Some animals are wholly pigmented during the summer and autumn, but through the winter and spring they are in the condition of extreme partial albinism and become almost complete albinos. Such instances are found in the Scotch blue hare (*Lepus timidus*), in the Norway hare, in the North American hare (*L. americanus*), in the arctic fox (*Canis lagopus*), in the stoat and ermine, and among birds, in the ptarmigan, and some other species of *Lagopus*. How the change from the autumnal to the winter condition takes place appears not to be definitely settled in all other cases, and accurate observations are much to be desired. In the case of the Norway hare, it has been stated that a general moult, including all the hairs and under fur, takes place and new white hairs are substituted. The process of moulding is said to begin in the middle of autumn and is completed before the end of December, by which time the fur is in its winter condition, and is closer, fuller and longer than in summer (*Naturalists' Library*, vol. vii.). On the other hand, it has been stated that during the whole of the transformation in the fur no hairs fall from the animal, and it is attributed to an actual change in the colour of the hair (*Edinburgh Philosophical Journal*, vol. xi. p. 191). In the case of the American hare, however, some very careful observations have been made by F. H. Welch. In this animal the long hairs (which form the pile) become white at their extremities, and in some of them this whiteness extends through their whole length. At the same time, new hairs begin to develop and to grow rapidly, and soon outstrip the hairs of the autumn pile. From their first appearance these new hairs are white and stiff, and they are confined to the sides and back of the body. It is not clear from Welch's account what is the cause of the whiteness of the tips of the hairs of the autumn coat, but his figures suggest that it is due to the development of gas in the interspaces between the keratin bridges and trabeculae of the hairs. There is nothing to show whether the pigment persists or is absorbed. Probably it persists. In this event, the whiteness of the tips will be due to the scattering or iridescence of light, as in the iridescence of the numerous gas bubbles. In the case of the ptarmigan the evidence is clear that the existing autumnal feathers do change, more or less completely, to white. But the evidence is not conclusive as to whether any part of the winter condition is additionally produced by moulding.

The condition of albinism thus assumed as a seasonal variation is never complete, for the eyes at least retain their pigmented state. The reason of this is readily understood when it is borne in mind how disadvantageous to the function of sight is the unpigmented condition of an albino's eyeball; a disadvantage which would be probably much accentuated, in the cases now under consideration, by the bright glare from the surface of the snow, which forms the natural environment of these animals at the particular period of the year when the winter change occurs. In some cases, as in all the varying hares, in addition to the eyes retaining their normal pigmentation, areas similar in extent and situation to those on the Himalayan rabbits also retain their pigmentation; and in the ptarmigan there is a black band on each side of the head stretching forwards and backwards from the eyeball, and the outer tail feathers are black.

Albinism is restricted to no particular class of the animal kingdom; for partial albinism at least is known to occur in Coelentera, worms, Crustacea, Myriapoda, Coleoptera, Arachnida and fishes. The individuals in which this diminished pigmentation is found are for the most part those living in caves, and it is probable that their condition is not truly albinotic, but only temporary and due to the absence of the stimulus of light. This may be also true of some of those instances that have occurred among frogs, in *Proteus*, and with an axolotl once possessed by the present writer. This latter animal was quite white, with the exception of the black eyeballs. At the end of four weeks after it was first purchased the dorsal or upper surface of its external gills developed a small amount of dark pigment. Within the next few weeks this increased in quantity and the dorsal surface of the head and of the front end of the trunk began to be pigmented. The animal died at the end of the eighth week, but it is possible that had it lived it would have become wholly pigmented. But, apart from these instances, albinism is known, according to W. E. Castle, who cites it on the authority of Hugh M. Smith, to occur among a breed of albinot trout, which breed true and are reared in the State fish-hatcheries of America. With birds and mammals, however, there is no doubt that complete albino individuals do occur; and among species which, like the jackdaw, certain deer and rabbits, are normally deeply pigmented.

Albinism occurs in all races of mankind, among mountainous as well as lowland dwellers. And, with man, as with other animals, it may be complete or partial. Instances of the latter condition are very common among the negroes of the United States and of South America, and in thurses a pigmented patch, of character, irregular white patches being scattered over the general black surface of the body. Occasionally the piebald patches tend to be symmetrically arranged, and sometimes the eyeballs are pigmentation (pink) and sometimes pigmented (black).

According to A. R. Gunn, of Edinburgh University, who has recently been investigating the subject of albinism in man, there is reason to believe that a condition of piebald albinism occurs also in Europeans (Scotsmen). He has examined subjects in which the whole of the hair of the body is white, but the eyeballs are pigmented, often deeply; and, conversely, he has also seen cases in which the eyes are pink but the hair is pigmented. The hair and the eyes may be regarded as skin patches, in which sometimes the one and sometimes the other is pigmentationless. He believes that, were it not for the generally very pale colour of white-skinned races, this piebald condition would be as manifest in them as in negroes, over the whole surface of the body.

In complete human albinoes, albinism is correlated, in addition to nystagmus, with a peculiar roughness of the skin, making it harsh to the touch. The skin is also milky-white in appearance. According to C. J. Selligmann, there exists among the Papuans and of South America, and in thurses a pigmented patch, of that of *cafe au lait*; the eyes are generally greenish, hazel or brown, and the hair is tow-coloured. The skin where unexposed is pinker than that of a normal North European. Like complete albinoes, this race suffers from photophobia, and is characterized by the albinotic facies.

Before we can inquire into the cause and meaning of albinism it will be necessary first to consider the nature of pigmentation. It has recently been ascertained that the coloration of certain sponges is due to the interaction of an oxidizing ferment, tyrosinase, upon certain colourless chromogenic substances. In 1901, Otto v. Furtth and Hugo Schneider showed that a tyrosinase could be obtained from the blood of certain insects, and, acting upon a chromogen present in the blood, converted it into a pigmenitary substance of melanin-like nature. Hans Prizibram also extracted a tyrosinase from the ink-sac of *Sepia*, and, causing it to act upon a watery solution of tyrosin, obtained a black pigment. From the blood of *Bonobys mari*, V. von Duescehes has also obtained a tyrosinase.

Subsequently (1903) L. Coen, in order to explain certain features in the hereditary transmission of coat colour in mice, postulated the hypothesis that the grey color of the wild mouse (which is known to be a compound of black, chocolate and yellow pigments) may be due either to the interaction of a single ferment and three chromogens, or *vice versa*, to one chromogenic substance and three ferments.

Since then (1904) Miss Florence Durham has shown that if the skins of young or embryonic mammals (rats, rabbits and guinea-pigs) be ground up and extracted in water, and the expressed juice be then incubated with solid tyrosin for twenty-four hours, with the addition of a very small amount of ferrous
sulphate to act as an activator, a pigmentsary substance is thrown down. The colour of this substance is that of the pigment in the skin or hairs of the animal used. Miss Durham interprets her results as indicating that the skin of these pigmented animals normally secretes one or more tyrosinases. The same result was obtained from the skins of some unhatched chickens. The skins of albinoes gave no results.

Not only have such results been obtained with sponges, insects, cephalopods, birds and mammals, but Em. Bourquelot and G. Bertrand have shown that certain fungi, the tissues of which, when exposed to the air by injury, become immediately coloured, do so owing to the action of tyrosinase upon one or more chromogenus substances present in the plant. We may conceive, then, that a pigmented animal owes its colour to the power that certain tissues of its body possess to secrete both tyrosinases and chromogenus substances. And the period at which this process is most active is at birth, or preceding it or immediately succeeding it. In spite of the inquiry being only in its initial stages, there is already good evidence to believe that Cuenot's theory is correct, and that an albino is an individual whose skin lacks the power to secrete either the ferment or the chromogen. It forms one but not both of these substances.

A moment's consideration, however, will show that, while an albino may be an individual in which one or more of the complementary bodies of pigmentation are absent, a pigmented animal is something more than an individual which carries all the factors necessary for the development of colour. For it must be borne in mind that animals are not only coloured but the colour is arranged in a more or less definite pattern. The wild mouse, rat and rabbit are self-coloured, but the domesticated forms include various piebald patterns, such as spotted forms among mice, and the familiar black and white hooded and dorsal-striped pattern of some tame rats.

Colour, therefore, must be correlated with some determinant (determining factor) for pattern, and it cannot, therefore, exist alone in an animal's coat. And we must conceive that each kind of pattern—the self, the spotted, the striped, the hooded and all others—has its own special determinant. Given the presence of all the necessary determinants for the development of pigment in a mammal's coat, some or all of the hairs may bear this pigment according to the pattern determinants, or absence of pattern determinants, which the cells of the hair papillae carry. And this brings us to the question as to whether in a piebald animal the pigmented hairs are in any way different from the pigmentless or white hairs. No adequate investigation of this subject has yet been made, but some observations made by the author of this article, on the piebald black and white rat, show that differences connected with the microscopic structure of the hairs may be correlated with other factors which determine pattern. And this leads to the inquiry as to whether albinoes ever exhibit evidence that they carry the pattern determinants in the absence of those for pigmentation. For it is to be expected a priori that, since albinoes were derived from pigmented progenitors and may at any time appear, side by side with pigmented brothers, in a litter from pigmented parents, they would be carrying the pattern determinants of some one or other of their pigmented ancestors. Now we know, from the numerous experiments in heredity which have resulted in the rediscovery of Mendel's principles, that an individual may carry a character in one of two conditions. It may be carried as a somatic character, when it will be visible in the body tissues, or it may be carried as a gametic character, and its presence can only then be detected in subsequent generations, by adequately devised breeding tests.

With regard to pattern, the evidence is now dear that albinoes may carry the determinants in both these ways. So far as they are carried gametically, i.e. by the sex-cells, it has been shown by Cuenot, by G. M. Allen for mice, by C. C. Hurst for rabbits, and by L. Doncaster and G. P. Mudge for rats, that in a cross between a coloured individual of known gametic purity and an albino, the individuals of the progeny in either the first or second, or both generations, may differ, and that the difference in some cases wholly depends upon the albino used. It has been shown that the individuals in such an offspring may bear patterns which never occurred in the ancestry of the coloured parent, but did in that of the albino; and, moreover, if the same coloured parent be mated with another individual, either albino or coloured, that their offspring may never contain members bearing such patterns. The particular pattern will only appear when the coloured parent is crossed with the albino, and yet the albino shows no somatic pattern or pigment. So clear is the evidence on this point that any one adequately acquainted at first hand with the phenomena, by employing an albino of known gametic structure and mating it with a coloured individual, also of known gametic constitution, could predict the result.

With respect to albinoes carrying pattern as a visible somatic character, i.e. in the body cells, no definite evidence has as yet been published. But W. Haacke has described some albinoes in which the familiar shoulder hood and dorsal stripe of the piebald rat is perfectly obvious, in spite of the absence of the slightest pigmentation. The hairs which occupy the region in which the pigmented individual is black, are longer, thinner and more widely separated than those in the regions which are white. As a result of this, the pink skin is quite visible where these hairs occur, but elsewhere it is invisible. The distribution of pink skin is similar in form with the black pattern of the piebald rat. Moreover, some of the albinoes possess these particular "pattern" hairs all over the body and obviously such individuals are carrying the self pattern. There are other details into which we cannot here enter, but which support the interpretation put upon these facts, i.e. that these particular albinoes are carrying in the soma the pattern determinants simultaneously with the absence of some of the factors for pigmentation.

Not only do albinoes thus carry the determinants for pattern, but it has been known for some time that they also carry gametic-ally, but never visibly somatically, the determinants for either the ferment or the chromogen for one or more colours. L. Cuenot was the first to show this for albino mice. He was able by appropriate experiments to demonstrate that when an albino is derived (extracted) from a coloured ancestry, and is then crossed with a coloured individual, both the colour of the pigmented parent and of the pigmented ancestry of the albino may appear among the individuals of the offspring.

Immediately subsequent to Cuenot, G. M. Allen in America demonstrated the same fact upon the same species of rodents. The pattern of pink skin is usually an albino, whether pure bred for eight generations at least, or extracted from pigmented parents, may carry the determinants for black or for black and grey. In this latter case the determinants for black are carried by separate gametes from those carrying grey, and the two kinds of sex-cells exist in approximately equal numbers. This is likewise true of albino mice when they carry the determinants for more than one colour.

Since Hurst's work, L. Doncaster and G. P. Mudge have both shown that albino rats also carry in their condition the determinants for black or grey. The experiments of the latter author show that, if a gametically pure black rat be crossed with an albino derived from a piebald black and white ancestry, all the offspring in successive litters will be black; but if the same black parent be crossed with albinoes extracted from parents of which one or both are grey, then both grey and black members will appear in the successive litters.

The proportions in which the various coloured individuals appear are approximately those demanded by the Mendelian principle of gametic purity and segregation. Cuenot and Hurst have also shown that when albinoes of one colour extraction are crossed with albinoes of another colour extraction the segregation of the colour determinants in the gametogenesis of the albinoes takes place in precisely the same way that it does in the
gametogenesis of a pigmented individual; that is, in Mendelian fashion. Or, to express it otherwise, an albino extracted from yellow parents, bred with an albino extracted from black parents, will give an albino offspring whose gametes in equal numbers are bearers of the black and yellow determinants. And when one of these albinoes is bred with a pure coloured individual, a mixed offspring will appear in the first generation. Some of the individuals will be one or other of the two colours, the determinants which were present in the albino, and others the colour of the pigmented parent. But in such albino crosses the colour characters are latent because albinoes do not carry the whole of the complements for colour production. They carry only some determinant or determinants which are capable of developing colour when they interact with some other determinant or determinants carried alone by pigmented individuals. Whether albinoes carry the tyrosinase or other ferment, or whether they carry the chromogen or chromogenes, is not yet settled. Miss Durham's work suggests that they carry the latter. But that they never bear both is proved by the fact that, when albinoes are crossed with each other, none but albinoes ever result in the offspring. One apparent exception to this rule only is known, and this almost certainly was due to error.

It is not only among albino animals that colour factors are carried in a latent condition, but also in white flowers. W. Bateson has shown this to be the case for the sweet pea (Lathyrus odoratus), var. Emily Henderson, and for certain white and cream stocks (Matthiola). When white Emily Henderson (the race having round pollen grains) is crossed with a blue-flowered pea, purple flowers are always white. Similarly, when white Emily Henderson (long pollen grains) is crossed with white Emily Henderson (round pollen grains), the offspring wholly consists of the reversionary purple type, and sometimes wholly of a red bicolor form known as "Painted Lady." These two types never appear in the same family. With the stocks, when a white-flowered and hairless form is crossed with a cream-flowered and hairless one, all the offspring are purple and hairy. Bateson considers that the purple colour is due to the simultaneous existence in the plant of two colour factors which may be designated by C and R. If either one of these two is absent in the plant, it is colourless. Cream-coloured flowers are regarded as white because cream is due to yellow plastids and not to sap colour. Thus the cream plant may carry C and the white one R. When they are crossed the two factors for colour production are brought together. Obviously, we may regard C as a tyrosinase and R as a chromogen, or vice versa; and in the case of the white sweet pea crossed with a blue-flowered one, and producing purple offspring, we may imagine that the white flower brought in an additional tyrosinase or a chromogen not present in the blue flower, which, when combined or met with blue pigments, gives the blue hue. A similar explanation may apply to C. Corren's experiment, in which he crossed white Mirabilis jalapa with a yellow form, and always obtained red-flowered offspring.

In heredity, complete albinism among animals is always recessive; and partial albinism (piebald) is always recessive to complete pigmentation (self-coloured). When an albino mouse, rat, guinea-pig or rabbit is crossed with either a pure self or pure pied-coloured form, the offspring are similar to, though not always exactly like, the coloured parent; provided, of course, that the albino is pure and is not carrying some colour or pattern determinant which is dominant to that of the coloured parent used. No albinoes, in such a case, will appear among the first generation, but if the individuals of this (F.1) generation are crossed inter se or back crossed with the albino parent, then albino individuals reappear among the offspring. In the former case they would form one-quarter of the individuals of this second (F.2) generation, and in the latter, one-half.

The recessive nature of albinism and its distribution in Mendelian fashion is almost certainly as true for man as for lower forms. This has been shown by W. C. Farabee for negroes in Coahoma county, Mississippi. The facts are as follows. An albino negro married a normal negro. They had three children, all males. All three sons married, and two of them had only normal children, judged of course by somatic characters. But the third son married twice; and by the first wife had five normal and one albino children, and by the second, six normal and three albino children. If we assume that the two negresses which the third son married were themselves carrying albinism recessive—an exceedingly probable condition considering that albino negroes are not uncommon—then the result is accurately in accord-ance, as W. E. Castle has shown, with Mendelian expectation. For there is expected in the offspring of this third son coloured individuals and albinoes in the proportion of 3:1. There is actually 11:4, which is the nearest possible approximation with the number 15.

The operation of Mendelian processes in human heredity is further shown by the close relationship that exists between the appearance of albinoes and cousin marriages. An albino is a homozygote; that is, all its gametes are carrying the character of albinism and none of them bear the alternative character—the allelomorph—of pigmentation. By pigmentation is here meant all those factors which go to its production. Now such a gametic (egg or sperm) constitution can only result when two individuals, all or some of whose gametes are pure with regard to the character albinism, meet in fertilization. Hence it is readily seen that it is among cousin marriages that the greater probabilities exist that two individuals bearing identical characters will meet, than in the population at large. This can be illustrated in the following scheme. Let A stand for a pure albino and (A)N for a normal person, who nevertheless carries the character albinism (A) recessive. Then, in the scheme below, if Aa and (A)N are two brothers who both marry normal wives N, their children N(A) in the first case will be all normal in appearance but will be carrying albinism recessive; and in the second case some will be pure normal individuals N, and some will be like the children of the first brother, i.e. N(A).

No other rational explanation of the close relationship between albinism and cousin marriages is at present forthcoming. And, when the whole facts are borne in mind, there can be no reasonable doubt that the Mendelian principles offer an intelligible solution of the problem.

A popular conception exists that albinoes are less constitutionally strong than the pigmented individuals of the same species. In support of this belief there is more or less scientifically ascertained evidence. Conversely, there is, however, conclusive evidence that in some instances and in respect of certain qualities the opposite belief is true.

To deal with the former belief first, we have the remarkable case cited by Charles Darwin on the authority of Professor I. J. Wyman. In Virginia the paint-root plant (Lachnanthes tinctoria) occurs abundantly, and Professor Wyman noticed that all the pigs in this district were black. Upon inquiry of the farmers he found that all the white pigs born in a litter were destroyed, because they could not be reared to maturity. The root of this plant, when eaten by white pigs, caused their bones to turn to a pink colour and their hoofs to fall off, but the black pigs could eat the same plant with impunity. Partial albinism in this case was undoubtedly correlated with some inherent constitutional defect, in virtue of which the individuals characterized by it were injuriously affected by the juice of a plant quite innocuous to their pigmented brethren. Heusinger has shown that white sheep and pigs are injured by the ingestion
ALBINONI

of certain plants, while the pigmented individuals may eat them without harm. In Devonshire and in parts of Kent the farmers entertain a marked prejudice against white pigs, because “the sun blisters their skin.” More remarkable is the case of certain cattle, whose skin is piebald, marked by a general ground colour over which are scattered patches of unpigmented coat. In these animals, in certain inflammatory skin eruptions, caused by the injection of harmless plants, in albino cases it is done. And with certain cutaneous diseases accompanied by constitutional disturbances which afflict cattle, the affection in the skin appears on the patches bearing white hairs, the other parts remaining apparently healthy. Such cases suggest that we should be more correct in regarding, not albinism as correlated with constitutional defects, but rather pigmentation as correlated with powers of immunity or increased resistance against certain injurious processes. In the West Indies “the only horned cattle fit for work are those which have a good deal of black in them; the white are terribly tormented by the insects and they are weak and sluggish in proportion to the black.”

Coming to man, it is known that some albino negroes are peculiarly sensitive to the bites of insects; and with Europeans it is a generally observed fact that the fairer individuals are more seriously affected by the bites of flies and bugs than are the darker ones. Dr Twining, in the British Association Reports for 1845, p. 79, cites some instances described by Humboldt, who says that the copper-coloured natives of the high plain of Bogoto, and at a lower level on the Magdalena river, were generally free from gout. Provost, of Whig Halliburton, in Swift’s Tale, states that on the east side of the Andes in Chile, in some of the races which live there, he did not see a single case of goutre, and yet in the white inhabitants, who live exactly as the natives, it prevails in a great degree.

Turning now to instances of the opposite kind, it is known that silkworms which spin colourless cocoons are more resistant to the attacks of a certain deadly fungus than are those which spin the yellow ones. In some parts of North America it is found that the white peaches are much less liable to the attack of a disease known as the “yellows” than are the yellow-shaded ones. In the region of the Mississippi, Farabee has observed that the albino negroes are taller and broader than the black-skinned individuals. We may assume that increased stature and breadth imply some sort of inherent physical superiority, and if such an assumption is valid we have in man evidence that albinism is correlated not with constitutional defectiveness but with greater perfectness.

But the question as to whether albinos are more or less constitutionally vigorous than pigmented individuals of the same species may be tested by exact measurement. In 1893 W. E. Castle found that the albino rabbit, G. C. Saunders, of Florence, showed, also, that it is red in albino. It was found that when they were intravenously injected into pigmented rabbits, coagulation of the blood resulted, but of the eight albino which they used, none clotted. At a subsequent period (1897) Halliburton and J. W. Pickering showed that the three synthesized colloids of Grimaux in the same way produced coagulation in pigmented animals, but failed to do so in albino. Pickering, still later, showed, in the case of four Norway hares, two of which were injected while in their pigmented or summer coat, and two while in their albino or winter coat, that coagulation occurred in the former cases but not in the latter.

Quite recently, however, the author of this article has made a more detailed examination of the question, operating upon several hundreds of rabbits. And he found that all albino do not fail to clot when intravenously injected with nucleo-proteids. Only about 6% of them thus failed absolutely to manifest any trace of coagulation. But about 7% showed an exceedingly limited coagulation, in which the clot was colourless and flocculent, and confined to the heart. The rest gave a typical and more or less wide-spread coagulation. Moreover, it was found that all the failures of coagulation occurred when the nucleo-proteid used was obtained from pigmented animals. When it was derived from albino no failures occurred.

pigmented animals clotted when the nucleo-proteid was derived from either source. The Himalayan rabbits reacted like complete albino, and 12% of them failed to clot when injected with nucleo-proteid extracted from pigmented animals.

The interesting fact was thus ascertained that all albinos are not alike. To students of heredity this is precisely what would have been expected. For, as the facts above described show, albinos, though apparently identical, are yet the carriers of different hereditary characters. Among albinos, for instance, the author of this article has reason to believe, upon theoretical grounds resting on an experimental basis, that probably no less than thirteen types exist. With rabbits and mice there must be a still larger number.

In the intravenous coagulation experiments above described, all the rabbits were carefully weighed, and the amount of nucleo-proteid injected until coagulation occurred was measured. This would give for albinos and pigmented individuals the amount per kilogramme of body-weight required to kill in each case, and would afford a measurement of the relative resistance of the two races. It was found that the resistance of albinos towards the coagulative effects of injected nucleo-proteids was to that of pigmented individuals as 1:5 to 1:0. In this case, the greater constitutional vigour of the albino is thus accurately demonstrated. But it does not necessarily follow that with other materials and with other constitutional qualities the state of things would not be reversed.

One other feature remains to be mentioned. Albinism appears, in some races of albinos, to be a hereditary defect, to be transmitted individually, and correlated with certain peculiar defects. It is well known that the long-haired albino rabbit, called Angora, when at rest, has the habit of swaying its head sideways in a peculiar fashion. C. C. Hurst has shown that the long-haired and albino characters are always accompanied in heredity with the swaying habit. The Angora character never occurs without it.

ALBINONI, TOMASSO (c. 1674-c. 1745), Italian musician, was born at Venice. He was a prolific composer of operas attracting contemporary veneration for their originality, but is more remembered as an extraordinary composer of instrumental music, which greatly attracted the attention of Bach, who wrote at least two fugues on Albinoni’s themes and constantly used his basses for harmony exercises for his pupils.
ALBINOVANUS PEDO, Roman poet, flourished during the Augustan age. He wrote a Thesaeis, referred to in a letter from his intimate friend Ovid (Ex Ponto, iv. 10), epigrams which are commended by Martial (ii. 77, v. 5) and an epic poem on the exploits of Germanicus. He had the reputation of being a most excellent raconteur, and Quintilian (x. i. 90) awards him qualified praise as a writer of epics. All that remains of his works is a beautiful fragment preserved in the Saturnalia (i. 13) of the orator and oratorian Seneca, from a description of the voyage of Germanicus (A.D. 16) through the river Ems to the Northern Ocean, when he was overtaken by the storm described by Tacitus (Ann. ii. 23). The cavalry commander spoken of by the historian is probably identical with the poet. Three elegies were formerly attributed to Pedo by Scaliger; two on the death of Maecenas (In Obitur Maccenatis et De Verbis Maccenatis mortuandis), and one addressed to Livia to console her for the death of her son Drusus (Consolatio ad Liviam de Morte Drusi or Epithomae Drusi; usually printed with Ovid's works); but it is now generally agreed that they are not by Pedo. The Consolatio has been put down as late as the 15th century as the work of an Italian imitator, there being no MSS, and no trace of the poem before the publication of the editio princeps of Ovid in 1471. There is an English verse translation of the elegies by Plumptre (1607).

See Böhrens, Poetae Latinae Minoris (1879) and Fragmenta Poetorum Latinorum (1886); Haupt, Opuscula, i. (1875); Haube, Beitrag zur Kenntnis des Albinovanus Pedo (1890).

ALBINUS (originally WEISS), BERNHARD SIEGFRIED (1609-1770), German anatomist, was born on the 24th of February 1609, at Frankfort-on-Oder, where his father, Bernhard Albinus (1653-1721), was professor of the practice of medicine.

In 1702 the latter was transferred to the chair of medicine at Leiden, and it was there that Bernhard Siegfried began his studies, having for his teachers such men as H. Boerhaave and Nikolaus Bidloo. Having finished his studies at Leiden, he went to Paris, where, under the instruction of Sébastien Vaillant (1669-1723), J. B. Winslow (1669-1700) and others, he devoted himself especially to anatomy and botany. After a year's absence he was, on the recommendation of Boerhaave, recalled in 1719 to Leiden to be a lecturer on anatomy and surgery. Two years later he succeeded his father in the professorship of these subjects, and speedily became one of the most famous teachers of anatomy in Europe, his class-room being resorted to not only by students but by many practising physicians.

In 1745 Albinus was appointed professor of the practice of medicine, being succeeded in the anatomical chair by his brother Frederick Bernhard (1715-1778), who, as well as another brother, Christian Bernhard (1750-1752), attained considerable distinction.

Bernhard Siegfried was twice married, the first wife of his university, died on the 9th of September 1770 at Leiden.

ALBION (in Ptolemy 'Αλβιών; Lat. Albion, Plyn. 4.1630,102), the most ancient name of the British Islands, though generally restricted to England. The name is perhaps of Celtic origin, but the Romans took it as connected with albus, white, in reference to the chalk-cliffs of Dover, and A. Holder (Alt-Keltischer Sprachschatz, 1896) unhesitatingly translates it Weissland, "white land." The early writer (6th cent. B.C.) whose periphas is translated by Avienus (end of 4th cent. A.D.) does not use the word; and Trench speaks of Pére'S Alben and 'Albaw ("island of the ferns and the Albiones"). So Pythaces of Massilia (4th cent. B.C.) speaks of 'Αλβιών and 'ιππό. From the fact that there was a tribe called the Albiones on the north coast of Spain in Asturia, some scholars have placed Albion in that neighbourhood (see G. F. Unger, Rhein. Mus. xxxvii., 1883, pp. 156-156). The name Albion was taken by medieval writers from Plyn and Plodoyer.

ALBION, a city of Calhoun county, Michigan, U.S.A., on the Kalamazoo river, 21 m. W. of Jackson. Pop. (1890) 3765; (1900) 4151, of whom 632 were foreign-born; (1910) 4945; (1920) 5833. Albion is served by the Michigan Central and the Jackson division of the Lake Shore and Michigan Southern railways, and by an inter-urban electric line. The city has a public park and a public library. The W. part of the city has most of the factories; the principal manufactures are flour, agricultural implements, windmills, gasoline engines, harness and proprietary medicines. On a commanding site in the E. part of the city is Albion College (Methodist Episcopal; co-educational), embracing a College of Liberal Arts, a preparatory department, a conservatory of music, a school of art, a school of oratory, a normal course, and a commercial department. The college was incorporated in 1835 as Spring Arbor Seminary, and in 1839 by an amended charter was located at Albion, where it was first opened in 1843 under the name of the Wesleyan Seminary of Albion; in 1849 it became the Wesleyan Seminary and Female Collegiate Institute, with power to grant degrees to women only; but in 1861 the present name was adopted and the college was permitted to grant degrees to men and women. In 1906 it had a library of 16,500 volumes, a faculty of 19, and an enrolment of 493 (211 being women). The municipality owns and operates the water-works, the water-supply being obtained from artesian wells. Albion was settled in 1821, was incorporated as a village in 1866 and was chartered as a city in 1885.

ALBION, a village and the county-seat of Orleans county, New York, U.S.A., about 30 m. W.N.W. of Rochester. Pop. (1890) 4586; (1900) 4477, (1919) 4479 (in 1886); (1905, state census) 5174; (1910) 5016. The village is served by the New York Central & Hudson River railway, by the Buffalo, Lockport & Rochester electric railway, and by the Erie Canal. In Albion are the Western House of Refuge for Women (a state institution established in 1890), a public park, a public library and a county library, the county buildings, including the court house, the jail and the surrogate's office; and about 2 m. to the S.E. is the beautiful Mount Albion Cemetery.

Albion is the centre of the Medina sandstone industry, and lies in the midst of a good farming region, of which it is the principal shipping point, especially for apples, cabbages and beans. The village manufactures agricultural implements, vinegar, evaporated fruit, and canned fruit and vegetables, and has two large cold-storage houses. Albion was settled in 1812, was incorporated in 1823 and became the county-seat in 1825.

ALBITE, a mineral of the felspar group, belonging to the division of the plagioclases (q.v.). It is a sodium and aluminium silicate, NaAlSiO₄, and crystallizes in the anorthic system. Like all the felspars it possesses two cleavages, one perfect and the other less so, which are here inclined at an angle of 86° 24'. On the more perfect cleavage, which is parallel to the basal plane (P), is a system of fine striae, parallel to the second cleavage (F), due to twinning according to the "albite law" (figs. 1 and 2). The hardness is 6, and the specific gravity 2.63. The colour is usually pure white, hence the name (from the Lat. albus) for the species.

Albite forms an essential constituent of many igneous and crystaline rocks; albite is of secondary (metamorphic) origin. The beautifully developed crystals so abundant in crystal-lined crevices of Alpine granites and gneisses have been deposited, with other minerals, from solution; the crystals lining veins in the slates of Tintagel in Cornwall have the same origin.

Several varieties of albite are distinguished, of which the following may be here specially mentioned. Pericline (from the Gr. περίκλεινειν, "sloping") is the name given to large opaque white crystals from the chlorite-schists of the Alps; they are tabular parallel to the direction of perfect cleavage and are twinned according to the "pericline law." Peristerite

FIG. 1. Twinned crystals of Albite.

FIG. 2. Albite.
'ALBO—ALBRET

(from the Gr. πους, a dove) is characterized by a beautiful bluish sheen, somewhat resembling that seen on the neck of a pigeon; it is found mainly in Ontario. Aurelitine and moonstone varieties occur, though these special appearances are more usually displayed by the oligoclase and orthoclase felspars respectively.

(1. J. S.)

'ALBO, JOSEPH, a Spanish Jewish theologian of the 15th century. He was a writer of a very popular book on the philosophy of Judaism, entitled 'Targanim or Fundamentals.' Maimonides in the 12th century had formulated the principles of Judaism in thirteen articles; Albo reduced them to three: (i) The Existence of God, (ii) Revelation and (iii) Divine Retribution. Albo set the example of minimizing Messianism in the formulation of Jewish beliefs. Though he fully maintained the Mosaic authorship of the Law and the binding force of tradition, he discriminated between the essential and the non-essential in the practices and beliefs of Judaism. An English translation of the 'Targanim appeared in the Hebrew Review, vols. i.-iii.

ALBOIN (d. 572 or 573), king of the Lombards, and conqueror of Italy, succeeded his father Audoin about 565. The Lombards were at that time dwelling in Noricum and Pannonia (archduchy of Austria, Styria and Hungary, west of the Danube). In alliance with the Avars, and Asiatic people who had invaded central Europe, Alboin defeated the Gepidae, a powerful nation on his eastern frontier, slew their king Cunimund, whose skull he fashioned into a drinking-cup, and whose daughter Rosamund he carried off and made his wife. Three years later (in 568), on the alleged invitation of Narses (q.e.), who was irritated by the treatment he had received from the emperor Justin II., Alboin invaded Italy, probably marching over the pass of the Predil. He overran Venetia and the wide district which we now call Lombardy, meeting with but feeble resistance till he came to the city of Ticinum (Pavia), which for three years (560-572) kept the Lombards at bay. While this siege was in progress Alboin was also engaged in other parts of Italy, and at its close he was probably master of Lombardy, Piedmont and Tuscany, as well as of the regions which afterwards went by the name of the duchies of Spoleto and Benevento. In 572 or 573, however, he was assassinated by his chamberlain Peredeo at the instigation of Queen Rosamund, whose Alboin had grievously insulted by forcing her to drink wine out of her father's skull. After his death and the short reign of his successor Cleph the Lombards remained for more than ten years in a state of anarchy.

The authorities for the history of Alboin are Procopius, Paulus Diaconus and Aquilus (in his history of the church of Ravenna).

ALBONI, MARIETTA (1823-1894), Italian opera-singer, was born at Cesena, Romagna, and was trained in music at Bologna, where she became a pupil of Rosinni. She had a magnificent contralto voice, and in 1843 made her first appearance at La Scala, Milan, being recognized at once as a public favourite. In England her reputation was established by her appearance at Covent Garden in 1847, and she had brilliant success all over Europe in the leading operatic rôles; in 1853 she repeated these triumphs in the United States. Indeed, with the exception of Malibran, she had no peer among the contraltos of the century, the old Italian school of singing finding in her a really great representative. She married first Count A. Pepoli, who died in 1866, and secondly (1877) a French officer, M. Zieger; she lived in Paris after her first marriage, and died at Ville d'Avray in 1894.

