one of the West India islands. The "New Orleans" does not differ specifically from the sea-island cotton, and is admitted by the planters of the South to be identical with the plant of Mexico, whence they procure their finest seeds. It is conjectured that it was from the neighboring coast of Mexico that the indigenous cotton of that country was introduced into the West Indies, and thence taken to the island of Bourbon. Hence we may account for *Gossypium Barbadense* being identical in species with the New Orleans and sea-island, as well as with the Bourbon cotton.

The Mexican plant is not a native of the temperate regions of that country, but of the *tierras calientes*, or hot districts. It is produced, for instance, in the neighborhood of Vera Cruz, and is represented as growing spontaneously near Valladolid, a town situated on the great plain of the Peninsula of Yucatan, described by Humboldt as one of the warmest regions in equatorial America. Mr. Stephens states that the spontaneous growth of cotton around that town had led to the erection of a cotton-factory in the place. Mr. Norman, in his "Rambles in Yucatan," says, "The cotton plantations, or, rather, the districts where the material is raised that is consumed in the manufactory in this city, are to the north, and known as the Tixemen district. The same spot is seldom cultivated for two successive seasons. After the crop is gathered, the ground is suffered to be overrun with weeds and brushwood, which, when years have elapsed, are cut down and burned, and the field is replanted." This rude method of culture is adduced only to show how little attention is paid to the plant in its native country. But, as it is desirable to know something precise respecting the climate of one at least of its native districts, we take from Professor Dove the subjoined notice of the means of observations made at Vera Cruz for thirteen years. This town, situated on the coast, in latitude 19° 12' north, and in longitude 96° 9' west, has a mean temperature of 77°.02 Fahrenheit, with a difference of only 12°.42 between the hottest and coldest months, thus:

January	69.98	July	81.50
February	71.90	August	82.40
March	73.40	September	80.66
April	72.17	October	78.44
May	80.48	November	75.38
June	81.66	December	71.06

The Mexican cotton has been introduced into Texas, as well as into Louisiana and Alabama. In the southern parts of Texas, where the climate is very congenial, the plant does not require to be renewed more frequently than once in three or four years, to yield a crop superior in quality and quantity to the annual planting of Louisiana. Cotton planting, in that part of Texas, commences in February, and picking begins at an earlier and continues for a longer period than in the other states; the average return, also, to the acre, is considerably greater in Texas than in the other states, and the expense of cultivation considerably less, in consequence, not only of the greater richness of the soil, but also of the peculiar mildness of the climate. The cotton, moreover, is of a superior quality, and planters of

acknowledged variety state that it is not uncommon to pick 4000 pounds of seed-cotton from an acre.

Mr. Featherstonhaugh, after crossing into Northern Texas, in about latitude 33° 40', observed that he had never seen the cotton plant growing in greater perfection before; for, in the cotton districts he had passed through, the plant was a low dwarfy bush, not exceeding two feet in height; but here the plants were five feet high, often bearing 800 bolls, and yielding from 1500 to 2500 pounds of seed-cotton to the acre, which gives from 25 to 80 per cent. in weight of raw, marketable fibre.

The most successful cultivation of cotton in the United States, it is well known, is in the lower parts of Georgia, Alabama, Mississippi, Louisiana, and Texas. In these regions there is comparatively little frost, and the winter is always mild, with considerable heat in summer; but this is tempered, to a great extent, by the pleasant and salutary effects of the sea breeze, which sets in from the Gulf or the Atlantic for a great part of the day. There are heavy dews at night, and frequent showers occur, in the spring as well as in the summer. In the interior and more northern portions of these states (which are in some parts elevated from

500 to 1000 feet above the level of the sea), frost is expected in October, and often continues until April; sometimes it occurs even in May, so as to injure, but does not then usually destroy, the plant. The heat of summer, though frequently high, still is tempered by the influence of the ocean or the Gulf of Mexico, and of the numerous great rivers, as well as by the dews and occasional showers. The cultivation of cotton is generally commenced about the beginning of April, when the land is still saturated with the winter rains, and difficulty is sometimes experienced in getting the land sufficiently dry; otherwise, a good shower is essential when cotton is first sown, and it is desirable also to have occasional showers during the planting, plowing, and hoeing seasons. The bolls begin to open about the middle of July, and continue to do so until the appearance of frost, from the middle to the end of October, and the first delivery of the new crop on the sea-board is from the first to the twentieth of August.

In order to have a more precise idea of the climates of the most favorable cotton districts, and for the advantage of comparing them with those of other countries, the subjoined Table is selected from Professor Dove, as published by the British Association:

MEAN TEMPERATURE.

Localities.	Lat. N.	Long. W.	Jan.	Feb.	March.	April.	May.	June.	July.	August.	Sept.	Oct.	Nov.	Dec.	Mean of Year.
Galveston, Texas	29° 18'	95° 10'	60.50	62.53	75.00	73.20	83.54	86.60	88.20	83.50	81.10	64.20	60.10	53.40	74.50
New Orleans, La.	29 58	90 70	58.75	58.99	66.68	72.41	77.26	81.18	82.22	83.12	79.42	69.71	68.71	52.25	69.81
Mobile, Ala. . . .	30 12	87 50	56.40	57.37	65.64	70.90	76.38	82.17	82.41	82.73	78.94	64.97	61.50	56.50	69.92
Baton Rouge, La.	30 34	91 51	57.57	51.80	61.55	68.69	76.58	82.00	82.84	82.84	76.53	60.84	62.47	58.59	68.15
Jackson, La. . . .	30 54	91 10	47.50	49.40	56.80	65.40	70.80	78.70	81.70	79.40	72.10	67.40	60.40	48.40	61.22
Houston, Texas.	31 54	95 50	65.70	60.50	68.70	72.70	85.50	80.10	84.20	81.40	78.50	73.90	62.90	60.40	73.90
Natchez, Miss. . .	31 34	91 25	50.15	50.82	62.20	69.93	72.72	80.62	81.75	80.15	74.99	64.53	56.23	49.90	66.10
Vicksburg, Miss.	32 24	91 00	51.40	53.72	63.90	74.01	76.84	80.65	82.43	80.11	76.40	64.92	55.26	50.91	67.56

To compare with these, we shall further adduce, from the same Tables, the mean temperatures of places on

the Atlantic coast, as in Florida, Georgia, and Carolina, as well as in the interior of the last two:

Localities.	Lat. N.	Long. W.	Jan.	Feb.	March.	April.	May.	June.	July.	August.	Sept.	Oct.	Nov.	Dec.	Year.
St. Augustine, Fla.	29° 50'	81° 27'	60.75	64.97	67.55	70.96	76.95	81.41	82.81	83.97	80.10	73.88	63.5	60.92	72.13
Savannah, Ga. . . .	32 5	81 10	52.15	53.74	61.19	67.36	73.14	77.89	82.22	82.93	75.96	66.92	57.4	50.50	66.70
Charleston, S. C. . .	33 47	79 57	49.42	53.80	58.34	63.20	75.19	78.85	80.70	80.15	74.30	66.70	58.90	51.80	66.91
Fort Johnston, S. C.	34 0	78 5	51.42	52.19	60.52	66.28	73.70	78.98	81.67	80.29	76.32	69.11	60.13	52.85	66.96

Augusta, Ga.	32 28	81 54	45.69	47.63	52.66	62.34	69.68	77.72	79.47	76.15	72.96	60.35	54.23	48.45	61.90

2. Climate of the Cotton Regions of the United States.

The climate of Georgia is somewhat warmer than that of Carolina, but the low, flat country of both, in summer and autumn, is moist, and somewhat unhealthy. The spring is commonly rainy, and the heat of summer is considerable, but is tempered by the gentle breezes which blow almost daily from the sea. The winds change from southeast to southwest about the end of July, but are variable, from storms of thunder, and the heavy rains of July and August. The cold weather seldom commences before the beginning of December, and terminates in March, but the winter is usually mild, and snow seldom falls near the sea, and soon melts away. The hilly parts, 200 miles from the sea, are agreeable and favorable to health. The winter is colder; snow falls to a depth of five or six inches. Though the preceding tables are sufficient to give a general idea of the climates, it would be desirable, for agricultural purposes, to have also the maxima and minima for the spring, summer, and autumnal months, for a series of years, as a night of frost may destroy the plants, and great heat, with drought, will be equally injurious, from drying them up. Cotton, as before observed, is sown in April; picking commences in July or August, and continues until November, and, on the coast, sometimes even as late as December. The sea-island plant yields about 125 or 130 pounds of clean ginned cotton per acre. Of the short staple, in the hill country, from the Mississippi to the Carolinas, not more than 500 pounds of seed cotton, or 150 pounds of clean cotton, can be obtained to the acre. The short staple cotton is more or less cultivated all the way from

the southern borders of Virginia, to the southwestern streams of the Mississippi. The mean quantity over all is estimated at 125 pounds of ginned cotton, of both sea-island and of the short staple, to an acre, but the amount of labor is much greater for the former than for the latter.

In comparing the climates of the cotton regions above described, with those of other countries, it is necessary to remember the peculiarity of that of America, with which this subject was commenced, and also how much the best cotton districts are influenced by the Atlantic, or the Mexican Gulf. The climate, to the west of the Alleghany Mountains, is considered more mild than that under the same parallels in the Atlantic states, and, by some, even to the extent of three degrees of latitude. This has been explained as caused by the warm air of the Gulf of Mexico being driven up the basin of the Mississippi and that of the Ohio. The direction of the valley, north and south, no doubt favors the course of the southern winds, while the regions of the Atlantic slopes, being transverse, oppose any such transmission, and also the migration of plants. The majority of the places of which the mean temperatures have been adduced are on the sea-coast, and necessarily participate, to some extent, in the peculiarities of an insular climate; that is, of seasons moderately contrasted. Still, the difference between the hottest and the coldest month of the year is much greater than at Vera Cruz; that is, than 12°; being, at Mobile, Galveston, and New Orleans, 27° 23', 29° 10', and 29° 06', respectively. But in the interior, at Natchez and Vicksburg, the differences are greater, being

32° 00' ences being while, being addition of the and of seen in sea, at Ma reasm winter consta gather hewen as low habitie bay of Ala state and u conside rally the 20 cotton thro from of raini ng, t are fe cus du of the 1000 the cl Lon is som it selo com the n melst thien wiate degra the t snow ary, Missi on t and sever with G scrib mon some wint the s some snow ever occa sect rain from phe gen sho in, v, are end cha mon cot cau its

82°-69 and 81°-57. In the Atlantic districts the differences are nearly as great as those on the south coast, being 81°-78 at Savannah, and 81°-09 at Charleston, while, in the interior, the differences are much greater, being 36°-02 at Augusta, and 88°-10 at Columbia. In addition to the foregoing, it is desirable to notice some of the general features of the climate, both of the Gulf and of the Atlantic states, as it will then be readily seen how much it is modified by the vicinity of the sea, and by the configuration of the coast:

Mississippi.—Near the Gulf of Mexico, the climate resembles that of the lower parts of Louisiana; the winter is mild, the summer warm, but tempered by the constant prevalence of the breeze from the Gulf, together with the elevation of the surface. At Natchez, however, the thermometer in winter sometimes stands as low as 10° Fahrenheit. In sickly seasons, the inhabitants frequently remove to the high banks of the bay of St. Louis.

Alabama.—In the low and southern parts of this state the heat is very great. The climate of the inland and upper parts resembles that of Georgia, and may be considered remarkably mild. Frost commences generally in October, and continues sometimes as late as the 20th of May, so as to injure, but not destroy, the cotton, in the more elevated parts. During summer, there is usually a prevalence of westerly winds. Those from the southeast are regarded as the sure harbingers of rain. At Mobile, from nine in the morning till evening, the pleasant and salutary effects of the sea breeze are felt. The rich verdure of the earth, with the copious dews that fall during the night, and the elevation of the soil, which, in the upland parts, is from 600 to 1000 feet above the sea, produce a beneficial effect on the climate.

Louisiana.—The climate of most parts of this state is somewhat variable. From the sea to Point Coupée, it seldom snows or freezes, except in the months of December and January, and then when the wind is from the north or north-west. There is less heat and more moisture than in similar latitudes on the Eastern Continent, and the climate is generally very mild. In winter, the thermometer seldom falls more than two degrees below the freezing point. In December, 1800, the thermometer sank to 12° near New Orleans, and snow fell for the first time in twenty years. In January, 1811, the mercury fell from 78° to 10°, and the Mississippi was completely frozen over. At the present time (February, 1856), it is reported as low as 20°, and the Mississippi as frozen quite over with the ice several inches in thickness, and the ground covered with ice and sleet to a depth of six or eight inches.

Georgia.—All the flat country of this state is described as moist and unhealthy during the warmer months, especially the "rice swamps;" the climate is somewhat warmer than that of South Carolina. The winter is the most pleasant season of the year, when the thermometer usually ranges from 40° to 66°, though sometimes a considerable degree of cold has prevailed; snow is uncommon, but frosts have been experienced even as late as April. A strong northeast wind will occasionally blight a promising field of cotton, as insects will sometimes destroy it. The spring is usually rainy, the summer inconstant, with a temperature of from 70° to 90° from June to September. The atmosphere feels springy and enlivening, being refreshed by gentle breezes, which blow almost daily from the seashore. About the 20th of July the summer rains set in, often accompanied with storms of thunder, and severe winds, which, though not tropical in their violence, are often so heavy as to deluge the fields. About the end of July, or beginning of August, the wind usually changes its direction from southeast to southwest. The month of August is the period of most solitude to the cotton-grower, as heavy rains at that time occasionally cause the plant to part with its young bolls, and even its leaves. The autumn is usually fine and clear; and

about the 20th of October frosts are expected, but do not often come before the end of the month. The inhabitants of the hilly tracts, two hundred miles from the coast, enjoy an agreeable climate, which is favorable to health. The winter is colder, snow sometimes falling to a depth of five or six inches. The summer is not so hot, and the winds of autumn are less violent; and the cotton, being less exposed, is allowed to hang longer, so as to become perfectly mature.

South Carolina.—The winter of the lower parts of this state is mild; and the difference between the mildest and severest winter is about seventeen degrees, often with heavy frosts, and sometimes snow, but with a hot sun during the day; though snow seldom falls near the sea. The winter may be considered as terminating in March, when snow and heavy rains usually occur; but April and May are commonly dry months. In the low country the heat of summer is intense; but the climate is liable to sudden changes of temperature, when it is damp with fogs and heavy dews. June, July, and August are generally the wettest months, and the rains consist of heavy bursts and frequent showers, which are liable to occur in spring, summer, and autumn. November is usually fine, even after the coming of frosts, which sometimes do not occur until December. The average quantity of rain, for ten years, was 49.3 inches; the largest quantity, 83.4 inches, and the least, 30.6 inches, in any one year. In the upper country, frost appears earlier and continues later; but the weather is not so variable. In winter the cold is considerable, but does not last very long. The climate of the Santee Hills, which are situated eighty or ninety miles from the coast, is similar in character.

Texas.—The climate of Texas is decidedly more healthy than that of Louisiana, or any other of the Gulf states; still, on the low alluvial coast, intermittents are prevalent during the summer and autumnal months; but the yellow fever is rarely known. Comparatively little rain falls from March to October, though gusts of wind, with thunder, frequently occur, with sufficient rain to make excellent crops. During the rest of the year, hot weather generally prevails. The winters are warm and mild on the coast, and, for some distance inland, snow is seldom seen, except on the higher table-lands or mountains. From April to September, the thermometer, near the coast, usually ranges from 60° to 100°. The greatest heats, however, are tempered by strong and constant breezes, which begin to blow soon after the rising of the sun, and continue until past noon. The nights throughout the middle regions are cool and refreshing during the year.—*Report of the Department of State of the United States.*

In connection with the climate of the United States, it is desirable to take some notice of that in which another species, the "Brazil" or "kidney" cotton, is cultivated. From the observations of the late Dr. Loudon, at Pernambuco, it is found, that the quantity of rain which falls at that place is considerable, and that the air must always be in a moist state. As Koester states that cotton succeeds better from 50 to 150 leagues interior, the climate may still be more moist than that on the coast.

3. *Climate of the Cotton Region of the Nile.*—The soil and climate of Egypt are adapted to the growth of cotton, but the yield depends greatly on the rise of the Nile. When the river is low the crop suffers, as little or no rain falls before December. Almost all the land in Lower Egypt is particularly well adapted to the growth of this product, yet it is not all equally good.

It rains frequently in the vicinity of Alexandria, and but seldom on the Delta.

The culture of cotton in Egypt, on a large scale, is comparatively recent. It was first undertaken by M. Jumel, a Freuchman, who, in 1821, laid before the Viceroy all the advantages and results arising from its production. Previous to that period, the cotton produced in that country was of inferior quality. A few plants

is applied every four days. The bolls begin to form in July, and the plants continue in flower from September until the latter part of February. The harvesting also commences in September, and lasts until the following spring.

5. *Climate of the Cotton Districts of other Parts of Africa.*—Cotton of a very good quality has been cultivated for some years at Natal, nearly at the southern extremity of Africa. The coast is low along the region, and, in some parts, even swampy; but the land within ten miles of the sea is considered most favorable to the cultivation of cotton, probably from the constant moisture of the atmosphere and the warmth of the climate; though, no doubt, it may be successfully grown farther in the interior. The country beyond is described as being better adapted to the purposes of grazing. Various attempts have been made to obtain cotton from the west coast of Africa, and the seed of the best varieties have been introduced from the United States. In Liberia, Dahomey, and other places, fine samples have been produced, principally from the green-seeded and kidney-seeded sorts. The climate is represented as favorable, but a different population is required for an extended and profitable production.

6. *Climate of the Cotton Regions and Islands of the Mediterranean.*—Considerable quantities of cotton are cultivated in other countries bordering on the Mediterranean. It is generally the product of the India species, though seeds have been introduced from Egypt and the United States. These are cultivated in Asia Minor, in parts of Greece, and the islands generally known as the Levant. The Italian cottons are produced in Sicily, in Calabria, near Naples, and in Malta. Those of Sicily, Calabria, and Castellamare are the best, and are usually produced from American seed. A Nankin cotton is cultivated in Malta, but is all manufactured for domestic use.

At Naples, the soil and climate are well suited to the growth of cotton, with the aid of artificial irrigation in times of drought. In some seasons, however, the plants receive injury from insects, as well as from fogs and mists, in July and August.

The manure, when employed, is the dung of animals, but no other fertilizer is used. The seed is planted in April, in rows, with sufficient space between them for the passage of water, for the purposes of irrigation. The plants are in flower in June and July; the cotton harvested from September to November; and the yield per acre, ginned, besides other crops between the rows, 600 pounds.

The soil and climate of Sicily are better adapted to the growth of cotton than those of Naples, particularly on the southeast side of the island, and within twenty miles of the sea. Farther inland, the heat is not sufficient to mature the crop. The maximum temperature of the cotton regions, from May till October, is 77° Fahrenheit; minimum, 61½°; the mean 68°. The quantity of rain which falls during the cotton-growing months is generally fully sufficient for the perfection of the plant. The principal injury to the crop is occasioned by long-continued north winds, which, however, but seldom occur.

7. *Climate of the Cotton Districts of British India.*—The British East India possessions embrace an almost boundless extent of territory, extending from the Himalaya range of mountains on the north, to the ocean, including nearly the whole of the peninsula of Hindostan, the island of Ceylon, and that portion of Burmah lying between the 20° of N. lat. and the bay of Bengal. In the peninsula of India, the climate is greatly influenced by the two monsoons—one from the northeast, which blows chiefly on the eastern coast, and the other from the southwest, which is mostly felt in Malabar and the western parts of the country. In some parts, the advantages of both monsoons are enjoyed; but in others, the change from the moisture of the rains to the heat and dryness which succeed them, is nearly as

marked in its character as at Saharunpore, and the cotton-plants suffer as much from the transition. Such being the extremes of temperature and of dryness, as well as the shortness of the several seasons in which the plant may be made to grow—that is, during the hot and dry weather, from March to June, or during the steaming moisture of the rainy season, followed, at first, by a hot and moist summer, and then by a cold and dry autumn, succeeded by a bracing winter—a plant must be hardy to sustain unharmed such extreme and sudden vicissitudes. But all India is not identical in climate. In some parts the accession of the rains is earlier, their termination more gradual, and the cold of winter less, or the country enjoys the advantages of a valuable monsoon; so that there is a longer period of growth.

Temperature, as we have seen, is only one of the elements of climate; and, though a very important one, is yet unable of itself to do any thing toward the growth of a plant, unless water be within the reach of its roots to dissolve and carry into the vegetable cells and vessels the elements of nutrition. It must be decomposed, in contact with air, not too dry, nor yet too damp, but containing its due proportion of oxygen and carbonic acid gas, and illuminated by the light of the sun. There is no doubt that cotton-plants may exist through a long range of temperature, and of moisture and dryness of the atmosphere; but it is equally certain that they will never attain healthy vigor of growth unless there is a due supply of moisture in a moderately warm, or rather hot atmosphere. Though the degree of heat may be measured with a thermometer, moisture is not always indicated by the rain-gauge, for rain may fall and run off the surface, or percolate the soil, and the earth and the atmosphere both be left in a parched state, even during the season of growth. The moisture can only be determined by the hygrometer, or the wet and dry-bulb thermometer; and, imperfect as the majority of such instruments are, the information obtained from many situations would be invaluable, as we might then be more sure of drawing correct inferences, because, though we might not be able to calculate correctly the exact quantity of moisture contained in the atmosphere, we could see whether this was in a state of saturation, or was capable of taking up a still larger quantity, and thus in the oneness checking, and in the other favoring, evaporation from the soil, and from the surface of plants. To the comparative moisture of the air on the sea-coast, and in places within the reach of the moist sea air, must chiefly be ascribed the preference of the cotton-plant for such situations, or, at least, for its successful culture in so many islands and along so many coasts. But to this it may be objected, that a long-stapled cotton is successfully grown in the dry climate of Egypt. In that country, however, copious irrigation produces the same beneficial effects in a warm, dry atmosphere. Excess of moisture in a warm climate, however, may prove as injurious as its deficiency; for then the parts of vegetation may be altogether stimulated, or may be in a state of continual growth, when plenty of branches and leaves are produced, but few flowers and very little cotton.

The seasons of India, over a great part of the country, are divided into the cold, the hot, and the rainy; names which sufficiently indicate the particular characteristics of each. If we take an equatorial climate, like that of Singapore, as a standard of comparison, we shall observe a very great difference between it and that of a northwestern situation in the plains, such as Saharunpore, in 30° of north latitude, the first being remarkable for uniformity, and the latter for a great range, both of the dry and wet-bulb thermometer. Plants which live throughout the year in the open air at Singapore, will, in most cases, suffer both from the cold and the heat of Saharunpore, though they may flourish in the rainy season almost as well in the one as the other.

—U. S. Patent Office Report, 1855.

III. COTTON TRADE OF THE UNITED STATES. 1. History.—Cotton, which administers so bountifully to the wants of civilized as well as to savage man, and to the wealth and economy of the countries producing it, stands pre-eminent in the United States, both as regards its superior staple and the degree of perfection to which its cultivation has been brought. One or more of its species is found growing wild throughout the torrid zone, whence it has been disseminated, and become an important object of culture in several countries thereto adjacent from time immemorial. It is mentioned by Herodotus as growing in India, where the natives manufactured it into cloth; by Theophrastus as a product of Ethiopia; and by Pliny as growing in Egypt, toward Anakia, and near the borders of the Persian Gulf. Nieuhoff, who visited China in 1655, says that it was then cultivated in great abundance in that country, where the seed had been introduced about 600 years before. Columbus found it in use by the American Indians of Cuba, in 1492; Cortez, by those of Mexico, in 1519; Pizarro and Almagro, by the Incas of Peru, in 1532; and Cabeça de Vaca, by the natives of Texas and California, in 1535.

Of the precise period of the first introduction of the cultivation of this plant into the North American colonies, history is silent. In a pamphlet entitled "Nova Britannia offering most excellent fruits by planting in Virginia," published in London in 1609, it is stated that cotton would grow as well in that province as in Italy. It is also stated, on the authority of Beverley, in his History of Virginia, that Sir Edmund Andros, while governor of the colony, in 1692, "gave particular marks of his favor toward the propagating of cotton, which, since his time, has been much neglected." It further appears that it was cultivated for a long time in the eastern parts of Maryland, Virginia, Carolina, and Georgia, in the garden, though not at all as a planter's crop, for domestic consumption. In another pamphlet, entitled "A State of the Province of Georgia, attested upon oath, in the Court of Savannah," in 1740, it was averred that "large quantities have been raised, and it is much planted; but the cotton, which in some parts is perennial, dies here in the winter; which, nevertheless, the annual is not inferior to in goodness,

but requires more trouble in cleansing from the seed." About the year 1742, M. DuRoiil invented a cotton gin, which created an epoch in the cultivation of this product in Louisiana. During the Revolution, the inhabitants of St. Mary's and Talbot counties, in Maryland, as well as those of Cape May county, New Jersey, raised a sufficient quantity of cotton to meet their wants for the time. It was formerly produced in small quantities, for family use, in the county of Sussex, in Delaware, near the head-waters of the Choptank. The seed of the sea-island cotton was originally obtained from the Bahama Islands, in about the year 1785, being the kind then known in the West Indies as the "Anguilla cotton." It was first cultivated by Josiah Tattnall and Nicholas Turnbull, on Skidaway Island, near Savannah; and subsequently by James Spaulding and Alexander Bisset, on St. Simon's Island, at the mouth of the Altamaha, and on Jekyll Island, by Richard Leake. For many years after its introduction it was confined to the more elevated parts of these islands, bathed by the saline atmosphere, and surrounded by the sea. Gradually, however, the cotton culture was extended to the lower grounds, and beyond the limits of the islands to the adjacent shores of the continent, into soils containing a mixture of clay; and lastly, into coarse clays deposited along the great rivers, where they meet the ocean tides.

Previous to 1794—the year after the invention of Whitney's saw gin—the annual amount of cotton produced in North America was comparatively inconsiderable; but since that period, there is probably nothing recorded in the history of industry, including its manufacture in this country and Europe, that would compare with its subsequent increase.

In the Eastern hemisphere, the growth of cotton is principally restricted to the maritime countries lying between the 40th degree of north latitude and a corresponding parallel south. On the easterly side of the Western Continent, this plant will perfect its growth in most of the districts adjacent to the tidal waters, including the regions bordering on the Mississippi, the Amazon, and the Parana, between latitude 39° north and 40° south; and on the west coast of America, be-

tween the 40th parallel north and a corresponding degree south.

The growth of this staple is chiefly confined to India, China, Japan, Australia, Persia, Turkey, southern Europe, Arabia, Egypt, Algeria, southern and western Africa, the southern section of the United States, British Guiana, New Granada, Venezuela, Peru, Brazil, Uruguay, the West Indies, and numerous other ocean isles.

According to Dr. Royle, who has recently investigated the subject, the different localities of the four varieties or species of cotton (see page 434) may be stated in the following manner:

1. *Gossypium indicum*, or *herbaceum*—the cotton plant of India, China, Arabia, Persia, Asia Minor, and some parts of Africa.

2. *Gossypium arboreum*—a tree cotton, indigenous to India.

3. *Gossypium Barbadense*—the Mexican or West Indian cotton, of which the sea-island, New Orleans, and upland Georgia, are varieties. It was long since introduced into the island of Bourbon, and thence into India; hence it acquired the name of "Bourbon cotton."

4. *Gossypium Peruvianum*, or *acuminatum*—which yields the Pernambuco, Peruvian, Maranham, and Brazilian cotton, especially distinguished by its black seeds, which adhere firmly together. This variety has long since been introduced into India.

The chief varieties cultivated in the United States are the black seed, or sea-island (*G. arboreum*), known also by the name of "long-staple," from its fine, white, silky appearance and long fibres; the green seed (*G. herbaceum*), called "short-staple," from its shorter, white staple, with green seeds, and commercially known by the name of "upland cotton;" and two kinds of Nankin or yellow (*G. Barbadense*), the Mexican and Petit Gulf. The average yield is about 500 pounds per acre.

The earliest record of sending cotton from this country to Europe is in the table of exports from Charleston, in 1747-'48, when seven bags were shipped; another parcel, consisting of 2000 pounds, was shipped in 1770; and a third shipment of 71 bags was made in 1781, which England seized, on the ground that America could not produce a quantity so great. The amount exported from the United States in 1791 was 189,316 pounds; in 1793, 487,600 pounds; in 1794, 1,601,760 pounds; in 1795, 6,276,300 pounds; in 1800, 17,789,803 pounds; in 1810, 93,261,462 pounds; in 1820-'21, 124,893,305 pounds; in 1830-'31, 276,979,784 pounds; in 1840-'41, 530,204,100 pounds; in 1850-'51, 927,237,089 pounds.

According to the Census returns of 1840, the amount cultivated was 790,479,275 pounds; of 1850, 967,449,600 pounds; showing an increase of 196,970,325 pounds.

It appears that the culture of cotton is rapidly diminishing in Virginia and North Carolina. In those states it is doubtless giving place to other productions of the soil. There has been a very heavy falling off also in Louisiana, and no appreciable increase in Mississippi; but the diminution in the former state, and the failure of any advance in the latter, are accounted for by the terrible inundations of the Mississippi and its tributaries. But for that calamity, it is probable that their increased yield would have equaled that of Alabama, which now occupies the first place as a cotton-planting state, and has almost doubled its production since 1810. Immense as the extent and value of this crop has become, it is not extravagant to anticipate a rate of increase for the current decennial period which will bring up the aggregate for the year 1860 to 4,000,000 bales.

The average annual yield for the five years ending with 1835 was estimated at 1,065,060 bales; for the same period ending in 1840, 1,440,000 bales; for a like period terminating with 1850, 2,270,000 bales. Had no disturbing cause interrupted the progressive in-

crease, the amount of 1850 would have exceeded 3,000,000 bales.

The export of cotton from the United States to the countries of northern Europe commenced some sixty years ago. In the year 1800, Holland, including the territory now known as the kingdom of Belgium, received 79,694 pounds; in 1855 the aggregate quantity exported to the two countries was 17,160,967 pounds. In 1803 Norway and Denmark first imported American cotton, amounting that year to 184,193 pounds; in 1855 the aggregate quantity exported to these two countries, including Sweden, was some 7,000,000 pounds. Prussia and Sweden began importing cotton from the United States in 1804. Russia, in 1809, received cotton from the United States for the first time, and to the amount of half a million of pounds; while in 1853, the year prior to the commencement of the late war, the exportation to that country amounted to more than 21 millions. The Hanse-towns received cotton from the United States prior to the year 1800, and the progress of the trade with those cities, which is exhibited in the subjoined statement, strikingly exemplifies, in connection with the remarks which have preceded, and the general statement which follows it, the rapid and powerful advancement of the king-staple, not of the United States only, but of the commercial world.

At the opening of the present century, the imports of cotton wool into Great Britain were about 75,000 bales per annum; now the consumption of that country is 2,600,000 bales annually, while the rest of Europe, and the United States, that then had no manufactures, use about 1,900,000 more, to say nothing of the consumption of Asia. Of this 4,000,000 bales, five-sixths are the product of this country. The result of the past three years proves, that neither the existence of a war involving the chief nations of Europe, nor the fluctuations in trade consequent on its cessation, have had any effect on the demand for our great southern staple; thus establishing the fact that, the next to the leading articles of human food, it has become a great and fixed necessity.

A document compiled from the very best data, by one peculiarly fitted for the task, was lately read before the Manchester Chamber of Commerce, exhibiting very important facts. The value of the cotton manufacturing industry of the world was estimated at £120,000,000 sterling, or \$600,000,000. Of this amount the entire population of Great Britain consumed, in value, about \$3.85 per head per annum. England exports to the United States manufactured goods at the rate of 77 cents for each individual in this country, but being ourselves large manufacturers, and in view of the general better condition of the bulk of our population, it is probable that our consumption of cotton goods will exceed that of Great Britain 50 per cent. per head. England exports to her North American colonies cotton goods at the rate of \$1.53 per head per annum, for the whole population; to Russia, only at a rate of three-fifths of a cent per head; to France, two cents per head; to her East India possessions, at the rate of 18 cents; but these three last countries manufacture at home, especially France, who mainly provides for her own wants, while Russia receives goods from several sources. Estimating the population of the globe at 850,000,000, the apportionment of the whole value of manufactured goods would be about 70 cents for every inhabitant, man, woman, and child.

The tendency of the age is gradually toward an equalization of the moral and physical condition of the human family. The wealthier and middle classes expend much more than heretofore in articles of taste and luxury, in household and personal adornment, whereby the artisan, mechanic, and laborer are benefited, and their condition improved. The barbarous and debased nations and tribes of the world are fast tending toward the habits, and acquiring the tastes of civilization; the first symptom of which is the exchange of

REMARKS.

1840—First large crop. Season remarkably fine throughout.
 1840—Unfavorable season. Overflow of Mississippi River.
 1841—Western crop good. Severe drought in Alabama, Georgia, Florida, and Mississippi.
 1842—Generally good season and early picking.
 1843—Late spring, rainy summer, and early frost.
 1844—Very good season, and early picking. Partial overflow of Mississippi River.
 1845—Mississippi River and Western crop good and early. Drought reduced the eastern crop 300,000 bales.
 1846—Late spring, early and general visitation of army worms; the latter destroying 400,000 to 500,000 bales.
 1847—Late season, but favorable fall. The occurrence of the French Revolution put down pickings, and 200,000 bales were held back to the country.
 1848—Summer rainy, but flood fall; 200,000 bales brought forward of previous crop.
 1849—Frost in spring, heavy rains in July, partial overflow of Mississippi River; Red River bottom overflooded in summer.
 1850—Backward spring, picking began unusually late. Partial overflow of Mississippi River.
 1851—Favorable summer and early picking.
 1852—Remarkably fine season, early picking, and late frost.
 1853—Late and rainy season.
 1854-'55—Backward season. About 250,000 bales kept back by lowness of the waters in Alabama, Louisiana, Arkansas, and Texas.
 1855-'56—Fine season. Early picking, sufficiently good to counterbalance an early frost. About 250,000 bales of last crop received, which, in fact, will make the actual product of 1854-'55, 3,097,900 bales, and reduce that of 1855-'56 to 3,377,800 bales.

Sea-Island Cotton. The crop of this important staple for the year ending Sept. 1, 1856, was 44,512 bales; 1854-'55, 40,841 bales, and in 1853-'54, 39,686 bales. The receipts in 1855-'56 being, from Florida, 10,900; Georgia, 13,245; South Carolina, 20,367.

The extraordinary crop of the year 1855-'56 in the United States (3,527,900 bales) has passed into the numerous channels of consumption at prices much higher than for five years past, leaving a stock on hand on 1st September last of only 52,000 bales in all the United States ports. This consumption is still going on throughout the British and Continental manufacturing districts; and the increase of machinery added to mills hitherto working, it is estimated, will require in Great Britain alone an additional weekly supply of 4000 bales.

ACCOUNT SHOWING THE DESTINATION OF THE COTTON EXPORTED FROM THE UNITED STATES IN 1847, 1848, AND 1849.

TABULAR COMPARATIVE STATEMENT SHOWING THE QUANTITIES OF COTTON EXPORTED FROM THE UNITED STATES TO THE PRINCIPAL COMMERCIAL COUNTRIES RESPECTIVELY, AND THE ANNUAL AVERAGE AMOUNTS THEREOF; AND THE ANNUAL AVERAGE AMOUNTS OF DUTIES DERIVED THEREFROM, FOR A PERIOD OF FIVE YEARS, FROM 1851 TO 1855, BOTH INCLUSIVE. THE DATA FOR THIS STATEMENT ARE DERIVED FROM THE UNITED STATES TREASURY REPORTS, IN WHICH THE COMMERCIAL YEAR CLOSES JUNE 30. THE YEAR IN BRITISH AND FOREIGN OFFICIAL DOCUMENTS CORRESPONDS WITH THAT OF THE CALENDAR: HENCE ONE CAUSE OF APPARENT DISCREPANCIES IN FIGURES FOR NOMINALLY THE SAME YEARS.

Countries to which exported.	Pounds of cotton exported from the United States in the years					Annual average amount of cotton.	Annual average amount of duties paid.

* The amount of duties paid are calculated on the customs rates given in the preceding table (7), although those rates, during the five years designated, have in some instances undergone changes. Belgium, for example, did not admit cotton free until the passage of the law of April 12, 1854.

† The amount is calculated on the medium of the *ad valorem* duty of Bremen and Hamburg, on an assumed valuation of 12 cents per pound.

‡ The amount is calculated on the rates of the existing tariff of January 31, 1856, prior to which cotton was either prohibited or subjected to a duty equivalent to prohibition.

§ United States Treasury reports do not give quantities to Norway distinct from those to Sweden. In the latter, cotton is free; in the former, the duty is nearly half a cent per pound.

EXPORT OF COTTON TO FOREIGN PORTS FROM SEPTEMBER 1, 1855, TO AUGUST 31, 1856.

1850-'51	494,108	1844-'45	380,006						

We give below a table of the amount of cotton consumed the past year in the States south and west of Virginia, and not included in the receipts at the ports. We have largely increased the estimate from the year previous, but give it only for what it purports to be, an estimate, which we believe approximates correctness.

There are no statistical returns of the quantities of cotton manufactured in the States south of Virginia; but it is well known that the yearly consumption in

those States is increasing, as well as in Virginia, Ohio, Illinois, and Missouri. At the last census the capital employed in the manufacture of cotton goods in the Southern States was as follows: Maryland, \$2,236,000; Virginia, \$1,908,000; North Carolina, \$1,058,000; South Carolina, \$857,000; Georgia, \$1,736,000; Florida, \$80,000; Alabama, \$651,000; Mississippi, \$38,000; Kentucky, \$239,000; Tennessee, \$639,000; Missouri, \$102,000. At this period [1856-7] these sums are probably doubled.

States.	1856.	1855.	1854.	1853.	1852.	1851.	1850.
North Carolina..... bales	22,000	18,500	20,000	20,000	16,000	13,000	20,000
South Carolina.....	15,000	10,500	12,000	10,000	10,000	10,000	15,000
Georgia.....	22,000	20,500	23,000	20,000	22,000	13,000	27,000
Alabama.....	6,500	5,500	6,000	5,000	5,000	4,000	6,000
Tennessee.....	7,000	4,000	6,000	5,000	7,000	8,000	12,000
On the Ohio, etc.....	42,000	26,000	35,000	30,000	16,000	12,000	27,500
Total to September 1...	117,500	85,000	105,000	90,000	75,000	60,000	107,500

To which, if added (for the past year) the stocks in the interior towns 1st Sept. (say 350,000 bales), the quantity now detained in the interior (say 20,000 bales), and that lost on its way to market the past year to the crop as given above, received at the shipping ports, the aggregate will show, as near as may be, the amount raised in the United States the past season—say, in round numbers, 3,335,000 bales (after deducting 1800 bales

new crop received this year to the 1st Sept., and some 250,000 bales detained in the interior Sept. 1st, 1855, by low rivers, etc., which it is fair to suppose runs forward the past season, and is already added to the receipts at the ports), against

1855..... bales, 3,175,000	1851..... bales, 2,450,000
1854..... " 5,000,000	1850..... " 2,212,000
1853..... " 3,240,000	1849..... " 2,357,000
1852..... " 3,700,000	1848..... " 2,860,000

STATEMENT SHOWING THE WEEKLY AND TOTAL RECEIPTS OF COTTON INTO THE PORTS OF THE UNITED STATES; ALSO THE WEEKLY AND TOTAL EXPORTS OF COTTON TO GREAT BRITAIN, FRANCE, NORTH OF EUROPE AND OTHER FOREIGN PORTS; TOGETHER WITH THE STOCK ON HAND IN THE SHIPPING PORTS; DURING THE LAST TWO YEARS. ARRANGED AND PUBLISHED BY WILLIAM P. WRIGHT, PER J. Y. COTTON BROKER, NEW YORK. (THE FIGURES REPRESENT THOUSANDS OF BALES.)

Table with columns for RECEIPTS, EXPORTS, and STOCK, split into two periods: SEPTEMBER 1, 1854, TO AUGUST 31, 1855, INCLUSIVE and SEPTEMBER 1, 1855, TO AUGUST 31, 1856, INCLUSIVE. Rows include months from Sept. to Aug. and a Total row.

both sides of the Atlantic, are down to a figure which encourages the expectation that quite as much, in the aggregate, will be required for active consumption, at home and abroad, in the course of the year...

To revert to details; our market opened steady in September, 1855, with a fair business, and during the remainder of that month and through October, under the influence of adverse accounts from Mexico, and heavy receipts at the South, a gradual decline in prices having fallen upward of one cent a day for all grades during that period.

November, we received advices of a heavy frost in some of the growing regions, which, in connection with the paucity of our stock, caused a reactionary movement; but the response from Liverpool to our freight accounts not proving as favorable as was expected, the market again took a downward turn, and prices gradually receded for several weeks...

speculation and the price peace port a period of last of Aug of fully on were, durin heavy op bales per seems to h exporters, such an ac recover the pointed, th

Table with columns Date and Price, listing dates from 1854 to 1856 and corresponding price values.

speculative shippers—when prices took another turn, and the improvement obtained on the strength of the peace propositions was quite lost. Subsequently, during a period of many weeks, which brings us down to the last of April, the market was very strong, and a rise of fully one cent was realized. Our domestic spinner were, during nearly the whole of this period, the most heavy operators, taking on an average 12 to 15,000 bales per week. Early in May, a complete change seems to have taken place in the minds of our leading exporters. Large holders, who had been sanguine of such an advance in Liverpool as would enable them to recover their investments in the staple, were disappointed, the market again becoming dull and drooping.

The depression was not of long duration, however, for the reduced supply not only here, but in every part of the United States, now began to attract attention, and holders became indifferent about offering their supplies; and as the high prices checked consumption, the market assumed an inactivity unusual for the season, which continued throughout July and August, holders all the time maintaining an unrelenting firmness.

The year closed with a reduced stock, both here and at the South, and the supply in the manufacturers' hands at the eastward being also limited, the inclination of prices was to a higher range.

The trade of New York has apparently fallen off; a

IV. COTTON GREAT BRITAIN the Cotton Trade The annual average countries into 338,334,984 pounds British authority three fourths, a equal average of which have been of the total quantity pounds for the one sixth of the British possessions

In 1781, Great of cotton to the the quantity the annual average of pounds. In 1848, 146,500 pounds were drawn from 60,000,000 quantity of American to the demand of the part of that import suggests the superior adaptability of the United States half of that in comparison between a difference of the cotton of 12 per cent. of waste, while 12 per cent. of the former.

In 1788, the commenced for the for the improv and the first ex made the same to 4,000,000

in transit cotton were purchasing from twenty to thirty thousand bales per week, and act unfrequently turning the staple over two or three times in the period which used to suffice, under the old system, of making but one fair profit out of it. The theory of certain parties, based upon an incorrect estimate of things as they are, favors the impression that the cotton trade of New York is on the wane, but like all other theories resting only upon the basis of the imagination, it fades away before the recital of the hard facts that stare it in the face.

New York being the centre of the world's trade on this continent—the grand focus of all the latest intelligence from the old world, and all sections of the new; the rendezvous of nearly all the most important lines of ocean steamers, the entrepôt of more than five eighths of the entire foreign commerce of the country, the readiest medium, financially and every other way, between the producer and the consumer, the planter and agriculturist here, and the factor and manufacturer there—New York being all this and much more besides, we repeat, it must continue to control the cotton trade

of the country for a century to come. But it is sometimes inferred that the American cotton trade at large is destined to an eventual decline, in consequence of the constant endeavors of Great Britain to seek new fields for its cultivation by means of what is called free labor, near the pyramids of Egypt, and among the sickly malarias of the East Indies. These experiments, we think, have been sufficiently tested to justify the conclusion, that the cotton planter of the United States has nothing to apprehend, for at least a generation to come, from any competition from these sources. Even did the endeavor to cultivate the plant in the Indies succeed to any considerable extent, it must be conceded that the remoteness of the producer from the manufacturer, must always give us such an advantage, as regards low freights and expeditious transit, as would render the colonial speculation comparatively profitless. There are many other considerations and arguments which might be adduced to substantiate this conclusion, but these, we take it for granted, are not required, to allay any serious apprehensions of domestic ruin from this species of foreign competition.

IV. COTTON TRADE OF THE UNITED STATES WITH GREAT BRITAIN. 1. General Information Respecting the Cotton Trade of the United States.—Great Britain.—

The annual average importation of cotton from all countries into England the last five years has been 838,335,984 pounds, of which quantities, according to British authorities, 601,529,220 pounds, or more than three fourths, were from the United States. The annual average exportation to the Continent and elsewhere has been 122,810,688 pounds, or about one sixth of the total quantity imported, leaving 715,525,296 pounds for the annual average consumption. About one sixth of the whole amount imported was from British possessions.

In 1781, Great Britain commenced the re-exportation of cotton to the Continent and elsewhere. In 1815 the quantity thus re-exported had risen from the annual average of 1,000,000 pounds to that of 6,000,000 pounds. In 1853, the aggregate amount exported exceeded 148,500,000 pounds, of which nearly 83,000,000 pounds were derived from the United States, and more than 60,000,000 pounds from the East Indies. The quantity of American cotton re-exported by Great Britain to the different markets of Europe, when compared with the quantities imported, is much less than that of that imported from other countries—a fact which suggests the superiority of the American article, and its better adaptation to purposes of fabric industry. For example, about one tenth of the cotton imported from the United States is re-exported, against nearly one half of that imported from the East Indies. A comparison between American and East India cotton, shows a difference of 100 per cent. in favor of the former; the cotton of the East Indies containing 25 per cent. of waste, while that of the United States contains only 12 1/2 per cent. The fibre, also, of the latter excels that of the former.

In 1788, the efforts of the East India Company commenced for the promotion of the growth of cotton, and for the improvement of its quality, in British India; and the first exportation of the article to England was made the same year. In 1814 the exportation amounted to 1,000,000 pounds; it now averages 165,000,000

pounds per annum. An area of about 8000 square miles is said to be devoted to the culture. Liverpool is the great mart of the cotton trade of Great Britain and of Europe generally. Thus, while the total imports of the article into the United Kingdom, according to British authorities, in 1852, amounted to 2,357,338 bales, the quantity at this port reached 2,205,738 bales. About six sevenths of the cotton received at Liverpool comes from the United States; and of this four fifths is estimated to be imported for the factories of Lancashire and Yorkshire. Since March, 1845, cotton has been admitted into British ports free of duty. Prior to that period the duty was, of and from British possessions, 8 cents; and from other places, 70 cents per 112 pounds. The number of spindles in operation in England is estimated at more than 20,000,000. The value of cotton supplied by the United States to Great Britain in 1853 was \$57,616,749, being about the average each year the last four. The quantity of cotton exported from the United States to England in 11 months of the fiscal year 1856, is estimated at 2,755,000 bales. It appears from "Commerce and Navigation," that the importation of raw cotton from the British West Indies into the United States has increased, for some years past, in a ratio quite proportional to the decrease of such importation into Great Britain. Thus, the importation of cotton into the United States and Great Britain, respectively, from the British West Indies, from 1851 to 1855, inclusive, was as follows:

Years.	Into the United States.	Into Great Britain.
1851.....	29,529 pounds.	446,529
1852.....	6,756	708,686
1853.....	262,592	844,080
1854.....	159,381	306,072
1855.....	850,217	No data.

The average price per pound of cotton from 1851 to 1855, inclusive, in the United States and Great Britain, respectively, is shown as follows:

Years.	In the United States.	At Manchester, G. B.
1851.....	12 1/4 cents.	12 1-4
1852.....	8.05 "	11 1-4 "
1853.....	9.85 "	12 4-4 "
1854.....	0.47 "	12 3-4 "
1855.....	8.74 "	12 1-1 "

The following statement shows the quantities of cotton imported into Great Britain, and the countries whence imported, from 1840 to 1855. The figures are derived from a "Statistical Abstract for the United Kingdom, presented to both Houses of Parliament, by command of her Majesty," by Mr. Albany W. Fonblanque, superintendent of the statistical department of the Board of Trade. The commercial year in En-

gland begins January 1; in the United States, July 1; hence, seeming discrepancies in figures for apparently the same periods of time. In the following table the column headed Egypt includes Turkey, Syria, and the Mediterranean generally; the East Indies includes British India generally; the West Indies, the West India Islands belonging to Great Britain, and British Guiana:

Annual average.....	124,465,219	66,186,158	2,498,608	407,348	55,852,488

Compiled from the monthly "Accounts Relating to Trade and Navigation," presented to the British Parliament, the only authority at hand from which to ascertain when the cotton exported was imported could be ascertained. Receipts gathered from these monthly accounts are sometimes from those given in the "Annual Statement of the Trade and Navigation of the United Kingdom," from which latter document was made up the table that follows.

Countries to which exported.	Pounds of cotton exported from Great Britain in the years—				Annual average.

The above figures show that the past year's consumption was double that of 1840. The aggregate production of the past 12 years sums up 37,297,500 bales, while the consumption has been 38,212,500; the latter being in excess of the former 925,000 bales, thus reducing the stock or new material by that much since 1845—a startling fact in view of the great interests involved.

From a reliable source of intelligence across the water, we learn that new machinery added to mills now working, together with manufactories now in process of erection, will require in 1857 about 4,000 bales of cotton per week more than the consumption of the present year, making an aggregate of nearly 45,000 bales per week. On the Continent, the extension of manufacturing power is supposed to be going on at about the same rate. Consequently prices will advance till they reach a point tending to a diminution of consumption. What that point will be we have yet to learn. Though the stock of cotton, at present, is larger in Liverpool than last year, it will be reduced very rapidly, as the imports up to the close of the year can scarcely be more than half so large as during the latter months of 1845, and perhaps not even that, in consequence of the lateness of the season and diminished receipts at our ports.

2. France.—Cotton constitutes in value more than two thirds of the domestic exports of the United States to France. By virtue of the treaty of 1822, it is imported, like all other "articles of the growth, produce, or manufacture of the United States," on the same terms, whether in United States or national vessels; but the importation must be direct, and the origin of the article duly authenticated. A ministerial decree

of December 17, 1851, enlarges the provision of the treaty relative to the direct voyage, so far as to extend the equality between the vessels of the two nations when importing cotton, even should the American vessel touch at a British port; but, in that case, the captain is required to exhibit a certificate from the French consul at that port, stating that no commercial transaction there took place. The French government is directing its efforts to the development and extension of the cotton culture in its colonial province of Algeria. To that end, in December, 1853, an aggregate value of 20,000 francs, in prizes, was offered by the emperor to the most successful cultivator of cotton in that province. The result is announced as most favorable. In December, 1854, the entire sum was divided between three rivals, whose merits were judged equal—two of them being French colonists, and one an Arab—a gold medal to each being also awarded. To the meritorious of the second rank, a silver medal to each was presented. The amount produced in 1854 was 180,562 pounds. Next to Great Britain, France is the largest importer of American cotton; and what Liverpool is to the former, Havre is to the latter. At those two points the importations are concentrated, and thence distributed to the different markets of either empire, or re-exported to foreign countries. The re-exportations of France are chiefly to Switzerland by railway; after which country, in this trade, come Sardinia and Holland; smaller quantities being sent also to Spain, the Zollverein and other countries. Next to the United States, France derives her supplies of cotton from the Levant; and the third place is held by South America. These facts are illustrated by the following statements, made up from the "Tableau Général du Commerce de la France," for the year designated. [The quantities are given in kilogrammes, each kilogramme being equal to about 2 1/5 pounds. Kilogrammes multiplied by 9 and divided by 4 will give pounds.]

TABULAR COMPARATIVE STATEMENT SHOWING THE QUANTITIES OF COTTON IMPORTED INTO FRANCE, AND THE COUNTRIES WHENCE IMPORTED, FOR A PERIOD OF THREE YEARS, FROM 1852 TO 1855, BOTH INCLUSIVE.

The only country in Europe which can, in any sense, be said to compete with Great Britain in the supply of the extra European demand for cotton goods is France. And when the character and extent of this branch of the French export trade are described it will be seen that this most formidable rival is not yet much to be dreaded.

TABLEAU COMPARATIVE STATEMENT EXHIBITING THE QUANTITIES OF COTTON IMPORTED INTO FRANCE FROM THE UNITED STATES, AND FROM OTHER COUNTRIES, INCLUDING BRAZIL, WITH THE AGGREGATE, FROM 1820 TO 1855.