ALBORNIZ, GIL ALVAREZ DE, Spanish cardinal, was born at Cuenca early in the 14th century. He was the son of Gil Alvarez de Albornoz and of Doña Teresa de Luna, sister of Kimen de Luna, archbishop of Toledo. He was educated at Saragosa, while his uncle was bishop of that see, and studied law at Toulouse. The powerful influence of his family opened him a public career early in life. He was made archdeacon of Calatrava, and was elected to the bishopric of the king's own diocese while young. In 1337 he was chosen archbishop of Toledo. In addition to his archbishopric he held the favour of the king, Alphonso XI. At the battle of Tarifa he fought against a great invasion from Africa in 1346, and at the taking of Algeciras in 1344 he led the armed levy of his archbishopric. In 1343 he had been sent to Pope Clement VI. at Avignon to negotiate a grant of a tax on the revenues of the Church for the Crusade. His military and diplomatic ability became known to the pope, who made him a cardinal in 1350. Albornoz left Spain on the death of the king Alphonso XI. in that year, and never returned. It has been said, but not on contemporary evidence, that he fled from fear of Peter the Cruel. In 1353 Innocent VI. sent him as a legate into Italy, with a view to the restoration of the papal authority in the states of the Church. He was recalled in 1357, but was sent again to Italy after a brief interval, and in 1362 had paved the way for the return of Urban V. to Rome. As legate, Albornoz showed himself to be an astute manager of men and effective fighter. He began by making use of Rienzi, whose release from prison at Avignon he secured. After the murder of the tribune in 1354 Albornoz pursued his task of restoring the pope's authority by intrigue and force with remarkable success. As a mark of gratitude the pope appointed him legate at Bologna in 1367, but he died at Viterbo the same year. According to his own desire his remains were carried to Toledo, where Henry of Castile caused them to be entombed with almost royal honours. A work by Albornoz on the constitution of the Church of Rome, first printed at Jesi in 1473, is now very rare. The college of St Clement at Bologna was founded by Albornoz for the benefit of Spanish students.

ALBRECHTSBERGER, JOHANN GEORG (1736-1809), Austrian musician, was born at Kloster-Neuburg, near Vienna, on the 3rd of February 1736. He studied musical composition under the court organist, Mann, and became one of the most learned and skilful contrapuntists of his age. After being employed as organist at Raab and Maria-Taferei, he was appointed in 1772 organist to the court of Vienna, and in 1792 Kapellmeister of St Stephen's cathedral. His fame as a composer attracted to him in the Austrian capital a large number of pupils, some of whom afterwards became eminent musicians. Among these were Beethoven, Hummel, Moscheles and Josef Weigl (1766-1846). Albrechtsberger died in Vienna on the 7th of March 1809. His published compositions consist of preludes, fugues and sonatas for the piano and organ, string quartets, &c.; but the greater proportion of his works, vocal and instrumental, exists only in manuscript. They are in the library of the Vienna Gesellschaft der Musikfreunde. Probably the most valuable service he rendered to music was in his theoretical works. In 1790 he published at Leipzig a treatise on composition, of which a third edition appeared in 1821. A collection of his writings on harmony, in three volumes, was published under the care of his pupil Ignaz von Seyfried (1776-1841) in 1826. There is an English version of this published by Novello in 1855. Beethoven knew his own needs when he put himself under Albrechtsberger on finding that Haydn was not thoroughly disposed for the trouble of training him; and though Albrechtsberger could see nothing in him, and warned his other pupils against "that young man who would never turn out anything in good style," he justified Beethoven's confidence.

ALBRET. The lordship (seigneurie) of Albet (Labrit, Lébret), situated in the Landes, gave its name to one of the most powerful feudal families of France in the middle ages. Its members distinguished themselves in the local wars of that epoch; and during the 14th century they espoused the English cause for some time, afterwards transferring their support to the side of France. Arnaud Amancieu, lord of Albet, helped to take Guienne from the English. His son Charles became constable of France, and was killed at the battle of Agincourt in 1415. Alain the Great, lord of Albet (d. 1522), wished to marry Anne of Brittany, and to that end fought against Charles VII. but his life was cut short by the English. When due to Maximilian of Austria, he surrendered Nantes to the French in 1486. At that time the house of Albet had attained considerable territorial importance, due in great part to the liberal grants.
which it had obtained from successive kings of France. John of Albrecht, son of Alain, became king of Navarre by his marriage with Catherine of Foix. Their son Henry, king of Navarre, was created duke of Albrecht and peer of France in 1550. By his wife Margaret, sister of the French king, Francis I., he had a daughter, Jeanne d’Albret, queen of Navarre, who married Anthony de Bourbon, duke of Vendôme, and became the mother of Henry IV., king of France. The dukedom of Albrecht, united to the crown of France by the accession of this prince, was granted to the family of La Tour d’Auvére in 1651, in exchange for Sedan and Raucourt.

To a younger branch of this house belonged Jean d’Albret, seigneur of Orval, count of Dreuze and of Rethel, governor of Champagne (d. 1524), who was employed by Francis I. in many diplomatic negotiations, more particularly in his intrigues to get himself elected emperor in 1519. (M. P.*).

ALBRIGHT, JACOB (1750-1808), American clergyman, was born near Pottstown, Pennsylvania, on the 1st of May 1759. He was of “Pennsylvania-German” parentage, his name being originally Albrecht, and was educated in the Lutheran faith. At an early age he became a tile-burner. In 1789 he was converted to Methodism, and in 1796 determined to devote himself to preaching that faith among the Pennsylvania Germans. His efforts met with great success, and in 1800 he founded what was virtually a new and independent church organization on the Methodist system, of which he became the presiding elder, and eventually (1807) bishop. This church is officially the Evangelical Association, but its adherents have been variously known as “New Methodists,” “Albrights,” and “Albright Brethren.” Albright died on the 18th of May 1868, at Mühlbach, Pennsylvania.

ALBUERA, or ALBUHERA, LA, a small village in Spain, in the province of Badajoz, 13 m. S.E. of the town of that name. Pop. (1900) 880. Albarea is celebrated on account of the victory gained there on the 16th of May 1811 by the British, Portuguese and Spaniards, under Marshal Beresford, over the French army commanded by Marshal Soul. (See Peninsula War.)

ALBUFERA DE VALENCIA, a lagoon, 7 m. S. of Valencia in Spain, about 13 m. in length and 4 in breadth, 12 ft. being its greatest depth. It communicates with the sea by a narrow outlet which can be opened or closed at pleasure. The lake is crown-shaped, and is of great value from the fish and wild-fowl with which it abounds. Rice is grown in large quantities by the inhabitants of the adjoining villages. In 1812 Marshal Suchet was created duke of Albufera by Napoleon for his conquest of Valencia, and invested with the dominion; but the battle of Vittoria in 1813 deprived him of his possession, though he still retained the title. Subsequently the revenues of Albufera were conferred upon the duke of Wellington in token of the gratitude of the Spanish nation. (See Peninsula War.)

ALBULAE AQUAE, a group of springs, 3 m. W. of Tibur, the water of which is bluish, strongly impregnated with sulphur and carbonate of lime, and rises at a temperature of about 75° F. Remains of a Roman thermal establishment exist near the principal spring, the so-called Lago della Regina (which is continually diminishing in size owing to the deposit left by the water), and dedicatory inscriptions in honour of the waters have been found. The baths are still frequented by the Romans, though the modern establishment is about 1 m. S. on the high road.

See T. Ashby in Papers of the British School at Rome, iii. 117.

ALBULA PASS, now the principal route from the N. to the Upper Engadine in the Swiss canton of the Grisons. It was already frequented in the 15th century, while a carriage road (highest point, 7595 ft.) was constructed across it in 1685, but for a long time it was not as much used as the easier and more direct Julier Pass (7504 ft.), until the opening of the railway in 1863, which has vastly increased its practical importance. Starting from Coire the Rhine valley is followed to Reichenau (61 m.), and then that of the Hinter Rhine to Thusis (103 m.). The line then runs through the grand Tschyn gorge (cut by the Albullo torrent) to Tiefenkastel (73 m.), where it leaves the Julier road on the right (S.) and continues to follow the course of the Albula past Flisur and Bergün (121 m.) to the mouth (5870 ft.) of the great tunnel (38 m. in length; highest point, 5987 ft.) which has been pierced below the pass. The descent lies through the Bevers Glen to Bever (24 m.), where the Upper Engadine is reached, about 5 m. below St. Moritz, which is 56 m. from Coire by this route. (W. A. B. C.)

ALBUMIN, or ALBUMEN (Lat. albus, white), an organic substance typical of a group of bodies (albumins or albumamines) of very complicated chemical composition. They are sometimes called the histogenetic bodies or protoids, because they are essential to the building up of the animal organism. The vegetable kingdom is the original source of albuminous substances, the albumin being found in greatest quantity in the seed. They also occur in the fluids of the living organism. The chemistry of the albumins is one of the most complicated and difficult in the whole domain of organic chemistry. It has attracted the attention of many workers, and has formed the subject of a huge literature. In this field Béchamp, Cohnheim, Albrecht Kossel, and, especially, Emil Fischer and his pupils have been extremely active. The general trend of these researches lies in the study of the decomposition or “breaking down” products of the albumin molecules; once these are accurately determined, the synthesis of an albumin is but a question of time. Already we have proceeded far in our knowledge of the decomposition products, and certain simple proteids have been synthesized.

The albumins contain in all cases the elements carbon, hydrogen, nitrogen, sulphur and oxygen; their composition, however, varies within certain limits: C = 50-55 %, H = 6-9.7 %, N = 15-19 %, S = 0-3-2-4 %, O = 19-24 %, crystallized albumin is C = 51-48 %, H = 6-76 %, N = 18-14 %, S = 0-96 %, O = 32-66 %, which points to the formula C₁₇H₁₉₁₉₆N₇S₄O₁₁, corresponding to the molecular weight 16054. A high molecular weight characterizes these substances, but so far no definite value has been determined by either physical or chemical means; A. P. Sabaninzev obtained the value 15,000 by Raoulit’s method for purified egg albumin. All albumins are laevo-rotatory; and on incineration a small amount of inorganic ash is invariably found. They are usually insoluble in water, alcohol and ether; and their presence as solutes in vegetable and animal fluids is not yet perfectly understood, but it is probably to be connected with the presence of salts or other substances. A remarkable change occurs when many albumins are boiled with water, or treated with certain acids, their solubility and general characters being entirely altered, and the fluid becoming coagulated. This change is seen...
in the transformation of the "white" of an egg on boiling. Albumins are generally detected by taking advantage of this property, or of certain color changes. The reagents in common use are: Millon's reagent, a solution of mercuric nitrate containing nitrous acid, this gives a violet-red coloration; nitric acid, which gives a yellow color, turning to gold when treated with ammonia (xanthoproteic reaction); fuming sulphuric acid, which gives violet solutions; and caustic potash and copper sulphate, which, on warming, gives a red to violet coloration (biuret reaction).

Boiling with dilute mineral acids, or baryta water, decomposes albumins into carbon dioxide, ammonia and fatty amino- and other acids. These decomposition products include: glycercoll or aminoacetic acid, NH₂CH₂COOH, alanine oraminopropionic acid, CH₂CH(NH₂)COOH, α-amino-butyric acid, α-aminovaleric acid, leucin or isobutyrl-α-aminoacetic acid, (CH₄)₂CH₂CH(NH₂)COOH, isoleucin, probably β-aminoacaproic acid, serin or α-amino-β-hydroxypropionic acid, HO-CH₂CH(NH₂)COOH, aspartic acid or aminosuccin acid, HOO-C₂H₂CH(NH₂)COOH, glutamic acid or a-amino-γ-glutamic acid, HOOC-(CH₂)₂CH(NH₂)COOH, diaminooacetic acid, α-δ-diamino-o-caproic acid, NH₂(CH₂)₆CH(NH₂)COOH, arginin or guanidino-a-amino-α-valeric acid, (NH₃)₂C=NH(CH₂)₆CH(NH₂)COOH, ornithin or α-β-diamino valerian acid, NH₂(CH₂)₈CH(NH₂)COOH, histidin or α-and β-imidazolopropionic acid, HOO-C₂H₂CH(NH₂)₂C₂H₂CH₃, or α-pyrrolidin carboxylic acid, HOOC-CH(NH₂)CH₂CH₃ hydroxypyrrole, phenyl alanine or phenyl-a-aminopropionic acid, C₆H₅CH₂CH(NH₂)COOH, tyrosin or o-protoplastic acid, α-aminopropionic acid, phenyl ethylamine, p-hydroxyphenyl ethtylamine, tryptophan or indol aminopropionic acid, A. cystin (protein-cystin) or α-amino-β-thioglycic acid " disulphide," (S-C₂H₅CH(NH₂)COOH), B. cystin (stone-cystin) or α-thio-β-aminoacrylic acid " disulphide," (NH₂CH₂CH₂S-COOH). This list is not exhaustive; other products are given in Gustav Mann, Chemistry of the Proteids (1906), to which reference should be made for a complete account of this class of compounds.

The complexity of composition militates in a great measure against a rational classification of albumins by purely chemical considerations. Such classifications have been attempted by A. Kossel and by W. Kühne and E. P. Fick; but in the present state of our knowledge, however, the older classification of E. Dreschel and F. Hoppe-Seyler, based primarily on solubilities and distribution, may be conveniently retained. This classification is with certain modifications as follows.—

I. Albumins proper: characterized by having colloidal solutions.

2. Globulins: serum-globulin, egg-globulin, lacto-globulin, cell-globulins.
4. Fibrinogen.
5. Myosin.
6. Phosphorus containing albumins (nucleo-albumins), caseins, vitellines, nucleo-albumins of the cell-protoplasm, mucoid nucleo-albumins.
8. Protamines.

II. Transformation products of the albumins proper.

1. Acid-albumins, alkali albuminates.
2. Albumoses, peptones and peptides.
3. Halogen-albumins, oxyprotein, oxyprotsulphonic acid, &c.

III. Proteids.

1. Nucleo-proteids.
2. Haemoglobin and allied substances.

IV. Albuminoids.

1. Collagen.
2. Keratin.
3. Elastin.
4. Fibroin.
5. Spongins, &c.
6. Amyloid.
7. Albumoid.
8. Colouring matters derived from albumin.

**Albumins proper.**—Albumins (as classified above) are soluble in water, dilute acids and alkalies, and in saturated neutral salt solutions; they are coagulated by heat. "Scrum-albumin," or "blood-albumin," possibly C₄₁H₀₂N₁₃O₂₇, is a gut protein, or "blood-serum," and is found in blood-serum, lymph, chyle, milk, &c.; its coagulation temperature is about 67°. It differs from egg-albumin in its specific rotation (−5° to −6°), and in being slowly coagulated by alcohol and ether. Egg-albumin is the chief constituent of the white of egg; this fluid also contains a globulin and a mucoid. It coagulates at about 56°, and its specific rotation is 30° to 70°. "Lacto-albumin" occurs in all kinds of milk. The globulins are insoluble in water and in dilute acids, but soluble in alkalies and in neutral salt solutions; these solutions are coagulated on boiling. " Serum-globulin," also termed globulin for fibro-protoplasm or fibrin, paraglobulin and paraglobulin, occurs in blood serum; "cell-globulins" occur in many organs, liver, kidneys, pancreas and the thyroid gland, also in muscle-plasmas; "crystalline," a globulin occurring in two forms α and β, is found in the lens of the eye; "egg-globulin" and "lacto-globulin" occur respectively in the white of egg and in milk. Plant albumins or phyto-albumins have been chiefly investigated in the case of those occurring in seeds; most are globulins, insoluble in pure water, but soluble in salt solutions; "edestin," a globulin of this class, is very widely distributed. Other varieties or classes of these compounds are: plant caseins, found in milk albumins and conglutins. Helico-proteid occurs in the blood plasma, and is changed by a ferment into fibrin, to which the clotting of blood is due. Fibrinogen is insoluble in water, but soluble in salt solutions; it has three different coagulation temperatures, 56°, 65°, 75°. Fibrin, produced from fibrinogen by a ferment, is a jelly-like substance, coagulable by heat, alcohol, &c. The muscle-albumins include "myosin" or paramyo-xygenogen, a globulin, which by coagulation induces rigor mortis, and the closely related "myosinogen" or myogen; myoglobin and myoalbumin are also found in muscles. The nucleo-albumins are phospho-globulins are insoluble in water and acids, but soluble in alkalies, and have a salt reaction. "Casingenogen" (after W. D. Halliburton) is the chief albumin of milk; its composition varies with the animal. It is insoluble in water, while its salts are readily soluble. "Eucasein" is the ammonium salt; "nutrose" and "plasmon" are sodium salts. By the rennet ferment caseinogen is converted into casein, a substance resembling caseinogen in being soluble in water, but differing in having an insoluble calcium salt. The formation of casein involves the curdling of milk. Other phospho-globulins are vitelline, found in the yoke of hens' eggs, and histulbin, found in the eggs of fish. Histones are a class of albumins soluble in water and acids, but essentially basic in character; hence they are precipitated by alkalies. It is remarkable that many histones are soluble in an excess of alkal. They do not exist in a free state, but in combination with a "prothetic group" (after A. Kossel) they give rise to important cell constituents—haemoglobin, nucleo-proteids, &c. "Thymus histone" occurs in the thymus gland; globin occurs in combination as haemoglobin; other histones have been extracted from the red blood corpuscles of the goose and the testes of fishes and other animals. The protamines are a well-characterized class of albumins found in the ripe spermatzoa of fishes.

**Albumoses and Peptones.**—The primary products of the dissociation of albumins are the albumoses, characterized by not being coagulable by heat, more soluble than the albumins, having a far less complex composition, and capable of being "salted
out by certain salts, and the peptones, similar to albumoses but not capable of being "salted out"; moreover, peptones are less complex than albumoses. By further decomposition peptones yield peptides, a certain number of which have been synthesized by Emil Fischer and his collaborators. Albumoses and peptones are white powders, readily soluble in water, with the exception of the hetero-albumoses—a subdivision of primary albumoses. They give the biuret and xanthoproteic reactions, and form salts with both acids and bases; the former are obtained by peptic digestion, the latter being termed peptic-peptones; tryptic digestion also produces peptones. Acids and moist heat induce similar changes.

**Proteids.**—These substances are combinations of one or more albumins with a radical of an essentially different nature, termed by Kossel a "prosthetic group." It is convenient to classify proteids by those groups. **Nucleo-proteids,** constituents of the cell-nucleus, are combinations of albumins and nucleic acid; they always contain iron. They are loose, white, non-hygroscopic powders, soluble in water and salt solutions, and resemble the oxygen reaction; they give the color reactions of albumins. Nucleic acid is at present of unknown constitution; decomposition products are: phosphoric acid, uracil or 2,6-dioxo-pyrimidin,1 cytosin or 2-oxo-6-amino-pyrimidin, thymin (nucleosin) or 2,6-dioxo-5-methyl pyrimidin hypoxanthin1 or 6-oxypurin, xanthin or 2,6-dioxypurin, adenine or 6-amino-purin, guanine or 2-amino-6-oxypurin, pentose (1-xylose), laevulinic acid, amonnia, etc. The nucleic acids vary with the source of the proteids, there being considerable differences in chemical composition. In general they are white, loose powders, slightly soluble in cold water, more soluble in hot water; they are precipitated by mineral acids, but dissolve in an excess. They are dextro-rotatory, and the specific rotation is numerically greater than that of albumen; hence the proteids are, in general, dextro-rotatory.

An important nucleo-proteid is haemoglobin or haemogobin, the colouring matter of the red blood corpuscles of vertebrates; a related substance, haemocyanin, in which the iron of haemoglobin is replaced by copper, occurs in the blood of cephalopods and crayfish. Haemoglobin is composed of a basic albumin and an acid substance haematin; it combines readily with oxygen; carbon dioxide and carbon monoxide to form loose compounds (see Nutrition). It coagulates at 64°. By a dilute acid haemoglobin is decomposed into globin, and "haematin," a ferri-pyrol derivative of the probable formula C24H27N3FeO6; under certain conditions the iron-free "haemoporphyrin" is obtained. This last substance may be reduced to mesoporphyrin, C25H32O8N6, which by further reduction gives haemopyrrol, C24H27N3, possibly methyl-propyl-pyrrol or butyl-pyrrol. Other derivatives are haematin, haemochromogen and the haematinic acids.

"Glyco-proteids" differ from nucleo-proteids in containing a carbohydrate radical, which is liberated only by boiling with mineral acids or alkalies. The mucins and mucoids belong to this group; they are acid and contain no phosphorus; they give the albumin colour reactions but are not coagulated by heat. Mucins occur in most of the slimy fluids of the body; they vary in composition with their source. Mucoids resemble mucins in their composition and reactions, but differ, in general, in their physical properties. They occur in tendons, bones and cartilage. The "phospho-glyco-proteids" resemble the mucins and mucoids in containing a carbohydrate residue, but differ in containing phosphorus. Ichthulin (see above) may be placed in this group; "helico-proteid," found in the serous gland of Helix pomatia, the vineyard snail, also belongs here.

**Albuminoids** is the anatomical name given to albuminous substances forming the connective tissues. Chemically they resemble the albumins, being split up by acids or ferments into albumoses, peptones and amino-acids, forming salts, and giving the same colour reactions. They are quite insoluble in water and in salt solutions, and difficulty soluble in dilute acids and alkalies. Typical albuminoids are gelatin, keratin, elastin, fibrin, spongian and concholin.

"Collagen" (Gr. κόλλα, glue, and root γεν- of γενέω, to produce, γεγενεκας, to become), the ground-substance of bones and fibres, is decomposed by boiling water or on warming with acids into substances named gelatin, glutin or glue. Gelatin is a white amorphous, insoluble commercial product; however, generally forms glassy plates. The decomposition products are generally the same as with the general albumin; it gives the biuret reaction; forms salts with acids and alkalies, but is essentially acid in nature. Immersed in cold water gelatin does not dissolve but swells up; it dissolves readily in hot water, forming, according to the quantity present, a thick jelly which solidifies to a hard mass on cooling (the "glue" of the woodworker), or a thin jelly (used in cookery). Gelatin occurs also in the cornea and the sclerotic coat of the eye; and in fish homogenee lattices, quite insoluble in cold water, and 2% of lecithylepiderin, a substance differing from gelatin in giving a well-marked Millon's reaction. Keratin (Gr. κερας, a horn), the chief constituent of horny material, occurs in hair, nails, hoofs and feathers. It is quite insoluble in water, dilute acids and alkalies. Related to this substance are "neuro-keratin," found in the medullary sheath of nerves, and "gorgonin," the matrix of the axial skeleton of the coral Gorgonia Caulinii. Elastin occurs either as thick strands or as membranes; it constitutes the "elastic tissue" of the anatomist. Its insolubility is much the same as keratin. "Fibroin" and silk-glue or sericin occur in natural silk fibres. Fibroin is soluble in water, acids and alkalies; silk-glue resembles gelatin in its solubility, but it is less readily gelatinized. "Spongian," the matrix of bath-sponge, is insoluble in water and dilute acids, but soluble in concentrated mineral acids. "Concholin," the matrix of shells of the mollusca, is only slightly soluble in acids. "Cornein" forms the framework of corals. "Amyloid" occurs as a pathological product, and also in the healthy aorta and in old cartilage. It is an albumin, and not a carbohydrate as was formerly held; and gives most of the colour reactions of albumins. It forms shiny, homogenee lattices, quite insoluble in cold water, and in salt solutions, but soluble in alkalies. The albumoids include, according to Cohnheim, substances which possess certain properties in common, but differ from the preceding groups. In general they resemble coagulated albumin, and also the gelatin-yielding tissues, but they themselves do not yield gelatin. Colouring matters derived from albumins include the "melamins" (Gr. μελας, black), substances which differ very considerably in composition, the sulphur and iron content being by no means constant; they do not give the reactions of albumins.

**Albuminuria (Physiological or Functional),** a term indicating the presence of albumin in the urine. This may depend on a number of morbid conditions, of which kidney troubles, acute illnesses and venous congestion are some of the commoner. But after exclusion of all known pathological causes, there still remains a large class of cases among subjects who appear to be in perfect health. This form has been called functional or physiological albuminuria, intermittent albuminuria, &c. Its recognition is of extreme importance, as it must be distinguished from the albuminuria due to Bright's disease and other troubles. The following are the main forms that have been described:

1. Dietetic Albuminuria. This form affects some people after partaking of a meal consisting largely of albuminous foods, such as eggs. In others any extra indulgence in the pleasures of the table may give rise to it. 2. Cyclic Albuminuria. This name was first used by the physiologist Pavy, but other observers have called the same condition "postural albuminuria." It occurs in people enjoying perfect health, and is characterized by

---

1. The pyrimidin ring is numbered 2N + C4C5. For the purin ring, see Purin.
soaked in the presence of albumin in the urine at certain times of the day. It has been shown to depend entirely on the assumption of the erect position, and it disappears as a result of the recumbent position at night. (3) Albuminuria from exercise. This form affects some people after any unusual muscular exertion. (4) Prolonged mental strain or worry may give rise to a transient form of albuminuria. (5) Adolescent albuminuria is met with in some subjects, especially boys. The question of the real significance of a temporary pathological state is one about which there is much difference of opinion. But its importance and recognition—especially in questions of life insurance—admits of no question.

**ALBUQUERQUE, ALPHONSO D'** (in Old Port. Affonso d’ ALBUQUERQUE) (1453-1515), surnamed THE GREAT, and THE PORTUGUESE MARSHALL, was born in 1453 at Alexandria, near Lisbon. Through his father, Gonçalvo, who held an important position at court, he was connected by illegitimate descent with the royal family of Portugal. He was educated at the court of Alfonso V, and after the death of that monarch he seems to have served for some time in Africa. On his return he was appointed *estruteco-mor* (chief equerry) to John II. In 1503 he set out on his first expedition to the East, which was to be the scene of his future triumphs. In company with his kinsman Francisco he sailed round the Cape of Good Hope to India, and succeeded in establishing the king of Cochin securely on his throne, obtaining in return for this service permission to build a Portuguese fort at Cochin, and thus laying the foundation of his country’s empire in the East. He returned home in July 1504, and was well received by King Emmanuel, who entrusted him with the command of a squadron of five vessels in the fleet of sixteen which sailed for India in 1506 under Tristan da Cunha. After a series of successful attacks on the Arab cities on the east coast of Africa, Albuquerque separated from Da Cunha, and sailed with his squadron against the island of Ormuz, in the Persian Gulf, which was then one of the chief centres of commerce in the East. He arrived on the 25th of September 1507, and soon obtained possession of the island, though he was unable long to maintain his position. With his squadron increased by three vessels, he reached the Malabar coast at the close of the year 1508, and immediately made the commission he had received from the king empowering him to supersede the governor Francisco de Almeida. The latter, however, refused to recognize Albuquerque’s credentials and cast him into prison, from which he was only released, after three months’ confinement, on the arrival of the grand-marshal of Portugal with a large fleet. Almeida having returned home, Albuquerque speedily showed the energy and determination of his character. An unsuccessful attack upon Calicut in January 1510, in which the commander-in-chief received a severe wound, was immediately followed by the investment and capture of Goa. Albuquerque, finding himself unable to hold the town on his first occupation, abandoned it in August, to return with the reinforcements in November, when he obtained undisputed possession. He next directed his forces against Malacca, which he subdued after a severe struggle. He remained in the town nearly a year in order to strengthen the position of the Portuguese power. In 1512 he sailed for the coast of Malabar. On the voyage a violent storm arose, Albuquerque’s vessel, the “Flor de la Mar,” which carried the treasure he had amassed in his conquests, was wrecked, and he himself barely escaped with his life. In September of the same year he arrived at Goa, where he quickly suppressed a serious revolt headed by Idalcan, and took such measures for the security and peace of the town that it became the most flourishing of the Portuguese settlements in India. Albuquerque had been for some time under orders from the home government to undertake an expedition to the Red Sea, in order to secure that channel of communication exclusively to Portugal. He accordingly laid siege to Aden in 1513, but was repulsed; and a voyage into the Red Sea, the first ever made by a European fleet, in order to prevent its falling into the hands of the Turks or the power of Egypt, he is said to have entertained the idea of diverting the course of the Nile and so rendering the whole country barren. His last warlike undertaking was a second attack upon Ormuz in 1515. The island yielded to him without resistance, and it remained in the possession of the Portuguese until 1622. Albuquerque’s great career had a painful and ignominious close. He had several enemies at the Portuguese court who lost no opportunity of stirring up the jealousy of the king against him, and his own injudicious and arbitrary conduct on several occasions served their end only too well. On his return from Ormuz, at the entrance of the harbour of Goa, he met a vessel from Europe bearing despatches annunciating that he was superseded by his personal enemy Soares. The blow was too much for him and he died at sea on the 16th of December 1515. Before his death he wrote a letter to the king in dignified and affecting terms, vindicating his conduct and claiming for his son the honours and rewards that were justly due to himself. His body was buried at Goa in the Church of Our Lady, and it is perhaps the most convincing proof possible of the justice of his administration that, many years after, Mussulmans and Hindus used to go to his tomb to invoke protection against the injustice of his successors. The king of Portugal was convinced too late of his fidelity, and endeavoured to atone for the ingratitude with which he had treated him by heaping honours upon his natural son Affonso. The latter published a selection from his father’s papers under the title *Commentarios do Grande Affonso d’Albuquerque*.

See the *Cartas de Albuquerque*, published by the Lisbon Academy (vol. 1870); also *The Life of Albuquerque* in the *Bibliothèque de l’instruction géographique* (January to June 1902) on “O antigo Imperialismo português, &c.” has especial reference to Albuquerque.

**ALBUQUERQUE** a city and the county-seat of Bernalillo county, New Mexico, U. S. A., situated in the central part of the territory, about 325 m. S. W. by S. W. Denver, on the E. bank of the Rio Grande, at an altitude of 4900 ft. Pop. (1890) 3752; (1900) 6238 (396 foreign-born and 226 negroes); (1910 census) 11,020. In 1800 Albuquerque was the largest city in the territory. It is the connecting point of two main lines of the Atchison, Topeka & Santa Fé railway system. A short distance E. of the city is the university of New Mexico, under territorial control, founded in 1889 and opened in 1893; in 1908 it had a college of letters and science, a school of engineering, a school of education, a preparatory school and a commercial school. Albuquerque is also the seat of the Harwood Industrial School (Methodist) for Mexican girls, of the Menaun Mission School (Presbyterian) for Mexican boys, and of a government Indian training school (1881) for boys and girls. The city has a public library. The excellent climate has given Albuquerque and the surrounding country a reputation as a health resort. The city is an important railway centre, has extensive railway repair shops and stock-yards, and exports large quantities of live-stock, hides and wool. The largest industrial establishment is the American Lumber Company’s plant, including a saw-mill, a saw, door and blind factory and a box factory. The timber used, chiefly white pine, is obtained from the Zuni mountains. The city has also flour and woolen mills, breweries and ice factories. The old Spanish town of Albuquerque (pop. in 1800 about 2000) lies about 1 m. W. of the present city; it was founded in 1706, and was named in honour of the duke of Albuquerque, viceroy of New Spain from 1702 to 1710. During the Civil War it was occupied, late in February 1862, by Confederate troops under General Henry Hopkins Sibley (1836-1880), who soon afterwards advanced with his main body into northern New Mexico. In his retreat back into Texas he made a stand on the 8th of April 1862 at Albuquerque, where during the whole day there was a fight at long range and with few casualties against a detachment of Union soldiers commanded by Colonel Edward S. Canby (1819-1873). The modern city dates its origin from the completion of the first railway to Albuquerque in 1880.

**ALBURNUM** sapwood, the outermost and youngest part of the wood of a tree, through which the sap rises. It is distinguished from the harder inner and older wood, the duramen or heart-wood.
ALBURY—ALCAMENES

ALBURY, a town in Goulburn county, New South Wales, Australia, 386 m. by rail W.S.W. of Sydney. Pop. (1901) 5,651. It stands near the border of Victoria, on the right bank of the Murray river, here crossed by two bridges, one built of wood carrying a road, the other of iron bearing the railway. The Murray is navigable for small steamers from this town to its mouth, a distance of 1,800 miles. Albury is the centre of a sheep-rearing and agricultural district; grapes, cereals and tobacco are largely grown, and the wine produced here is held in high repute throughout Australia. The tree under which the first explorers encamped here in November 1824 is still standing in an enclosed space.

Albury became a municipality in 1859.

ALCABAS (ALCAIBAS), Greek lyric poet, an older contemporary of Sappho, was a native of Mytilene in Lesbos and flourished about 600 B.C. His life was greatly mixed up with the political disputes and internal feuds of his native city. He belonged to one of the noble families, and sided with his class against the "tyrants" who at that time set themselves up in Mytilene. He was in consequence obliged to leave his native country, and spent a considerable time in exile. He is said to have become reconciled to Pittacus, the ruler set up by the popular party, and to have returned to Lesbos. The date of his death is unknown. The subjects of his poems, which were composed in the Aeolic dialect, were of various kinds: some were hymns to the gods; others were of a martial or political character; others breathed an ardent love of liberty and hatred of tyrants; lastly, some were love-songs. Alcaeus was allotted the second place among the nine lyric poets in the Alexandrian canon. The considerable number of fragments extant, and the well-known imitations of Horace, who regarded Alcaeus as his great model, enable us to form a fair idea of the character of his poems. A new fragment has recently been discovered, together with some fragments of Sappho (Classical Review, May 1909).

See Bergh, Poetae Lyrici Graeci (1882); also The Songs of Alcaeus by J. Easby-Smith (Washington, 1901); Pfeil, Lesbicorum Liber (1826); Flach, Geschichte der griechischen Lyrik (1883-1884); Farnell, Greek Lyric Poets (1891).

ALCAICS, in ancient poetry, a name given to several kinds of verse, from Alcaeus, their reputed inventor. The first kind consists of five feet, viz. a spondee or iambic, an iambic, a long syllable and two dactyles; the second of five and two trochees. Besides these, which are called dactylic Alcaics, there is another, simply styled Alcaic, consisting of an epyrite, two choriamba and a bacchius; thus—

Cur timet flávum Tiberim | tangere, cur olivum?

The Alcaic ode is composed of several strophes, each consisting of four verses, the first two of which are always eleven-syllable alcaics of the first kind; the third verse is an iambic dimeter hypercaletic consisting of nine syllables; and the fourth verse is a ten-syllable alcaic of the second kind. The following strophe is of this species, which Horace calls Alcaei minaeas camenae—

Non possidentem multa vocaveris
Recte beatum; rectius occupat
Nomen beati, qui decurum
Muneribus sapienter uti.

There is also a decasyllabic variety of the Alcaic metre.

The Alcaic measure was one of the most splendid inventions of Greek metrical art. In its best examples it gives an impression of wonderful vigour and spontaneity. Tennyson has attempted to reproduce it in English in his

O mighty-mouthed inventor of harmonies,
O skilful to sing of time or eternity,
God-gifted voice of England,
Milton, a name to remember for ages.

German is, however, the only modern literature in which alcaics have been written with much success. They were introduced by Klostock, and used by Hölderlin, and Voss in his translations of Horace, by A. Kopsch and other modern German poets.

ALCALÁ (Moosrhal Kala, the "Fortress" or "Castle"), the name of thirteen Spanish towns, all founded or named by the Moors. Alcalá de Henares (pop. 1900 11,356) is separately described on account of its historical importance. Alcalá la Real (15,072), a picturesque town with a fine abbey, is situated in the province and country in the extreme south of the Jarama. Its distinctive name, "the Royal," was conferred in memory of its capture by Alphonso XI. of Leon in 1340. In 1810 the French under Count Sebastiánidu here defeated the Spanishiards. Alcalá de los Gazules (8877), on the river Barbate, in the province of Cadiz, has a thriving trade in cork and agricultural produce. Alcalá de Guadaira (8108), on the river Guadaira, near Seville, is popularly called Alcalá de los Panaderos, or "Alcalá of the Bakers," because it supplies Seville with large quantities of bread. Alcalá de Chisbért (6293) is situated on the coast of Castellon de la Plana (ALKALõS), on the Guadalquivir, 6 m. N. of Seville; Alcalá del Júcar (2658), on the Júcar, in Albacete; Alcalá de la Selva (1490), on the southern slopes of the Sierra del Gúdar, in Teruel; Alcalá de la Vega (712), on the river Cabriel, in Cuenca; Alcalá de Guadaira (632), on the river Seton, in Huesca; Alcalá del Obispo (432), in the same province; Alcalá de Ebro (388) and Alcalá de Moncayo (367), both in Saragossa.

ALCÁLÁ DE HENARES, a town of Spain, in the province of Madrid, 17 m. E.N.E. of Madrid, on the river Henares, and the Madrid-Saragossa railway. Pop. (1900) 11,356. Alcalá de Henares is the centre of a rich and well-populated country and has a considerable number of inhabitants, but its commercial importance is slight and its main interest is historical. The town has been identified with the Roman Complutum, which was destroyed about the year 1000, and was rebuilt by the Moors in 1083. In later times it was renowned for its richly endowed university, founded by Cardinal Jimenes de Cisneros in 1456, which at the height of its prosperity numbered 12,000 students, and was second only to that of Salamanca. Here the famous edition of the Bible known as the Complutensian Polyglot was prepared from 1514 to 1517. The college of San Idelfonso, completed in 1585, was the chief university building. It was modernized and partly destroyed by the Cistercians, but the Colegiata, contains the 16th century marble monument of Jimenes (d. 1517) and a fine retables. The greatest of Spanish writers, Cervantes, was born at Alcalá de Henares, and baptized in the otherwise insignificant church of St. Maria on the 9th of October 1547. A tablet, set up in 1840, marks the house in which he is said to have been born. Other illustrious natives of the town were the emperor Ferdinand I. (1503-1554) and the Spanish dramatist and historian Antonio de Solís (1610-1666). After the removal of the university to Madrid in 1856 the town rapidly declined, and the new University of Alcalá, erected by Cardinal Jimenes in the 16th century into a depot for the archives of various state departments. Here are kept very complete and curious documents of the Inquisition, showing all its workings from the 15th to the 19th century. One of the principal libraries is the former palace of the archbishops of Toledo.

For a fuller description of Alcalá see the Guía del viajero en Alcalá de Henares, by L. A. de la Torre (Alcalá, 1882). The following works are mainly of historical interest—M. de Ayala and F. Sastre, Alcalá de Henares (Madrid, 1890); J. C. García, Ensayo de una tipografía Complutense (Madrid, 1886); M. Portilla y Esquivel, Historia de la ciudad de Compluto (Alcalá, 1725-1728); and the "Anales Complutenses" and "Chronicon Complutense" in España Sagrada, by H. Florez and others (Madrid, 1754-1879).

ALCALDE (from the Arab. al-quādir, the "Cadi" or "judge"), the title in Spanish for officials of somewhat varied functions, in which, however, there is always a judicial element. Alcalde de corte was a judge of the palace court, having jurisdiction in and about the residence of the king. But the mayor of a town or village who discharged the functions of a justice of the peace was also an alcalde. It is in this sense that the title is now exclusively used. He is subject to yearly election and the post has often been an undesirable one in Spain. The title of alcalde must be carefully distinguished from alcaldiz, which is derived from the Arabic al-quādir, a general, and means the governor of a fortress.

ALCAMENES, a Greek sculptor of Lemnos and Athens. He was a younger contemporary of Pheidias and noted for the delicacy and finish of his works, among which a Hephaestus
and an Aphrodite "of the Gardens" were conspicuous. Pausanias says (v. 10. 8) that he was the author of one of the pediments of the temple of Zeus at Olympia (see Greek Art), but this seems a chronological and stylistic impossibility. At Pergamum there was discovered in 1903 a copy of the head of the Hermes "Propylaeus" of Alcamenes ("Athenische Mittheilungen," 1904, p. 180). As, however, the deity is represented in an archaic and conventional character, this copy cannot be relied on as giving us much information as to the usual style of Alcamenes, who was almost certainly a progressive and original artist. It is safer to judge him by the sculptural decoration of the Parthenon, in which he must almost certainly have taken a share under the direction of Phidias.

**ALCAMO**, a town of Sicily, in the province of Trapani, 24 m. W.S.W. of Palermo direct (53 1/2 m. by rail). Pop. (1881) 37,497; (1901) 51,809. It was founded in A.D. 828 by the Saracen chief Al-Kamuk, who erected the castle (which still stands, though considerably altered), but was christianized by the emperor Frederick II. in 1233, who removed the site lower down. It possesses some medieval buildings of interest. The surrounding district is very fertile and the trade in agricultural products is considerable.

**ALCANTARA**, a small seaport of Brazil, in the state of Minas Gerais, on the shore of the bay of São Marcos, 16 m. from the city of Maranhão by water. It has a fairly good harbour, and excellent cotton and rice are grown in the vicinity and shipped thence.

**ALCANTARA**, a town of western Spain, in the province of Cáceres, situated on a rocky height on the left bank of the river Tagus, 7 m. from the Portuguese frontier. Pop. (1900) 3248. Alcántara (in Arab., "the bridge") owes its name to the magnificent Roman bridge which spans the Tagus on the north-west. This was originally built about A.D. 105, in honour of the Roman emperor Trajan and at the cost of eleven Lunetan communities.

It is entirely constructed of granite blocks, without cement, and consists of six arches of various sizes, with a total length of 616 feet and a height of about 190 ft. in the middle piers, which are surmounted by a fortified gateway. One of the arches was broken down in 1223 and rebuilt in 1553; another was blown up by the British troops in 1809, and, though temporarily reconstructed, was again destroyed in 1836, to prevent the passage of the Carlist forces. But in 1860 the whole was restored. A small Roman temple, dedicated to Trajan and other deified emperors, stood on the left bank, adjoining the bridge. It is difficult, however, if Alcántara marks the site of an ancient Roman town, though archaeologists have sometimes identified it either with Norba Caesarea or with Interamnium. It first became famous about 1215 as the stronghold of the knightly Order of Alcántara. Many of the grand masters of this order lie buried in the 13th-century Gothic church. The town possesses another interesting church built in 1506. See *Antiguiedades y santos de la muy noble villa de Alcántara*, by J. Arias de Quintanadueñas (Madrid, 1661); and *Retrato de Alcántara*, by L. Santibáñez (Madrid, 1779).

**ALCÁVALA** (Spanish, from Arab. al-qaabalab, "tax," quabala, "to receive"); cf. Fr. gabelle), a duty formerly charged in Spain and its colonies on all transfers of property, whether public or private. Originally imposed in 1347 by Alphonso XI. to secure freedom from the Moors, it was an *ad valorem* tax of 10, increased afterwards to 14%, on the selling price of all commodities, whether raw or manufactured, chargeable as often as they were sold or exchanged. It subjected every farmer, manufacturer, merchant and shopkeeper to the continual visits and examinations of the tax-gatherers, whose number was necessarily very great. This monstrous impost was permitted to ruin the industry and commerce of the greater part of the kingdom up to the time of the invasion of Napoleon. Catalonia and Aragon purchased from Philip V. an exemption from the alcazav, and, though still burdened with other heavy taxes, were in consequence in a comparatively flourishing state.

**ALCÁZAR DE SAN JUAN**, or **ALCÁZAR**, a town of Spain, in the province of Ciudad Real, in the plain of La Mancha, at the junction of the Madrid-Manzanares and Madrid-Albacete railways. Pop. (1900) 11,459. Owing to its position on two important railways, Alcázar has a flourishing transit-trade in the wines of Estremadura and Andalusia; the soda and alkali of La Mancha are used in the manufacture of soap; and gunpowder, chocolate and inlaid daggers are also made here. Alcázar is sometimes identified with the Roman *Alce*, captured by Tiberius Sempronius Gracchus in 180 B.C. It derives its existing name from its medieval Moorish castle (*al-kasr*), which was afterwards garnished by the knights of St. John. The townsfolk contend that the great Cervantes was a native of Alcázar; and, although this claim must be disallowed, much of the action of his masterpiece, *Don Quixote*, takes place in the neighbourhood. El Toboso, for instance, a village 12 m. w.e. of Alcázar [pop. (1899) 1895], was the home of the Lady Dulcinea del Toboso; Argamasilla de Alba (1905), 22 m. s.e., is declared by tradition to be the birthplace of Don Quixote himself. Local antiquaries even identify the knight with Don Rodrigo de Pacheco, whose portrait adorns the parish church; and the same authorities hold that part of the romance was written while Cervantes was a prisoner in their town. An edition of *Don Quixote* was published at Argamasilla in 1864.

**ALCESTER, FREDERICK BEAUCHAMP PAGET SEYMOUR**, 2nd Earl (1813–1885), was a British admiral, son of Colonel Sir Horace Beauchamp Seymour and cousin of Francis George Hugh Seymour, 5th marquess of Hertford, was born on the 12th of April 1821. Entering the navy in 1834, he served in the Mediterranean and the Pacific, was for three years flag-lieutenant to his uncle Sir George Seymour, and was promoted to be commander in 1847. He served in Burma as a volunteer in 1852, was made a captain in 1854, took the "Meteor" iron-clad battery out to the Black Sea and home again in 1856, was captain of the "Pelorus" on the Australian station from 1857 to 1863, and commanded the naval brigade in New Zealand during the Maori War, 1860–61, for which he was made a C.B. He became a rear-admiral in 1870; in 1871–1872 he commanded the flying squadron, was a lord of the admiralty in 1872–1874, and commanded the Channel fleet, 1874–1876. On the 31st of December 1876 he was made a vice-admiral, a K.C.B. on the 2nd of June 1877. In 1880–1883 he was commander-in-chief of the fleet in the Mediterranean, and in 1880 had also the chief command of the European squadron sent to the coast of Albania as a demonstration to compel the Forte to cede Dulcigno to Montenegro. On the 24th of May 1883 he was made a G.C.B., and on the 6th of May 1883 was promoted to the rank of admiral. In July 1882 he commanded at the bombardment of Alexandria and in the subsequent operations on the coast of Egypt, for which service he was raised to the peerage as Baron Alcester of Alcester in the county of Warwick, received a parliamentary grant of £25,000, the freedom of the city of London and a sword of honour. On his return from the Mediterranean he was for a couple of years again at the admiralty, and in 1886 he was placed on the retired list. For the next nine years he lived chiefly in London, but latterly his health was much broken, and he died on the 30th of March 1895. He was unmarried and the peerage became extinct.

**ALCESTER,** [pronounced *Auster*], a market-town in the Stratford-on-Avon parliamentary division of Warwickshire, England, 16 m. W.S.W. from Warwick by the Great Western railway, served also by the Birmingham-Evesham branch of the Midland railway. Pop. (1901) 2303. It is pleasantly situated among low wooded hills at the junction of the small stream Alne with the Arrow, a northern tributary of the Avon. On the summit of St. Edmonds Hill, which is almost surrounded by the town, is a tower, a reconstruction of 1734; among several monuments is a fine example of Chantry's work, to the 2nd marquess of Hertford (d. 1822). There are a picturesque town hall (1621), raised on stone columns, and a free grammar school. The manufacture of needles is less important than formerly, having been absorbed into the centre of the industry at Redditch in the neighbouring county of Worcestershire. There are implement works and cycle works, and brewing is prosecuted.
ALCESTIS—ALCHEMY

The name (Alcestes, Alycester) signifies “the camp on the Alcyon” or “Alycester.” The British town or village was situated here, on the road which runs from Derby and Wall, near Lichfield, to join the Fosse Way near Cirencester. Its name is not known. A relief figure in stone, some pavements, potsherds, coins, and a number of inscriptions have been found here to indicate an important station. No written document relating to Alcestes exists before the reign of Henry I. No mention occurs in Domesday, but it is given in a list of towns and villages on the Manor of Anjou belonging to the borough in the time of Henry I., and in 1177 it rendered four marks’ aid with the other boroughs of the county. However, there is no evidence of a grant of a royal charter, and the title of borough was not established until 1298. Sir John Beauchamp, who purchased the manor in 1324, was granted the borough by Henry III. The moiety of the manor was purchased by Sir Walter Beauchamp, who granted a charter to the inhabitants of the town establishing a Tuesday market for corn, cattle, and cloth, and also granted a moiety of the manor to the feasts of St Giles (afterwards transferred to the feast of St Faith) and St Barnabas. In 1444 Sir John Beauchamp purchased the remaining moiety of the manor, and was granted an additional fair at the feast of St Dunstan. From this date the Beauchamps were lords of the whole manor until it passed by female descent to the Grevilles in the reign of Henry VIII. In 1140 a Benedictine monastery was founded here by Ralph Boteler of Oversley, and received the name of the Church of Our Lady of the Isle, owing to its insulation by a moat meeting the river Arrow. The monastery was suppressed among the smaller houses in 1536. Traces of the most ancient buildings are still to be seen in Priory Close. The ancient fairs survived to the end of the 16th century. In 1830 the needle-manufacture employed nearly a thousand hands.

ALCESTIS (Alkestis), in Greek legend the daughter of Pellas and Anaxibia, and wife of Admetus, king of Phere in Thessaly. She consented to die in place of her husband, and was afterwards rescued by Heracles. This beautiful story of conjugal devotion forms the subject of the Alcestis of Euripides, which furnished the basis of Robert Browning’s Baladoun’s Adventure. Sophocles also wrote an Alcestis, of which only fragments remain.

See Diesel, Der Mythos von Admetus und Alkestis, 1882.

ALCHEMY. In the narrow sense of the word, alchemy is the pretended art of making gold and silver, or transmuting the metals alloys which simulate gold and are intended to be used in the manufacture of imitation jewellery. Possibly this is one of the books about gold and silver of which Diocletian decreed the destruction about A.D. 290—an act which Gibbon styles the first authentic event in the history of alchemy (Decline and Fall, chap. xiii.). The author of these receipts is not under any delusion that he is transmuting metals; the MS. is merely a workshop manual in which are described processes in daily use for preparing metals for false jewellery, but it argues considerable knowledge of methods of making alloys and colouring metals. It has been suggested that the workers in these processes, which were a monopoly of the priestly caste and were kept strictly secret, though fully aware that their products were not truly gold, were in time led by their success in deceiving the public to deceive themselves also, and to come to believe that they actually had the power of making gold from substances which were not gold. Philosophical sanction and explanation of this belief was then found by bringing it into relation with the theory of the prima materia, which was identical in all bodies but received its actual form by the adjunction of qualities expressed by the Aristotelian elements—earth, air, fire and water. Some support for this view is gained from study of the alchemical writings of the period. Thus, in the treatise known as Physica et Mystica and falsely ascribed to Democritus (such false attributions are a constant feature of the literature of alchemy), various receipts are given for colouring and gilding metals, but the conception of transmutation does not occur. This treatise was probably composed at a date not very different from that of the Leiden papyrus. Later, however, as in the Commentary on this work written by Synesius to Dioscorus, priest of Serapis at Alexandria, which probably dates from the end of the 4th century, a changed attitude becomes apparent; the more practical parts of the receipts are obscured or omitted, and the processes for preparing alloys and colouring metals, described in the older treatise, are by a mystical interpretation represented as resulting in real transmutation.

But while there are thus some grounds for supposing that the
idea of transmutation grew out of the practical receipts of Alexandrian Egypt, the alchemy which embraced it as a leading principle was also strongly affected by Eastern influences such as magic and astrology. The earliest Greek alchemistical writings, abundantly with references to mortal authorities and traditions. Thus the pseudo-Democritus, who was reputed the author of the *Physica et Mystica*, which itself concludes each of its receipts with a magical formula, was believed to have travelled in Chaldaea, and to have had as his master Ostanes1 the Mede, a name mentioned several times in the Leiden papyrus, and often by early Christian writers such as Tertullian, St Cyprian and St Augustine. The practices of the Persian adepts also are appealed to in the writings of the pseudo-Democritus, Zosimus and Symesius. The philosopher’s egg, as a symbol of creation, is both Egyptian and Babylonian. In the Greek alchemists it appears as the symbol at once of the art and of the universe, enclosing within itself the four elements; and there is sometimes a play of words between τὸ δὲ and τὸ φως. The conception of man, the microcosm, containing in himself all the parts of the universe or macrocosm, is also Babylonian, as again probably is the famous identification of the metals with the planets. Even in the Leiden papyrus the astronomical symbols for the sun and moon are used to denote gold and silver, and in the *Meteorologica* of Olympiodorus lead is attributed to Saturn, iron to Mars, copper to Venus, tin to Hermes (Mercury) and electrum to Jupiter. Similar systems of symbols, but elaborated to include compounds, appear in Greek MSS. of the 10th century, preserved in the library of St Mark’s at Venice. Subsequently electrum (an alloy of gold and silver) disappeared as a specific metal, and tin was ascribed to Jupiter instead, the sign of mercury becoming common to the metal and the planet. Thus we read in Chaucer (Chansons Yemannes Tale):—

The bodies seene eek, lo! hem heer anoon: Sol gold is, and Luna silver we threpe, Mars yren, Mercure quick-silver we clepe, Saturnus kel and Jupiter is tyn, And Venus coper, by my fader kin!

**Literature of Alchemy.**—A considerable body of Greek chemical writings is contained in MSS. belonging to the various great libraries of Europe, the oldest being that at St Mark’s, just mentioned. The contents of these MSS. are all of similar composition, and in Berthelot’s opinion represent a collection of treatises made at Constantinople in the 9th or 9th century. The treatises are nearly all anterior to the 7th century, and most appear to belong to the 3rd and 4th centuries; some are the work of authentic authors like Zosimus and Symesius, while of others, such as profess to be written by Moses, Democritus, Ostanes, &c., the authorship is clearly fictitious. Some of the same names and the same works can be identified in the lists of the *Kitāb-al-Fihrist*. But the Arabs did not acquire their knowledge of this literature at first hand. The earliest Hellenic culture in the East was Syrian, and the Arabs made their first acquaintance with Greek chemistry, as with Greek philosophy, mathematics, medicine, &c., by the intermediary of Syriac translations. (See Arabian Philosophy and Syriac Literature.) Examples of such translations are preserved in MSS. at the British Museum, partly written in Syriac, partly in Arabic with Syriac characters. In Berthelot’s opinion, the Syriac portions represent a compilation of receipts and processes undertaken in the Syrian school of medicine at Bagdad under the Abbasids in the 9th or 10th century, and to a large extent constituted by the earlier translations made by Serpulus of Ressena in the 6th century. They contain, under the title *De Doctrina et De发展壮大io* or *De Hominum* is a fairly methodical treatise in ten books comprising the *Arsygoepesia* and *Chrysopyesia* of the pseudo-Democritus, with many receipts for colouring metals, making artificial precious stones, effecting the *diplosis* or doubling of metals, &c. They give illustrations of the apparatus employed, and their close relationship to the Greek is attested by the frequent occurrence of Greek words and the fact that the 1 An alchemistical work bearing the name of Ostanes speaks of a divine water which cures all maladies—an early appearance of the universal panacea or elixir of life.
their authority. If this view be accepted, an entirely new light is thrown on the achievements of the Arabs in the history of chemistry. Gibbon asserts that the Greeks were inactive until the introduction of alchemy into Greece, and attributing the credit of the origin and improvement of the science to the Arabs (Decline and Fall, chap. viii.), gives the Arabs the credit of the origin and improvement of the science (chap. lii). But the chemical knowledge attributed to the Arabs has been so attributed largely on the basis of the contents of the Latin Geber, regarded as a translation from the Arabic Jaber. If, then, those contents do not represent the knowledge of Jaber, and if the contents of other Latin translations which there is reason to believe are really made from the Arabic, show little, if any, advance on the knowledge of the Alexandrian Greeks, evidently the part played by the Arabs is less. If it be assumed that the Westerns greater, than Gibbon is prepared to admit, the descent of alchemistic doctrine can thus be traced with fair certainty for a thousand years, from the Greeks of Alexandria down to the time when Latin alchemy was firmly established in the West, and began to be written of by historians such as Albertus Magnus, Roger Bacon and Arnoldus Villanovanus in the 13th century. But side by side with this literary transmission Berthelot insists that there was another mode of transmission, by means of the knowledge of practical receipts and processes traditional amongst jewellers, painters, workers in glass, and alchemists, and the chemical knowledge of Egyptian metallurgists and jewellers, he holds, was early transmitted to the artisans of Rome, and was preserved throughout the dark ages in the workshops of Italy and France until about the 13th century, when it was mingled with the theories of the Greek alchemists which reached the West by way of the Arabs. Receipts given in the Leiden papyrus reappear in the Compositiones ad Tingenand and the Mappae Clavicula, both workshop recept books, one known in 8th-century MS. at Lucca, and the other in a 10th-century MS. in the Bolognese library, and the book of the De Arithus Romanorum of Eracus and the Schedula Diversarum Artium of Theophrastus, belonging to the 12th or 13th century. 

Theory of Transmutation. —The fundamental theory of the transmutation of metals is to be found in the Greek alchemists, although in details it was modified and elaborated by the Arabs and the Latin alchemists. Regarding all substances as being composed of one primitive matter—the prima materia, and as owing its specific differences to the presence of different qualities imposed upon it, the alchemist hoped, by taking away these qualities, and by adding others, to get from it the particular substance he desired by the help of the appropriate qualities. The prima materia was early identified with mercury, not ordinary mercury, but the "mercury of the philosophers," which was the essence or soul of mercury, freed from the four Aristotelian elements—earth, air, fire and water—or rather from the qualities which they represent. Thus the operator had to remove from ordinary mercury, earth or an earthly principle or quality, and water or a liquid principle, and to fix it by taking away air or a volatile principle. The prima materia thus obtained had to be treated with sulphur (or with sulphur and arsenic) to confer upon it the desired qualities that were missing. This sulphur again was not ordinary sulphur, but some principle derived from it, which constituted the philosopher's stone or elixir—white for silver and yellow or red for gold. This is briefly the doctrine that the metals are composed of mercury and sulphur, which persisted in one form or another down to the 17th century. Of course there were numerous variations and refinements. Thus in The Speculatio of Vincent of Beauvais (c. 1259) it is said that there are four spirits—mercury, sulphur, arsenic and sal ammoniac—and six bodies—gold, silver, copper, tin, lead and iron. Of these bodies the two first are pure, the fourth last impure. Pure white mercury, fixed by the virtue of white non-corrosive sulphur, engenders in mines a matter which fusion changes into silver, and united to pure clear red sulphur it forms gold, while with various kinds of impure mercury and sulphur the other bodies are produced. Vincent attributes to Rhazes the statement that copper is potentially silver, and an "alum" or salt can eliminate the red colour will bring it to the state of silver, for it is copper in outward appearance, but in its inmost nature silver. This statement represents a doctrine widely held in the 13th century, and also to be found in the Greek alchemists, that everything endowed with a particular apparent quality possesses a hidden opposite quality, which can be rendered apparent by fire. Later, as in the works attributed to Basil Valentine, sulphur, mercury and salt are held to be the constituents of the metals. It need only be noted that the processes described by the alchemists of the 13th century are not put forward as being miraculous or supernatural; they rather represent the methods employed by nature, which is the end of the alchemist's art to reproduce artificially in the laboratory. But even among the late Arabic alchemists it was doubted whether the resources of the art were adequate to the task; and in the West, Vincent of Beauvais remarks that success had not been achieved in making artificial metals identical with the natural ones. Thus he says that the silver which has been changed into gold by the projection of the red elixir is not rendered resistant to the agents which affect silver but not gold, and Alchemist X. would have "ascribed the De Alchemia attributed to him is spurious—states that alchemy cannot change species but merely imitates them—for instance, colours a metal white to make it resemble silver or yellow to give it the appearance of gold. He has, it adds, tested gold made by alchemists, and found that it will not withstand six or seven exposures to fire. But scepticism of this kind was not universal. Roger Bacon—or more probably some one who usurped his name—declared that with a certain amount of work the boy could transmute a million times as much base metal into gold, and that the work was not finished the boast, "Mare tingerem sic mercurius esset." Numerous less distinguished adepts also practised the art, and sometimes were so successful in their deceptions that they gained the ear of kings, whose desire to profit by the achievements of science was in several instances rewarded by an abundant crop of counterfeit coins.

Later History of Alchemy. —In the earlier part of the 16th century Paracelsus gave a new direction to alchemy by declaring that its true object was not the making of gold but the preparation of medicines, and this union of chemistry with medicine was one characteristic of the iatrochemical school of which he was the precursor. Increasing attention was paid to the investigation of the properties of substances and of their effects on the human body, and chemistry profited by the fact that it passed into the hands of men who possessed the highest scientific culture of the time, Still, belief in the possibility of transmutation long remained orthodox, even among the most distinguished men of science. Thus it was accepted, at least academically, by Andreas Libavius (d. 1616); by F. de la Boê Sylvis (1641-1672), though not by his pupil Otto Thomasius, and by J. R. Glauber (1603-1668); by Robert Boyle (1627-1691) and for a time at least, by Sir Isaac Newton and his rival and rival and 2 Cf. Chaucer, Canpons. Yenamans Tale, where, however, mercury figures both as a spirit and a body—

"The firste spirit quik-silver calleth is, The seconde orpiment, the thirde wyse Sal ammoniac, and the forthre brimstoon."
contemporary, G. W. Leibnitz (1646-1716); and by G. E. Stahl (1660-1734) and Hermann Boerhaave (1668-1738). Though an alchemist, Boyle, in his "Sceptical Chemist" (1661), cast doubts on the "experiments" whereby vulgar Spagyrists are wont to endeavour to erect what salt, sulphur and mercury are to be the true particles of things, and a "corrected" version of chemical elements as those constituents of matter which cannot be further decomposed. With J. J. Becher (1633-1682) and G. E. Stahl, however, there was a reversion to earlier ideas. The former substituted for the salt, sulphur and mercury of Basil Valentine and Paracelsus three earths—the mercurial, the vitreous and the combustible—and he explained combustion as depending on the escape of this last combustible element; while Stahl's conception of phlogiston—not fire itself, but the principle of fire—by virtue of which combustible bodies burned, was a near relative of the mercurials of the philosophers, the soul or essence of ordinary mercury.

Perhaps J. B. van Helmont (1577-1644) was the last distinguished investigator who professed actually to have changed mercury into gold, though impostors and mystics of various kinds continued to claim knowledge of the art long after his time. So late as 1782, James Price, an English physician, showed experiments with white and red powders, by the aid of which he was supposed to be able to transform fifty and sixty times as much mercury into silver and gold. The metals he prepared had been known to have proved genuine on assay; whereas, however, in the following year he was challenged to repeat the experiments he was unable to do so and committed suicide.

In the course of the 19th century the idea that the different elements are constituted of different groupings or condensations of one primal matter—a speculation which, if proved to be well grounded, would imply the possibility of changing one element into another—found favour with more than one responsible chemist; but experimental research failed to yield any evidence that was generally regarded as offering any support to this hypothesis. About the beginning of the 20th century, however, the view was propounded that the spontaneous production of helium from radium may be an instance of the transformation of one element into another. (See Radioactivity; also Element and Matter.)

See M. P. E. Berthelot, Les Origines de l'alchimie (1882); Collection des anciens alchimistes grecs (text and translation, 3 vols., 1887-1888); Introduction à l'étude de la chimie des anciens et du moyen âge (1886); La Chimie du moyen âge (text and translation, 2 vols., 1893). Much bibliographical and other information about the later writers on alchemy is contained in Bibliographia Chimica (2 vols., Glasgow, 1906), a catalogue by John F. Pettigrew of the collection of James Young of Fettes (printed for private distribution).

ALCIATI, ANDREA (1492-1550). Italian jurist, was born at Alzano, near Milan, on the 12th of January 1492. He displayed great literary skill in his exposition of the laws, and was one of the first to interpret the civil law by the history, languages and literature of antiquity, and to substitute original research for the servile interpretations of the glossators. He published many legal works, and some annotations on Tacitus. His "Emblemes," a collection of moral sayings in Latin verse, has been greatly adapted and emended into French, Italian and Spanish. Alciati's history of Milan, under the title Rerum Patareorum, seu Historiae Medicolanensis, Libri IV., was published posthumously at Milan in 1625. He died at Pavia in 1550.

ALCIBIADES (c. 450-404 B.C.), Athenian general and politician, was born at Athens. He was the son of Cleinias and Deinomache, who belonged to the family of the Alcmeonidae. He was a near relative of Pericles, who, after the death of Cleinias at the battle of Coroneia (447), became his guardian. Thus early deprived of his father's control, possessed of great personal beauty and the love of great wealth, which was increased by his marriage, he showed himself self-willed, capricious and passionate, and indulged in the wildest fads and most insolent behaviour. Nor did the instructors of his early manhood supply the corrective which his boyhood lacked. From Protagoras, Prodicus and others he learnt to laugh at the common ideas of justice, temperance, holiness and patriotism. The laborious thought, the ascetic life of his master Socrates, he was able to admire, but not to imitate or practise. On the contrary, his ostentatious vanity, his amours, his debaucheries and his impious revels became notorious. But great as were his vices, his abilities were even greater.

He took part in the battle of Potidaea (432), where his life was saved by Socrates, a service which he repaid at the battle of Delium (424). As the reward of his bravery, the wealthy Hippocrates bestowed upon him the hand of his daughter. From this time he took a prominent part in Athenian politics during the Peloponnesian war. Originally friendly to Sparta, he subsequently became the leader of the war party in opposition to Nicias, and after the peace of 421 he succeeded by an unscrupulous trick in duping the Spartan ambassadors, and persuading the Athenians to conclude an alliance (420) with Argos, Elis and Mantinea (Thuc. v. 56, 76). On the failure of Nicias in Thrace (418-417) he became the chief advocate of the Sicilian expedition, seeing an opportunity for the realization of his ambitious projects, which included the conquest of Sicily, to be followed by that of Peloponnesus and possibly of Carthage (though this seems to have been an afterthought). The expedition was decided upon with great enthusiasm, and Alcibiades, Nicias and Lamachus were appointed joint commanders. But, on the day before the expedition sailed, there occurred the mysterious mutiny of the Helots which was to lead to the death of Aeschylus, and which, but for the timely intervention of his cousin, Phrynix, would have cost Alcibiades his life. The fleet avoided his vengeance and settled on the shores of Italy, where Alcibiades' ideas of a Persian satrap Tissaphernes. But in a few months he had lost the confidence of the Spartans, and at the instigation of Agis II, whose personal hostility he had excited, an order was sent for his execution. Receiving timely information of this order he crossed over to Tissaphernes (412), and persuaded him to adopt the negative policy of leaving Athens and Sparta to wear themselves out by their mutual struggles. Alcibiades was now bent on returning to Athens, and he used his supposed influence with Tissaphernes to effect his purpose. He entered into negotiations with the Persians through Demetrius of Pharos, but when these led to no result he attached himself to the fleet at Samos which remained loyal to the democracy, and was subsequently recalled by Thrasybulus, although he did not at once return to Athens. Being appointed commander in the neighbourhood of the Hellespont, he defeated the Spartan fleet at Abydos (411) and Cyzicus (410), and recovered Chalcedon and Byzantium. On his return to Athens after these successes he was welcomed with unexpected enthusiasm (407); all the proceedings against him were cancelled, and he was appointed general with full powers. His ill success, however, and the defeat of Athens at the battle of Leuctra, led to his recall, and his lieutenant Antiochus, led the Athenians to dismiss him from his command. He thereupon retired to the Thracian Chersonesus. After the battle of Aegospotami, and the final defeat of Athens, he crossed the Hellespont and took refuge with Pharnabazus in Phrygia, with the object of securing the aid of Artaxerxes against Sparta. But the Spartans induced Pharnabazus to put him out of the way; as he was about to set out for the Persian court his residence was set on fire, and on rushing out on his assassins, dagger in hand, he was killed by a shower of arrows (404).

There can be no doubt that his advice to Sparta in connexion with Syracuse and the fortification of Decelea was the real cause of his country's downfall, though it is only fair to him to add that had he been allowed to continue in command of the Sicilian expedition he would undoubtedly have overruled the fatal policy of Nicias and prevented the catastrophe of 413. His relations
ALCINIANO, PETRUS (c. 1487–1527), Italian classical scholar, was born at Venice. After having studied Greek under Marcus Musuris of Candia, he was employed for a short time by Aldus Manutius as a corrector of the press, and in 1522 was appointed professor of Greek at Florence through the influence of Giulio de’ Medici. When his patron became pope in 1523 under the title of Clement VII., Alcinicio followed him to Rome and remained there until his death. Alcício published at Venice, in 1521, a Latin translation of several of the works of Aristotle, which was shown by the Spanish scholar Sepúlveda to be very incorrect. He wrote a dialogue entitled Medicis Legatos, sine de Exilio (1522), in connexion with which he was charged with plagiarism by his personal enemy, Paulus Manutius. The accusation, which Tiraboschi has shown to be groundless, was that he had taken the finest passages in the work from Cicero’s lost treatise De Gloria, and had then destroyed the only existing copy of the original in order to escape detection. His contemporaries speak very unfavourably of Alcício, and accuse him of haughtiness, uncothurtness, vanity and licentiousness.