1837.....	36,460,000	7,361,000	43,821,000	1855.....	71,807,000	4,214,000	76,021,000				

From the foregoing table it will be seen that the importation of cotton into France from other countries than the United States, including Brazil, from 1820 to 1855, has fallen off more than 50 per cent.; while from the U. States it has increased more than 600 per cent. The French tariff in 1858 imposed five different rates of duty on raw cotton imported in French vessels, according to where it came from; and three other rates of duty, similarly being imposed, on cotton imported in foreign vessels. The duty most extensively operative—that on American cotton entering in French bottoms—was 20 francs per 100 kilograms, or about sixteen shillings per 220 pounds. And as the whole quantity imported (75,021,000 kilograms) yielded to the revenue 17,276,000 francs, giving an average of 22-23 francs per 100 kilograms, it is probable that by far the greater part of what was imported actually paid this rate of duty. The bounty on exportation was 25 francs per 100 kilograms of manufactures or yarn. It was allowed in 1855 on 7,117,864 kilograms of manufacture and on 198,904 kilograms of yarn. This, with a moderate allowance for waste of the raw material, though called a bounty, could in effect have been little, if at all, more than a drawback of the import duty.

It would seem that the French exports in this kind are not more than a tenth in value of our own. And where were they sent, and why? The largest customer for these French manufactures (taking two parts in seven of the whole value) was Algeria; but Algerian consumption may be deemed practically French consumption. The two customers next on the list, when arranged in order of magnitude, are the United States and the United Kingdom. These took between them two other seventh parts of the whole. And the goods sold in the English and American markets are well known to owe their peculiar value rather to the designer and the dyer than to the spinner and weaver. Their consumption does not admit of any very rapid or wide increase. French taste and French chemistry have deservedly won for the French textile fabrics, wherever they are applicable, a superiority as well known as it is incontestable. But this has little effect in determining the locality of the cotton manufacture of the whole. With a few trifling exceptions, of which

cotton lace imported from Belgium is the only one worthy of notice, no cotton foreign manufactures were in 1853 admitted to French consumption.

The following table will show the exports of cotton to France for six years, ending with June 30, 1855, and the value; as also the total value of domestic exports to France during the said years, respectively.

Years.	Pounds.	Value.	Total Value domestic exports.
1850.....	15,538,491	\$14,368,449	\$17,550,271
1851.....	179,164,571	18,214,512	25,328,263
1852.....	186,214,270	15,348,586	22,100,070
1853.....	189,226,913	19,248,076	26,120,806
1854.....	144,428,360	14,522,712	30,905,262
1855.....	210,113,869	19,035,423	31,023,888

French official documents furnish the following facts relative to our cotton trade with that empire. By the custom-house returns for 1855, it appears that there were received for the following years from all countries:

1852..... 168,400,000 pounds.
 1853..... 168,000,000 " "
 1854..... 157,650,000 " "
 1855..... 167,200,000 " "

The following table shows the quantities of cotton imported into Havre from all countries for a period of four years, ending with 1855:

Years.	From the United States.		From Brazil.		From elsewhere.		Total.
	Bales.	Pounds.	Bales.	Pounds.	Bales.	Pounds.

3. *Spain.*—Tabular comparative statement, showing the quantities of cotton imported into Spain, and the countries whence imported, for a period of five years, from 1851 to 1855, both inclusive.

The statistical office has no official Spanish data from which to make up the statement required.

The quantities of cotton exported from the United States to Spain, according to United States' Treasury reports, the year specified, were as follows:

Year.	Pounds.	Year.	Pounds.
1851.....	34,372,925	1854.....	35,024,074
1852.....	29,341,928	1855.....	39,077,705
1853.....	39,851,013	Average (5 years)	33,708,892

From Cuba, in the same years, according to *Balanzas Generales* of that island, the quantities exported to Spain were as follows:

Year.	Pounds.	Year.	Pounds.
1851.....	18,415	1851.....	1,489
1852.....	800,225	1855.....	No data.
1853.....	188,625	Average (4 years)	118,488

From Porto Rico, according to official *Balanzas* of that island, as follows:

Year.	Pounds.	Year.	Pounds.
1851.....	815,083	1854.....	No data.
1852.....	141,807	1855.....	No data.
1853.....	245,852	Average (3 years)	294,147

From Brazil, according to the *Proposta e Relatório* of that empire, for the years 1852-'3, and 1853-'4, the quantities of cotton exported to Spain were as follows:

Year.	Pounds.	Year.	Pounds.
1852-'3.....	2,291,573	Average (2 years)	2,921,428
1853-'4.....	2,851,379		

Spain, according to the *Cuadro General* of that kingdom for 1849, imported that year, from countries of production, 26,150,881 pounds of cotton; of which quantity the United States supplied 21,609,441 pounds; Cuba, 3,371,830 pounds; Brazil, 832,604 pounds; Porto Rico, 370,881 pounds, and Venezuela 21,316 pounds.

4. *Hanse Towns.*—The states of Germany are supplied with the cotton consumed in their factories chiefly through the Hanseatic cities, Hamburg and Bremen. Bremen sent to the Zollverein, in 1853, cotton imported direct from the United States, to the value of \$984,772 1/2, and to Austria to the value of \$156,155 21. The factories of Prussia and Saxony are numerous, and import not only the raw material from the cities, but also large quantities of yarns. The number of spindles in operation in the states composing the Zollverein is estimated at upward of 1,000,000. This is, doubtless, an under estimate, as the industrial enterprise of the Zollverein has made rapid progress since the date of the official document from which these figures are derived. The export of cotton tissues from the Zollverein in 1853 amounted in value to \$2,394,497 3/4, of which amount \$2,075,299 68 in value came from the factories of Saxony.

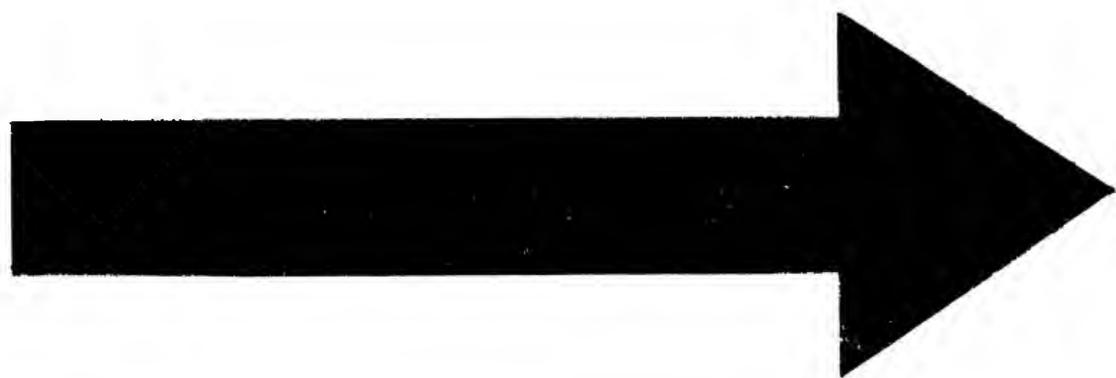

The Hanse Towns, from geographical position, are, and must always continue to be, the great marts from which raw material of all descriptions will be supplied to the states of the Germanic commercial Union. Hence exports of American cotton and tobacco to these points are heavy, and constantly increasing. These commercial cities receive their supplies of raw cotton not only from the United States, in direct trade, as well as from Brazil and other countries of South America, but also in the indirect trade from English ports and other entrepôts of Europe. In 1855, the Zollverein sent through the Hanse ports to the United States cotton fabrics to the value of more than \$1,500,000 in return for the raw material.

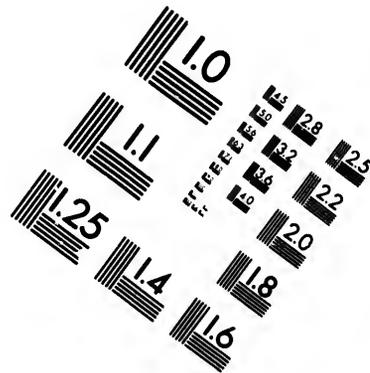

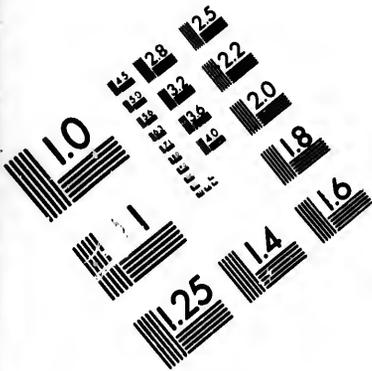

The following statement shows the quantities of cotton exported from the United States to the Hanse Towns every 10 years, for a period of 51 years, from 1805 to 1855:

In 1805.....	Pounds.	In 1835.....	Pounds.
" 1815.....	122,093	" 1845.....	2,688,147
" 1825.....	1,340,283	" 1855.....	17,204,094
" 1835.....	577,109		30,809,931

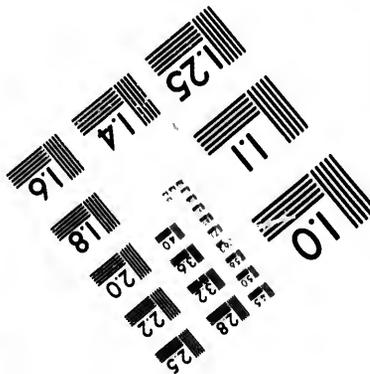

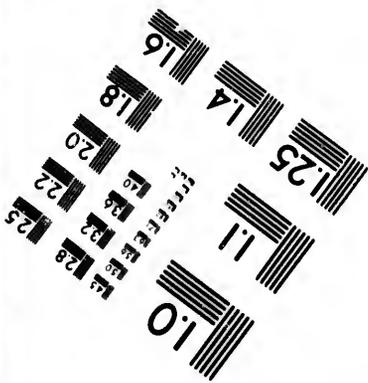

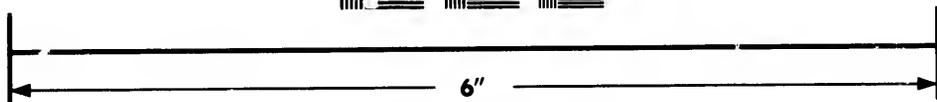

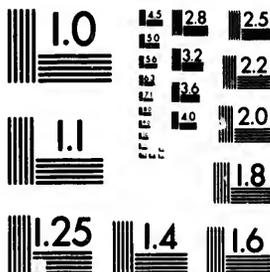

Tobacco is borne in direct voyage from the United States; not so, however, with cotton, in the carrying trade, of which Great Britain has been for many years an active competitor. Entering the ports of the United Kingdom free of duty, her merchant flag can realize a profitable trade in its re-exportation to the various ports of continental Europe. Thus the Hanse Towns receive their supplies of raw cotton not only from the United States in the direct trade, but also in the indirect trade from English ports and other entrepôts of Europe. The annual average quantity of cotton exported from the United States to the Hanse Towns, including Prussia, during the 4 years from 1851 to 1854, both inclusive, was 24,811,626 pounds; while the annual average exports from Great Britain during the 4 years ending Dec. 31, 1854, was 36,563,996 pounds.

The annual average quantities of cotton exported from the same countries, respectively, during the same periods, to the other nations of northern Europe, exhibit similar results. These facts are illustrated by the subjoined statement, and suggest a strong argument for the serious consideration, by the navigation interests of the United States, of such measures as would be likely to promote the direct exportation of our great staple from our own ports, in our own vessels, to those of the countries by which it is consumed.

admitted, as in England, free of duty, the United States would, most probably, supply, in the direct trade, the whole quantity consumed in that empire. As it is, the commercial reforms in Russia, already announced officially, and now in progress, comprehending, as they do, the establishment of American houses at St. Petersburg, must necessarily tend to that result. There are at present in Russia, or there were previously to the war, 495 cotton factories, employing 112,427 operatives, and producing annually 40,907,786 pounds of yarn, and corresponding amounts of textiles.

9. *Sweden*.—The importations of cotton in 1851, according to Swedish official authorities, amount to 7,989,426 lbs. against 1,832,481 lbs. in 1841, and 749,484 pounds in 1831. In 1843, these authorities show an importation of 2,600,000 pounds against 3,833,572 pounds in 1853; which latter amount exceeded that of the importation of 1852 by 1,247,041 pounds, and that of 1850 by more than 6,200,000 pounds, being the largest of any preceding year. In 1848 the amount was 8,074,020 pounds. The value of cotton manufactures exported from Sweden in 1850 was \$46,000 against \$7,500 only in 1851.

10. *Portugal*.—In the year 1855, the quantity of raw manufactured cotton imported into Oporto amounted to 6,697,454 pounds, the value of which is estimated at \$1,516,644, on which the duty paid was \$299,579 13. This kingdom imported 1,911,451 pounds of cotton in 1855, of which quantity 144,006 pounds were exported from the United States, and the residue from Brazil. In 1853-54, according to Brazilian official reports, Portugal received thence 2,673,766 pounds of cotton. Her imports of yarn in 1855 were 1,518,157 pounds, valued at \$171,817 07, and paying an aggregate of duties of \$61,142 84.

11. *Brazil*.—The exportations of cotton from Brazil, in 1843-44 and 1853-54, are stated by Brazilian official authorities as follows:

	Pounds.
1853-54.....	23,429,830
1843-44.....	26,056,100
Increase in ten years.....	2,364,160

The growth and export of cotton from Brazil appear to be nearly stationary. Great Britain, which is the largest customer, imported from Brazil the following quantities:

In 1855.....	22,000,000 pounds.
In 1855.....	22,824,000

In 1852-53 the exportation amounted to 31,933,050 pounds, of which quantity Great Britain received 28,881,201 pounds, Spain 2,291,578 pounds, Portugal 1,896,286 pounds, and France 889,048 pounds. Of the total exportations in 1853-54, Great Britain received 22,575,122 pounds, Spain 2,351,279 pounds, Portugal 2,673,766 pounds, and France, 543,611 pounds. Exports from Brazil to England began in 1781. There are insuperable drawbacks to the extension of the cotton culture in Brazil, among which may be reckoned the ravages of insects, the peculiarities of the climate, and the expense and difficulties attendant upon its transmission from the interior to the coast. It has long since been ascertained in Brazil that the cotton plant will not flourish near to the sea, and the plantations have, in consequence, receded further inland, as well to avoid this difficulty as to seek new and fresh lands. Pernambuco is the principal cotton-growing province of Brazil. The exports from that province were, according to Brazilian authorities, in

	Sales (of 160 lbs. each).	Bales (of 160 lbs. each).
1832.....	70,735	33,549
1830.....	61,152	21,827
1835.....	52,142	19,455

12. *Egypt*.—The cotton culture in Egypt commenced in 1818, and exportation to England in 1823. The comparative tabular statement subjoined, derived from Egyptian sources, showing the quantities exported at the port of Alexandria, and the countries to which exported, respectively, for a period of 8 years, from 1853

to 1855, both inclusive, would indicate an increase in the culture by no means rapid in successive years:

Years.	Pounds of Cotton exported from Egypt to				
	Great Britain.	France.	Austria.	Elsewhere	All countries.
1853....	26,438,900	10,738,500	8,321,000	387,800	45,885,200
1854....	24,988,700	7,454,100	10,155,800	683,500	43,282,100
1855....	23,829,100	9,451,300	13,774,900	683,100	47,738,300
Total....	85,256,700	27,653,900	32,251,700	1,454,400	144,906,700
Average	23,462,900	9,210,600	9,758,700	634,800	43,106,000

If to the aggregate exported be added from 5 to 6 million pounds worked up in the country, a liberal estimate of the annual amount of the cotton crops of Egypt will have been made. The factories established by Mehemet Ali are, it is stated, going rapidly to ruin. The cotton goods manufactured are coarse "cafias," or soldiers' "nizam" uniform. Much cotton is used, also, in making up divans, the usual furniture in Egypt. The Egyptian bale is estimated at Alexandria at 300 pounds. The United States' consul general at that port, in a despatch dated the 1st instant, from which are derived the above facts, says: "The new crop is now coming in, and is supposed to be a little above the average."

13. *Cotton Culture in Mexico*.—The United States' consul at Tampico has furnished the following interesting information, in relation to the varieties, culture, and manufacture of cotton in Mexico, in answer to a circular issued by the Commissioner of Patents in February last: "The greatest production in this country of this article is on the coast of Vera Cruz, and southward from the capital of the State of that name toward Alvarado, and westward toward Tlaxcalapan and in its neighborhood. A little over seventy-five pounds of seed cotton yields, when ginned, twenty-five pounds of cotton wool. The quality is good, and the whole is sent up the country for consumption in the factories of Jalapa, Orizaba, and Puebla. From Vera Cruz to Matamoros, notwithstanding the territory being so extensive, and so admirably adapted for the growth of cotton, none is produced beyond a little in the neighborhood of Papantle, which the Indians cultivate for their own use, and spin in the same primitive manner as did their ancestors at the time of the conquest, viz., by means of a species of wooden spindle, the point of which is put in a common wooden bowl, and its gyrations given by the fingers. From the yarn thus spun they manufacture a narrow cloth, and this is still the custom in many parts of the country. In the neighborhood of Matamoros cotton is raised, but in limited quantities, and is also cultivated in Monclova. One hundred pounds of seed are required to produce twenty-five pounds of clean cotton. All that is produced in these places is consumed in the factories of Saitillo.

"On the west coast mention may be made of Santiago, a place situated between Tepic and Mazatlan, where a considerable quantity is raised, which is disposed of by the factories of Tepic. Further south, and between the towns of Antlan and Colima, and downward toward the sea, a very rich cotton country is to be seen, and where immense quantities could be raised were there more hands to attend to its cultivation; as it is, however, sufficient is gathered for the supply of the factories of Colima, and some of it even finds its way to Guadalajara, the capital of the State of Jalisco.

"From Colima, a stretch must be made to the neighborhood of Acapulco, where cotton is raised, but by no means in abundance; but all that is gathered in that section of the country is sent to the market at the city of Mexico. That part of the country is called 'Costa Grande,' and is separated from the 'Costa Chica' by the river Papagayo. On the latter, and in the neighborhood of Ayutla, cotton is raised, but in limited quantities, and sent to Puebla for sale. The cotton on the whole of this coast only requires seventy-five pounds of seed to produce twenty-five pounds of cotton-wool when ginned. The whole of the east, as well as

that of the west coast, for about 40 leagues inland, is admirably adapted for the growth of cotton. The country is, however, entirely unpopulated, and considerable difficulty is experienced in getting in the harvest in consequence thereof. There are very few landed proprietors who devote their attention to the cultivation of cotton, except on the coast of Vera Cruz. All the rest is raised by small farmers (rancheiros) who are content to get about one half the amount of its value. Such payments are made in a few goods and groceries, in anticipation for which they are charged exorbitant prices. An experiment has been made to raise cotton on a farm about 12 leagues from San Luis Potosi, between 6 and 7 thousand feet above the level of the sea, and the result has been favorable. An enterprising Spaniard is now raising cotton 5 leagues from Tula, with every prospect of a satisfactory return. His farm is not above 4500 or 5000 feet above the level of the sea. No care is bestowed on the plant. The seed is put into the ground, and no further notice is taken of it until it is quite ripe and ready for picking. The consequence is, that the staple is not so long, nor the cotton very fine, although quite good enough for the manufactories of this country. The growth of cotton throughout Mexico is perennial."

V. CAPACITY OF THE COTTON BALE.—The commercial standard of quantity in the cotton trade is generally the bale. The weight of the bale, however, is by no means uniform. Indeed, scarcely any weight, measure, or standard of capacity may be considered less so. It varies, from different causes, in different countries, and in different sections of the same country, at different periods, and according to the different kinds or qualities of the article. Improvements in pressing and packing, to diminish expense in bagging and freight, tend constantly to augment the weight of the bale. Thus, in 1790, the United States' bale was computed at only 200 pounds. In 1824, the average weight of bales imported into Liverpool was 266 pounds; but, increasing constantly, 12 years later the average was 319 pounds. McCulloch, however, has considered 800 to 810 pounds a fair average; and in 1830. At the same time, the upland cotton bale was estimated at 320 pounds, and the sea island at 280 pounds. According to Pitkins, the Egyptian bale weighed at one time but 90 pounds, though it now weighs more than 8 times as many. At the same period the Brazilian bale contained 180 pounds, though it now contains but 160 pounds, while the West Indian bale weighed 850 pounds, and the Colombian bale 101 pounds, or the Spanish quintal. According to Burns, the United States' bale at Liverpool averaged 845 pounds, the Brazilian, 180 pounds, the Egyptian, 220 pounds, the West Indian, 300 pounds, and the East Indian, 890 pounds. At the Lowell factories, in 1831, according to Pitkins, the bale averaged 361 pounds. In 1836, the bale of the Atlantic cotton States was estimated at 300 and 325 pounds, and that of the Gulf States at 300 and 450 pounds. In Liverpool, at the same time, the estimate for the bale of upland or short staple cotton was 321 pounds; for Orleans and Alabama, 402 pounds; for sea island 322 pounds; for Brazil, 173 pounds; for Egyptian, 218 pounds; for East Indian, 360 pounds; and for West Indian 280 pounds; while, according to Burns, bales imported into France were computed at only 200 pounds each. Waterston's *Manual of Commerce*, a reliable British publication (1855), gives the Virginia, Carolina, Georgia, and West Indian bale at 300 to 310 pounds; that of New Orleans and Alabama at 400 to 500 pounds; East Indies at 320 to 360 pounds; Brazil at 160 to 200 pounds; Egyptian at 180 to 280 pounds. Alexander's *Universal Dictionary of Weights and Measures* gives the bale of Alabama, Louisiana, and Mississippi at 500 pounds, that of Georgia at 375 pounds, and that of South Carolina at 362 pounds. At Rio de Janeiro the Brazil bale is estimated at 160 pounds.

Prior to 1855, the United States' "Commerce and Navigation" gave exports of cotton in pounds only. They are now given in bales as well as in pounds—the aggregate amount of the year ending June 30, 1855, being 2,300,408 bales, or 1,008,424,601 pounds: the bale, accordingly, averaging about 438 pounds. Some bales, however, are evidently much heavier, and some much lighter than this. For example, the 210,113,809 pounds of cotton exported to France give 446 pounds to each of the 470,298 bales; and the 955,114 pounds exported to Austria give 492 pounds to each of the 1,989 bales; while the 7,527,079 pounds exported to Mexico give only 290 pounds to each of the 25,917 bales in which they were contained.

Liverpool Weight.—The relative average weights and cubical contents of bales of cotton imported into Liverpool, in 1852, are thus given:

Description of bale.	Average wt. in lbs.	Contents in cu. ft.
Mobile.....	394	83
New Orleans.....	455	82
Upland.....	390	87
Sea Island.....	338	95
East Indian.....	333	15
Egyptian.....	245	27
West Indian.....	213	25
Brazilian.....	189	27

These figures show not only the great variety of bales that enter Liverpool, but that the most eligible form of bale is that of the East Indies—double the weight being packed within the same compass as in any other description of bale. In the great cotton marts of Liverpool and Havre, as in those of New Orleans and Mobile, the article is almost invariably treated of by merchants, brokers, and commercial men, by the bale. Thus, a report on the trade of Liverpool gives the import of cotton into Great Britain, in 1852, at 2,537,838 bales. The aggregate of cotton imported in that year is given in the official report by the Board of Trade, at 629,782,448 pounds; the bales averaging, accordingly, 395 pounds each.

Cotton Manufacture. This subject will be considered under the general heads of, I. Origin and Introduction. II. Invention and Improvements. III. Cotton Manufactures of Foreign Countries. IV. Statistics of Cotton Manufacture. V. Origin and Early History of Cotton Manufactures in America. VI. Cotton Manufacture in the United States.

I. ORIGIN AND INTRODUCTION.—The manufacture of cotton had its origin in the East, where the cotton plant is indigenous, and where the climate renders a light and absorbent fabric a suitable clothing for the people. It has in consequence been long established over every part of Asia, although it was only in India that the fabric was manufactured extensively, with a view to foreign exchange. Ariari mentions cotton cloth among the commodities which the Romans brought from India; but the quantity imported by them was inconsiderable, arising from the preference which they gave to woolen clothing. Dr. Robertson remarks, that the difference between the cargoes imported from India in ancient and in modern times appears to have arisen, not from any diversity in the nature of the goods prepared for sale in that country, but from variety in the tastes or in the wants of the nations with which they have successively traded.

The antiquity of the manufacture of cotton can not be reached by any authentic records. Neither wool, silk, nor linen, can claim a higher antiquity. One thing is pretty certain, that its first manufacture may be traced to India, whence it passed to all the rest of the world. India, indeed, has been the source of many of the arts of civilized life. It was, in all probability, the cradle of mankind, and the source of Assyria, Egyptian, and Persian civilization.

The Indians have in all ages maintained an unapproached and almost incredible perfection in their fabrics of cotton. Indeed, some of their muslins might be thought the work of fairies or insects rather than of

* Bala

man; but these are produced in small quantities, and seldom have been exported. In the same province of India from which the ancient Greeks obtained the finest muslin then known, namely, Bengal, these astonishing fabrics are manufactured at the present day.*

We are told by two Mohammedan travelers, who went to India in the 9th century, that "in that country they make garments of such extraordinary perfection, that nowhere else are the like to be seen. They are woven to that degree of fineness, that they may be drawn through a ring of moderate size." Marco Polo, in the 16th century, mentions Coromandel, and especially Masulpatam, as producing "the finest and most beautiful cottons that are to be found in any part of the world;" and this is still the case as to the flowered and glazed cottons, called chintzes.

The Portuguese adventurers who went to India immediately after the discovery of the route by the Cape of Good Hope, speak of "the great quantities of cotton cloths admirably painted, also some white, and some striped, held in the highest estimation, which were made in Bengal." Caesar Frederick, a Venetian merchant, who traveled in India in 1663, describes the extensive trade carried on between St. Thomé (a port 150 miles from Negapatam) and Pegu, in bumbaest (cotton) cloth of every sort, painted, which is a rare thing, because this kind of cloth shews as if it were gilded with divers colors; and the more they are washed, the livelier the colors will become. And there is made such account of this kind of cloth, that a small bale of it will cost 1000 or 2000 ducats.

Tavernier, who traveled in India about 200 years ago, speaks of the white calcoes (so called from the city of Calcutt, in India, where they were first seen by Europeans), or muslins woven in Bengal, and rendered so remarkably white by being dipped in lemon juice. He says: "Some calcoes are so fine that you can hardly feel them in your hand; and the thread, when spun, is scarcely discernible." The same writer says that "there is made at Seceeng, in the province of Malwa, a sort of calicot so fine, that when a man puts it on, his skin shall appear as plainly through it as if he was quite naked; but the merchants are not permitted to transport it, for the governor is obliged to send it all to the Great Mogul's seraglio and the principal lords of the court, to make the sultaneses and noblemen's wives' shifts and garments for the hot weather. And the king and the lords take great pleasure to behold them in these, and see them dance with nothing else upon them." Speaking of the turbans of the Mohammedan Indians, Tavernier says: "The rich have them of so fine a cloth, that 25 or 30 ells of it put into a turban will not weigh 4 ounces."

Eighteen hundred years ago, according to Arrian, author of the "Periplus," there were thousands of men, women, and children employed at Baroche, in Guzerat, and the adjacent villages, in the manufacture of cotton, from the coarsest sail-cloth to the finest muslins. So that it is a great mistake to suppose that cotton manufactures are of a modern origin. They existed in India centuries before the Christian era.

The ingenuity of the Hindoo cotton manufacturers is truly wonderful. The late Rev. William Ward, a missionary of Serampore, says that "at two places in Bengal muslins are made so exceedingly fine that four months are required to weave one piece, which sells at 500 rupees. When this muslin is laid on the grass, and the dew has fallen upon it, it is no longer discernible." We might cite a great number of creditable authorities in proof of the fineness of India cotton manufactures, and the ingenuity of the Hindoos, but these will suffice. The oriental hyperbole, which describes the muslins of Decca as "*webs of woven wind*," is less poetical than is generally supposed. No modern European manufacturer of cotton at all approaches the Hin-

doos in respect to the fineness of his fabrics. The extreme of fineness to which yarns for muslins are now spun in Great Britain is 250 hank to the pound, though cotton yarn has been spun in England making 850 hanks to the pound. This was, however, only an experiment, to ascertain how fine cotton could be spun. No such yarn is or could be used in making muslins, or for any other purpose. The Hindoos are the only ones who have ever woven such yarn into fabrics.—Dr. Bow's *Industrial Resources*.

The implements used by the Indians in the different processes of the cotton manufacture, from the cleaning of the wool to its conversion into the finest muslin, may be purchased for the value of a few shillings, and are so rude and simple a construction as to be evidently the invention of a very early period. With the exception of the loom, none of them deserve the name of a machine, or display the slightest mechanical ingenuity. They spin the yarn upon the distaff; and yet, with all the advantages which we in this country derive from machinery, we have only recently been able to equal, either in fineness or quality, the yarn which is produced by means of this primitive instrument. The well managed use of the finger and thumb of the Indian spinner, patiently and carefully applied in the formation of the thread, and the moisture at the same time communicated to it, are found to have the effect of incorporating the fibres of the cotton more perfectly than can be accomplished by our most improved machines.

The loom is composed of a few sticks or reeds, which the Indian carries about with him, and puts up in the fields under the shade of a tree, or at the side of his cottage. He digs a hole large enough to contain his legs and the lower part of the "ger," and fastens the balance to some convenient branch over-head. Two loops underneath the ger, in which he inserts his great toes, serve as traddles; and he employs the shuttle, formed like a large netting-needle, but of a length somewhat exceeding the breadth of the cloth, as "battoon," using it alternately to draw through the warp and strike it up. The reed is the only part of the weaving apparatus which approaches, in the perfection of its construction, to the instruments we use. The loom has no beam, and the warp is laid out upon the ground the whole length of the piece of cloth. The weavers live entirely in villages, as they could not, if shut up in towns, work in this manner. Upon this rude machine, worked in the way we have mentioned, the Indians produce these muslins, which have long been such objects of curiosity from the exquisite beauty and fineness of their texture.

It is probable that the whole of the implements which we have just described existed as we now find them before the people of India were divided into castes. The transmission of the same employment from father to son (which, although not specially enjoined by the Hindoo code, is the invariable practice in India), while it has the effect of conveying unimpaired the knowledge acquired in any art, tends to check its further advancement. It is the opinion of Mr. Rickards, who so ably advocated the interests of the natives of India in the discussion in the British Parliament on the renewal of the Company's charter (1814), that latterly this form of society, with all its dependencies, habits, and restraints, has been held together chiefly by the oppression of the fiscal exactions, the want of a free trade, and the consequent universal poverty of the people. In support of this opinion, he refers to what the Hindoo population of Calcutta and Bombay have achieved in the pursuits of commerce. We trust, however, that we may now look forward to the speedy abolition of this system, so much opposed to all development of talent; and which, by reducing man to the condition of a machine, has paralyzed the exertions and arrested the improvement of the people of India.

* Baine's History of the Cotton Manufacture, p. 55.

To the same cause, however, which thus prevented improvement in India is to be attributed that dexterity in his particular employment which the Indian artisan possesses. From the earliest age he learns to spin and weave under the direction of his father; and having no hope or desire of advancement in any other line, he gains, through constant practice, that wonderful skill, which may thus be considered almost as a family inheritance. To be able to manage his ill-constructed loom, even in the production of ordinary fabrics, he is obliged to acquire such a sleight of hand, that it is not surprising if, out of the multitude trained in this manner, a few should be found capable of producing those muslins which are said, when spread upon the grass, to appear like the gossamer web. From the superiority of these goods, and from their retaining the beauty of their appearance longer than European muslins, it has been supposed that the cotton of which they are made is of better quality than any known to the European manufacturers. This, however, is a mistake; there is no cotton in India of a quality superior to the best sea islands. The excellence which these muslins possess is to be ascribed wholly to the skillful tact of the workman in the processes of spinning and weaving. The long cloths and fine pulicats are made chiefly within the presidency of Madras, the coarse piece goods and pulicats in Surat, the finest calicoes at Musulipatam, and table-cloths of a superior quality at Patna. Each district varies from the others in the nature of its productions, as may be seen from the different denominations of cotton goods to be found in every consignment coming from India.

An apprehension has sometimes been expressed that the inhabitants of India, in possession of the raw material, may obtain a knowledge of machinery, and by combining with its peculiar advantages their cheaper labor and superior manual dexterity, may be enabled to undersell to such a degree as to ruin and put an end to British manufacture; but in the state of the people of India there are circumstances which render this impossible, without a change being first produced upon

COMPARATIVE STATEMENT OF THE COST OF ENGLISH AND INDIAN COTTON YARN IN THE YEARS 1812 AND 1850, FURNISHED BY MR. KENNEDY OF MANCHESTER TO THE COMMITTEE OF PARLIAMENT ON EAST INDIA AFFAIRS, AND CONTINUED TO 1854.

It might have been expected that this change would have produced most distressing effects upon the crowded population of a country such as India, which in all ages has been a great manufacturing and exporting community; but no materially unfavorable consequences have resulted from it. In India, every manufacturer is, at the same time, a husbandman. When not employed in making a web, he supports his family by agricultural labor. It thus happened, that in proportion as the demand for goods for export declined, the natives, without difficulty, and without that distress which generally attends a change of employment in other countries, were able to direct their attention more and more to agriculture; and the result has hitherto been rather an improvement in their condition than otherwise.

The cotton manufacture of China is of immense amount, and is carried on almost entirely for home consumption; but its origin is not of the same remote

their moral condition, their institutions, and their habits. The training which makes the Indian, with such imperfect tools, able to perform his work so well, disqualifies him from doing it in any other way, or with any other implements than those to which he has been familiarized from his infancy. The attempt to introduce machinery into India is, however, now being made. A spinning-mill has been built at Calcutta; and although the private company which commenced the undertaking has failed, the work continues to be carried on. There are at present nearly 700 persons employed in the mill, engaged at the rate of about seven shillings each per month; but these people, it is found, can not continue to work beyond a few hours at a time; and a succession of hands to carry on the operations through the day is required. To train them, in such circumstances, to dexterity and skill is impossible; and, accordingly, the yarn spun is not only of inferior quality, but even with the low nominal wages, costs so much as to disqualify it for competition with the yarn of Great Britain. An attempt is now being made to establish a cotton-spinning mill at Bombay.

The extensive introduction of machinery into Great Britain has, meanwhile, by reducing the price of manufactures, enabled them to maintain a successful competition with the Indian goods at home, by sending cotton manufactures to a large amount to India itself. A complete revolution has in consequence taken place in the nature of the exports from that country to Europe, and, indeed, to all the markets on this side of the Cape of Good Hope. When England first got possession of India, her investments at home were principally (in point of value almost entirely) composed of manufactured produce. They are now, in a great measure, made up of the produce of the soil, indigo, cotton, wool, raw silk, saltpetre, &c., etc.

The following table shows the difference of the cost of cotton yarn produced in India and in Great Britain, and indicates the changeless nature of unaided human labor in the former, whilst by mechanical appliances in the latter, cheapness and plenty result:

date as that of India. Indeed, the lateness of its rise, and the slowness of its progress, in a situation so favorable, appear extraordinary. In the accounts of the revenues and of the arts in China during the period of the celebrated dynasty, which commenced about 1100 years before the Christian era, and lasted for some centuries, no mention is made of the cotton plant; nor, indeed, is there any notice of cotton in these records until about 200 years before the Christian era; from which period to the sixth century, the cotton cloth, which was either paid in tribute, or offered in presents to the emperors, is always mentioned as a thing rare and precious.

The cotton-tree was introduced into China at the time of the conquest of that country by the Mogul Tartars, in the year 1280; after which period every encouragement was given by government to the culture and manufacture of cotton. But there were considerable difficulties to be encountered, in the preju-

dices of the people, and in the opposition of those engaged in the manufacture of woolen and linen; and it was not until the year 1868 that these obstacles were altogether surmounted. After that date the progress of cotton manufacture was rapid, and now nine tenths of the population are clothed in its fabrics.

Almost the only cotton goods exported from China are nankeens. Barrow states the production of all the fabrics of the Chinese manufacture at the time he visited the country (in 1782), to be stationary, attributing this to the want of proper encouragement from the government, and to the rigid adherence of the people to ancient usages. To keep a manufacture in a progressive state, there must be a progressive demand for its products; and the Chinese manufacturers having no means of disposing of any surplus quantity, must accommodate the supply to the wants of their own consumption. It is said by travelers who have obtained access to that country, that the people show a great desire for articles of foreign manufacture. How valuable, then, to that country, as well as to others, must be the establishment of a free intercourse, and how conducive, probably, to the increase of the productions of all! The Chinese, over and above the cotton wool which they raise at home, import largely from British India, and from the Burmese territories. This intercourse commenced toward the close of the eighteenth century.* A famine, which happened in China about that period, induced the government to direct, by an imperial edict, that a greater proportion of the land should be thrown into the cultivation of grain. Since then, the importation of cotton from India has been considerable, although constituting but a small part of what is consumed in their manufacture. The amount of their importations is stated at 40,000 bales.

Introduction into Europe.—The manufacture of cotton goods in Europe is said to have been first attempted by the commercial states of Italy, before the discovery of the passage to India by the Cape of Good Hope. These enterprising communities were the entrepôts through which the cotton fabrics of India passed to the different markets of the West; and being situated in the neighborhood of countries where the cotton wool was grown, and familiar with manufacturing processes, it is supposed that they were led to attempt the imitation of articles so much valued, and bringing so high a price. Another account assigns the introduction of the cotton manufacture into Europe to a later date, and gives to the people of the Low Countries the honor of having been the first manufacturers of these articles, in imitation of the cotton fabrics which the Dutch, about the beginning of the seventeenth century, began to import from India. But this last account can not be correct; for Guicciardini, in 1560, in a very full list which he gives of the different articles annually imported into and exported from Antwerp, then the greatest commercial mart in Europe, specifies fustians and dimities of many fine sorts among the manufactured articles imported from Milan, and mentions cottons generally among those brought from Venice. But in the articles exported from Antwerp, although we find linens sent to almost every country, cotton cloth is not once mentioned. Italy, therefore, at that time had a cotton manufacture, which, it is probable, soon after made its way to the Netherlands; for we know it was brought from the latter country to Britain by Protestant refugees about the close of the sixteenth or early in the seventeenth century.

For the introduction and after improvement of many of these articles, Great Britain is indebted to the late Mr. John Wilson, of Ainsworth. This gentleman was originally a manufacturer of fustians at Manchester, but had early engaged in the manufacture of cot-

ton velvets, which by persevering efforts he succeeded in bringing to the utmost degree of perfection. His improvement of the mode of dressing, of finishing, and particularly of dyeing these goods, acquired for them so high a character, that both in the home and foreign market his articles sold in preference to those of every other manufacturer. His plan for cleaning off the loose and uneven fibres, was by the use of razors. He afterward successively employed for this end, singeing by spirits of wine and the application of a hot iron resembling a weaver's drying iron, which last instrument had been introduced for the same purpose in the manufacture carried on in the Manchester House of Correction by Mr. Whitlow, governor of that institution. At a later period, Mr. Wilson effected his object by drawing the goods rapidly over a cylinder of cast iron heated to redness, by which they were in a superior manner cleared of the down or pile which had been raised upon them in the various operations of weaving, washing, bleaching, or dyeing. These successive inventions of Mr. Wilson, for performing this process, give us some idea of the manner in which improvements are introduced into the manufactures, when, fortunately, the efforts of self-interest are directed by intelligence and talent. Mr. Wilson, having a turn for chemical inquiries, investigated the different known processes of dyeing; and, by the improvements he introduced in the application of them to his own manufacture, materially advanced that art. Having succeeded to his satisfaction in dyeing the other rich colors, he procured from the Greeks of Smyrna, the secret of dyeing Turkey red. An account of this process was given by him in two essays, read to the Philosophical and Literary Society of Manchester, and which, on his retiring from business, he printed and distributed among his friends. The many valuable improvements introduced by Mr. Wilson into the different processes connected with the cotton manufacture had the effect not only to establish it more firmly, but rapidly to enlarge its extent.

II. INVENTIONS AND IMPROVEMENTS IN COTTON MANUFACTURE.—It has been said that the yarn produced a century ago in England, by the one-thread wheel, the only spinning machine known, did not exceed in quantity what 50,000 spindles of the present machinery can yield. To have reared and trained hands sufficient to have doubled this quantity, had it been possible, must have been the work of a length of time, and the amount of manufacture would still have been insignificant. A change in the system, therefore, had become indispensable; and we find that different ingenious individuals had already begun to employ themselves in contriving a better mode of spinning. When we contrast the splendid inventions connected with the cotton manufacture, which from this period burst forth in rapid succession, with the passive acquiescence in the use of imperfect machinery during the long period which preceded, we are apt to ascribe these improvements to the circumstance alone of a number of men of genius having at that moment arisen, and to forget that the ultimate cause exists in the times which called their energies into action. About the year 1750, the fly-shuttle had been invented by Kaye of Bury—one of the most important steps in the progress of the art of weaving; and in the year 1760 improvements had begun to be made in the carding process.

James Hargreaves, a weaver at Stanhill, near Church, in Lancashire, England, an illiterate man, possessed of no great mechanical knowledge, had adapted the stock cards, used in the woolen manufacture, to the carding of cotton, and had besides greatly improved them. By his invention a person was able to do double the work, and with more ease than by hand-carding. In the stock cards, one of the cards is fixed, while the other, being suspended by a cord over a pulley, is worked by the carder; and in this way, two or three cards can be applied to the same stock. This

* See Macpherson's *Annals of Commerce*.

contrivance was soon succeeded by the cylinder cards, or carding engine. It is not ascertained who was the inventor of this valuable machine; but it is known that the father of the late Sir Robert Peel was among the persons who first used it; and that, so early as 1762, he, with the assistance of Hargreaves, erected a carding engine with cylinders, at Blackburn. This machine did not differ materially from that now in use, except that it had no contrivance for detaching the cotton from the cards, an operation which was performed by women with hand-cards.

These successful advantages show that the minds of the manufacturing class had been awakened to discovery, and must have encouraged and stimulated the efforts that were then making to effect corresponding improvements in spinning.

There had been several unsuccessful attempts to improve the mode of spinning before the year 1767, when James Hargreaves, whom we have already mentioned, invented the "spinning-jenny." The idea of this machine is said to have been suggested to him by seeing a common spinning-wheel, which had been accidentally overturned, continue its motion while it lay on the ground. If such was the cause, it marks a mind of no common description, which from so casual an occurrence could elicit an invention of so much importance. After several unsuccessful attempts to carry into execution the conception he had formed, he succeeded in producing a rudely-constructed jenny of eight spindles, turned by hands from a horizontal wheel. In it the eight rovings were passed between two pieces of wood laid horizontally the breadth of the machine; and these being grasped in the spinner's hand, and drawn out by him, formed the rovings into threads. The structure of this jenny was soon afterward greatly improved, and it was at last brought to work as many as eighty spindles. This machine, although of limited powers when compared with the beautiful inventions which succeeded it, must be considered as the first and leading step in that progress of discovery which carried improvement to every branch of the manufacture—which, as it proceeded, changed the nature and character of the means of production, by substituting mechanical operations for human labor—which caused the manufactured article to become more and more a product of capital. The progress of invention after this was rapid; for when it was seen that, with the aid of the few mechanical combinations we have mentioned, the spinner had been enabled to increase his power of production eightyfold, the attention of those engaged in other branches of manufacture, was awakened to the possibility of introducing changes equally beneficial into their peculiar employments.

Hargreaves' invention occasioned great alarm among those who earned their subsistence by the old mode of spinning, and even produced popular commotion. A mob broke into his house and destroyed his machine; and some time after, when a better knowledge of the advantage of his invention had begun to bring his spinning-jenny into general use, the people rose a second time, and scouring the country, broke to pieces every carding and spinning-machine they could find. Hargreaves himself had by this time removed to Nottingham, where he was engaged in erecting a small spinning-work, about the same period that Mr. Arkwright came to settle there, who had also been driven from Lancashire by the fear of similar violence.

The jenny in a short time put an end to the spinning of cotton by the common wheel; and the whole wools used in the manufacture continued to be spun upon that machine, until the invention of the "mule-jenny," by which it was in its turn superseded. Hargreaves died, in great poverty, a few years after his removal to Nottingham.

While Hargreaves was producing the common jenny, Mr. Arkwright (afterward Sir Richard Arkwright) was employed in contriving that wonderful

piece of mechanism, the spinning-frame, called first the water-frame, and afterward the throstle, which, when put into motion, performs of itself the whole process of spinning, leaving to the workman only the office of supplying the roving or prepared material, and of joining or piecing the thread when it happens to break. In the year 1769, Mr. Arkwright obtained his patent for spinning with rollers, and Mr. Need, and Mr. Strutt became his partners in the concerns to be carried on under it. He erected a mill at Nottingham, which he worked by horse-power. But this mode of giving motion to the machinery being expensive, he, in the year 1771, built another mill at Cromford, in Derbyshire, to which motion was given by water. We shall now proceed to give an account of the different machines used in cotton-spinning, invented by Sir Richard Arkwright, and of those afterward invented by others, describing them in the order in which they are employed. In this manner we shall be able to exhibit a view of the present state of the art. The instruments used in the preparation and spinning of cotton-wool, are the following:

The opener; the scutcher, and spreading-machine; the carding-engine; the lap-machine; the drawing-frame; the slabbing fly-frame; the intermediate fly-frame; the finishing fly-frame; the throstle-frame for coarse warps; the self-acting jenny for numbers below 50; and the hand-mule jenny for higher numbers. The first three of these instruments are employed in the rude process of cleansing the raw cotton, and separating its matted locks. In the carding-machine it is carded and further purified; in the lap-machine it is fashioned in flat folds; and in the drawing-frame it is formed into a loose rope, the fibres of which have a parallel arrangement. In the slabbing-frame it is slightly twisted; and in the intermediate and finishing-frame it is still further twisted, particularly in the higher numbers; but it is not yet yarn. The throstle-frame is chiefly used for coarse warps; while upon the self-acting and hand-mule jennies, both coarse and fine yarns are spun.

This description of the carding-machine is still applicable for numbers of yarn above 100, which are made from sea-island cotton. For numbers above 50, a system of twice carding it is still employed. The engines are generally 36 inches wide. The cotton is partially carded in the breaker or first card; it is then re-formed into a lap; and is lastly passed through the finisher or second card; for the finest yarns, however, combing is substituted.

To make the operations of the various machines just enumerated more plain, we will give the metaphors of a bale of cotton, from the time it is brought to the manufacturers until it becomes yarn ready to be made into cloth. Women and girls in the mill take the cotton from the bale by handfuls, and feed with it the opening-machine. The cotton, laid upon an endless apron, is caught between the teeth of revolving rollers, which effectually tear and separate the locks asunder; the cotton is opened into a light and flocculent mass, and the few remaining seeds and the dirt are expelled. Then the scutching-machine comes into requisition; again is the cotton placed upon an endless apron, and again exposed to the action of revolving rollers; and the impurities are yet further separated, and the beautiful downy cotton becomes lapped in a continuous sheet upon a cylinder. These sheets of down—these softest of all soft layers—how do we convert them into delicate yarn? The broad, soft sheets go to the carding-machine, where a number of wire combs, or rather wire brushes, comb the cotton out into straight fibres; and these fibres are dexterously whipped off by a "doffing" apparatus, to assume the form of delicate, narrow ribbons, or *slivers*. Next we see all these slivers joined by another machine, so as to form a continuous lap; and this lap is again carded and doffed, by which the substance becomes equalized

as much to the state into use the yarn or the roving-machine we see in cotton is and gives delicate yarn elaborated

as much as possible. The cotton is thus again brought to the state of a ribbon or sliver; and then are brought into use the machines which convert this ribbon into a yarn or thread. The drawing, the slubbing, and the roving-machines, all have relation to this conversion; we see numerous pairs of rollers, between which the cotton is drawn; the drawing rounds it, equalizes it, and gives it a slight twist; until at length we see the delicate yarn—fine, perchance, as a spider's web—elaborated from the thick but soft ropes of cotton.

More correctly, however, we should say that the cotton does not become yarn till after the spinning. Nothing excites more astonishment in cotton factories than the self-acting mule. The complex carriage, 20 or 30 feet long, with its army of spindles (sometimes as many as 800 in number), travels slowly to and fro, and draws out delicate threads to a state of still greater delicacy and tenacity; the drawing out thins the cotton, the rapid revolution twists it; and thus by drawing and spinning do the Houldsworths and the Bazleys of the nineteenth century produce cotton-yarn whose fineness almost exceeds belief. And while the mule-machine is thus making fine yarn for wet-threads, the throstle-machine, by a different mode of action, produces the stronger yarn for warp-threads; then again, if it be sewing-cotton, or hosiery-cotton that is required, we trace the yarn to the doubling-machine, where two or more are twisted, one around another, whereby a much denser thread is produced. The amount of machinery in the spinning-rooms of some of the mills is astonishing; in some cases 75,000 spindles whirling away at once in one room, each one requiring the co-operation of a number of other delicate little pieces of mechanism.

We have noticed, in speaking of the carding-engine, which Mr. Peel erected in 1762, that at that time the cotton was taken off the finishing-cylinder by means of hand-cards. But by the time Mr. Arkwright began his spinning, this operation was performed by the application of a roller with tin plates upon it like the floats of a water-wheel, which, revolving with a quick motion, scraped off the cotton from the card. This was a rude contrivance, and in its operation injured both the cotton and the cards. Mr. Arkwright substituted for it a plate of metal, toothed at the edge like a comb, which, in place of being made to revolve like the other, was moved rapidly in a perpendicular direction by a crank, and with slight but reiterated strokes on the teeth of the cards, detached the cotton from them in a uniform fleece. He employed narrow fillet-cards, wound round the doffing-cylinder in a spiral form, by which contrivance a continuity of fleece was produced, which, as it left the card, was gradually contracted in its size by being passed through a kind of funnel, and then flattened or compressed between two rollers; after which it was received into a tin can in the state of a uniform, continued carding. The taking off the cotton from the cards in this manner, is one of the most beautiful and curious operations in the process of cotton-spinning; and although the crank, which forms a part of the apparatus, had perhaps been used in some way or other prior to the date of Mr. Arkwright's second patent (as was urged in the action for having it set aside), the comb for taking off the fleece, and the spiral card which produces its continuity, were inventions indisputably his own.

Description of the Mule-jenny.—The mule, in its structure and operation, is a compound of the spinning-frame and of Hargreaves' jenny, from which circumstances it has probably received its name. It contains a system of rollers like that belonging to the twist-frame; but in place of having every four or six of them in separate hands, as is the case in that machine, the whole are coupled together; and the rove being drawn through them, is, in its conversion into thread, received on spindles revolving like those of the jenny. The carriage on which these spindles are placed is

movable, and is made to recede from the rollers a degree faster than the thread is given out. After a certain quantity of the roving has been thus delivered by the rollers, they are stopped; but the carriage continues to recede somewhat further; and the spindles continuing also to revolve, the thread is drawn out to the fineness required, and then receives its proper portion of twist. This last operation resembles that performed by the common jenny, and produces a similar effect.

In an account of the means which contributed to that fall in the price of spinning which we have mentioned, we must not omit the progressive improvement in the cultivation of the raw material, and in the application of its different qualities to their most profitable uses. Previous to the year 1793, the cotton used in the coarser articles of the manufacture, with the exception of a small quantity imported from India and from the Levant for the fustian-trade, was wholly the growth of the English and of the French West India Islands. That for the better kind of goods was raised in Demerara, Surinam, and Berbice. The wool for fine goods was grown in the Brazils; and that for the few very fine muslins then manufactured, in the Isle of Bourbon.

In 1787 the descriptions of cotton imported into Britain appear to have been as follows:

	Pounds.
From the British West Indies.....	6,500,000
From the French and Spanish colonies....	6,000,000
From the Dutch.....	1,700,000
From the Portuguese.....	2,500,000
From the Isle of Bourbon, by Ostend....	100,000
From Smyrna and Turkey.....	6,700,000
Total.....	23,900,000

Had Britain continued to derive her sole supply of cotton from these countries, the progress of the manufacture would have been greatly retarded, not only from the difficulty of making the production of the raw material keep pace with the increasing consumption, but from the impossibility of obtaining the qualities of wool suited to the finer descriptions of goods, which the improved machinery enabled us to undertake.