ALCIPHRON, Greek rhetorician, was probably a contemporary of Lucian (2nd century A.D.). He was the author of a collection of fictitious letters, of which 124 (118 complete and 6 fragments) have been published; they are written in the purest Attic dialect and are considered models of style. A fragment of a work speaking extempore on every conceivable subject. Aristotle (Rhet. iii. 3) criticizes his writings as characterized by pomposity of style and an extravagant use of poetical epithets and compounds and far-fetched metaphors. Of other works only fragments and the titles have survived: Μεστρικος, advocating the freedom of the Messenians and containing the sentiment that “all are by nature free”; a Eulogy of Death, in consideration of the wide extent of human sufferings; a Τεχνη or instruction-book in the art of rhetoric; and a Ψευδος λογος. Lastly, his Μεστρος (a work of half-freedom containing the narrative of the contest between Homer and Hesiod, 2 fragments of which are found in the ‘Αγορα Ὀμυρου καὶ Πεβόου, the work of a grammarians in the time of Hadrian. A 3rd-century papyrus (Flanders Petrie, Papryri ed. Mahaffy, 1891, pl. xxv) probably contains the actual remains of a description by Alcidos.

See the edition by Blass, 1881; fragments in Müller, Oratones Attici, ii. (1858); Vahlen, Der Rhetor Alkidasmon (1864); Blass, Die ed. Bruns-Berlenbach, 1880.

ALCINOUS (ALKINOS), in ancient Greek legend, king of the fabulous Phaeacians, in the island of Scheria, was the son of Nautilus and grandson of Poseidon. His reception and entertainment of Odysseus, who when cast by a storm upon the island was relieved by the king’s daughter, Nausicaa, is described in the Odyssey (vi.–xiii). The gardens and palace of Alcinoos and the wonderful ships of the Phaeacian mariners were famous in antiquity. Scheria was identified in very early times with Corcyra, where Alcinoos was revered as a hero. In the Argonautic legend, his abode was the island of Drepane (Apoll, Rhodius iv. 990).

ALCINOUS, the Platonic philosopher, lived probably in the time of the Caesars. He was the author of an Εντομα τιν Πλατων θυμων, an analysis of Plato’s philosophy according to later writers. It is rather in the manner of Aristotle, and freely attributes to Plato any ideas of other philosophers which appeared to contribute to the system. He produced in the end a synthesis of Plato and Aristotle with an admixture of Pythagorean or Oriental mysticism, and is closely alluded to the Alexandrian school of thought. He recognized a God who is unknowable, and a series of beings (σαλπόσε) who hold intercourse with men. He recognized also Ideas and Matter, and borrowed largely from Aristotle and the Stoics.

The ‘Εντομα has been translated by Pierre Balbi (Rome, 1469) and by Marsilio Ficino; into French by J. I. Combes-Dournou (Paris, 1800), and into English by Thomas Stanley in his History of Philosophy (Leipzig, 1785); in Aldine Edition of Apuleius (Venice, 1521; Paris, 1532); Fell (Oxford, 1667). See Ritter, Geschichte der Philosophie, iv. 249.
ALCMAEONIDAE, a noble Athenian family, claiming descent from Alcmaeon, the great-grandson of Nestor, who emigrated from Pylus to Athens at the time of the Doric invasion of Peloponnesus. During the archonship of an Alcmaeonid Megacles (? 632 B.C.), Cylon, who had unsuccessfully attempted to make himself "tyrant," was treacherously murdered with his followers. The curse or pollution thus incurred was frequently in later years raked up for political reasons; the Spartans even demanded that Pericles should be expelled as accused at the beginning of the Peloponnesian war. All the members of the family went into banishment, and having returned in the time of Solon (594) were again expelled (538) by Peisistratus (q.v.). This forced them to continue their exile to enhance their reputation and secure the favour of the Delphian Apollo by rebuilding the temple after its destruction by fire in 548. Their importance is shown by the fact that Cleisthenes, tyrant of Sicyon, gave his daughter Agariste in marriage to the Alcmaeonid Megacles in preference to all the assembled suitors after the undignified behaviour of Hippocleides. Under the statesman Cleisthenes (q.v.), the issue of this union, the Alcmaeonids became supreme in Athens about 510 B.C. To them was generally attributed (though Herodotus disbelieves the story—see Greece, Ancient, Section "I.") the treacherous raising of the shield as a signal to the Persians at Marathon, but, whatever the truth of this may be, there can be little doubt that they were not the only one of the great Athenian families. The Alcmaeons were still in the service of the Persians to the middle of the 5th century B.C. They were considered the inventors of the Doric lyric poetry. He was evidently fond of good living, as his love of Asiatic luxury seems out of place amidst Spartan simplicity. The fragments are scanty, the most considerable being part of a Parthenion found in 1855 on an Egyptian papyrus; some recently discovered hexameters are attributed to Alcman or Erinna (Öxynyxhynus papyri, i. 1898).

For general authorities see Alceaus.

ALCMEN, or Alcmæon (the former being the Doric form of the name), the founder of Doric lyric poetry, to whom was ascribed the first among the nine lyric poets of Greece in the Alexandrian canon, flourished in the latter half of the 7th century B.C. He was a Lydian of Sardis, who came as a slave to Sparta, where he lived in the family of Agesias, by whom he was emancipated. His mastery of Greek shows that he must have come very early to Sparta, where, after the close of the Messenian wars, the people were able to bestow their attention upon the arts of peace. Alcman composed various kinds of poems in various metres; Parthenia (maiden's songs), hymns, paean, prosodia (processional), and love-songs, of which he was considered the inventor. He is evidently fond of good living, as his love of Asiatic luxury seems out of place amidst Spartan simplicity. The fragments are scanty, the most considerable being part of a Parthenion found in 1855 on an Egyptian papyrus; some recently discovered hexameters are attributed to Alcman or Erinna (Öxynyxhynus papyri, i. 1898).

For general authorities see Alceaus.

ALCMENÉ, in ancient Greek mythology, the daughter of Electryon, king of Mycena, and wife of Amphitrion. She was the mother of Heracles by Zeus, who assumed the likeness of her husband during his absence, and of Iphicles by Amphitrion. She was regarded as the ancestress of the Heracleidae, and worshipped at Thebes and Athens.

See Winter, Alkmene und Amphitryon (1876).

ALCOBAÇA, a town of Portugal, in the district of Leiria, formerly included in the province of Estremadura, on the Alcoa and Baça rivers, from which it derives its name. Pop. (1900) 2309. Alcobaca is chiefly interesting for its Cistercian convent, now partly converted into schools and barracks. The ministered buildings, which form a square 725 ft. in diameter with a huge conical chimney rising above them, were founded in 1148 and completed in 1222. During the middle ages it rivalled the greatest European abbeys in size and wealth. It was supplied with water by an affluent of the Alcoa, which still flows through the kitchen; its abbot ranked with the highest Portuguese nobles, and, according to tradition, 999 monks continued the celebration of mass without interruption throughout the year. The convent was partly burned by the French in 1810, secularized in 1834 and afterwards gradually restored. Portions of the library, which comprised over 100,000 volumes, including many precious MSS., were saved in 1810, and are preserved in the public libraries of Lisbon and Braga. The monastic church (1222) is a good example of early Gothic, somewhat defaced by Moorish and other additions. It contains a fine cloister and the tombs of Peter I. (1357-1367) and his wife, Iñez de Castro.

ALCOCK, JOHN (1430-1500), English divine, was born at Beverley in Yorkshire and educated at Cambridge. In 1461 he was made dean of Westminister, and henceforward his promotion was rapid in church and state. In the following year he was made master of the rolls, and in 1470 was sent as ambassador to the court of Castile. He was consecrated bishop of Chester in 1472, and was successively translated to the sees of Worcester (1476) and Ely (1489). He was a distinguished preacher of lord chancellor, and exhibited great ability in the negotiations with James III. of Scotland. He died at Wigsbeach Castle on the 1st of October 1500. Alcock was one of the most eminent pre-Reformation divines; he was a man of deep learning and also of great proficiency as an architect. Besides founding a charity at Beverley and a grammar school at Kingston-upon-Hull, he restored many churches and colleges; but his greatest enterprise was the erection of Jesus College, Cambridge, which he established on the site of the former college of St Radegund.

Alcock's published writings, most of which are extremely rare, are: Mons Perfectionis, or the Hill of Perfection (London, 1497); Gallicanium Johannis Alcock episcopi Eliensis ad fratres suos curatos in prope Blandford Baptistiam (1498), a good specimen of early English printing and quaint illustrations; The Castle of Labour, translated from the French (1536), and various other tracts and homilies. See J. Bass Mullinger, Hist. of the University of Cambridge, vol. i.

ALCOCK, SIR RUTHERFORD (1809-1867), British consular and diplomatist, was the son of Dr Thomas Alcock, who practised at Ealing, near London, and himself followed the medical profession. In 1836 he became a surgeon in the marine brigade which took part in the Carlist war, and gaining distinction by his services was made deputy inspector-general of hospitals. He retired from this service in 1837, and seven years later was appointed consul at Fuchow in China, where, after a short official stay at Amoy, he performed the functions, as he himself expressed it, "of everything from a lord chancellor to a sheriff's officer. Fuchow was one of the ports opened to trade by the treaty of 1842, and Mr Alcock, as he then was, had to maintain an entirely new position with the Chinese authorities. In so doing he was eminently successful, and earned for himself promotion to the consulate at Shanghai. Thither he went in 1846 and made it an essential part of his duties to superintend the establishment and laying out of the British settlement, which has developed into such an important feature of British commercial life in China. In 1858 he was appointed consul-general in the newly opened empire of Japan, and in the following year was promoted to be minister plenipotentiary. In those days residence in Japan was surrounded with many dangers, and the people were intensly hostile to foreigners. In 1860 Mr Alcock's native interpreter was murdered at the gate of the legation, and in the following year the legation was stormed by a body of Ronins, whose attack was repulsed by Mr Alcock and his staff. Shortly after this event he returned to England on leave. Already he had been made a C.B. (1860); in 1862 he was made a K.C.B., and in 1863 hon. D.C.L. Oxon. In 1864 he returned to Japan, and after a year's further residence he was transferred to Pekin, where he represented the British government until 1871, when he retired. But though no longer in official life his leisure was fully occupied. He was for some years president of the Royal Geographical Society, and he served on many commissions. He was twice married, first in May 1841 to Henrietta Mary, daughter of Charles Bacon, who died in 1853, and secondly (July 8, 1862) to the widow of the Rev. John Lowder, who died on the 13th of March 1899. He was the author of several works, and was one of the first to awaken in England an interest in Japanese art; his best-known book is The Capital of the Tycoon, which appeared in 1863. He died in London on the 2nd of November 1897.
ALCOFARDO, MARIANNA (1640-1723), Portuguese author, wrote of the Letters of a Portuguese Nun, which was the daughter of a landed proprietor in Alemtejo. Beja, her birthplace, was the chief garrison town of that province, itself the principal theatre of the twenty-eight years' war with Spain that followed the Portuguese revolution of 1640, and her widowed father, occupied with administrative and military commissions, placed Mariana in her childhood in the wealthy convent of the Conception for security and education. She made her profession as a Franciscan nun at sixteen or earlier, without any real vocation, and lived a routine life in that somewhat relaxed hospice, and received a passion which in the later part of the century has lost nothing of its heat. Perhaps her dominant note is reality, and, sad reading as they are from the moral standpoint, their absolute candour, exquisite tenderness and entire self-abandonment have excited the wonder and admiration of great men and women in every age, from Madame de Sevigné to W. E. Gladstone. There are signs in the fifth letter that Mariana had begun to conquer her passion, and after a life of rigid penance, accompanied by much suffering, she died at the age of eighty-three. The letters came into the possession of the Duke of Berwick, director of the Gazette de France, who turned them into French, and they were published anonymously in Paris in January 1669. A Cologne edition of the same year stated that Chamilly was their addressee, which is confirmed by St Simon and Duclos, but the name of their authoress remained undivulged. In 1810, however, Boissonead discovered Mariana's name written in a copy of the first edition by a contemporary hand, and the veracity of this assumption has been placed beyond doubt by the recent investigations of Luciano Cordeiro, who found a tradition in Beja connecting the French captain and the Portuguese nun. The letters created a sensation on their first appearance, running through five editions in a year, and, to exploit their popularity, second parts, replies and new replies were issued from the press in quick succession. Notwithstanding that the Portuguese original of the five letters is lost, their genuineness is as patent as the spuriousness of their followers, and though Rousseau was ready to wager they were written by a man, the principal critics of Portugal and France have decided against him. It is now generally recognized that the letters are a verbatim translation from the Portuguese.

The foreign bibliography of the Letters, containing almost one hundred numbers, will be found in Cordeiro's admirable study, Seror Mariana, A Fria Portuguesa, 2nd ed. (Lisbon, 1891).

Besides the French editions, versions exist in Dutch, Danish, Italian and German; and the English bibliography is given by Edgar Prestage in his translation The Letters of a Portuguese Nun (Mariana Alcoforado), 3rd ed. (London, 1905). The French text of the editio princeps was published in one volume, and to avoid the use of an almanac, which is a hydrometer graduated so as to read per cents by weight (degrees according to Richter) or volume per cents (degrees according to Tralles). Other methods consist in determining the vapour tension by means of the vaporimeter of Geissler, or the boiling point by the ebulliometer. In the United Kingdom "proof spirit" is defined as having a specific gravity of 0.8216 at 15°C compared with water at the same temperature. The "quantity at proof" is given by the formula:

\[ \text{Proportional quantity} = \frac{21}{17} \times \text{specific gravity} \]

ALCOFARDO—ALCOHOL

ALCOHOL, in commerce, the name generally given to "spirits of wine"; in systematic organic chemistry it has a wider meaning, being the generic name of a class of compounds (hydroxy hydrocarbons) of which ordinary alcohol (specifically ethyl alcohol) is a typical member (see ALCOL). The word "alcohol" is of Arabic origin, being derived from the particle al and the word kohl, an impalpable powder used in the East for painting the eyebrows. For many centuries the word was used to designate any fine powder; its present-day application to the product of the distillation of wine is of comparatively recent date. Thus Paracelsus and Librizius both used the term to denote a fine powder, the latter distinguishing one of the alcohols derived from antimony. At the same time Paracelsus uses the word for a volatile liquid; alcohol or alcohol vinis occurs often in his writings, and once he adds "id est vino ardentie." Other names have been in use among the earlier chemists for this same liquid. Eau de vie ("elixir of life") was in use during the 13th and 14th centuries; Arnoldus Villanovanus applied it to the product of distilled wine, though not as a specific name.

The primordial alcohol, which we shall frequently refer to by its specific name, ethyl alcohol, seldom occurs in the vegetable kingdom; the unripe seeds of Heracleum giganteum and H. Spondylium contain it mixed with butyrate. In the animal kingdom it occurs in the urine of diabetic patients and of persons addicted to alcohol. Its important source lies in its formation by the "spirituous" or "alcoholic fermentation" of saccharine juices. The mechanism of alcoholic fermentation is discussed in the article FERMENTATION, and the manufacture of alcohol from fermented liquors in the article SPIRITS.

The qualitative composition of ethyl alcohol was ascertained by A. L. Lavoisier, and the quantitative by N. T. de Saussure in 1808. Sir Edward Frankland showed how it could be derived from, and converted into, ethane; and thus determined it to be ethane in which one hydrogen atom was replaced by a hydroxyl group. Its constitutional formula is therefore CH₃OH. It may be synthetically prepared by any of the general methods described in the article ALCOHOLS.

Pure ethyl alcohol is a colourless, mobile liquid of an agreeable odour. It boils at 78°-5 C. (760 mm.); at -90° C. it is a thick liquid, and at -230° C. it solidifies. In the use of an alcoholometer, which is a hydrometer graduated so as to read per cents by weight (degrees according to Richter) or volume per cents (degrees according to Tralles). Other methods consist in determining the vapour tension by means of the vaporimeter of Geissler, or the boiling point by the ebulliometer. In the United Kingdom "proof spirit" is defined as having a specific gravity of 0.8216 at 15°C compared with water at the same temperature. The "quantity at proof" is given by the formula:
of sample X (degrees over or under proof + 100) divided by 100.

The presence of water in alcohol may be detected in several ways. Aqueous alcohol becomes turbid when mixed with benzene, carbon disulphide or paraffin oil; when added to a solution of barium oxide in absolute alcohol, a white precipitate of barium hydroxide is formed. A more delicate method consists in adding a very little anthraquinone and sodium amalgam; absolute alcohol gives a green coloration, but in the presence of minute traces of water a red coloration appears. Traces of ethyl alcohol in solutions are detected and estimated by oxidation to acetaldehyde, or by conversion into iodoforom by warming with iodine and potassium hydroxide. An alternative method consists in converting it into ethyl benzoate by shaking with benzoyl chloride and caustic soda.

Alcohol is extensively employed as a solvent; in fact, this constitutes one of its most important industrial applications. It dissolves most organic compounds, resins, hydrocarbons, fatty acids and many metallic salts, sometimes forming, in the latter case, crystalline compounds in which the ethyl alcohol plays a rôle similar to that of water of crystallization. This fact was first noticed by T. Graham, and, although it was at first contradicted, its truth was subsequently confirmed. In general, gases dissolve in it more readily than in water; 100 volumes of alcohol dissolve 7 volumes of hydrogen, 25 volumes of oxygen and 16 volumes of nitrogen.

Potassium and sodium readily dissolve in ethyl alcohol with the production of alcohohates of the formula $\text{C}_2\text{H}_5\text{OK}$ (Na).

**Reactions.** These are voluminous white powders. Sulphuric acid converts it into ethyl sulphuric acid (see EtHER), and sulphur trioxide gives carbyl sulphate. The phosporous haloids give the corresponding ethyl haloid. Ethyl chloride (from the phosphorus chlorides and alcohol) is an ethereal liquid boiling at $124^\circ\text{C}$. soluble in alcohol, but sparingly so in water. Oxidation of ethyl alcohol gives acetaldehyde and acetic acid. Chlorine oxidizes it to acetaldehyde, and under certain conditions choral (q.v.) is formed.

In almost all countries heavy taxes are levied on manufactured alcohol mainly as a source of revenue. In the United Kingdom the excise duty is eleven shillings per proof gallon of alcohol, while the customs duty is eleven shillings and fivepence; the magnitude of these imposts may be more readily understood when one remembers that the proof gallon costs only about sevenpence to manufacture. The great importance of alcohol in the arts has necessitated the introduction of a duty-free product which is suitable for most industrial purposes, and at the same time is perfectly unfit for beverages or internal application.

In the United Kingdom this "denaturised" alcohol is known as methylated spirit as a distinction from pure alcohol or "spirits of wine." It was first enacted in 1855 that methylated spirit, a specific mixture of pure alcohol and wood-naphtha, should be duty-free; the present law is to be found in the Customs and Inland Revenue Act of 1890, and the Finance Act (sect. 8) of 1902. From 1858 to 1861 methylated spirit was duty-free when it was required for manufacturing processes, and the methylation or "denaturizing" was carried out in accordance with a prescribed process. During the next three decades (1861-1891) the law was extended, and methylated spirit was duty-free for all purposes except for use as beverage and internal medicinal applications. This spirit ("unmineralised methylated spirit") consisted of 90 parts of alcohol of 60-66 proof-over (91-95% of pure alcohol) and 10 parts of wood-naphtha. It was found, however, that certain classes were addicted to drinking this mixture, and since 1891 the sale of such spirit has been confined to manufacturers who must purchase it in bulk from the "methylators." For retail purposes the "ordinary" methylated spirit is mixed with 3.57% of mineral naphtha, which has the effect of rendering it quite undrinkable. The Finance Act of 1902 allows a manufacturer to obtain a license which permits the use of duty-free alcohol, if he can show that such alcohol is absolutely essential for the success of his business, and that methylated spirit is unsuitable. Notwithstanding this permission there have been many agitation on the part of chemical manufacturers to obtain a less restricted use of absolute alcohol, and in 1905 an Industrial Alcohol Committee was appointed to receive evidence and report as to whether any modification of the present law was advisable.

In the United States the same question was considered in 1896 by a Joint Select Committee on the use of alcohol in the manufactures and arts. Reference should be made to the reports of these committees for a full account of the use, manufacture and statistics of "denaturised" spirits in various European countries.

In Germany, the use of duty-free spirit is only allowed to state and municipal hospitals, and state scientific institutions, and for the manufacture of fulminates, fuses and smokeless powders. The duty-free "denaturised" spirits may be divided into two groups—"completely denaturised" and "incompletely denaturised." In the first category there are two varieties:—(1) A mixture of 100 litres of spirit and 2/3 litres of a mixture of 4 parts of wood-naphtha and 1 of pyridine bases; this spirit, the use of which is practically limited to heating and lighting purposes, may be mixed with 30 g.s. of lavender or rosemary, in order to destroy the noxious odour of the pyridine bases. (2) A mixture of 100 litres of spirit, 1/4 litres of methylated spirit, 1/4 litres of methyl violet solution, and from 2 to 20 litres of benzol; this fluid is limited to combustion in motors and agricultural engines. The second category, or "incompletely denaturated" spirits, include numerous mixtures. The "general" mixture consists of 100 litres of spirit, and 5 litres of wood spirit or 1 litre of pyridine. Of the "particular" varieties, we can only notice those used in the colour industry. These consist of 100 litres of spirit mixed with either 10 litres of sulphur ether, or 1 litre of benzol, or 1/4 litre of turpentine, or 0.025 litre of aniline oil.

The German regulations are apparently based on a keen appreciation of the fact that while one particular denaturizing agent may have little or no effect on one industry, yet it would be quite fatal to the success of another; there is consequently a great choice of denaturizing agents, and in certain cases it is sufficient to mix the alcohol with a reagent necessary for the purpose in hand, or even with a certain amount of the final product, it being only necessary to satisfy the state that the spirit is not available as a beverage.

In France, the general denaturizing agent is wood-spirit of at least 80%-proof, containing 5% of acetone and 2.5% of "impurités pyrogenes"; 10 litres of this spirit denaturizes 100 litres of alcohol. This mixture is supplied to manufacturers and corresponds to the British unmineralised methylated spirit; but the regulations are more stringent. When sold for lighting and heating purposes, it is further admixed with 0.5% of heavy benzene boiling at 150-200° C. Provisions are also made for special denaturizing processes as in Germany.

In America the internal revenue tax on denaturised alcohol (formerly duty-free only to scientific institutions) was removed by Congress in 1906 (act of June 7th).

**Pharmacology, Toxicology and Therapeutics of Alcohol.** Alcohol is of great medicinal value as a solvent, being used to form solutions of alkaloins, resins, volatile oils, iodoforom, &c. In strength of about 10% and upwards it is an antiseptic. If applied to the skin it rapidly evaporates, thereby cooling the skin and diminishing the amount of sweat excreted. This refrigerant and anodynic action is employed to soothe the many forms of headache by bathing the forehead with eau de Cologne. If, on the other hand, the alcohol be rubbed into the skin, its consequent evaporation be prevent by placing a watch-glass—it absorbs water from the tissues and thus hardens them.

Thoroughly rubbed into the skin alcohol dilates the blood-vessels and produces a mild counter-irritant effect. Many alcoholic liniments are therefore employed for the relief of pain, especially muscular pains, as in lumbago and other forms of so-called "muscular rheumatism." Given internally in small quantities and in sufficient dilution, alcohol causes dilatation of
the gastric blood-vessels, increased secretion of gastric juice, and greater activity in the movements of the muscular layers in the wall of the stomach. It also tends to lessen the sensibility of the stomach and so may relieve gastric pain. In a 50% solution or stronger—as when neat whisky is taken—alcohol precipitates the pepsin in which is an essential of gastric digestion, and thereby arrests this process. The desirable effects produced by alcohol on the stomach are worth obtaining only in cases of acute diseases. In chronic disease and in health the benefit of alcohol as an aid to digestion is without the support of clinical or laboratory experience, the beneficial action being at least neutralized by undesirable effects produced elsewhere. The continued use of large doses of alcohol produces chronic gastritis, in which the continued irritation has led to overgrowth of connective tissue, atrophy of the gastric glands and permanent cessation of the gastric functions.

A single dose of concentrated alcohol (e.g. brandy) produces very valuable reflex effects, the heart beating more rapidly and forcibly, and the blood-pressure rising. Hence the immediately beneficial effect produced in the cases of "fainting" or syncope. After absorption, which is very rapid, alcohol exerts a marked action upon the blood. The oxygen contained in that fluid, and destined for consumption by the tissues, is retained by the influence of alcohol in its combination with the haemoglobin or colouring matter of the red blood corpuscles. Hence the diminished oxidation of the tissues, which leads to the accumulation of unused fat and so to the obesity which is so often seen in those who habitually take much alcohol. The drug exerts a noteworthy action upon the body-temperature. As it dilates the blood-vessels of the skin it increases the subjective sensation of warmth. The actual consequence, however, is that more heat than before is necessarily lost from the surface of the body. Alcohol also diminishes the oxidation which is the main source of the body-heat. It follows that the drug is an antipyretic, and it is hence largely used in fevers as a means of reducing the temperature. This reduction of the temperature, carried to an undesirable extreme, is the reason why the man who has copiously consumed spirits "to keep out the cold" is often visited with pneumonia. The largest amount of alcohol that can be burnt up within the healthy body in twenty-four hours is 1½ oz., but it must be consumed in great dilution and divided into small doses taken every four hours. Otherwise the alcohol will for the most part leave the body unused in the urine and the expired air. In fever the case is different. The raised temperature appears to facilitate the oxidation of the substance, so that quantities may be taken and completely utilized which would completely intoxicate the individual had his temperature been normal. It follows that alcohol is a food in fever, and its value in this regard is greatly increased by the fact that it requires no primary digestion, but passes without change, and without needing change, to the tissues which are to use it. According to Sir Thomas Fraser nothing else can compete with alcohol as a food in desperate febrile cases, and to this use must be added its antipyretic power already explained and its action as a soporific. During its administration in febrile cases the drug must be most carefully watched, as its action may prove deleterious to the nervous system and the circulation in certain classes of patients. The state of the pulse is the best criterion of the action of alcohol in any given case of fever. The toxicology of alcohol is treated in other articles. It includes acute alcoholism (i.e. intoxication), chronic alcoholism, delirium tremens, and all the countless pathological changes—extending to every tissue but the bones, and especially marked in the nervous system—which alcohol produces. (See Drunkenness; Delirium.)

After death the presence of alcohol can be detected in all the body fluids. Its especial affinity for the nervous system is indicated by the fact that, when all traces of it have disappeared elsewhere, it can still be detected with ease in the cerebro-spinal fluid.

**ALCOHOLS,** in organic chemistry, a class of compounds which may be considered as derived from hydrocarbons by the replacement of one or more hydrogen atoms by hydroxyl groups. It is convenient to restrict the term to compounds in which the hydroxyl group is attached to an aliphatic residue; this excludes such compounds as the hydroxy-benzenes, naphthalenes, &c., which exhibit many differences from the compounds derived from the aliphatic alcohols.

Alcohols are classified on two distinct principles, one depending upon the number of hydroxyl groups present, the other on the nature of the remaining groups attached to the carbon atom (i.e. the hydrocarbon). More specifically, the monohydric alcohols contain only one hydroxyl group; diatomic, two, known as glycols (q.v.); triatomic, three, known as glycerols (q.v.); and so on.

The second principle leads to alcohols of three distinct types, known as primary, secondary and tertiary. The genesis and formulation of these types may be readily understood by considering the relation which exists between the alcohols and the parent hydrocarbon. In methane, CH₄, the hydrogen atoms are of equal value, and hence only one alcohol, viz. CH₂OH, can be derived from it. This compound, methyl alcohol, is the simplest primary alcohol, and it is characterized by the grouping -CH₂OH. Ethane, CH₃H₂, in a similar manner, can only give rise to one alcohol, namely ethyl alcohol, CH₃CH₂OH, which is also primary. Propane, CH₃CH₂CH₃, can give rise to two alcohols—a primary alcohol, CH₃CH₂CH₂OH (normal propyl alcohol), formed by replacing a hydrogen atom attached to a terminal carbon atom, and a secondary alcohol, CH₃CH(OH)CH₃ (iso-propyl alcohol), when the substitution is effected on the middle carbon atom. The grouping CH₂OH characterizes the secondary alcohols; isopropyl alcohol is the simplest member of this class. Butane, CH₃CH₂CH₂CH₃, contains the two isomeric forms—normal butane, CH₃CH₂CH₂CH₂H, and iso-butane, CH₃CH(CH₃)₂. Each of these hydro-carbons gives rise to two alcohols: n-butanediol gives a primary and a secondary; and iso-butanediol a primary, when the substitution takes place in one of the methyl groups, and a tertiary, when the hydrogen atom of the CH group is substituted. Tertiary alcohols are thus seen to be characterized by the group -CH₃, in which the residual valencies of the carbon atom are attached to alkyl groups.

In 1860 Hermann Kolbe predicted the existence of secondary and tertiary alcohols from theoretical considerations. Regarding methyl alcohol, for which he proposed the name carbinol, as the simplest alcohol, he showed that by replacing one hydrogen atom of the methyl group by an alkyl residue, compounds of the general formula R-CH₂OH would result. These are the primary alcohols. By replacing two of the hydrogen atoms, either by the same or different alcohols, compounds of the formula (R-R')CH₂(OH) (i.e. secondary alcohols) would result; while the replacement of the three hydrogen atoms would generate alcohols of the general formula (R-R-R')O-H, i.e. tertiary alcohols. Furthermore, he exhibited a comparison between these three types of alcohols and the amines. Thus:

- R-NH₂
- R-CH₂OH
- R₂N
- R₂CH₂OH

Primary. Secondary. Tertiary.

To distinguish Primary, Secondary and Tertiary Alcohols.—Many reactions serve to distinguish these three types of alcohols. Of chief importance is their behaviour on oxidation. The primary alcohols are first oxidized to aldehydes (q.v.), which, on further oxidation, yield acids containing the same number of carbon atoms as in the original alcohol. Secondary alcohols yield ketones (q.v.), which are subsequently oxidized to a mixture of two acids. Tertiary alcohols yield neither aldehydes nor ketones, but a mixture of two or more acids. Another method is based upon the different behaviour of the corresponding nitro-alcohol with nitrous acid. The alcohol is first acted upon with phosphorus and iodine, and the resulting alkyl iodide is treated with silver nitrite, which gives the corresponding nitro-alcohol. The nitro-alcohol is then treated with potassium nitrate, and concentrated potash, and sulphuric acid is added. By this treatment a primary nitro-alcohol yields a nitric acid, the potassium salt of which forms an intense red solution; a secondary nitro-alcohol forms a pseudo nitroil, which gives an
intense blue solution, while the tertiary compound does not act with nitrous acid. The reactions outlined above may be thus represented:

\[
\begin{align*}
\text{R-CH}_2\text{OH} & \rightarrow \text{R-CH}_2\text{I} & \rightarrow \text{R-CH}_2\text{NO}_3 & \rightarrow \text{R-C}^+\text{NO}_2^- \\
\text{Acetaldheyde.} & & & \\
\text{Primary alcohol.} & & & \\
\text{R}^+\text{OH} & \rightarrow \text{R}^+\text{HI} & \rightarrow \text{R}^+\text{CH}=\text{O} & \rightarrow \text{R}^+\text{C}=\text{NO}_2^- \\
\text{Nitric acid.} & & & \\
\text{Secondary alcohol.} & & & \\
\text{(R}_3\text{R}_2\text{R})^+\text{O} & \rightarrow \text{(R}_3\text{R}_2\text{R})^+\text{C}=\text{I} & \rightarrow \text{(R}_3\text{R}_2\text{R})^+\text{CH}=\text{O} & \rightarrow \text{(R}_3\text{R}_2\text{R})^+\text{C}=\text{NO}_2^- \\
\text{Pseudo nitro.} & & & \\
\text{Tertiary alcohol.} & & & \\
\end{align*}
\]

By heating to the boiling point of naphthalene (218°) tertiary alcohols are decomposed, while heating to the boiling point of antracene (360°) suffices to decompose secondary alcohols, the primary remaining unaffected. These changes can be followed out by determinations of the vapour density, and so provide a method for characterizing alcohols (see Compt. Rend. 1904, 138, p. 984).

Tertiary alcohol.

It is interesting to note that, whereas zinc methyl and ethyl give tertiary alcohols, zinc propyl only gives secondary alcohols. During recent years (1900 onwards) many brilliant syntheses have been effected by the aid of magnesium-alkyl-haloaloids.

The alcohols are neutral in reaction, and the lower members possess the property of entering into combination with salts, in which the alcohol plays the rôle of water of crystallization. Sodium or potassium dissolves in them with the formation of alcoholates, the hydrogen of the hydroxyl group being replaced by the metal. With strong acids water is split off and esters are formed. The haloid esters of the paraflin alcohols formed by heating the alcohols with the halogen acids are the monohaloid derivatives of the paraflins, and are more conveniently prepared by the action of the phosphorous haloid on the alcohol. Energic dehydration gives the olefine hydrocarbons, but under certain conditions ethers (see Ether) are obtained.

The physical properties of the alcohols exhibit a gradation with the increase of molecular weight. The lower members are colourless mobile liquids, readily soluble in water and exhibiting a characteristic odour and taste. The solubility decreases as the carbon chain increases. The normal alcohols containing 1 to 16 carbon atoms are liquids at the ordinary temperatures; the higher members are crystalline, odourless and tasteless solids, closely resembling the fats in appearance. The boiling points of the normal alcohols increase regularly about 16° for each CH₂ increment; this is characteristic of all homologous series of organic compounds. Of the primary, secondary and tertiary alcohols having the same empirical formula, the primary have the highest, and the tertiary the lowest boiling point; this is in accordance with the fairly general rule that a gain in symmetry is attended by a fall in the boiling point.

The following monatomic alcohols receive special treatment under their own headings: ALCOHOL, ETHYL, ALKYL, ALCOHOL, AMYL, BENZYLALCOHOL, BUTYLALCOHOLS, METHYLALCOHOL, and PROPYL ALCOHOLS.
beautiful old age in his Concord home, the Orchard House, where evergreens were provided by his daughter Louisa (q.v.). Alcott was gratified at being able to become the nominal, and at times the actual, head of a Concord "Summer School of Philosophy and Literature," which had its first session in 1879, and in which—in a rudely fashioned building next his house—thoughtful listeners were addressed during a part of several successive summer seasons on many themes in philosophy, religion, and letters. Of Alcott's published works the most important is Tablets (1868); next in order of merit is Concord Days (1872). His Sounds and Consounds (1882) are chiefly interesting as an old man's exercise in verse. He left a large and sheen of personal jottings and memorabilia, most of which remain unpublished. He died in Boston on the 4th of March 1888. Alcott was a Garrisonian abolitionist.