The year 1770 has always been stated as the period at which the planters of the southern States began to turn their attention to the raising of cotton-wool. But we happen to know that in 1764, William Rathbone, an extensive American merchant in Liverpool, received from one of his correspondents in the southern States a consignment of eight bags of cotton. This cotton, on its arrival at Liverpool, was seized by the custom-house officers, on the allegation that it could not have been grown in the United States, and that it was liable to seizure under the shipping-act, as not being imported in a vessel belonging to the country of its growth. When afterward released, it lay for many months unsold, in consequence of the spinners doubting whether it could be profitably worked up. But fortunately, about the year 1770, the planters in the southern States began to turn their attention to raising cotton-wool; and besides carrying the cultivation of the article to a great extent, they produced qualities of cotton before unknown. In 1792 the quantity of cotton exported from the United States was only 138,328 lbs., no manufacture of cotton goods having been attempted in America for many years after that period. In 1831 they exported 619,000 bales to Great Britain, 127,000 to France, and 27,000 to other parts. In 1845 the quantity grown in the United States was 2,100,537 bales, and it is estimated that 3,500,000 bales will be shipped in 1857.

The American cotton-wool first taken to Great Britain was very ill-cleaned, and, in consequence, was indiscriminately applied to the manufacture of the coarser species of goods. It was soon, however, perceived that the cotton raised upon the coast, termed *sea island cotton*, had a finer and longer staple than that grown further back in the country, and known by

the name of *upland cotton*. But it was not for several years, and until after a succession of trials, that this wool was ascertained to be of a quality in every respect superior to the cotton of the Isle of Bourbon. Indeed, it was only in the year 1786 that the finest description of it was applied to the purposes for which Bourbon wool had till then been used, and which it soon entirely supplanted. The second quality of it about the same time supplanted the Brazil wool in many kinds of goods.

The cotton received from Egypt is found to be among the most useful that is grown, and that raised from sea island seed ranks in quality next to American sea island.

III. COTTON MANUFACTURE OF FOREIGN COUNTRIES.—Having succeeded in the production of cotton, the Pasha of Egypt thought he might advance another step, and have it spun into yarn and woven into cloth. He accordingly formed establishments for spinning and weaving in Cairo, Rosetta, and other places; and so early as 1828 he had at work 61 mills, moved by the power of buffaloes. The machinery was supplied from France and England, orders in council having been obtained in the latter country to authorize its export. Power-looms were also sent out, but did not succeed. A few years later, the pasha shipped 1,000 bales of yarn to Calcutta for sale; but it was not of a quality to enter into competition with English yarn, and it was found to be unsalable, except at a most disadvantageous price. He ordered it, therefore, to be woven into cloth, in Calcutta, on his own account, and to be re-shipped to Egypt, in a manufactured state. Clapperton and Landers, on their expedition to trace the courses of the Niger, found the inhabitants everywhere clothed in cotton. They mention that cotton-wool is produced in the different districts in the interior, and is spun into cloth on the spot. There exists, therefore, in the heart of Africa, an extensive manufacture of cotton cloth. It is to be regretted that they give no information of the way in which the yarn is spun, and no description of the loom employed to weave it. It would be interesting to know the nature of the instruments used by the natives in these processes, as such knowledge might enable us to trace whence the Africans derive their acquaintance with the art of weaving, and thus perhaps throw some light on African history. It appears that the people of Eboe, and of the countries near the coast, are chiefly clothed in Manchester cotton goods; a circumstance which would lead us to expect, should we succeed in obtaining a commercial intercourse with the interior of Africa, that a valuable market for the manufactures may be found in that country.

Within the last 20 years (1854) the American settlers of Liberia have established a communication across the country to Timbuctoo, and have found there a considerable market for cotton cloths. For more extended information of this trade, see LINEN.

In France, cotton yarn is often made in a different place from cotton cloth. Paris and the northern departments are the chief quarters for the supply of the former article, which is sent in quantities to Rouen, St. Quentin, and other places. In former years, cotton yarn used to be smuggled in great quantities from England; but this is now limited to the finer qualities. The cotton manufactures of the more substantial kind, called *bonneterie*, such as stockings and caps, are carried on in the Ardennes, in Normandy, and the department of the Gard, in Languedoc, is also noted for this manufacture. The exportation of cotton goods from France in 1846, reached 5,000,000 kilogrammes, valued at 105,752,443 francs. The importation of cotton thread from England in 1853, was 90,002 kilogrammes, in value, 1,559,311 francs. That of raw cotton in 1839 was 40,534,278 kilogrammes, in value, 71,204,784 francs; in 1840, 52,941,561 kilogrammes, in value, 94,005,975 francs. The cotton manufactures

of France consume between 50 and 60 millions of kilogrammes, annually imported.

We shall now resume our account of the progress of the manufacture in Great Britain. From Sir Richard Arkwright having commenced his operations at Nottingham, the seat of the stocking manufacture, and from his connection with Mr. Need, who was largely engaged in it, the whole produce of his spinning was at first devoted to that trade. The cotton yarn for this manufacture requires to be particularly smooth and equal; and to secure these qualities, it is spun by a process differing a little from that employed for ordinary twist. Being from two roves in place of one, it is called double spun twist. The introduction of this article produced a great change upon the stocking manufacture. Hand-spun cotton was entirely laid aside; and stockings made of twist were of so superior a quality, that in a short time they wholly supplanted thread stockings.

The manufacture of cotton stockings in Nottinghamshire, Derbyshire, and Leicestershire, is now of great extent.

About the year 1773, Mr. Need and Mr. Strutt made the important discovery, that the yarn produced by the spinning-frame had sufficient strength to fit it for warp, although its firmness and hardness rendered it less suitable for weft. The weft, therefore, continued to be spun by Hargreaves' jenny; and from this time the calicoes, and other articles in imitation of India goods, which had hitherto been manufactured with linen warp, came to be made wholly of cotton; and the progressive increase of these manufactures, particularly of calicoes, after this time, was unexampled.

After having made a considerable quantity of these goods, Mr. Need and Mr. Strutt discovered that, when printed, they were subject to double the duty charged upon calicoes woven with linen warp, and that their sale was even prohibited in the home market. After a long and expensive application to the legislature, they succeeded in procuring the repeal of these impolitic laws. Nearly about the same period, calicoes entirely of cotton were begun to be made at Blackburn, and also at Preston; which places soon became the seat of their manufacture, and for a long time the great market to which the printers from all parts of the kingdom resorted for their supplies. This branch went on increasing for many years in a most extraordinary degree. About the year 1805, it was calculated that the number of pieces sold annually in the Blackhurst market was not less than a million; and by that time the manufacture of this article was not confined to the country around Blackburn, but had spread into the north-west district of Yorkshire, principally about Colne and Bradford, from which part of the country 20,000 pieces weekly are said to have been sent to Manchester.

The nomenclature of Cotton Goods, and the admission of new names, are among the oddities of the cotton manufacture. What these names mean, it would, perhaps, not be very easy to say; sometimes they indicate a degree of fineness in the goods; sometimes the mode of weaving; sometimes a color, a pattern, a garment for which they are suitable, or a distinguished personage who first wore them; sometimes a foreign product which they imitate; sometimes a country for whose market they are intended, or a town which is the chief seat of their manufacture, or a firm which takes a lead in their production—it matters little what the meaning may be; a new name has a commercial

value; a rose by its name is to be in sh over a bu hams and checked by the h mandels, book mu sacharilla lias, Viet leno mus musline, of the mu huckabac rians, an surongs, panos da family, dimities, a velvetteen ings, calli other cott be almost relations gingham f threads of stripes, etc and severa velvet, with uncut; da brics, are fixen good to increas coes, sheeti duck, are v varying in yard printe ings, and m goods, most is almost in The first commenced gw about t was no yar that spun u of this, it v quality. value; and the Shakespearian dictum concerning "a rose by any other name," etc., is not always assented to in shopkeeping philosophy. Let us run hastily over a bundle of these names. We have dress gingham and fancy gingham, and umbrella gingham, checked and striped gingham, and gingham known by the high-sounding names of Camperdowns, Coronandels, matallas, vicunas, and briolas. We have book muslins, jaconet muslins, bishop lawn muslins, sacharilla muslins, tarlatan muslins, Scotch lawn muslins, Florida muslins, India and Swiss mull muslins, leno muslins, striped muslins, lappet muslins, spot muslins, sprig muslins, and a number of other members of the muslin family. We have table-cloths, diapers, huckabacks, jean-stripes, clan tartans, galas, Hungarians, and Derries—all made of cotton. There are sarongs, crossovers, selampores, Granvilles, denlins, panes da costa—all, we believe, of the cotton shawi family. There are counterpanes, quiltings, vestings, dimities, awansdowns, moleskins, doekskins, lambekins, riveteens, beaverteens, rustlans, long-cloths, shirting-calloes, calicoes, everlastings, nankeens, cotils, and other cotton goods, the enumeration of which would be almost wearisome. A few groupings will show the relations between these goods. For instance, the *gingham* family consists of *stout* cotton, in which threads of two or more colors are woven together into stripes, etc.; *Jasians*, *beaverteens*, *riveteens*, *moleskins*, and several others, are woven on the same principle as velvet, with a nap or pile, which is either cut or left uncut; *damaaks*, *huckabacks*, *diapers*, *ticks*, and *cambrics*, are cotton limitations of the similarly-named linen goods; *quilts* and *counterpanes* have downy tufts to increase the thickness and softness; *shirting calicoes*, *sheeting calicoes*, *printing calicoes*, *long-cloth*, and *duck*, are varieties of plain, serviceable cotton goods, varying in stoutness; *chintz* is a stout calico, afterward printed in several colors; *corduroys*, *jeans*, *quiltings*, and many other varieties, are very strong cotton goods, mostly twilled. As for muslins, their variety is almost interminable.

The first attempts to make muslins in Great Britain commenced simultaneously in Lancashire and at Glasgow about the year 1780, but without success. There was no yarn fitted for the weft of these goods, except that spun upon Hargreaves' Jenny; and when made of this, it was found they were not of a marketable quality. Recourse was then had to wets brought from India; and although a better article than the former was by this means produced, it was still not of a quality to compete successfully with Indian muslin. As soon, however, as the invention of the mule jenny enabled the spinner to produce yarns suited to such fabrics, the manufacture of the finest cotton articles became an important branch of trade in Great Britain. That machine, as has been mentioned, came into use at the end of the year 1785, upon Sir Richard Arkwright's patent being cancelled; and it is from that period we ought to date the commencement of this part of the manufacture. So rapid was its progress, that in 1737 it was computed that 600,000 pieces of muslin were in that year manufactured in Great Britain.

Muslin began to be made nearly at the same time at Bolton, at Glasgow, and at Paisley, each place adopting the peculiar description of fabric which resembled most those goods it had been accustomed to manufacture; and in consequence of this judicious distribution at first, each place has continued to maintain a superiority in the production of its own article.

Jaconet, both coarse and fine, but of a stout fabric, checked and striped muslins, and other articles of the heavier description of this branch, are manufactured in Bolton and in its neighborhood.

Book, mull, and lino muslins, and jaconets of a lighter fabric than those made in Lancashire, are manufactured in Glasgow. Sewed and tamboured muslins

are almost exclusively made there and in Paisley. A machine of most ingenious contrivance for performing the operation of tambouring, was, in the year 1807, invented by Mr. John Duncan of Glasgow, and a patent taken out for the discovery. Each machine contains about 40 tambouring needles, and is superintended by a girl, who pieces the thread when it breaks. This beautiful and, at first, promising piece of mechanism has never come into general use. At present there are only three or four machines kept at work by the Messrs. Mitchells of Glasgow, who at an early period became proprietors of the patent. What are called fancy goods, woven in the loom, were first made at Paisley, which had been the chief seat of the silk gauze manufacture of this country. In the silk trade, which was then beginning to fall into decay, a body of most ingenious workmen had been bred. By employing them, the taste and invention which had produced the varieties displayed in that beautiful article were immediately transferred to the production of similar fabrics of muslin. From this circumstance, Paisley for a long time retained the exclusive possession of this branch; but being only seven miles distant from Glasgow, the general seat of the cotton manufacture of Scotland, and the mart to which most purchasers of muslin resort, many of its principal manufacturers have been induced to move their establishments to that city, although the weaving of these muslins continues to be executed in Paisley and its neighborhood.

There is a curious circumstance to be noticed with regard to the manufacture of the very fine fabrics of muslins in Scotland—that a great part of the yarn used for them is brought from Manchester, in consequence of the Scotch spinners not having yet been able to produce the very fine numbers of yarn of the best quality. This inferiority does not proceed from a less perfect construction of the machinery employed in Scotland, the mechanics and the machine-makers of Glasgow being admitted to be excellent workmen; neither does it arise from the want of skill in those who conduct the business, or from any difference in the processes employed in the two countries; but it is to be attributed to the same cause which produces the superior yarn of India, namely, an adroitness and mechanical dexterity of hand in the operative spinners of Manchester, acquired by a few out of the great multitudes bred there. The manufacture of the thicker cotton fabrics was, at the same time, rapidly rising in importance. The manufacture of dimities has been exclusively confined to the north of England, all attempts to make them in Scotland having proved unsuccessful. Balason handkerchiefs were first manufactured about Preston and Chorley, where they still continue to be made. The manufacture of gingham was for a long time confined to Lancashire, but for many years it has been extensively introduced at Glasgow, although Lancashire continues to be the chief seat of this branch.

Pullicat handkerchiefs were first made about the year 1785, at Glasgow, where the manufacture of them has been carried on to a great extent. They were not made in Lancashire till some time afterward, and the manufacture of them there has never been to the same amount; Glasgow, therefore, continues to be the principal mart for this article.

Blue and white checks and stripes for exportation were at first of a linen fabric, but were afterward woven with linen warp and cotton weft; and when Sir Richard Arkwright's discovery enabled the spinner to produce cotton yarns of sufficient strength to be used for warps, a great proportion of these goods came to be made wholly of cotton. This manufacture is carried on in Lancashire, and in the county of Fife, and to a small extent at Aberdeen; its chief seat, however, is Carlisle.

The manufacture of cotton cambric was begun about the same period, and was separated into two branches; into cambric to be used in garments in a

white or printed state, and into cambric made in imitation of French linen cambric, to be used for the same purpose as that article. The first is made nearly altogether in Lancashire, where the manufacture of it is carried on to a great extent; and the second, of much less amount, wholly at Glasgow. The Scotch manufacturers have never been able to rival the Lancashire in the first, nor the Lancashire manufacturers to rival the Scotch in the last.

Bandana handkerchiefs, and Bandana cloths for garments, were first made by Mr. Henry Monteith, at Glasgow, about the year 1802, and are now manufactured there to a considerable amount. The cloth is dyed a bright Turkey red; and the color is discharged from those parts which form the pattern or figure, by passing a chemical mixture through them. Glasgow still continues to be the chief seat of this manufacture, and there are in that city several large works for carrying it on. The demand for Bandanas, however, has utterly fallen off, while, in consequence of the repeal of the impolitic duty on printed cloths, the consumption of these has greatly increased; and most of the proprietors of the Turkey-red dyeing establishments have therefore been induced to add calico-printing to their former business.

The value of the present annual production of the cotton manufacture of Great Britain is estimated at £54,000,000 sterling, of which nearly £33,000,000 is the value of goods and yarn made for exportation. The capital invested in buildings and machinery may be calculated at nearly the same as the annual amount of the manufacture, and more than double what it was 30 years ago, while the quantity of goods annually produced is much more than triple; yet, from the improvement of the processes, and consequent diminution of the expense of production, with the reduction which has taken place at the same time in the price of the raw material, this more than tripled quantity of the manufactured article does not represent more capital than was represented by, and required for the bringing to market the lesser amount during the preceding period. In the year 1812, when Mr. Crompton applied to Parliament for a remuneration for his invention, he found by as accurate an investigation as he could make, that the number of mule spindles in the country was between four and five millions; and Mr. Kennedy, in his memoir of Mr. Crompton, has stated, that the number in 1829 had increased to 7,000,000. In 1817, he estimated the number of persons employed in the spinning of cotton in Great Britain at 110,763, and the number of spindles in motion at 6,645,833, and the quantity of yarn produced at 99,687,500 pounds. The quantity of cotton yarn spun in 1832 was 222,000,000 pounds, of which 132,000,000 pounds have been manufactured into cloth, giving employment to 203,373 looms; but in 1853 the yarn spun was 685,440,000 pounds.

IV. STATISTICS OF THE COTTON MANUFACTURE.—It is obvious that the home consumption in the United States has always borne a most disproportioned ratio to the entire growth, and that even in the last four years, when it had attained to the highest point which it has yet reached, the quantity reserved for domestic use never exceeded a seventh part of the whole, and generally fell considerably below it. It is deserving of notice, however, that in the period of time which this table comprehends, the internal consumption of the United States has been troubled; but large as this increase may seem in the eye of a native economist, the conclusion from it will not be satisfactory if the collateral circumstances are not considered; and the chief of these is, that it is an increase on small quantities, and indicates no more than the gradual growth of an infant trade, which the cotton manufacture was in North America in 1829. We believe that in this manufacture Great Britain has as yet little to fear from competition; but we are not equally confident that its prosperity may

not be exposed to risk from her ill-judged anxiety to secure a monopoly of its advantages. The practice of excluding from her markets the manufactures of other countries is not only contrary to sound political principles, but gives rise to a spirit of hostility unfavorable to her interests, and places her in such a state that when other nations in retaliation, exclude her manufactures from their markets, she has no right to complain.

That we may not decide this question rashly, let us examine what is the danger to which she would be exposed if she were to take the opposite system, and open her ports to the manufactures of other countries. If they can now export annually to the value of about £22,000,000 sterling of cotton goods, which, burdened with freight, charges, and the exporter's profit, they are able to sell in competition with foreign manufacture, can they have any thing to fear from a competition with that manufacture in her home market, where the circumstances of the competing parties would be reversed? So far from the introduction of foreign manufacture into her market being an evil, we are inclined to think that it would be advantageous to her interests; and that, in the interchange of various fabrics which would be the result, the sale of her own manufactures would be increased. Commerce being altogether a matter of barter, it is necessary for every country to purchase in order that she may sell; and, fortunately, even in the same branch of manufacture, there is always room for such exchanges. There are shades of difference in the fabric of every article, upon which taste or fashion, or caprice, never fails to fix an arbitrary value, thereby constituting them into separate commodities capable of being exchanged. But the view we are taking of this important question does not rest altogether upon theory. Happily we have experience in support of it. No one disputes the advantage resulting from the interchange of commodities between Maine and Louisiana, or alleges that it would be for the benefit of either to have the manufacture of the other excluded from its market. Yet these two districts have their dependence upon manufactures which in their general features are the same.

It is well known regarding the commercial treaty with France, in which some approach was made to a free trade between the two countries, that while it lasted, the sale warehouses of London and Manchester were resorted to by purchasers from the different towns of France, with the same freedom, and in nearly an equal proportion of numbers, as from the towns in England. And although in these warehouses French and English commodities of a similar description were to be found, and British shopkeepers were at the same time daily resorting to France to make purchases, in no period were her manufactures in a state of greater progressive prosperity than during the eight years (from 1786 to 1793) that this treaty existed. There is no one, we believe, who has taken the trouble to investigate the matter, that will not say that both were benefited by this treaty, and probably exactly in the degree that the exclusive system in both had been departed from.

In addition to this, it may be proper to notice, that Switzerland and Saxony have always been open to the reception of cotton goods free of duty; and that in no other countries on the Continent is the cotton manufacture in a more thriving state. Might it not, therefore, be a wise measure to withdraw their restrictions against the importation of foreign manufactures, since the interference of these with her own products in the home market, supposing no interchange of the two to take place, never could counterbalance the amount of the sale she may be deprived of by following the opposite policy, and thus inducing the exclusion of her own goods from the foreign market?

Fears have been expressed that the lower wages for which the laborers of other countries that compete

with upon they take this, l ers th now l dimin the in for ex work pieceer thousa not m halt in been th po r,

with Great Britain in the manufacture can work, and upon which, from the cheapness of their provisions, they can afford to live, may ultimately enable them to take the manufacture out of her hands. In reply to this, it may, perhaps, be sufficient to recall to our readers the small part of the cost of the commodity which now belongs to the labor of the hand, and the daily diminution which is taking place even of that part, by the introduction of new mechanical substitutes. Thus, for example, in 1787, each spindle required a person to work it; but now one man, with the aid of a few pleers to take up and join his broken ends, can work a thousand spindles. In Lancashire, in 1818, there were not more than 2000 power-looms, and of these not a half in employment; while in 1832, so extensive had been the change from hand-weaving to weaving by power, the number had increased to 80,000.

TABULAR COMPARATIVE STATEMENT SHOWING THE ENLARGED VALUE OF COTTON MANUFACTURES OF ALL KINDS, AND COTTON YARNS EXPORTED FROM GREAT BRITAIN FROM 1840 TO 1850, BOTH INCLUSIVE.

Looking at the production of the past and the demands for the future, it is not strange that the cotton manufacturers should show uneasiness lest their spindles should be idle for want of the raw material. The consumption of raw cotton has rapidly increased during the last few years, and the unusually large crop of last year has been fully used up, leaving no residue,

though with the prospect of better prices. As an illustration of the increased consumption for the past year, we give the quantities of raw cotton consumed in Great Britain since 1847. It will be seen, that of the increase for the last year—equal to 15 per cent.—over three fourths, or 11 per cent.—came from the United States.

According to official tables, the cotton industry of Great Britain and Ireland yielded last year about fifty-four millions sterling, and which may be regarded as half the cotton industry of the whole world; but foreign countries, besides taking half of the raw cotton sent to market, receive large supplies of cotton yarns from

Great Britain; and in Asia and Africa cotton is still largely spun by hand; hence the world's cotton industry may be valued at 120,000,000, which would afford to every man, woman, and child, on the face of the earth, 2s. 9d. worth of cotton manufactures, or about fourteen yards per head per annum of excellent calico.

V. ORIGIN AND EARLY HISTORY OF COTTON MANUFACTURES OF AMERICA.—Cotton is of indigenous American growth. On the first landing of the Spaniards in Mexico, they found it in considerable perfection. The Mexicans are said to have been solely dependent upon this product, the wool of rabbits and hares, feathers, and a fibrous plant called maguet, for their clothing materials. They had neither wool, hemp, nor silk, and their flax was not used for these purposes. Out of cotton they fabricated webs of exceeding tenacity, and their cloths were woven into beautiful figures. Mantles, bed-curtains, and carpets, they finished elegantly with mingled cotton and feathers. Cortez sent to Charles V. of Spain, "cotton mantles, some all white, others mixed with white and black, or red, green, yellow, and blue, waistcoats, handkerchiefs, counterpanes, tapestries, and carpets of cotton." A peculiar cotton paper was made in Mexico, small cloths of the same material constituted a part of their currency, and their warriors are said to have had cotton cuirasses. The modern Mexicans have lost the perfection of their ancient art of manufacture. The American plant was not confined to Mexico alone; Columbus found it wild in Hispaniola and on the continent of South America, where it had already grown into an article of use for clothing and other purposes. The Brazilians say their beds of it. The Abbe Cavigero says, that of "cotton, the Mexicans made large webs, and as delicate and fine as those of Holland, which were so highly esteemed in Europe. They wove their cloths of different figures and colors, representing different animals and flowers. Of feathers, interwoven with cotton, they made mantles, bed-curtains, carpets, gowns, and other things, not less soft than beautiful. With cotton, also, they interwove the finest hair of the belly of rabbits and hares, after having spun it into thread; of this they made most beautiful cloths, and in particular, winter waistcoats for their lords." Cochineal and indigo being native products of Mexico, they were well supplied with dyeing materials; but the fact of their having carried the arts of manufacturing and dyeing cotton to such a high stage of perfection, is proof that they must have received their knowledge from India, by way of the west.

Mageilan, Drake, Cavendish, Dampier, Van Noort, all agree that cotton was one of the articles of dress among the American savages, on the discovery of the country. At St. Salvador the women are described as dressed in cotton coats. Even as far north, says M. Sealrook, as the Mos-chacebe, or Mississippi, the earliest explorers of that river, and its tributary streams, saw cotton growing wild in the pod, and in great plenty. These facts, and they might almost be indefinitely multiplied, are introduced to rebut the opinion founded on the negative testimony of Captain Cook, that the gossypium is not a native of the western hemisphere. That celebrated voyager found no cotton between New Zealand, 36° S., and the Sandwich Islands, 20° N. In addition to flax, and the bark of the mulberry-tree, in which Captain Cook says that the inhabitants of those regions were habited, the nations all over the continent nearly, used as articles of dress, besides cotton, feathers, the wool of rabbits, the maguet, and silk-grass. In 1726, cotton was a staple product of Hispaniola. In 1753, Jamaica exported 2,000 bags. On an average of eight years, from 1740 to 1748, the export of cotton from Barbadoes was 600 bags annually. In 1787, St. Domingo, St. Christopher, Grenada, Dominica, Antigua, Montserrat, and Nevis, and the Virgin Islands, exported the same commodity. In 1803, there were grown five varieties of cotton in Jamaica, the common, the brown-bearded, the Naukin, the French, and the Brazilian. From these facts, Mr. Baines draws the conclusion that the manufacture of cotton must therefore be supposed to be coeval with the original settlement of America; but

learned men are much divided as to the date of this event, some carrying it nearly as high as the deluge, and others contending for a much later period. The American manufacture may at all events claim a high degree of antiquity.

VI. COTTON MANUFACTURES IN THE UNITED STATES.—*Historical Sketch of the Rise and Progress of the Cotton Manufactories in the United States.*—As early as the year 1787, a society was formed in Philadelphia, under the name of the "Pennsylvania Society for the Encouragement of Manufactures and the Useful Arts," which made some progress in the manufacturing of various kinds of goods, such as jeans, corduroys, fustians, plain and flowered cottons, flax linens, tow linens, etc. But the machinery employed in this manufacture seems to have been of the very rudest kind. A short time before the formation of this society, an attempt to spin cotton-yarn by machinery had been made at Bridgewater and Beverly, in the State of Massachusetts. Two mechanics from Scotland, Alexander and Robert Barr, brothers, were employed by a Mr. Orr, of East Bridgewater, to make carding, spinning, and roving-machines, which they completed; and on the 16th of November, 1786, the General Court of Massachusetts made them a grant of £200, lawful money, for their encouragement, and afterward added to the bounty, by giving them six tickets in the State land lottery, in which there were no blanks.

In March, 1787, Thomas Somers, an English midshipman, constructed a machine, or model, under the direction of Mr. Orr; and, by a resolution of the General Court, £20 were placed in the hands of the latter, to encourage him in the enterprise.

The above remained in the possession of Mr. Orr for the inspection of all disposed to see them, and he was requested by the General Court, to exhibit and give all information or explanation regarding them. It is believed that the above were the first machines made in the United States for the manufacture of cotton.

The Beverly Company commenced operations in 1787, and are supposed to be the first company that made any progress in the manufacture of cotton goods (that at Bridgewater had been on a very limited scale), yet the difficulties under which they labored—the extraordinary loss of materials in the instruction of their servants and workmen—the high prices of machines, unknown to their mechanics, and both intricate and difficult in their construction, together with other incidents which usually attend a new business—were such that the company were put to the necessity of applying to the State legislature for assistance, to save them from being compelled to abandon the enterprise altogether.

In their petition to the Senate and House of Representatives of Massachusetts, presented June 2d, 1790, only three years after they had commenced operations, they state: "That their expenditure had already amounted to nearly £4,000, while the value of their remaining stock was not equal to £2,000, and a further very considerable advance was absolutely necessary to obtain that degree of perfection in the manufacture, which alone could ensure success."

Accordingly a grant of £1,000 was presented them, to be appropriated in such a way as would effectually promote the manufacturing of cotton piece-goods in the commonwealth.

The petition above referred to, and other collateral facts, sufficiently prove that cotton-spinning in this country, further than the hand-card and one thread-wheel, was carried through its first struggles by the Beverly Company in Massachusetts. And from this State the manufacture was carried to Rhode Island—though it must be acknowledged that both States were indebted to foreign emigrants for instruction and assistance in spinning and weaving, as well as in preparing the cotton.

Cotton-spinning commenced in Rhode Island in 1786,

in which year Daniel Anthony, Andrew Dexter, and Lewis Peck, all of Providence, entered into an agreement to make what was then called "home-spun cloth." The idea at first was to make jeans of linen warp spun by hand; but hearing that Mr. Orr, of Bridgewater, and the Beverly Company, had imported some models or draughts of machinery from England, they sent thither and obtained drawings of them, according to which they constructed machinery of their own. The first they made was a carding-machine, which was something similar to those now used for carding wool, the cotton being taken off the machine in rolls, and afterward roped by hand. The next was a spinning-frame, something similar to the water-frame, or rather the common jenny, but a very imperfect machine. It consisted of eight heads of four spindles each, being 32 spindles in all, and was wrought by means of a crank turned by the hand; this, after being tried for some time in Providence, was taken to Pawtucket and attached to a wheel propelled by water; the work of turning the machine was too laborious to be done by hand, and the machine itself was too imperfect to be turned by water. Soon after, these machines were sold to Moses Brown, of Providence; but as all the carding and roving was done by hand, it was very imperfect, and but very little could be done in this way. Such were the rude machines used for spinning cotton previous to 1790; and the wonder is, not that the manufacturers failed in their undertakings, but rather that they were able to persevere. And we can now perceive that from these small beginnings, the present brightened prospects received their foundation.

The first cotton-mill of the United States was erected in Pawtucket, Rhode Island, by the late Mr. Samuel Slater, a native of Pelper, Derbyshire, England, in 1790. The machinery was that of the Arkwright patent. There is evidence that Hargreave's jennies were in use in this country previous to 1790, but by whom, and when introduced, is not known. They were worked principally by Scotch and Irish weavers, who produced mixed goods of linen and cotton. Great Britain, at that time, used every means to prevent the introduction of her spinning machinery into other countries. Her law expressly forbid its exportation; and every attempt to import the machinery into America had failed. The Hon. Tench Coxe, of Philadelphia, entered into a bond with a person, who engaged to send him from London complete brass models of Arkwright's patents. The machinery was completed and packed, but was detected by the examining officer, and forfeited, according to the existing laws of Great Britain. No way remained to obtain the benefit of the British inventions but to manufacture them on our own soil. For this purpose Mr. Slater came to America. He had been a pupil of Arkwright, and was perfectly familiar with all his patents. He brought with him neither patterns nor memoranda to assist him in his work, but depended entirely on his memory, a thing which the statutes of Great Britain could not reach. The King of England had frequently made proclamations against any tradesman leaving the kingdom, and had called on his officers for their most vigilant watch against it; but the professions of men leaving the kingdom could not be always detected.

Some of the first yarn made by Mr. Slater in America, and some of the first cotton cloth made from it, was sent to the Secretary of the Treasury, on the 15th of October, 1791; and it is probably in existence now. It is stated that Mr. Clay had some of the first yarn in his possession in 1836. It was as fine as a No. 40.

Mr. Slater was induced to leave his employment under Mr. Arkwright, in England, to come to America, by seeing a premium offered by the Pennsylvania Society for a certain machine to spin cotton.

Mr. Slater labored under the greatest disadvantages for the want of suitable materials, and mechanics of sufficient ingenuity to assist him. The history of his

first labors is deeply interesting, for the details of which we must refer the reader to his biographer. His first machine was what is called a water-frame, of only 24 spindles. Such was the humble origin of cotton manufacturing in America. From that first machine the advancement of the cotton manufacture has been truly astonishing. It has caused hundreds of populous villages, towns, and even cities, to spring up as if by magic, where only a few years ago nothing was seen but a barren wilderness. Astonishing as has been the increase of the various manufacturing towns and villages in the United States, Lowell, in Massachusetts, surpasses every thing of the kind that has been witnessed within the memory of man. In 1810 its site was a wilderness, whither sportsmen went to shoot game. The entire population of the territory around it did not exceed 200 souls. It was a poor, barren district, with but a few houses on the spot where the city now stands; and the inhabitants supported themselves principally by fishing in the Concord and Merrimac rivers, at the junction of which Lowell is situated. A company of wealthy men in Boston, seeing the valuable water-privileges of the spot, purchased it for manufacturing purposes. The first cotton mill was erected there in 1822; and in 1830 the population of the place had increased to 6477 persons. In 1840 the population had increased to 20,796; and the value of property there was \$12,400,000. In 1856 the number of cotton-mills was 35, spindles 850,548. Thus, what only 30 years ago was a wild pasture-ground has become a large and flourishing city; a proof of what a water-power, seconded by capital and enterprise, can do for a place. Lowell is a splendid example of an American manufacturing city, and excites the attention, and in some measure the jealousy, says Mr. McCulloch, of Manchester and Glasgow. We need no better proof of what manufactures can accomplish than the history of Lowell. The Lowell cotton-mills, owned by twelve manufacturing companies, extend in a continuous line of about a mile, from the Merimac to the Pawtucket Falls.

The rapid growth of the cotton manufacture in this country is unparalleled in the history of industry. The second cotton-mill in America was erected in 1795, at the same place as the first. No more were built until 1803, when a third was erected in Massachusetts, followed by a fourth in 1804. During the three following years ten more mills were erected in Rhode Island, and one in Connecticut, making in all fifteen mills, with 8000 spindles, producing 300,000 pounds of yarn annually. By a report made to the government in 1810. It appears that 87 additional mills had been erected by the end of 1809, of which 62 were then in operation by horse and water-power, running 31,000 spindles. The cotton manufacture continued to spread, and received a considerable impulse from the war of 1812. In that year there were in Rhode Island 33 cotton factories, with 80,000 spindles. In Massachusetts there were 20 mills, with 17,371 spindles.

A report made to Congress in 1816 gives the following statement of the consumption of cotton by our mills, showing how rapidly the cotton manufacture had advanced. The consumption of cotton was, in

1800.....	500	1810.....	19,000
1802.....	1,000	1815.....	90,000

The following statement is also officially made in the same report, showing the state of the cotton manufacture at that time:

Capital employed in 1816.....	\$40,000,000
Males employed over 17 years old.....	10,000
Women and female children.....	60,000
Boys under 17 years.....	24,000
Cotton cloth manufactured..... yards	81,000,000
Cost of same.....	\$24,000,000
Raw cotton..... 90,000 bales, or lbs.	27,000,000

The subject of protection was then extensively agitated. The importations of cotton goods in 1815 and 1816 were immense, and created great alarm among

manufacturers. The amount of importations of those two years was about \$180,000,000. During the years 1817, 1818, 1819, and 1820, great distress prevailed among the manufacturers, but Congress was not disposed to grant their petitions in full.

Tariff laws were passed in 1824, 1828, and 1832, in each of which the duty upon foreign cotton goods imported was 25 per cent. *ad valorem*. These duties, though they did not prevent our markets from being glutted with foreign goods, caused our manufactures to gradually increase.

In 1820, the first cotton mill in Pennsylvania was erected at Manayunk by Captain John Towers. There were then only two small cottages on the spot. It now contains 500 dwellings, 5 churches, 15 stores, and about 30 mills.

Among the numerous towns that have sprung into existence, owing to the influence of manufactures, may be mentioned—Waltham, Paterson, Ware, Fall River, Taunton, Pawtucket, Lowell, Lawrence, Providence, Rhode Island, Saco, Lewiston Falls, Maine, &c.

* Made up from British and United States' official documents, respectively, the commercial year of the former ending December 31, and of the latter June 30.
† The pound sterling is computed at five dollars.

The articles Cotton and Cotton Manufactures have been compiled principally from the official report of the Statistical Office to Congress in 1856, United States' Patent Office Reports, tables prepared by Mr.

W. P. Wright, cotton broker, New York city, Encyclopaedia Britannica, eighth edition, and De Bow's Industrial Resources of the United States, the latter now published at Washington, D. C.

STATEMENT EXHIBITING THE FOREIGN IMPORTATIONS AND RE-EXPORTATIONS, DOMESTIC EXPORTATIONS AND HOME CONSUMPTION OF FOREIGN COTTON GOODS, TOGETHER WITH THE CONSUMPTION OF FOREIGN COTTON GOODS OVER DOMESTIC EXPORTATIONS; THE NUMBER OF TONS OF SEA-ISLAND AND OTHER COTTON ANNUALLY EXPORTED FROM THE U. S.

Cotton Dyeing. (*Teintures de Coton*, Fr.; *Baumwollenfärberei*, Germ.) Cotton and linen yarns and cloths have nearly the same affinity for dyes, and may therefore with propriety be treated, in this respect, together. After they have acquired the proper degree of whiteness, they are still unfit to receive and retain the dyes in a permanent manner. It is necessary, before dipping them into the dye-bath, to give them a tendency to condense the coloring particles within their cavities or pores, and to communicate such chemical properties as will fix these particles so that they will not separate, to whatever ordinary trial they may be subjected. All the colors which it would be desirable to transfer to these stuffs, unfortunately do not possess this permanence. Men of science engaged in this important art, have constantly aimed at the discovery of some new processes which may transfer into the class of fast colors those dyes which are at present more or less fugitive. Almost all the goods manufactured of cotton, flax or hemp, are intended to be washed, and ought, therefore, to be so dyed as to resist the alkaline and soapy solutions commonly used in the laundry. Vitalis distinguished dyed cottons into three classes: 1. the *fugitive*, or fancy-colored (*petit teint*), which change their hue or are destroyed by one or two boils with soap; 2. those which resist five or six careful washings with soap, are *good* dyes (*bon teint*); and those which were still more durable, such as Turkey reds, may be called fast colors (*grand teint*). The colors of Brazil-wood, log-wood, annatto, safflower, etc., are *fugitive*; those made with madder without an oily base, are *good*; and those of madder with an oily mordant, are *fast*.

Cotton-wood. (*Populus argentea*.) This species is scattered over a great extent of country, comprising the middle, southern and western States. It is, however, quite rare in the middle States. New York city may be considered as the most northern point at which it grows. It is quite common along the Mississippi river. The cotton-tree grows sometimes to the height of 70 or 80 feet, and 2 or 3 feet in diameter. The leaves, while very young, are covered with a thick, white down, which gradually disappears, leaving them smooth above, and slightly downy beneath. The wood of the cotton-tree is soft, light, and unfit for use, and inferior to that of most of the other poplars. It is appropriated to no particular use in the arts or for fuel.—BROWNE, *Sylva Americana*.

Counterfeiting. Large sums of money have been expended with a view to devise plans for the prevention of counterfeiting bank notes, bank checks, etc., but thus far no successful plan has been devised. The New England Society for the Prevention of Counterfeiting, has for some years been in operation at Boston, and is aided by the treasury of Massachusetts to the extent of \$2,500 per year. This society has been the means of detecting and punishing numerous counterfeiters. Forging of government certificates of United States stock, land warrants, etc., is, by act of Congress, punishable by imprisonment not over 10 years. For counterfeiting a post-office frank, a fine of \$10 will be imposed. The counterfeiting of coins of the United States, or of foreign coins, shall be punished by imprisonment between 3 and 10 years, or imprisonment of 5 years and a fine of \$1,000.—See DUNLAP'S *Digest Laws U. S.*, pp. 76, 403, 404, 726, 728, 1002.

Countermark. In Numismatics, a stamp frequently seen on ancient coins, often obliterating a large part of the impression. The countermark is generally a figure or inscription, and some antiquaries have considered that their use was to augment the value of the money; others, that it was only struck on money taken from an enemy.

Coupons, from the French, is a term employed in England and elsewhere, to denote the warrants for the payment of the periodical dividends or interest on

public stocks, a number of which being appended to the bonds, are severally cut off for presentation as the dividends fall due, generally semi-annually—sometimes quarterly. The practice of appending coupons to bonds is now generally adopted by States and corporations, as they facilitate the collection of the semi-annual or quarterly interest thereon.

Courier (Fr. *courir*, to run), a messenger sent post or express with dispatches. The couriers employed by the ancients were of two kinds; first, those who ran on foot, called by the Greeks *hemerodromi*, or day-runners, regarding whom Pliny, Cornelius Nepos, and Cæsar mention that some of them would run twenty, thirty, thirty-six, and in the circus even forty leagues a day; second, riding couriers (*cursores equestrantes*), who changed horses as modern couriers do. Xenophon attributes the first couriers to Cyrus. Herodotus says they were very common among the Persians, and that there was nothing in the world more swift than such messengers. That prince, says Xenophon, proved how far a horse could run in a day, and built stables at corresponding distances; and at each station a courier was always ready with a fresh horse to forward the package to the next stage, and so on throughout the empire. But it does not appear that either the Greeks or Romans had any regular system of couriers till the time of Augustus. Under that prince they traveled in cars, about 24 a.c., though it would appear that they afterward went on horseback. Under the Western Empire they were called *riatores*; and under that of Constantinople *crisores*. Couriers or posts are said to have been instituted in France by Charlemagne, about A. D. 800. The couriers or posts for letters were established in the early part of the reign of Louis XI. of France, owing to this monarch's extraordinary eagerness for news. They were the first institution of the kind in Europe, A. D. 1463.

Court-plaster is a considerable object of manufacture. It is made as follows: Black silk is strained and brushed over ten or twelve times with the following preparation: Dissolve $\frac{1}{2}$ an ounce of balsam of benzoin in 6 ounces of rectified spirits of wine; and in a separate vessel dissolve 1 ounce of isinglass in as little water as may be. Strain each solution, mix them, and let the mixture rest, so that any undissolved parts may subside. When the clear liquid is cold it will form a jelly, which must be warmed before it is applied to the silk. When the silk coated with it is quite dry, it must be finished off with a coat of a solution of 4 ounces of China turpentine in 6 ounces of tincture of benzoin, to prevent its cracking.

Court of Claims. This is a new court, established by act of Congress of the United States, February 24, 1854, having jurisdiction of claims by individuals against the United States, arising from disputed cases at the Treasury. This obviates the necessity of petitioning Congress for indemnity for losses sustained under government contracts, etc. See DUNLAP'S *Digest Laws U. S.*, pp. 1457—1459.

Coutts, Thomas. This distinguished London banker, whose death caused much excitement in the metropolis, was at one time, in wealth and importance, at the head of the banking and moneyed interest in England. He was at first a partner in the house at St. Mary Axe, London, and afterward admitted it to his brother's banking-house, in the Strand, London. His own bank stands on nearly the centre of the site where stood, many years ago, an exchange, similar to Exeter Exchange. It was then considered one of the best-constructed places of safety in Great Britain, except the Bank of England.

Mr. Coutts died on the 24th of February, 1822, having attained the age of *ninety-one*. His will was read the Sunday evening after his death, in the presence of his family. To the surprise of many, he bequeathed his whole property, to the amount of £200,000, to Mrs. Coutts, formerly Miss Mellon, an actress, at her own

disposal, without leaving a single shilling to any of his legatees, except to others, would of Coutts and of dett Coutts, is don.—See *Ban*

disposal, without mentioning any other person, or leaving a single legacy. This was, probably, to escape the legacy duty, which, if his fortune were left to others, would have amounted to £60,000. The firm of Coutts and Co., said to be controlled by Miss Burdett Coutts, is still among the banking-houses of London.—See *Bankers' Mag.*, N. Y., 11. p. 825 (1848).

Cove. An inlet on a rocky coast. It is a term nearly synonymous with *harbor*: the word *cove* being generally, though not always, used when the indentation on the coast is too shallow or narrow to admit first-class vessels.

Cowes, West, a seaport-town of the Isle of Wight, at the mouth of the Medina, 4 miles N. of Newport, and 78 miles from London. It occupies a rising ground on the W. bank of the river, presenting a striking appearance from the sea. The streets are narrow and irregular; but many of the modern buildings are handsome, and in the vicinity are numerous elegant villas. It is much resorted to for sea-bathing, and has numerous hotels and lodging-houses for the accommodation of visitors. The harbor is safe and convenient, and its entrance is defended by a battery. It forms the rendezvous of the Royal Yacht Club, who hold their annual regatta here. It has a very considerable coasting trade. Exports, chiefly agricultural produce and malt; imports, coal, colonial produce, manufactured goods, etc. Ship-building is extensively carried on. On the opposite side of the river, which is here about half a mile broad, is East Cowes, where is the custom-house of the port, and near which is Osborne House, the marine residence of her Majesty. Pop. (1851), 4,786.—E.B.

Cowitch or **Cowitoh** (Hind. *Kiwach*), the fruit or bean of a perennial climbing plant (*Dolichos pruriens*, Lin.) It is a native of India, as well as of several other Eastern countries, and of America. The pod is about 4 or 5 inches long, a little curved, and contains from 3 to 5 oval and flatish seeds; the outside is thickly covered with short, bristly, brown hairs, which, if incautiously touched, stick to the skin, and occasion intolerable itching.—AINSLIE'S *Materia Indica*.

Cowries (Ger. *Kauris*; Du. *Kauris*; Fr. *Coris*, *Cauris*, *Boynes*; It. *Cori*, *Porcellane*; Sp. *Bucios* *Zimbos*) are small shells brought from the Maldives, which pass current as coin in smaller payments in Hindostan, and throughout extensive districts, in Africa. They used to be imported into England previously to the abolition of the slave trade, in which they were subsequently employed. They are an article of trade at Bombay. The best are small, clean, and white, having a beautiful gloss; those that are yellow, large, and without lustre, should be rejected. The freight is calculated at 20 cwt. to the ton.—MILNER'S *Orient. Com.*

Cozening, tricking, defrauding. In law it denotes an offense where any thing is done deceitfully, either with regard to contracts or otherwise, and which can not properly be defined by any special name. In the civil law it is called *stellionatus*.

Cranberries, or **Red Whortleberries**, the fruit of a moss plant, the *Vaccinium oxycoccus* of Linnaeus. The berries are globular, about the size of currants; are found in mossy bogs. Cranberries have a peculiar flavor, and a sharp, acid, agreeable taste; they are easily preserved, and are extensively used in making tarts. They are very abundant in North America, and in the northern parts of Russia; the latter being of a superior quality. It is said that some very fine ones have recently been brought from New South Wales. Considerable quantities are produced in New England on the marshy lands near the coast.

Crank, in sea language, is applied to a vessel when, from too much top weight, or the want of sufficient ballast, or cargo, or from any other cause, she can not bear much sail without danger of oversetting.

It also denotes an iron brace for supporting the lanterns of the poop-quarters of the ship.

Crape (Fr. *Crêpe*; Ger. *Flohr*, *Krausflor*; It. *Es-pumilla*, *Sopillo*; Rus. *Flior*; Sp. *Crespon*), a light, transparent stuff, in manner of gauze, made of raw silk, gummed and twisted on the mill, and woven without crossing. When dyed black it is much worn by ladies as a mourning dress. Crape is crisped (*crêpé*) or smooth; the former being double, are used in close mourning, the latter in less deep. White crape is appropriate to young unmarried females, and to virgins on taking the veil in nunneries. The silk destined for the first is spun harder than for the second; since the degree of twist, particularly for the warp, determines the degree of crisping which it assumes after being taken from the loom. It is for this purpose steeped in clear water, and rubbed with prepared wax. Crape is all woven and dyed with the silk in the raw state. They are finished with a stiffening of gum-water. Crape is a Bolognese invention, but has been long manufactured with superior excellence at Lyons, in France, and Norwich, in England. There is now a magnificent fabric of it at Yarmouth, by power-loom machinery. There is another kind of stuff, called *crépon*, made either of fine wool, or of wool and silk, of which the warp is twisted much harder than the weft. The *crépons* of Naples consist altogether of silk.

Crayons. Colored cylinders used for drawing upon paper; they are usually made of a fine pipe-clay, colored with metallic pigments or carmine. Crayons containing plumbago are styled *solid lead pencils*.

Cream. (Fr. *Crème*.) A semi-fluid yellowish substance which collects on the surface of milk, and which is made into butter by the process of churning. When the milk of any animal is allowed to stand for some time, it spontaneously undergoes certain changes—this substance rises to the surface and forms a thin stratum, which is called cream, and which consists chiefly of oily particles; while the milk below, which of course is thinner than it was before the cream separated from it, is of a pale bluish color, and consists of curd, coagulum, or the matter of which cheese is made. When cream is kept for some days it gradually becomes thicker, and partially coagulated; and if put into a linen bag and suspended from the ceiling of a cool room, it will acquire the consistence of cheese; and this is one among other modes of making cream cheeses. When cream is shaken by churning, it is resolved into its component parts, and hence we have butter and buttermilk. In order to make butter it is not always necessary that the cream should be separated from the milk; but whether separated or not, the process is facilitated by allowing the liquid to stand for some time, during which a part of the sugar contained in the serum is changed into an acid, which shortens the process of churning by facilitating the separation of the butter from the milk. When either cream or milk is churned without having previously become sour, the process is much more tedious; and sometimes, from causes not easily accounted for by the dairy-maid, it is unsuccessful, and the milk is said to be bewitched. The true cause, however, is the want of acidity; because it has been found that the addition of a small portion of vinegar will dissolve the charm, and cause the almost immediate appearance of butter. Cream, when separated from milk and kept till it has become acid, is frequently mixed with milk newly drawn from the cow; and this eaten with sugar is one of the most delicious preparations of the dairy. Costorphan cream, so called from a village of that name in the neighborhood of Edinburgh, is made by putting the milk of three or four days together with the cream into a vessel, and allowing it to remain there till it has become sour and coagulated. The whey is then drawn off and fresh cream added; and when it is brought to table it is eaten with sugar,

and in the strawberry season, with that fruit. Devonshire cream is simply sour curd, or sour cream eaten with fresh milk, or fresh cream, with or without the addition of sugar. Devonshire scalded or clotted cream is milk and cream heated to the boiling point, and suffered to cool, when the cream will be found to have separated from the milk; and when skimmed off may either be made into butter or eaten with fresh cream and sugar. Common clotted cream is simply milk and cream in a boagulated state, and sour. When the clotted cream is broken and stirred, and the whey drawn off, the mass may be turned into cheese by artificial pressure, by which the whey is separated instantaneously; or by suspending it in a porous bag, in a cool, airy situation, when it will be separated by degrees. See BUTTER, CHEESE.—BRAND'S *Encyc. of Art.* See BUTTER DIARY.

Credentials, Letters of. The instrument, in the form of a letter, from one government to another, which constitutes the evidence of the title of a minister at a foreign court to the power which he exercises. There are two sorts of credentials: the one sealed, drawn up and countersigned by the minister of foreign affairs; the other open, signed only by the government. Unless the minister be mentioned expressly in his credentials as an ambassador, he has only a right to the observances due to foreign ministers of inferior rank.

Credit, in the sense in which we generally treat of it, is the trust which is given to a person when he obtains a loan of money, or purchases any article, the payment of which is to be made at an after period. Every sum of credit, therefore, must be founded on a transfer of a corresponding sum of capital; and the whole amount of credit existing at any time can never exceed that of the lent capital. Credit is, in reference to the person who gives it, the power of lending, and him who receives it, the power of borrowing. The basis of credit is confidence, and this is found to exist extensively only where good faith and punctuality have been allowed to grow into habit, and where laws afford to creditors the easy and certain means of recovering their debts.

In young countries, before dealings have become multiplied, we find people inattentive to their money engagements, when there is no want of property with the debtor, and even when the payment of the debt has been fixed by document to a positive term. But as transactions increase, and population presses more closely together, a knowledge of the circumstances of individuals is rendered difficult, and a necessity for punctuality arises, to prevent doubts being entertained of the ability to pay. And this apprehension of discredit entertained by the debtor, and of its consequences to his future transactions, has more effect to establish and maintain good faith and exactness than the operation of the laws is able to produce. When capital is abundant, relatively to the means of employing it, the competition of capitalists produces a facility of obtaining credit; and parties become enabled to borrow and purchase upon credit who could not do so before. Credit is then said to be high, but it is the value of the capital which, from the overstock, has become low. The capitalist, in these circumstances, grows less scrupulous about his security, that he may bring within the range of his dealings a greater body of borrowers or purchasers, and thereby be enabled to keep up his price.