See A. Bronson Alcott, His Life and Philosophy (2 vols., Boston, 1893), by F. B. Sanborn and William T. Harris; New Connecticut as an Autobiographical Poem (Boston, 1887), edited by F. B. Sanborn; and Lowell's criticism in his Fable for Critics. (C. P. R.)

ALCOTT, LOUISA MAY (1832–1888), American author, was the daughter of Amos Bronson Alcott, and through of New England parentage and residence, was born in Germantown, now part of Philadelphia, Pennsylvania, on the 29th of November 1832. She began work at an early age as an occasional teacher and as a writer—her first book was Flower Pikes (1854), tales originally written for Ellen, daughter of R. W. Emerson. In 1872–1873, she wrote for the Atlantic Monthly, and was a nurse in the Union Hospital at Georgetown, D.C., for six weeks in 1862–1863. Her home letters, revised and published in the Commonwealth and collected as Hospital Sketches (1863, re-published with additions in 1869), displayed some power of observation and record; and Moods, a novel (1864), despite its uncertainty of method and of touch, gave considerable promise. She soon turned, however, to the rapid production of stories for girls, and, with the exception of the creepy tale entitled Work (1873), and the anonymous novelette A Modern Mephisto- philes (1877), she did not return to the more ambitious fields of the novelist. Her success came from the appearance of the first series of Little Women: or Meg, Jo, Beth and Amy (1868), in which, with unfailing humour, freshness and lifeliness, she put into story form many of the sayings and doings of herself and sisters. Little Men (1871) similarly treated the character and ways of her nephews in the Orchard House in Concord, Massachusetts, in which Miss Alcott's industry had now established her parents and other members of the Alcott family; but most of her later volumes, An Old-Fashioned Girl (1879), A Daughter of the House (1879), and Jo's Boys (1886), &c., followed in the line of Little Women, of which the author's large and loyal public never wearied. Her natural love of labour, her wide-reaching generosity, her quick perception and her fondness for sharing with her many readers that cheery humour which radiated from her personality and her books, led her to produce stories of a diminishing value, and at last she succumbed to overwork, dying in Boston on the 6th of March 1888, two days after the death of her father in the same city. Miss Alcott's early education had partly been given by the naturalist Thoreau, but had chiefly been obtained from her father himself. In early womanhood she had fully shared the trials and poverty incident to the life of a peripatetic idealist. In a newspaper entitled "Transcendental Wild Oats," afterwards reprinted in the volume Silver Pitchers (1876), she narrated, with a delicate humour, which showed what her literary powers might have been if freed from drudgery, the experiences of her family during an experiment toward communistic "plain living and high thinking" at "Fruitlands," in the town of Harvard, Massachusetts, in 1843. Her own romance has been fully and frankly told in Mrs Ednah D. Cheney's Louisa May Alcott: Her Life, Letters and Journals (Boston, 1888). (C. F. R.)

ALCOWE (through the Span. alecto, from the Arar. al- the, and quqbool, a vault), an architectural term for a recess in a room usually screened off by pillars, balustrade or drapery.

ALCOY, a town of south-eastern Spain, in the province of Alicante, on the small river Sérpis, and at the terminus of a branch railway connected with the Barcelona-Valencia-Alicante line. Pop. (1900) 32,653. Alcoy is built on high ground at the entrance to a gorge in the Moncaber range (4547 ft.). It is a thriving industrial town, devoid of any great antiquarian or architectural interest, though founded by the Moors. It owes its prosperity to its manufacture of linen, woolen goods and paper, especially cigarette paper. Many of the factories derive their motive power from the falls of a mountain torrent known as the Salto de las Aguas. Labour disturbances are frequent, for, like Barcelona, Alcoy has become one of the centres of socialist and revolutionary agitation, while preserving many old-fashioned customs and traditions, such as the curioous festival held annually in April in honour of St George, the patron saint of the town.

COCENTAINA (pop. 1900, 7093) is a picturesque and ancient town, 4 m. N.E. by rail. It is surrounded by Roman walls, which were partly rebuilt by the Moors, and it contains an interesting fortified palace, owned by the dukes of Medinaceli.

For an account of the festival of St George of Alcoy, see Apuntes historicos acerca de las festividades celeb stream Rodríguez y de como se celebren a su patron San Jorge, by J. A. Llobet y Vallesos (Alcoy, 1853).

ALCUIN (ALCHUINE), a celebrated ecclesiastic and man of learning in the 8th century, who liked to be called by the Latin name of ALBINUS, and at the Academy of the palace took the surname of FLACCUS, was born at Eboracum (York) in 735. He was related to Willibrord, the first bishop of Utrecht, and his biography he afterwards wrote. He was educated at the cathedral school of York, under the celebrated master Ælbert, with whom he also went to Rome in search of manuscripts. When Ælbert was appointed archbishop of York in 766, Alcuin succeeded him in the headship of the episcopal school. He again went to Rome in 780, to fetch the pallium for Archbishop Eanbald, and at Parma met Charlemagne, who persuaded him to come to his court, and gave him the possession of the great abbeys of Ferrières and of Saint-Loup at Troyes. The king counted on him to accomplish the great work which was his dream, namely, to make the Franks familiar with the rules of the Latin language, to create schools and to revive learning. From 781 to 790 Alcuin was his sovereign's principal helper in this enterprise. He had as pupils the king of the Franks, the members of his family and the young clerics attached to the palace chapel; he was the life and soul of the Academy of the palace, and we have still, in the Dialogue of Pegus (son of Charlemagne) and Alcuin, a sample of the intellectual exercises in which they indulged. It was under his inspiration that Charles wrote his famous letter de litteris colendi (Boretius, Capitularia, i. p. 78), and it was a man of such description that his sensualism returned to his own country, to which he had always been greatly attached, and stayed there some time; but Charlemagne needed him to combat the Adoptionist heresy, which was at that time making great progress in the marches of Spain. At the council of Frankfort in 794 Alcuin upheld the orthodox doctrine, and obtained the condemnation of the heresarch Felix of Urgel. After this victory he again returned to his own land, but on account of the disturbances which broke out there, and which led to the death of King Æthelred (796), he bade farewell to it for ever. Charlemagne had had him ordained priest, and thrust him into the disturbed life of the court, he passed his last years. He made the abbey school into a model of excellence, and many students flocked to it; he had numerous manuscripts copied, the calligraphy of which is of extraordinary beauty (v. Léopold Delisle in the Mémoires de l'Académie des Inscriptions, vol. xxxi., 1st part, 1885). He wrote numerous letters to his friends in England, to Arno, bishop of Salzburg, and above all to Charlemagne. These letters, of which 332 are extant, are filled chiefly with pious meditations, but they further form a mine of information as to the literary and intellectual conditions of the time. The most reliable authority for the history of humanism in the Carolingian age. He also trained the numerous monks of the
Alcyone

Alcyone is the most prominent figure of the Carolingian Renaissance, in which have been distinguished three main periods: in the first of these, up to the arrival of Alcuin at the court, the Italians occupy the chief place; in the second, Alcuin and the Anglo-Saxons are dominant; in the third, which begins in 804, the influence of the Goth Theodulf is preponderant. Alcuin transmitted to the ignorant Franks the knowledge of Latin culture which had developed in England and in the Frankish Beds. We still have a number of his works. His letters have already been mentioned; his poetry is equally interesting. Besides some graceful epistles in the style of Fortunatus, he wrote some long poems, and notably a whole history in verse of the church at York: *Versus de patribus, regibus et sanctis Eboracensis ecclesiae*. We owe to him, too, some manuals used in his educational work; a grammar and works on rhetoric and dialectics. They are written in the form of dialogues, and in the two last the interlocutors are King Charles and Alcuin. He wrote, finally, several theological treatises: a treatise of *Fide Trinitatis*, complete copies of the Bible, &c. The complete works of Alcuin have been edited by Froben: *Alcumin opera*, 1 vol. in 4 parts (Regensburg, 1777); this edition is reproduced in Migne's *Patrolog.*,

ALCYONE, or Halcyn, in Greek mythology, daughter of Aeolus and wife of Ceyx. For their presumption in changing themselves Zeus and Hera they were changed into birds—Alcyone into a diver, Ceyx into a kingfisher. According to another story, Ceyx was drowned and his body cast on the shore. His wife found the body, and the gods, out of compassion, changed both her and her husband into kingfishers. By command of Zeus (or Aeolus) the winds ceased to blow during their breeding-time, for seven days before and after the shortest day, that the eggs might not be carried away by the sea. Hence the expression "halcyon days," used in ancient and modern times to denote a period of calm and tranquillity.

ALDABRA, the collective name of a group of islands in the Indian Ocean, forming part of the British colony of Seychelles. They lie in 0° 35' S., 40° E., are 265 m. N.W. of the northern point of Madagascar and 900 m. S.W. of Mahé, the principal island of the Seychelles archipelago. The Comoro Islands lie 220 m. S. by W. of Aldabra. The Aldabra Islands consist of three separate islands: The Aldabra Islands constitute an atoll consisting of an oval ring of land, some 40 m. m. in circumference and about 15 m. broad, enclosing a shallow lagoon. Channels divide the ring into four islands. Grande Terre or South Island forms three-fifths of the circumference. The other islands are West Island or Ilé Picard, Polémienne and Middle Island. There are in addition several islets in the lagoon, the most important being Ilé Michel. The total land area is estimated at about 60 sq. m., the lagoon 16 m. long and 4 m. wide, covering a somewhat larger area. Pop. (1956) 127. The islands rise from 20 to 80 ft. above the sea, and consist of rugged coral rock and limestone, there being very little terraced land, and hedges generally overhanging cliff, but in a few places are sandy beaches and low sandhills. Dense scrub covers most of the land, but the inner (lagoon) shore is everywhere bounded by mangrove swamps. The flora and fauna of the island present features of unusual interest. They are chiefly noted as the habitat of the gigantic land tortoise (*Testudo elephantina*), now carefully preserved, and of several rare and peculiar birds, including a rail (*Dryolimnas aldobranus*), an ibis (*Ibis abbottii*) and a dove (*Alectroenas sgoninzii*). Crustacea are abundant. They include oysters, crabs of great size, and a small mussel, found in enormous numbers. The flora includes mangroves, *Rhizophora*, *Sonneratia* and other forms requiring more than pure coralline material for their growth. Writing of the fauna and flora generally, Mr. R. Dupont, curator of the Botanic station at Mahé, who visited Aldabra in 1906, says: "The specimens represented, besides being partly peculiar, mostly belong to the Mascarenes, Madagascar and Comoros species. Many species are also common to East Africa and to India. The predominant species are Madagascar plants and birds, which are carried by the currents and the winds. . . . There are comparatively few (10) species of plants which are endemic as far as the flora has been investigated, and it is probable that most of them are also existing in the Comoros, where the flora is not well known. . . . Endemic inferior animals and mammals are practically non-existent, except two bats and one scorpion, which are allied to Madagascar species or introduced. The reptiles (tortoises) are also nearly allied to the Mascarenes and Madagascar species which once existed. With regard to birds and land shells the relation is much closer to the Comoros species, and the latter, of which I have collected seven species besides *Rachis aldobrae*, may serve to point out more than the birds the land connexion of Aldabra with the neighbouring countries." Aldabra, however, although situated in that region of the Indian Ocean which forms part of the site of the Indo-Madagascar continent of the Secondary period, is not a peak of the submerged land. It has been built up from the sunken remains of the old continent by a deposit, in the opinion of Professor A. Voeltzkow, of foraminiferal remains (mostly coccoliths and rhodoliths). In any case, however Aldabra was formed, there can be no suggestion of its ever having been joined to any other land (Stanley Gardiner). Dupont states that at Aldabra the coral foundation is totally above water. The coral limestone of the atoll has a peculiar vitrified appearance and gives out a ringing sound when struck or simply walked on. The coral is generally reddish, but the colouring ranges from light yellow to chocolate-brown.

Aldabra was visited by Portuguese navigators in 1511. The islands were already known to the Arabs, from whom they get their name. They became in the middle of the 18th century dependencies of the French establishments at Bourbon (Réunion), whence expeditions were made for the capture of the giant tortoises. In 1810 with Mauritius, Bourbon, the Seychelles and other islands, Aldabra passed into the possession of Great Britain. The inhabitants are emigrants from the Seychelles. Rice, bread and coco-nuts cultivated, but fishing is the chief industry. With other outlying islands Aldabra is held under lease from the Seychelles government, the lessees having exclusive trading privileges.

ALDBOROUGH, a village in the Ripon parliamentary division of the West Riding of Yorkshire, England, 16 m. W.N.W. of York, and 1 m. E. of the market town of Boroughbridge, which has a station on a branch of the North-Eastern railway. Aldborough formerly returned two members to parliament, but was disfranchised by the Reform Act of 1832. The place is remarkable from its numerous ancient remains. It was the *Isurium Brigantium* of the Romans, originally perhaps a capital of the Brigantes tribe, and afterwards a Romano-British town of a considerable size. A Roman fort of large dimensions is generally referred to as an ancient fortress, but on nearer traces of comfortable houses have been found, with many potsherds, coins and bronze, iron and other objects; and a large part of the town walls, several mosaics and parts of buildings, can be seen.
The aldehydes may be prepared by the careful oxidation of primary alcohols with a mixture of potassium dichromate and sulphuric acid,—$3\text{R-CHO}+\text{K}_2\text{Cr}_2\text{O}_7+4\text{H}_2\text{SO}_4\rightarrow\text{R-SO}_3\text{H}+\text{Cr}_2\text{(SO}_4)_3+7\text{H}_2\text{O}+3\text{Cr}_2\text{O}_7$. By distilling the calcium salts of the fatty acids with calcium formate; and by hydrolysis of the acetals. L. Bouveault (*Bull. soc. chim.*, 1904 [3], 31, p. 1306) prepares aldehydes by the gradual addition of disubstituted formamides (dissolved in anhydrous ether) to magnesium alkyl haloids, the best yields being obtained by the use of diethyl formamide. Secondary reactions take place at the same time, yielding more particularly hydrocarbons of the paraform series. G. Darzens (*Comptes Rendus*, 1904, 139, p. 1214) prepares esters of disubstituted glycidic acids, by condensing the corresponding ketone with monochlorecetic ester, in the presence of sodium ethylate. These esters on hydrolysis yield the free acids, which readily decompose, with loss of carbon dioxide and formation of an aldehyde,

$$\text{OCR}_1^2\text{R}_1^2+\text{COOCH}_2\text{H}_2\rightarrow\text{OCR}_1^2\text{R}_1^2\text{COOCH}_2\text{H}_2\rightarrow\text{CO}_2+\text{CH}_2\text{R}_1^2\text{CHO}.$$  

In the German Patent 152573 (1904) it is shown that by the action of at least two molecular proportions of an alkyl formate on two molecular proportions of a magnesium alkyl or aryl haloid, a complex addition compound is formed, which readily decomposes into a basic magnesium salt and an aldehyde, $\text{CH}_3\text{MgBr}+\text{HCOOR}\rightarrow\text{RO-CH}_2\text{CH}_3\text{OMgBr}→\text{MgBr}_2\text{OR}+\text{CH}_2\text{CHO}$. The aldehydes are characterized by their great chemical reactivity. They act as reducing agents, silver nitrate in the presence of ammonia being readily reduced to the condition of metallic silver. They are easily oxidized to the corresponding fatty acid, in many cases simply by exposure to air. Nassept hydrogen reduces them to primary alcohols, and phosphorus pentachloride replaces the carbonyl oxygen by chlorine. They form many addition compounds, combining with ammonia to form aldehyde amononies of the type $\text{R-CH(OH)-NH}_2$. These are colourless crystalline compounds, which are most readily prepared by passing ammonia gas into an ethereal solution of the aldehyde. With sodium bisulphite they form the so-called bisulphite compounds $\text{R-CH(OH)-SO}_3\text{Na}$, which are readily resolved into their components by distillation with dilute acids, and are frequently used for the preparation of the pure aldehyde.

With hydrocyanic acid aldehydes form the cyanohydrins $\text{R-CH(OH)-CN}$. They react with hydroxylamine and phenylhydrazine, with the formation of aldoximes and hydrazones. (For the isomerism of the aldoximes see Oximes.) The hydrazones are crystalline substances which are of value in the characterization of the aldehydes. Both oximes and hydrazones, on boiling with dilute acid, regenerate the parent aldehyde. The hydrazones are best prepared by mixing the aldehyde with phenylhydrazine in dilute acetic acid solution, in the absence of any free mineral acid. Semioxamidazid $\text{NH}_3\text{CO-CO-NH-NH}_2$ has also been employed for the identification of aldehydes (W. Kerp and K. Unger, Berichte, 1897, 30, p. 585). Aldehydes are converted into resins by the action of caustic alkalies. On heating with alcohols to $100^\circ$ C. they form acetals, and they also form condensation products with para-amido-di-methyl-aniline (A. Calm, Berichte, 1884, 17, p. 2939). They react with the zinc alkyls to form addition products, which are decomposed by water with formation of secondary alcohols (K. Thurnlach, Annalen, 1885, 123, p. 360) thus:

$$\text{Zn(C}_2\text{H}_5)_2\rightarrow\text{CH}_2=\text{CH-C}_6\text{H}_5\text{O}_2\text{ZnC}_2\text{H}_5\rightarrow\text{CH}_3=\text{CH-C}_6\text{H}_5\text{H}+\text{ZnO}+\text{C}_2\text{H}_6.$$  

The reaction is a general one for all aldehydes with zinc methyl and zinc ethyl, but not with the higher zinc alkyls. V. Grignard (*Comptes Rendus*, 1900 et seq.) showed that aldehydes combine with magnesium alkyl iodides (in absolute ether solution) to form addition products, which are decomposed by water with the
ALDEHYDES

formation of secondary alcohols, thus from acetaldehyde and magnesium methyl iodide, isopropyl alcohol is obtained.

\[\text{CH}_2\text{CHO} + \text{CH}_3\text{MgI} \rightarrow \text{CH}_3\text{CH} = \text{CHO} + \text{MgI}_2\]

The lower members of the aliphatic series are characterized by their power of polymerization (see FORMALIN, and the account of Acetaldehyde below), and also by the so-called "aldol" condensation, acetaldehyde in this way forming aldol, \(\text{CH}_2\text{CHOH-CH}_2\text{CHO}\). These aldols generally lose the elements of water readily and pass into unsaturated compounds; aldol itself on distillation at ordinary atmospheric pressure gives crotonaldehyde, \(\text{CH}_2 = \text{CH-CHO}\).

Aldehydes are characterized by the reddish-violet colour which they give with a solution of fuchsin that has been de-colored by sulphurous acid (H. Schiff, *Ann.*, 1866, 150, p. 131). With diazobenzene sulphonic acid in the presence of alkali and a trace of sodium amalgam, a reddish-violet coloration is formed on standing (E. Fischer, *Ber.*, 1883, 16, p. 657). A. Angeli (Gazz. chim. Ital., 1866, 22, ii. 17) has shown that aldehydes in the presence of nitrohydroxylamic acid form hydroxamic acid. The aldehydes condense readily with acetoacetic ester in the presence of ammonia, to pyridines (see PYRIDINE), whilst O. Doebner and W. v. Miller (*Ber.*, 1892, 25, p. 2864; 1896, 29, p. 597) have shown that in the presence of aniline and sulphuric acid they give substituted quinolines. (See also C. Beyer, *Ber.*, 1887, 20, p. 1908).

The chief aldehydes are shown in the following table:

For formaldehyde see FORMALIN. *Acetaldehyde*, CH\(_2\)-CHO, was first noticed by C. Scheele in 1774 and isolated and investigated by J. v. Liebig (Annalen, 1835, 14, p. 133). It is prepared by oxidizing ethyl alcohol with dilute sulphuric acid and potassium bichromate, and is a colourless liquid of boiling point 20-28 °C, possessing a peculiar characteristic smell. Its specific gravity is 0.8000 (6 °C). It is miscible in all proportions with alcohol, ether and water. It is readily polymerized, small quantities of hydrochloric acid, zinc chloride, carbonyl chloride, &c, converting it, at ordinary temperatures, into paraldehyde, (CH\(_2\)O)\(_n\), a liquid boiling at 124 °C. and of specific gravity 0.998 (15 °C). Paraldehyde is moderately soluble in water, and when distilled with sulphuric acid is converted into the ordinary form. Metaldehyde, (C\(_n\)H\(_{2n}\)), is produced in a similar way to paraldehyde, but at lower temperatures (e.g. in presence of a freezing mixture). It is a crystalline solid, which sublimes at 112-115 °C. It is insoluble in water, and is only slightly soluble in alcohol and ether. When heated in a sealed tube at 120 °C. it is completely converted into the ordinary form. Paraldehyde is oxidized by dilute nitric acid, with formation of much glyoxal, (CHO)\(_2\). (For trichloroacetalddehyde see CHLORAL).

The action of acetaldehyde on alcohol at 100 °C, acetal, \(\text{CH}_2\text{CHO(OCH}_3\text{)H}_2\), is produced. It may also be prepared by oxidizing ethyl alcohol with manganese dioxide and sulphuric acid (A. Wurtz). It is a colourless liquid of specific gravity 0.934 (20 °C) (J. W. Bright) and boiling point 124 °C. Dilute acids readily transform it into alcohol and aldehyde, and chromic acid oxidizes it to acetic acid. Chlor- and brom-acycetals have been described.

Thioaldehydes are also known, and are obtained by leading sulphuretted hydrogen into an aqueous solution of acetaldehyde. By this means a mixture is obtained which by distillation or the action of hydrochloric acid yields thirboxaldehyde, (CH\(_2\)H\(_2\)). For the constitution of these substances see E. Baumann and E. Fromm (*Berichte*, 1861, 24, p. 1420). Aldehyde ammonia, \(\text{CH}_2\text{CH(OH)}\cdot\text{NH}_3\), is formed when ammonium gas is passed into an ethereal solution of acetaldehyde. It crystallizes in glistening rhombohedra, melting at 70°-80° C., and boiling at 100 °C. It is completely resolved into its components when warmed with dilute acids.

The higher aldehydes of the series resemble acetaldehyde in their general behaviour. Unsatuated aldehydes are also known, corresponding to the olefine alcohols; they show the characteristic properties of the saturated aldehydes and can form additive compounds in virtue of their unsaturated nature. The simplest member of the series is acrolein, CH\(_2\)H\(_2\)O or CH\(_2\)-CHO, which can be prepared by the oxidation of allyl alcohol or by the abstraction of the elements of water from glycerin by heating it with anhydrous potassium bisulphate. It is also produced by the action of sodium on a mixture of epichlorhydrin and methyl iodide, CH\(_2\)HOCI+CH\(_2\)-I+2Na=CH\(_2\)H\(_2\)O+NaI+NaCl+CH\(_4\). It is a colourless liquid, with a very pungent smell, and attacks the mucous membrane very rapidly. It boils at 52-4 °C and is soluble in water. It oxidizes readily: exposure to air gives acrylic acid, nitric acid giving oxalic acid, bichromate of potash and sulphuric acid giving carbon dioxide and formic acid. It combines with bromine to form a bromohydrin, from which E. Fischer, by the action of baryta water, obtained the synthetic sugars α- and β-areose (*Berichte*, 1859, 22, p. 360). Metacrolein, (CH\(_2\)O\(_2\)), is a polymer of acrolein. By passing acrolein vapour into ammonia, acrolein ammonia, CH\(_2\)H\(_2\)NO, is obtained. It is a reddish amorphous mass, insoluble in alcohol, and when distilled yields picoline (methyl pyridine) (A. Baeyer, *Ann.*, 1870, 155, p. 285). Citronellal, rhodinal and geranial are also unsaturated aldehydes (see TERPENES).

The aromatic aldehydes resemble the aliphatic aldehydes in most respects, but in certain reactions they exhibit an entirely different behaviour. They do not polymerize, and in the presence of caustic alkalies do not resinate, but oxidize to aldehydes and acids (see BENZALDEHYDE for Cannizzaro's reaction). When heated with alcoholic potassium cyanide they are converted into benzoins (q.v.). Vanillin does not give the Cannizzaro reaction, but with alcoholic potash forms vanillin acid, (HOOC\(_1\)\(_2\)-CHO\(_2\)-OH\(_4\), and vanillol. With ammonia, benzaldehyde does not form an aldehyde ammonia, but condenses to hydrobenzamide, (CH\(_2\)CH\(_2\))-N\(_2\), with elimination of water. Cumic aldehyde (cuminal), (C\(_6\)H\(_5\))CH\(_2\)-CHO, is found in Roman caraway oil and in oil of the water hemlock. It is a liquid, boiling at 235 °C., and has a specific gravity of 0.973. On distillation with zinc dust it forms cyrene (1:4 methyl isopropyl benzene).

Salicyclic aldehyde (ortho-hydroxybenzaldehyde), HO\(_1\)\(_2\)-CHO, an aromatic oxylaldehyde, is a colourless liquid of boiling point 106 °C. and specific gravity 1.172 (15 °C). It is found in the volatile oils of Spinae, and can be obtained by the oxidation of the glucoside salicin, (C\(_6\)H\(_5\)O\(_2\)), which is found in willow bark. It is usually prepared by the so-called "Remin" reaction (Ber., 1876, 5, p. 268), in which chloroform acts on phenol in the presence of a nitric alkali.

\[\text{CH}_2\text{OH}+\text{CHCl}_3+\text{KHO}=\text{KCl}+\text{H}_2\text{O}+\text{KO}-\text{CH}_2\text{-CHO}\]

It is some para-oxenylaldehyde being formed at the same time.
is volatile (para-oxybenzaldehyde is not) and gives a violet coloration with ferric chloride. For dioxybenzaldehydes and their derivatives see PIPERONAL and VANILLIN.

Cinnamic aldehyde (β-phenyl acrolein), C₆H₅-CH:CH-CHO, an unsaturated aromatic aldehyde, is the chief constituent of cinnamon oil. It is prepared by oxidizing cinnamon alcohol, or by the action of sodium ethylene on a mixture of benzylddehyde and acetaldehyde. It is a colourless aromatic-smelling oily liquid, which boils at 247°C, and readily oxidizes on exposure.

By condensation of aldehydes with pyruvic acid and naphthalhydrazides, the α-alkyl-naphthoquinoline-γ-carboxylic acids are produced; the same reaction takes place with the aromatic amines, giving the Reform Acts, 1835, and other acts, consolidated by the Municipal Corporations Act, 1882, the aldermen are elected by the councillors for six years, one-half going out every three years. The number of councillors in each borough varies according to its magnitude. One-fourth of the municipal council consists of aldermen and three-fourths of councillors.

In the counties, too, the number of aldermen is one-third of the number of councillors, except in London, where it is one-sixth. In the municipal corporations of Scotland there is no such title as alderman, the office-bearers of corresponding rank there being termed bailies. The corporation of the city of London was not included in the Borough Reform Act, and the antiquated system remains there in full force. The court of aldermen consists of twenty-six, twenty-five of whom are elected for life by the freemen of the respective wards, who return two persons, one of whom the court of aldermen elect to supply the vacancy. The city is divided into twenty-six wards; twenty-four of these send up one alderman each, the other two combine to choose a twenty-fifth. The twenty-sixth alderman serves for the indeterminate period, appointed by the other aldermen, who generally select the senior from among themselves when a vacancy occurs. The lord mayor is elected from such of the aldermen as have served the office of sheriff; of these the Common Hall, which consists of the freemen of the different wards, select two, and the aldermen elect one of these to the mayoralty. The court of aldermen has the power of appointment to certain offices, exercises judicial functions in regard to licensing and in disputes connected with the ward election, has some power of disposal over the city cash account and magistrates, and, as there is no such title as alderman, the office-bearers for the whole city, and: by virtue of his office exercising the functions of a justice of the peace. The aldermen are members of the court of common council, the legislative body of the corporation, which consists in all of 232 members, the remainder being elected annually by the freemen. In the United States aldermen form as a rule a legislative rather than a judicial body, although in some cities they hold courts and possess very considerable magisterial powers.

ALDERNEY (Fr. Aurligny), one of the Channel Islands, the northermost of the principal islands of the group, belonging to England. It lies in 49° 45' N. and 2° 12' W., 9 m. W. of Cape La Hague on the coast of Normandy. The harbour, on the north coast in the bay of Braye, is 25 m. from St Peter
Port, Guernsey, by way of which outer communications are principally carried on, and 55 m. S. by E. of Portland Bill, the nearest point of England. The length of the island from N. E. to S. W. is 33 m., its average breadth 1 m., its area 1062 acres, and its population (1901) 2062.

The Strait between the island and Cape La Hague, called the Race of Alderney (French Raz Blanchard), confined by numerous rocks and reefs off either coast, is rendered very dangerous in stormy weather by conflicting currents. Through this difficult channel the scattered remnant of the French fleet under Tournville escaped after the defeat of La Hogue in 1692.

To the west is the narrower and also dangerous channel of the Swinge (Singe), partly navigable. Alderney, formed of chalk, stretches east and west, and five infantry barracks called after battles (other than those of Wellington), of the wars with France, 1793-1815. There are also barracks for the Royal Army Medical Corps. The old permanent barracks (which were built for the most part about 1857) have been renamed Wellington Lines, with cavalry and artillery barracks; and three infantry barracks called after Wellington's victories in the Peninsula. For the sick there are the Connaught Hospital in the Marlborough Lines, the Cambridge Hospital in Stanhope Lines, and the Union Hospital in Wellington Lines. Besides the Aldershot Military Hospital for men and children and the isolated infection hospital.

The drainage of the station is all modern, and the sewage is disposed of on a sewage farm under the direction of the war department. The water supply is partly from the Aldershot Water Company, and partly from springs and reservoirs collecting water from a reserved area of war department property.

The most of the barracks can accommodate not only the units they are constructed for, but also detachments going through training for other purposes, and especially the military technical schools of art and arms, for both officers and men; and especially the military technical schools of art and arms, for both officers and men; and especially the army of mounted infantry, Army Service Corps, Royal Army Medical Corps, and veterinary duties. The work of these schools is, however, only a small part of the military training afforded at Aldershot; of greater importance is the field and musketry training, for the carrying out of which a considerable extent of land is essential. The land required for these purposes extends at present over an area about 93 m. in extreme length by 72 m. in extreme width. In addition to this there is the land at Sandhurst and the Staff College (Camberley) about 61 m. distant, and at Woolmer Forest, 12 m. distant. The musketry practice of the troops at Aldershot is carried out at the Ash ranges, 2 m. east of the barracks, while the Pitbrick ranges, alongside those of the National Rifle Association at Bisley, are utilized by the Household Cavalry and Guards, who are encamped there in succession. Suitable grounds in the vicinity of the barracks, of which Caesar's Camp, the Long Valley and Laffan's Plain are best known, are utilized for company, battalion and brigade training of infantry, while the mounted training is there carried out at Pirbright, and the engineers carry out their practice where most convenient. For the field-days of the combined arms, the whole of the war department property is available. Aldershot is the headquarters of the "Aldershot Army Corps," which is the largest organized force maintained in the United Kingdom.

Besides the troops in barracks, during the drill season there is often a considerable force in camp, both regular troops from other stations and militia and volunteer units, so that, including the regular garrison, sometimes as many as 40,000 by the Basingstoke canal, were then acquired by the crown. Wooden huts were erected in 1835, and permanent buildings to replace them were begun in 1881. Under the Barracks Act 1890, and the Military Works Act of 1897 and 1899, large sums were provided for completing the work. The former division of North and South camps and permanent barracks no longer obtains. North camp is now named Marlborough Lines, with a field artillery barrack and five infantry barracks called after Marlborough's victories. South camp is now named Stanhope Lines, after Mr Stanhope, who was the Secretary of State for War when the Barracks Act 1890 was passed and the reconstruction commenced in earnest. They contain barracks for the Royal Engineers, Royal Artillery and Royal Marines, together with installations for the engineer's work. The island is remarkable for its lawns and efflorescence. It is a remarkable projecting block of sandstone, called La Roche Pendante (Hanging Rock) overhanging the cliff. Sandstone (mainly along the north-east coast), granite and porphyry are the chief geological formations. There are a few streams, but water is obtained mainly from wells. Trees are scarce. The town of St Anne stands almost in the centre of the island overlooking and extending towards the harbour. Here are the courthouse, a gateway commemorating Albert, prince-consort, the clock tower, which belonged to the ancient parish church, and the Officers' Mess (1872), in Early English style, an excellent example of the work of Sir Gilbert Scott. The church is a memorial to the family of Le Mesurier, in which the hereditary government of the island was vested until the abolition of the office in 1825. There is a chain of forts round the north coast from Claque Fott on the west to Fort Essex on the east; the largest is Fort Albert, above Braye Bay. In 1847 work was begun on a great breakwater west of the harbour, the intention being to provide a harbour of refuge, but although a sum exceeding one and a half million sterling was spent the scheme was unsuccessful. The soil of Alderney is light, fertile and cultivated; grain and vegetables are grown and early potatoes are exported. A large part of the island is under grass, affording pasture for cattle. The well-known term "Alderney cattle," however, has lost in great measure its former signification of a distinctive breed. Alderney is included in the bailiwick of Guernsey. It has a court consisting of a judge and six jurats, attorney-general, prévôt, greffier, and sargent; but as a judicial court it is subordinate to that of Guernsey, and its administrative powers are limited to such matters as the upkeep of roads.

For its relations to the constitution of the bailiwick, and for the history of the island, see CHANNEL ISLANDS.
troops have been concentrated at the station for training and manoeuvres.