When the supply of capital continues in this state for any length of time, it gives rise to an imprudence of conduct which lays the foundation of much after evil. Sales and loans are made at credits far beyond the ordinary periods; and those into whose hands the extra capital by this means passes, considering it as a fund with which they may trade, go on also extending their dealings and credits, until the whole system is put upon the stretch. In this situation any inter-

ruption to the sale of commodities occasions instant confusion and distress. The confidence which had prevailed gives place to alarm and distrust, and the same effect is produced for the time by the retardment of the circulation that would have been experienced had the capital itself been withdrawn.

By the operation of credit, not only is the circulation of capital facilitated, and its employment increased; but by its means alone certain descriptions of capital can be brought into action. When an article is sold upon credit, the seller places, for the time, a portion of his capital at the command of a party who may have no capital of his own. This person, nevertheless, by another operation of credit, is enabled to sell upon credit also, and still keep his engagement with the party from whom he bought. This he accomplishes by calling in the assistance of the money capitalist, the banker, who advances to him the amount of the sale upon his and his purchaser's joint security, and receives in consideration a rent for the sum advanced. By this process facility and extension are given to circulation, beyond what could take place if the commodity could be exchanged only for immediate value; while an opportunity is, at the same time, afforded of employing a branch of capital which would otherwise remain inactive and without use. It is almost unnecessary to remark, that it is by the operation of credit that a return is got from the capital of persons who are incapable of employing it themselves, and which can be put into a state of useful activity only by lending it to others.

In Scotland, after the disposition to commercial pursuits began to manifest itself, the progress was retarded, by the total want of commercial capital in the country. To get the better of this difficulty, and draw to these employments any little capital that otherwise existed, it became the practice, when a commercial undertaking was to be entered upon, to associate in the adventure some persons of known substance, and upon the joint credit of the parties forming the company, to borrow the capital necessary for carrying it on. The credit which was thus established is called company credit, and is essential to its proposed end of borrowing or purchasing with advantage, according to the supposed responsibility of the parties of whom the company is composed. Up to the year 1793 a considerable proportion of the manufacturing and mercantile concerns of Scotland were carried on upon this plan; and to give strength to their credit, and encourage those who had money to lend to place it with them, a rule was established, and confirmed by decisions of the courts of law, that, in case of bankruptcy, a creditor of a company should be entitled to claim upon each of the partners' separate estates, in competition with the party's individual creditors, for the balance of his debt unpaid from the company's effects.

When a party purchasing or borrowing capital gives a written obligation for the amount, payable to the order of his creditor at a certain fixed period, he embodies a sum of credit capable of being exchanged again for capital; and the transference of these documents to new parties, who replace to the former creditor the capital he had lent upon them, is what is called a circulation of credit. Indeed, without the use of bills, or of some instrument of similar powers, credit must have been confined to a single operation between first contracting parties, and the circulation of capital limited to what could have been effected in this way. But a transferable document of the sum to be received becomes itself a negotiable or marketable article; and the collective credit of the parties through whose hands it may successively pass continuing to be engrafted upon it, a new facility is gained to circulation by every movement which it makes. The whole of the credit embodied by bills, however, is not brought into circulation; a part only

of the sellers or lenders requiring to have their capital replaced to them by anticipation. But it is according to the expected facility with which payment may be thus anticipated, that credit is at first freely and readily given; and whenever any thing occurs to impede the circulation of credit, there is an immediate disposition in the merchant to withhold or limit it.

Every transfer of capital made upon a buyer or borrower's own obligation of payment creates a new sum of transferable credit; and this is the case, although it should be the same capital that is again and again transferred. But a sale of goods, or an advance of money upon the obligation of a third party, indorsed to the seller or lender, forms no addition to the sum of circulating credit, the transaction being the circulation, not the creation, of a sum of credit. Neither does a succession of purchases or borrowings, effected by means of the same document indorsed from the one party to the other, add to the sum of credit in circulation. For although each of these transactions is the ground of a separate obligation between the parties contracting, there is with the whole but one absolute creditor, the holder of the bill, and one absolute debtor, the acceptor of the bill, the others being merely contingent debtors to the one, and contingent creditors of the other.

Circulated credit is to be classed into that circulated by loan, and that which is circulated by means of sale. The first is the circulation of the credit founded upon the obligation of individuals or private companies, and called private credit; the second, of that founded upon the obligations of the state, or the transfers of the stock of corporate bodies, and called public credit. The documents of these two descriptions of credit possess different and distinct qualities, and are differently negotiable. It may be proper, therefore, to examine how they are employed as means of borrowing or purchasing, what are their separate powers, and what is the probable extent of the circulation of each. We shall begin with those belonging to private credit, which are as follows:

First, Obligations payable to the bearer on demand, and which, being passed without recourse, are employed as money. *Secondly*, Transferable obligations payable at an after date, as notes of hand and bills of exchange, which, being negotiated with recourse upon the preceding obligants, are taken as guaranteed pledges of a sum to be received when they become due.

The circulation of obligations, payable to the bearer on demand, or notes employed as money, is the circulation of a credit borrowed by the issuer of the note from the public; the holder of the note at the time is the creditor; and the property he gave in exchange for it is a loan from him to the banker. As it is in the power of the party giving this credit at any time to put an end to it by calling for his money, these notes circulate upon the credit of the issuer alone. No assurance of payment is required from the person from whom they are received, as is the case with bills; the payment of which being at a future date, it is thought necessary to reserve recourse against the parties through whose hands they have passed. The circulation of notes payable on demand is therefore a circulation of what may be termed single credit, and bills a circulation of collective credit.

When bank-notes are issued by a banker in discount of a bill, it may be supposed that a twofold credit is put into circulation: a credit to the party to whom the bill has been discounted, and a counter credit from him to the issuer of the notes. But in this stage of the transaction, no circulation of credit has taken place. Credit is circulated only when exchanged for capital, and in this case it has been but the exchange of one credit for another. The banker, indeed, in giving his notes payable on demand in exchange for a bill payable at a future date, gives what is of a quality different from that which he receives;

for what he gives is immediately exchangeable for capital, and to the person receiving it is the same as capital.

But still it is only credit he has parted with, which will not be in a state of circulation until it comes to be exchanged for capital. In as far as relates to circulation, the transaction is the same with that of a person lending his credit to another, by accepting a bill to him without value. A sum of credit is thereby created, but is not circulated until the bill comes to be exchanged for value. The credit that is in circulation from the exchange of bank-notes for a bill, is a credit from the party who at the time has given capital or value for the notes. When the banker "cashes" them, he becomes the creditor, but while they remain in circulation the public is the creditor.

The amount of credit from the circulation of cash notes never can be pushed beyond what would have been the value of the specie that would have been in circulation had the currency been of the precious metals, which the notes only are to represent. Should the notes cease to be convertible into specie, their amount, indeed, may be augmented at the pleasure of the issuer; but their value, and the credit in circulation from them, will still be regulated by this limit. The increased sum will represent the value which the smaller did before, and each note will be reduced in its value, in the proportion of the increase that may have taken place of the whole. This description of circulating credit is of a quality different from the others. From supplying the place of capital, in its character of currency, it is lent out as capital; but loans from this fund are precarious, its amount depending upon the state of public confidence, and being liable to be diminished by every call upon the banks to replace the notes with specie.

Circulating notes, not convertible into specie, issued under the authority of the state, have been called a fabric of unreal credit. But this currency, however unsuitable to its proper ends, affords a circulation of real credit. It is indeed exposed to constant fluctuation of value, according to the amount of it in the circle; and the party taking it is obliged, for his own safety, to include in the price of what he gives for it, sufficient to cover the difference between it and specie, and the risk of further depreciation while it may remain in his hands. Still, however, an amount of credit, to the value of what has been given for the notes, in the first instance, is put into circulation, and an amount continued in circulation, to the value always of what they are exchangeable for at the time; the holders of them always remaining creditors of the issuer, to the extent of the whole sum which the notes profess to pay. A currency of this description, however, is inapplicable as a measure of value, and therefore unfit to be employed as a circulating medium. And as to the other object, intended by its issuers to supply an amount of funds to the state; the depreciation with which it must be issued at first, and the loss to be sustained from taking it back again at par, render it an expensive means of borrowing.

With regard to obligations payable at a future date, which constitutes the second branch of private credit, and which we are next to consider, the credit founded on them is circulated, either in the transfers of the ordinary capital in sales, as when the credit of indorsed bills is employed to purchase goods, or in the transfers of the banking capital in loans, as when the credit of indorsed bills is employed to borrow money; the transfer under the latter, when the bill is exchanged for money, being often a further circulation of a credit previously circulated under the former, when the bill was exchanged for goods.

A fictitious bill, that is, an acceptance given without value, vests in the person in whose favor it is drawn a sum of transferable credit not less than

would have been the case if it had been the document of a sale, or loan of property. Mr. Thornton, in his treatise on Paper Credit, established the doctrine, till then disputed, that the credit of a bill does not rest upon the nature of the transaction in which it has originated, but upon the conceived ability of the obligants to discharge the debt. The being able to embody in bills every sum of credit, has furnished the means of employing, with incalculable advantage to commerce, a portion of the capital of the country, which otherwise, it is probable, would have remained inactive. The security they afford for the repayment, at a stipulated period, of the sums lent upon them, furnishes the means of an interim employment of money held for after occasions, which the party would not otherwise venture to lend out; of money which formerly lay idle in the hands of parties unacquainted with any safe means of using it; and of the money which traders are daily receiving in the course of their business, but which they do not immediately require. These different sums collected in the hands of a banker, form what is called the banking capital of the country; and which, lent out upon such securities, produces not only a profit to him, but interest to the parties who have placed them at his disposal. The importance of this intermediary fund in the transactions of the country is such, that when, from distrust, at any time, these deposits are withheld or withdrawn from the bankers, the mercantile body is convulsed throughout.

We now come to the second division of credit, that circulated by sale; the documents of the first branch of which are, the negotiable obligations of government, as exchequer bills, navy bills, etc., and the whole of the public funds, constituting what is termed the credit of state. When capital is to be competed for, this credit has an advantage in the market over the former. Its price rises according to the demand; and by that means it is enabled to secure whatever share it may require of the supply. This is not the case with the credit circulated by transfers of capital upon loan, the price or stipulated rent of which can not, whatever may be the demand, rise beyond a prescribed limit. It has the effect, in these circumstances, to force the capital applicable to this part of the circulation to seek the employment of the other; so that the inconvenience produced by an interruption of circulation from a diminution of the general capital, falls entirely upon the circulation of bill credit, the supply for the circulation of the credit transferable by sale being kept full, at the expense of that applicable to the circulation of credit transferable by loan.

The transferable shares of public stock companies, from being occasionally a means of temporary investment of capital, have by some been considered as forming a part of the circulating credit of the country. But this is not the case. The stocks of these companies form a part of the ordinary circulating capital; and of consequence, the transfers of their shares are not operations of credit, but exchanges of capital between the buying and selling parties. The transfers of the premiums, however, paid in the purchase of this description of stock, which, although no part of the capital, form an immediate part of the price, may be fairly considered as a circulation of credit, to be added to the amount of the circulating credit of the country. The mode of circulating this credit being the same with tint of the public funds, and its market value rising or falling with the general abundance or scarcity of capital, its circulation, when capital is scarce, immediately interferes with the circulation of credit by simple borrowing.—E. B. See also "Hooper on Currency, Boston, 1856. *Bankers' Magazine*, N. Y., 1855-1856. See *Huxv's Mer. Mag.* (C. F. ADAMS), ii. p. 185. *Democratic Rev.*, ii. p. 167; iii. p. 195; v. p. 147. *Encyclopedia Amer.*

Credit Mobilier. The *Crédit Mobilier* Bank, according to the provisions of its charter, is a joint-stock company, organized at Paris, for the purpose of developing works of public improvement by consolidating the securities of various enterprises into one common fund. Its capital stock is fixed at 60,000,000 francs, divided into shares of 500 francs each, payable to bearer. It is authorized to subscribe for or acquire public funds, the shares or bonds of any joint-stock company, and more particularly of railways, canals, mining, and other public works, now existing, or hereafter to exist; also to bid for any loan, or for the stock of any kind of public works, and to dispose of and realize the same. It is also authorized to issue its own bonds for an amount equal to its subscriptions and purchases; such bonds may be issued to the extent of ten times its capital (that is, 600,000,000), but they shall not have less than forty-five days to run. This privilege has not yet been availed of, the Government having requested them to postpone the proposed issue of 240,000 bonds (120,000,000 francs) in 1855, in order not to interfere with the forthcoming State loans, as well as to guard against increased embarrassment in the money market. The aggregate amount of money received in account current, and of bonds issued having less than a year to run, can not exceed twice the amount of capital paid in (that is, not over 120,000,000 francs). The company has authority to sell or hypothecate its securities, and to exchange the same for others. It can loan on public funds, shares and bonds, and open credit in account current on the various securities; it can take charge of all collections for account of joint-stock companies, pay their coupons and dividends, and make other disbursements for them. *It is, however, expressly understood (so runs the statute) that it shall not sell "short" or buy on time. (Il est expressément entendu que la société ne fera jamais de ventes à découvert, ni d'achats à prime.)*

The company, which was created in November, 1852, has, thus far, issued but three very condensed and incomplete reports, and extensive as are its operations thus far, it states that from its inability to issue bonds at present, it has not yet been able to show the world the full merits of its working. The reports refer to the operations of the calendar years of 1853, 1854, and 1855, and bear date April, 1854, 1855, 1856.

	1854.		
	1853.	1854.	1855.
	Francs.	Francs.	Francs.
Capital paid in, Dec. 31.....	54,500,000	60,000,000	60,000,000

Railroad and other Bonds.....	17,100,000	17,200,000	82,500,000
Stock contracts.....	25,000,000	21,000,000	87,800,000
Total.....	109,000,000	124,760,000	353,800,000
Total purchases through the year.....	146,000,000	164,000,000	823,000,000
Total sales through the year.....	111,000,000	110,000,000	217,000,000

The particular nature of the purchases and sales is not made public. We do not find in the papers before us any reference to the dividends or total profits, except for the year 1855. But the profits or investments and stock transactions at the Bourse alone, amounted to 3,618,000 francs in 1853, and to 6,207,000 francs in 1854; and the profits of all kinds to 26,000,000 francs in 1855. The profits on the "quick terms" at the Bourse are set down at 2,000,000 francs in 1853, and

3,400,000 francs in 1854, and to 10,000,000 francs in 1855. The profits on the "quick terms" at the Bourse are set down at 2,000,000 francs in 1853, and

3,400,000 in 1854; there is no means of ascertaining those of 1865, the report being silent on the subject. Full particulars are wanting as to the various transactions of the company relating to subscriptions to the capital stock of new companies, to loans to companies already established, and to the negotiations in which the company, without engaging its fund, acts simply as sponsor and intermediary. But the following comprise the chief transactions which have contributed to give *credit* to this active corporation: In 1853 it confined itself to previously existing corporations. In 1854 it created the company of the Grand Hotel du Louvre, in the Rue de Rivoli, with a capital of 24,000,000 francs; the Maritime Company (of clippers), with 30,000,000 francs capital; and the Austrian Railway Company, with a capital of 200,000,000 francs, the shares of which were issued in the beginning of 1855. In 1855 it subscribed for a large portion of the new stock of the Saint Rambert Railway, the Western Railroad of France (*Ouest*), and the Central Railroad of Switzerland, and the Elro Canal Company—amounts not mentioned.

In 1859 it took a large amount of the *Crédit Foncier* bonds, and 30,000,000 francs of the Grand Central Railroad bonds, and 6,000,000 francs of the Viëille Montagne (Zinc) Company's bonds. In the same year it sold out all the *Crédit Foncier* bonds, and most of the Viëille Montagne; the Grand Central bonds were, most of them, still unsold at the beginning of 1855. In 1854 it took about 5,500,000 francs of the Eastern Railroad (*Est*) bonds, and purchased sixteen thousand bonds of the Dole and Salins Railroad bonds; the amount of these bonds is not mentioned, probably 500 francs each. In 1855 it guaranteed the sales of 18,000,000 francs of the Western Railroad stock (*Ouest*), and of 100,000 bonds of the Southern railroads (*Midi*), representing 28,000,000 francs; and it took charge of the loan of 82,000,000 francs for the Austrian Railway Co., which passed rapidly and almost wholly into the hands of German capitalists.

The company acted as sponsor or agent in 1854, for the re-formation of the mines of the Loire, and for the fusion of the several omnibus companies in Paris into one joint concern; and in 1855 for the consolidation of the various Parisian gas companies. It has, moreover, been preparing for two years past the consolidation of the Eastern and Southern Salt Works. It put in a bid for the last government loan of 780,000,000 in behalf of itself and its correspondents, for no less a sum than 625,000,000; but its share was reduced when the bids were adjudicated to 1,281,000 francs of the 3 per cent. rentes. At the close of last year it embarked in grand speculations, which remained unsettled at the date of the last balance-sheet, but they appear there as yielding an estimated loss of 500,000 francs. The amounts received in account current are mostly from large companies, and can only be withdrawn, according to express stipulation, to be expended on their respective works. Individuals are also allowed to make deposits, the company agreeing to take charge of their investment and stock speculation.

In order to fully appreciate the power of this vast machine as a speculative agent, it must be borne in mind that the managers and leading depositors are men in the enjoyment of extraordinary resources of wealth and position, and that in their speculative operations at the Bourse, they and the company all act in concert, thus acquiring a power over the market which nothing, in the absence of extraordinary circumstances, can hope to resist. This power is made the greater from the large amounts employed by the company in carrying stocks for brokers and outside speculators, in the shape of stock contracts, or as the French call them, *reports*, which contracts mostly mature on the same day in each month. The company are thus enabled to depress the Bourse when they

wish to buy, by refusing to make new contracts when settlement-day comes, thereby forcing sales on a tight money market; and to promote a rise when they wish to sell, by granting a great increase of facilities to other dealers in stocks.—*N. Y. Times*. See *Bankers' Magazine*, N. Y.: July 1856. **Creek** (*Saxon creca*, said to be derived from the Latin *cripida*) is a shore or bank on which the water beats, running in a small channel from any part of the sea. It is also applied to any part of a large river which is resorted to as a harbor or landing-place by small craft. In the United States, the term creek is used as synonymous with the English words brook and rivulet.

Creoles. (In Spanish *Criollo*.) A name given to the descendants of whites born in Mexico, South America, and the West Indies; in whom the European blood has been unaltered with that of other races. The various jargons spoken in the West India islands by slaves, etc., are called Creole dialects.

Creosote, or the *fish-preserved*, from *creca* and *ota*, is the most important of the five new chemical products obtained from wood tar by Dr. Reichenbach. The other four, *paraffine*, *eupion*, *picamar*, and *pitacal*, have hitherto been applied to no use in the arts, and may be regarded at present as mere analytical curiosities. Creosote may be prepared either from tar or from crude pyroigneous acid. The tar must be distilled till it acquires the consistence of pitch, and at the utmost till it begins to exhale the white vapors of paraffine. The liquor which passes into the receiver divides itself into three strata, a watery one in the middle, placed between a heavy and a light oil. The lower stratum alone is adapted to the preparation of creosote. Creosote exists in the tar of beech-wood, to the amount of from 20 to 25 per cent., and in crude pyroigneous acid, to that of 14. It ought to be kept in well-stoppered bottles, because when left open it becomes progressively yellow, brown, and thick. Creosote has considerable power upon the nervous system, and has been applied to the teeth with advantage in odontalgia, as well as to the skin in recent scalds. But its medicinal and surgical virtues have been much exaggerated. Its flesh-preserving quality is rendered of little use, from the difficulty of removing the rank flavor which it imparts.

Cresset, a great light set on a beacon, lighthouse, or watch tower. It also signifies a lamp or torch; a large light or lantern fixed on a pole. *Mfnshen* derives the word from the Dutch *keers*, *kandela*; but it is more probably from the French *croisnet*, a little cross—that symbol having been usually placed upon beacons.

Crew, the company of sailors belonging to any ship or vessel. Ready obedience to the lawful orders of their superiors, ability to discharge their duties, and alacrity in their performance, at all times and under the most perilous circumstances, are the distinguishing characteristics of good seamen.—See *SEAMEN*. See *KENT'S Com. Manual for Consuls*. **PARSONS' Mercantile Law**.

Crimea, a peninsula in the Black Sea, forming part of the Russian government of Taurida, with the mainland of which it is connected by the isthmus of Perekop. It is situate between 44° and 46° N. lat., and 32° and 37° E. long. It is of an irregular square, or rhomboid form, measuring diagonally about 190 miles from east to west, and 123 from north to south, and containing an area of about 8,000 square miles. Its south-eastern, western, and north-western coasts, are washed by the Black Sea, and the eastern by a shallow lagoon, called the *Sivash*, or Putrid Sea, which is connected with the Sea of Azoff by a very narrow strait, and separated from it by a tongue of land, consisting of sand and broken shells, about 70 miles in length, and 1 to 1½ in breadth. The eastern part of the Crimea forms a minor peninsula,

stretching eastward to the strait of Kertah or Caffa, or Jonkaleh, the ancient Cimmerian Bosphorus, which forms the communication between the Black Sea and the Sea of Azoff, but it is not navigable by large or deeply-laden vessels. The most valuable commercial production is salt, which, as already mentioned, is obtained in very large quantities from *tuzlas*, or salt lakes, near Perekop, Koslov, Kaffa, and Kertah. It is a government monopoly, and yields a considerable revenue. The other principal articles of commerce and exports are wine, honey, wax, leather, hides, wool, and lambskins; of the last of which, called *akemaki*, great quantities are exported yearly to Poland and other neighboring countries. The only manufacture worth notice is what is called morocco leather, which is produced of good quality. The mountains contain masses of red and white marbles, full of cracks and fissures, which make them well adapted for quarrying, if there were a demand.

Criminals. By the laws of the United States, consular officers are required, in cases of the intended shipment of passers, or pardoned criminals, to the United States, to give timely notice of the fact, both to the Department of State and to the collector of customs of the port to which the vessel having them on board may be bound; furnishing the names of the parties, a description of their persons, the name of the vessel, and the date of sailing, in order that proper steps may be taken for the enforcement of such police regulations as may have been adopted by the several States upon the subject.—*Manual for Consuls.*

Crockery. In use, and made mention of as produced by the Egyptians and Greeks, so early as 1890 B.C. The Romans excelled in this kind of ware, many of their domestic articles being of earthen manufacture. Crockery, of a fine kind, in various household utensils, was made at Faenza, in Italy, about A.D. 1810; and is still called *faience* in French. Earthenware vessels were in use among the most ancient nations. Various domestic articles were made by the Romans, 715 B.C. The art was revived and improved in Italy, A.D. 1810. Wedgwood's patent ware was first made in 1762. His pottery in Staffordshire was extended to a variety of curious compositions, subservient not only to the ordinary purposes of life, but to the arts, antiquity, history, etc., and thereby rendered a very important branch of commerce, both foreign and domestic.

Cronstadt, or Kronstadt, a strongly-fortified seaport town of Russia, and the great naval station of the Russian fleet in the northern seas, is situated on the island of Kotline (frequently also called Cronstadt, from the town), at the head of the Gulf of Finland, 20 miles west of St. Petersburg, in N. lat. 59° 59' 26"; E. long. 29° 46' 30". The population in 1849 was 25,120; but it varies considerably at different times of the year, and in summer generally amounts to about 50,000. The island of Kotline is in general outline an acute triangle, 7 miles in length by about 1 in breadth, with its base toward St. Petersburg, and its apex extending obliquely seaward. The eastern or broad end is occupied by the town of Cronstadt; and 1½ miles from the western point of the island is the lighthouse of *Tobocchin* or *Tolbeacon*. The streets are regular, and in general well paved; but the houses, with the exception of those belonging to government, are chiefly of one story. The town was originally built of wood, and wooden structures are still numerous; but such buildings are now forbidden by law, and the majority of the houses are now built of brick, and plastered. Cronstadt is divided into two parts—the *Morskaja chast*, sea district, and the *Koopacheskaja chast*, or commercial district—and into four subdivisions. Of the two canals which traverse the town, that of St. Peter, constructed of granite, is 2,160 feet long, by about 80 yards wide. It commences between the Merchant and Middle Harbors,

and is in the form of a cross, of which one arm communicates with a dock, where ten slips of the line can be repaired at once. The Catherine canal, 1,880 fathoms in length, communicates with the Merchant Harbor, and thus enables vessels to take their stores, munitions, etc., directly from the store-houses. Between the two canals stood the old Italian palace of Prince Menschikoff, the site of which is now occupied by a large building used as a school for pilots, and educating above 300 pupils. On the northern side of the island the passage is impracticable, except for very small craft, being obstructed by rows of piles and large masses of stone, extending from the island to Lial Noas, on the mainland. The southern channel is the only practicable passage from the Gulf of Finland to St. Petersburg, and it is strongly defended on both sides by forts and batteries. The principal of these are Forts Alexander, Risbank, Peter, Cronslott, and that of Menschikoff, already mentioned. The Great Road is commanded by Forts Alexander and Risbank, about 1,600 yards apart. The former, on the left side of the passage, consists of a front with 4 tiers of embrasures, and two flanks of 3 tiers each, and a rear wall mounted with guns *en barbette*. It is built of blocks of granite on a foundation of piles in 18 feet of water, and commands the road by 116 8 and 10-inch guns, all in casemates. Fort Risbank, which was not finished last year (1853), on the opposite side, is also of granite, resting on a foundation of piles, in 16 feet of water, and is armed with tiers of guns of the heaviest calibre. Further eastward, on the left, is Fort Peter, or Citadel Fort, with 3 towers or bastions joined by 2 curtains; the first commanding the approach to the rear of Fort Alexander, while the second and third sweep the main channel. These bastions have 28 guns in casemates, and 28 guns above *en barbette*: the curtains have no casemates, but mount 20 guns *en barbette*. To the right of the Little Road is Cronslott, an irregular pentagon, originally built by Peter the Great. It presents to the sea a low line of timber casemates, forming a battery of 40 guns placed *a fleur d'eau*, and disposed in the half of each of two bastions with a connecting curtain. All this work, however, has been destroyed, and last year (1853) the piles had been driven on which a granite fort was to be built, which by this time (October, 1854) is probably complete. The mole forming the western flank of the Merchant Harbor mounts 70 guns, besides 12 mortars; and the channel, between Cronslott and the mole, is only 250 yards wide. Almost all vessels bound for St. Petersburg touch at Cronstadt, and those drawing more than 7 feet of water load and unload here—the goods being conveyed to and from the quay in lighters. Vessels of 10 feet draught have, however, been known to go up with high water. The port is ice-bound during the winter, from November to April. Cronstadt was founded by Peter the Great, 1703.—E. B.

Cronstadt is the port through which the foreign commerce of St. Petersburg is principally conducted. The number of vessels cleared in 1848-49, was as follows:

Years.	Entered.	Cleared.
1848.....	1,515	1,470
1849.....	1,570	1,550

In these figures Great Britain held the first rank. The number of British vessels entered and cleared was 920, measuring an aggregate of 209,318 tons. Under the French flag there entered and cleared 55 vessels, of 8,598 tons. The total value of French cargoes imported in 1849, reached about \$5,000,000, against \$1,000,000 of exports direct to France. Official returns for 1853 exhibit a total of 1,898 vessels, under all flags, having entered during that year; and the following table gives the nationality and number of these arrivals from each nation:

Countries.	No. of vessels.	Countries.	No. of vessels.
England.....	684	Hanover.....	45
Holland.....	254	Oldenburg.....	49
Denmark.....	199	United States.....	41
Sweden.....	184	France.....	41
Prussia.....	116	Naples.....	22
Norway.....	97	Bremen.....	8
Laboe.....	88	Hamburg.....	8
Russia.....	88	Greece.....	1
Mecklenburg.....	59		

Cross-trees, in a ship, pieces of oak timber, supported by the cheeks and trestle-trees, at the upper ends of the lower and top-masts to sustain the frame of the tops in the one, and to extend the top-gallant boards on the other.

Croton Oil is expressed from the seeds of a euphorbiaceous shrub, the *Croton tiglium*, a native of Hindostan and of the warmer parts of Asia. The fruit is about the size of a hazel-nut, of an ovate triangular shape, and containing three ovate seeds, about the size of a pea. The kernels of these yield, on pressure, about 50 per cent. of oil, which is of a pale amber color, and a thickish consistence, like castor oil. It has no odor, but has a peculiar acrid taste, which is felt most strongly in the back of the palate and throat. Croton oil is a speedy, powerful, and sure cathartic, in small doses, of one to three drops; and it possesses two valuable properties: 1st, that however active and powerful the purgative action may be, it soon ceases, and leaves no debility; and, 2d, that it excites the biliary secretion, more powerfully than any known medicine. In consequence of one or two drops being a dose, and its action commencing very shortly after its administration, it is invaluable in impending apoplexy, and in almost all diseases in which torpor or paralysis exists. In hydrocephalus, even when effusion of water on the brain appears to have taken place, the late Dr. Abercrombie stated that it would often bring about the recovery of the patient. It is a medicine which deserves far more attention than it has yet received.—E. B.

Crown, in Commerce, a common name for coins of several nations, which are about the value of a dollar. See COINS, TABLE OF.

Crown Glass, the best kind of window-glass. The hardest and most colorless, is made almost entirely of sand and alkali, and a little lime, without lead or any metallic oxyd, except a very small quantity of manganese, and sometimes cobalt. Crown glass is used in connection with flint glass for dioptric instruments, in order to destroy the disagreeable effect of the aberration of colors. Both kinds of glass are now made in the highest perfection, in Benedictbura, where Reichenbach's famous manufactory of optical instruments is situated.

Crucibles (*Cruetsels*, Fr.; *Schmelztiegel*, Germ.) are small conical vessels, narrower at the bottom than the mouth, for reducing ores in decimasy by the dry analysis; for fusing mixtures of earthy and other substances; for melting metals, and compounding metallic alloys. They ought to be refractory in the strongest heats, not readily acted upon by the substances ignited in them, not porous to liquids, and capable of bearing considerable alterations of temperature without cracking; on which account they should not be made too thick. The best crucibles are formed from a pure fire-clay, mixed with finely-ground cement of old crucibles, and a portion of black-lead or graphite. Some powdered coke may be mixed with the plumbago. The clay should be prepared in a similar way as for making pottery ware; the vessels after being formed must be slowly dried, and then properly baked in the kiln. Platina crucibles are not fusible, but are too costly for general use.

Cruise, (Germ., *Kreuzen*, to cross.) A voyage within certain limits, for the purpose of meeting with enemy's ships, prizes, etc., or for mere exercise, or for the relief of vessels in distress.

Cruisers, in naval affairs, vessels, as the name imports, employed on a cruise. The name is commonly given to small men of war, made use of to secure merchant ships and vessels from the enemy's small frigates and privateers. They are generally formed for fast sailing, and well-manned.

Cuba, the largest and richest of the West India islands, and the most important colony of Spain, was discovered by Columbus on the 28th October, 1492, during his first voyage. It was first called *Juana* in honor of Prince John, son of Ferdinand and Isabella; but after Ferdinand's death it received the name of *Fernandina*. It was subsequently designated *Santiago*, from the patron saint of Spain; and still later *Ave Maria*, in honor of the Virgin. Its present name is that by which it was known among the natives at the time of its discovery. It was then divided into nine independent principalities, under as many *caciques*.

The island of Cuba is long and narrow, somewhat in the form of an irregular crescent, with its convex side toward the north. It divides the entrance to the Gulf of Mexico into two passages: that to the N.W. being 32½ leagues wide at the narrowest part, between the points of Hicacos in Cuba, and Tancha on the Florida coast; and the S.W. passage 88 leagues wide between the Cabo de San Antonio of Cuba, and the Cabo de Catoche, the most salient extremity of the peninsula of Yucatan. Cuba lies between 74° and 85° W. long., and 19° and 28° N. lat. Its length, following a curved line through its centre, is 790 miles, and its greatest breadth (from Cape Mismilios to Mota Cove) is 107 miles. The area is estimated at 81,468 square miles, or, including the other small islands attached to it, 92,807 square miles. The coast of Cuba is generally low and flat, and is surrounded by numerous islands and reefs, which render the approach both difficult and dangerous to those not acquainted with the proper channels. The low nature of the coast subjects it to frequent floods and inundations; and especially on the north side of the island, there are many large lagoons from which a considerable quantity of salt is obtained. No island, however, in proportion to its size, has a greater number of excellent harbors, many of them accessible even to ships of the line. A range of mountains extends from one end of the island to the other, dividing it into two unequal portions, of which the northern is generally the narrower. The highest are those at the S.E. extremity of the island, to the N.W. of Santiago de Cuba, and have, according to Humboldt, an elevation of 1,200 toises, or 7,673 English feet. This Cordillera is one great calcareous mass, resting on a schistose formation. The summits are for the most part rocky and naked, occasionally interrupted by more gentle undulations. The central and western parts of the island contain two formations of compact limestone, one of clayey sandstone, and another of gypsum. The limestone formations abound in caverns. The secondary formations, east of Havana, are pierced by syenitic and euphotide rocks united in groups. The syenitic strata are intercalated with serpentine, and inclined to the N.W. In some places petroleum runs out of rents in the serpentine; and abundant springs of this fluid are also found in the eastern part of the island. The rivers in general are necessarily short, and flow toward the north and south. The largest is the Cauto, rising in the Sierra del Colbre, and falling into the bay of Buena Esperanza on the southern coast, after a course of 59 leagues, for 20 of which it is navigable, though at low water obstructed by bars. The Sagna la Grande rises in the Sierra del Escambray, passes Santo Domingo, & falls into the sea in front of the Boca de Maravillas, being navigable for five leagues. The principal of the other rivers are the Sagna la Chica, the North and South Atibonica, the Cayaguatoje, Sasa, Agobama, and the Hanabana. On some of the rivers are beautiful cascades, while

several of them flow, during part of their courses, under ground.

The mineral riches of the island have not yet been explored to any considerable extent. Though gold and silver have undoubtedly been found on the island, the quantity has never been sufficient to repay the labor of search. Gold was sent to Spain from this island by the early settlers, but it was more probably the accumulated wealth of the aborigines in previous centuries, wrested from them by tyranny and rapine at the period of the conquest, than the product of honest labor on the part of the colonists. Traces of auriferous sand are found in the rivers Holguin, Escawbray, etc. Some specimens of the finest gold have been obtained in recent times from the workings of Agabama and Sagua la Grande, but at an expense of time and labor that could not remunerate the parties engaged in it. In 1827, silver and copper were discovered in the jurisdiction of Villa Clara, and the first ore gave no less than 7 oz. of pure silver to the quintal (= 107½ lbs.) of ore; but they have become less productive, probably from not being properly worked. The copper mines near Santiago, in the eastern part of the island, are of great extent, and very rich, employing nearly 900 persons, and yielding an ordinary average of about 27 per cent. of pure metal. They were wrought with some success during the 17th century, but had been abandoned for more than 100 years. About the year 1830, Mr. Hardy, a landed proprietor in the island, happened, when on a visit to that part, to carry off some of the refuse of the old workings in order to subject them to analysis, the result of which was, that the metal was found so rich as amply to repay the expense of sending it to England for smelting. Several other mining companies have since been established; and the amount of copper ore exported in 1850 was 552,288 quintals, or nearly 25,100 tons. Of the 35,683 tons of copper ore imported in 1851 into the United Kingdom, 20,825 tons came from Cuba. Coal of a highly bituminous character, affording a strong heat, and leaving very little solid residue in the form of ashes or cinders, is very abundant. In some places it degenerates into a form resembling asphaltum, and near the coast it is often found in a semi-liquid state like petroleum or naphtha. In the quarries near Havana a thick slate is found, fit for floors and pavements. Marbles and jaspers of various colors, and susceptible of a high polish, are found in many parts of the island, and particularly in the Isle of Pines. It is generally believed that iron exists in various parts of Cuba; and many parts of the great Cordillera undoubtedly contain rocks of a ferruginous nature; but from the difficulty of access, the scarcity of fuel, and the want of capital, no extensive mining operations have been engaged in. Native loadstone, however, has been found in various parts, and chalybeate springs are numerous.

The circulating medium of Cuba, was until lately composed entirely of the precious metals; paper money is now issued by the bank which has just gone into operation. The coins in use are the Spanish doblon, or *onza de oro*, which is a legal tender for 17 hard dollars, and at the ordinary rate of exchange of 8 4-37 per cent., is worth £3 10s. 10d. sterling; and the subdivisions of the doblon, the half, the quarter, the eighth, and the sixteenth—the last being equivalent to a dollar and half a real. The Mexican, Colombian, and other South American doblons are a legal tender for 16 hard dollars, equal to £3 6s. 8d. sterling, and are sometimes in demand for exportation at a premium; their divisions are worth, 8, 4, 2, and 1 dollar respectively. Of silver coins, the Spanish dollar and its divisions, and also Mexican, United States, and South American dollars, are legal tenders at their nominal value.

The principal port is Havana, or Havanaah, on the north coast of the island of Cuba, of which it is the

capital, the Moro castle being, according to Humboldt, in lat. 23° 8' 15" N., long. 82° 22' 45" W. The population of the city and suburbs was said to be, in 1851, about 200,000. In 1827, the resident population amounted to 64,023; viz., 46,621 whites, 8,215 free colored, 15,347 free blacks, 1,010 colored slaves, and 22,830 black slaves. The port of Havana is the finest in the West Indies, or perhaps in the world. The entrance is narrow, but the water is deep, without bar or obstruction of any sort, and within it expands into a magnificent bay, capable of accommodating 1,000 large ships—vessels of the greatest draught of water coming close to the quays. The city lies along the entrance to, and on the west side of, the bay. From its position, which commands both inlets to the gulf of Mexico, its great strength and excellent harbor, Havana is, in a political point of view, by far the most important maritime station in the West Indies. As a commercial city it also ranks in the first class. The ports of the island licensed for foreign trade are Havana, Santiago, Puerto Prince, Matanzas, Trinidad, Baracoa, Gibara, Cienfuegos, and Manzanilla. A bank has been recently established in Cuba, under a Royal charter.

It is impossible, from the conflicting accounts of the different writers upon the subject, to arrive at any thing like certainty as to the number of inhabitants on the island at the time of its conquest; but it may be estimated at probably from 800,000 to 1,000,000. There is little doubt, however, that before 1560 the whole of this population had disappeared from the island. The first census of Cuba was taken in 1775, when the population was 170,862. In 1791 it was 272,140. The following table gives the population since that period:

Year.	Whites.	Free Blacks.	Slaves.	Total.
1811	374,000	114,000	242,000	690,000
1817	280,021	115,691	225,395	620,990
1827	311,051	106,494	280,942	718,487
1841	418,291	152,838	490,495	1,001,624
1846	425,769	149,226	328,759	898,752
1849	457,133	164,110	323,807	945,049
1850	605,560	205,570	496,100	1,247,230

Neither of the last two censuses include the garrison, crews of vessels, or the floating population.

The following is a more minute classification of the people of the island, according to the census of 1850:

Creole whites.....	520,000
Spaniards.....	30,000
Troops and marines.....	25,000
Foreigners.....	10,560
Floating population.....	17,000
Total whites, 605,560	
Free mulattoes.....	118,200
Free blacks.....	87,370
Total free colored population, 205,570	
Slaves, mulattoes.....	11,100
Slaves, blacks.....	425,000
Total slaves, 436,100.	
Grand total.....	1,247,230

The present population, adding garrison and floating population, is nearly 1,400,000. The census of 1816 gives the population of the principal towns as follows: Havana, 106,968; Puerto Prince, 19,168; Santiago de Cuba, 24,005; Matanzas, 16,986; Trinidad, 13,222. The population of Havana, in 1849, is given at 442,002, and in 1850, at 550,561.

The chief agricultural products of Cuba are sugar, coffee, and tobacco. The cultivation of these has advanced with great rapidity since 1809, when the ports of the island were more freely opened to foreigners. The cultivation of coffee advanced for a time with equal or even greater rapidity than that of sugar; but latterly, from the low prices of coffee, the cultivation of sugar has become the more profitable, and in a great measure supplanted coffee. Among the other productions are Indian corn, rice, beans, plantains, cotton, cocoa, pine-apples, lemons, oranges, limes, figs, melons, etc. Of the manufactures, the principal are the

making of sugar, molasses, rum, and segars, and the preparation of coffee and wax.

The latest and most reliable statistics of the island present the following divisions of agricultural industry, viz.: sugar estates, 1,442; coffee estates, 1,618; tobacco estates, 3,102; and grazing farms, 9,930, on which are reared about 898,199 head of cattle. Besides these, large herds of cattle are also reared on the extensive and fertile prairies of the uncultivated portion of the island.—E. B.

Politically, the island of Cuba is divided into three departments: the Oriental, the Central, and the Occidental; and these are again subdivided into a number of governments, sub-governments, and colonies. The Central and Occidental departments form the civil province of Havana, and the Oriental the civil province of Cuba.

In 1809, the restrictions imposed upon Cuba, of trading to no foreign country whatever, were removed; and from that period to the present, official returns of the population, agriculture, commerce, and revenue of the island have been annually prepared, and, apparently, with great care. These reports, or "Balanzas Generales," exhibit a regular and marked progress in the industrial and commercial movements of Cuba, from the period above specified—its trade with foreign nations steadily advancing, and the supplies of its more prominent staples regularly keeping pace with the increased demands of an enlarged and comparatively emancipated commerce. In 1775, the entire population of the island was 170,370. In 1850, it had risen to 1,247,230, showing an increase during the intervening 75 years of 1,076,860, or about 700 per cent.

Commerce with Cuba.—The increase of the trade of the United States with the port of Havana over that of all other nations, notwithstanding the bad feeling that has existed between the two countries, is truly wonderful. The *Havana Mercantile Report* of the 7th of August, 1856, gives a statement of the number of vessels, their tonnage, and the nations to which they belong, which entered the port of Havana during the first 6 months of the 10 years last past. The increase in the total tonnage for the first 6 months of the year, from 1846 to 1855, is a trifle more than 100 per cent. While the American tonnage has increased more than 200 per cent., the Spanish and British are nearly stationary. For the first 6 months in 1846, the American tonnage employed in this trade was 71,722; the Spanish, 55,528; and the British, 32,969. The total number of vessels which entered that port during the 6 months ending July 1st, 1855, was 1,080, of a tonnage of 364,033; and of these, 570, of a tonnage of 231,484, were American; 58,338 Spanish; 32,165 British. The French tonnage has increased from 1,761, in the first 6 months of 1846, to 8,269, for the same period of 1854, and 23,283, more than two thirds of the British, in 1855. In the tonnage of other nations, Belgian, Dutch, Danish, Bremen, Hamburg, and others, there has been no material increase. Prior to the removal of the restrictions on foreign commerce, there was some trade carried on between the United States and Cuba, by virtue of Spanish grants and occasional relaxations of the law; but it was generally limited to the importation of articles necessary to supply the people of the island with the means of subsistence.

The wars between the mother country and the Spanish American republics having driven the Spanish flag from the ocean, the laws of differential duties remained in abeyance, and the commerce of Cuba, existing chiefly with the United States, was carried on in American bottoms, which even extended their services to Spain, bringing the oil and wine of the Peninsula to the colonists. The gradual settlement of the difficulties with the revolted provinces enabled the flag of Spain again to come upon the sea, and her mercantile marine received a new impulse. During the pe-

riod that had elapsed since the opening of the ports, the natural increase of the wants of the colonists, attendant upon an exchange of their products with those of foreign countries, opened a market in Cuba for many of the products of mechanical industry, which found their way there through the ports of the United States; so that, at the close of this era, in the year 1830, the foreign commerce of the island was confined almost exclusively to our marts, to which she looked even for those articles which were not produced in this country. This was the season of the most prosperous commerce between Cuba and the United States. The re-birth of the Spanish merchant-marine brought with it clamors for protection, and the tariff of Cuba was altered, imposing a differential duty upon goods imported in foreign bottoms. The object of this duty was to encourage the employment of national vessels in the trade of the island with this country. Spanish ships very soon made their appearance in American ports, and were rapidly obtaining a large share of the carrying trade, which had, before that period, been enjoyed exclusively by American vessels.

About this time, repeated but unavailing representations had been made to the Spanish government of the injustice of its course in imposing such discriminating duties both on the navigation and commerce of foreign countries, and in favor of Spanish bottoms. Negotiations having proved abortive, a system of defensive or retaliatory measures was recommended, as the only means of self-protection, in an elaborate report made by the Committee on Commerce of the House of Representatives, in May, 1834, which concludes thus: "Your committee, therefore, from a view of all the circumstances, have deemed it their duty to report a bill, authorizing the Secretary of the Treasury to collect such additional tonnage duties upon Spanish vessels entering the ports of the United States from Cuba and Porto Rico as shall be equivalent to the discriminating duty that would have been imposed upon the cargoes of such vessels, respectively, if the same had been exported from Havana in American bottoms; and also upon Spanish vessels clearing out from the ports of the United States, such additional tonnage duty as would be equivalent to the discriminating duty payable upon their cargoes, respectively, if imported into Havana in American bottoms."

The bill reported became a law in June, 1834, and conformably to its provisions, the Secretary of the Treasury, in February, 1835, issued to the collectors of the customs his circular, in the following words: "I have to call the attention of the officers of the customs to the accompanying copy of the act of Congress concerning tonnage duty on Spanish vessels, approved the 30th June last, and which goes into operation on the 1st day of March next. Tabular statements are annexed, showing the rate of duty to be levied, in the nature of tonnage duty, on the arrival of Spanish vessels at any port in the United States, coming from the islands of Cuba or Porto Rico, either directly or after touching at any port or place, laden with merchandise subject to discriminating duty when exported from the port of Havana in American bottoms, together with the rate of duty to be exacted from the aforesaid vessels departing from a port of the United States, with a cargo destined, directly or indirectly, to either of the islands before described."

The above extract from the circular contains, in substance, the first 8 sections of the act of 1834. The 5th section shows the purport and scope of the act, and that it was designed by the committee from which it emanated, as well as by Congress in its adoption, to force the government of Spain into a more liberal and just course of legislation in regard to the commerce between the United States and this island, by placing Spanish vessels, with their cargoes, coming into or departing from the United States, in the same

condition, as to imposts of all kinds, that American vessels are subjected to in the colonies of Spain. This equality was demanded as imperatively in behalf of the interests of Cuba and Porto Rico, as in vindication of our commercial rights; and the 5th section expressly limits its continuance and restricts its application to the accomplishment of that end. This section is in these words:

"And be it further enacted, That whenever the President of the United States shall be satisfied that the discriminating duties in favor of Spanish bottoms levied upon the cargoes of American vessels in the ports of Cuba and Porto Rico have been abolished, or whenever, in his opinion, a satisfactory arrangement upon the subject of the said duties shall have been made between the United States and Spain, the President is hereby authorized to declare the same by proclamation, and thereupon this act shall cease to have any further force or effect."

In 1849 the Treasury Department ascertained that certain privileges had been accorded on the part of the Spanish government to vessels of the United States entering and departing from ports in the island of Cuba. A circular was immediately issued from that department, which, after citing the provisions of the acts of 1832 and 1834, and specifying the privileges alluded to, says: "It consequently follows, that where no tonnage duty or discriminating duty on the cargoes of American vessels entering or departing from ports or places in the island of Cuba is imposed and collected thereat, Spanish vessels coming from such ports or places are to be similarly treated, as regards tonnage duty, in the ports of the United States. The collectors of the customs are, therefore, instructed to abstain from the exaction of any tonnage duty on Spanish vessels coming from ports or places in the island of Cuba, in ballast, or when laden with cargoes of molasses taken in at either of said ports."

In 1852 a similar circular was issued to collectors, instructing them to admit Spanish vessels arriving from Spanish or any other foreign ports, those of Cuba and Porto Rico excepted [the royal decree of 3d January, 1852, excepted Cuba and Porto Rico from the privileges thus reciprocated], to entry on the same footing as American vessels, as regarded tonnage duty, light-money, and all other dues to the United States, so far as respects vessels. These acts (of 1832-34) have been in force now during a period of 22 years, and, with the exception of the slight privileges which called for the circulars already referred to, have failed to produce the effect contemplated by their enactment. The commerce between the United States and these islands, in the aggregate, has not fallen off; but the increase has not been such as should be expected from the great expansion of our general commerce, and the increased development of the agricultural and industrial resources of Cuba, since that period. The most obvious effect has been to exclude Spanish ships from our ports, and to destroy, in a measure, all that portion of the carrying trade hence to Cuba which comprised articles of foreign product; for the Spanish vessels, no longer permitted to engage in the carrying trade between the United States and Cuba, on more favorable terms than American vessels, were soon driven from our ports, and supplied the wants of the island from the countries where the articles were produced; and thus the hardware, glass, delf, and drygoods of England, that had been previously brought to the United States in American packet-ships, principally, from London and Liverpool to New York, were now directly imported into Cuba; and the same result has attended the carrying trade from France in her silks and fancy wares, and Germany in her cottons, linens, and hosiery.

The following table exhibits the number and nationality of vessels employed in the trade of Cuba during the three years 1826, 1829, and 1834:

	ENTERED.		
	1826.	1829.	1834.
Spanish.....	188	896	797
United States.....	1,106	949	945
All other.....	395	237	294
Total.....	1,659	1,702	2,036

	CLEARED.		
	1826.	1829.	1834.
Spanish.....	127	306	717
United States.....	914	890	910
All other.....	247	814	290
Total.....	1,288	1,670	1,917

An analysis of the preceding figures will show an aggregate increase in the number of vessels entered from 1826 to 1829, of 43; and to 1834, of 377; and in vessels cleared, an increase, for the first period, of 282, and for the second, of 629. The increase in Spanish vessels entered from 1826 to 1829 was 208, and to 1834, 609 vessels. The decrease from 1826 to 1829 in the United States vessels was 157, and to 1834, 161; and the decrease in vessels from all other nations, for the first period, was 28, and to 1834, 71 vessels.

Total.....	\$14,925,704	\$18,695,856	\$18,668,300

The preceding tables show an increase in the aggregate value of imports into the island in 1829 over 1826 of \$3,770,102; while, during the second period, from 1829 to 1834, this trade remained stationary. A minute analysis of the figures, however, will show the significant fact that, while the carrying trade in Spanish bottoms has risen from \$841,826 in 1829 to \$4,570,018 in 1834, the imports from the United States, during the same period, fell from \$5,734,765 to \$3,690,101. During the three years compared, the imports into the United States from Cuba remained stationary, being in 1826 \$3,894,597; in 1829, \$3,191,535; and in 1834, \$3,824,724.

Imports of Flour.—During the periods under review—indeed, at all times—provisions form the largest item in the imports from the United States. The enormous discrimination in favor of the national flag on flour has always had the effect of restricting almost exclusively to national vessels the trade in this article. Thus, in 1829 the value of flour imported into Cuba, in Spanish vessels, was \$1,582,768, while from the United States it amounted only to \$345,315, and from all other places to \$13,662; and in 1849, or twenty years after, the value of flour imported in Spanish bottoms was \$2,075,262; from the United States, \$9,331; and from all other places, \$1,725. The acts of 1802 and 1831 can, unquestionably, be traced in this great falling off in the article of flour; but, that other causes also contributed in securing for the Spanish flag so complete a monopoly of the trade in this article is demonstrated by the fact that, while the value of flour imported from all other places (than the United States) in 1829 amounted to \$13,662, representing 1,093 barrels, we find this figure in 1849 dwindled down to \$1,725, representing only 136 barrels. That the repeal of these acts would largely augment the export as well as the import trade of the United States with Cuba, there can be no question; but, until the discriminations in favor of the national flag are modified or removed, the carrying trade between the United

States a unjust ly Spar Comm of Spain is adher as rigor entire so States a dicato th this line tervailing continue modifio the indu diplomac the king vicerey o "Be car the culti ample pr the king's products tions wemphatic perfectly necessary charge ar cultu." fo the w trade in 1610, rru is no prac inations a policy; w virtually staples, fo sanly loo Until a adopts the characterizes lowers the e and other necessary commerce but with must ren centry—petent as —inadeq almost pu is burden the island comfortal itants, un If the p, or t with the the latter provinces acts and r mercial r liberal rec very shor the rich any Islam eminently render in the motie

IMPORTS OF FLOUR

1826
1834
1852

States and that island would, under their unequal and unjust operation, be almost exclusively monopolized by Spanish bottoms.

Commercial Policy of Spain.—The restrictive policy of Spain, especially as regards the trade of her colonies, is adhered to to-day, in Cuba and Porto Rico, almost as rigorously as when she was mistress of nearly the entire southern portion of this continent; and the stationary condition of the trade between the United States and these islands since 1834 would seem to indicate the fruitlessness of any efforts to force her from this line of policy by measures of retaliation or countervailing acts. So long as the system itself shall continue to be the colonial policy of Spain but little modification in its details need be looked for, whether the influence to that end be countervailing acts or diplomacy. "Be careful," says the instructions of the king and Council of the Indies to Luis de Velasco, viceroy of New Spain, early in the sixteenth century, "Be careful not to foster manufactures, nor to allow the cultivation of vines, inasmuch as there was always ample provision of these things, and the commerce of the kingdom should not be impaired by such colonial products;" and in the year 1610 these royal instructions were repeated, with the addition of the following emphatic language: "Inasmuch as you understand perfectly how much the observance of these rules is necessary for the dependence of the colonies, we charge and command you to see to their faithful execution." The same spirit that dictated this protection for the wine and oil of Spain, and for the exclusive trade in these articles to her American colonies, in 1610, remains unchanged in any degree (because there is no practical distinction between prohibitive discriminations and positive prohibitions) in the commercial policy, which, in 1856, two centuries and a half later, virtually excludes American flour, and many other staples, for which the inhabitants of Cuba must necessarily look to a foreign market.

Until the system itself is abolished, and Spain adopts the more liberal commercial policy which characterizes the present enlightened age; until she follows the example of Great Britain, Belgium, Holland, and other neighboring countries, in removing all unnecessary shackles from commercial enterprise, the commerce of Cuba, not only with the mother country, but with the United States, and all foreign nations, must remain as it has during the past quarter of a century—crippled, restricted, and struggling; incompetent as a source of revenue to the home government—inadequate to meet the expenses of the colonial, and almost powerless, from the restrictions with which it is burdened, in developing the exhaustless resources of the island, or even in supplying the necessary means of comfortable subsistence to the great bulk of its inhabitants, unless at prices far above their scanty means.

If the government of Spain could be induced to propose, or to agree, to a similar commercial reciprocity with the United States to that now existing between the latter country and the British North American provinces, it would not only supersede countervailing acts and retaliatory measures, by establishing the commercial relations between them on a basis of just and liberal reciprocity; but, it is believed that, while in a very short period it would make the island of Cuba the richest in wealth, as it is in natural resources, of any island of the same size in the world, it would also eminently contribute to cement more strongly, if not render indissoluble, the bonds of union between it and the mother country.

IMPORTS OF TOBACCO INTO THE UNITED STATES FROM CUBA, FOR THE YEARS ENDING JUNE 30TH, 1853, 1854, 1855.

	Unmanufactured.		Segars.	
	Pounds.	Value.	M.	Value.
1853	4,295,580	\$764,529	117,944	\$2,896,020
1854	4,052,187	700,871	171,822	2,760,229
1855	8,718,986	523,112	157,307	2,581,453

The following table exhibits the value of exports from the United States to Cuba during two periods, embracing three years each:

Years.	Value.	Quantity of Flour.	Value.
1834	\$8,000,101		
1835	5,406,919		
1836	6,536,281		
1838	6,237,509	1,587 bbla.	\$7,790
1854	8,551,752	11,598	82,488
1855	8,004,583	8,428	83,176

It will be seen from this table that the export trade of the United States to Cuba in 1853 is less than it was in 1836, while the increase in 1854 and 1855 is by no means proportionate to the rapid increase of our general commerce, and of the agricultural products of Cuba. Were the discriminations removed, flour would unquestionably become our leading staple export to Cuba. The importations of this article into Cuba in 1847, were 235,243 barrels, of which 175,870 barrels were from Spain, and 59,373 barrels from the United States. In 1848 the number of barrels imported fell to 231,119, of which only 18,175 barrels were from the United States. The most moderate estimate puts the consumption of flour in Cuba, were it admitted at reasonable duties, at from 890,000 to 900,000 barrels. That this trade would be enjoyed almost exclusively by the United States is evident from the fact that flour is among our heaviest articles of export, and European competition with a country within a few days' sail of the island would be out of the question.

The balance of trade between the United States and Cuba is enormously against the former. In 1863, this balance amounted to \$12,297,796; in 1855 it was \$10,620,757. The value of 500,000 barrels of flour, fixing the price at \$5 per barrel, would be \$2,500,000; or one fifth of the balance against the United States would be realized on the single article of flour alone. The increased quantities of bacon, pork, lard, and provisions generally, of domestic manufactures, etc., would render the commerce between this country and Cuba more equal, as well as more just; while the exports from Cuba to the United States would be proportionably augmented. One year's trade, if conducted on principles of reciprocity, would be sufficient to demonstrate the advantages which would result to both countries from the adoption of a policy commended alike by the products and wants of each, respectively, and by every principle of commercial economy.

Great as is the productiveness of Cuba at present, some writers assert that under a good government it would be increased fivefold; its mineral resources would then be fully developed, and it would be able fully to take advantage of its admirable position to develop its trade. The continuance of the present line of policy in reference to Cuba must in time lead to a revolution which Spain will be unable to quell.

Since the adoption of the Spanish tariff of the year 1830, in Cuba, several revisions have been made, and the rates of duty from time to time have been materially diminished, to the eminent advantage of the revenue; but there has still been retained, and in many instances increased, the differential duties in favor of Spanish products and national bottoms. The following instances of the operation of these differential duties will sufficiently exhibit their general character.

Lard.—An article of great consumption in Cuba, imported almost exclusively from the United States, is subject to a duty of 4½ cents per pound when brought from this country in American bottoms; the coarser qualities of oil (olive), which are imported for the same purposes, are delivered with a duty of 2-4-5 cents per pound; and the result is, that 10,000,000 pounds of lard, being a vastly superior article, are imported, while 8,500,000 pounds of oil from other countries, far inferior to lard, are enabled to compete with it in the markets of Cuba, because of the difference in price, in its favor, produced by the duty.

Productions.—Aguardiente (tafia, or rum) is distilled from molasses and the refuse of sugar-works. It is sold per pipe of 125 gallons, with or without cask, according to agreement; good tafia is of not less than 20 degrees, clear and transparent, slightly brown in color, and smooth taste. The exports of this article for the year 1856 were about 15,473 pipes, of which 7536 went to Spain; 150 to the United States; 294 to Great Britain; 2091 to Cowes, or Falmouth and a market; 640 to Hamburg and Bremen; 2637 to France; 588 to Trieste and Venice; 1879 to South America and Mexico; and the balance to Italy, Gibraltar, and a market. The exports of 1855 very considerably exceed any previous year, and from the number of extensive distilleries recently established, the article is likely to form a considerable item of exportation in future. It has commanded the last year as high as \$45 and \$48 per pipe during a portion of it; at the termination of the year it was quoted at \$40 to \$42, brisk. The number of pipes shipped were 21,102, of which 840 went to the United States; 3499 to Great Britain; 798 to Germany; 2114 to France; 12,787 to Spain; 809 to South America and Mexico; and the balance to Italy and other countries.

Leaf Tobacco.—Tobacco is one of the most important articles of production in the island of Cuba. The planters commence to plant in August or September, after the heavy rains are over, and when the northerly wind is looked for, which generally come accompanied by a drizzling rain that is favorable to the plant. In February or March, and as late as April, the tobacco is cut and taken to a house or shed, erected for the purpose of affording shade, and at the same time a free circulation of air; it is placed on *cujes* (poles), laid horizontally at some distance from the ground, where it is allowed to become perfectly dry until the spring rains commence, when the humidity seizes the leaf, causes it to swell, and to take the silky appearance peculiar to it. It is then taken from the poles and laid in a heap on the ground, the leaves being slightly sprinkled with water; in this state it undergoes a species of fermentation. After this operation is gone through, the leaves are placed in *manojos* (hands); afterward it is a very common practice to take a quantity of refuse leaves and infuse them in a certain quantity of water, and, in some instances, wine, and even alcohol, or, rather, tafia is used when the tobacco is light colored and weak, and it is desired to give it increased strength. This infusion undergoes a state of fermentation, after which the refuse leaves deposit themselves at the bottom. The tobacco is dipped into this preparation before being hung up in a room almost air-tight, where it undergoes the sweating, to which the name of *calentura* (fever) is given; the process of dipping is performed as many times as the tobacco may require. I am under the impression that this process might be used to great advantage with the Connecticut tobacco. The qualities of Cuba tobacco vary according to the section or district in which it is produced: that grown on the western end of the island is the celebrated *Vuelta Abajo* tobacco; that raised in other parts of the island, which is very inferior in quality, is known under the name of *Vuelta Arriba*. There is another class, called *Taru*, from which Puerto Principe cigars are made.

The best *Vuelta Abajo* tobacco is grown on the margins of certain rivers, which are periodically overflowed, and is called *tobacco de rio*, distinguished from other tobacco by a fine sand found in the creases of the leaves. Good tobacco is aromatic, of a rich brown color (this color is preferred by those who are fond of a strong cigar, but there is many a light-colored leaf that is quite as strong), without stains, and the leaf thin and elastic, burns well without bitter or biting taste. There is probably no production of the earth that offers so many disappointments: the raising of it is subjected to many *contretemps*. If I am not mis-

taken, only one good crop is made in three years on an average. Tobacco is usually divided into five classes, to wit:

Calidad or Libra; this is the best tobacco; the bales always contain 80 hands or *manojos*, of 4 gavillas or fingers, of about 25 leaves each, and marked #60. The strongest cigar is made with this leaf. **Infuriado Principal or Primera (firsts):** has less flavor than *Libra*, and is generally of lighter color. The leaves should be whole and elastic; 80 hands, of 4 gavillas (of 30 leaves), are in each bale, which is marked B 80. **Segundas (seconds):** many good wrappers in these; but the majority of the leaves are stained, have a bad color, or have been slightly touched by the worm. This wrapper is weaker than the firsts. This class is put up in bales of 80 *manojos*, of 4 gavillas, each of these of 35 to 40 leaves, and marked Y 2 a 60. **Terceras, or thirds,** constitute the best fillers, and some wrappers are found among them, especially if the tobacco is new. The bales have 80 *manojos*, of 4 gavillas, having upward of 40 leaves each; the bales are marked 3 a 80. **Cuartas, or fourths:** the most inferior class, fit only for fillers. The bales contain 80 *manojos*, of 4 gavillas; no determined number of leaves in the gavillas; marked 4 a 80. **Vuelta Arriba** tobacco is put up in the same, or a similar, manner.

It would be difficult, indeed, for any one to attempt to fix prices for tobacco; they vary from, say \$10 to \$170 generally, but occasionally fabulous prices are paid for that which is very good in quality, and which offers a fair prospect of yielding a large number of cigars. I have it from a very reliable source, that a little over a month since, the celebrated factory of *La Hija de Cabañas y Carbajal* paid the sum of \$10,000 cash for a lot of only 45 bales, none of which exceeded 100 lbs. in weight. By the following quotations, given by our latest price-current, it will be perceived how varied the prices are for tobacco:

\$120 to \$140 for firsts, seconds, and thirds.	} According to quality, selection, and renown; all is <i>Vuelta Abajo</i> .
60 to 80 for fourths.	
40 to 50 for fifths.	
20 to 30 for sixths.	
17 to 20 for sevenths and <i>Capadura</i> .	

When tobacco is shipped, it is generally covered with crash.

Cigars are made of all classes of tobacco, and of various sizes and shapes, and therefore of various values. There is probably no manufactured article so difficult to estimate the true value of as cigars; there are certain well-known brands that can command almost any price; they have a fixed value; such, for instance, as those of *La Hija de Cabañas y Carbajal*, *Cabargas*, *Pataargas*, *La Higueru*, etc., and even among those of high reputation, and having apparently fixed prices, cigars are delivered at lower rates than those appearing in the bill of rates to persons that advance them large sums of money for the purchase of tobacco, and receive in payment large quantities of these cigars per month. These celebrated brands are known to be the purchasers of the best and highest priced tobacco; at the same time, it is well known that they purchase cigars from smaller factories, make selections with great care, pack them in their own boxes with their own brands, and obtain for these the same prices as for the cigars made at their own manufactories; and just as good an article may be procured elsewhere for half the price. But very few of the cigars proceeding from those celebrated factories are consumed on the island; and there are even some, but comparatively few of whose cigars are sent to the United States, and there are many whose works all go to the States. I mean, in the above remarks, in the way of trade. It would be quite impossible to give any positive figures in regard to the extent of manufacture of cigars in this island; notwithstanding all my diligence in procuring information, and the various modes employed for the purpose, my efforts have failed. The only mode I could find to

make an article factored in the island block—“calculated as million an

make an approximating estimate of the quantity manufactured is by estimating first the number of smokers in the island. And here I met one greet stumbling-block—"What is the population of Cuba?" It is calculated as low as under one million and as high as one million and a half.

It must be borne in mind that almost every man, and a very large portion of women, in the island smoke cigars; and although it is very true that a large number use the cigarritos or paper cigars, still, it is known that a very large portion of these also consume the other kind, or *puros*. My object has been to ascertain, in the first place, the home consumption. In my efforts to estimate the number of smokers by inquiries from both Spaniards and Germans, I find the estimate varying between 300,000 and 1,000,000. Ten cigars per day is considered about the average quantity consumed by each person. As my basis of calculation, I have put down the number at 400,000. This would give for the consumption of the island the almost incredible amount of 1400 millions of cigars per annum, equal to 1,400,000 boxes of 1000 each. Calculating each thousand to weigh 12 lbs., each smoker consumes 44 lbs. per annum. This, taken in connection with the amount of exports from all parts of the island, that can not be less than the consumption, swells the figures to an extent that is startling, and makes no doubt the basis of my calculation. And yet I am told by many that I am rather under than over the number of smokers, and the quantity they consume per day.—*Consular Report to the Department of State, United States.*

Sugar.—This is considered the greatest staple of the island of Cuba. The grinding of the cane generally commences in the month of December, and the sugars are brought to market from January, and sometimes as early as the middle of December, until July; the greatest quantities come in March, April, and May. There are two kinds made, known as "clayed" and "Muscovado;" the greatest quantity by far is clayed. Of this, the principal division is: Florote, white, yellow, brown, and Cogueho. It is packed on the plantations. The clayed is put in boxes, weighing from 350 to 500 pounds gross; the tare usually is 47 pounds. A merchantable box of sugar must weigh 16 arrobas (of 25 lbs.) net; if a little under, a deduction of 50 cents per box is made; and if much under, the sugar is rejected, as the export duty is upon the box, and it would not be for the interest of the shipper or exporter to accept any box weighing less than 16 arrobas. Muscovado is put in casks, weighing from 1200 to 1500 pounds gross; tare, 10 per cent. Clayed sugar is usually sold in lots, assorted half whites and half yellow or browns, per sample, by licensed brokers; it is examined before received, and that which is not equal to sample rejected. When sugar remains long in store it becomes moist and loses its grain.

The export of sugar from Havana, according to Humboldt, amounted, in the four years, 1760-'63, every year only to about 13,000 boxes. Nine years, 1770-'78, every year only to about 50,000 boxes.

The great increase in the production of sugar in this island commenced about the year 1820, when steam was substituted upon plantations for ox or mule power. Nearly two-thirds of the quantity exported is from Havana, and the largest portion on American bottoms. The official returns of exports can not be considered as correct; for many a vessel has been cleared as laden with a full cargo of molasses when she carried a full cargo of sugars, and thereby not only defrauded the royal revenue of the export duty upon the sugar, but had her tonnage duty not levied or returned to her, and in former years many vessels having a full load of sugars cleared in ballast; but even supposing that they gave the true quantity exported, they certainly give no idea of the extent of the crop. The consumption on the island it is impossible to estimate; the quantity is almost incredible. No country in the

world consumes so much sugar as the people of this island in proportion to the population. Rich and poor, every table—almost without exception, exclusive of the negroes upon plantations—is furnished, more or less, with the preserved fruits of the country; and the quantity of preserved fruits sent to all parts of the world is very great. And then is to be considered the sugar that is consumed in a country where every white inhabitant, and a large portion of the colored population also, take coffee three or four times a day. The prospects of the present crop, from all parts of the island, were never more flattering. It is probable that there will be a large increase over the last year's crop. Contracts have already been entered into, paying as high as \$22 per box. The boxes and casks are paid for separately, as will be exhibited in the *pro forma* invoices given in continuation. The brokerage upon sugar is 1 per cent., of which the purchaser pays a half per cent. and the seller the other half per cent.—*Consular Returns, United States, 1854-'55.*

Coffee.—The production of this article has rapidly diminished during the last 14 or 15 years on the north part of Cuba, owing to the low prices, scarcity of laborers, and consequent high rates of wages, and the larger profits in the cultivation of the sugar-cane. The berry begins to ripen about August, when the picking is commenced, and continued until December or January next. It begins to flower in February, March, April, or May; the third flower gives the best coffee; the article is brought to market throughout the year; but in December, January, and February, and even as late as March, it comes in greatest quantities. The packing in sacks of from 6 to 8 arrobas of 25 pounds is effected on the plantations; the tare of a sack is 2 pounds. Coffee is sold by regular licensed brokers by sample, and before being received is examined, and if not equal to the sample is rejected. It is usually classed into five grades: Superior, First, Second, Third, and Tréache. There is a class called *Caracollo*, a round bean, the produce of the first bearing year, when the pods have only one kernel; after the first year the pods have two kernels. Coffee, when a long time in store, loses its aroma, and fades in color; when good, the berries are smooth, equal, and unbroken, free from stones or unpleasant smell, and of a fresh green color. The cultivation of coffee was introduced in the island of Cuba in 1797-'98 by the French emigrants from Hayti. In 1804 the exports were 50,000 arrobas; in 1809, 320,000 arrobas.

It will be observed how sadly the production of coffee has decreased within the last few years. The time is now fast approaching when none will be raised on this side of Cuba, and then the inhabitants will have to depend upon the coffee raised in the district of St. Jago de Cuba, which is still quite large in quantity; and were it not for the immense quantity of beans, corn, and other grain that are roasted and mixed with the real coffee, the quantity of the latter would scarcely suffice for the consumption of a country where it is used in such great quantities. It is believed by many that the time will arrive when the island of Cuba will have to import coffee for the consumption of her inhabitants.—*Consular Returns, United States.*

Custom-house.—Business transacted at the custom-house in Havana is all done in writing, and pretty much all upon stamped paper, mostly at 50 cents a sheet, excepting that for outward register, called *papel de libretes*, costing \$8 the sheet. Vessels that go to outports to load have to pay anchorage and other small fees, averaging some \$15 or \$16 each. At Cienfuegos every vessel pays the health commissioner \$2, and as much more if ordered to quarantine. At Matanzas, besides the charges recovered as here, the government exacts \$4, and the royal exchequer \$4. At Sagua an extra fee is exacted of \$4 if she enters in ballast and leaves with cargo, and \$8 if she brings cargo and carries away cargo.

1853 ".....	601,036	".....	472,738

Meats.—The existence of a differential duty on meats imported in Spanish bottoms, draws the supply of this article in the markets of Cuba from Buenos Ayres to the extent of 30,000,000 pounds annually; while from the United States it comes to a very limited extent, notwithstanding the quality of the article imported from the United States is far superior to that from South America.

The following table exhibits the quantity of jerked beef imported into Cuba during the years, 1850, 1851, 1852, and 1853, and the countries whence exported. The arroba equals about 25 lbs.

1851.....	3,091,525	29,251	650
1852.....	3,971,909	91,664	2,725
1853.....	2,677,791	29,830	80,149

The duty in Cuba on flour imported from Spain is \$2 50; on that imported from the United States, in American or other foreign bottoms, is \$10 81; the effect of which is to drive the American article entirely from the Cuban market, except at such times as when scarcity may have carried it up to famine point. The tonnage duty that exists on Spanish bottoms is 62 1/2 cents per ton, and on foreign shipping \$1 50 per ton, contributing, in combination with other differential duties and restrictions, to the Spanish flag, advantages in the carrying trade of the products of that island to the northern European ports.

The imports of flour into Cuba from the United States, from 1853 to 1856 inclusive, are shown in the following table:

Year ending June 30.	Barrels.	Value.
1853.....	1,537	\$7,730
1854.....	11,593	\$2,489
1855.....	3,429	\$3,176
1856.....	3,806	\$3,066

Board of Trade.—The annual report of the Board of Trade of the island, to the superintendent of the royal treasury, of the general navigation and commercial movements of the island, in the year 1850, sets forth these facts in a manner worthy attention. It shows that in 1850 there had been an increase over the last year of \$2,088,226 in the value of goods imported in national vessels, but that the importation in foreign vessels had only increased \$574,540; a result to be ascribed to the protective and differential system which

favors Spain present to actly the the expos while the \$447,104. both in re the nation which for island, on the general u port duty In the \$26,320,44 \$885,892— been exce and in the appears, in preserved butter, an increased scale of qu than 8,000 year, in co Manila; a creased ar articles of would hav tion. The imports under the Spanish flag exceeded those of 1850 by \$1,444,104—a result that was considered chiefly attributable to the system of duties in force; under foreign flags, the importations, which for several years had rarely exceeded eleven millions of dollars, increased in 1851 to the amount of \$1,884,098 over the previous year. The merchandise brought from Spanish ports amounted to more than eight and a half millions of dollars, being \$352,181 more than the total imports from the United States; \$1,225,900 more than those from Great Britain; \$5,740,461 more than those from the former Spanish possessions, and nearly 25 per cent. on the total amount of imports from all countries.

The exports of 1851 exceeded those of 1850 by \$5,709,735, which was an increase over 1849 of more than three millions of dollars. The following will show the relative proportion of the exports in Spanish and foreign bottoms in 1851:

	Imports.	Exports.
In national vessels.....	\$1,309,176	\$3,204,653
In foreign vessels.....	12,413,354	23,187,029
Total in 1851.....	\$32,311,490	\$31,341,682

Of the exports this was an increase over 1850 of \$184,013 in national ships, and \$5,525,721 in foreign ships; which was nearly equal to the value of the increased production and exports of the island over the preceding year. The quantity of sugar exported from the island in 1851 was 281,361 boxes over 1850, which exceeded the previous year nearly 150,000 boxes. The increase of the important staples of molasses, coffee, and tobacco (raw and manufactured), though less so great, was highly important. These facts are significant of the force of foreign reciprocal duties, and forcibly demonstrate that any discriminating export or tonnage duty on foreign vessels, sufficiently effective to give this onward movement to the Spanish flag, must fatally injure the productiveness, national commerce, and industry of the island.

The amount of shipping which entered the ports of Cuba during 1850 and 1851, was as follows:

Under the national flag.....	84,112	276,176 tons.
Under foreign flags.....	99,364	127,814 "
Total.....	128,976	907,090 "

A comparison of the returns for the year 1845 with those for the year under review gives to the Spanish flag an increase, during that period, of nearly one hundred per cent.

The value of the importations diminished in the year 1852 \$2,531,188, and the exportations \$3,887,746, below those of the previous year. The falling off in imports was on the articles rice, 91,382 arrobas; pork, 187,413 pounds; hams, 878,532 pounds; lard, 3,891 arrobas; butter, 133,775 pounds; jerked beef, 118,317 arrobas; and in exports, on cotton, 1,036 pounds; sugar, 130,982 boxes; molasses, 55,834 hogsheds; copper, 51,412 quintals; segars, 127,746,000. The great falling off in the item of sugar could not have failed to act in a corresponding manner on the amount of tonnage, and measurably, on the value of imports.

The importations in 1853 reached an aggregate value of \$27,789,800—an amount exceeded, the preceding year, by \$1,000,441. The articles which suffered the greatest diminution were codfish, flour, beef, lard, cheese, jerked beef, bacon, Spanish and foreign wines. While thus the value of imports diminished, that of exports considerably increased. The total increase over 1852 amounted to \$3,756,468.

The United States exported to Cuba in 1853 goods to the value of \$7,809,263, being a decrease on the exportations of the preceding year of \$195,819 and imported to the value of \$24,485,693, showing an increase of \$5,810,234. The total trade between Cuba and the United States is usually about the third part, or 33 1/3 per cent., of the total imports and exports of the island. The total number of vessels entering the ports of Cuba in 1853 was 3,918; total number cleared, 3,827. The following table exhibits the nationality of these vessels:

Nationality.	Entered.	Cleared.
Spanish.....	901	889
United States.....	2,907	2,178
British.....	865	461
French.....	126	121
Belgian.....	45	26
Dutch.....	24	18
German.....	57	67
Danish.....	20	23
Swedish.....	17	22
Russian.....	7	11
Prussian.....	17	7
Spanish American.....	13	11
Italian.....	6	5
Brazilian.....	2
Austrian.....	8
Total.....	3,913	3,827

In 1854 the total trade of Cuba ascended to \$64,078,509, viz.: imports to \$31,394, 578, and exports to \$32,683,931. This movement exhibited the following result, when compared with the trade of the preceding year:

	Imports.	Exports.
1854.....	\$31,394,578	\$32,683,931
1853.....	27,789,800	31,210,465

An analysis of the returns from which the preceding figures are derived exhibits the following details: Of imports, the increase is perceived especially on the articles codfish, flour (national and foreign), pork, beef, hams, lard, cheese, jerked beef, bacon, and foreign wine; while there was a slight decrease on the articles rice, butter, and Spanish wine. Of exports, the increase fell, chiefly, on rum, sugar, coffee, wax, woods, honey, copper ore, leaf tobacco, and segars; while the articles raw cotton and molasses show a slight falling off. Under the national flag, the increase of importations over those of 1853, was, in value, \$2,254,524; in foreign bottoms there was a similar increase of \$1,350,453. The increase in exports, under the Spanish flag, was \$1,292,759; under foreign flags, \$240,566. The exports from Cuba to the United States, during this year, amounted in value to \$11,641,813, or more than one third of the exports of the island to all countries; the imports into Cuba from the United States, during the same period, reached, in value, \$7,807,080, or over one fourth of the total imports from all countries. Of the imports into Cuba from the United States, only \$19,755, in value, was carried in Spanish vessels; while the value of such imports, under foreign flags, reached as high as \$7,817,925. The exports from Cuba to the United States were exclusively borne in foreign bottoms—two arrivals, one from Havana, carrying a value of \$219; the other from Gibara, with freight amounting to \$540; in all, \$759—being too insignificant to constitute a noticeable exception.

The following "statements" of revenue collected by the maritime and terrestrial custom-houses of that island in the year 1855, compared with the preceding year, published in the government Gazette, by order

of the superintendent-general of the royal exchequer, indicate increased activity of trade; the excess of revenue collected in December, 1855, over the same month in 1854, being nearly \$254,000, and the excess for the whole of 1855 over the whole of 1854 amounting to \$350,428 43¢.

Revenue collected in 1855, \$18,980,100, and in 1854, \$18,589,671, an increase in 1855 of \$390,428.

* Error in original: the figures should be 9,234,061. † Error of \$5,618—excess. ‡ Error of \$4,700—excess.

It may be proper to remark in this place, that the *Balanzas Generales*, from which the preceding and subsequent tables are derived, are not to be considered as giving the precise quantities and values of the commercial exchanges of the island of Cuba with foreign nations. They, doubtless, present the minimum amounts of each, as it would seem to be the policy of the custom-house officials, by whom these annual reports are prepared, to undervalue the foreign trade of the island. As far back as the year 1825, the unreliability of these *Balanzas*, as authority in statistical compilations, requiring precise accuracy, was noticed by Baron Humboldt, in that portion of his "Personal Narrative" which relates to the island of Cuba. Alluding to them, he observes: "I have examined, in another work, fifteen years since, the basis upon which are founded the tables published under the fallacious title of '*Balanzas de Comercio*.'" Since that period, it would seem that but little improvement has been made in the preparation of these

annual exhibits of trade; for the Department is officially advised, as late as 1853, that, in respect of values, the amounts stated in the *Balanzas* are fully one fourth less than the real market value both of imports and exports. However this may be, the statements and tables given are all which are accessible; none other being published or prepared; and for all useful purposes, they will serve the statistician as well as if the greatest accuracy had been attained.

The commerce of Cuba with foreign nations for the year 1854, is fully set forth in the annexed statements, taken from the "*Balanzas Generales*" for that year. It is followed by two other tables, made up from the *Balanzas*, designed to illustrate the commercial movements of Cuba during a period of twenty-nine years, from 1826 to 1854, both inclusive; while a third table exhibits a comparative view of the foreign commerce of Cuba and Porto Rico, with the duties received, and the number of vessels entered and cleared, during a period of seven years, from 1848 to 1854.

Years.	NUMBER OF VESSELS WHICH ENTERED THE PORTS OF THE ISLAND.				AMOUNT OF DUTIES RECEIVED IN THE COMMERCIAL MOVEMENT.			* From 1841 to 1845, these totals include the value of goods placed on deposit, as well as of those actually imported or exported, and are thus considerably augmented. Prior to 1845, no distinct column was devoted to deposit in the Balanza Generala; but since that year such distinction has been observed, and the result is perceived in the diminution of the amounts of values.
	National vessels.	Foreign vessels.	Total.	Tonnage.	Duties on imports.	Duties on exportation.	Total.

General Port Regulations. 1. Ships leaving with a full cargo of molasses are free of tonnage duties. 2. Ships arriving in ballast, and leaving in the same state, pay no tonnage duty; but if they should take return cargoes of the fruits, or other articles of the island (entire cargoes of molasses only excepted), they pay the regular duty. 3. Ships arriving in distress for water, or other necessities, are free from tonnage duty; but when they discharge the whole or part of their cargo (unless every part is again taken in, and no more), or load with produce, foreign or native (molasses excepted), they are subjected to the entire tonnage duty. 4. Vessels, foreign or national, which have left a port of the island, having paid the proper tonnage duty, and which enter any port of the island to repair damages they may have sustained at sea, by reason of storm or other casualty, are exempt from further tonnage duty. 5. Vessels entering the ports of the island with mineral coal, in equal or greater quantity than the number of tons per their register, pay only 50 cents per ton for tonnage duty, even if they bring other merchandises besides. They are also exempt from all other local charges (excepting captain of the port's fee), such as ponton and health dues, custom-house visit, entry and clearance fees, wharfage, stage-hire, &c. Such as bring coal, solely, in less quantity than their tonnage

measure, pay 80 cents per ton upon the portion occupied by coal; and the difference between this portion and the number of tons that the vessel may prove to have, by Spanish measurement, will be subjected to the payment of the full tonnage duty; but these vessels are allowed the exemption from all other charges except captain of the port's fees. Vessels having on board, besides coal in less quantity than their measurement, other cargo, are in the same case respecting the tonnage dues, but are subject to the ponton, health visit, registering and other usual dues. Malt steamer, recognized as such, are permitted to bring and carry 3 tons of cargo without paying tonnage dues. If the cargo discharged exceeds 3 tons, they pay duty on such excess over and above the 3 tons. Vessels going from one port to another of the island, carry a sea-letter of introduction to the custom-house of the other port, stating that the regular charges have been paid. This letter costs \$4. By order of November 4, 1854, all vessels having to perform quarantine must go either to Havana or to St. Jago de Cuba for that purpose. Quarantine fee, \$1 per day. Besides the foregoing general regulations, which are in force at all the ports of the island, there are others of a more local character, applicable to some, and not to others. These relate more especially to tonnage and port duties, and other charges.

..... under 150 tons.....	4 00	4 00

* This fee is received by the boarding physician, and is applied to the general board of health. He receives the bill of health, which must be authenticated by the Spanish consul at the port of departure, under a penalty of being sent to quarantine for seven days, and a fine of fifty dollars.

† For Spanish measurement; in addition to this duty, one per cent. balance upon the result of the tons, multiplied by it, is charged.

Plotage. It is optional for a vessel to take a pilot, unless she goes into the inner harbor beyond the shoals; in which case, whether she takes one or not, she has to pay \$10 coming in as far as the inner harbor, \$10 going out, and \$10 from any part of the outer harbor into the inner. Foreign men-of-war pay no port charges. If a pilot is taken, the rate charged

is the same as paid by Spanish men-of-war.—\$7 in, and the same out.

Mode of Collecting Duties. The collection of the duties is made in a very simple manner. The island of Cuba is divided into customs intendencies, of which Havana is the principal. The Intendency is organized into seven branches, viz.: the intendant, the superior counsel of the hacienda, the tribunal of accounts, the accountant-general, the treasurer-general, the administration of the customs, and the administration of the internal revenue. The administration of the customs is comprised of the administrator or collector, the accountant, and the treasurer. When a vessel arrives at the Havana, she is first boarded by the health officer, after whom comes the revenue officer and the smuggling-preventive service. A copy of the custom-house regulations, in Spanish, French, and English, is handed to the captain, and a manifest required of him of all the particulars of his vessel and cargo. Every article on board the vessel, omitted in the manifest, is subject to confiscation. Within forty-eight hours after the entry of the vessel, every consignee must deliver detailed statements of the articles coming to him, with their quantities, weights, and measures, all reduced to the legal standard.

All the documents and papers relating to a vessel, are stitched together in a book, with the signatures and seals of all the government officers, through whose hands the several documents pass. A copy of this

book is made for the use of the inspectors and appraisers; the latter function being restrained within very narrow limits, by a printed tariff of all articles of import, with a valuation to each, which valuation, in a great degree, defines the duties of the *ad valorem* character. As fast as the inspection and appraisal take place, the consignee is permitted to remove the goods, by procuring the signature of some responsible person to the words inscribed in the book, "I make myself answerable for the duties." The inspection and appraisal being concluded, the book is returned to the accountant's office, where the liquidation of the duties is forthwith made. The payment is then proceeded with. These payments are mostly cash; that is to say, on some articles, whatever may be the amount, cash is required; upon other articles, the duties are cash under \$1,000.

If the amount is greater, a credit of one fourth is given for sixty days, and one fourth payable at the end of each succeeding month—making five months' credit in all. The security for this credit consists simply in the promissory note of the consignee, without indorsement, with the power, in case of a failure, to convert every other note of the same individual into a cash debt; the individual to be forever after incapacitated to enter goods, except for cash.

This system has been in force many years, and un-

der it no loss whatever has been sustained by the government.

Formerly, the same credits required the endorsement of a holder of real estate; but this was abandoned on account of its insecurity.—MACCORMACK'S *Statistics*; *U. S. Com. Dig.* For further information, refer to *Am. Quar. Rev.*, vii. xi., 230; HUNT'S *Mag.*, vi., vii., xvii.-xxi., 519; *North. Am. Rev.*, xxix.; DR BOW'S *Rev.*, viii., p. 513, ix., 164; *Ch. Examr.*, vi., 259, xxiii., 82; FRASER'S *Mag.*, xii.; LITTELL'S *Living Age*, xxii.; *Foreign Quar.*, iii., p. 400; BLACKWOOD, xl.; *Southern Quarterly*, iv., xxi.

Cubebs (German *Kübeben*; French, *Cubebe*; Italian, *Cubebi*; Spanish, *Cubebas*; Russian, *Kubebii*; Latin, *Piper Cubeba*; Arab, *Kebâbek*; Javanese, *Kumankus*; Hindostan, *Cubab-chinie*), the produce of a vine or climber extensively grown in Java. It is a small dried fruit, like a pepper-corn, but somewhat longer. Cubebs have a hot, pungent, aromatic, slightly bitter taste; and a fragrant, agreeable odor. They should be chosen large, fresh, sound, and the heaviest that can be procured.

Cubit. This was a measure of the ancients, and is the first measure we read of; the ark of Noah was made and measured by cubits.—HOLMEX. The Hebrew sacred cubit was two English feet, and the great cubit eleven English feet. Originally it was the distance from the elbow, bending inwards to the extremity of the middle finger.—CALMET.

Cucumber, a tropical plant, of which there are many varieties, largely cultivated in hot-houses in England.

Cucumber-tree. *Magnolia acuminata*. In all parts of the United States where this tree is found, it is known only by the name of *cucumber-tree*. It is a beautiful vegetable, equal in height and diameter to the big laurel. The most northern point at which this tree grows, is near the falls of Niagara, in latitude 43°. It abounds along the whole tract of the Alleghanies, to their termination, in Georgia, over a distance of 900 miles. It is also found on the Cumberland Mountains. The situations peculiarly adapted to its growth are the declivities of mountains, narrow valleys, and the banks of torrents, where the air is constantly moist, and where the soil is deep and fertile. At the distance of forty or fifty miles from the mountains, either way, this tree is met with only accidentally upon the steep banks of rivers, where the atmosphere is constantly refreshed by the evaporation from their surface. We may conclude, then, that this tree is a stranger to all parts north of the river Hudson, and to all the Atlantic parts of the United States, to the distance of 100, 150 and 200 miles from the sea; the nature of the soil, and the extreme heat of the climate in summer, being utterly uncongenial to its growth. It is also rare in the parts of Kentucky and West Tennessee which are most remote from the mountains, where the face of the country is less uneven. The cucumber-tree sometimes exceeds 80 feet in height, with a diameter of 3 or 4 feet. The trunk is perfectly straight, of a uniform size, and often destitute of branches for two thirds of its length. The summit is ample and regularly shaped, and the tree is one of the finest in the American forests. The leaves are 6 or 7 inches long, and three or four inches broad, upon old trees; upon saplings growing in moist places, they are sometimes twice as large.

On old stocks the bark of this tree is grayish, and deeply furrowed. The perfect wood is soft, and of a yellowish brown. It is fine-grained, and susceptible of a brilliant polish.

Being a rare tree, it is only accidentally employed in the arts. Sawn into boards, it serves in joinery for the interior of wooden houses, and for its size and lightness, it is selected for large canoes. Most of the inhabitants of the country bordering on the Alleghanies, gather the cones of this tree about midsummer,

when they are half ripe, and steep them in whisky; a glass or two of this liquor, which is extremely bitter, they habitually take in the morning, as a preservative against autumnal fevers.—BROWN'S *Syleta Americana*.

Cudbear, a purple or violet-colored powder, used in dyeing violet, purple, and crimson, prepared from a species of lichen (*Lichen tartareus* Lin.), or crustaceous moss, growing commonly on limestone rocks in Sweden; Scotland, the north of England, &c. About 130 cms of this lichen are annually exported from Sweden. It commonly sells in the port of London for about 20*l.* per ton; but to prepare it for use it must be washed and dried; and by these operations the weight is commonly diminished a half, and the price, in effect, doubled. Though possessing great beauty and lustre at first, the colors obtained from cudbear are so very fugacious, that they ought never to be employed but in aid of some more permanent dye, to which they may give body and vivacity. In this country it is chiefly used to give strength and brilliancy to the blues dyed with indigo, and to produce a saving in that article; it is also used as a ground for madder reds, which commonly incline too much to yellow, and are made *rosy* by this addition. The name cudbear was given to this powder by Dr. Cuthbert Gordon, who, having obtained a patent for the preparation, chose in this way to connect it with his own name.—BANCROFT, *Philosophy of Colors*.

Culeus, in *Roman Antiquity*, the largest measure of capacity for things liquid, containing twenty amphore or 40 urns; equivalent to 115 gallons, 16 pints English. Culeus also denoted a sack or bag. Parricides were punished at Rome by being thrown into the Tiber in a sack, along with a cock, an ape, and a viper.

Culm (Welsh *ceilm*), a variety of coal. It is difficult of ignition, but burns for a long time, without flame or smoke, but emitting a disagreeable smell. It does not cake, and it leaves but few ashes. Culm is the *bitumen oxygenatum* of Linnaeus, and the *glaz kohle* of Werner. It is otherwise known as *anthracite*.—See *Coal*.

Culina, in Hindostan, a town in the British district of Burdwan, presidency of Bengal, on the right bank of the river Hooghly, on the route from Cutwa to the town of Hooghly, 20 miles east of the city of Burdwan. It is the port of the district, and has long been noted for its trade in rice, grain, silk, and cotton. Of late years the traffic of the place has greatly increased, in consequence of its being found a convenient station for steamers plying between Calcutta and the upper provinces. The bazaar consists of 1000 shops, and the population of the town has been stated at 60,000. Lat. 23° 14'; long. 88° 20'.

Culpee, a town of Bengal, district of Hooghly, on the eastern bank of the river Hooghly. It stands 33 miles below Calcutta, at the mouth of a creek that gives shelter to boats from the impetuosity of the tide, which runs there with great violence. Opposite the town is the place of anchorage for large ships which can not get higher up the river. The shores here are a bed of mud, and the banks of the river are covered with thick jungle. Culpee is considered extremely unhealthy, on account of the swamps and woods by which it is surrounded. E. long. 88° 18'; N. lat. 22° 6'.

Cumberland river, a large river of Kentucky and Tennessee, which flows through Kentucky and falls into the Ohio. Its entire length is about 600 miles, and navigable for large steamboats to Nashville, 203 miles, and for boats of 15 tons, 300 miles. Large quantities of cotton, corn, and tobacco, are transported by flat-boats and steamboats from numerous counties on this river, to New Orleans.

native of Egypt, but extensively cultivated in Sicily and Malta. They have a strong, peculiar, heavy odor, and a warm, bitterish, disagreeable taste. They are long and slender.

Cumnock, or Old Cumnock, a village of Ayrshire, in Scotland, on the Lugar Water, 12 miles east of Ayr. It is noted for the manufacture of snuff-boxes, similar to those of Laurencekirk, the peculiarity of which is the "invisible wooden hinge." See article *Snuff-boxes*.

Cupel, a shallow earthen vessel, somewhat of a cup shape, generally made of bone earth. It is used in the assays of the precious metals, which are fused upon a cupel with lead. Cupellation means the refining of gold or silver upon a cupel.

Cupellation is a mode of analyzing gold, silver, palladium, and platinum, by adding to small portions of alloys, containing these metals, a bit of lead, fusing the mixture in a little cup of bone earth called a cupel, then by the joint action of heat and air, oxydizing the

copper, tin, etc., present in the precious metals. The oxyds thus produced are dissolved and carried down into the porous cupel in a liquid state, by the vitrified oxyd of lead. See *Assay, Gold, and Silver*.

Curacao. This island is situated in the Caribbean Sea, near the coast of Venezuela, and is about 42 miles long, and from 10 to 15 miles broad. The chief staples are tobacco, sugar, indigo, and maize. There are numerous harbors, but that of Santa Anna is considered the best and safest. The principal merchandise exchanged in the coasting-trade of Curacao consists of hides, goat-skins, dye-woods, corn, cochineal, sugar, indigo, and hats. The chief articles of internal trade is salt, this being the only article manufactured for export. The following table exhibits, in one view, the general commerce of the island with the United States during three years, ending with 1853. It will be seen that the export trade to the United States is yearly increasing, and that in 1853 the increase over 1851 is nearly 100 per cent.

Curacao, a liquor which derives its name from the island of Curacao. It is prepared in great perfection by the Dutch. It derives its flavor from Seville orange peel, with a small quantity of cinnamon and mace.

Curni (*soipui*), in *Antiquity*, a sort of malt liquor or ale, made of barley, and which, according to Dioscorides, was used by many nations instead of wine. This writer also relates that in the western part of Iberia, and in Britain, a similar beverage was in his time prepared from wheat.

Currants (Fr. *Raisins de Corinthe*; Ger. *Korinthen*; It. *Uve passe di Corinto*; Lat. *Pussule Corinthice*; Rus. *Korinka*, *Opoek*; Sp. *Passa de Corinto*), a small species of grape, largely cultivated in Zante, Cephalonia, and Ithica, of which islands they form the staple produce; and in the Morea, in the vicinity of Patras. The plant is delicate; and as 6 or 7 years must elapse, after a plantation has been formed, before it begins to produce, its cultivation requires a considerable outlay of capital. The crop is particularly liable to injury from rains in harvest, and is altogether of a very precarious description. After being dried in the sun, the currants are exported packed in large butts. They are in extensive demand

in Europe and the United States, and, when mixed with flour and suet, make a dish that is peculiarly acceptable to the lower classes.

Current (Lat. *currens*, from *curro*, to run, to flow), literally signifies running, flowing, passing. Hence, passing from person to person, or from hand to hand; circulating, as current opinions, current coin. In commerce it is applied in an analogous sense to the price of any commodity: as current value—that is, the ordinary or present value. As applied to time, it is equivalent to now present or passing; as the current month or year. It is applied chiefly to the progressive movement of fluids, especially of air, electricity, and water.

Currents in the ocean arise from various causes, either occasional or constant. They may be occasioned by an external impulsion, for example, a gale of wind; from a difference in the temperature of different parts of the sea; from the inequality of evaporation, the melting of the polar ice, or in short any cause tending to disturb the hydrostatic equilibrium. It is difficult in many cases to trace their causes, or to give any satisfactory theory of their existence; but on account of their importance to navigation they have been observed, especially of late years, with

great care. Among those which have a permanent or general character, there are two which are very remarkable. The first is that of the tropical waters westward round the globe, and the second that which constantly flows from each pole toward the equator. The tropical or westerly current is chiefly confined within the zone, extending to about 30° on each side of the equator, and its velocity is estimated by Humboldt at about 9 or 10 miles a day. In the Atlantic it separates into two branches, one of which forms the *Gulf Stream*; and the other flows along the coast of Brazil, and passes through the Straits of Magellan. The *Gulf Stream* flows northward through the middle of the Atlantic, till it reaches the Cape Verd Islands; it then passes through the Caribbean Sea, between Cuba and the peninsula of Yucatan, sweeps round the Gulf of Mexico, and rushes out by the Bahama Channel; then, spreading out to a greater breadth, it continues its course along the shores of the United States to Newfoundland, where it is deflected eastward by a current setting in from Baffin's Bay; and, passing the Azores and Canary Islands, returns in a great measure into itself. Its breadth is 51 leagues in the Bahama Channel, and velocity from 3 to 5 miles an hour. (MURRAY'S *Geography*, p. 186.) The polar currents flow constantly from the poles toward the equator, though it is evident that their sources must be supplied by currents in a contrary direction. Their existence is proved by the great masses of ice which are carried every year from the polar seas to tropical latitudes. Oceanic currents, by carrying with them the temperature of the regions whence they flow, contribute in no small degree to modify the temperature of the atmosphere, and give a character to the climate of the countries to which they are contiguous. On the parallel of New York, Humboldt found the temperature of the *Gulf Stream* 72° of Fahrenheit, while out of the current, the heat of the ocean at the surface was only 63° . The current which flows along the eastern coast of Africa, and doubles the Cape of Good Hope in a stream 130 miles broad, is from 7° to 8° warmer than the contiguous sea. See *Gulf Stream*.

Currents of water, like currents of air, meeting from various directions, create gyration, which in some parts of the sea, as on the coast of Norway, assume the appearance of whirlpools, as though the water were drawn into a chasm below. The celebrated Maelstrom is caused by such a conflict of tidal or other streams. Admiral Beechey, R.N., has given diagrams illustrative of many "rotatory streams in the English Channel, a number of which occur between the outer extremities of the Channel and the stream of the oceanic or parent wave." "They are clearly to be accounted for," says he, "by the streams acting obliquely upon each other." It is not necessary to associate with oceanic currents the idea that they must of necessity, as on land, run from a higher to a lower level. So far from this being the case, some currents of the sea actually run up hill, while others run on a level. The *Gulf Stream* is of this class. The currents which run from the Atlantic into the Mediterranean, and from the Indian Ocean into the Red Sea, are the reverse of this. Here the bottom of the current is probably a water level, and the top an inclined plane, running down hill. Take the Red Sea current as an illustration. That Sea lies, for the most part, within a rainless and riverless district. It may be compared to a long and narrow trough. Being in a rainless district the evaporation from it is immense; none of the water thus taken up is returned to it either by rivers or rains. It is about 1,000 miles long; it lies nearly north and south, and extends from latitude 13° to the parallel of 30° north.

Mediterranean Currents.—With regard to an under current from the Mediterranean, we may remark that there is a current always setting in at the surface

from the Atlantic, and that this is a salt-water current, which carries an immense amount of salt into that sea. We know, moreover, that that sea is not salting up; we might infer the existence of an under-current, through which this salt finds its way out into the broad ocean again.

The Currents of the Indian Ocean.—By carefully examining the physical features of this sea, and studying its conditions, we are led to look for warm currents that have their genesis in this ocean, and that carry from it volumes of overheated water, probably exceeding in quantity many times that which is discharged by the *Gulf Stream* from its fountains. The Atlantic Ocean is open at the north, but tropical currents bound the Indian Ocean in that direction. The waters of this ocean are hotter than those of the Caribbean Sea, and the evaporating force there is much greater. That it is greater, we might, without observation, infer from the fact of a higher temperature and a greater amount of precipitation on the neighboring shores. These two facts, taken together, tend, it would seem, to show that large currents of warm water have their genesis in the Indian Ocean. One of them is the well-known Mozambique current, called at the Cape of Good Hope the Lagullas current. Another of these currents makes its escape through the Straits of Malacca, and, being joined by other warm streams from the Java and China Seas, flows out into the Pacific, like another *Gulf Stream*, between the Philippines and the shores of Asia. Thence it attempts the great circle route for the Aleutian Islands, tempering climates, and losing itself in the sea on its route toward the north-west coast of America. Between the physical features of this current and the *Gulf Stream* of the Atlantic, there are several points of resemblance. Sumatra and Malacca correspond to Florida and Cuba; Borneo to the Bahamas, with the Old Providence Channel to the south, and the Florida Pass to the west. The coasts of China answer to those of the United States, the Philippines to the Bermudas, the Japan Islands to Newfoundland. As with the *Gulf Stream*, so also here with this China Current, there is a counter current of cold water between it and the shore. The climates of the Asiatic coast correspond with those of America along the Atlantic, and those of Columbia, Washington, and Vancouver are duplicates of those of Western Europe and the British Islands; the climate of California (State) resembling that of Spain; the sandy plains and rainless regions of Lower California reminding one of Africa, with its deserts between the same parallels, etc. Moreover, the North Pacific, like the North Atlantic, is enveloped, where these warm waters go, with mists and fogs, and streaked with lightning. The Aleutian Islands are almost as renowned for fogs and mists as are the Grand Banks of Newfoundland. A surface current flows north through Behring's Straits into the Arctic Sea; but in the Atlantic the current is from, not into the Arctic Sea; it flows south on the surface, north below; Behring's Straits being too shallow to admit of mighty under currents, or to permit the introduction from the polar basin of any large icebergs into the Pacific.

The Currents of the Pacific.—The contrast has been drawn between the China or "Gulf Stream" of the North Pacific, and the *Gulf Stream* of the North Atlantic. The course of the China Stream has never been satisfactorily traced out. There is along the coast of California and Mexico, a southwardly movement of waters, as there is along the west coast of Africa toward the Cape de Verd Islands. In the open space west of this, southwardly set along the African coast, there is the famous Sargasso Sea, which is the general receptacle of the drift-wood and seaweed of the Atlantic. So, in like manner, to the west from California of this other southwardly set, lies the

pool into which the drift-wood and sea-weed of the North Pacific are generally gathered, but in small quantities. The natives of the Aleutian Islands, where no trees grow, depend upon the drift-wood cast ashore there for all the timber used in the construction of their boats, fishing-tackle, and household gear. Among this timber, the camphor-tree, and other woods of China and Japan, are said to be often recognized. In this fact we have additional evidence touching this China Stream, as to which, but little, at best, is known. "The Japanese," says Lieutenant Bent, in a paper read before the American Geographical Society, January, 1856, "are well aware of its existence, and have given it the name of 'Kuro-Siwo,' or Black Stream, which is undoubtedly derived from the deep blue color of its water, when compared with that of the adjacent ocean." From this we may infer that the blue waters of this China Stream also contain more salt than the neighboring waters of the sea.

The Cold Current of Okotsk.—Inshore of, but counter to the China Current, along the eastern shores of Asia, is found a streak or layer, or current of cold water answering to that between the Gulf Stream and the American coast. This current, like its fellow in the Atlantic, is not strong enough at all times sensibly to affect the course of navigation; but, like that in the Atlantic, it is the nursery of most valuable fisheries. The fisheries of Japan are quite as extensive as those of Newfoundland, and the people of each country are indebted for their valuable supplies of excellent fish to the cold waters which the currents of the sea bring down to their shores.

Humboldt's Current.—The currents of the Pacific are but little understood. Among those about which most is thought to be known, is the Humboldt Current of Peru, which the great and good man whose name it bears, was the first to discover. This current is felt as far as the equator, mitigating the rainless climate of Peru as it goes, and making it delightful. The Andes, with their snow-caps, on one side of the narrow Pacific slopes of this inter-tropical republic, and the current from the Antarctic regions on the other, make its climate one of the most remarkable in the world; for, though torrid as to latitude, it is such as to temperature that cloth clothes are seldom felt as oppressive during any time of the year, especially after nightfall.