**ALDHELM (c. 640–709)**, bishop of Sherborne, English scholar, was born before the middle of the 7th century. He is said to have been the son of Kenten, who was of the royal house of Wessex, but who was certainly not, as Aldhelm's early biographer Faritius asserts, the brother of King Ine. He received his first education in the school of an Irish scholar and monk, Malidulf, Malidubh or Meldun (d. c. 673), who had settled in the British stronghold of Bladon or Bladaw on the site of the town of Maldeubert, Maldesbury, Meldunseburg, etc., and finally Malmesbury, after him. In 668 Pope Vitalian sent Theodore of Tarsus to be archbishop of Canterbury, and about the same time came the African scholar Hadrian, who became abbot of St Augustine's at Canterbury. Aldhelm was one of his disciples, for he addresses him as the "venerable preceptor of my rude childhood." He must, nevertheless, have been thirty years of age when he began to study with Hadrian. His studies included Roman law, astronomy, astrology, the art of reckoning and the difficulties of the calendar. He learned, according to the doubtful statement of the early Aldhelm was the first Englishman. He certainly introduces many Latinized Greek words into his works. Ill-health compelled him to leave Canterbury, and he returned to Malmsbury, where he was a monk under Malidulf for fourteen years, dating probably from 661, and including the period of his studies with Hadrian. When Malidulf died, Aldhelm was appointed in 675, according to a charter of doubtful authenticity cited by William of Malmsbury, by Lutharius, bishop of Dorchester from 671 to 676, to succeed to the direction of the monastery, of which he became the first abbot. He introduced the Benedictine rule, and secured the right of the election of the abbot to the monks themselves. The community at Malmesbury increased, and Aldhelm was able to find two other monasteries to be centres of learning at Frome and at Bradford on Avon. The little church of St Lawrence at Bradford dates back to his time and may safely be regarded as his. At Malmsbury he built a new church to replace Malidulf's modest building, and obtained considerable grants of land for the monastery. His fame as a scholar rapidly spread into other countries. Artwil, the son of an Irish king, submitted his writings for Aldhelm's approval, and Cellanus, an Irish monk from Peronne, was one of his disciples. The monk Ealdhelm, the first Englishman, he far as we know, to write in Latin verse, and his letter to Acricius (Aldfrith or Eadfrith, king of Northumbria) is a treatise on Latin prosody for the use of his countrymen. In this work he included his most famous productions, 101 riddles in Latin hexameters. Each of them is a complete picture, and one of them runs to 83 lines. That his merits as a scholar were early recognized in his own country is shown by the encomium of Bede (Ecclesiastical History, v. 18), who speaks of him as a wonder of erudition. His fame reached Italy, and at the request of Pope Sergius I. (687–701) he paid a visit to Rome, of which, however, there is no notice in his extant writings. On his return, bringing with him privileges for his monastery and a magnificent altar, he received a popular ovation. He was appointed by a synod of the church in Wessex to remonstrate with the Britons of Domnonia (Devon and Cornwall) on their differences from the Roman practice in the shape of the tonsure and the date of Easter. This he did in a long and rather acrimonious letter to their king Geraint (Gerantius), and their ultimate agreement with Rome is referred by William of Malmsbury to his efforts. In 703, or perhaps earlier, Hædil, bishop of Winchester, died, and the diocese was divided into two parts. Sherborne was the new see, of which Aldhelm reluctantly became the first bishop. He wished to resign the abbey of Malmsbury which he had governed for thirty years, but yielding to the remonstrances of the monks he continued to direct it until his death. He was now an old man, but he showed great activity in his new functions. The cathedral church which he built at Sherborne, though replaced later by a

1 For the disputed etymology of Malmsbury, which some connect with Aldhelm's name, see Bishop Browne, _St Aldhelm: his Life and Times_, p. 73.

2 Cuthburga, sister of King Ine of Wessex, and therefore related to Aldhelm, left her husband Aldfrith, king of Northumbria, to enter the nunnerly at Barking. She afterwards founded the nunnery of Wimborne, of which she became abbes.

vol. i, new edition (1880); M. Manutius, Geschichte der christlich-
lateinischen Poesie &c. (Stuttgart, 1891), pp. 487-496; also
H. Hahn, Bonsius und Lule ihre angelsächsischen Korrespondenten,
chap. i. (Leipzig, 1883). The two last-named works contain many
furn to find a scholarical references.

ALDINE PRESS, the printing office started by Aldus Manutius at
the end of the 15th century in Venice, from which were issued
the celebrated Aldine editions of the classics of that time.
(See MANUTIUS.) The Aldine Press is famous in the history of
typography (q.v.), among other things, for the introduction of
italics.

ALDINI, GIOVANNI (1762-1834), Italian physicist, born at
Bologna on the 10th of April 1762, was a brother of the statesman
Count Antonio Aldini (1756-1816) and nephew of L. Galvani,
whose treatise on muscular electricity he edited with notes in
1791. He became professor of physics at Bologna in 1798, in
succession to his teacher Sebastiano Canterzani (1734-1819).
His scientific work was chiefly concerned with galvanism and
its medical applications, with the construction and illumination
of lighthouses, and with experiments for preserving human life
and material objects from destruction by fire. He wrote in
French and English in addition to his native Italian. In recogni-
tion of his merits, the emperor of Austria made him a knight of
the Iron Crown and a councillor of state at Milan, where he died
on the 17th of January, 1834. He left by will a considerable
sum to found a school of natural science for artisans at Bologna.

ALDRED, or EALDRED (d. 1069), English ecclesiastic, became
abbot of Tavistock about 1027, in 1044 was made bishop of
Worcester, and in 1060 archbishop of York. He had considerable
influence over King Edward the Confessor, and as his interests
were secular rather than religious he took a prominent part in
affairs of state, and in 1046 led an unsuccessful expedition
against the Welsh. In 1050 he was largely instrumental in
restoring Swyn, the son of Earl Godwin, to his earldom, and
about the same time went to Rome "on the king’s errand." In
1057 he was sent to the emperor Henry III of Germany to
obtain confirmation of mon-
arch’s influence in securing the return to England of Edward,
son of Edmund Ironside, who was in Hungary with King Andrew I.
In this mission he was successful and obtained some insight into
the working of the German church during a stay of a year with
Hermann II, archbishop of Cologne. After his return to England
he took charge of the sees of Hereford and Ramsbury, although
not appointed to these bishoprics; and in 1058 made a pilgrimage
to Jerusalem, being the first English bishop to take this journey.
Having previously given up Hereford and Ramsbury, Aldred
was elected bishop of Rochester in 1060, and was annexed
in Rome to receive the pallium. On his return there, however,
various charges were brought against him by a synod, and Pope
Nicholas II. not only refused his request but deposed him
from the episcopate. The sentence was, however, subsequently
reversed, and Aldred received the pallium and was restored to
his former station. It is stated by Florence of Worcester that
Aldred crowned King Harold II. in 1066, although the Norman
authorities mention Stigand as the officiating prelate. After
the battle of Hastings Aldred joined the party who sought to
bestow the throne upon Edgar the Atheling, but when these
efforts appeared hopeless he was among those who submitted to
William the Conqueror at Berkhamstead. Selected to crown
the new king he performed the ceremony on Christmas Day
1066, and in 1068 performed the same office at the coronation
of Matilda, the Conqueror’s wife. But though often at court, he
seems to have been no sympathiser with Norman oppression,
and is even said to have beard the king himself. He died at
York on the 12th of September 1069 and was buried in his own
cathedral. Aldred did much for the restoration of discipline
in the monasteries and churches under his authority, and was
liberal in his gifts for ecclesiastical purposes. He built the
monastic church of St. Peter at Gloucester, and rebuilt a large
part of that of St John at Beverley. At his instigation, Folcard, a
monk of Canterbury, wrote the Life of St John of Beverley.

ensis, edited by J. Raine (London, 1879-1904); E. A. Freeman,

ALDRICH, HENRY (1647-1710), English theologian and
philosopher, was born in 1647 at Westminster, and was educated
at the collegiate school there, under Dr Busby. In 1662 he
entered Christ Church, Oxford, and in 1689 was made dean in
succession to the Roman Catholic, John Massey, who had fled
to the continent. In 1692 he was vice-chancellor of the Uni-
versity. In 1702 he was appointed rector of Wem in Shropshire,
but continued to reside at Oxford, where he died on the 14th of
December 1710. He was buried in the cathedral without any
memorial at his own desire. Aldrich was a man of unusually
large gifts. A classical scholar of fair merits, he is best known
as the author of a little book on logic (Compendium Artis Logicae),
a work of little value in itself, but used at Oxford (in Mansel’s
revised edition) till long past the middle of the 19th century.
Aldrich also composed a number of anthems and church services
of high merit, and adapted much of the music of Palestrina and
Carissimi to English words with great skill and judgment. To
him we owe the well-known catch, "Hark, the bonny Christ-
Church bells.” Evidence of his skill as an architect may be seen
in the church and campus of the All Saints, Oxford, and in
three sides of the Peckwater Quadrangle of Christ Church, which
were erected after his designs. He bore a great reputation for
conviviality, and wrote a humorous version of the popular ballad—

A soldier and a sailor,
A waiter and a tailor, &c.

Another specimen of his wit is furnished by the following epigram
of the five reasons for drinking—

Sit bene quidem menini, causae sunt quinque bibendi;
Hospitis adversus, praesens siilis aquae futura,
Nec nisi beverage et quaeque aliena causa.

The translation runs—

If on my theme I rightly think,
There are five reasons why men drink—
Good wine; a friend; because I’m dry;
Or lest I should be by and by;
Or—any other reason why.

ALDRICH, NELSON WILMARTH (1841— ), American
politician, was born at Foster, Rhode Island, on the 6th of
November 1841. His first political service was as a member
(1865-1875) and president (1871-1872) of the Providence
common council. He was a member of the lower house of the
Rhode Island legislature in 1875 and 1876, and speaker in the
latter year. By this time he had become a power in Republican
state politics, and in 1878 and 1880 was elected to Congress.
Early in his second term he was chosen United States senator,
and was re-elected in 1886, 1892, 1898 and 1905. In the Senate
he was looked upon as the special representative of the high
protective industries and moneyed interests, and he took a
prominent part in all legislation dealing with the tariff, banking
and the merchant marine.

ALDRICH, THOMAS BAILEY (1836-1907), American author.
born in Portsmouth, New Hampshire, on the 11th of
November 1836. When he was but a child his father moved
to New Orleans, but after ten years the boy was sent back
to Portsmouth—the "Rivermouth" of several of his stories—to
prepare for college. This period of his life is partly described in
his Story of a Bad Boy (1870), of which "Tom Bailey" is the
juvenile hero.1 His father’s death in 1872 compelled Aldrich
to abandon the idea of college and enter a business office in
New York. Here he soon became a constant contributor to the
newspapers and magazines, and the intimate friend of the young
poets, artists and wits of the metropolitan Bohemia of the early
sixties, among whom were E. C. Stedman, R. H. Stoddard, Bayard
Taylor and Walt Whitman. From 1856 to 1859 he was on the
staff of the New York Herald, then edited by N. P. Willis, while

1 This book has been translated into French as Education et
réclamation, and into German as a specimen of American humour.

ALDRINGER—ALE

537
during the Civil War he was himself editor of the New York Illustrated News. In 1865 he moved to Boston and was editor for ten years for Ticknor and Fields—then at the height of their prestige—of the eclectic weekly Every Saturday, discontinued in 1875. From 1881 to 1890 he was editor of the Atlantic Monthly. Meanwhile Aldrich had written much, both in prose and verse. His genius was many-sided, and it is surprising that so busy an editor and so prolific a writer should have attained the perfection of form for which he is justly famous. His prose has an almost Renaissance idiom and his verse, chiefly The Ballad of Babie Bell (1836), Pamphlet, and Other Poems (1861), Cloak of Gold (1874), Flower and Thorn (1876), Friar Jerome's Beautiful Book (1881), Meadows and Late Lyrics (1883), Wyndham Towers (1889), and the collected editions of 1865, 1882, 1897 and 1900, showed him to be a poet of lyrical skill, dainty touch and felicitous conceit, the influence of Herrick being constantly apparent. He repeatedly essayed the long narrative or dramatic poem, but seldom with success, save in such earlier work as Garmnut Hall. But no American poet has shown more skill in describing some single picture, mood, conceit or episode. His best things are such lyrics as "Hesperides," "When the Sultan goes to Ishpahan," "Before the Rain," "Nameless Pain," "The Tragedy," "Seadrift," "Tiger Lilies," "The One White Rose," "Palabras Carinosas," "Destiny," or the eight-line poem "Identity," which did more to spread Aldrich's reputation than any of his writing after Babie Bell. Beginning with the collection of stories entitled Marjorie Daw and Other People (1873), Aldrich applied to his later prose work that minute care in composition which had previously characterized his verse—taking a near, new or salient situation, and setting it before the reader in a perfectly harmonious and perfectly reticent humour. In the novels, Prudence Palfrey (1874), The Queen of Sheba (1877), and The Stillwater Tragedy (1880), there is more rapid action; but the Portsmouth pictures in the first are elaborated with the affectionate touch shown in the shorter humorous tale, A Rivermont Romance (1877). In An Old Town by the Sea (1893) the author's birthplace was once more commemorated, while travel and description are the theme of Front Ponkapog to Peth (1883). Aldrich died at Boston on the 10th of March 1907.
His Life was written by Ferris Greenslet (1908).

ALDRINGER (Aldringer, Aldringen), JOHANN, COUNT von (1558–1634), Austrian soldier, was born at Diedenhofen (Thionville) in Lorraine. After travelling as page to a nobleman in France, Italy and the Netherlands, he went to the university of Paris. In 1606 he entered the service of Spain, in which he remained until 1618, when he joined the imperial army. Here he distinguished himself in the field and in the cabinet. Made a colonel in 1622, two years later he was appointed on the council of civil and military affairs in the Netherlands. At the bridge of Dordrecht 1626 he performed very distinguished service against Ernst von Mansfeld. He and his constant comrade Matthias Gallus (q.v.) were ennobled on the same day, and in the course of the Italian campaign of 1630 the two officers married the two daughters of Count d'Arco. Aldringer served as Count Rombold Collalto's major-general in this campaign and was present at the taking of Mantua. The plunder of the duke of Mantua's treasures made Gallus and Aldringer wealthy men. Back in Germany in 1631, he served after Breitenfeld as Tilly's artillery commander, and, elevated to the dignity of count of the Empire, he was present at the battle of the Lech, where he was wounded. When Tilly died of his wounds Aldringer succeeded to the command. Made field-marshal after the assault of the Alte Veste near Nuremberg, at which he had been second in command under Wallenstein, duke of Friedland (with whom he was a great favourite), he was next placed at the head of the corps formed by Maximilian I. of Bavaria to support Wallenstein. In this post his tact and diplomatic ability were put to a severe test in the preservation of harmony between the two dukes. Finally Count Aldringer was war and on diplomatic missions. After Wallenstein's death Aldringer commanded against the Swedes on the Danube, and at the defence of Landshut he fell (July 22, 1634). His great possessions descended to his sister, and then to the family of Clary and Aldringer.

See Brohm, Johann von Aldringen (Halle, 1889), and Hermann Hallwich, Johann von Aldringen (Leipzig, 1885); also Allgemeine Deutsche Biographie, s.v. Gallus, correcting earlier biography of Aldringer in the same work.

ALDROVANDI, ULISSI (1522–1603), Italian naturalist, was born of noble parentage at Bologna on the 15th of September 1522. He was apprenticed to a merchant in Brescia, but a commercial career being distasteful to him, he turned his attention to law and medicine, studying first in his native town and afterwards at Padua. In 1550 he was accused of heresy, but succeeded in clearing himself before the Inquisition. In 1553 he took his doctor's degree in medicine at Bologna, and in the following year was appointed professor of philosophy and also lecturer on botany at the university. In 1560 he was transferred to the chair of natural history. At his instance the senate of Bologna established in 1568 a botanical garden, of which he was allowed to be the first director, at least as regards the allocation of poverty. Published records of the senate of Bologna show that it liberally supported Aldrovandi in his undertaking, doubling his salary soon after his appointment as professor, and bestowing on him from time to time sums amounting in all to 40,000 crowns. If, therefore, he died in the public hospital, he probably went there for the better treatment of his disease. His death occurred on the 10th of May 1603. Aldrovandi was chiefly remarkable for laborious and patient research. He seems to have been totally devoted to the critical faculty, and hardly any attempt is made in his great work to classify facts or to distinguish between the true and the fabulous, the important and the trivial. Much is thus included that is of no scientific value, but it also contains much information of very great interest to the naturalist.

ALE, an old word for a fermented liquor obtained chiefly from malt. In England "ale" is nowadays practically synonymous with "beer." Before the introduction of hops into England from Flanders in the 16th century ale was the name exclusively applied to malt liquor, the term beer being gradually introduced to describe liquor brewed with an infusion of hops. This distinction that does not apply at the present time, except in so far as the term ale is not applied to black beers (stout and porter) nor to lager beer. In the United States, however, it is customary to confine the designation beer to the article obtained by the bottom fermentation process. In former times the Welsh and Scots had two distinct kinds of ale, called common and spiced ales, the relative values of which were appraised by law in the following terms: "If a farmer have no mead, he shall pay two casks of spiced ale, or four casks of common ale, for one cask of mead." There are numerous varieties of English ales, such as mild ale, which is a full, sweetish beer, of a dark color, and with relatively little hop; pale ale, which is relatively dry, of light colour and of a more pronounced hop flavour than the mild ale;
ALEANDRO—ALECSANDRI

and bitter and stock ales, the latter term being generally reserved for superior beers, such as are used for bottling. The terms pale, bitter, stock, light, &c., are to be regarded as trade distinctions and not as exact definitions of quality or type. (See Beer and Brewing.)

Parish Ales.—In old England an "ale" was synonymous with a parish festival or merry-making at which ale was the chief drink. The word was generally used by composition. Thus there were leet-ales (that held on leet or manorial court day); lamb-ales (that held at lamb-shearing); Whitsun-ales, clerk-ales, church-ales and so on. The word bridal is really bride-ale, the wedding feast. Bid-ales, once very common throughout England, were "benefit" feasts to which a general invitation was given, and all the neighbours attending were expected to make some contribution to help the object of the "benefit." (See "Bidding-Weddings" under BRIDE.) These parish festivals were of much ecclesiastical and social importance in medieval England. The chief purpose of church-ales and clerk-ales, at least, was to facilitate the collection of parish-dues, or to make an actual profit for the church from the sale of the liquor by the church wardens. These profits kept the parish church in repair, or were distributed as alms to the poor. At Sygate, Norfolk, on the gallery of the church is inscribed—

God speed the plough
And give us good ale now . . .
Be merry and glad
With good ale was this work made.

On the beam of a screen in the church of Thorpe-le-Soken, Essex, is the following inscription in raised Gothic letters, on a scroll held by two angels—"This cost is the bachelors made by ales then be ther med." The date is about 1480. The feast was usually held in a barn near the church or in the churchyard. In Tudor times church-ales were held on Sundays. Gradually the parish-ales were limited to the Whitsun season, and these still have local survivals. The colleges of the universities used formerly to brew their own ales and hold festivals known as college-ales. Some of these ales are still brewed and famous, like "chancellor" at Queen's College, and "archdeacon" at Merton College, Oxford, and "thorpe" at Trinity, Cambridge.

ALEANDRO, GIROLAMO (Hieronymus Aleander) (1480–1542), Italian cardinal, was born at Motta, near Venice, on the 13th of February 1480. He studied at Venice, where he became acquainted with Erasmus and Aldus Manutius, and at an early age was reputed one of the most learned men of the time. In 1508 he went to Paris on the invitation of Louis XII. as professor of belles lettres, and held for a time the position of rector in the Collège de France. After the death of Erhard, protonotary, bishop of Liége, he was sent by that prelate on a mission to Rome, where Pope Leo X. retained him, giving him (1519) the office of librarian of the Vatican. In the following year he went to Germany to be present at papal nuncio at the coronation of Charles V., and was also present at the diet of Worms, where he headed the opposition to Luther, advocating the most extreme measures to repress the doctrines of the reformer. His conduct evoked the fiercest denunciations of Luther, but it also displeased more moderate men and especially Erasmus. The edict against the reformer, which was finally adopted by the emperor and the diet, was drawn up and proposed by Aleandro. After the close of the diet the papal nuncio went to the Netherlands, where he kindled the flames of persecution, two moncks of Antwerp, the first martyrs of the Reformation, being burnt in Brussels at his instigation. In 1523 Clement VII., having appointed him archbishop of Brindisi and Oria, sent him as nuncio to the court of Francis I. He was taken prisoner along with that monarch at the battle of Pavia (1529), and was released only on payment of a heavy ransom. He was subsequently employed on various papal missions, especially to Germany, but was unsuccessful in preventing the German princes from making a truce with the reformers, or in checking to any extent the progress of the new doctrines. He was created cardinal in 1530 by Paul III. (at the same time as Reginald Pole) and died at Rome on the 1st of February 1542.

Aleandro compiled a Lexicon Graeco-Latinum (Paris, 1512), and wrote Latin verse of considerable merit inserted in M. Tuscanus's Carmina illustrium poetarum Italorum. The Vatican library contains a volume of letters and other documents, written by him in connexion with his various missions against Luther. They were utilized by Pallavicino in his Istoria del Concilio Tridentino (i. 23-28), who gives a very partial account of the conference.

Aleandro, who is sometimes called "the elder," must be distinguished from his grand-nephew, also called Girolamo Aleandro (1530–1600). The son of Aleandro was a noted humanist scholar, and wrote Psalms poenitentiales versibus elegiacis expressi (Treves, 1593), Gazi, veteris juris consulti Institutionum fragmenta, cum commentario (Venice, 1660), Expositio veteris tabulae marmoreae solis efigie symbolique exculptae (Rome, 1616).

ALEARDI, ALEARDO, COUNT (1812–1878), Italian poet, was born at Verona on the 4th of November 1812, and thus soon after his birth became a Roman poet. Inspired from his cradle with a hatred of the foreigner, he found himself disqualified for the position in the public service to which his rank would have entitled him, and unable to publish his patriotic verses. Arnaldo da Rocco, a narrative poem, nevertheless appeared in 1842, and the revolutionary year 1848 made an opening for his Lettere a Maria. He took an active part in the popular uprising, and was for some time imprisoned. In 1856 he produced the finest of his pieces, an ode to the maritime cities of Italy, and in 1858 a poem on his own misfortunes. After the expulsion of the Austrians from Lombardy he returned to Verona, published his poems in a collected edition (1862), became professor at the Academy of Fine Art, member of the Italian parliament and eventually senator. He died on the 17th of July 1878. Aleardi's warmth of patriotic feeling hardly finds adequate expression in his poetry; it is his merit to excel in description, but his fault to substitute description for action.

ALE-CONNOR, an officer appointed yearly at the court-lee of ancient English manors for the assize of ale and ale-measures. The gustatores cervisiae—called in different localities by the different names "ale-tasters," "ale-founders," and "ale-conners"—were sworn to examine beer and ale, to take care that they were good and wholesome and were sold at proper prices. In London four ale-conners, whose duty it is to examine the measures used by beer and liquor sellers to guard against fraud, are still chosen annually by the liverymen in common hall assembled at Midsummer Day. Since ale and beer have become excisable commodities the custom of appointing ale-tasters has in most places fallen into disuse. (See also ADULTERATION.)

ALECSANDRI, or ALEANDRI, VASILE (1821–1890), Rumanian lyric poet, was born at Bacau in Moldavia on the 21st of July 1821. His father was the Spatar Alecsandri, of Jewish and Italian origin, who had settled in Moldavia in the 18th century. Vasile was educated first in Jassy and afterwards (1834–1839) in Paris. In 1839 he started on a long journey through the Carpathian Mountains, and was the first to collect Rumanian popular songs, no doubt influenced by Western examples. He first published his collection in 1844. His Doine și Lacrimoare, lyrical poems, appeared at Paris in 1852, and in 1852–1853 he published in Jassy a fuller collection of popular ballads and songs. He then adapted some French plays for the newly founded Rumanian theatre, and wrote some original pieces. His connexion with the revolutionary movement of 1848 compelled him to seek shelter in the west of Europe, and he visited England, where a beautifully illuminated edition of his poems was printed in the original Rumanian language. In 1867 he published some fugitive pieces, written in a lighter vein, and entitled Pastel; these were followed in 1871 by the Legende of similar character. More serious are his dramatic writings which began with Despot Voda and culminated in Ordet. In later life Alecsandri took an active part in politics; he became minister for foreign affairs from 1859 to 1860, and in 1885 was appointed Rumanian minister in Paris. He died on the 26th of August 1890 at his country seat, Mircești. His best title to fame consists in the fact that he
Alemán—Alembert

539

On leaving college he returned to the house of his foster-mother, where he continued to live for thirty years. Having studied law, he was admitted as an advocate in 1738, but did not enter upon practice. He had, however, indulged in the study of medicine, but his natural inclination proved too strong for him, and within a year he resolved to give his whole time to mathematics. In 1741 he received his first public distinction in being admitted a member of the Academy of Sciences, to which he had previously presented several papers, including a Mémoire sur le calcul intégral (1739).

In his Mémoire sur le réfraction des corps solides (1741) he was the first to give a theoretical explanation of the phenomenon which is witnessed when a body passes from one fluid to another more dense in a direction not perpendicular to the surface which separates the two fluids. In 1743 he published his Traité de l’équilibre et du mouvement des fluides, and all the problems before solved by geometrarians came in some measure its corollaries. This discovery was followed by that of the calculus of partial differences, the first trials of which were published in his Réflexion sur la cause générale des vents (1747).

This work was crowned by the Academy of Berlin, and was dedicated to Frederick the Great, who had made him a life member of the Academy of Sciences, and invited him to settle in Berlin. In 1753 he visited Berlin, and on that occasion finally refused the office of president of the Academy of Berlin, which had been already offered to him more than once. In 1747 he applied his new calculus to the problem of vibrating chords, the solution of which, as well as the theory of the oscillation of the air and the propagation of sound, had been given but incompletely by the geometrarians who preceded him. In 1749 he furnished a method of applying his principles to the motion of any body of a given figure; and in 1754 he solved the problem of the precession of the equinoxes, determined its quantity and explained the phenomenon of the nutation of the earth’s axis.

In 1752 he published an Essai d’une nouvelle théorie sur la résistance des fluides, which contains a large number of original ideas and new observations. In 1746 and 1748 he published in the Mémoirs of the Academy of Berlin "Recherches sur le calcul intégral," a branch of mathematical science which is greatly indebted to him. In his Recherches sur divers points importants du système du monde (1754-1756) he perfected the solution of the problem of the perturbations of the planets, which he had presented at the académie in 1747. Alembert’s association with Diderot in the preparation of the Dictionnaire Encyclopédique led him to take a somewhat wider range than that to which he had previously confined himself. He wrote for that work the Discours préliminaire on the rise, progress and affinities of the various sciences, which he read to the French Academy on the day of his admission as a member, the 18th of December 1754. He also wrote several literary articles for the first two volumes of the Encyclopædia, and to the remaining volumes he contributed mathematical articles chiefly. One of the few exceptions was the article on "Geneva," which involved him in a somewhat keen controversy and in regard to Calvinism and the suppression of theatrical performances within the town. During the time he was engaged on the Encyclopædia he wrote a number of literary and philosophical works which extended his reputation and also exposed him to criticism and controversy, as in the case of his Mélanges de Philosophie, d’Histoire, et de Littérature. His Essai sur la société des gens de lettres avec les grands was a worthy vindication of the independence of literary men, and a thorough exposure of the evils of the system of patronage. He broke new ground and showed what general unsuscrupulous interests interested philosophers and moralists chose of Tacite. One of his most important works was the Éléments de Philosophie published in 1759, in which he discussed the principles and methods of the different sciences. He maintained that the laws of motion were necessary, not contingent. A treatise, Sur la destruction des Jésuites (1763), involved him in a fresh controversy, his own share in which was...
ALEMBIC—ALENCON

rendered very easy by the violence and extravgance of his adversaries. The list of his more noteworthy literary works is completed by the mention of the Histoire des membres de l'Academie francaise, containing biographical notices of all the members of the Academy who died between 1700 and 1772, the year in which he himself became secretary. Alembert was much interested in music both as a science and as an art, and wrote Elements de musique thôrique et pratique (1779), which was based upon the system of J. P. Rameau with important modifications and differences.

Alembert's fame spread rapidly throughout Europe and procured for him more than one opportunity of quitting the comparative retirement in which he lived in Paris for more lucrative and prominent positions. The offer of Frederick the Great has already been mentioned. In 1762 he was invited by Catherine of Russia to become tutor to her son at a yearly salary of 100,000 francs. On his refusal the offer was repeated with the additional inducement of accommodation for as many of his friends as he chose to bring with him to the Russian capital. Alembert persisted in his refusal, and the letter of Catherine was ordered to be engrossed in the minutes of the French Academy. In 1755, on the recommendation of Pope Benedict XIV, he was admitted a member of the Institute of Bologna. A legacy of £200 from David Hume showed the esteem in which he was held by that philosopher.

Alembert continued to the end to lead the quiet and frugal life dictated by his limited means as well as by his simple tastes. His later years were saddened by circumstances connected with a romantic attachment he had formed for Mademoiselle de Lespinasse, whose acquaintance he made at the house of Madame de Duffaut, a noted resort of literary men and savants. She nursed him assiduously during an illness he had in 1765, and from that period till her death in 1776 they lived in the same house without any scandal. On her part there seems to have been from first to last nothing more than warm friendship, but his feelings towards her were of a stronger kind and her death deeply affected him. He never recovered his elasticity of spirits, though he continued to occupy himself with his favourite pursuits, and to frequent the society of his brother philosophers. After the death of Voltaire (1778), whose friend and correspondent he had been for more than thirty years, he was regarded as the leader of the philosophical party in the Academy. He died at Paris on the 29th of October 1773.

The chief features of Alembert's character were benevolence, simplicity and independence. Though his income was never large, and during the greater part of his life was very meagre, he contrived to find means to support his foster-mother in her old age. Educated the children of his first teacher, and to help various deserving friends, he contrived to keep up his independent character. His cheerful conversation, his smart and lively sallies, a singular mixture of malice of speech with goodness of heart, and of delicacy of wit with simplicity of manners, rendered him a pleasing and interesting companion; and if his manner was sometimes plain almost to the extent of rudeness, it probably set all the better an example of a much-needed reform to the class to which he belonged. The controversy as to the nature of his religious opinions, arising as it did chiefly out of his connection with the Encyclopædia, has no longer any living interest now that the Encyclopædisticians generally have ceased to be regarded with unqualified suspicion by those who count themselves orthodox. It is to be observed, moreover, that as Alembert confined himself chiefly to mathematical articles, his work laid him less open to charges of heresy and infidelity than that of some of his associates. The fullest revelation of his religious convictions is given in his correspondence with Voltaire, which was published along with that with Frederick the Great in Bossange's edition of his works.

The scientific works of Alembert have never been published in a collected form. The most important of them have been mentioned above, with the exception of the Opuscula mathematica (1761-1771), a collection of scientific literatures and documents carefully collected and edited by Bastien (Paris, 1805, 18 vols. 8vo). A better edition by Bossange was published at Paris in 1821 (5 vols. 8vo).

The best account of the life and writings of Alembert is contained in Condorcet's Éloge, presented to the Academy and published in 1784.

ALEMBIC (Arab. al, definite article, anbiq, a still; cognate to the Gr. αμβλ, a cup), an apparatus for distillation, used chiefly by the alchemists, and now superseded by the retort and the worm-still. It varied considerably in form and construction, but consisted essentially of three parts—_a vessel_ containing the material to be distilled and called, from its goose-like shape, the cucurbit or mattres; a vessel to receive and condense the vapour, called the head or capital; and a receiver for the spirit, connected by a pipe with the capital. The entire apparatus was sometimes constructed of glass, but it was more usual to make the cucurbit of copper or earthenware, and the capital alone of glass.

ALEMTEJO (i.e. "Beyond the Tagus"), an ancient province of central and southern Portugal; bounded on the N. by Beira, E. by Spanish Estremadura and Andalusia, S. by Algarve and W. by the Atlantic Ocean and Portuguese Estrémica. It was divided in 1805, 416,105; area 9219 sq. m. Alemtejo is traversed by several mountain ranges, whose height does not generally rise much above 2000 ft. The low and sandy coast has a length of less than 25 m. and includes no harbour, except at the unimportant town of Villa Nova de Milfontes (pop. 1900, 825), which overlooks the Mira estuary. The principal rivers are the Tagus, which divides Alemtejo from Beira; its tributary the Zatas, or Sorraia, fed by a whole system of lesser affluents; the Guadiana, which, crossing the Spanish frontier, flows southwards through the province; the Sado, which rises in the Serra de Monchique, and flows to the north; and the Mira, which winds its way between the Caldeirão and Monchique ranges. There are several extensive plains, notably those of Alemtejo, lying south-west of the Serra de Portalegre; of Beja, between the Sado and Guadiana; and of Ourique, farther south between the same rivers. Some portions of these plains are fruitful, others marshy, while large tracts are mere desolate wastes.

The climate in the lower parts of the country is exceedingly hot and is rendered unhealthful in summer by the stagnant marshes. Towards the Spanish frontier the soil is fertile, and in the south the country is covered by extensive forests of oak, pine, chestnut, cork and ilex, especially on the sides of the Mezquita and Caldeirão ranges. In the more fertile parts, grapes, figs, citrons, pomegranates and other fruits are produced. Wheat, maize and rice are grown, and some attention is given to the rearing of mules, asses, goats, cattle and sheep; while the Altar breed of horses, named after the villages of Altar do Chão and Altar Pedroso (1371), near Portalegre, is often quoted the best in the kingdom. Agriculture, however, is in a backward state, the province containing mostly villages estratified in the towns, leaving extensive districts uncultivated and almost unknown to the stranger. Droves of swine are fed on the waste lands, growing to a great size and affording excellent hams. The mineral wealth of Alemtejo is little exploited, although there are copper and iron mines and marble quarries. Medicinal springs exist at Aljustrel (3790), Castello de Vide (5192), Mértola (3873), Portalegre, Vimeiro (1838) and elsewhere. Chief among the local industries are the preparation of exceptionally fine olive oil, and the manufacture of cloth, pottery and leather. Alemtejo is traversed by three important main lines of railway, the Madrid-Cáceres-Lisbon, Madrid-Badajoz-Lisbon and Lísbon-Fez, while the two last are connected by a branch line from Casa Branca to Evora and Elvas. For administrative purposes the province is divided into the districts of Portalegre in the north, Evora in the central region and Beja in the south; but the titles of these new districts have not superseded the ancient name of Alemtejo in ordinary usage. The chief towns Beja (8889), Elvas (13,581), Estremoz (9720), Evora (16,020) and Portalegre (11,820) are described in separate articles.

ALENCON, COUNTS AND DUKES OF. The first line of the counts of Alençon was founded by Yves, lord of Bellesme, who in the middle of the 10th century possessed and fortified the town of Alençon. His successors, involved in all the wars of the kings of England in Normandy, were alternately deprived and
repossessed of their domains, according to the fluctuations of fortune between the rival parties. Mabille, countess of Alençon and heiress of this family (d.1682), married Roger of Montgomery, and from them descended a second house of Alençon which became extinct in the person of Robert IV.; the county of Alençon was then joined to the royal domain. It was successively granted as an appanage to Peter, son of St Louis (1268), and to Charles, count of Valois, brother of Philip the Fair (1293). The third house of Alençon sprang from Charles, second son of the count of Valois, who was killed at the battle of Crécy in 1346. The countship of Alençon was raised to a peerage in 1367 and into a dukedom in 1414. John, 1st duke of Alençon, was killed at Agincourt on the 25th of October 1415, after having with his own hand slain the duke of York. His son, also named John, was dispossessed of his duchy by the king of England, but, reconquered it in 1449. In 1524 the dukedom of Alençon reverted to the crown, in consequence of the death of the duke Charles IV. without issue of his marriage with Margaret, sister of Francis I. It was given as a jointure to Catherine de' Medici in 1559, and as an appanage to her son Francis in 1566. It was pawned by Henry IV. to the duke of Württemberg, and subsequently it passed to Gaston, duke of Orleans, by grant of Louis XIII.; to Elizabeth of Orleans, Duchess of Guise; to Charles, duke of Berry, grandson of Louis XIV. (1716); and to Monsieur (Louis XVIII.), brother of Louis XVI.