Currents of the Atlantic.—The principal currents of the Atlantic will be described in the article on the Gulf Stream. Besides these, its offsets are the Equatorial Current and the St. Roque or Brazil Current. Their fountain-head is the same. It is in the warm waters about the equator, between Africa and America. The former, receiving the Amazon and the Orinoco as tributaries by the way, flows into the Caribbean Sea, and becomes, with the waters in which the vapors of the trade-winds leave their salts, the feeder of the Gulf Stream. The Brazil Current, coming from the same fountain, is supposed to be divided by Cape St. Roque, one branch going to the south under this name, the other to the westward. This last has been a great bane to navigators, principally on account of the difficulties which a few dull vessels falling to leeward of St. Roque have found in beating up against it. It was said to have caused the loss of some English transports in the last century, which fell to leeward of the Cape on a voyage to the other hemisphere; and navigators, accordingly, were advised to shun it as a danger. This current has been an object of special investigation during my researches connected with the Wind and Current Charts, and the result has satisfied me that it is neither a dangerous nor a constant current, notwithstanding older writers. Horsburgh, in his East India Directory, cautions navigators against it; and Keith Johnston, in his grand physical Atlas, published in 1848, thus speaks of it:

"This current greatly impedes the progress of those vessels which cross the equator west of 28° west longitude, impelling them beyond Cape St. Roque, when they are drawn toward the northern coast of Brazil, and can not regain their course till after weeks or months of delay and exertion." So far from this being the case, my researches abundantly prove that vessels which cross the equator five hundred miles to the west of longitude 28° have no difficulty on account of this current in clearing that Cape. I receive almost daily the abstract logs of vessels that cross the equator west of 30° west, and in three days from that crossing they are generally clear of that Cape. A few of them report the current in their favor; most of them experience no current at all; but, now and then, some do find a current setting to the northward and the westward, and operating against them at the rate of twenty miles a day. The inter-tropical regions of the Atlantic, like those of the other oceans, abound with conflicting currents, which no researches yet have enabled the mariner to unravel so that he may at all times know where they are and tell how they run, in order that he may be certain of their help when favorable, or sure of avoiding them if adverse.

Under Currents.—Lieutenant J. C. Walsh, in the U. S. schooner *Taney*, and Lieutenant S. P. Lee, in the U. S. brig *Dolphin*, both, while they were carrying on a system of observations in connection with the Wind and Current Charts, had their attention directed to the subject of submarine currents. They made some interesting experiments upon the subject. A block of wood was loaded to sinking, and, by means of a fishing-line or a bit of twine, let down to the depth of one hundred or five hundred fathoms, at the will of the experimenter. A small barrel as a float, just sufficient to keep the block from sinking further, was then tied to the line, and the whole let go from the boat. To use their own expressions, "It was wonderful, indeed, to see this *barrega* move off, against wind, and sea, and surface current, at the rate of over one knot an hour, as was generally the case, and on one occasion as much as 1½ knots. The men in the boat could not repress exclamations of surprise, for it really appeared as if some monster of the deep had hold of the weight below, and was walking off with it." Both officers and men were amazed at the sight. The experiments in deep-sea soundings have also thrown much light upon the subject of under currents. There is reason to believe that they exist in all, or almost all parts of the deep sea, for never in any instance yet has the deep-sea line ceased to run out, even after the plummet had reached the bottom. If the line be held fast in the boat, it invariably parts, showing, when two or three miles it are out, that the under currents are sweeping against the bit of it with what seamen call a *swigging force*, that no sounding twine has yet proved strong enough to withstand. Lieutenant J. P. Parker, of the United States' frigate *Congress*, attempted, in 1852, a deep-sea sounding off the coast of South America. He was engaged with the experiment eight or nine hours, during which time a line nearly ten miles long was paid out. Night coming on, he had to part the line (which he did simply by attempting to haul it in) and return on board. Examination proved that the ocean there, instead of being over ten miles in depth was not over three, and that the line was swept out by the force of one or more under currents.—*MAURY'S Physical Geography.*

Currency. (Lat. *curro*, 1 run.) In Political Economy, a term sometimes used to express the collective amount of the money, and of the bills, checks, and other substitutes for money, employed in selling or buying, or in the distribution of the commodities and services among the different ranks and orders of the community.—See *Articles BANKS, COINAGE, CREDIT, and GOLD.*

Currencies in United States. The Treasury Department of the United States issued, on the 19th of September, 1851, the following instructions to collectors and officers of the customs: "In view of the embarrassments existing at some of the principal ports, and the want of uniformity in the practice of assessing duties upon merchandise invoiced in depreciated foreign currencies, it is deemed proper to establish some uniform regulations on the subject, for the future government of officers of the customs. The law requires invoices of all imported merchandise subject to an *ad valorem* duty to be made out in the currency of the country or place where the importation is made. The basis of value upon which the duties are to be assessed is the true market value in the principal markets of the country at the period of exportation to the United States, exhibited in such foreign currency at its intrinsic value, and converted into money of the United States according to the rates of value at which said currency may have been determined agreeably to law. Congress has fixed the value of some of the foreign currencies at specific rates; but where the invoice cost of goods, wares, or merchandise is exhibited in a depreciated currency issued and circulated under the authority of any foreign government, the President of the United States is duly authorized by law to cause to be established 'fit and proper regulations' for estimating the duties on any such goods, wares, and merchandise. In all cases, therefore, where the foreign currency is depreciated, its value in money of the United States is to be ascertained in the mode prescribed by the circular instructions issued by the Department, by direction of the President, under the dates of the 14th of May and the 16th of August, 1831, and the 16th of October, 1832. Although the consular certificate, required by said instructions, of the value in United States' money of any foreign depreciated currency is ordinarily to be received and taken as evidence of such value, yet it is not to be deemed conclusive in cases where facts or circumstances may exist, producing a rational belief that manifest error attaches to such certificate. Where Congress has fixed the value in American money of any foreign currency, it is to be understood that the value is to attach in all cases in estimating that duty; and, should any of the said currencies become depreciated, either by the issue of government paper money or otherwise, the collectors nevertheless will make no alteration in the value in estimating duties, without the previous authority of the Department, which authority will be promptly given in all cases, so soon as the fact of such depreciation is authentically brought to his knowledge. Such information has been received as regards the Austrian florin, which, until further instructions on the subject, the collectors will consider as depreciated currency, and levy the duty accordingly on invoices stated in it. The foreign currencies alluded to above, the value of which is fixed by various acts of Congress, are noted at foot, for your information and government.

"It frequently happens that invoices stated in the currency of the country of shipment have expressed on the face of them, in the currency of another country, the amount for which bills of exchange may have been drawn in payment of the goods, or for other causes. In cases where both currencies have a specie basis, any difference which may exist between the two amounts thus exhibited is presumed to arise from the interest on the sight of the bill, or a regular difference of exchange between the two points; and where the currency of the country of shipment is depreciated, a similar difference may exist between the specie value of the foreign currency thus expressed on the face of the invoice, and the consular certified specie value of the local depreciated currency in which the invoice is stated. As the law provides that the duties shall be estimated on the specie value of the

currency of the country whence the shipment is made, that mode, as a general rule, will therefore be adopted; yet where the difference between the value of two currencies, expressed upon the face of the invoice, is so great as to excite a well-founded belief that either deception or error exists, the appraisers are required to investigate the facts, and if they ascertain that there has been error, either in the consular certificate in giving the specie value of a depreciated currency, or that otherwise the true specie value in currency of the United States has not been correctly set forth, it will become their duty to correct said error by advancing the cost or value given in the invoice or on the entry, either in the price of the goods or the estimated specie value of the depreciated currency."

Curicle (Lat. *curriculum*, a chariot), a carriage with two wheels, drawn by two horses abreast, and supported by a pole connected with a bar across the horses' backs.

Currying of Leather (*Corroyer*, French; *Zurichten*, German) is the art of dressing skins after they are tanned, for the purposes of the shoemaker, coach, and harnessmaker, etc., or of giving them the necessary smoothness, lustre, color, and suppleness. The currier's shop has no resemblance to the tanner's premises, having a quite different set of tools and manipulations. Every kind of tanned leather not intended for soles or such coarse purposes, is generally curried before being delivered to the workmen who fashion it, such as shoemakers, coachmakers, saddlers, etc. The chief operations of the currier are four: 1. Dipping the leather, which consists in moistening it with water, and beating it with the *mace*, or a mallet, upon the hurdle. He next applies the *cleansers*, both blunt and sharp, as well as the head-knife, to remove or thin down all inequalities. After the leather is shaved, it is thrown once more into water, and well scoured by rubbing the grain side with pumice-stone, or a piece of slaty grit, whereby it parts with the bloom, a whitish matter, derived from the oak bark in the tan-pit. 2. Applying the pommel to give the leather a granular appearance, and correspondent flexibility. The leather is first folded with its grain side in contact, and rubbed strongly with the pommel, then rubbed simply upon its grain side; whereby it becomes extremely flexible. 3. Scraping the leather. This makes it of uniform thickness. The workman holds the tool nearly perpendicular upon the leather, and forcibly scrapes the thick places with both his hands. 4. Dressing it by the round-knife. For this purpose he stretches the leather upon the wooden cylinder, lays hold of the pendent under edge, with the pliers attached to his girdle, and then with both hands applies the edge of the knife to the surface of the leather, slantingly from above downward, and thus pares off the coarser fleshy parts of the skin. This operation requires great experience and dexterity; and when well performed, improves greatly the look of the leather.

The hide or skin, being rendered flexible and uniform, is conveyed to the shed or drying-house, where the greasy substances are applied, which is called dubbing (daubing) or stuffing. The oil used for this purpose is prepared by boiling sheepskins or doeskins in cod oil. This application of grease is often made before the graining-board or pommel is employed. Before waxing, the leather is commonly colored by rubbing it with a brush dipped into a composition of oil and lamp-black on the flesh side, till it be thoroughly black; it is then black-sized with a brush or sponge, dried, tallored with the proper cloth, and slicked upon the flesh with a broad, smooth lump of glass; sized again with a sponge; and when dry, again curried as above described. Currying leather on the hair or grain side, termed black on the grain, is the same in the first operation with that dressed on the flesh, till it is scoured.

Then the solution between rut urine is to make now stuff is, rubbed on the g slicked w kles, and raised wi ing it to thorough ways. It nearly as grain.

Then the first black is applied to it while wet, by a solution of copperas put upon the grain, after this has been rubbed with a stone; a brush dipped in stale urine is next rubbed on, then an iron slicker is used to make the grain come out as fine as possible. It is now stuffed with oil. When dry, it is seasoned; that is, rubbed over with a brush dipped in copperas-water, on the grain, till it be perfectly black. It is next slicked with a good grit-stone, to take out the wrinkles, and smooth the coarse grain. The grain is finally raised with the pommel or graining-board, by applying it to the leather in different directions. When thoroughly dry, it is grained again in two or three ways. Hides intended for covering coaches are shaved nearly as thin as shoe hides, and blacked upon the grain.

Curtains. Window-curtains are now made in great variety, both of materials and manufacture, the principal difference being as to the former, which consist chiefly of 8-silk, wool, and cotton. Silk is employed in *damasks* and *tabarets*, mixed with wool, the former being a flowery pattern of silk on a woolen foundation, whilst the latter is a satin stripe arranged in the same way as regards the composing materials. A species of *terry-velvet* is also now used in which the two materials are blended, and which makes a rich and elegant curtain; this is made also in wool without silk, and then called *repp*. When wool is used by itself, it then forms a *broad-cloth* suited to dining-rooms, or a *damask*, which is not so beautiful to the eye as the *silk damask*, but still sufficiently so for common purposes, or else a *warren*, either plain or watered, or a *chall*, which is a thin trill material, printed with chintz patterns. Cotton is made into a plain article, without any thing but a mere web and woof, which, when printed and glazed, is called chintz.

Customs are duties charged upon commodities on their being imported into or exported from a country. They were collected upon merchandise in England, under Ethelred II., in 979. The king's claim to them by grant of Parliament was established 3 Edward I., 1274. [This is questionable.] The customs were farmed to Mr. Thomas Smith, for £20,000 for several years, in the reign of Elizabeth.—Stowe. They were farmed by Charles II. for £390,000 in the year 1666.

—DAVENANT. The duties collected in England were,

The customs in Ireland were, in the year 1224, viz., on every sack of wool, 3d.; on every last of hides, 6d.; and 2d. on every barrel of wine.—*Annals of Dublin*. Custom-house officers, and officers of excise, were disqualified from voting for the election of members of Parliament, by statute 22 George III., 1782.

Customs duties seem to have existed in every commercial country. The Athenians laid a tax of a fifth on the corn and other merchandise imported from foreign countries, and also on several of the commodities exported from Attica. The *portoria*, or customs payable on the commodities imported into, and exported from, the different ports in the Roman empire, formed a very ancient and important part of the public revenue. The rates at which they were charged were fluctuating and various, and little is now known respecting them. Cicero informs us, that the duties on corn exported from the ports of Sicily were, in his time, 5 per cent. Under the imperial government, the amount of the *portoria* depended as much on the caprice of the prince as on the real exigencies of the state. Though sometimes diminished, they were never entirely remitted, and were much more frequently increased. Under the Byzantine emperors, they were as high as 12½ per cent.

Customs duties existed in England previous to the Conquest. They appear to have derived their name from having been immemorably or customarily charged on certain articles when conveyed across the principal forries, bridges, etc., within the kingdom, and on these and other articles of native and foreign produce, when exported from or imported into the kingdom. In 1206 the entire customs revenue of England, including that derived from tolls and fairs, amounted to only £4,958 7s. 3½d. It is not, therefore, true, as has sometimes been stated, that the king's first claim to the customs was established in the reign of Edward I. But that able and politic prince, by rendering the levy of the old duties more effectual, and procuring the sanction of Parliament to the imposition of new duties, was the first who made the customs revenue of any material importance. The duties were at first principally laid on wool, woollens (shoepelkins), and leather when exported. There were also extraordinary duties paid by aliens, which were denominated *parva custodia*, to distinguish them from the former, or *magna custodia*. The duties of tonnage and poundage, of which mention is so frequently made in English history, were customs duties; the first being paid on wine by the tun, and the latter being an *ad valorem* duty of so much a pound on all other merchandise. When these duties were granted to the crown, they were denominated *subsidies*; and as the duty of poundage had continued for a lengthened period at the rate of 1s. a pound, or 5 per cent., a subsidy came, in the language of the customs, to denote an *ad valorem* duty of 5 per cent. The new subsidy granted in the reign of William III. was an addition of 5 per cent. to the duties on most imported commodities.—*Treatise on Taxation*, by J. R. McCulloch, 2d ed., p. 234.

The various customs duties were collected, for the first time, in a book of rates published in the reign of Charles I.; a new book of rates being again published in the reign of George I. But, exclusive of the duties entered in these two books, many more had been imposed at different times; so that the accumulation of the duties, and the complicated regulations to which they gave rise, were productive of the greatest embarrassment. The evil was increased by the careless manner in which new duties were added to the old, a per centage being sometimes added to the original tax; while at other times the commodity was estimated by a new standard of bulk, weight, number, or value, and charged with an additional impost, without any reference to the duties formerly imposed. The confusion arising from these sources was still further augmented by the special appropriation of each of the duties, and the consequent necessity of a separate calculation for each. The intricacy and confusion inseparable from such a state of things proved a serious injury to commerce, and led to many frauds and abuses.

Customs duties, like all duties on particular commodities, though advanced in the first instance by the merchant, are ultimately paid by those by whom they are consumed. When a government lays a duty on the foreign commodities which enter its ports, the duty falls entirely on such of its own subjects as purchase these commodities; for the foreigners would cease supplying its market with them, if they did not get the full price of the commodities, exclusive of the tax; and, for the same reason, when a government lays a duty on the commodities which its subjects are about to export, the duty does not fall on them, but on the foreigners by whom they are bought. If, therefore, it were possible for a country to raise a sufficient revenue by laying duties on exported commodities, such revenue would be wholly derived from others, and it would be totally relieved from the burden of taxation, except in so far as duties might be imposed by foreigners on the goods it imports from them. Care, however, must be taken, in imposing duties on exportation, not

cents, United States' currency, and no consular certificate will be required, unless the currency should be depreciated. All former acts authorizing the currency of foreign gold or silver coins, and declaring the same a legal tender in payment of debts, are hereby repealed; but it shall be the duty of the director of the mint to cause assays to be made, from time to time, of such foreign coins as may be known to our commerce, to determine their average weight, fineness, and value, and to embrace in his annual report a statement of the results therefor.

The certificate of the United States' consul, showing the value of the currency of the country from which the merchandise is imported, and in which the invoice is made out, in United States' or Spanish silver dollars, must be required in every case in which the value of such foreign currency is not fixed by the laws of the United States. And in case the foreign currency in which the invoice is made out, whether its value is fixed by the laws of the United States or not, is depreciated, the certificate of the United States' consul, stating the rate of depreciation, must be produced on the entry, and the officers of the customs are governed by such certificate in computing the foreign market value of the merchandise.

Customs Duties consist for the most part of taxes levied upon goods, and produce brought for consumption from foreign countries; such duties are sometimes collected upon exports made to foreign countries, and upon goods and produce passing from one port to another in the same country.

The earliest statute passed in England, whereby the crown was authorized to levy customs duties, was the 3d of Edward I. The mode long employed in the collection of these duties, was to affix a certain rate or value upon each kind or article of merchandise, and to grant what was called a *subsidy* upon these rates. This subsidy was generally 1 shilling of duty for every 20 shillings of value assigned in the book of rates. The early acts which grant these duties speak of them as subsidies of tonnage and poundage. The word tonnage was applied to a specific duty charged on the exportation of each ton of beer; and the word poundage was applied to other articles valued as already explained.

The first "book of rates agreed upon by the House of Commons" is believed to be that compiled by a committee in 1642, during the reign of Charles I., and published under the authority of the House by Lawrence Blacklock. The next book of rates of which we have any record, was published by order of the House of Commons, in 1660, the year of the restoration of Charles II.—*Nat. Cyclo.* See HUNT'S *M. M.*, v. 145 (J. HOWING), vi. 9 (C. RAUERT), ix. 448 (C. C. WALTERSLEY), iv. (G. TUCKER), xiv. 456 (by C. C. JEWETT). See also *Encyc. Am., Art. Taxes*.

Custom-house, an office established by law in maritime cities or seaports, for the receipt and management of the customs and duties imposed on goods imported or exported.

Customs of Merchants. The law merchant is a peculiar system which prevailed throughout the whole of the Anglo-Saxon times; it was especially recognized in the time of Edward III.; when the staple was ordained, a mayor was to be chosen in every town, skilled in the law merchant to do right to every man according to that law. The modern law merchant is composed of three distinct elements, viz., the customs of merchants, the ordinances of foreign states, and the statute law—as art precedes science, so customs precede law. Long are these customs practiced before they are committed to writing. But though not written or declared by the legislative power, they acquire all the authority of law, and are gradually engrained upon the common law of the country. The customs of merchants are part of the law. Judicial determinations settle what is the custom of merchants, and they become the *lex mercatoria* as to the different

questions. In order that a custom be binding, it must be either the usage of the whole mercantile world, or of a particular trade universally known as such. A usage of a particular place, or of a particular class of persons, would not be binding on other persons unless these were acquainted with those usages and adopted them. In all cases, however, no custom can be set against an express statute law. Among the most important customs among merchants are the establishment of boards of trade, the settlement of disputes by arbitrations, and the binding force of the decision of a referee. See LEVY'S *Manual of Mercantile Law*.

Cutlass, a short sword used by seamen. The art of fencing with it is different from that with the small sword or broad sword. A guard over the hand is an advantage. It is, if well understood, a very effectual weapon in close contest; on account of its shortness, it can be handled easily, and yet it is long enough to protect a skillful swordsman.

Cutlery (Fr. *coutellerie*; Lat. *culter*, a knife), generally speaking, includes all cutting tools made of steel. Various countries and cities have at different periods excelled in the manufacture of some particular article, as Damascus for a beautiful sword blade, which has hitherto baffled all attempts at imitation. If this blade is made, as is commonly supposed, by welding together extremely fine wires of iron, steel, and gold, laid alternately on each other, the dexterity required is such as must astonish the most active and experienced workmen of other countries. The peculiar wave, usually called the water, so universally admired, is effected by the application of a weak acid to the polished surface of iron and steel. At Damascus, sulphate of alumine is used; but any dilute acid seems to answer the purpose. The cutlery of England is deservedly held in high estimation in every part of the civilized world. The finer articles, as razors, penknives, scissors, and surgical instruments, are made of cast steel, that is, steel purified and equalized by fusion. Dexterity and nice attention on the part of the workman to a variety of circumstances, as the quality of the steel, nature of the fuel, accuracy in the process of hardening and tempering, and many other minor considerations, are essential to the production of a good cutting instrument. For table-knives, and all cutlery of that description, shear-steel is generally used; the tang and shoulder of the table knife and fork are iron, united to the blade by welding. The celebrated Indian steel called wootz is not used in the manufacture of British cutlery.

The principal seat of the cutlery trade of England is at Sheffield, where all kinds of table cutlery, razors, penknives, scissors, surgeons' instruments, and every variety of cutting instruments, are manufactured. There are also some small manufactures of similar articles in London; but much the greater proportion of the cutlery sold as London-made, is actually manufactured in Sheffield, although bearing the name of London manufacturers. Sheffield cutlery has deservedly obtained a high degree of reputation in almost every part of the civilized world; and it is of the greatest importance to the commercial interests of the country that this high character should be maintained. But here it must not be omitted to be mentioned, that there is also an extensive manufacture of an inferior description of cutlery, principally consisting of table knives and forks, scissors, and pocket-knives, which are professedly made for export to the less civilized portions of the globe, but also retailed in large quantities in this country. It is manufactured by casting from a species of pig-iron. This iron is, from the superabundance of its carbon, highly susceptible of liquidity, and readily casts into the required form. In this state the cast-iron cutlery is extremely hard, and as brittle as glass; but it is reduced from this hardness by decomposition—being subjected to a strong and long-continued fire in close vessels, in contact with

iron ore, oxyd of iron, or any substance containing oxygen, with which the superabundant carbon combines, and flies off in the state of carbonic acid gas. This cast-iron cutlery is, when finished, not always distinguishable in appearance from that made at the forge, and can, of course, be afforded at a much lower price. This very fusible iron may be applied to many purposes. It is hardly necessary to add, that it is quite unfit for any description of edge instrument.

These observations apply generally to every description of knife used in surgery; but the nature of each particular operation should not be considered, in judging of the requisite degree of strength or delicacy of edge. Next in importance to the knives are the saws used in surgery. All of these must be of the best spring temper, which, for the cast-steel blade, is about 570° of Fahrenheit, and for one of Indian steel 600°, or quite the boiling point of mercury. Of another class of instruments, namely, those denominated blunt, it will be sufficient to observe, that what is known by the name of shear-steel is best adapted for the purpose. Case-hardened iron has been most improperly used, this hardening being very superficial. It is, in fact, converting the surface only into steel, by heating it to redness, in a close vessel, in contact with animal charcoal, such as charred bone, leather, or horn, and quenching it when red-hot in a cold fluid. Iron thus treated, will take a beautiful polish; but, except for ornamental purposes, it ought never to be employed. Some instruments are necessarily made of gold or silver; as catheters, and other tubes and probes. When for these ductility is required, the metals should be unalloyed; the extra expense of which, will be more than compensated by the convenience of giving to the instruments, in all cases, the desired curve and form.

The handles of instruments, together with all ornamental parts, must in a great measure depend on the taste and choice of the purchaser. It would be well, however, to avoid such materials as are known to produce chemical action when in contact with polished steel. Ivory, mother-of-pearl, and ebony are much used; but the fine walnut-tree, such as the London gunmakers employ, is perhaps of all the woods the best for the purpose. Sandal-wood answers very well, although it by no means deserves all the credit which has been given to it as a preservative of steel from rust. The instrument-maker who wishes to excel will do well to avail himself of every opportunity of witnessing the operative part of surgery; that he may observe how far the instrument is mechanically and physically adapted to its purpose, and, if necessary, be the better able to make the requisite alteration.—E. B.

The value of hardwares and cutlery exported from Great Britain in 1855, was £2,960,391. In the New England States the manufacture of cutlery is rapidly increasing. In Massachusetts about \$400,000 is invested in this branch, with an annual product of about \$800,000.

Quietly, but rapidly, we are day by day gaining on the old world, and the time is not far distant when it will be discovered that the majority of our manufactures are actually superior to those of Europe. As an illustration of this, we will venture to assert that there are very few persons, not concerned in the business, who are aware of the degree of excellence which the manufacture of cutlery has attained in the United States, or that, if it were generally known and encouraged, we should in all probability be entirely self-dependant as regards its production. On this subject, Fleischmann, whose work on the "Branches of Industry in the United States" has contributed more than any other book to enlighten Germany as to our country, remarks as follows:

"The manufacturers of cutlery in the United States have far surpassed those of the old world in the manufacture of tools, and that not merely in the excellence of the metal used, but especially in the practical utility

of their patterns, and in the remarkable degree of finish of their work."

It is a somewhat remarkable fact that American hardware is every year developing in its shapes a practical economy of material and a straight-forward adaptation to the end in view which are unknown to the greater part of Europe. The American laborer or mechanic, it is well known, even where not gifted with a greater degree of physical ability, will still, as a rule, turn out more work in a day than a foreigner under the same circumstances. With such men, who go directly at their work and stick to it, there is no play and no trifling with labor. A result of this is shown in the fact that the American ax, which, in its well-known form, is entirely a native American pattern, is far more practically useful than the miserable European ax which it has supplanted. And not in axes alone, but in many other implements there has been a marked progress, and a gradual, though unnoticed, communication of practical patterns to English manufacturing. In our factories, which are themselves very generally proofs of the same principle of economy and of keeping directly at the object proposed, there is actually more of the first quality English steel used, than in England itself. Of Hoop L, the best quality of English steel, there is annually ten times as much used as in England, though that country manufactures about fifty times as much cutlery as we do.

Could our American mechanics receive the credit so justly their due, for the improvements which they have gradually introduced into the shape of carpenters' tools, and could the world be made aware of the degree to which of late years the English trade has been indebted to them for these improvements, we will venture to state that there are few who would not be amazed. The European—especially the continental—suffers in this respect under a tyranny of "old customs," which no Yankee mechanic would believe. If we look through Paris, if we examine the pattern-plates published, we are amazed at the luxuriance of beautiful and practical forms annually produced, which glitter in shop windows, or are displayed at exhibitions. But go into the country, and we find the same clumsy, unpractical old implements which were used three centuries ago. The seed falls on stony ground.

At the present day, American cutlery is extensively imitated in Germany, even to the marks and names of our manufacturers. This is also done by English goods, but the complimentary fraud has been of late years greatly on the increase as regards our own. We will not assert that there is not, especially in England, a vast amount of inventiveness, nor that a corresponding degree of improvements has not been made. But a practical invention is less likely to die in the birth in America, and we confidently assert, without fear of refutation, that if any one will study the history of cutlery patterns adopted for the last 50 years, including all the allied branches of manufacture, he will find that by far the greater proportion of practical improvements have been of American origin.—LUNN'S *Merchants' Magazine*.

Cutter. A vessel with one mast and a bowsprit, of considerable breadth in proportion to her length. The distinction between a cutter and other vessels of one mast, which are called sloops, is, that in the cutter the jib has no stay to support it.

Cutters, Revenue. These vessels are usually about 100 or 150 tons, built as fast sailers, to aid the revenue officers. The captains and lieutenants of revenue cutters of the United States, are appointed by the President. Their reports are made to the Treasury Department; the vessels subject to the direction of the collector of the port. Their officers and seamen are placed upon the navy pension list, when disabled. Congress has recently authorized the construction or purchase of steam revenue cutters, which will furnish material aid to the government officers in extraordinary cases.

Cyclopædia. (More commonly *Encyclopædia*, from the Greek words *ἐν κύκλω παιδεία*; *instructions in a circle*.) A work containing definitions or accounts of the principal subjects in one or all departments of learning, art, or science. Its arrangement may be either according to divisions into the various sciences, etc., or the subjects may be arranged and treated in alphabetical order. The *Encyclopédie Française*, or *Dictionnaire Encyclopédique*, and the *Encyclopædia Britannica*, have been the most celebrated works of this species; but the earliest appears to be the *Lexicon Technicum* of Harris, published in 1706. The great French work, the *Encyclopédie Methodique*, consists, not of one, but of a series of encyclopedias or dictionaries.

Cypress, a forest tree, of which there are many varieties, the species denominated the evergreen cypress (*Cupressus sempervirens*) and the white cedar (*Cupressus Thuyoides*) being the most celebrated. The cypress is indigenous to the southern parts of Europe, to several parts of Asia, and to America. It grows to a great size, and is a most valuable species of timber. It is never attacked by worms; and exceeds all other trees, even the cedar, in durability. Hence the Athenians, when desirous to preserve the remains of their heroes and other great men, had them inclosed in cypress coffins; and hence, also, the external covering of the Egyptian mummies is made of the same enduring material. The cypress is said to live to a great age; and this circumstance, combined with its thick, dark, green foliage, has made it be regarded as the emblem of death and the grave. In his *Geography and History of the Western States*, Mr. Timothy Flint has given the following account of the cypress-trees found in the southern parts of the valley of the Mississippi: "These noble trees rear their straight columns from a large cone-shaped buttress, whose circumference at the ground is perhaps 3 times that of the regular shaft of the tree. This cone rises from 6 to 10 feet, with a regular and sharp taper, and from the apex of the cone towers the perpendicular column, with little taper after it has left the cone, from 60 to 80 feet, clear shaft. Very near the top it begins to throw out multitudes of horizontal branches, which interlace with those of the adjoining trees, and, when bare of leaves, have an air of desolation and death, more easily felt than described. In the season of vegetation the leaves are short, fine, and of a verdure so deep as almost to seem brown, giving an indescribable air of funereal solemnity to this singular tree. A cypress forest, when viewed from the adjacent hills, with its numberless interlaced arms covered with this dark-brown foliage, has the aspect of a scaffolding of verdure in the air. It grows, too, in deep and sickly swamps, the haunts of fever, mosquitoes, moccasins, snakes, alligators, and all loathsome and ferocious animals, that congregate far from the abodes of man, and seem to make common cause with nature against him. The cypress loves the deepest, most gloomy, inaccessible swamps; and south of 33° is generally found covered with sable festoons of long moss, hanging, like shrouds of mourning vesture, almost to the ground. It seems to flourish best when water covers its roots for half the year. Unpromising as are the places and circumstances of its growth, no tree of the country where it is found is so extensively useful. It is free from knots, it is easily wrought, and makes excellent planks, shingles, and timber of all sorts. It is very durable, and incomparably the most valuable tree in the southern country of this valley." Of whatever materials the building is constructed, the roof is universally covered with cypress shingles, which, if made of trees felled in the winter, last forty years. Cypress boards are preferred to those of pine for the inside of brick houses, and for window-sashes, and the panels of doors exposed to the weather; cabinet-makers also choose it

for the inside of mahogany furniture. It is highly proper for the masts and sides of vessels, and wherever it grows it is chosen for canoes, which are fashioned from a single trunk, and are often 30 feet long and 5 feet wide, light, solid, and more durable than those of any other tree. It makes the best pipes to convey water under the ground; especially the black variety, which is more resinous and solid.—BROWN'S *Trees of America*.

Cyprus (*Kypris*), an island in the N. E. corner of the Levant, lying at about equal distances from the shores of Cilicia and Phœnicia. Its extreme length from the promontory of Dinaretum to that of Acamas is about 140 miles; its extreme breadth, from the promontory of Crommyon to that of Curias, about 70 miles. The area is roughly estimated at about 4,500 English square miles. The greater part of the island is occupied by the central ridge and spurs of the Stavro-Vuno and Santo Croce mountains (the ancient Olympus). The loftiest peaks of this range attain a height of from 8,000 to 10,000 feet above the sea. The northern slopes are rocky and bare, but on the side of the south they are well wooded and highly picturesque, and inclose, in various parts of their course, valleys of unrivaled fertility. Considerable part of the wealth of ancient Cyprus arose from its copper mines, the most important of which were those of Tamassus in the centre of the island, Soll on the north coast, and Amathus and Cyrium on the south coast. In these mines gold and silver were also found. The precious stones of Cyprus were also highly valued. The chief of these were the emerald, agate, malachite, jasper, opal, and the minerals asbestos and rock crystal.

The first settlers in Cyprus appear to have been of Phœnician origin. Under Augustus it became an imperial province, and was governed by a præconsul, with a staff of inferior officers. Before the close of the 1st century of the Christian era, the Jewish population of the island had greatly increased, and in the reign of Hadrian, is said to have risen in rebellion, and slain 200,000 of the other inhabitants. In the 7th century, Cyprus fell into the hands of the Saracens; and in the 9th, it owned the supremacy of the "good" Haroun Al Raschid. At the close of the 12th century, it was conquered by Richard Cour de Lion, who made it over first to the Knights of the Temple, and ultimately to Guy of Lusignan, titular king of Jerusalem. For three centuries the island remained in the family of Lusignan, till, in 1473, it became an appendage of the Venetian republic. Cyprus was retained by the Venetians till in 1571 it was overrun by an army of Turkish invaders, who stormed Lefkosia and Fmagoستا, and made a general massacre of the inhabitants. Since that date the island has remained in possession of the Turks, and now forms a pashalic in the Eyalet of Djizalra. Under the Turkish rule the material prosperity of Cyprus has greatly declined. In the times of the Venetian supremacy, the island maintained a population of 1,000,000; its present population is only about 150,000, of whom the great majority are Greeks. Many parts of the island, formerly healthy and fertile, are now, from malaria and other causes, barren and uninhabitable. Its trade was at one time valuable and important; now the value of its annual imports does not exceed £20,000; of its exports, about £60,000. Besides corn, of which it produces about 120,000 quarters annually, Cyprus yields in considerable quantities cotton, wine, various kinds of fruit, opium, and madder; while the mountain districts furnish olives, vines, and many species of valuable timber. On the island are found great quantities of the *Fruita græca*, which the Cypriote applies to a great variety of domestic purposes. This is the plant whose uses are feigned by the poets to have been taught to mortals of old by Prometheus.

D.

Dacca, the capital of an extensive and rich district in the eastern quarter of the province of Bengal, a large city, and for 80 years the capital of Bengal, of which it is still the third city in point of extent and population. It is situated beyond the principal stream of the Ganges, on the northern bank of a very large branch of that river, called the Boor Gunga, or old Ganges, at the distance of a hundred miles from the mouth of the Ganges. Its position is admirably well adapted for inland trade, as the river which flows past it communicates with all the other inland navigations by a direct course. The present town covers a great deal of ground, extending four miles along the bank of the river, though it is not of proportional breadth. The houses of the wealthy are built of brick, but there are many thatched houses, with very narrow and crooked streets; the bazaars are only tiled or thatched; and as every vacant spot is covered with trees, the town looks from a distance like a grove. Owing to the effects of British competition, the manufactures of Dacca are at this time scarcely deserving of notice; but here were formerly manufactured the most beautiful muslins, which were exported to all quarters of the world, and which had long been famed for their delicacy and beauty. The spinning of the thread was carried on with wonderful nicety. The operation was performed with the fingers on a fine steel spindle by young women, who could only work during the early part of the morning while the dew was on the ground; for such was the extreme tenuity of the fibre that it would not bear manipulation after the sun had risen. Such was the skill of the darners that they could remove an entire thread from a piece of muslin, and replace it by one of a finer texture. From their wonderful fineness these muslins were called Abrawan, or "flowing water," and Shabnam, "evening dew."—E. B.

Daguerreotype. The name given to a process invented by M. Daguerre of Paris, in 1839, by which perfect fac-similes of objects are transferred upon thin copper plates with plated silver. The images are produced by the action of light upon the iodine, through the focus of the camera obscura. An apparatus somewhat kindred in design, was in contemplation about the same time by M. Niepce, and about five years previously by Henry Fox Talbot of London; the original idea, however, is traceable as far back as the days of Roger Bacon. By means of the Talbotype, a recent improvement upon the above process, pictures in colors are produced both on paper and plates. So important a discovery in the fine arts was the daguerreotype deemed by the French government, that it awarded to its inventor a life pension of 6000 francs.—HAYDN. See SHILLMAN'S *Journal of Science*, xxxvii., p. 69; xl., p. 137; xliii., p. 185; *Foreign Quarterly Rev.*, xliii., p. 213; *Westminster Rev.*, xxxiv., p. 434.

In 1802 Mr. Thomas Wedgwood and Sir Humphrey Davy succeeded in forming pictures of objects laid on paper prepared with nitrate of silver, and in taking profiles (silhouettes) by means of shadows. They proposed to obtain similar effects by means of the camera obscura, but their paper was not sufficiently sensitive. The effectual bar to their proceedings was, however, this: that they could discover no means of *fixing the shadows* which they had obtained, or preventing the whole surface of the paper from being gradually blackened by exposure to light.

In 1814 J. NICEPHORE NIEPCE, a retired proprietor at Chalons sur Saône, entered into a similar inquiry, but by methods quite different. He employed the solar effect upon resinous bodies, and some, at least, of his pictures were executed upon plates of pewter or

of rotted silver. They were mostly copies of engravings, and the light parts corresponded to the lights of the originals. He, however, at length succeeded in fixing impressions of views in the camera obscura, though in an imperfect manner, and after very long exposure. The pictures thus obtained had this in common with more perfect processes, that the luminous impression was first brought into view by a chemical process subsequent to exposure in the camera. In 1825 Nicephore Niepce became associated with Daguerre, who had previously been engaged in the same research; they agreed to communicate the results of their several experiments. The result, as is well known, was the invention of the DAGUERRETYPE, not improperly called after Daguerre, who seems really to have worked it out almost entirely for himself after the death of Niepce in 1833; while so patient and determined was Daguerre in keeping his secret till brought to perfection, that he did not even show his results until early in 1839, when the numerous specimens he had to exhibit rivaled in delicacy any thing that the art has since produced.—*Ency. Brit. Pro. Dissertation*, by FORNES.

Dahlia. This beautiful flower was imported from China, of which it is a native, early in the present century, and amateurs in flowers have annually laid out hundreds of pounds in England, and thousands of francs in France, in the purchase of it. The Swedish botanist, Professor Dahl, first cultivated and made it known. It soon attracted notice in England, where, from the beauty of its form and variety of color, it became at once an especial favorite. In 1815, about 2 months after the battle of Waterloo, it was introduced into France, and the celebrated florist, Andre' Thouin, suggested various practical improvements in its management. The botanist, Noeuz, had shortly before this introduced it at St. Petersburg; and hence it is, that to this day the dahlia is known throughout Germany under the name of *Georgia*.—HAYDN.

Dairy. Milk, either in its natural state, or in the form of butter and cheese, is an article of diet so wholesome and so palatable, that the health and comfort of people, especially such of them as dwell in cities, depend much upon their having a pure and plentiful supply of it at all seasons. DAIRY MANAGEMENT, which includes every thing about the production and treatment of milk, is consequently a very important branch of husbandry, and one in which every body feels interested. The physical conditions of the different countries of the world have determined in each case the particular milk-yielding animal most suitable to be there used for dairy purposes. The Laplander obtains his supplies of milk from his reindeer, the roving Tartar from his mares, and the Bedouin of the desert from his camels. In the temperate regions of the earth many pastoral tribes subsist mainly upon the milk of their sheep. In some rocky regions the goat is invaluable for this purpose; and the buffalo is equally so amid the swamps and jungles of tropical climates. The milking of ewes was once a common practice in Great Britain; but it has fallen into disuse because of its hurtful effects upon the flock. A few milk asses and goats are kept for the benefit of infants or invalids; but with these exceptions the cow is the only animal now used for dairy purposes in this country and Europe.

Butter is made either from cream only, or by churning the whole milk and cream together. The best butter is obtained from the cream which rises during the first 12 hours after milking, and the next best by churning the whole milk. In the former case the new milk, after being carefully strained, is poured into

shallow vessels of glazed earthenware, glass, tinned iron, wood, lead, or zinc, of which the 8 first-named sorts are the best. The wooden vessels are objectionable from the difficulty of cleaning them thoroughly; and the last two from the noxious salt which is produced by the action of the acid of the milk on the metal. When it is intended to extract as nearly the whole of the butter from the milk as is practicable, the 1st skimming takes place at the end of 24 hours, and is followed up by one or more skimmings at further intervals. The cream is stored in jars, which should be kept in a place separate from the milk-room, that the milk in the coolers may not be prematurely acidulated by the proximity of the sour cream. The latter is either stirred repeatedly, or poured from one vessel to another, to prevent the formation of a tough coat upon it before enough is accumulated for churning. In large dairies it is usual to churn daily. Three days is as long as the cream can ordinarily be kept with safety to the quality of the butter. When a cow has recently calved, her milk is comparatively rich in butter and poor in curd; but soon the relative proportions of these constituents change places, the cream diminishing and the milk becoming thicker. A very sensible change in the quality also usually takes place when a cow again becomes pregnant. In not a few cases the cream is so affected by this circumstance, that double or treble the length of time is required to churn it that sufficed before, and the butter is at the same time of inferior quality. If cows are flurried and heated, either by gadding in the pasture, or by being overdriven in bringing them home for milking, their milk becomes peculiarly liable to corrupt, the yield of butter is sensibly lessened, and its quality is impaired. The success of the process of churning depends much on the temperature of the cream being nicely regulated. A mean temperature of 60° Fahrenheit seems to be the best. The temperature of the cream usually rises about 10° during the process of churning. About 55° is therefore the desirable starting-point. Advantage is derived from rinsing the churn with cold water in summer and with warm water in winter. The addition to the cream of small quantities of cold or hot water, as the case requires, is also found beneficial. Box or barrel churns are preferred when the cream only is churned, the former being best adapted for small dairies, and the latter for large ones.—E. B. See *Butter and Cheese*.

Damaged Goods, in the language of the customs, are goods, subject to duties, that have received some injury either in the voyage home or in the bonded warehouses.

Damar, a kind of indurated pitch or turpentine, exuding spontaneously from various trees indigenous to most of the Indian islands. Different trees produce different species of resin, which are designated according to their color and consistence. "One is called *Damar-butu* in Malay, or *Damar-selo* in Javanese, which means hard or stoney resin; and another in common use, *Damer-Puteh*, or white resin, which is softer. The trees which produce the damar yield it in amazing quantity, and generally without the necessity of making incisions. It exudes through the bark; and is either found adhering to the trunk or branches in large lumps, or in masses on the ground under the trees. As these often grow near the seaside, or on the banks of rivers, the damar is frequently floated away, and collected in distant places as drift. It is exported in large quantities to Bengal and China; and is used for all the purposes to which we apply pitch, but principally in paying the bottoms of ships. By a previous arrangement, almost any quantity may be procured at Borneo, at the low rate of $\frac{1}{4}$ dollar per picul."—*CHAW-FORU, East Archip.*, v. 1, p. 455, v. iii., p. 420.

Damascus. This city was in being in the time of Abraham.—*Gen.* xiv. It is, consequently, one of the most ancient in the world. From the Assyrians,

Damascus passed to the Persians, and from them to the Greeks under Alexander; and afterward to the Romans, about 70 B.C. It was taken by the Saracens A.D. 633; by the Turks in 1066; and was destroyed by Tamerlane in 1400. It was in a journey to this place that the apostle Paul was miraculously converted to the Christian faith, and here he began to preach the gospel, about A.D. 50. Damascus is now the capital of a Turkish pachalic.—**HAYDN**. Damascus is the seat of an extensive trade both with India and with Europe. The productions of India, consisting chiefly of spices, cotton manufactures, coarse and fine muslins, and gold stuffs, are in great demand, and bring high prices. They are brought from India by the Persian Gulf, Bassora, Bagdad, and Aleppo. The manufactures of England are much sought after, and held in very high esteem, particularly light woolen cloths of gay colors, printed cottons and chintzes, and silk and cotton shawls made in imitation of those of Cashmere; also needles, pine, knives, scissars, and fine hardware, as well as china and earthenware, whether English or Indian. These goods being generally imported through Saïda, Beirut, and Tripoli, are sold at very high prices. Iron, lead, tin, cochineal, sugar, and other European articles, are also imported through the same channel. Wearing apparel for fashionable persons of both sexes at Damascus, and clothes that have been worn, are brought from Constantinople; and being distributed all over the country, are frequently the means of spreading the contagion of the plague. Among the various manufactures to be found in the bazaars are superb caparisons for horses, of which the Turks, as well as all the other eastern nations, are extremely fond. These are made in European Turkey; and a number of fine bristles, martingales, and silver and embossed breast-pieces, come also from Persia. The firearms are chiefly of French and German manufacture, being prepared in an ornamental style expressly for this market. The sabre blades are almost all of the old Persian or Damascus manufacture. The art of making them, however, is no longer known or practiced in this city; so that they grow daily more valuable, as no modern sword can compare with them in temper and quality. The silk seen in the bazaars of Damascus is principally of Chinese and Indian manufacture; the furs come from Russia, Georgia, Circassia, and Armenia; the velvet from Italy; copper from Asia Minor; the manufactures of Britain through Smyrna; and various other articles of an inferior kind from Germany and France. There are few manufactures in Damascus; and these consist chiefly of silk stuffs, plain, colored, and embroidered with gold; fabrics of plain cotton, and cotton and silk mixed, all for home consumption, and mostly of broad, striped, or wavy patterns, for the caftans of the Turkish dress.

Commerce, as in all other places in the East, is carried on by means of caravans, of which the principal is that which goes with the annual pilgrimage to Mecca. It is conducted by the pas's, who receives the standard of the Prophet from the governor of the castles, and gives a solemn pledge for its restoration. This expedition unites commercial with religious objects. A caravan accompanied by a numerous train of armed men goes thrice a year to Bagdad, the journey occupying 30 days; that to Aleppo travels twice or thrice a month. Besides these, many other caravans go to different parts of Syria, Damascus being a great rendezvous and emporium of trade. Provisions and fruits of all kinds are abundant; also ice and snow, which may always be obtained from the neighboring mountains. Damascus is generally regarded as the oldest city in the world, its history remounting beyond the time of Abraham, whose steward Eliezer was a native of this place. A great era in its history is its conquest by the Saracens.—E. B. See *Am. Whig Rev.*, vol. viii.

town, from 8 to 9 feet. Moles have been erected on both sides the entrance to the harbor; that on the eastern side, which is most exposed, is constructed of granite, but is not yet completed; the other is partly of stone and partly of timber.

Trade.—Next to Petersburg, Dantzic is the most important commercial city in the north of Europe. It owes its distinction in this respect to its situation; the Vistula, with its important tributaries the Bug, Narew, etc., giving it the command of a great internal navigation, and rendering it the *entrepôt* where the surplus products of West Prussia, Poland as far as Hungary, and part of Lithuania, are exchanged for those imported from the foreigner. The exports of wheat from Dantzic are greater than from any other port, (Odessa excepted. There are four sorts of wheat distinguished here; viz. *white, high-mixed, mixed, and red*, according as the white or red predominates. The quality of Dantzic wheat is for the most part excellent; for, though small in the berry, and not so heavy as many other sorts, it is remarkably thin-skinned, and yields the finest flour. The white Polish wheat exported here is the best in the Baltic. Rye is also very superior, being both clean and heavy; the exports of barley and oats are comparatively inconsiderable, and the qualities but indifferent. Very fine white peas are exported. Next to grain, timber is the most important article of export from Dantzic, but lately the supply has been diminishing, and the quality is said not to be so good as formerly.—*Meek.* The principal supply of fir timber, masts, etc., is brought by the river Narew, which, with its branches, rises in old Prussia and Lithuania, and falls into the Bug near the confluence of the latter with the Vistula. Oak planks, staves, etc., are brought down from the higher parts of the Vistula, and the tributary streams of Dunajetz, Wieprez, etc. Salted pork, weed ashes, linseed and rapeseed, mats, bones, zinc, spruce beer, feathers, etc., are also exported.

Imports.—These consist principally of iron and steel, herrings, wine, sugar, coffee, cotton and cotton yarns, spices, salt, coal, tobacco, dyewoods, spirits, rice, etc.; but their value is seldom more than half that of the exports.

DUTIES ON PILOTAGE AND POLICE PASSPORTS AT DANTZIC.

Money.—Accounts used formerly to be wholly kept in guildens, guilders, or florins of 30 groschen. The rixdollar=3 florins=90 groschen=270 schillings=1,620 pfennings. The florin or guilder=9d. sterling, and the rixdollar=2s. 3d. A new system was, however, introduced into all parts of the Prussian dominions, conformably to the decrees of the 30th of September, 1821, and of the 22d of June, 1823. The Cologne mark (containing 3,609 English grains) is the weight at present used in the Prussian mint in weighing the precious metals. The fineness of the coins is not determined, as previously, by carats or loths, but the mark is divided for this purpose into 288 grains. Accounts are now kept in the public offices in thalers or dollars (R.), silver groschen, and pfennings; 1 dol. =30 sil. gr.=12 pf. The only silver moneys now coined are dollars and $\frac{1}{2}$ dollar pieces; but smaller coins are in circulation, of former coinages. The Prussian silver coins have $\frac{1}{2}$ of alloy; and as the

mark is coined into 14 dollars, each should contain 257.68 English grains pure silver, and be worth about 2s. 11 $\frac{1}{2}$ d. sterling; but the assays do not always strictly coincide with the mint valuation. The gold coins are Frederic d'ors, double, single, and half pieces. The mark of 288 grains, having 260 grains of fine gold, is coined in 85 Fred. d'ors. The Fred. d'or is worth from 5 dol. 18 sil. gr. to 5 dol. 22 sil. gr., according to the demand.

Weights and Measures.—The commercial weights are, 32 loths = 1 ounce. 16 ounces = 1 pound. 16 $\frac{1}{2}$ pounds = 1 $\frac{1}{2}$ pound. 20 pounds = 1 small stone. 83 pounds = 1 large stone.

110 lbs.=1 centner; 3 centners=1 shippound (360 lbs.); 100 lbs. of Dantzic=103.3 lbs. avoird.=46.85 kilogram.=94.7 lbs. of Amsterdam=96.6 lbs. of Hamburg.

The liquid measures are, for beer, 5 quarts = 1 anker. 4 ankora = 1 ahm. 14 ahms = 1 hhd. 2 hds. = 1 both. 2 boths = 1 $\frac{1}{2}$ der. 2 fuders = 1 last=620.4 Eng. wine gals.

In wine measure, which is less than beer measure, the ahm=39 $\frac{1}{2}$ Eng. gallons. The pipe=2 ahms.

The last of corn=5 $\frac{1}{2}$ malters=60 scheffels=240 vier-tels=960 metzen; and weighs 4,680 lbs. Dantzic weight in rye. The scheffel=547 of a hectolitre=1.552 Winchester bushels. Hence the last of 60 scheffels=11 quarters 3 bushels; the last of 55 $\frac{1}{2}$ scheffels=10 quarters 7 bushels.

The Dantzic foot=11.3 Eng. inches, or 100 Dantzic feet=94.16 Eng. feet. The ell is 2 feet Dantzic measure. The Rhineland or Prussian foot=3138 French metres, or 12.356 Eng. inches; hence 100 Prussian=102.8 English feet. The Prussian or Berlin ell has 25 $\frac{1}{2}$ Prussian inches=26.256 Eng. ditto. 100 Berlin ells=72.98 Eng. yards; and 137.142 Berlin ells=100 Eng. yards. 14 $\frac{1}{2}$ Prussian miles are equal to 15 geographical miles.