The title of duc d'Alençon was given to Ferdinand of Orleans, son of the duc de Nemours, and grandson of Louis-Philippe. (M. P.)

ALENCON, a town of north-western France, capital of the department of Orne, 36 m. N. of Le Mans on a branch line of the Western railway. Pop. (1906) 14,378. Alençon, a clean, regularly built town with broad handsome streets, is situated in a wide and fertile plain, on the Sarthe at its confluence with the Briante. The only remains of the ancient castle of Alençon are two towers of the 15th century, which serve as a prison, and a third built on the same site by Countess Anne de Couronnee, to which they are united. Notre-Dame, the chief church, dates from the 14th century. It is remarkable for a porch ornamented in the richest Gothic style, and for its stained windows of the 16th century. Alençon has a large circular corn-market and a cloth-market. The manufacture of the point d'Alençon lace has greatly diminished. The weaving and bleaching of cloth, which is of less importance than formerly, the manufacture of vehicles, and tanning are carried on; there is a large trade in the horses of the district, and granite is worked in the neighbourhood. Alençon is the seat of a prefect and a court of assizes. It has tribunals of first instance and of commerce, a board of trade-arbitrators, a lycée, training-colleges and a chamber of arts and manufactures.

ALENIO, GIULIO (1589-1649), Italian Jesuit missionary, was born at Brescia. He entered the Society of Jesus and was sent to the East. He landed at Macao in 1610, and while waiting a favourable opportunity to penetrate into China busied himself for three years in teaching mathematics. His thirty years' residence in China was marked by unceasing zeal and considerable success. He adopted the dress and manners of the country, was the first Christian missionary in Kwang-ki, and built several churches in Fo-Kien. He wrote in Chinese a Life of Christ (Pekin, 1635-1637, 8 vols.; often reprinted, e.g. in 1887 in 3 vols., and used even by Protestant missionaries) and a cosmography (Iche fang wai ki Hang-chow, 1623, 6 vols.), which was translated into Manchu under the title The True Origin of 10,000 Things, a copy of which was sent from Pekin to Paris in 1759. Alenio died at Fu-chow in 1649.

ALEPO (native Haleb). (1) A vilayet of Asiatic Turkey, comprising N. Syria and N.W. Mesopotamia, with an extension N. of Taurus to the neighbourhood of Gorun. It comprises three sanjaks, Aleppo, Marash and Urfa. About half is mountain, but there are fertile plains of great extent N. of Antakia, S. of Marash and around the city of Aleppo (see below). The only seaport of importance is Alexandretta (q.v.). The exports are, on the average, over one million sterling, and imports about double in value. The settled population is barely a million; but there is a considerable unsettled element in the S.E. which cannot well be estimated. The Christians, mainly Jacobite Syrian, but including also Armenians of several denominations (e.g. those of Marash and Zeitun), Maronites and Greeks, form about one-fifth. There are some 20,000 Jews, resident chiefly in the provincial capital; and of the Moslem majority the bulk is Arab, Turkoman and Ansarieh. In the N.W. and N. is a considerable Kurdistan population.

(2) The provincial capital (anc. Halep; Gr. Chalybon-Beroe), situated on a plateau in the valley of the Kuwait (anc. Chalbus) about 10 m. above its dissipation in the great salt-marsh of Matkh. Pop. about 130,000, three-quarters Moslem. Aleppo is about 63 m. by railway between the sea and the Euphrates, a little nearer the latter.

The modern city stands on both banks of the Kuwait, and the older portions are contained within a Saracenic wall, 33 m. in circuit with seven gates. The European residents and Christians live outside in the Kitab and new Azizieh quarters, and the Jews in that of Bahsita. A modern citadel occupies the N.W., the medieval castle on its mound (partly artificial and not a strong position, according to Jastakhi) being almost deserted but still forbidden to visitors. There are two mosques of interest—Ulum (or Zakaria) on the site of a church ascribed to the emperor Heraclius, and of, which is said to be the tomb of the Baptist's father, and the Kakun. Many minor ones serve the needs of a population traditionally fanatical. Gardees extend for miles along the river, and the bazaars and khans are unusually large. The climate is cold, dry and healthy, despite the prevalence of the famous "Aleppo button," a swelling which appears either on the face or on the hands, and breaks into an ulcer which lasts a year and leaves a permanent scar. It has been ascribed to a fly, to the water and to other causes; but it is not peculiar to Aleppo, being rife also at Antwah, Bagdad, &c.

The attempt made by the British Euphrates expedition in 1841 to connect Aleppo with the sea by steamer through the nearest point on the Euphrates, Meskiné, failed owing to the obstructed state of the stream and the insecurity of the riparian districts. The latter drawback has been minimized by the continued success of the Aleppo administration in inducing the Anazeh Bedouins to become felloskin; but river traffic has not been resumed. A railway, however, connects southwest with the Beirut-Damascus line at Rayak. Aleppo is an important consular station for all Eastern European powers, the residence of the Greek and Armenian Patriarchs of Antioch, and of Jacobite and Maronite bishops, and a station of Roman Catholic and Protestant missions. It is the emporium of N. Syria, and manufactures textiles in silk, cotton and wool, carpets and leather commodities, besides being the centre of a large district growing cereals, pistachios and fruit. The Turks regard it as one of the strongholds of their dominion and faith, and a future capital of their empire should they be forced to yield into Asia. As a centre from which good natural roads lead N., N.E., W. and S., Aleppo would make a good capital.

History and Remains.—The site lies high (1400 ft.) on eight hillocks in a fertile oasis plain, beyond which stretch on the S. and S.E. grassy steps merging ere long into desert, and on the other quarters rather sterile downs. It has superseded Antioch as the economic centre of N. Syria, and Palmyra as the great road-station for eastern caravans. But it is rather a revived than a new capital; Halep was a very ancient Syrian and probably "Hittite city of importance, known from Babylonian, Assyrian and Egyptian records. Seleucus Nicator gave it a Macedonian name, Beroea; but Chaleis, some distance S., was the capital of the province, Chalcidice (later, Kinnasrin), in which it lay, and the centre of that hellenized region, now a vast field of ruins, which stretches W. to the Orontes. Halep-Beroea, we may infer, remained a native town and a focus of Aramaic influence, a fact which will explain the speedy oblivion
of its Macedonian name and the permanent revival of its ancient title, even by Greeks.

As Beroea we hear of the place in Seleucid wars and dissensions. There Menelaus, the fomenter of war with the Asmoneans, was put to death by Lysias in 164 B. C., "as the manner is in that place" (Macc. ii. 13. 4), being thrown into a lofty tower full of cinders. There Heracleon, the court favourite and murderer of Antiochus Grypus, was born and made himself a principality (p6 B.C.); and there the son of the latter king besieged his brother Philip in the last struggle for the heritage of Seleucus. As Chalybon, the town is called by Ptolemy head of a district, Chalybonitis; but we continue to hear of it as Beroea up to the Arab conquest, e.g. in the history of Julian's eastward march in A.D. 363, and in that of the Persian raid of 540. It was occupied in 611 by Chosroes II. Overwhelmed by the Saracen flood in A.D. 638, Beroea disappears, and as Moslem society settles down Hailep emerges again as the great gathering-place of caravans passing from Asia Minor and Syria to Mesopotamia, Bagdad and the Persian and Indian kingdoms. Like Antioch it suffered from earthquakes, and late in the 12th century, after a terrible shock, had to be rebuilt by Nur ed-Din. But neither earthquakes nor the plague, to which it was also peculiarly liable, could divert trade and prosperity from it. It belonged to the Eastern Caliphate (the Hamdondots) until temporarily reoccupied by John Zimisces, emperor of Byzantium and a native of neighbouring Hierapolis (q.v.), A.D. 974, after an abortive attempt by Nicophorus thirteen years earlier. Thirteen years later it was recognized and received the Fatimides, and passed under various Moslem dynasties, forming part of the Seljuk dominion from 1000 to 1117. The crusading princes of Antioch never held the place, though they attacked it in 1124; and Saladin, who took it in 1183, made it a stronghold against them and the northern capital of himself and his successors until the Tartar invasion of 1260. Thereafter the Mameluks took and kept possession, despite the renewed Tartar inroad of 1401, until the final conquest by the Ottomans in 1517. Under the strong hand of the latter the trade of Aleppo with the East revived. One of the first provincial factories and consulates of the British Turkey (Levant) Company was established there in the reign of James I.; and a British agent had been in residence there even in Elizabeth's time. As the eastern outpost of the company's operations, it was connected with the western outpost of the East India Company in Bagdad by a private postal service, and its name became very familiar in England from the part that its merchants (largely Jewish) bore in the transmission of Eastern products to Europe (cf., e.g. Shakespeare, Macb. i. 3. 7: Oth. v. 2. 352). Through it passed the sail of Bambysse, called baniyas, the light vessels of Moslem (merchants) and many other commodities for the wealthy and luxurious.

The first blow was struck at this trade by the discovery of the Cape route to India; the second by the opening of a land route through Egypt to the Red Sea; the third and final one by the making of the Suez Canal. Long ere this last event, however, Aleppo had been declining from internal causes. In the latter part of the 18th century and the first years of the 19th it was constantly the scene of bloody dissensions between two rival patriarchs or jisrawis, one jisrawi, the other the shereif (religious); and the Ottoman governors took the side, now of one, now of the other, in order to plunder a distracted city, too far removed from the centre to be controlled by the sultans, and too near the rebellious pashah of Acre and the unsettled district of Lebanon not to be affected by the disorders natural to a frontier province. This state of things led to the suspension of the British consulate by the Turkey Company in 1791; and it was not revived till 1800, after which date till 1825 it was maintained jointly by the East India Company. In 1808 Jezzar of Acre advanced as near as Hamah; but his death occurred in the following year; and after a sanguinary rising in 1809, Aleppo settled down, but was not at peace, even after a local jisrawi massacre in 1814, till Mahmud II. had dealt finally with the corps at headquarters (1826). Meanwhile there had been a frightful earthquake in 1822, and a visitation of cholera in the following year. More cholera in 1827 and 1832 and another earthquake in 1830 had left the place a wreck, with only half its former population, when Mehmet Ali of Cairo invaded and took Syria. Aleppo shared, and to some extent headed, the Syrian discontent with Egyptian rule, and was strongly held by troops whose huge barracks are still one of the sights of the town. But ready to rise and renew a barbarism in 1839, it was only prevented by the news of Neziz. Throughout the massacres of Christians occurred in 1850 and 1862, accompanied by great destruction of property; but on the whole, since the consolidation of Ottoman rule over Syria by Abdul Mejid's ministers, Aleppo has been reviving, although its trade is more local than of old.

ALES (ALESIUS), ALEXANDER (1500–1562), Scottish divine of the school of Augsburg, whose family name was ALANE, was born at Edinburgh on the 25th of April 1500. He studied at St Andrews in the newly-founded college of St Leonard's, where he graduated in 1525. Some time afterwards he was appointed a canon of the collegiate church, and at first continued vigorously for the scholastic theology as against the doctrines of the Reformers. His views were entirely changed, however, on the execution of Patrick Hamilton, abbot of Fern, in 1528. He had been chosen to deliver the inroad confession, with a view to convincing him of his errors, but the arguments of the Scottish proto-martyr, and above all the spectacle of his heroism at the stake, impressed Alesius so powerfully that he was entirely won over to the cause of the Reformers. A sermon which he preached before the Synod at St Andrews against the dissoluteness of the clergy gave great offence to the provost, who cast him into prison, and might have carried his resentment to the extreme limit had not Alesius contrived to escape to Germany in 1532. After travelling in various countries of northern Europe, he settled down at Wittenberg, where he made the acquaintance of Luther and Melancthon, and signed the Augsburg confession. Meanwhile he was tried in Scotland for heresy and condemned without a hearing. In 1533 a decree of the Scottish clergy, prohibiting the reading of the New Testament by the laity, drew from Alesius a defence of the right of the people, in the form of a letter to James V. A reply to this by John Cochraneus, also addressed to the Scottish king, occasioned a second letter from Alesius, in which he not only amplifies his argument with great force, but enters into more general questions connected with the Reformers' doctrines. In 1534 he was in the university of Leipzig, and a few others were excommunicated at Holyrood by the deputy of the archbishop of St Andrews. When Henry VIII. broke with the church of Rome Alesius was induced to go to England, where he was very cordially received (August 1533) by the king and his advisers Cranmer and Thomas Cromwell. After a short residence at Lambeth he was appointed, through the influence of Cromwell, then chancellor of the university, to lecture on theology at Cambridge; but when he had delivered a few expositions of the Hebrew psalms, he was compelled by the opposition of the papal party to retire to Leiden, from which he was at times obliged to go out by practising as a physician. In 1537 he attended a convocation of the clergy, and at the request of Cromwell conducted a controversy with Stokesley, bishop of London, on the nature of the sacraments. His argument was afterwards published under the title Of the Acceptable of the Word of God concerning the number of the Sacraments. In 1539 Alesius was compelled to flee for the second time to Germany, in consequence of the enactment of the statute of the Six Articles. He was appointed to a theological chair in the university of Frankfort-on-Oder, where he was the first professor who taught the reformed doctrines. In 1543 he quitted Frankfort for a similar position at Leipzig, his contention that it was the duty of the civil magistrate to punish fornication, and his sudden departure, having given offence to the authorities of the former university. He was in England again
ALESIAS, ALEZZO (1512-1572), Italian architect, was born at Perugia, and was probably a pupil of Caporali. He was an enthusiastic student of ancient architecture, and his style gained for him a European reputation. Genoa is indebted to him for a number of its most magnificent palaces, and specimens of his skill may be seen in the churches of San Paolo and Santa Vittoria at Milan, in certain parts of the Escorial, and in numerous churches and palaces throughout Sicily, Flanders and Germany. See Rossi, Di Galeazzo Alesi memory (Perugia, 1873).

ALETHIOLOGY (from the Gr. ἀλήθεία, truth), an uncommon expression for the doctrine of truth, which was evolved by Sir William Hamilton in his philosophical writings when treating of the rules for the discrimination of truth and error.

ALETRIUM (mod. Alatri), a town of the Hernici, about 6 m. due N. of Frusino, Italy, mentioned in 306 B.C. for its fidelity to Rome. In Cicero's time it was a munificium, and continued in this position throughout the imperial period. It is chiefly remarkable for its finely preserved fortifications constructed of tufa, measures about 17 ft. in length, 5 ft. in height, 6 ft. thick; some 200 ft. in length, 30 ft. in height, 6 ft. thick. These were excavated by Napoleon III., and may be seen to best advantage at a height of about 100 ft., enclosed by a roughly rectangular wall. Above the wall is a flat surface partly formed by smoothing off the rock and partly by the erection of huge terrace walls which rise to a height of over 50 ft., enclosing a roughly rectangular area of 235 by 115 yds. Two approaches to the citadel were constructed, both passing through the wall; the openings of both are rectangular. The architrave of the larger, known as Porta di Civita, measures about 19 ft. in height, 6 ft. thick; that of the smaller is decorated with three phalli in relief. Later, though probably in ancient times, a ramp was added on the northern side. In the centre of the arch was a building on the site of the present cathedral, of which only a small portion is reserved. Remains of a high-pressure aqueduct, which supplied the town with water and was constructed with other public buildings (Corp. Insit. Lat. x., Berlin, 1883, p. 5807) by L. Belitennus Varus, may still be traced. A temple was excavated in 1886 about 3/4 m. to the north of the town, and many fragments of the painted terra-cottas with which it was decorated were found. A reconstruction of it has been erected in the Museo di Villa Giulia at Rome. The present town (pop. in 1901, 15,322) has a picturesque aspect, and contains many buildings in the Gothic style.

See R. Baselli, Centrallatt der Bauverwaltung, 1881, 121, p. 124; H. Winnefeld, Römsche Mittheilungen, 1889, 126; G. Fiorelli in Notizie degli Scavi, 1882, 417. (T. A.)

ALEURITES (Gr. ἀλεύριτης, pertaining to ἀλεύρων, ground, meal, from ἄλευρος, to grind), a genus of trees belonging to the central order Euphorbiaceae. Alteles clusiana, or triloba, is widely cultivated throughout the tropical and sub-tropical parts of the world for its fruit, which is about the size of a walnut, and contains several seeds which are rich in oil. The oil is extracted and used for food and light; it is known in India as kokuma, and the tree as the "candle-nut." In the Sandwich Islands the nuts are strung upon strips of wood and used as torches. The oil is exported to Europe for candle-making. A. cordato flourishes in China, where it is known as the "varnish-tree," on account of the lac contained in its seeds.

ALEUTIAN ISLANDS (possibly from Chukchi alit, "island"), a chain of small islands situated in the Northern Pacific Ocean, and extending about 12,000 m. westward from the extremity of
the Alaskan peninsula toward the peninsula of Kamchatka; they constitute part of the District of Alaska, U.S.A. The islands, of which an alternative collective name is the Catherine Archipelago, comprise four groups—the Fox, Andreanof, Rat and Near Islands. They are all included between 52° and 55° N. lat. and 172° E. and 163° W. long. The latter part of the Archipelago near the mainland of Alaska has a S.W. trend, but near the 120th meridian its direction changes to the N.W. This change of direction corresponds to a curve in the line of volcanic fissures which have contributed their products to the building of the islands. Such curved chains are repeated about the Pacific Ocean in the Kurile Islands, the Japanese chain, the Philippines, &c. The general elevation is greatest in the eastern islands and least in the western. The island chain is really a western continuation of the Aleutian Range on the mainland.

The great majority of the islands bear evident marks of volcanic origin, and there are numerous volcanic cones on the north side of the chain, some of them active; many of the islands, however, are not wholly volcanic, but contain crystalline or sedimentary rocks, and also amber and beds of lignite. The coasts are rocky and surf-worn and the approaches are exceedingly dangerous, the land rising immediately from the coasts to steep, bold mountains.

The climate of the islands is oceanic, with moderate and fairly uniform temperatures and heavy rainfall. Fogs are almost constant. The summers are much cooler than on the mainland at Sitka, but the winter has never been of the island, and south-eastern Alaska is very nearly the same. The mean annual temperature for Unalaska, the most important island of the group, is about 38° F.; being about 30° for January and about 52° for August. The highest and lowest temperatures recorded on the islands are 78° and 5°. The average annual amount of rainfall is about 80 in., and Unalaska, with about 250 rainy days per year, is said to be the rainiest place within the territory of the United States. The growing season lasts about 135 days, from early in May till late in September, but agriculture is limited to the raising of a few vegetables. With the exception of some stunted willows the islands are practically destitute of trees, but are covered with a luxuriant growth of herbage, including grasses, sedges and many flowering plants. On the less mountainous islands the raising of sheep and reindeer is believed to be practicable. The principal occupations of the natives have always been fishing and hunting, and the women weave basketry of exquisite fineness. From the end of the 18th century the Russian fur traders had settlements here for the capture of the seal and the sea otter and the blue and white fox. The American régime seal fishing off the Aleutians saved by the natives has been abandoned, but the depletion of the Pribilof herd, the almost complete extinction of the sea otter, and the rapid decrease of the foxes and other fur animals, have threatened the Aleuts (as the natives are commonly called) with starvation. In recent years enterprising traders have raised foxes by culture and by especially protecting certain small islands, and this has furnished employment to whole communities of natives. Fish and sea-fowl are extremely abundant.

The natives are rather low in stature, but plump and well shaped, with well formed necks, swarthy faces, black eyes and long black hair. Young men of the Esquimaux habit but differ greatly from the Eskimo of the mainland in language, habits, disposition and mental ability. They were good fighters until they were cowed by the treatment of the Russians, who practically reduced them to slavery. Sporadic efforts to Christianize the Aleuts were made in the latter half of the 18th century, but little impression was made before the arrival in 1824 of Father Ivan Veniaminov, who in 1825 became the first Greek bishop of Alaska. While the missionaries of the Greek Church have nominally converted the natives to Christianity, white adventurers have more effectually converted them to various bad habits. In dress and mode of life they have adopted outwardly civilized customs. From the position of the Aleutian islands, stretching like a broken bridge from Asia to America, some ethnologists have supposed that by means of them America was first peopled. Raised shore-lines, occasional earthquakes, and slow measurable elevation of the land about active volcanoes, indicate that elevation is now in progress, but the geological evidence shows no sign of former submergence of a connecting isthmus. There is granite at the core of the Shaler range of mountains in south America.

It is stated that before the advent of the Russians there were 25,000 Aleuts on the archipelago, but that the barbarities of the traders eventually reduced the population to one-tenth of this number. The number of Aleuts in 1800 was reported as 608; the total population of the archipelago in 1900 was 2000.

The principal settlements are on the Unalaska Island. Of these Iliuliuk (also called Unalaska), the oldest, settled in 1760-1775, has a custom house, a Russian-Greek Church, and a Methodist Mission and orphanage, and is the headquarters for a considerable fleet of United States revenue cutters which patrol the sealing grounds of the Pribilofs; adjacent is Dutch Harbor (so named, it is said, because a Dutch vessel was the first to enter it), which is an important port for Bering Sea commerce. The volcanic Makushin (5691 ft.) is visible from Iliuliuk, and the volcanic islets Bogoslof and Grewingk, which rose from the sea in 1706 and 1883 respectively, lie about 30 m. W. of the bay. The latter is still active; in 1906 a new cone rose between the two earlier islets, and in 1907 still another: these were nearly demolished by an explosive eruption on the 1st of September, 1907. The population of Unalaska Island in 1900 was 575 Aleuts and 66 whites. The Commander Island group was bought by the United States in 1867. The southernmost point of the Asiatic coast is geographically, but since the acquisition of the Russian possessions in America not politically, a part of the Aleutian system.

In 1741 the Russian government sent out Vitus Bering, a Dane, and Alexei Chirikov, a Russian, in the ships "Saint Peter" and "Saint Paul" on a voyage of discovery in the Northern Pacific. After the ships were separated by a storm, Chirikov discovered several eastern islands of the Aleutian group, and Bering discovered several of the western islands, finally being wrecked and losing his life on the island of the Commander group that now bears his name. The survivors of Bering's party reached Kamchatka in a boat constructed from the wreckage of their ship, and reported that the islands were rich in fur-bearing animals. Siberian fur-hunters at once flocked to the Commander Islands and gradually moved eastward across the Aleutian Islands to the mainland. In this manner Russia gained a foothold on the north-western coast of North America. The Aleutian Islands consequently belonged to Russia, until that country in 1867 transferred the United States all Alaska. The Aleuts, who had been in the United States since 1859, were finally returned in 1900.

ALEXANDER (ALEXANDER OF BATTENBERG) (1837-1863), first prince of Bulgaria, was the second son of Prince Alexander Hesse and the Rhine, by his marriage with Countess Herhold zu Hohenklaus (q.v.), daughter of Count Javoun von Hauke. The title of Prince of Battenberg, derived from an old name of Bulgaria, the grand-dukes of Hesse, was conferred, with the prefix Durchlaucht or "Serene Highness," on the countess and her descendants in 1838. Prince Alexander, who was born on the 5th of April 1837, was nephew of the tsar Alexander II, who had married a sister of Prince Alexander of Hesse; his mother, a daughter of Count Moritz von Hauke, had been lady-in-waiting to the tsaritsa. In his boyhood and early youth he was frequently at St Petersburg, and he accompanied his uncle, who was much attached to him, during the Bulgarian campaign of 1877. When Bulgaria under the Berlin Treaty was constituted an autonomous principality under the suzerainty of Turkey, the tsar recommended his nephew to the Bulgarians as a candidate for the newly created throne, and
ALEXANDER I.—ALEXANDER THE GREAT

Prince Alexander was elected prince of Bulgaria by unanimous vote of the Grand Sobranje (April 29, 1879). He was at that time serving as a lieutenant in the Prussian life-guards at Potsdam. Before proceeding to Bulgaria, Prince Alexander paid visits to the tsar at Livadià, to the courts of the great powers at London and Paris. The tsar was then conveyed on a Russian war-ship to Varna, and after taking the oath to the new constitution at Tîrnova (July 8, 1879) he repaired to Sofia, being everywhere greeted with immense enthusiasm by the people. 

For the political history of Prince Alexander's reign, see Bulgaria. Without any previous training in the art of government, the young prince from the outset found himself confronted with difficulties which would have tried the sagacity of an experienced ruler. On the one hand he was exposed to numberless humiliations on the part of the representatives of official Russia, who made it clear to him that he must be expected to play the part of a roi fantaisiste on the other he was compelled to make terms with the Bulgarian politicians, who, intoxicated with newly won liberty, prosecuted their quarrels with a crude violence which threatened to subvert his authority and to plunge the nation in anarchy. After attempting to govern under these conditions for nearly two years, the prince, with the consent of the tsar Alexander III., assumed absolute power (May 9, 1881), and a suspension of the ultra-democratic constitution for a period of seven years was voted by a specially convened assembly (July 13). The experiment was successful; however,公子 Alexander's relations with Eastern Rumelia were in a state of constant tension, and the real power fell into the hands of two Russian generals, Sobolev and Kaulbars, who had been specially despatched from St Petersburg. The prince, after vainly endeavouring to obtain the recall of the generals, restored the constitution with the concurrence of all the Bulgarian political parties (September 18, 1883). A serious breach with Russia followed, which was widened by the part which the prince subsequently played in encouraging the national aspirations of the Bulgarians. The revolution of Philippopolis (September 18, 1885), which brought about the union of Eastern Rumelia with Bulgaria, was carried out with his consent, and he at once assumed the government of the revolted province. In the anxiou year which followed, the prince gave evidence of considerable military and diplomatic ability. He rallied the Bulgarian army, now deprived of its Russian officers, to resist the Servian invasion, and after a brilliant victory at Slîvnitza (November 19) pursued King Milan into Servian territory as far as Pîrot, which he captured (November 27). Although Servia was protected from the consequences of defeat by the intervention of Austria, it was left in a position of great inferiority in relation to Russia. As a result, Alexander suspended the constitution of Servia, and after long negotiations he was nominated governor-general of that province for five years by the sultan (April 5, 1886). This arrangement, however, cost him much of his popularity in Bulgaria, while discontent prevailed among a certain number of his officers, who considered themselves slighted in the distribution of rewards at the close of the campaign. A military conspiracy was formed, and on the night of the 20th of August the prince was seized in the palace at Sofia, and compelled to sign his abdication; he was then hurried to the Danube at Ruse, transported thence to Constantinople at the point of the sword, and finally handed over to Russian authorities, by whom he was allowed to proceed to Lemberg. He soon, however, returned to Bulgaria, owing to the success of the counter-revolution led by Stamboloff, which overthrew the provisional government set up by the Russian party at Sofia. But his position had become untenable, partly owing to an ill-considered telegram which he addressed to the tsar on his return; partly in consequence of the attitude of Prince Bismarck, who, in conjunction with the Russian and Austrian governments, forbade him to punish the leaders of the military conspiracy. He therefore issued the manifesto resigning the throne, and left Bulgaria on the 8th of September 1886. He now retired into private life. A few years later he married Fräulein Loisinger, an actress, and assumed the style of Count Hartenau (February 6, 1889). The last years of his life were spent principally at Gratz, where he held a local command in the Austrian army. Here, after a short illness, he died on the 23rd of October 1893. His remains were brought to Sofia, where they received a public funeral, and were eventually deposed in a mausoleum erected in his memory. Prince Alexander possessed much charm and amiability of manner; he was tall, dignified and strikingly handsome. His capabilities as a soldier have been generally recognized by competent authorities. As a ruler he committed some errors, but his youth and inexperience and the extreme difficulty of his position must be taken into consideration. He was not without aptitude for diplomacy, and his intuitive insight and perception of character sometimes enabled him to outwit the crafty politicians by whom he was surrounded. His principal fault was a want of tenacity and resolution; his tendency to unguarded language undoubtedly increased the number of his enemies.

ALEXANDER I., king of Epirus about 342 B.C., brother of Olympias the mother of Alexander the Great, and son-in-law of Philip of Macedon, whose daughter Cleopatra he married (356). In 332 he crossed over to Italy to assist the Tarentines against the Lucanians, Bruttians and Samnites. He gained considerable successes and made an arrangement with the Romans for a joint attack upon the Samnites; but the Tarentines, suspecting him of the design of founding an independent kingdom, turned against him. Although the advantage at first rested with Alexander, he gradually lost it, and his supporters dwindled away. In 330 (or earlier) he was defeated at Pandosia and slain by a Lucanian emigrant.

See Justin viii. 6, ix. 6, xii. 2; Livy viii. 13, 27, 44; Aulus Gallius xvii. 21; and article Macedonian Empire.

ALEXANDER II., king of Epirus, succeeded his father Pyrrhus, 272 B.C. He attacked Antigonus Gonatas and conquered the greater part of Macedonia, but was in turn driven out of both Epirus and Macedonia by Demetrius the son of Antigonus. He subsequently recovered his kingdom by the aid of the Acrapaniacs and Aetolians. He died about 260 (Polybius ii. 45, ix. 34; Plutarch, Pyrrhus, 9; Justin xviii. i, xxvi. 2, xxvii. 1).

ALEXANDER III., known as THE GREAT (336-323 B.C.), king of Macedon, was the son of Philip II. of Macedon, and Olympias, sister of Epirus. His father was pre-eminent for practical genius, his mother a woman of half-wild blood, weird, visionary and terrible; and Alexander himself is singular among men of action for the imaginative splendours which guided him, and among romantic dreamers for the things he achieved. He was born in 356 B.C., probably about October (Hogarth, pp. 284 ff.). The court at which he grew up was the focus of great activity, for Philip, by war and diplomacy, was raising Macedonia to the headship of the Greek states, and the air was charged with great ideas. To unite the Greek race in a war against the Persian empire was set up as the ultimate mark for ambition, the theme of idealists. The great literary achievements of the Greeks in the 5th century lay already far enough behind to have become invested with a classical dignity; the meaning of Hellenic civilization had been made concrete in a way which might sustain enthusiasm for a body of ideal values, authoritative by tradition. And upon Alexander in his fourteenth year this sum of tradition was brought to bear through the person of the man who beyond all others had gathered it up into an organic whole: in 343-342 Aristotle (q.v.) came to Pella at Philip's bidding to direct the education of his son. We do not know what faculty the master-thinker may have had for captivating this ardent spirit; at any rate Alexander carried with him through life a...
passion for Homer, however he may have been disposed to greyer philosophic theory. But his education was not all from books. The coming and going of envoys from many states, Greek and Oriental, taught him something of the actual conditions of the world. He was early schooled in war. At the age of sixteen he commanded in Macedonia during the absence of Philip's envoys and quelled a rising of the hill-tribes on the northern border; in the following year (338) he headed the charge which broke the Sacred Band at Chaeronea. Then came family dissensions such as usually vex the polygamous courts of the East. In 337 Philip repudiated Olympias for another wife, Cleopatra, Alexander went with his mother to her home in Epirus, and, though he soon returned and an outward reconciliation between father and son was contrived, their hearts were estranged. The king's new wife was with child; her kinmen were in the ascendant; the succession of Alexander was impeached. Some theologians which Pldxanrr, the satrap of Caria, opened with the Macedonian court with a view to effecting a marriage alliance between his house and Philip's, brought Alexander into fresh broils. In 336 Philip was suddenly assassinated whilst celebrating at Aegae the marriage of his daughter to Alexander I. of Epirus in the presence of a great concourse from all the Greek world. It is certain that the hand of the assassin was prompted by some one in the background; suspicion could not fail to fall upon Alexander among others. But guilt of that sort would hardly be consistent with his character as it appears in those early days. Alexander, the mountain warfare of the tribes by a precision of discipline which, probably, no other army of the time could have approached, and traversed the land of the Thriballians (Rumelia) to the Danube. To gratify his own imagination or strike the imagination of the world he took his army over the Danube and burnt a settlement of the Getae upon the other side. Meanwhile the Ilyrians had seized Pelion (Piasa), which commanded the passes on the west of Macedonia, and from the Danube Alexander marched straight thither over the hills. He had hardly restored Macedonian prestige in this quarter when he heard that Greece was in a ferment and in such a manner that he took the Thebans completely by surprise, and in a few days the city, which a generation before had won the headship of Greece, was taken. There were to be no half-measures now; the city was wiped out of existence with the exception of its temples and the house which had been Pindar's. Greece might now be trusted to lie quiet for some time to come. The Panhellenic alliance (from which Sparta still stood aloof) against the barbarians was renewed. Athens, although known to be hostile at heart to the cities of Macedonian power, Alexander treated all through with equal courtesies. In the spring of 334, Alexander crossed with an army of between 30,000 and 40,000 men, Macedonians, Illyrians, Thracians and the contingents of the Greek states, into Asia. The place of concentration was Arisbe on the Hellespont.
Mytilene and the great plan collapsed. A Persian fleet still held the Aegean, but it effected little, and presently fresh Graeco-Macedonian squadrons began to hold it in check. It was, however, the need to ensure command of the sea and free all lines of communication behind him that determined Alexander's plan for the next campaign. If he mastered the whole coast-line of the Levant, the enemy's fleet would find itself left in the air. The Syrian coast was accordingly his immediate objective when he broke up from Gordium for the campaign of 333. He was through the Civic Gates before the Persian king, Darius III., had sent up a force adequate to hold them. His passage through Cilicia was marked by a violent fever that arrested him for a while in Tarsus, and meantime a great Persian army was waiting for him in northern Syria under the command of Darius himself. In the knot of mountains which close in about the head of the Gulf of Alexandretta, Alexander, following hard by the coast, marched past the Persian outposts and encamped on the plains to the east. To cut Alexander's communications with the rear, Darius now committed the error of entangling his large force in the mountain defiles. Alexander turned, and near the town of Issus fought his second pitched battle, sending Darius and the relic of his army in wild flight back to the east. It was an incident which did not modify Alexander's plan. He did not press the pursuit far, although the great king's camp with his harem fell into his hands. The chivalrous courtesy which he showed to the captive princesses was a favourite theme for later rhetoricians, and it is generally held that he ravaged Syria and Phoenicia. It is now that we get definite evidence as to the reach of Alexander's designs; for Darius opened negotiations in which he ultimately went so far as to offer a partition of the empire, all west of the Euphrates, to be Alexander's. Alexander refused the bargain and definitely claimed the whole. The conquest of the Phoenician coast was not to be altogether easy, for Tyre shut its gates and for seven months Alexander had to sit before it—one of those obstinate sieges which mark the history of the Semitic races. When it fell, Alexander had the old Tyrian people scattered to the winds, 30,000 held as slaves. Gaza offered resistance equally heroic, lasting two months, and here too the old population was dispersed. The occupation of the rest of Syria and Palestine proceeded smoothly, and after the fall of Gaza Alexander's way lay open into Egypt. Egypt was the last of the Mediterranean provinces to be won, and here no defence was made. To the native Egyptians Alexander appeared as a deliverer from the Persian tyranny, and he sacrificed piously to the gods of Memphis. The winter (332-331) which Alexander spent in Egypt saw two memorable actions on his part. One was the expedition (problematic in its motives and details) to Assyria and the Tigris (which lasted from November, 332, to May, 331), where Alexander was hailed by the priest as son of the god, a belief which the circle of Alexander, and perhaps Alexander himself, seem hereafter to have liked to play with in that sort of semi-serious vein which still allowed him in the moments of every-day commonplace to be the son of Philip. The other action was the foundation of Alexandria at the Canopic mouth of the Nile, the place destined to be a new commercial centre for the eastern Mediterranean world which Alexander had now taken in possession, to rise to an importance which the founder, although obviously acting with intention, can hardly have foreseen (E. Keller, Alex. d. Gr. Geschichte nach der Schlacht bei Issus, 1904).