Oak planks, deals, and pipe staves are sold by the shock of 60 pieces; wheat, rye, etc., are sold by the last of 56 $\frac{1}{2}$ scheffels.—*Kelly's Cambist; Neckenbrecher, Manual Universal.*

Corn Trade of Dantzic.—Grain is almost wholly brought to Dantzic by water, in flat-bottomed boats suited to the navigation of the Vistula, Bug, etc. The English consul estimated the expense of the conveyance of wheat and rye, including the duty at Thorn and the charges of turning on the river, till put into the granary, as follows:

	Per Imp. quarter.
s. d. "	
From the upper provinces on the Bug, a distance of from 700 to 500 miles.....	9 2 to 7 10
From the provinces of Cracow, Sandomir, and Lublin, 500 to 850.....	6 6 " 5 4
From Warsaw and its neighborhood, about 240 miles.....	4 9 " 3 11
From Wlascawek and its neighborhood, about 140 miles.....	4 9 " 3 5
From Grandenz, a distance of about 70 miles, no duty at Thorn, and when not turned on the river.....	0 10 " 0 9

The Bug has many windings, and its navigation, which is tedious and uncertain, can only be attempted in the spring, when the water is high. It is the same, though in a less degree, with some of the rivers that fall into the Vistula before it reaches Warsaw; and toward Cracow the Vistula itself is frequently un-navigable, especially in dry seasons, except in spring, and after the midsummer rains, when the snow melts on the Carpathian mountains. The navigation of the Polish rivers in some seasons is more than usually bad. The corn from the upper provinces does not reach Dantzic till from 2 to 4 months later than usual, and is burdened with a very heavy additional expense. In fact, the supplies of grain at Dantzic depend quite as much on the abundance of water in the rivers, or on their easy navigation in summer, as on the good-

ness of the harvests. "There are," says Mr. Jacob, "two modes of conveying wheat to Dantzie by the Vistula. That which grows near the lower parts of the river, comprehending Polish Russia, and part of the province of Plock, and of Masovia, in the kingdom of Poland, which is generally of an inferior quality, is conveyed in covered boats, with shifting-boards that protect the cargo from the rain, but not from pilfering. These vessels are long, and draw about 15 inches water, and bring about 150 quarters of wheat. They are not, however, so well calculated for the upper parts of the river. From Cracow, where the Vistula first becomes navigable, to below the junction of the flag with that stream, the wheat is mostly conveyed to Dantzie in open flats. These are constructed on the banks, in seasons of leisure, on spots far from the ordinary reach of the water, but which, when the rains of autumn, or the melted snow of the Carpathian mountains in the spring, fill and overflow the river, are easily floated. Barges of this description are about 75 feet long, and 20 broad, with a depth of 2½ feet. They are made of fir, rudely put together, fastened with wooden trenails, the corners dovetailed and secured with slight iron clamps—the only iron employed in their construction.

"A large tree, the length of the vessel, runs along the bottom, to which the timbers are secured. This roughly-cut keelson rises 9 or 10 inches from the floor, and hurdles are laid on it, which extend to the sides. They are covered with mats made of rye straw, and serve the purpose of dammage; leaving below a space in which the water that leaks through the sides and bottom is received. The bulk is kept from the sides and ends of the barge by a similar plan. The water which these ill-constructed and imperfectly-calced vessels receive, is dipped out at the end and sides of the bulk of wheat. Vessels of this description draw from 10 to 12 inches water, and yet they frequently get aground in descending the river. The cargoes usually consist of from 180 to 200 quarters of wheat. The wheat is thrown on the mats, piled as high as the gunwale, and left uncovered, exposed to all the inclemencies of the weather, and to the pilfering of the crew. During the passage, the barge is carried along by the force of the stream, oars being merely used at the head and stern, to steer clear of the sand-banks, which are numerous and shifting, and to direct the vessel in passing under the several bridges. These vessels are conducted by 6 or 7 men. A small boat precedes, with a man in it, who is employed sounding, in order to avoid the shifting shoals. This mode of navigating is necessarily very slow; and during the progress of it, which lasts several weeks, and even months, the rain, if any fall, soon causes the wheat to grow, and the vessel assumes the appearance of a floating meadow. The shooting of the flures soon forms a thick mat, and prevents the rain from penetrating more than an inch or two. The main bulk is protected by this kind of covering, and, when that is thrown aside, is found in tolerable condition. The vessels are broken up at Dantzie, and usually sell for about ⅓ of their original cost. The men who conduct them return on foot. When the cargo arrives at Dantzie or Elbing, all but the grown surface is thrown on the land, spread abroad, exposed to the sun, and frequently turned over, till any slight moisture it may have imbibed is dried. If a shower of rain falls, as well as during the night, the heaps of wheat on the shore are thrown together in the form of a steep roof of a house, that the rain may run off, and are covered with a tanned cloth. It is thus frequently a long time after the wheat has reached Dantzie, before it is fit to be placed in the warehouses.

"The warehouses (*speckers*) are very well adapted for storing corn. They consist generally of 7 stories, 3 of which are in the roof. The floors are about 9 feet asunder. Each of them is divided by perpendicular

partitions, the whole length, about 4 feet high, by which different parcels are kept distinct from each other. Thus the floors have two divisions, each of them capable of storing from 150 to 200 quarters of wheat, and leaving sufficient space for turning and screening it. There are abundance of windows on each floor, which are always thrown open in dry weather to ventilate the corn. It is usually turned over three times a week. The men who perform the operation throw it with their shovels as high as they can, and thus the grains are separated from each other, and exposed to the drying influence of the air. The whole of the corn warehouses now left (for many were burnt during the siege of 1814) are capable of storing 500,000 quarters of wheat, supposing the quarters to be large enough to fill each of the 2 divisions of the floors with a separate heap; but as of late years it has come down from Poland in smaller parcels than formerly, and of more various qualities, which must of necessity be kept distinct, the present stock of about 280,000 quarters is found to occupy nearly the whole of those warehouses which are in repair, or are advantageously situated for loading the ships. Ships are loaded by gangs of porters, with great despatch, who will complete a cargo of 500 quarters in about 3 or 4 hours."—*First Report.*

Banking Establishments.—There is none such here, excepting a branch of the Royal or Government bank of Berlin. This was founded partly in the view of receiving deposits of money under litigation in the courts of the province; moneys the property of minors and charitable institutions, the former until disposable or placed on good security; and moneys belonging to individuals not merchants, and at times, also, those of the latter. Interest is paid on such deposits as follows, viz.: 3 per cent. on sums belonging to minors; 2½ per cent. on sums belonging to charitable institutions, churches, and sums deposited by the courts of justice, and 2 per cent. on all other deposits.

The principal is demandable at pleasure, unless otherwise stipulated. The bank makes advances on grain and some other kinds of goods at 5 per cent. interest; discounts bills with 3 signatures, not having more than 2 months to run, at 6 per cent., and sometimes, when money is plenty, at a lower rate. It also makes advances at 4 per cent. on deposits of Fred. d'ors and certain foreign moneys; and it occasionally buys bills for account of, and sells bills on, the Berlin Bank. It does not issue notes. The amount of its capital is not fixed; but government guaranties its transactions. It is relieved from the payment of postage on money, and it is not required to use the stamps fixed by law, on bills for its deposit transactions, but only those of 10 s. gr. (about 11½d.); while individuals must use stamps for such bills of 5 s. gr. for every 400 r. of not longer date than 3 months, and for every 200 r. of longer date. On negotiable bills, however, the bank must use the stamps fixed by law, say of 5 s. gr. (about 5½d.) for sums of 50 dol. to 100 dol., and at the same rate for every additional sum between 100 dol. and 400 dol. Bills from and to foreign places, negotiated at Dantzie, are not subject to the stamp duty. The affairs of the bank are not made public. Being a government concern, there are no dividends. It is not supposed to be very profitable, at least in the present circumscribed state of trade, although enjoying the advantages of exemption from postage of moneys, and paying less stamp duty. It is true, however, that the direct advantage of the lower stamp duty is enjoyed by the borrower.

Credit, Brokerage, &c.—Very few goods are consigned from abroad for sale, for such consignments rarely turn to good account. Imports are seldom sold for cash, but generally at 1, 2, and 3 months' credit, or longer. The discount allowed for cash payments, when sold on time, is usually 6 per cent., but it varies according as money is plentiful or otherwise. Any

person, being a burgher of the town (which any one of good character may become), may transact business as a commission merchant or factor; but brokers must be chosen by the elders of the corporations of merchants, approved by the regency of the province, and sworn in by the magistracy of the town.

Danube (German, *Donau*; anc. *Danubius* and *Ister*), an important river, and, next to the Volga, the largest in Europe, originates in the *Berge*, a mountain town, at which rises in the E. declivity of the Schwarzwald, in Baden, at an elevation of 2,850 feet above the level of the sea. The stream, when joined by the *Brigach*, and by the waters of a spring from the castle garden of Donaueschingen, takes the name of the Donau. It flows first generally E. N. E., through an alpine country to Ulm, thence E. N. E. and S. E., to Passau, it traverses the plain of Bavaria. From Passau to Vienna, E. S. E., it intersects a hilly region, and the remainder of its course, E. S. E. to Waitzón, S. to Ilace, and E. to the Black Sea, is through a country generally flat, except at the defile of the "iron gate," E. of Orsova. Length (direct), 1,000 miles; or, including windings, 1,725 miles. It drains a surface of about 250,000 square miles; its average fall is 18 inches per mile, but below Pesth it is only 3 inches; at Ulm it is 1.40, at Regensburg 1,000, at Passau 800, at Vienna 450, and at Pesth 300 feet above the level of the sea. Its breadth at Ulm is 108 feet, and in its lower course 6,000 feet; depth at Ulm, 6 feet; at Passau, 16 feet; and lower down, average 20 feet. It passes Sigmaringen and Ulm in Württemberg, Dillingen, Hochstätt, Donauwörth, Ingolstadt, Regensburg, and Passau, in Bavaria; Linz, Dierstein, Korneuburg, and Vienna, in Austria; Presburg, Komorn, Gran, Waitzan, Buda, Pesth, Peterwardein, and Carlowitz, in Hungary; Belgrade, Semendria, and Orsova, in Servia; Widin, Nicopol, Rutchuk, Silistria, and Hirschova, in Bulgaria; Giurgevo and Brailov in Wallachia. The chief affluents of the Danube are, on the right, the Iller, Lech, Isar, Inn, Enns, Raab, Drave, Save, Morava, Timok, Isker, Vid, and Jantra; and on the left, the Altmühl, Nab, Regen, March, Waag, Gran, Theisa, Temes, Chyl, Aluta, Jalomnizza, Sereth, and Pruthi. Near its mouth in the Black Sea, it separates into several branches, the southernmost of which, called the branch of St. George, forms, by the treaty of Adrianople, the boundary between the Ottoman empire and Russia. It communicates by canals with the Elbe, by means of the Moldau, and with the Rhine by the Altmühl. It is navigable for vessels of 100 tons from Ulm. Steam packets were established on the Danube in 1830, and there are 10 steam vessels employed between Presburg, Pesth, and Constantinople, and 2 between Regensburg and Linz.—See FLETCHER'S *Mag.*, xxii., 560, 684; QUIN'S *Steam Voyage down the Danube*.

The ports of Bala and Galatz are appointed as ports on the Danube for the commerce of neutral powers, both as regards exportation and importation. The vessels of neutral powers coming from the Black Sea can return freely into that sea after having received their cargoes in the ports above mentioned, on condition always that they abstain, before entering the Black Sea, from touching at any port on the Danube. Consequently these vessels, before quitting the ports of Braila and Galatz, must present their documents to the Russian consular agent, who will furnish them gratis with a certificate showing the destination of the ship, and bearing the formal declaration, that if before entering the sea they should disembark corn or provisions upon any point of the right bank of the Danube, they will, by this contravention, incur sequestration. Neutral vessels which wish to ascend the Danube in order to proceed at once into the Austrian States, and which carry down cargoes destined either for Brila or Galatz, or for exportation by the Black Sea, will be liable to the same formality of a Russian certificate indicating their destination, and

K K

prohibiting them, under similar penalties, from entering into any traffic on the right bank of the Danube. Neutral vessels wishing to descend the Danube will not meet with any hindrance, provided that on their passage by Orsova they furnish themselves at the Russian consulate with a certificate, stating that they belong, *bonâ fide*, to a neutral power, and that their cargo is not destined for one of the Turkish ports of the Danube.—P. J. of T. 1856.

Dardanelles (Straits of the), form the communication between the Sea of Marmora and the Archipelago. This channel, through which there flows a constant current out of the Sea of Marmora into the Archipelago, is upward of 50 miles long, and varies in breadth from 1 mile toward its western, to 10 miles at its eastern extremity. It derives its name from two ancient fortresses on either side of the river, of which one is built on the site of the ancient Sestos, and the other on the site of the ancient Abydos. About 20 miles to the west of these are two modern fortresses called the New Castles, and between the old and the new forts are military works of various descriptions. The total number of guns mounted on these fortresses is 689, some of which discharge stons shot, and require a charge of more than 3 cwt. of powder. It derived its ancient name of the Hellespont from the tradition of Phryxus and Helle, and is celebrated in ancient times for the bridge of boats built over it by Xerxes. It is memorable also as the scene of the death of Alexander.—E. B.

The gallant exploit of forcing the passage of the Dardanelles was achieved by the British squadron under Admiral Sir John Duckworth, Feb. 19th, 1807; but the admiral was obliged to retrace them, which he did with great loss, and immense damage to the fleet, March 2, following; the castles of Sestos and Abydos hurling down rocks of stone, each of many tons' weight, upon the decks of the British ships.—HAYDN. So long as the shores of the Black Sea were exclusively possessed by Turkey, that sea might with propriety be considered a *mare clausum*; and there seems no reason to question the right of the Ottoman Porte to exclude other nations from navigating the passage which connects it with the Mediterranean, both shores of this passage being at the same time portions of the Turkish territory; but since the territorial acquisitions made by Russia, and the commercial establishments formed by her on the shores of the Euxine, both that empire and the other maritime powers have become entitled to participate in the commerce of the Black Sea, and consequently to the free navigation of the Dardanelles and the Bosphorus. This right was expressly recognized by the 7th article of the treaty of Adrianople, concluded in 1829 between Russia and the Porte, both as to Russian vessels and those of other European States in unity with Turkey. The 7th article of the treaty of 1830, between the United States and the Ottoman Porte, provides that merchant vessels of the United States, in like manner as vessels of the most favored nations, shall have liberty to pass the canal of the Imperial Residence, and go and come in the Black Sea, either laden or in ballast; and they may be laden with the produce, manufactures and effects of the Ottoman empire, except such as are prohibited, as well as of their own country.—WHEATON'S *International Law*, p. 241.

Daric. A Persian gold coin (so called by the Greeks, from Darius, the name of several Persian sovereigns), having upon the obverse an archer, crowned and kneeling upon one knee, and on the reverse a quadrata incusa, or deep cleft. The weight of the daric is about 110 grains.

Darien (Isthmus of). "The Isthmus of Darien, or, as it is more commonly styled, the Isthmus of Panama, connects North and South America, and is principally comprised in the republic of Granada. On the northern side is the Caribbean Sea and the Gulf

of Darien; on the south the Gulf of Panama. In length the isthmus proper is about 200 miles, with an average breadth of 40 miles; but in long. 79° it narrows down to less than 30 miles. At this point it is proposed to establish the ship canal. The country is undulating, with chains of small mountains, but very fertile and well timbered. The expense of a commodious ship canal, say 80 miles long and 200 feet wide, would not be less than \$50,000,000. When it is considered that one half the world's commerce would in all probability pass through this canal, the expense is trifling. All the India and China trade, instead of doubling Cape Horn, would find passage through the canal. It should be free to all nations who assist in the construction by money or credit."

An appropriation was embraced in the naval appropriation bill of 1864, giving a sum not to exceed \$25,000, to be paid to officers selected by the Secretaries of War and Navy "for the purpose of making explorations and verification of the surveys already made of a ship canal near the Isthmus of Darien, to connect the waters of the Pacific and the Atlantic by the Atrato and Truando rivers."

Dates (German, *Datteln*; French, *Dattes*; Italian, *Datteri*; Spanish, *Dátiles*), the fruit of the palm-tree (*Phoenix dactylifera* Linn.). This tree is abundant in Egypt, Barbary, Arabia, Persia, and the adjacent countries, particularly on the confines of the desert, and wherever there is sufficient moisture. It is a tall, majestic tree; and repeated references are made to it in the sacred writings (Ecclus. xiv. 14), and in the Koran. Mohammed, in one of his sayings, beautifully compares the upright and generous man to the palm-tree: "He stands erect before his Lord; in his every action he follows the impulse received from above, and his whole life is devoted to the welfare of his fellow-creatures." But the veneration in which the palm-tree is held in the East is to be ascribed more to its utility than to its beauty. Dates form the principal part of the subsistence of the inhabitants of many parts of Arabia and Barbary, and they are held in the highest estimation wherever they are met with. "They are," says Burckhardt, "by far the most essential article of food for the lower classes of Medina; their harvest is expected with as much anxiety, and attended with as much general rejoicing, as the vintage in the south of Europe; and if the crop fails, which often happens, as those trees are seldom known to produce abundantly for 3 or 4 successive years, or is eaten up by the locusts, universal gloom overspreads the population, as if a famine were apprehended."—*Travels in Arabia*, vol. iv., p. 214.

There is an endless variety of dates. Generally, however, they may be described as being somewhat in the shape of an acorn, but usually larger, consisting of a thick, fleshy substance, including and freely separating from an oblong stone or kernel, having a furrow on the one side. Their taste is agreeably sweet, accompanied with a slight astringency. The new fruit is called by the Arabs *rutab*. When the dates are allowed to remain on the tree till they are quite ripe, and have become soft and of a high red color, they are formed into a hard, solid paste or cake, called *adpone*. This is formed by pressing the ripe dates forcibly into large baskets, each containing about 2 cwt. "In this state," says Burckhardt, "the Bedouins export the adpone; in the market it is cut out of the basket, and sold by the pound. It forms part of the daily food of all classes of people; in traveling it is dissolved in water, and thus affords a sweet and refreshing drink. During the moonson, the ships from the Persian Gulf bring adpone from Bussorah to Djidda, for sale, in small baskets, weighing about 10 pounds each; this kind is preferred to every other. Ships bound from Arabia to India take with them a considerable quantity of adpone, which is readily disposed of among the Mohammedans of Hindostan."—*Travels in Arabia*, vol. i., p. 57.

The Arabians and Egyptians use the leaves of the trees in the preparation of bags and baskets; the boughs, the outer and inner bark of the trunk, and the fleshy substance at the root of the leaves, where they spring from the trunk, have all their respective uses; and besides this, the kernels of the fruit, notwithstanding their hardness, are used as food for cattle; they are soaked for 2 days in water, when they become softened, and are given to camels, cows, and sheep, instead of barley; they are said to be much more nutritive than that grain. There are shops at Medina in which nothing else is sold but date kernels; and the beggars are continually employed in all the main streets in picking up those that are thrown away.—*Burckhardt*, vol. ii., p. 212. All the refinements of Arabian cookery are exhausted in the preparation of dates; and the Arabs say that a good housewife will daily supply her lord for a month with a dish of dates differently dressed. Palm-trees are raised by shoots; and Dr. Shaw mentions that they arrive at their vigor in about 30 years, and continue so 70 years afterward, bearing yearly 15 or 20 clusters of dates, each of them weighing 15 or 20 pounds; after this period they begin to decline.—*Travels in the Levant*, p. 142, 4to ed.

The best dates imported are said to come from Tunis, but they are most commonly brought from Smyrna and Alexandria. They should be chosen large, softish, not much wrinkled, of a reddish yellow color on the outside, with a whitish membrane betwixt the flesh and the stone. Those that are dry and hard are of little value.

The date-tree is indigenous to Syria, Arabia, and the lower parts of Persia, Egypt, and northern Africa, whence it was introduced into the south of Europe; and it is also more or less cultivated in British India, South Africa, and in some parts of America. Though belonging to the extensive family of palms, which abound and flourish in most tropical regions, it attains perfection only in comparatively high latitudes, and doubtless would be adapted to the soil and climate of the more arid regions of California and of our southern States.

The date is a lofty tree, growing to a height of 60 feet, with a rugged trunk, crowned with leaves 6 or 8 feet long, with pinnae 3 feet long, and a little more than an inch broad. The flowers of both sexes, which grow on separate trees, come out in very long bunches, from the trunk, between the leaves, and are covered with a spatula, which opens and withers. Those of the male tree have 6 short stamens, with narrow, four-corded anthers, filled with pollen. The female flowers have a roundish germ, which afterward becomes an oval berry, with a thick pulp, inclosing a hard, oblong stone. This berry is the fruit known as the date of commerce, upon which a considerable portion of the people of Egypt, Arabia, and Persia, almost entirely subsist. A single tree will produce from 100 to 200 pounds of this fruit in the season. They come into bearing at from 6 to 10 years of age, and are fruitful for upward of 200 years.

The extensive importance of the date-tree, in the countries where it occurs, is perhaps one of the most curious subjects to which a traveler can direct his attention. Independent of the use of the fruit as food, the inhabitants make a conserve of it with sugar, and even grind the hard stones, to feed to their camels. In Barbary they form handsome beads of these stones. From the leaves they make couches, baskets, bags, mats, brushes, and fly-traps; the trunk is split, and employed in erecting small buildings, also for fences to gardens; and the stems of the leaves are used for making cages for their poultry. The threads of the web-like integument at the base of the leaves are twisted into ropes, which are employed in rigging small vessels. The amyloseous central part of the trunk is also good to eat, and the buds are esteemed a delicate vegetable; and even the young shoots are said

to resemble asparagus. The sap, which is sweetish when first collected, and may be drunk as a mild beverage, is distilled into a kind of spirit, known in eastern countries by the name of "arrack." It is obtained by cutting off the head of the tree, and scooping out a hollow in the top of the stem, where, in ascending, it lodges. 8 or 4 quartas may be obtained daily from a single palm, for 10 or 15 days.—*U. S. Patent Office Report*, 1855, p. 56.

Davits, beams of wood or iron, with sheaves or blocks at their ends, projecting over a vessel's side or stern, to hoist in the boats.

Days of Grace. These vary in almost all mercantile towns and countries, but the tendency of modern legislation is to abolish them altogether. In France, Belgium, Lombardy, Tuscany, the Two Sicilies, and other States where the French code has been introduced, there are no days of grace. So throughout the German States they are altogether done away. In Great Britain, and Ireland, and the United States of America, there are 3 days; in Denmark there are 8 days; in Sweden, 6 days; in Russia, 3 days for bills at sight, 10 days for bills at a fixed time; in the Canton of Berne, Switzerland, 6 days; in Spain and Portugal, none; and in the Netherlands, none.

The law merchant respects the religion of different peoples. A Jew would not be bound to pay a bill on a day sacred to him. So if the first day of grace should be on Saturday, and Monday Christmas-day, and the maker a Jew, the note would be payable on Friday. The word month means generally a calendar month. A note dated on the 30th of August would end with the corresponding day of the month. In calculating the day when the bill falls due, the day of the date is always excluded; so a bill drawn on the 1st of January at 10 days after date would become due on the 11th, and not on the 10th.—*Manual of Mercantile Law*, by LEONE LEVI. In New York and other States statutes have been adopted by the Legislature, providing that when a bill falls due on a public holiday (Christmas, 4th of July, Thanksgiving Day, New-Year's Day, and, in New Orleans, January 8th, for instance) the bill shall be payable the day preceding.

Dead-lights, ports or shutters to close in the cabin-windows of a ship in bad weather.

Dead-reckoning, in *Navigation*, the estimation that is made of the place where a ship is situated, without having recourse to observation of the celestial bodies. It is made by observing the distance she has run by the log, and the course on which she has been steered, making allowances for drift, lee-way, &c.

Dead Sea or Lake Asphaltites (Arabian, *Bahr-el-Lout*, "Sea of Lot"), a lake of Palestine, celebrated in Scripture as the site of Sodom and Gomorrah, between lat. $31^{\circ} 5'$ and $31^{\circ} 52' N.$, and long. $35^{\circ} 28'$ and $35^{\circ} 43' E.$, its N. extremity nearly 20 miles E. Jerusalem. Mean length N. to S. about 35 miles; average breadth from 10 to 12 miles; but its size varies greatly in different seasons and years.—ROBINSON. It is inclosed in a valley, bounded by bare limestone mountains, and according to recent researches, its depth is about 350 fathoms, and its surface 1,312 feet below that of the Mediterranean Sea; it being thus by far the deepest known fissure on the earth's surface. The river Jordan enters it on its north side. Its waters are thoroughly impregnated with salt; and it has not been proved that any animal exists in this sea. A mountain of rock salt on its S. W. side, called *Hajr Usdam*, "Stone of Sodom," preserves the name of that city, ruined with others, as described in Genesis xix., 24-28; and traces of towns or buildings are reported, on doubtful authority, to have been seen at certain times in its bed. Asphaltum was thrown to the surface at its southern extremity in large quantities after the earthquakes of 1834 and 1837. Messrs. Robinson and Smith have found the "*Asclepias gigantea*," growing at Engedi, on its western coast, the fruits of which

(the famed "apples of Sodom") though inviting in appearance, crumble in the hand into powder.—See *N. A. Rev.*, 1, p. 203 (by B. B. EDWARDS); *Lib. Sac.*, v. 397, vii. (by Dr. ROBINSON); SULLIMAN'S *Jour.*, xxviii. viii., 217; *North Brit. Rev.*, ii., p. 201; *Living Age*, xxviii. (same article); so *Lit. Mess.*, xiv. (M. F. MAURY); *Methodist Quar. Rev.*, ix., 633; *Living Age*, xxxi., 807.

"In undertaking to explore the physical geography of the sea, I have found myself standing side by side with the geologist on the land, and with him, far away from the sea-shore, engaged in considering some of the phenomena which the inland basins of the earth—those immense indentations on its surface that have no sea-drainage—present for contemplation and study. Among the most interesting of these is that of the Dead Sea. Lieutenant Lynch, of the United States' Navy, has run a level from that sea to the Mediterranean, and finds the former to be about 1,300 feet below the general sea-level of the earth. In seeking to account for this great difference of water-level, the geologist examines the neighboring region, and calls to his aid the forces of elevation and depression which are supposed to have resided in the neighborhood; he then points to them as the agents which did the work. Truly, they are mighty agents, and they have diversified the surface of the earth with the most towering monuments of their power. But is it necessary to suppose that they resided in the vicinity of this region? May they not have come from the sea, and been, if not in this case, at least in the case of other inland basins, as far removed as the other hemisphere? This is a question which I do not pretend to answer definitely. But the inquiry as to the geological agency of the winds in such cases is a question which my investigations have suggested. It has its seat in the sea, and therefore I propound it as one which, in accounting for the formation of this or that inland basin, is worthy, at least, of consideration.

"Is there any evidence that the annual amount of precipitation upon the water-shed of the Dead Sea, at some former period, was greater than the annual amount of evaporation from it now is? If yea, from what part of the sea did the vapor that supplied the excess of that precipitation come, and what has cut off that supply? The mere elevation of the rim and depression of the lake basin would not cut it off. If we establish the fact that the Dead Sea at a former period did send a river to the ocean, we carry along with this fact the admission that when that sea overflowed into that river, then the water that fell from the clouds over the Dead Sea basin was more than the winds could convert into vapor and carry away again; the river carried off the excess to the ocean whence it came.

"In the basin of the Dead Sea, in the basin of the Caspian, of the Sea of Aral, and in the other inland basins of Asia, we are entitled to infer that the precipitation and evaporation are at this time exactly equal. Were it not so, the level of these seas would be rising or sinking. If the precipitation were in excess, these seas would be gradually becoming fuller; and if the evaporation were in excess, they would be gradually drying up; but observation does not show, nor history tell us, that either is the case. As far as we know, the level of these seas is as permanent as that of the ocean, and it is difficult to realize the existence of subterranean channels between them and the great ocean. Were there such a channel, the Dead Sea being the lower, it would be the recipient of ocean waters, and we can not conceive how it should be such a recipient without ultimately rising to the level of its feeder. It may be that the question suggested by my researches has no bearing upon the Dead Sea; that local elevations and subsidences alone were concerned in placing the level of its waters where it is. But is it probable that, throughout all the geological periods, during all the changes that have taken place in the

distribution of land and water surface over the earth, the winds, which in the general channels of circulation pass over the Dead Sea, have alone been unchanged? Throughout all ages, periods, and formations, is it probable that the winds have brought us just as much moisture to that sea as they now bring, and have just taken up as much water from it as they now carry off? Obviously and clearly not. The salt-beds, the water-marks, the geological formations, and other facts traced by Nature's own hand upon the tablets of the rock, all indicate plainly enough that not only the Dead Sea, but the Caspian also, had upon them, in former periods, more abundant rains than they now have. Where did the vapor for those rains come from? and what has stopped the supply? Surely not the elevation or depression of the Dead Sea basin."—*MAURY'S Phys. Geog. of the Sea*, p. 222.

Dead-water. The water that closes in with a ship's stern.

Deals, or Deal-boards (German, *Dielen*; Dutch, *Deelen*; Danish, *Deler*; Swiss, *Tiljor*; French, *Planches minces*; Italian, *Tavole, Piane*; Russian, *Dorski*; Polish, *Tarcie*), a thin kind of fir planks, much used in carpentry. They are formed by sawing the trunk of a tree into longitudinal divisions, of greater or less thickness, according to the purposes they are intended to serve. They are imported from Dantzic, Petersburg, Narva, and many other ports in the Baltic, and from North America; but those from Christiansia, the capital of Norway, are the best, and bring the highest price. They are distinguishable from those produced in the contiguous provinces of Norway; their superiority has been said to depend principally on their being more perfectly sawed; but it really depends on the greater care with which the sap-wood and other defective portions of the timber are cut away, and on the quality of the timber. A Russian standard deal is 12 feet long, 11 inches wide, and 1½ inch thick; 400 feet of 14 inch plank make a load. A Christiansia standard deal is 11 feet long, 9 inches wide, and 1½ inch thick. There is another standard of Norway deals at Dram, 10 feet long, 9 inches wide, and 1½ inch thick.

Debiture, a term used at the custom-house to signify the certificate subscribed by the customs officers, and given to the exporter of goods on which a drawback is allowed, bearing that the exporter has complied with the required regulations, and that he is entitled to such drawback.

Debt, in law, is a species of contract, whereby a *chose in action*, or right to a certain sum of money, is mutually acquired and lost; usually divided into debts of record, debts by special contract, and debts by simple contract. A debt of record is a sum which appears to be due by the evidence of a court of record; such as a debt on judgment or recognizance. Debt by specialty is where a sum is acknowledged to be due, or becomes due, by instrument under seal; such as a covenant, bond, &c. Both these species of debts, being contracted by a man for himself and his heirs, attach on his lands and tenement; and bind them in the hands of his heir or devisee. Debt by simple contract is either by parole or by written obligation unsealed; within which class fall bills of exchange and promissory notes. Debt is also a personal action of contract, in which the plaintiff seeks the recovery of debt; i. e. a liquidated or certain sum of money alleged to be due to him.

Debt, Imprisonment for. See *HUNT'S M. Mag.*, iv. pp. 72, 538; *N. A. Review*, xxxii. (by A. H. EVERETT); *Am. Almanac*, 1848, 181; *Westminster Review*, ix., xix., xx., xlv; *British and For. Rev.*, x.; *Hankers' Magazine*, iii. p. 88.

Decade (Latin, *decas*, from Greek *deka*, ten). A word used by some old writers in a general sense for the number ten, or an enumeration by tens; but more peculiarly appropriated to the number of books into which the history of the Roman empire by Livy is divided, each division consisting of ten books or *decades*.

It was also the name given to the space of 10 days, which in the French republican calendar was substituted for the ordinary week. The 10th, or last day, was termed *decadi*. Thus, except in bissextile years, the whole number of decades was 364; the days of the half decades, falling at the close of the year, were at one time called *sanctulities*, and afterward *complementary*; and dedicated respectively to Virtue, Genius, Labor, Opinion, and Reconnoissance.

Decimal Coinage, a system of monetary calculation advancing to infinity from a fixed standard of value, and performing its multiplications by any increasing progression of tens, and its divisions by a decreasing progression which is also decimal.

This system, whose superiority to all others now in use is universally acknowledged, was first organized and established by the Constituent Assembly of France in 1790. It forms a part of that vast decimal metrical system of weights and measures, which, since the close of the last century, has obtained in France, and is slowly spreading thence into the other countries of Europe and America. The subject was so widely and keenly agitated throughout Great Britain in the opening months of 1853, that the House of Commons appointed a committee to investigate the whole matter. The report of this committee was laid before the House on the 1st of August of that year. This document was introduced with a strong recommendation of the decimal system of coinage, and proposed that the basis of that system when introduced should be the present pound sterling. By the retention of the pound, the decimal system might be introduced with the least possible change. Its 10th part already exists in the shape of the florin or two-shilling piece, while an alteration of 4 per cent. in the value of the present farthing will serve to convert that coin into the lowest step of the decimal scale, which it is necessary to represent by means of an actual coin, viz., the one-thousandth part of a pound. To this lowest denomination it was proposed by the committee to give the name of *mil*, in order to mark its relation to the unit of value. The addition of a coin to be called a cent, of the value of 10 *mil*s, and equal to the 100th part of a pound, or the 10th part of the florin, would serve to complete the list of coins necessary to represent the moneys of account, which would accordingly be pounds, florins, cents, and *mil*s. As to the coins by means of which the decimal system will be developed, it is proposed that some of those now in use be retained, and that new coins be substituted for others of them. The coins thus retained would be the present sovereign (1000 *mil*s), the half-sovereign (500 *mil*s), florin (100 *mil*s), and shilling (50 *mil*s, or 5 cents). The present sixpence, under the denomination of 25 *mil*s, might be retained; and the crown-piece, or a piece of 250 *mil*s, of which few are in circulation, need not be withdrawn. On the other hand, it would be desirable to withdraw the half-crown, and the threepenny and fourpenny pieces, which are inconsistent with the decimal scale. In the United States the decimal system has been introduced into the coinage with great advantage; and an effort is now being made to introduce it into weights and measures, which it is hoped will succeed in a few years.

Decimal Fractions, are fractions which have for their denominator 10, 100, 1000, &c., or in general some power of 10. The use of decimal fractions is merely an extension of the ordinary scale of arithmetical notation. Setting out from the unit's place, the 1st figure to the left (in the expression of any whole number) denotes so many tens, the 2d to the left so many hundreds, the 3d so many thousands, and so on; so that in the number 765, for example, each unit of the 6 is the 10th part of each unit of the 7, and each unit of the 5 a 10th of each unit of the 6. In like manner, in the expression of a decimal fraction, setting out from the unit's place, the 1st figure to the right expresses so many 10th parts, the 2d to the right so

many 100th parts, the 8d so many 1000ths, and so on; so that each figure, as before, expresses parts, which are each 10 times smaller than those expressed by the figure immediately preceding. By expressing fractions in this manner, the operations of addition, subtraction, multiplication, and division, are exactly the same as in integer numbers. In order to distinguish the integral from the fractional part of a numerical expression, a point or comma is placed between them. Various marks have been used for this purpose at different times; but the point is now most commonly employed, and, according to the practice of Sir Isaac Newton, it should always be placed near the top of the figure, thus 2.46, which prevents it from being confounded with the ordinary marks of punctuation. Decimal fractions appear to have been introduced by Regiomontanus, about the year 1464; but Stevinus was the first who wrote an express treatise on the subject in his *Pratique d'Arithmetique*, published in 1582. They are now universally employed in all arithmetical calculations; and it is much to be regretted that a decimal division of weights, measures, money, etc., has not been adopted in all civilized countries, by which the reduction of fractional parts from one scale to another would be obviated, and all the applications of arithmetic to the ordinary purposes of life greatly simplified. A subdivision of weights and measures on this principle was adopted in France at the time of the Revolution, but has not been imitated by other countries.

Decimal Weights and Measures. *I. Introduction of the Decimal System.*—The introduction of the decimal system is so important to all nations, and the advantages so apparent, that any discussion on the subject will be of interest. The facility of transacting every business, and the saving of labor, would be much increased by having a *general* and convenient system of weights and measures. The good result of the introduction of the decimal system into our coinage is so universally admitted, that efforts should be made to carry the system out in all our standards. The importance of the clause in the Magna Charta, and expressed in an old English law of older date, is not folly felt, that *there shall be only one measure and one weight throughout the land*. This has never been realized either in England or this country, though many efforts have been made to introduce a common system. Commercial intercourse would be facilitated, and many of the embarrassments and delays would be obviated, could a system be made universal in all maritime countries. There is no bar to the introduction of such a system; for whatever difference there may be in the systems adopted or in the notation used, yet they are all founded on the Arabian numbers. All have the same numerical system for a foundation, though the superstructures are varied. It would be scarcely practicable to introduce into the whole world a general system at once; but it is practicable for the principal maritime nations, who are so much interested, to have a congress, and unite upon some complete system that would take the place of the many disjointed and empirical ones now in use. The rest of the world would follow in time, from the fact that convenience and advantage are more than equal to custom. However, the principal end would be attained in a short time—*commercial intercourse* would be carried on among nations with one standard; having, if necessary, the notation admitted into each country affected by the language, but yet to be equivalent in values. It is a very interesting question what shall be the standard; and one where rival claims can be brought forward, each standard of measure, of weight, and of coinage having some advantages; and it may be difficult to decide what are the best. It seems, however, to be admitted that the decimal division is the only perfect one. It being stated as a general principle, that for convenience a standard varying but little from some old standard, should, if possible, be used.

II. The Natural Standard or Unit for the Base of the System.—In respect to coinage, our standard of a dollar for a unit seems to answer every purpose, and is the most convenient of any in use in the world. So it will, perhaps, be sufficient to examine with respect to weights and measures. The standard or unit for measurement that would seem to be given by nature, is the circumference of the earth taken at a given latitude. We have there an unvarying base, and one always practicable to measure. For convenience, we would naturally take a part of this circle, using any natural division. This is given to us at once by the rotation of the earth on its axis, and the arc a fixed star traverses in a given time, and then dividing by a decimal division this time of rotation, gives a standard of convenient length. Having to call in the aid of astronomy to determine this distance, the notation used in that science, of degrees and minutes, etc., was naturally adopted. It was found that one degree, or 3600th part of the earth's circumference divided into 60 parts, was about equal to a mile of the old empirical system. A very small change will be therefore necessary, taking this mile as a unit. From this unit a table is constructed that will give the most convenient measures, with the least possible change from the old system, and one that could be adopted at least by the United States and Great Britain with advantage:

III. 1. General Table of New Lineal Measure proposed

10 tenths	=	1 inch.
10 inches or 100 tenths,	=	1 foot.
6 feet or 60 inches	=	1 fathom.
1000 fathoms or 6000 feet	=	1 mile.
40 miles	=	1 degree on the meridian.

Measures of Temperature and Air.—The centigrade thermometer generally used in France and other countries, having its zero at the freezing point—the only invariable point of temperature in nature—and its 100th degree determined by the temperature of boiling water, when the barometer stands at 24½ inches of the new lineal measure proposed to be adopted in preference to Fahrenheit's scale. The barometer to be marked in inches and 10ths of the new measure. The new standard of lineal measure to be the fathom of 6 feet marked on a rod of brass or other metal, and made equal to 6 feet 0.92548 inch of our present measure at the temperature of 62.6 degrees of Fahrenheit, or 17 degrees of the centigrade thermometer. This proportion will make the proposed mile equal to 1012.715 fathoms of our present measure, being the mean length of the minute of a degree of terrestrial meridian, according to Mr. Airy's treatise on the figure of the earth.—*Ency. Metro.* Should more extensive surveys of meridional areas, since made or in progress, lead to a more accurate value of the said minute, it is proposed that the necessary correction shall be effected, not by changing the standard rod, but by altering the legal temperature to a higher or lower point than 17 degrees centigrade.

For measuring works of architecture and engineering, the foot and its decimal subdivisions will be used, and measurements by 10 feet and 100 feet, and not by the yard or rod.

2. For Land Measure.—The fathom to be the unit, and 10th and 100th for fractions, and all square-work to be so measured:

1000 square fathoms	=	1 acre.
1000 acres	=	1 mille.

3. For Solid Measure.—The foot to be the unit:

1000 cubic inches	=	1 foot.
-------------------	---	---------

Liquids to be measured by solid measurements:

10 cubic inches	=	1 pint.
100 cubic inches	=	1 gallon.
100 cubic gallons or 10 cuhite feet	=	1 barrel.

4. Measures of Weight Proposed.

10 tenths	=	1 ounce.
10 ounces	=	1 pound.
100 pounds	=	1 hundred-weight.
1000 pounds	=	1 thousand-weight.
2000 pounds	=	1 ton.

And I pound be the weight of 1-60th of a cubic foot of water at 17 degrees centigrada, and the barometer standing at 24½ inches of the new lineal measure. By this arrangement, 100 pounds will be equal to about 108 pounds of the present avoirdupois weight. All the weights for coins, bullion, apothecaries' weights, etc., be regulated by this system, and all customs and duties collected by these tables. This would soon introduce the system without any compulsory measures.

IV. Some of the Advantages of the New System of Measures and Weights.—The mile proposed is the nautical or geographical mile, and used exclusively for the purposes of navigation by all the maritime nations, and inserted in all the scales of charts and maps of the world, is the only universal measure now recognized. Also the weights, as well as the measures, are decimal parts of the unit, as far as can be, without a total change of our present systems. The French metrical system has proved a failure practically. Theoretically it is perfect; taking the degree for a unit, and using the decimal divisions throughout. But our whole notation in astronomy and navigation is founded upon the division of the degree into 60 parts, and we can not have a complete change until we manufacture our clocks and watches so as to mark time by decimal divisions, and change our hours and minutes into corresponding 10ths and 100ths; in fact, abandon entirely our present system. This is too great a change ever to be practicable, especially where so many different people have to conform. The system that has been proposed, only introduces the decimal divisions into the standards already adopted, and is not only practicable, but the change can readily be made, as in the case of our coinage. It will be sufficient to convince the most skeptical of the necessity of a change, to make an examination of the tables of weights, measures and coins in the world. And as no better time to correct an evil can be had than the present, it is hoped that our government will lead the way in so useful a change. The British government have already taken measures to have an examination and researches made for this object, as may be seen from the following:

“Sir John Wrottesley brought the decimal system of coinage, weights, etc., before Parliament, February 25th, 1824, but it was not till May, 1838, that a commission of inquiry was appointed at the instance of the then Chancellor of the Exchequer, Mr. Spring Rice, since Lord Montague; and in June 20, 1843, another commission was appointed; they both consisted of eminent scientific men, and both reported strongly in favor of the change. A committee of the House of Commons reported to the same effect, August 1st, 1853. Mr. Gladstone, however, while admitting the advantages of this system, thought its introduction premature. In June, 1854, an association was formed for the purpose of obtaining the adoption of the system. In July, 1855, the commissioners for inquiry were again appointed.” See *Weights and Measures*. See *Bankers' Magazine*, N. Y., 1856; *Bankers' Register*, N. Y., 1857.

Declination of the Needle. Professor Christopher Hansteen, of Christiania, in Norway, is the person who has given, probably, the greatest impulse, in recent times, to the efforts to methodize the facts and laws of the earth's magnetism. M. Hansteen was born September 26, 1783, and is Professor of Astronomy in the University of Christiania, and Director of the Observatory. His dissertation, entitled *Magnétismus der Erde*, published in 1819, which received a prize from the Royal Danish Academy, recapitulated all the authenticated facts obtained by voyagers and others, from the earliest times. It will be recollected that Halley had represented the magnetic variation at different parts of the globe by lines traced on Mercator's chart, and passing through all the places where the variation (or declination) of the needle from the

true north was equal; and being well aware of the progressive (or secular) changes in the course of these lines, he proposed the hypothesis of 2 pairs of magnetic poles interior to the globe, of which 1 pair revolve slowly.

Professor Hansteen also constructed charts of the lines of equal dip. In certain positions between the tropics the dip is nothing, or the freely-suspended magnetic needle remains horizontal. The line connecting these places is called the magnetic equator. It is an undulating line, inclined somewhere near 12° or 13° to the terrestrial equator, and cutting it in 2 points, not exactly opposite, but in about 3° 20' and 174° 80' of E. long. from Paris, according to Admiral Duperry's observations in 1825. The position of these nodes is, however, variable. The north end of the needle (as is well known) dips more and more in the northern hemisphers, until in a certain place it becomes vertical, when therefore the horizontal component of the magnetic force is nothing, and the common compass loses altogether its directive power. Similar phenomena occur in the southern hemisphere. Lines of dip of 10°, 20°, etc., may be drawn, and where the dip is 90° there is a true magnetic pole. The best observations serve to show that there is but one such true pole in each hemisphere.—E. B. *Preliminary Dissertation*, by J. D. FORNBERG, F.R.S.

Deed is a written contract, sealed and delivered. It must be written before the sealing and delivery, otherwise it is no deed; and, after it is once formally executed by the parties, nothing can be added or interlined; and therefore, if a deed be sealed and delivered, with a blank left for the sum, which the obligee delivers up after sealing and delivery, this will make the deed void. A deed must be made by parties capable of contracting, and upon a good consideration, and the subject-matter must be legally and formally set out. The formal parts of a deed are the premises containing the number, names, additions, and titles of the parties, the covenants, which are clauses of agreement contained in the deed, whereby the contracting parties stipulate for the truth of certain facts, or bind themselves to the performance of some specific acts; the conclusion, which mentions the execution and date of the deed, or the time of its being given or executed, either expressly, or with reference to some day and year before-mentioned. Every deed must be founded upon good and sufficient consideration, not upon an usurious contract, nor upon fraud, collusion, either to deceive *bona fide* purchasers, or just and lawful creditors; any of which considerations will vacate the deed, and subject the parties to forfeiture, and in some cases to imprisonment. A deed, also, without any consideration, is void. A deed must be executed by the party himself, or by another for him in his presence, or with his direction; or, in his absence, by an agent authorized so to do by another deed, also under seal; and in every such case, the deed must be made and executed in the name of the principal. A deed takes effect only from the day of delivery; and therefore, if it have no date, or a date impossible, the delivery will, in all cases, ascertain the date of it; and if another party seal the deed, yet, if the party deliver it himself, he thereby adopts the sealing and signing, and by such delivery makes them both his own. The delivery of a deed may be alleged at any time after the date; but unless it be sealed and regularly delivered, it is no deed. Another requisite of a deed is, that it be properly witnessed or attested. The attestation is, however, necessary rather for preserving the evidence than as intrinsically essential to the validity of the instrument. There are four principles adopted by the courts of law for the exposition of deeds, viz.: 1. That they be beneficial to the grantee, or person in whose favor they are intended to operate. 2. That where the words may be employed to some intent, they shall not be void. 3. That the words be con-

strued according to the meaning of the parties, and the intent of the parties be carried into effect, provided such intent can possibly stand on a law. 4. That they are to be expounded consonantly to the rules of law, and reasonably, without injury to the grantor, and to the greatest advantage of the grantee.—F. A.

Degree of Latitude is the space or distance, on the meridian, through which an observer must move to vary his latitude by 1 degree, or to increase or diminish the distance of a star from the zenith by 1 degree; and which, on the supposition of the perfect sphericity of the earth, is the 860th part of the meridian. The length of a degree of a meridian, or other great circle on the surface of the earth, is variously determined by different observers, and the methods made use of are various; and, therefore, without entering into the history of all attempts of this kind, we shall present our readers with the following

TABLES OF THE DIFFERENT LENGTHS OF A DEGREE, AS MEASURED IN VARIOUS PARTS OF THE EARTH, THE TIME OF ITS MEASUREMENT, THE LATITUDE OF ITS MIDDLE POINT, &c.

Date.	Latitude.	Extent in English miles and decimals.	Measurers.	Countries.
1525	49° 30' N.	68769	M. Fernel	France.
1620	52 4 N.	66991	Snellius	Holland.
1635	53 15 N.	69545	Norwood	England.
1644		75066	Riccioli	Italy.

Degree of Longitude is the space between 2 meridians that make an angle of 1° with each other at the poles, the quantity or length of which is variable according to the latitude. The following table expresses the length of a degree of longitude in different latitudes, supposing the earth to possess a perfect sphericity:

Lat.	Miles.	Lat.	Miles.	Lat.	Miles.	Lat.	Miles.
0	6907	23	6351	46	4793	69	2473
1	6906	24	6308	47	4746	70	2429
2	6903	25	6253	48	4691	71	2387
3	6897	26	6202	49	4629	72	2347

22	6397	45	4874	68	2585		

A degree of the meridian on the surface of the globe has been variously determined by different observers. M. Picart measured a degree in the latitude of 49° 21', and found it equal to 67,000 French toises. But the French mathematicians who examined Picart's operations, found that the degree in that latitude is 57,183 toises. Mr. Norwood measured the distance between London and York, and found it 905,751 English feet, and finding the difference of latitudes 2° 28', determined

the quantity of 1 degree to be 867,196 English feet, or 69 English miles and 288 yards. Maupeirtuis measured a degree in Lapland, in the latitude of 66° 30', and found it 57,488 toises. A degree was measured at the equator by other French mathematicians, and found to contain 66,767-8 toises. From these measurements it appears that the earth is not a sphere, but an oblate spheroid.—E. B.

Delaware, one of the middle United States, next to Rhode Island the smallest in the Union, and in population the least, is bounded north by Pennsylvania, east by Delaware River and Bay, south and west by Maryland. It is between 38° 27' and 39° 50' N. lat., and between 75° 04' 42" and 76° 56' W. long., and between 1° 13' and 1° 57' E. long. from W. It is 92 miles long and 23 broad, and contains 2,120 square miles, or 1,356,800 acres. The population in 1790 was 59,094; in 1800, 64,272; in 1810, 72,674; in 1820, 72,749; in 1830, 76,739; in 1840, 78,085; in 1850, 91,532.

Early History.—That Delaware Bay was already known to the Spaniards a long time before Hudson, there is no doubt. But the question is what they called it. Benson, in his memoir on the names of the State of New York, says that they called it *The Bay of all Saints*. He does not give his authority. In the most ancient Spanish description of the east coast which we have (that of Oviedo), this "Bay of all Saints" is not mentioned all. But Oviedo mentions a *Bahia de S. Christoval* on the east coast, and says that it stands under 39° N. lat. This is nearly exactly the latitude of Delaware Bay, which therefore probably is designated by him under that name. If it is true that the Spanish *Cabo de las Arenas* is our Cape Henlopen, then that large bay which the Spanish maps invariably point immediately to the north of this cape, must be *Delaware Bay*. The figure which they give to this bay, as well as to the river which they make run into it, corresponds with the configuration of our bay and river. Often we find on the maps the name given by Oviedo—that of *Bahia de S. Christoval* or *Christoval* (St. Christophorus Bay), written to it. So for instance on a Spanish map of 1580, so on a French map made after a Spanish original of 1587; but sometimes other names appear here; for instance, that of *Bahia de la Buelta* (Repulse Bay), or that of *Rio de S. Antonio*, probably only because the map-makers confounded all those names in a most irregular way. As to the Spanish navigator who brought home the sketch of our bay, and gave it the name of *St. Christophorus Bay*, there is yet some doubt.

The first navigator whom we can prove to have been at the entrance of the bay, is Henry Hudson, when (1609) he sailed along the coast from Chesapeake Bay toward the north. He looked into the bay, found it full of shoals, did not explore it, gave to it no name, and "suspected, from the currents which came out from it, that there was a river leading into it." It is pretty generally said that Lord Delaware, when (in the year 1610) he sailed to Chesapeake Bay, was thrown out of his way and touched at this bay, and that it was therefore called by him, or by his companions, and the first English settlers in Virginia, *Delaware Bay*. This was not only the first English, but upon the whole the first name under which the bay became more generally known in Europe. We see it for the first time mentioned and written in the letter of Captain Argall, of the year 1612, in Purchas's Pilgrims. The old Virginian writers spelled or corrupted the name in very different ways. Sometimes they write "*My Lord Delaware's Bay*," sometimes *Delawar Bay*, and sometimes *Delaware Bay*. Later French map-makers (for instance Bellin) made of this *Bay Delaware* or *Lapar*. The first map on which we find this name, is a little map of the greater part of the east coast by Captain Smith, of the year 1624. For the first time, pretty well drawn, the bay is to be found on the first map of Maryland, of the year 1635.

After Hudson and Lord Delaware, Dutch skippers and navigators were the first who entered this bay. The Dutch Captain Hendrickson called (1610) up into the bay and river as far as Schuylkill river. Captain Cornelius May entered the bay 1623, explored it, sailed up in the river as high at least as the present site of the city of Philadelphia, and built there a fort called "Fort Nassau." The bay was from him called "New Port May." The river was called by the Dutch *Zuyde rivier* (the South river), with respect to the second great river of the New Netherlands to the north (Hudson's river). It is not evident, but it is probable that the Dutch commenced at once after Hudson's discovery to designate the river under that name. The first book in which the name *Zuyde rivier* is mentioned and printed is the "New World" of Laet, 1624. From the river also the bay was generally called *Zuyde Bay*, the South Bay, and this name became among the Dutch so common that the other name, New Port May, was soon forgotten. Another Dutch name for the bay was that of Godyn's Bay, from the well-known Amsterdam merchant, Samuel Godyn, who purchased from the Indians Cape May, and a tract of country from this cape along the shores of the bay. Other Dutch names of this river sometime used were *Nassau rivier*, *Prince Hendrick's rivier*, and *Charles rivier*. This latter name was in use as well among the English as among the Dutch. We find in an English document of the year 1648, the name *Delaware* or *Charles rivier*. And so we find on the Italian map by Lucini, taken from a Dutch original in about the year 1631, the name *Rio Carlo*. We do not know in honor of which Charles the river was so called. The English claimed the bay and river in consequence of Cabot's and Delaware's discovery, and from different other reasons. The Dutch claimed it from Hudson's discovery, and took possession of it about 1623, through Captain May. In the year 1629 they built another fort there, called *Svanandael*, and 1633 the great navigator, David Pieters de Vries, entered the bay and river, explored it, and made there also a temporary little settlement, *Fort Upland*.

But all these Dutch settlements disappeared again, and were partly destroyed by the Indians, and the river and bay were without any habitation from 1633 to 1638, when at last the Swedes entered it under Peter Minolt, Minuet, or Menewe. They changed the whole geography of the bay and river. The river was under them called *The New Swedeland Stream*, and the bay *New Swedeland Bay*, and the Swedes erected also new forts and gave Swedish names to the old Dutch forts, which they partly rebuilt. The greater number of the Swedish and Dutch settlements on Delaware river and bay were made on the western shore, and this first Dutch and Swedish population formed from the beginning a peculiarly situated community. What since 1638 was called *New Swedeland*, comprised principally the territory of the present State of Delaware. The Swedes remained 17 years in possession of the river and bay, and one of their engineers, Lindstrom, who accompanied the Swedish governor Rising, in the year 1654, made a minute exploration and the first special map of the whole. In the following year, 1655, however, the Dutch governor of the New Netherlands, Stuyvesandt, appeared with some men of war in the bay, and subdued the whole little New Sweden to the Dutch. They reintroduced the old and some new Dutch names, but retained possession only for 9 years. When the English (1684) conquered this land from the Dutch, it was, until 1681, attached to the great province of New York. But during the same time the founders of Maryland considered it to be comprised under this name and to be a part of their *colony of Maryland*. In this period were formed the 3 counties of which the State still to-day consists, and the whole tract was usually called the *three lower counties on the Delaware*. In the year 1681 William Penn bought these 3 coun-

ties from the Duke of York, and they made now a part of Pennsylvania, under the usual name of *The Territories of Pennsylvania*, or the *Three Lower Counties*. They remained in connection with Pennsylvania until 1776, when these territories separated from Pennsylvania and declared themselves independent, under the name of the *State of Delaware*.—J. G. Kohl.

A somewhat elevated table-land passes through a portion of the State from north to south, dividing the waters which fall into Chesapeake Bay from those which flow into Delaware Bay. This table-land contains a chain of swamps in the western part of this State, from which its principal streams originate. The soil in the north is a strong clay. Along Delaware River, and for about 10 miles west of it, the soil is generally a rich clay, well adapted to agriculture; but between this and the swamps the soil is light and sandy. Proceeding toward the south, the soil becomes more sandy, and in Sussex county sand greatly predominates. Kalingo, or porcelain clay, is found in the northern portion, bog-iron ore in the southern, and shell marl throughout the State. There were in 1860, 580,862 acres of land improved, and 375,282 of unimproved in farms. Cash value of farms, \$18,850,931; and the value of implements and machinery, \$510,379.

Live Stock, &c.—Horses, 13,852; asses and mules, 791; milch cows, 19,243; working oxen, 9,797; other cattle, 24,166; sheep, 27,503; swine, 56,261; value of live stock, \$1,819,281; of slaughtered animals, \$373,665.

Agricultural Products, &c.—Wheat, 482,511 bushels; rye, 8,066; Indian corn, 8,145,642; oats, 604,518; barley, 56; buckwheat, 8,615; peas and beans, 4,120; potatoes, 240,542; sweet potatoes, 65,443; value of products of the orchard, \$46,574; produce of market gardens, \$12,714; pounds of butter made, 1,055,308; of cheese, 3,187; molasses, 50 gallons; beeswax and honey, 41,248 pounds; wool, pounds produced, 57,768; flax, 11,174; hops, 348; hay, tons of, 30,159; clover-seed, 2,525 bushels; other grass seeds, 1,403; flax-seed, 904 bushels; and were made 145 gallons of wine; value of home-made manufactures, \$38,121.

Manufactures, &c.—There were in the State in 1850, 12 cotton factories, with a capital invested of \$583,100, employing 413 males and 425 females, producing 5,205,000 yards of sheeting, &c., valued at \$538,439; 5 woollen factories, with a capital invested of \$136,500, employing 113 males and 86 females, manufacturing 157,000 yards of cloth, valued at \$244,510; 13 establishments making pig-iron, with a capital of \$373,500, employing 250 persons, and making 8,630 tons of castings, &c., valued at \$267,462; 2 establishments, with a capital invested of \$15,000, employing 50 persons, manufacturing 550 tons of wrought iron, valued at \$55,000; 70 flouring-mills, 83 saw-mills, 16 tanneries, with a capital of \$95,350, employing 108 persons; value of products, \$193,742; 8 printing-offices, issuing 2 semi-weekly, and 8 weekly newspapers. Capital invested in manufactures, \$2,978,945; value of manufactured articles, \$4,640,206.

The principal port is Wilmington, a port of entry, and the principal commercial town of the State, situated between Brandywine and Christina Creeks, 1 mile above their junction. On Brandywine Creek are some of the finest flouring-mills in the United States, to which vessels drawing 8 feet water can come. Christina Creek is navigable for vessels drawing 14 feet of water, and gives to Wilmington considerable commerce. The tonnage of the port in 1850, was 13,665 tons. The foreign trade of Delaware is carried chiefly through Baltimore, New York, and Philadelphia, especially the last; so that its direct foreign commerce is very inconsiderable. During 1850, 16 vessels were built, of an aggregate burden of 1,848 tons, viz., 12 schooners, 3 sloops, and 1 steamer. The Chesapeake and Delaware Canal connects these two bays.

* Nine months to June 30, and the fiscal year begins July 1.

Delaware Bay, at the mouth of the Delaware River, is a large arm of the sea, 75 miles long, 20 miles wide between Cape May on the north, and Cape Henlopen on the south, and 30 miles wide in the middle. The navigation is difficult and dangerous, being interrupted by many shoals. Its low and sandy shores were without harbors until the construction of the Delaware Breakwater within Cape Henlopen.

Delaware Breakwater. This breakwater is situated at the entrance into Delaware Bay, near Cape Henlopen. The anchorage ground, or roadstead, is formed by a cove in the southern shore, directly west of the pitch of the cape, and the seaward end of an extensive shoal called *The Shears*. The entrance from the ocean is 1,950 feet in width, and is accessible during all winds from the sea. The depth of water is from 24 to 36 feet deep, at low tide, throughout the harbor. There are two dykes, one of 1,500 feet, and the other of 6,000 feet, giving a secure harbor of seven tenths of a square mile. The objects of this artificial harbor are to protect vessels from winds from east to north-west, by way of north, and against the floating ice of the bay.

Delaware River, a river of the United States, which rises on the west side of the Catskill Mountains, State of New York, and after separating Pennsylvania from New York and New Jersey, falls into the Delaware Bay 5 miles below Newcastle. It is formed by the union of two streams. The Mottawok, or western and main branch, rises from a small lake in latitude 42° 45' N., at an elevation of 1866 feet above the sea, and flows south-west for nearly 60 miles, when it turns suddenly to the south-east, flowing in that direction for 5 miles to the Pennsylvania boundary line in latitude 42° N. Eight miles below this spot it is joined by the Popotan branch, which has a previous south-west course of about 50 miles. After the union of these two streams, the river pursues a winding south-

east course between New York and Pennsylvania for 60 miles to the north-west corner of New Jersey, where it receives the Neversink River. It then turns south-west, along the base of the Kittanning range, for 85 miles, in passing through which it forms what is called the "Water Gap," a great natural curiosity. The banks here rise precipitously from the water's edge to the height of 1,600 feet, overlying by immense masses of rock, and at the south-east entrance leaving scarcely room for a road. The passage, however, widens toward the north-west. Its entire length is about 2 miles. From this point it pursues a south-east and then a south-west course to Easton, where it receives the Lehigh, a large tributary, from the west. A little below this the river passes through South Mountain, and has a south-east course to Trenton, 60 miles below Easton; having in that distance 25 rapids, with a total fall of 165 feet. These falls are navigable at high water. The river below Trenton turns to the south-west until near the bay, which it enters in a south-east direction, after an entire course of 309 miles. It is navigable for vessels of the largest class to Philadelphia, 40 miles, and for sloops 85 miles further, to Trenton. Above the falls at Trenton it is navigable for boats of 8 or 9 tons for 100 miles. The Delaware is connected with the Hudson River and the bays of New York by the Delaware and Hudson Canal, the Morris Canal, and the Delaware and Raritan Canal.

Del Credere Commission. All agents who sell goods for their principals, and guaranty the price, are said abroad to act under a *del credere commission*. In the United States, this phrase is seldom used, nor is such guaranty usually given, except by commissioner merch. ants. And where such guaranty is given, the factor is still but a surety, so far that his employers must first have recourse to the principal debtor. But his promise is not "a promise to pay the debt of another," within the statute of frauds. Nor does he

guaranty the safe arrival of the money received by him in payment of the goods, and transmitted to his employer, but must use proper caution in sending it. If he take a note from the purchaser, this note is his employer's; and if he take depreciated or bad paper, he must make it good.—*Panoso on Mercantile Law*, ch. x., p. 159.

In mercantile law, a term derived from the Italian (*credere*, to trust), which denotes a commission granted by a merchant to a factor to dispose of goods; the factor, for the consideration of an additional percentage, agreeing to guaranty the solvency of the purchaser.

Delft or Delf (German, *Fayence*, *Unachtes Porzellan*; Dutch, *Delfs porcelijn*; French, *Faience*), a coarse species of porcelain, originally manufactured at Delft, whence its name. It is a kind of pottery of baked earth, covered with an enamel of white glazing, which gives it the appearance and neatness of porcelain. Some kinds of this enameled pottery differ from others, either in their sustaining sudden heat without breaking, or in the beauty and regularity of their forms, enamel, and the painting with which they are ornamented. In general, the fine and beautifully-enameled potteries, which approach the nearest to porcelain in external appearance, are, at the same time, those which least resist a brisk fire; while those which sustain a sudden heat are coarse, and resemble common pottery.

Demand and Supply are terms used in political economy to express the relations between consumption and production—between the demand of purchasers and the supply of commodities by those who have them to sell. The relations between the demand for an article and its supply, determine its price or exchangeable value: the relations between the demand for labor and its supply, determine the amount of wages to be earned by the laborer. For causes explained elsewhere, the price of an article will rarely vary, for any length of time, very much above or below its cost of production; nor will the wages of labor, for any length of time, much exceed or fall below the amount necessary to maintain laborers and their families in such comforts as their habits of life have accustomed them to believe necessary for their subsistence; but bearing in mind that, in the prices of commodities and labor, there is a certain point, determined by causes independent of demand or supply, above or below which prices can not materially vary for any considerable time: all variations of price, if the medium in which they are calculated remain unchanged, may be referred to the proportion which exists between the demand for commodities and the supply of them—between the quantities which purchasers are willing and able to buy, and the quantities which producers are able and willing to sell.

To have any influence upon prices, a demand must be accompanied by the means of purchasing. A demand is not simply a want—a desire to obtain and enjoy the products of other men's labor; for if this were its meaning, there would never be the least proportion between demand and supply: all men would always want every thing, and production could not keep pace with consumption. But an "effective demand," as it is termed by Adam Smith, exists whenever one man is anxious to exchange the products of his labor for that of other men. It is, therefore, of an effective demand only that political economists are speaking when they examine the circumstances of demand and supply in connection with prices.

But although a demand, without the means of purchase, can not affect prices, the universal desire of mankind to possess articles of comfort and luxury suggests other important considerations. As this desire is natural to man, and too often is so strong as to tempt him even to commit crime, it obviously needs no encouragement; men will always gratify it whenever they have the means, and these means consist in

the products of their own labor. Hence all that is required to convert this desire of acquisition into an effective demand is ample employment for industry. Increase the production of all commodities and an increased consumption of them is the certain result; for men, having larger products of their own labor to offer in exchange for the products of other men's labor, are enabled to purchase what they are always eager to acquire. Production, therefore, is the great object to be secured, not only as furnishing a supply of commodities necessary and useful to mankind, but also as creating an effective demand for them. When trade is depressed by a languid demand, it is commonly said that increased consumption is all that is required to restore its prosperity. But how is this consumption to be caused? The desire to consume is invariable, and thus any falling off in consumption must be attributed to a diminished production in some departments of industry which causes an inability to consume. When production is restored, an effective demand for all articles will immediately follow; but until the productive energies of the consumers are in a state of activity, it is in vain to expect from them an increased demand.

These considerations lead us to the conclusion that a universal glut of all commodities is impossible. The supply of particular commodities may easily exceed the demand for them, and very often does exceed it; but as the constant desire to obtain commodities needs nothing but the power of offering other commodities in exchange, to become an effective demand, it is evident that a universal increase of production is necessarily accompanied by a proportionate increase of consumption. Men are stimulated by no love of production for its own sake, but they produce in order to consume directly, or because, by exchanging their produce with others, they are able to enjoy the various comforts and luxuries which they are all desirous of obtaining. Active production, therefore, in all departments of industry, causes a general and effective demand for commodities, which will continue to be equal to the supply unless it be checked by war, by restrictions upon commerce, or by other circumstances which prevent a free interchange of commodities.

A country is in the highest prosperity when there is an active and steady demand for commodities and labor, and a sufficient supply of them. Any disturbance of the proportion between one and the other is injurious to the community; and the injury is greater or less according to the extent and duration of such disturbance. When the proportion is well adjusted, the whole community derive benefit from the circumstance, both as producers and consumers; when it is disturbed, they are injured in both capacities.

Having described, thus generally, the nature and causes of demand, and its intimate connection with supply, it becomes necessary to examine the influence of demand and supply upon one another, and upon production, consumption, prices, and profits. This influence varies according to the circumstances of the market, and the nature of the commodities to which its law may be applied. These may be best understood by considering, 1st, the effects of a demand exceeding the supply; and 2dly, of a supply exceeding the demand.

1. The first effect of a demand exceeding the supply of a commodity, is to raise its price. As more persons want to buy the commodity than the producers are able or willing to supply, they can not all obtain what they desire; but must share the supply between them in some manner. But their wants are very much regulated by the cost of gratifying them. One man would purchase an article for a dollar for which he may be unwilling or unable to pay two; while others, rather than forego the purchase, will consent to pay that amount. Those who have commodities to sell, finding that they have more customers than they can

satisfy, in too cheap stock at raised, which not restraint principle, in the nation obtain the rises with the highest market, he perceptible prices demand, but their demand advantage.

satisfy, immediately infer that they are selling them too cheaply, and that they could dispose of all their stock at a higher price. The price is accordingly raised, when the sale becomes limited to those who are not restrained from buying by the increased price. In principle, though not in outward form, the market is in the nature of an auction. The sellers endeavor to obtain the highest price for their goods; the price rises with the eagerness of those who wish to buy, and the highest bidders only secure the prizes. In the market, however, the competition of the buyers is not perceptible among themselves, except through the prices demanded. Their competition determines the prices, but the sellers judge of its extent, and regulate their demands so as to obtain the greatest possible advantage from it.

Some commodities are positively necessary for the support of the people, of which the supply may fall very short of the demand and be incapable of increase. This is the case when there is a bad harvest in a country which is excluded from a foreign supply by war or by fiscal restrictions. Here the price rises in proportion to the deficiency of the crops. The competition for food is universal. Some, indeed, may be driven to the consumption of inferior articles of food, and others to a diminished consumption; but all must eat. The number of consumers is not diminished, while the supply is reduced; and the price must, therefore, rise and continue high until a fresh supply can be obtained. In a siege the competition is still greater. The prices of provisions become enormous; the rich alone can buy; the poor must starve or plunder.

A similar effect is produced if the supply, without being deficient, be confined to the possession of a small number of persons, who limit it to the consumers in order to secure higher prices. However abundant corn might be in a besieged town, if one man were exclusively authorized by law to sell it, it might rise to a famine price, unless the people broke into the granaries, or the government interfered with the monopoly. Less in degree, but similar in principle, is the effect upon prices of every limitation of the market by fiscal restrictions. When any sellers are excluded, the others are enabled to raise their prices.

These are cases in which the supply can not be increased to meet the demand, or in which the supply is monopolized. But the greater number of commodities may be increased in quantity, and the supply of them is not artificially limited. The price of these also rises when the demand exceeds the supply: but the increased price raises the profit of the producer, and attracts the competition of others in the market. Fresh capital and labor are applied to the production of the profitable article, until the supply is accommodated to the demand, or exceeds it. The prices gradually fall, and at length the profits are reduced to the same level as the profits in other undertakings, or even lower. The encouragement to further production is thus withdrawn, and prices are adjusted so as to secure to the producer the ordinary rate of profits, and no more.

But sometimes the demand for a commodity is diminished, if the supply fall short of it for any considerable time. There are various articles useful and agreeable to mankind, but not essential to their existence, which they are eager to enjoy as far as they can, but for which they are not prepared to make great sacrifices. When the price of an article of this description is raised by a deficient supply, continuing for some length of time, it is placed beyond the reach of many persons who learn to regard it with indifference. They would buy it if it were cheap; but as it is dear, they go without it, or are satisfied with a substitute. In this manner the number of consumers is diminished. Others again, who will not be deprived of an accustomed luxury, enjoy it more sparingly, and consume it

in less quantities. But so long as the supply is not increased, the price will continue high, because the consumers who still purchase the article, notwithstanding its price, keep up an effective demand equal to the whole supply; while there is still a dormant demand, only awaiting a reduction of price to become effective.

For the same reasons, a demand for articles is diminished when their price is artificially raised by taxation. The demand is gradually confined to a smaller number of persons, and many consume more sparingly.

In these various ways demand and supply become adjusted through the medium of price, whenever the one exceeds the other. This is the result of natural laws, the operation of which is of the highest value to mankind. If the supply be incapable of increase, it economises consumption; if the supply can be increased, it encourages production. In either case, it is of great benefit to the consumer. To revert, for a moment, to the example of a bad harvest, in a country excluded from all foreign supply. Suppose that prices did not rise, but remained precisely the same as if the harvest had been abundant, what would be the consequence? The whole population would consume as much bread as usual, and use flour in every way that luxury points out, unconsciously of any scarcity. Farmers might even feed their cattle with wheat. By reason of this imprudence, the whole of the corn would be consumed before the next harvest, and the horrors of famine would burst, without any warning, upon a people living as if they were in the midst of plenty. This evil is prevented by a rise of prices, which is a symptom of scarcity, just as pain is a symptom of disease. By timely precaution the danger is averted. A high price renders providence and economy compulsory, and thus limits consumption. The supply, therefore, instead of being exhausted before the next harvest, is spread over the whole year. In the case of food, it is true that such economy is painful and presses heavily upon the poor; but this evil is a mercy compared with famine. If no privation had been endured before scarcity became alarming, none but rich men could buy a loaf: for every one who had a loaf to sell, would be risking his own life if he sold it.

These observations are also applicable in some measure to cases in which prices are raised by the supply being confined to one or to a few persons, who have contrived to buy up the whole or nearly the whole of any commodity. But such exclusive possession (sometimes improperly called a monopoly) can not exist, for any length of time, in articles of which the supply is capable of increase. The extreme case has been put of a besieged town, in which the whole supply of corn was monopolized by one man. Under those circumstances of course he would demand a high price; but unless his exclusive supply were upheld by law, it does not follow that the inhabitants would suffer on that account. A most provident consumption of food is absolutely necessary for the defense of a town, and no organization could distribute provisions according to the wants of the people so well as a system of purchase restrained by a high price. It must also be recollected that, without any such exclusive possession, the fact of the siege alone must raise prices by cutting off fresh supplies. If the siege continue, provisions are more likely to last out by the instrumentality of prices than by any other means. At the same time the sole possessor of the corn would be restrained from keeping back the supply beyond the actual necessity of the occasion by many considerations. He would know that if a popular tumult arose—if the town were relieved, the siege raised, a capitulation agreed to, or the place suddenly carried by assault—the value of his exclusive property would be destroyed. His own interest, therefore, is coincident with that of the people. It is better for both that the

supply should be meted out with parsimony; it is dangerous to both that it should be immoderately stinted.

In circumstances less peculiar than these, very little evil can arise from an exclusive possession of any commodity not protected directly or indirectly by law. If the supply be capable of increase, and the demand be sufficient to enable the owner to secure a high price, for reasons already explained, the market would rapidly be supplied from other quarters. If the supply can not be increased, that fact alone would raise the price; and it is probable that the supply would not have been so great without the extraordinary activity of the capitalist who had been able to secure for his country the whole accessible supply to be collected from the markets of the world.

A monopoly, properly so called, is of a totally different character: for, however abundant the supply of an article may be, it may, nevertheless, be inaccessible to the consumer.

When prices are high by reason of the demand exceeding the supply, it is by no means necessary that the profits of those who sell the dear commodities should always be greater than the profits in other branches of trade. It must always be recollected, that where scarcity is the cause of the high price, the sellers who demand it have the less to sell. Where scarcity is not the cause, but the demand is great because the supply, notwithstanding the exertions of producers, can not keep pace with it, the profits are undoubtedly greater than usual, until the supply has been increased.

II. It is now time to consider the effects of a supply exceeding the demand, and this division of the inquiry will require less elucidation, as the effects of such a condition of the market may be stated to be the very reverse of those which we have just been examining. When there is more of a commodity than people are prepared to buy, its price must fall. Its sellers must offer it for sale at the price at which they can induce people to purchase. All is now in favor of consumers. They are no longer bidding against each other: but the sellers are competing among themselves to get rid of their goods. The price falls generally in proportion to the excess of the quantity, but this result is very much qualified by the nature of the article. If there is an excess of supply in perishable goods, there is nothing to prevent the natural fall of prices. When fish is unusually abundant, it must be cheap, or a great part of it will be destroyed: it must be eaten at once, or not at all; and to induce people to eat it, it must be offered to them at a low price. But with articles which may be held back, in expectation of higher prices, their value may be partially sustained. Production may be reduced, and the stock gradually brought into the market, until the supply has been equalized with the demand; and wherever the article is such as to admit of voluntary increase or diminution, the natural result of an excessive supply is to reduce production, until the balance of supply and demand has been restored. This mutual adjustment is in perpetual operation, and is ordinarily effected with such precision, that it may be said, without exaggeration, that a large city is supplied exactly with every thing its inhabitants require—even down to an egg or a pint of milk. There is always enough of every thing, and rarely too much.

Whenever there is an excessive production of any commodity, it is an evil almost as great as scarcity. It is true that the consumer derives benefit from it, but the producing classes are most injuriously affected. In order to raise the value of the produce of their labor, they must cease to produce, or must produce in less quantities. The workmen are thus either deprived of employment altogether for a time, or are employed for a portion of their time only, at reduced wages; while their employers are disposing of their goods at low prices, which scarcely repay the outlay of their capital.

Nor does the penalty of over-production fall exclusively upon those engaged in the trade in which supply has exceeded the demand. Their distresses extend to other classes. It has been shown already that it is to production we must look as the cause of sustained consumption, and thus the pressure upon any considerable branch of productive industry must be sensibly felt by those who have the produce of their own labor to sell. Production has failed, and consumption must therefore be diminished.

The ruinous consequences of gluts, in particular staples of trade and manufacture, are too well known, especially in this country, to require any further illustration; but their causes are not always agreed upon. Such gluts are often attributed to the facility with which manufactures are produced by machinery; but we have shown that over-production in all branches of industry is impossible; and if that be true, it is evident that when partial gluts are produced by the aid of machinery, that powerful agent must have been misapplied. It is not contended that nothing can be produced in too great abundance. Whether machinery be used or not, production must be governed by the same laws of demand and supply. Those things only must be produced for which there is a demand, and they must not be produced in greater abundance than the demand warrants. But the more generally machinery is used, the more abundant will be the products which men will have to exchange with each other, and therefore the better will be the market. It follows that machinery can only cause a glut when applied excessively to particular objects, precisely in the same manner as an excessive quantity of labor would cause one if applied where it was not needed by the demands of commerce.

The supply of markets is a very speculative business, and is often conducted with more zeal than discretion. When a particular trade is supposed to be more prosperous than others, capitalists rush into it in order to secure high profits; and in this country the abundance of capital, the perfection of our machinery, and the skill of our workmen, enable them to produce with extraordinary facility. Over-production in that particular trade is the consequence, and all engaged in it suffer from the depreciation in the value of their goods; but if, instead of rushing into the favorite trade, they had distributed their enterprises more widely, their own interest and that of the community would have been promoted. When a ship is wrecked, if all the crew precipitate themselves into one boat, they swamp it; but if they wait till all the boats are lowered, and apportion their numbers to the size of each, they may all reach the shore in safety. And so it is in trade: one trade may easily be glutted, while there is room in other trades for all the capital and industry that need employment.

In proportion to the extent of the market and the variety and abundance of commodities to be exchanged, will be the facility of disposing of the products of capital and labor; and this consideration points out as the most probable antidote to gluts, a universal freedom of commerce. When the free interchange of commodities is restricted, not only is a glut caused more easily, but its causes are more uncertain, and dependent upon unforeseen events. With the whole world for a market, the operation of the laws of demand and supply would be more equitable, and the universality of the objects of exchange would make gluts of rare occurrence. The market would still be liable to disturbance by bad harvests, by errors in the monetary system, by shocks to public credit, and by war; but apart from these causes of derangement, demand and supply would be adjusted, and the productive energies of all nations called into full activity.—*Bohn's Cyclo. thus, *Principles of Political Economy*; RICARDO, ch. 30; MILL, *Essays on Unsettled Questions of Political Economy*, Essay II.

Demurrage, in commercial navigation, is an allowance made to the master or owners of a ship by the freighter, for detaining her in port longer than the period agreed upon for her sailing. It is usually stipulated in charter-parties and bills of lading, that a certain number of days, called running or working days, shall be allowed for receiving or discharging the cargo, and that the freighter may detain the vessel for a further specified time, or as long as he pleases, on payment of so much *per diem* for such over-time. When the contract of affreightment expressly stipulates that so many days shall be allowed for discharging or receiving the cargo, and so many more for over-time, such limitation is interpreted as an express stipulation on the part of the freighter, that the vessel shall in no event be detained longer, and that if detained he will be liable for demurrage. This holds even in cases where the delay is not occasioned by any fault on the freighter's part, but is inevitable. If, for example, a ship be detained, owing to the crowded state of the port, for a longer time than is allowed by the contract, demurrage is due; and it is no defense to an action for demurrage, that it arose from port regulations, or even from the unlawful acts of the Custom-house officers. Demurrage is not, however, claimable for a delay occasioned by the hostile detention of the ship, or the hostile occupation of the intended port; nor is it claimable for any delay wilfully occasioned by the master, or owners, or crew of the vessel. The claim for demurrage ceases as soon as the ship is cleared out and ready for sailing, though she should be detained by adverse winds, or tempestuous weather.

—CHITTY'S *Commercial Law*.

Professor Parsons in his admirable work on *Mercantile Law* [Boston, 1856], says:

"As time has become of the utmost importance in commercial transactions, both parties to this contract should be punctual, and cause no unnecessary delay; and for such delay, the party injured would have his remedy against the party in fault. The charter-party usually provides for so many 'lay-days,' and for so much 'demurrage.' Lay-days, or working-days, are so many days which the charterer is allowed for loading, or for unloading the vessel. These lay-days are counted from the arrival of the ship at the dock, wharf, or other place of discharge, and not from her arrival at the port of destination, unless otherwise agreed on by the parties. In the absence of any custom or bargain to the contrary, Sundays are computed in the calculation of lay-days at the port of discharge; but if the contract specifies "working lay-days," Sundays and holidays are excluded. If more time than the agreed lay-days is occupied, it must be paid for; and 'demurrage' means what is thus paid. Usually the charterer agrees to pay so much demurrage a day. If he agrees only to pay demurrage, without specifying the sum, or if so many working days are agreed on, and nothing more is said, it would, generally, at least, be considered that the number of lay-days determined what was a reasonable and proper delay, and that for whatsoever was more than this, the party in fault must pay a reasonable indemnity. If, after the lay-days allowed for unloading, have commenced, and, of course, after a safe arrival, but before the cargo is unladen, ship and cargo, or cargo alone, is lost, without the fault of the ship, of the owner, or of the master, the freight or charter-money is due, because that was earned by the arrival.

"If time be occupied in the repairs of the ship, which are made necessary, without the fault of the owner or master, or of the ship itself, that is, if they do not arise from the original unseaworthiness, the charterer pays during this time. Many cases have arisen where the ship was delayed by different causes,

and the question occurred, which party should pay for the time thus lost. On the whole, we should say, that no delay arising from the elements, as from ice, or tide, or tempest, or from any act of government, or from any disability of the consignee, which could not be imputed to his own act, or to his own wrongful neglect, would give rise to a claim on the charterer for demurrage.

"Demurrage seems essentially due only for the fault or voluntary act of the charterer; but if he hires at so much on time, that is, by the day, week, or month; then, if the vessel be delayed by seizure, embargo, or capture, and the impediment is removed and the ship completes her voyage, the charterer pays for the whole time. If she be condemned, or otherwise lost, this terminates the voyage and the contract.

"The contract may be dissolved by the parties, by united consent, or against their consent, by any circumstances which make the fulfillment of the contract illegal; as, for example, by a declaration of war on the part of the country to which the ship belongs, against that to which she was to go. So either an embargo, or an act of non-intercourse, or a blockade of the port to which the ship was going, may either annul or suspend the contract of charter-party. And we should say they would be held to suspend only, if they were temporary in their terms, and did not require a delay, which would be destructive to the purposes of the voyage.

"In reference to all these points, it is to be understood, that if the parties know the circumstance, which they make their bargain, and provide for it, any bargain they choose to make in relation to it would be enforced, unless it required one or the other of the parties to do something prohibited by the law of nations, or of the country in which the parties resided, and to whose tribunals they must resort.—PARSONS'S *Mercantile Law*, p. 362-367. See KENT'S *Com.*, 111., pp. 264, 265.

Denarius, in *Roman Antiquity* the chief silver coin, among the Romans, worth in sterling money, about 74*d*, or about 15 cents. It was originally of 62 grains weight; and was considered equivalent to the Attic *drachma*, which, however, weighed 67 grains. It was originally one-seventh, but afterward fell to one-eighth ounce. (See *Arbutnot on Coins*.) There was also a golden denarius, of which there is a specimen in the British Museum weighing 60 grains, besides others of less weight. As a weight, it was equal to the seventh part of a Roman ounce. Denarius was also used as of the value of an English penny.

Denier, a small French coin—copper coin, of which there were 12 to a sol.

Denmark, a kingdom in the north of Europe, small in extent and scanty in population, but known in history from an early period of the Christian era. There is no authentic account of the origin of the name of Denmark, nor of the quarter from which the country received its early inhabitants. From the similarity of the Danish and German languages, as well as from the general course of migration in early ages, it seems probable that Denmark was peopled by immigrants from the south—from Holstein, Hanover, and Saxony. There are no means of ascertaining whether natives of Denmark formed part of the formidable hordes which passed the Roman frontiers in the fifth and sixth centuries; but the attacks on this empire were probably made by tribes less remote, the expeditions of the Danes being in general maritime. For such expeditions they were remarkable as early as the eighth and ninth centuries, as was proved by their repeated invasions of England, their occasional descents on Scotland, and their conquest, followed by permanent occupation, of Normandy. To cross a sea of three or four hundred miles in breadth was a bold undertaking for men unacquainted with the use of the compass; but the number of islands in Denmark early accustomed the in-

habitants to navigation, and gave them a practical dexterity in it, similar to that acquired by the Dutch from their vicinity to arms of the sea, and to the mouths of great rivers. Both countries proved the advantage of a maritime position, for in those days neither France nor England were capable of sending forth a naval armament.

Denmark is a portion of the great European plain, and may be described as almost uniformly level, with partial inequalities of surface, particularly in Schleswig and Holstein, and the islands of Funen and Zealand. The kingdom consists of two great divisions, the one a long peninsula, extending from the Elbe to the Scagerrack, and the other a cluster of islands separating the Cattagat from the East Sea. The western coasts of the peninsula are a continuous level of marsh-land; the interior is dry and sandy; and the islands partake of the same characteristics. The soil of the low-land is generally fertile, producing the finest pasture, and excellent corn crops. The climate is milder than the northern situation of the country would indicate; but the sky is very frequently obscured with vapors and moist fogs, a great summer lasts only from June to the middle of August. The climate, however, is not unwholesome. The mass of the population consists of Danes, who occupy the islands, North Jutland, and the northern part of Schleswig. Germans occupy the southern part of Schleswig, Holstein, and Lauenburg; Frisians and Angles live on the islands and other parts of the W. coasts. Agriculture and fisheries are their principal occupations. From 1660 till 1848 the kingdom was an Absolute Monarchy; but in the latter year a constitution was granted by the king; and the legislative power is now vested in two parliamentary bodies, the *Volksting* and *Landsting*, both consisting of elective members; the former resembling the House of Representatives, and the latter the Senate, of the Congress of the United States of North America, rather than the Lords and Commons of Great Britain. Denmark is a small and poor country, and her naval and military power corresponds with her small resources. She possesses in Europe the Faroe Islands, and the large, volcanic, and poor island of Iceland, with a portion of West Greenland.

Lubeck and Dantzic.—The chief mercantile intercourse of Denmark in the fourteenth century was with Lubeck and the north-west of Germany. To the Baltic Lubeck was nearly what Venice was to the Mediterranean, the earliest commercial town of consequence. There was also some traffic from Denmark to the mouths of the Vistula; the name of Dantzic or Danzick (Danish town or port) indicating that a Danish colony, aware of the advantages of the situation, had established itself there. The more remote provinces of Courland and Esthonia were also objects of ambition to the Danes; but they did not find it practicable to keep settlements there. Holstein was more within their control, and much more advantageous, from the comparative civilization of its inhabitants.

Hanse Towns.—During the fourteenth century, the association of the Hanse Towns had acquired considerable strength, and asserted strenuously the freedom of commerce in the north of Europe. Denmark commanding the great entrance into the Baltic by the Sound, was the power most interested in laying merchant vessels under a toll of regular contribution; and the result was repeated contentions, followed at times by open war, between the Danish government and this powerful confederacy.

Shipwrecked Vessels.—The rude habits of the age were strongly marked by the difficulty which the Danish government found in putting a stop to the practice of plundering merchantmen shipwrecked on the coast. Vessels proceeding to and from the Baltic necessarily approached the coast of Jutland, particularly in an age when the ignorance of mariners led to their consider-

ing the vicinity of the land in the light of a protection. Shipwrecks were constantly of frequent occurrence there, and were generally turned to the profit of the nobility, who were proprietors of the maritime districts. We may here remark, that the nobles claimed not only the soil, but even the persons of the peasantry; for the principle of personal bondage was until lately maintained in Denmark. The practice was to collect in the vicinity of a wreck such a number of the inhabitants, as to prevent the master or mariners from opposing the seizure of the merchandise. Even bishops residing on the coast, though humane in their treatment of the crews, did not scruple to aid in taking forcible possession of the cargo; so crude were in those days the notions of justice toward merchants. It is a remarkable fact, that a law passed by the king about the year 1521 for the prevention of these practices was abrogated and publicly burned at the instance of the barons and clergy a few years after, when a new sovereign had succeeded to the crown.

Navy.—The following was the state of the Danish navy in 1854:

5 Ships of the Line.....	8 of 84 guns — 252 guns.
1 " " 66 " " 66 "	1 " 66 " " 66 "
1 " " 60 " " 60 "	1 " 60 " " 60 "
6 Frigates.....	8 " 48 " " 48 "
1 " " 44 " " 44 "	1 " 44 " " 44 "
4 Corvettes.....	1 " 28 " " 28 "
2 " " 30 " " 30 "	2 " 30 " " 30 "
1 Barque.....	1 " 14 " " 14 "

120	883 "

The financial state of the kingdom will best appear from the following summary of revenue for the whole monarchy, with the exception of Lauenburg, as contained in the Budget for 1854-5:

Douanls.....	£180,748
Surplus from Lauenburg.....	34,683
Lotteries.....	5,625
Posts and Telegraph.....	2,691
Soune, River, and Canal Dues.....	288,208
Customs, Stamps, etc.....	733,391
Sundries.....	81,217
Interest on State Capital.....	154,300
Floating Debt.....	146,250
Total revenue.....	£1,536,068
EXPENDITURE, 1854-1855.	
Civil List.....	£70,000
Appanage of the Royal Family.....	56,133
Privy Council.....	5,190
Foreign Department.....	25,842
War.....	521,337
Marine.....	185,480
Finance.....	47,750
Pensions.....	171,410
Interests, etc.....	834,660
Extraordinary Expenses.....	16,751
Total expenditure.....	£1,935,523

Besides these, there are special estimates for each of the Duchies, and also for Denmark Proper. The total amounts of each for the above year are as follows, viz.:

General Receipts.....	£1,535,000
Special Receipts of the Kingdom.....	572,719
" " of the Duchy of Schleswig.....	290,696
" " of the Duchy of Holstein.....	238,528
" " of the Duchy of Lauenburg.....	94,226
Total.....	£2,611,469
General Expenses.....	£1,935,523
Special Expenses of the Kingdom.....	322,065
" " of the Duchy of Schleswig.....	81,996
" " of the Duchy of Holstein.....	91,720
" " of the Duchy of Lauenburg.....	24,720
Total.....	£2,435,054
The national debt in 1853 amounted to £13,612,500.

Sound Dues.—In 1490 the reigning king of Denmark made a commercial treaty with Henry VII. of England, by which the English engaged to pay the Sound dues on all vessels entering or returning from the Baltic; and in return they were allowed to have mercantile consuls in the chief seaports of Denmark and Norway. By this time the extension of trade had given rise in Denmark, as in England, to a middle class, among whom the sovereign found in each country the means of balancing the political weight of the nobility; hence a grant was made by the kings of Denmark of various privileges to traders, and relief from a number of local imposts on the transit of merchandise. See *Danish Sound Dues*.

The Armed Neutrality.—One of the principal political questions between England and Denmark occurred in the year 1780, in the midst of a war between England, France, Spain, and the North American colonies. During that arduous contest, England, superior at sea, had no difficulty in obtaining, by her own merchantmen, a supply of hemp, cordage, and other naval stores, from the Baltic, while France and Spain trusted to receiving such supplies by neutral vessels. But the British government denied the right of neutrals to carry warlike stores; and the northern powers, headed by the ambitious Catherine of Russia, entered into a compact, called the Armed Neutrality, by which, without resorting to actual hostility, they sought to overawe England, and to continue the questionable traffic. Happily no bloodshed followed this diplomatic menace, and the question fell to the ground in 1782, on the negotiation for a general peace.

The king of Denmark, subject all along to imbecility, became after 1784 quite incapable of governing. His son, the crown prince, was therefore appointed regent, and soon passed several judicious enactments. The peasantry living on the crown lands were gradually emancipated—an example followed by a number of the nobility on their respective estates. In the abolition of the African slave-trade Denmark had the honor of taking the lead among the governments of Europe. The crown prince, guided by the counsels of Count Bernstorff, son of the minister already mentioned, long remained neutral in the political convulsions engendered by the French Revolution. He continued to adhere steadfastly to this plan until in 1801 the Emperor Paul of Russia having, as in the case of the armed neutrality, formed a compact of the northern powers hostile to England, a British fleet was sent into the Baltic under the orders of Sir Hyde Parker, with Lord Nelson as his second in command.

It was this fleet which taught the Danes that their capital was not impregnable, and that the long line of men-of-war moored in front of the harbor was an insufficient defense against such enterprising opponents. The attack took place on the 2d of April, 1801; and the resistance of the Danes was spirited, but fruitless. The loss of the English in killed and wounded exceeded 1000 men, but that of their opponents was much greater, and most of their shipping was destroyed. Happily little injury was done to the capital. A cessation of hostilities took place forthwith, and was followed by a treaty of peace. The death of the Emperor Paul, which occurred soon afterward, dissolved the compact between the northern courts.

But no treaty of peace could be regarded as permanent during the ascendancy of Napoleon. After defeating first Austria, and then Prussia, that extraordinary man found means to obtain the confidence of the Emperor Alexander of Russia, and in the autumn of 1807 threatened to make Denmark take part in the war against England. Although the Danish government discovered no intention to violate its neutrality, the English ministers, eager to please the public by acting on a system of vilage, despatched to the Baltic both a fleet and an army, in order to compel the surrender of the Danish navy upon condition of its being restored

at a peace. To such a demand the crown prince gave an immediate negative, declaring that he was both able and willing to maintain his neutrality, and that his fleet could not be given up on any such condition. On this the English army landed near Copenhagen; laid siege to that city; and soon obliged the government to purchase its safety by surrendering the whole of its naval force.

This act, the most questionable in point of justice of any committed by the British government during the war, can hardly be defended on the score of policy. The battle of Trafalgar had ere this been fought; and after that great victory her superiority at sea was so decisive as to exempt her from the necessity of offending foreign powers by adopting extreme measures. The resentment felt on that occasion by the Emperor of Russia was so great as to deprive England during four arduous years of the benefit of his alliance; and the seizure of the Danish fleet so exasperated the crown prince and the nation at large, that they forthwith declared war against England, throwing themselves completely into the arms of France.

The hostilities between England and Denmark were carried on by sea, partly at the entrance of the Baltic, and partly on the coast of Norway. These consisted of a series of actions between single vessels or small detachments, in which the Danes fought always with spirit, and not infrequently with success. In regard to trade, both nations suffered severely; the British merchantmen in the Baltic being much annoyed by Danish cruisers, while the foreign trade of Denmark was in a manner suspended by England's naval superiority.

Population.—The increase and distribution of the population of Denmark will appear from the following table:

	1769.	1834-35.	1845.
Denmark Proper....	514,238	1,225,797	1,850,827
Schleswig.....	249,104	387,878	562,900
Holstein.....	278,968	435,596	478,384
Lauenburg.....	40,456

The population of Denmark Proper, 1st February, 1850, was as follows:

	Towns.	Rural Dist.	Total.
Zealand and Moen.....	170,392	295,068	568,460
Bornholm.....	9,451	18,176	27,927
Funen, etc.....	91,324	136,494	227,818
Lolland and Falster.....	14,184	67,553	81,737
North Jutland.....	68,234	296,291	664,525
Total.....	290,565	1,117,182	1,407,747

The population of the principal towns of Denmark Proper (1st February, 1850) was as follows, viz.: Copenhagen, 129,600; Odensee, 11,100; Helsingør, 8,000; Aarhus, 7,800; Aalborg, 7,700; Randers, 7,300; Horsens, 5,800; Rønne, 4,700; Svendborg, 4,500; Fredericia, 4,300; Viborg, 4,000; Slagelse, 4,000; and Roskilde, 3,800. In the duchy of Schleswig, the principal towns with their populations on 1st February, 1840, was as follows, viz.: Flensborg, 12,561; Schleswig, 11,294; Haderslev, 6,165; Eckernsforde, 4,058; and Apenrade, 4,021. In that of Holstein as follows, viz.: Altona, 28,095; Kiel, 12,944; Rendsburg, 10,009; and Glückstadt, 5,939.

The principal ports are Copenhagen and Elsinore. Copenhagen, capital of Denmark, situated on the east coast of the island of Zealand, in the channel of the Baltic called the Sound, in lat. 55° 41' N., long. 12° 35' 46" E. The water in the channel is from 25 to 35 feet deep; but it is narrow, and the navigation difficult. Vessels not intending to come into the harbor bring up in the roads, at from one quarter to one half a mile from shore, in about 25 feet water. In the harbor, within the boom, the water is from 17 to 18 feet deep, and vessels unload alongside of the quay. The anchorage in the roads is good and safe.

and of Soeland. It stands at the narrowest part of the Sound, opposite the Swedish town of Helsingborg, from which it is three miles distant. All merchant vessels are obliged, under certain reservations depending on the weather, to salute the castle by lowering their top-sails in passing. In the vicinity is Marienlyst (Mary's delight), still lately a royal chateau, now the property of the corporation, and let to a private family. The towns of Altona and Wansbek are included under the head of foreign commerce, as standing within the toll-regulations of the kingdom.

The navigation from the north of Germany to Denmark, around the northern point of Jutland, being always tedious, and sometimes dangerous, gave rise to the idea of uniting the two seas by means of a canal, communicating with the river Eyder. The work was commenced in 1777, and finished in the course of seven years, at a great expense. This is the Canal of Kiel, which begins near the town of that name, on the side of the Baltic, and extends eastward about twenty-three miles, when it comes in connection with the Eyder. This canal is nearly 100 feet wide at the surface, and 54 at the bottom; it has six locks, and its least depth of water is 10 feet; it admits vessels of 120 tons burden; and of such small shipping no less than from 2,000 to 3,000 pass in a year. Of no less importance is the Stecknitz Canal, which, along with the railway between Altona, Glückstadt, and Kiel, serves to promote the commerce of the duchies. There are also railways from Copenhagen to Elsinore, and from Copenhagen to Roskilde; and one has been recently opened from Tønning to Flensburg, with a branch to Rendsburg. Tønning is the port on the east coast, and the length of navigation from there to the Baltic is about 105 miles.

The passage to the Baltic by the Sound continues to be followed by English, Dutch, and other vessels of heavy burden, as well as by Swedes and Norwegians, on account of the vicinity of their respective countries to the Sound; but coasting vessels and other traders from Oldenburg, Hamburg, the mouth of the Elbe, as well as from Tønning and the ports of Schleswig, and still more small Danish barks belonging to the islands, find it a great convenience to traverse the Canal of Kiel. The hazard on the north coast of Jutland arises from extensive sand-banks and a number of currents.—E. B.

The customs regulations of Denmark did not assume any fixed or permanent character until toward the close of the last century. No regular system of commercial policy was pursued; and the regulations which, from time to time, were enforced, were issued more with the immediate view of recruiting the treasury of the crown, than with any regard to the encouragement of the industrial or commercial enterprise of the country. High and prohibitory duties were imposed; exclusive privileges were granted by the crown to such companies as were either rich or favored enough to secure them; competition, so essential to success in every pursuit, was prevented; and the industrial energies of the nation, the only true basis of individual as well as of national wealth, were crushed by the monopolizing spirit and grasping cupidity of these privileged associations. They enjoyed the exclusive right of trading, even with the colonists; of supplying their wants; taking in exchange their surplus productions at such valuations and prices as they thought proper to fix and were willing to pay. About the period already referred to, a better system was gradually introduced. Many of the restrictions which had hitherto contributed to fetter and depress the foreign trade of Denmark were taken off; a new tariff was adopted; and the whole system of regulations was consolidated into the "ordinance 31, Christian VII., dated the 1st of February, 1797, relating to the customs;" which, with the various enactments since adopted, constitutes the basis of the present commercial policy of Denmark.

Under these regulations, a distinction is drawn be-

tween privileged and unprivileged nations. The former are those with which, by treaty, convention, or otherwise, a reciprocity and equality of commerce and navigation have been established—such treaty, convention, etc., prescribing the terms on which reciprocity is granted; the latter are subject to extra duties, amounting to as high as 50 per cent. above the rates fixed in the general tariff. To the former class the United States belong, the treaty by which entire reciprocity and equality of commerce and navigation are guaranteed, dating as far back as April, 1826. The following abstract embraces the principal stipulations of this treaty, so far as it relates to commerce and navigation:

No particular favors in respect of commerce or navigation to be granted to other nations, which shall not become common to the other party, on like or equivalent terms. Commerce and navigation between the two countries to rest on the liberal basis of perfect equality and reciprocity; and the citizens and subjects of each to enjoy all rights, privileges, and exemptions, in the territories of the other, which native citizens or subjects do or shall enjoy; Iceland, the Faroe islands, and Greenland, and the places situated beyond the Cape of Good Hope, and the direct trade between Denmark and the Danish West India colonies, being excepted from the operation of the treaty. Duties to be alike on all manufactures or merchandise of any country that can be lawfully imported into either country, whether such importation be made in the vessels of one nation or the other. Similar equality to exist in respect to exportations or re-exportations from either country, and in the vessels of either. The produce and manufactures of each country, when imported into either, to be subject to no other or higher duties than similar produce or manufactures of any other country; and this equality to extend to exports from either country to the ports of the other. Article 5th stipulates that neither the vessels of the United States nor their cargoes shall, when they pass the Sound or the Belts, pay higher or other duties than those which are or may be paid by the most favored nation.

West India Colonies.—In the intercourse between the United States and the Danish West India colonies, it is agreed that whatever can be lawfully imported into or exported from the said colonies, in vessels of one party, from or to the ports of the United States, or from or to the ports of any other foreign country, may, in like manner, and with the same duties and charges applicable to vessel and cargo, be imported into or exported from the said colonies in vessels of the other party. The treaty to continue in force ten years, with the usual stipulation for twelve months' notice if either party should desire to terminate it after that period.

The general foreign navigation of Denmark, in 1844, employed 33,845 vessels, measuring 1,266,417 tons, and, as appears from official returns, floating 765,475 tons of merchandise.

It may be interesting to inquire to what extent the national flag of Denmark participated in this general movement. The total number of vessels which entered and cleared on foreign voyages in 1844 was 83,845, with a tonnage of 1,266,417 tons, and conveying 765,475 tons of freight. Of these vessels, there were under the Danish flag 22,275, with a tonnage of 717,891 tons, and conveying 459,079 tons of freight. Thus, Denmark had,

1st. In the number of vessels.....	65.8 per cent.
2d. In the tonnage.....	52.7 "
3d. In the cargoes.....	60 "

Leaving for all other nations,

1st. In the number of vessels.....	34.2 per cent.
2d. In the tonnage.....	47.3 "
3d. In the cargoes.....	40 "

The aggregate tonnage of vessels employed in the trade between the United States and Denmark in 1844, was 8,458 tons. In 1851, it had decreased to 2,908; in 1856, it was 2,913.

Total number of vessels, 5,154; steamers, 87. Tonnage of sailing vessels, 108,171; steamers, 1,819. Horse-power, 2,459. See *Gota Almanac*, 1857.

From official returns of the foreign trade of Denmark, it appears that in 1847 the imports and exports united amounted to \$46,500,000; a sum nearly equally divided between Denmark Proper and its dependencies. In estimating the true relative value of this commercial movement, we must bear in mind that the Kingdom of Denmark contains a population of 1,850,000 inhabitants, and comprises an area of 683 Danish superficial leagues; while the duchies contain a population of 842,000 souls, spread over an area of only 318 Danish miles. The Danish miles are given as found in the authorities from which these facts are condensed, and because they will suffice for the purpose of comparison. Denmark and dependencies in Europe contain an area of 1,031,075 geographical miles, and a population of 2,296,587, exclusive of Greenland, Iceland, and the Faroe Islands. Thus, the latter, with a territory less than one half, and a population more than one third less, contributes more than its proportionate share to the general commerce of the country. The importance which Denmark attaches to the sovereignty of the duchies is thus accounted for. They are not only the granaries from which her cereal supplies are obtained, but they also constitute the commercial conduits through which her principal products—live cattle, horses, etc.—pass to a market. The loss of the duchies would, besides, inflict an irreparable injury upon Denmark, by cutting off the enormous revenue which she has so long derived from the Sound dues; as, in the event of a separation, the Schleswig-Holstein Canal would soon become the principal route to the Baltic.