In the spring of 331 Alexander could at last leave the Mediterranean to strike into the heart of the Persian empire, for by his occupation of the coasts the Persian command of the sea had inevitably collapsed. Returning through Syria, and stopping at Tyre to make final arrangements for the conquered provinces, he traversed Mesopotamia and struck the Tigris some four marches above the site of Nineveh. It was near Nineveh that Darius was waiting with the immense host which a supreme effort could muster from all parts of the empire. The happy coincidence of a lunar eclipse gave us the 20th of September 331 as the exact date upon which the Macedonian army crossed the Tigris. Alexander came within sight of the Persian host without any difficulty of movement, and he found himself left in the air. The Syrian coast was accordingly his immediate objective when he broke up from Gordium for the campaign of 333. He was through the Civic Gates before the Persian king, Darius III., had sent up a force adequate to hold them. His passage through Cilicia was marked by a violent fever that arrested him for a while in Tarsus, and meantime a great Persian army was waiting for him in northern Syria under the command of Darius himself. In the knot of mountains which close in about the head of the Gulf of Alexandretta, Alexander, following hard by the coast, marched past the Persian outposts and encamped on the plains to the east. To cut Alexander's communications with the rear, Darius now committed the error of entangling his large force in the mountain defiles. Alexander turned, and near the town of Issus fought his second pitched battle, sending Darius and the relic of his army in wild flight back to the east. It was an incident which did not modify Alexander's plan. He did not press the pursuit far, although the great king's camp with his harem fell into his hands. The chivalrous courtesy which he showed to the captive princesses was a favourite theme for later rhetoricians, and it is generally held that he ravaged Syria and Phoenicia. It is now that we get definite evidence as to the reach of Alexander's designs; for Darius opened negotiations in which he ultimately went so far as to offer a partition of the empire, all west of the Euphrates, to be Alexander's. Alexander refused the bargain and definitely claimed the whole. The conquest of the Phoenician coast was not to be altogether easy, for Tyre shut its gates and for seven months Alexander had to sit before it—one of those obstinate sieges which mark the history of the Semitic races. When it fell, Alexander had the old Tyrian people scattered to the winds, 30,000 held as slaves. Gaza offered resistance equally heroic, lasting two months, and here too the old population was dispersed. The occupation of the rest of Syria and Palestine proceeded smoothly, and after the fall of Gaza Alexander's way lay open into Egypt. Egypt was the last of the Mediterranean provinces to be won, and here no defence was made. 3 The story of Alexander's visit to Jerusalem rests on no better authority than a later Jewish romance.
Macedonians, and at Prophthoraes the commander of the Macedonian cavalry Philotas, the son of Parmenio, and certain others were arraigned before the army on the charge of conspiring against the king's life. They were condemned and put to death. Not satisfied with procuring this, Alexander had Parmenio himself, who had been left in command in Media, put to death by secret orders. It is perhaps the worst crime, because the most cold-blooded and ungenerous, which can be laid to his charge. By the winter of 329–328 Alexander had reached the Kabul valley at the foot of the Paropamisades (Hindu Kush).

The ordinarily received chronology makes Alexander reach the Kabul valley in the winter of 330–329. That to fit the actions and distances covered by Alexander into such a scheme, assuming that he went by Seistan and Kandahar, would involve physical impossibilities has been pointed out by Count Vorck v. Wartenburg and Mr D. G. Hogarth. Kaeest and Beloch continue to give the ordinary chronology untroubled.

In the spring of 328 Alexander crossed the Hindu Kush into Bactria and followed the retreat of Bessus across the Oxus and into Sogdiana (Bokhara). Here Bessus was at last caught and treated with the barbaric cruelty which the rule of the old Persian monarchy prescribed for rebels. Till the spring of 327 Alexander was moving to and fro in Bactria and Sogdiana, beating down the recurrent rebellions and pushing Greek culture. When he had crossed the Danube, he now made one raid across the frontier river, the Jaxartes (Sir Daria), to teach the fear of his name to the outlying peoples of the steppe (summer 328). And meanwhile the rift between Alexander and his European followers continued to show itself in dark incidents—the murder of Citrus at Maracanda (Samarqand), when Alexander struck down an old friend, both being hot with wine; the claim that Alexander should be approached with prostration (proskynesis), urged in the spring of 327, and opposed boldly by the philosopher Callisthenes, Aristotle's nephew, who had come in the king's train; the conspiracy of the pages at Bactria, which was made an occasion for putting Callisthenes to death. It was now that Alexander completed the conquest of the provinces north of the Hindu Kush by the reduction of the last mountain strongholds of the native princes. In one of them he captured Roxana, the daughter of Oxyartes, whom he made his wife. Before the summer of 327 he had once more crossed the Hindu Kush on his way to India (for the campaignus in the N.E. see F. von Schwarz, Alex. d. Grossen Feldzuge in Turkistan, 1853, v.).

With the heavier troops moved down the Kabul valley to Penceloottis (Charasadda) under Perdiccas and Hephaestion, Alexander with a body of lighter-armed troops and cavalry pushed up the valleys which join the Kabul from the north—through the regions now known as Bajour, Swat and Buner, inhabited by Indian hill peoples, as fierce then against the western intruder as their Pathan successors are against the British columns. The books give a number of their "cities," reduced by Alexander—walled mountain villages which can in some cases be identified more or less certainly with places where the clans are established to-day. The crowning exploit was the reduction of Aornus,1 a stronghold perched on a precipitous summit above the Indus, which it was said that Hercules had failed to take. How much of the story of Alexander's discovery of the sacred mountain of the Nya and the traces of Dionysus in India is due to the invention of Aristobulus and Clitarchus (Arrian did not find it in Ptolomy) we cannot say. Meantime Perdiccas and Hephaestion had built a bridge over the Indus, and by this the spring of 326 Alexander passed into the Punjab (at Ohind, 26 m. above Attock, according to Foucher, Notes sur la géogr. anc. du Gandhâra, 1902). The country into which he came was dominated by three principalities, that of Ambhi (Gr. Omphis, Curt. viii. 12. 6) between the Indus and the Hydaspes (Jhelum, 1

Jhelum), centred in the great city of Takkaasla (Gr. Taxila), that of the Paurara rajah (Gr. Porus) between the Hydaspes and Acesines (Chenab), and that of Abisares (Gr. Abisares) between the same two rivers higher up, on the confines of Kashmir (Stein, Rajmahal, before trans. mx. 180, v. 217). The kings of Taxila and Porus were at enmity, and for this cause the invaders could reckon upon Omphis as a firm ally. Porus was prepared to contest the passage of the Hydaspes with all his strength. Abisares preferred to play a double game and wait upon events. Alexander reached the Hydaspes just as the rains broke, when the river was already swollen. Porus held the opposite bank with a powerful army, including 200 elephants. Alexander succeeded in taking a part of his forces across the river higher up during a night of torrential rain, and then governors were sent out to lose his great troops in Asia, the one which put to proof more shrewdly than any of the others the quality of the Macedonian army as an instrument of war, and yet again emerged victorious. Porus fell sorely wounded into his hands.2 Porus had saved his honour, and now Alexander tried, and not in vain, to gain him as a friend. When he continued his progress eastwards across the Acesines, Porus was an active ally. Alexander moved along close under the hills. After crossing the Hydrâotes (Râvi) he once more came into contact with hostile tribes, and the work of storming petty forts, and the destruction of the great river to its mouth (for the exploration of the Indian provinces, see especially Niese, vol. i. pp. 590 f.). The fleet prepared on the Hydaspes sailed in October, while a land army moved along the bank. The confluence of the Hydaspes and Acesines passed, the Macedonians were once more in a region of hostile tribes with towns to be stormed. It was at one of these, a town of the Malii, that a memorable incident occurred, such as characterized the personality of Alexander for all succeeding time. He leapt from the wall with only three arrows in his quiver, and when he reached the apex of the Indus delta abandoned his country and fled. It was the high summer of 325 when Alexander reached Patala. From here he explored both arms of the delta to the ocean, now seen by the Macedonians for the first time. He had determined that the Indus fleet should be used to explore this new world and try to find a waterway between the Indus and the Persian Gulf. A great part of the land-forces had been already sent off under Craterus in the earlier summer to return west by Kandahar and Seistan; the fleet was to sail under the Greek navigation to reach Alexander himself with the rest of the land-forces set out in October to go by the

3 There seems no reason why the exact spot of this town; the common identification with Multan is, according to Ravery and V. Smith, certainly wrong.
by man through his chamber to bid him farewell. On the 28th (June 7) Alexander died.\footnote{Alexander's funeral, see F. Jacoby in Rhein. Mst. (1993), pp. 461 f.}

His son by Roxana, the so-called Alexander “Aegus” was born a few months later. He and his uncle Philip, as joint kings, were placed under the guardianship of Perdiccas, Peiton and Antipater in succession. After the death of Antipater (319) Roxana fled with him to Epirus, and was afterwards taken back to Macedonia, together with Olympias, by Polyperchon. All three fell into the hands of Cassander; Alexander and his mother were in 310-309 put to death by order of Cassander (Justin xiv. 6, xv. 2). The meaningless surname of Aegus, still given in some books to this Alexander, is derived simply from a conscious misunderstanding of the text of the Astronomical Canon, ΑΛΓΟΤ for ΑΑΑΟΤ.

Alexander the Great is one of the instances of the vanity of appealing from contemporary disputes to “the verdict of posterity”; his character and his policy are estimated to-day as variously as ever. Certain features—the high physical courage, the impulsive energy, the fervid imagination—stand out clear; beyond that disagreement begins. That he was a great master of war is admitted by most of those who judge his character unfavourably, but even this has been seriously questioned (e.g. by Beloch, Geschichte der altertumskunde, ii. 2, 1894, 68, 190). There is a dispute as to his real designs. That he aimed at conquering the whole world and desired to be worshipped as a god is the traditional view. Droysen denies the former, and Niese maintains that his ambition was limited by the bounds of the Persian empire and that the claim to divine honours is fabulous (Historische Zeitschr. lxxix., 1897, f. 1). It is true that our best authority, Arrian, fails to substantiate the traditional view satisfactorily; on the other hand those who maintain it urge that Arrian’s interests were mainly military, and that the other authorities, if inferior in trustworthy, are complete in range of vision. Of those again, who maintain the traditional view, some, like Niebuhr and Grote, regard it as convicting Alexander of mad ambition and vainglory, whilst to Kaerst Alexander only incorporates ideas which were the timely fruit of a long historical development.

The policy of fusing Greeks and Orientals again is diversely judged. To Droysen and Kaerst it accords with the historical conditions; to Grote and to Beloch it is a betrayal of the prerogative of Hellenism.

Some notion of the personal appearance of Alexander may be got from the literature and the surviving monuments. He is described as of an athletic frame, though not taller than the common, and a white and ruddy complexion. The expression of his eyes had something “liquid and melting” (τῶν ἤματων τῆς διάχυσιν καὶ γνήμονα), and the hair which stood up over his forehead gave the suggestion of a lion. He had a way of carrying his head somewhat askant. (See especially Plut. Alex. 4; de Alex. fort. ii. 2.) The greatest masters of the time executed portraits of him, Lyssippus in sculpture, Apelles in painting and Pyrgoteles in graven gems. Among surviving monuments, we have no completely certified portraits except the Tivoli herm (now in the Louvre) and the coins struck by his successors. The herm is a dry work and the head upon the coil shows various degrees of idealization. There are, however, a considerable number of works which can make out a better or worse claim either to be portraits of Alexander or to reproduce his type, and a large field of discussion is therefore open as to their values and classification (F. Kopp, Über das Bildnis Alexanders d. Grossen (1852); K. J. Ujfalvy, Le Tyde physique d’Alexandre le Grand (1902); T. Schreiber, Studien über das Bildnis Alexanders d. Grossen (1903); J. J. Bernoulli, Die erhaltenen Darstellungen Alexanders d. Grossen (1903). Alexander shaved clean, and set the fashion in this respect for the Graeco-Roman world for the next 500 years.

Bibliography.—The campaigns and life of Alexander did not lack contemporary historians, some of them eye-witnesses and even associates. They included the philosopher Callisthenes, put to

By the sea of Baluchistan, through the appalling sand-wastes of the Mekran. He would seem to have kept down to the coast until the headland of Ras Malan was reached, scattering before him the bands of Arabitae and Ortite who were the inhabitants of this well-provisioned tract. For the 150 miles between Ras Malan and Pasini Alexander was compelled by the natural barriers to march inland, and it was here that his troops sank under the horrors of heat and thirst and sand. The coast once regained, the way was easy; no such desert had to be traversed, when Alexander again struck inland for the chief city of the Gedrosiains (Pura), and thence made his way into Carmania. Here the spent troops rested; here the army of Craterus joined them, and Nearchus came to announce his safe arrival at the entrance of the Persian Gulf.\footnote{The Western campaigns of Alexander see especially McCrindle, Invasion of India by Alexander the Great (1836); Vincent A. Smith, Early History of India (1904), and the references there given to the researches of Sir T. H. Holdich, Raverty and Foucher; A. Ansche, de Ges. Magn of expedit. ind. (1905).}

The machine of empire had not functioned altogether smoothly while the king had been absent, and on Alexander’s re-appearance many incapables and rogues in high office had to be replaced by better men. In Carmania, in Persis, complaints from the provinces continued to reach him, as well as the news of disorders in Macedonia and Greece. New orders and appointments served to bring the empire into hand again, and at Susa in the spring of 324 Alexander rested, the task of conquering and compressing the Alexander’s achievement was now at an end. The task of its internal re-organization now began to occupy him—changes, for instance, in the military system which tended to assimilate Macedonians and Orientals. The same policy of fusion was furthered by the great marriage festival at Susa, when Alexander took two more wives from the Persian royal house, married a number of his generals to Oriental princesses, and even induced as many as he could of the rank-and-file to take Asiatic wives. This policy did not allay the discontent of the Macedonian army, and when Alexander in the summer of 324 moved to the cooler region of Media, an internal mutiny of the Macedonians broke out on the way at Opis on the Tigris. It was occasioned by the discharge of the Macedonian veterans, and only the personal magnetism of Alexander and his threat to entrust himself altogether to the Orientals availed to quell it. At Ecbatana the death of Hephæstion for a time plunged Alexander into a passion of mourning. But by the winter (324–323) he was again active, bringing the hill-tribes on the S.W. border of Media, the Cossaei, into subjection. In the spring of 323 he moved down to Babylon, receiving on the way embassies from lands as far as the confines of the known world, for the eyes of all nations were now turned with fear or wonder to the figure which had appeared with such internal re-organization, and effect upon the world’s stage. The embassy from Rome, however, is almost certainly a later, and an inevitable, invention. The exploration of the waterways round about the empire was Alexander’s immediate concern, the discovery of the presumed connexion of the Caspian with the Northern Ocean, the opening of a maritime route from Babylon to Egypt round Arabia. The latter enterprise Alexander designed to conduct in person; under his supervision was prepared in Babylon an immense fleet, a great basin dug out to contain 1000 ships, and the water-communications of Bacthylonia taken in hand. Innovations were carried out in the tactical system of the army which we are to modify considerably the methods of future battle-fields. At last all was ready; the 20th of the month Dæsius (? June 5) was fixed for the king’s setting forth. On the 15th and 16th Alexander caroused deep into the night at the house of the favourite Medius. On the 17th he developed a fever; for a time he treated it as a momentary impediment to the expedition; but on the 27th his speech was gone, and the Macedonian army were suffered to pass man

1 For the Indian campaigns of Alexander see especially McCrindle, Invasion of India by Alexander the Great (1836); Vincent A. Smith, Early History of India (1904), and the references there given to the researches of Sir T. H. Holdich, Raverty and Foucher; A. Ansche, de Ges. Magn of expedit. ind. (1905).
death by Alexander in 327, whose history went up to the death of Darius, Alexander's general Ptolemy, afterwards king in Egypt, Nebuchadnezzar fled from Babylon across the Persian Gulf, Onesicritus who served as pilot in the same fleet, Aristobulus who was with Alexander in India, Cltarchus, a contemporary, not an eye-witness, important from the point of view of his higher position, preserved the life of the king for us, often the popular authority for the succeeding centuries. Besides the historical narrative, there were works mainly geographical or topographical left by Strabo and Pomponius Mela to whom the maps employed (as βυζαντινα) to survey the roads over which he passed. All such original sources have now perished. The fragments are collected in the Didot edition of Arrian by Karl Müller. Not reckoning the fragmentary work of Ptolemy upon six campaigns, of Diodes, book xvii. (c. 20 B.C.), the work of Quintus Curtius (c. A.D. 42), Plutarch's (c. 45-152 A.D.) Life of Alexander, Arrian's Anabasis and Indica (c. A.D. 150), the relevant books of Justin's abridgment (2nd century) of the history of Trogus (c. 15 B.C.). To these we may add the Latin Itinerarium Alexandri, a skeleton outline of Alexander's campaigns dedicated to the emperor Constantius (A.D. 324-361), printed at the end of the Didot edition of Arrian, and the Epitome Rerum Gestarum Alexanderi magni, an abridgment made in the 4th or 5th century of a lost Latin work of uncertain date, combining history with elements of the Romance (edited by O. Wagner, Leipsic, 1900). The relation of these works to the various original sources constitutes the critical problem before the modern historian in reference to the history of Alexander. Among the works in English, A. Scholten's Alexander Magni scriptorum imprimis Arriani et Plutarchi justitios (1870); Fraenkel, Die Geschichtsschreiber Alex. d. Grossen (1883); O. Muls, Klistarch und Dioder (Petersburg, 1894); Kaerzt, Forschungen zur Geschichte Alex. d. Grossen (1887), and Gesch. d. Keltischen Zeitalters (vol. i., 1901), pp. 421 f.; F. L. Scholte, Diodorstudien (1991); E. Schwartz, articles "Aristobulus (1)," "Aristarchos," "Quintus Curtius," "Diodores," "Oxia," "Wissowa" in Realeycylopaedie. The modern views of Alexander see Thirlwall, History of Greece; Niebuhr, Lectures on Ancient History (Eng. trans. rev. by author, 1852); Grote, History of Greece; Droysen, Geschichte der Hellenthal (translation by Bouché-Lecan; Eng. trans., 1898); B. Niese, Gesch. der griech. u. maked. Staaten (vol. i.), Kaerzt, Gesch. des hellenist. Zeitalters (1901); J. Beloch, Griechische Gesch. (vol. iii., 1904); J. B. Bury, History of Greece (1902); A. von Gutschmid, Geschichte des christl. Erwerbs (1866). Among the monographs and special articles, reference may be made to Freeman, Historical Essays, 2nd ser., pp. 182 f.; Dodge, Alexander (in a series called Great Captains) 1900; Mahaffy, Problems in Greek History (1892); ch. viii.; D. G. Hogarth, Philip and Alexander of Macedon (1897), a striking effort of historical imagination to reconstruct Alexander as a man of the real world; Benjamin I. Wheeler, Alexander the Great (1900) in the "Heroes of the Nations Series. The purely military aspect of Alexander's campaigns is treated in general histories of warfare (Rustow-Kochly, Bauer, Delbruck, Verdy du Vernois), and in special monographs by Hogarth, 1888; Tuch, Untersuchungen über A. des Gr. Heerwesen (1888), and Graf Yorck von Wartenburg, Kurze Übersicht der Feldzüge A. des Gr. (1897). For further references to the literature, see Kaerzt's article in Pauly-Wissowa's Realencyclopaedie (1894). (E. R. B.)

The Romance of Alexander.

The figure of Alexander naturally impressed itself upon the imagination of the world which his career had shaken. Even in India we are told that he was held in honour by the native kings who took his farthest provinces in possession. But Eastern tradition, so tenacious of the old myths of primitive man, has a short memory for actual history, and five centuries later Alexander was only remembered in India as the accused dunce who died of a stroke (Kosa) in the light of the sun. He had at the same time preserved by causing translations to be made into "Roman," that the East to-day has so much to tell about Alexander is only due to the fact that old mythical stories of gods or heroes who go travelling through lands of monsters and darkness, of magical fountains and unearthly oceans, became attached to his name in the popular literature of the Roman empire, and this mythical Alexander was reintroduced in the 7th century A.D. into the farther East, where the historical Alexander was almost forgotten.

The romance of Alexander is found written in the languages of nearly all peoples from the Indian Ocean to the Atlantic. But all these versions are derived, mediate or immediately, from the Greek original which circulated under the false name of Callisthenes. The Greek pseudo-Callisthenes (otherwise Asipos we possess in three recensions, based all upon a book produced in Egypt in the 2nd century A.D. But this book itself was a farrago of heterogeneous elements—pieces of genuine history, ancient stories once told in Babylon of Gilgamesh or Etana, literary forgeries of the days soon after Alexander, like the oldest part of the "Testament of Alexander," variations due to Egyptian patriotic sentiment, like that which made Alexander the son of the last Pharaoh, Nectanebus. As the story was reproduced, variations were freely introduced according to the bent of different times and peoples; in the Persian version Alexander (Iskander) became a son of Darius; among the Mahomedans he turned into a prophet, hot against idols; the pen of Christian monks made him an ascetic saint.

The Alexander romance found its way into Europe through the medium of Latin, but originated mainly from the versions of the pseudo-Callisthenes, not from the more sober narrative of Quintus Curtius. The pseudo-Callisthenes, in a recension which has not been preserved, was translated into Latin by Julius Valerius about the end of the 3rd century, and an epitome of this translation, also in Latin, was made some time before the 9th century, and is introduced by Vincent de Beauvais into his Speculum historiale. Much of the legend is a running travesty of the true history of the conqueror. The first book deals with his birth and early exploits. The trace of Alexanderian influence is to be found in the pretence that his actual father was Nectanebus, a fugitive king of Egypt. The latter was a great magician, able, by operating upon waxen figures of the armies and ships of his enemies, to bring about their destruction. Obdurate, however, to flee to Pella in Macedonia, he established himself as an astrologer, and as such was consulted by the childless Olympias. Having promised that Zeus Ammon would visit her in the form of a dragon, he himself assumed the disguise. In due course Alexander was born, and Philip's suspicions were overcome by a second appearance of the dragon, which was held to prove the divine fatherhood. The child was small and somewhat deformed, but of great courage and intelligence. When he was twelve years old he was instructed in starcraft by Nectanebus, who was killed by a fall in hunting. The first book also relates his conquests in Italy, Africa, Syria and Asia Minor; his return to Macedonia and the submission of Greece. The second book continues the history of his conquests, and the third contains the victory over Porus, the relations with the Brahmins, the letter to Aristotlet on the wonders of India, the histories of Candace and the Amazons, the letter to Olympias on the marvels of Farther Asia, and lastly the account of Alexander's death in Babylon.

The most widespread Latin version of the story, however, was that of Historia de Alexander, translated and printed at Strassburg in 1486, which began to supersede the Epitome of Julius Valerius, in general favour about the end of the 13th century. It is said to have been written by the Neapolitan arch-presbyter Leo, who was sent by Johannes and Marinus, dukes of Campania (941-965) to Constantinople, where he found his Greek original. Auxiliary sources for the medieval romance-writers were:—the opusculum (4th century) known as Alexandri magni ter ad Paradisum, a fable of Eastern origin directed against ambition; the Historiarum Alexandri (340), based partly on Julius Valerius and dedicated to Constantine, son of the emperor Maxentius; the letter of Alexander to Aristotle (Epist. de situ et mirabilibus Indiæ), and the correspondence between Alexander and the king of the Brahmins, Dindims, both of which are often contained in MSS. of the Epitome; and the treatise (based on a lost history of Alexander by Onesicritus), De gentibus Indiæ et Brahmantius, ascribed without certainty to Palladius (d. c. 430), successively bishop of Helenopolis and Aspasia.

The Ethioptic versions are of great interest as a striking example of literary "accommodation." Not only is the whole atmosphere Christian in colouring, but we actually find the Greek gods in the guise of Enoch, Elijah, &c., while Philip is a Christian martyr, and Alexander himself a great apostle, even a saint; quotations from the Bible are frequent. Syrian and Armenian versions were made in the 3rd century. Persians and Arabs told the

French.

The earliest known French romance of Alexander, by Alberic of Besançon (or more properly Briançon), was until the discovery of a fragment of 100 lines at Florence in 1852, known only through the German adaptation by Lamprecht, the poet, who wrote towards the end of the 12th century, and by the version made by a Poitevin poet named Simon in deca-

yllabic lines. Alberic followed the epitome of Julius Valerius. He had some knowledge of authentic history, and rejected the more marvellous elements of the story.

The incident of the Indian Conqueror, for instance, was not derived from the Historia de prodìlis, but was interpolated in the second section, is assigned to a certain Eustache. The redaction of the whole work is due to Alexander de Bernai, who replaced the original assimon by rhyme. According to all the traditions of romance it was necessary to avenge the death of Alexander. At the end of the 12th century Gui de Cambrai and Jean le Nevalon (or Nevala or Nevalis), each wrote a Vengeance d'Alexandre. Jean le Nevalon relates how Alior, the son of Alexander and Candace, avenged his father's death on Antipater and others. Between 1310 and 1315 Jacques de Longuyon (or Longayon) introduced into the account written by the Indian Conqueror, the Romanesque and fantastic episode very loosely connected with Alexander. It is interesting for its connexion with the 15th-century romance of Percéforest, since in it Alexander visits Britain, where he bestows Scotland on Cadifer and England on Betsis (otherwise Percéforest). Les Vaux du paon enjoyed great popularity, and had two sequels, Le Restor du paon, written before 1338 by Jean Brisebour de Douai, and Le Parfalt du paon, written in 1340 by Jean de la Mote. Florimont, a 14th-century poem by Aimon de Varenne, relates to a fictitious personage said to have been the grandfather of Alexander. This poem gave rise to two prose romances—La Conquete de Grece faite par Philippe de Meisson, by Perrinet du Pin, first printed in 1527, and Histoire du roi Florimond (1528). Quintus Curtius was largely used for the Alexandreis (c. 1180) of Gaultier de Lille or de Châtillon (Galtherus ab Insulis or de Castellione). It is a Latin poem in ten books of hexameters, and contains a curious admixture of Biblical history. It was translated at the end of the next century into Flemish by J. van Maerlant and into German by Ulrich von Eschenbach.

Of the French prose versions of the Historia de prodìlis may be noticed, the late romance, L'Histoire du noble et vaillant roy Alexandre le Grand (1506). After an account of the ancient history of Macedonia and of the intrigue of Nectanebus we are told how Philip dies, and how Alexander subdues Rome and receives tribute from all European nations. He then makes his Persian expedition; the Indian campaign gives occasion for descriptions of all kinds of wonders. The conqueror visits a cannibal kingdom and finds many marvels in the palace of Paurus, among them a vine with golden branches, emerald leaves and fruit of other precious stones. In one country he meets with women who, after the burial in the winter, become alive again in the spring full of youth and beauty. Having reached the ends of the earth and conquered all nations, he aspires to the dominion of the air. He obtains a magic glass cage, yoked with eight griffins, flies through the clouds, and, thanks to enchanters who know the language of birds, gets information as to their manners and customs, and ultimately receives their submission. The excessive heat of the upper regions compels him to descend, and he next visits the bottom of the sea in a kind of diving-bell. The fish crowd round him and pay homage. Alexander returns to Babylon, is crowned with much pomp and mass is celebrated. He dies by poison soon afterwards.

English Versions.—The Alexander cycle was no less popular in Great Britain. The letter from Alexander to Aristotle and his correspondence with Dindimus are found in Early English versions dating from the 11th century. These are printed by O. Cockayne in his Narratiunculae Anglice conscriptae (1861). The Monk (De Cas. ill. vit.) in Chaucer's Canterbury Tales prefaces his account of Alexander with the statement that his story is so common that

That every knight that hath discrecion

Hath herd somewhat or all of his fortune.

There are two considerable fragments of an English alliterative romance on the subject written in the west midland dialect, and dating from the second half of the 14th century. The first, The Gestes of the Worthy King and Emperor Alisaunder of Macedoine (ed. W. W. Skeat, E.E.T.S., 1877, with William of Palerne) contains an account of the wars of Philip, of Nectanebus and of the education of Alexander. A second fragment (ed. Skeat, E.E.T.S., 1878) contains Alexander's visit to the Gymnosophists and his correspondence with Dindimus. Another alliterative poem in the northern dialect, of 15th-century origin, is based on the Historia de prodìlis, and was edited by Skeat for the E.E.T.S. (1888) as The Warris Wende of Alexandre. Earlier than any of these is the rhyming Lyfe of Alisaunder (c. 1330) which is printed in H. Weber's Meval Romancs (vol. i., 1810). It is written in unusually picturesque and vigorous language, and is based on the Roman de toute chevalerie, a French compilation made about 1250 by a certain Eustace or Thomas of Kent. Fragments of another rhyming poem (pr. c. 1550) are preserved in the British Museum. The Scots Buke of the most noble and valyeand Conqueror Alexander the Great, printed by Alexander Arbuthnot (d. 1585) about 1580, reprinted in 1581 for the Bannatyne Club, is not very useful. It contains three episodes, the fight with the Barbarians, the Taking of the Fuerre de Gardes (or but from the Assaut de Tyr in the Romans d'Alisaunder), "The Awoves of Alexander," and "The Great Battel of Effesoun," taken from the Vaux du paon. Many passages in John Barbour's Bruce are almost identical with this book, and it is suggested by G. Neilson (John Barbour, Poet and Translator, London, 1900) that Barbour was the author, although the colophon states that it was written in 1458. Bruce at Bannockburn makes the same oration as Alexander at "Effesoun." A Bake of the Conqueror Alexander the Great by Sir Gilber Hay (fl. 1456) is in MS. at Taymouth Castle.

Bibliography.—The best sketch of the Alexander romance literature is by Paul Meyer, Alexandre le grand dans la littérature française au moyen âge (2 vols., Paris, 1886). The first volume contains some French texts, and the second a detailed discussion of the various versions from the pseudo-Callisthenes downwar ds. See also J. Zacher, Pseudo-Callisthenes, Forschungen zur... Alexanderage (Halle, 1867), and for Oriental versions, T. Nöldke, "Beiträge zur Geschichte des Alexanderromans" (Denkschriften der k. k. Akad. d. Wissenschaften, phil.-hist. Klasse, 13, Vienna, 1890). For early printed versions see Brunet, Manuel du libraire, s.v. "Alexandre.

The text of the pseudo-Callisthenes was edited by C. Wuller from three MSS, in the Bibl. Nat. and in the Arrian of the Coll. Didot (Paris, 1846), and by H. Meusel (Leipzig, 1871) from a Leiden MS. A. Mai edited Julius Valerius (Milan, 1817) and the Historia de prodìlis by Alexandreis (Camerino, 1841). J. Zacher, the Epitome (Halle, 1867) and Alex. tier ad Paradisum (Regensburg, 1895); the Oxford MS. of the Epitome was edited by G. Cill (Strassburg, 1903); G. Landgraf, Die "Vita Alexander... des Archiprestes Leo (Historia de prodìlis), (Erlangen),
ALEXANDER, tagus or despot of Phrecia in Thessaly, ruled from 360 to 358 B.C. His tyranny caused the Alcmead of Larissa to invoke the aid of Alexander of Macedon, whose intervention was successful, but after his withdrawal Alexander treated his subjects as cruelly as before. The Thessalians now applied to thebes; Pelopidas, who was sent to their assistance, was treacherously seized and thrown into prison (368), and it was only with the help of Epaminondas and Euphorbus that he was able to escape and return to his release. Alexander's conduct caused renewed intervention; in 364 he was defeated at Cynoscophaeae by the Thebans, although the victory was dearly bought by the loss of Pelopidas, who fell in the battle. Alexander was at last crushed by the Thebans, compelled to acknowledge the freedom of the Thessalian cities and to limit his rule to Phrecia, and forced to join the Bocotian league. He was murdered by his wife's brother at her instigation. Ancient accounts agree in describing Alexander as a typically cruel and suspicious tyrant.

[858] ALEXANDER, son of Casimir IV, king of Poland, was elected grand-duke of Lithuania in 1492, and king of Poland on the death of his brother John Albert in 1501. His extreme impiety turned him from the first to the papal and nobles (zastachii), who deprived him of the control of the mint—then one of the most lucrative sources of revenue of the Polish kings—causing his prerogative, and generally endeavour to reduce him to a subordinate position. This ill-timed parsimony reacted injuriously on Polish politics. Thus, for want of funds, Alexander was unable to assist the Grand Master of the Order of the Sword against Muscovite aggression, or prevent Tsar Ivan III. from ravaging Lithuania with the Tatars. The utmost the king could do was to garrison Smolensk and other fortresses and employ his wife Helena, the tsar's daughter, to mediate a truce between his father-in-law and himself. During his reign Poland suffered much humiliation from the attempts of her subject principalities, Prussia and Moldavia, to throw off her yoke. Only the death of Stephen, the great hospodar of Moldavia, enabled her to hold on to the Dniester. Alexander was unable to reconcile the liberty of Pope Julius II., who issued no fewer than 20 bulls in favour of Poland and granted Alexander Peter's Pence and other financial help, enabled the Polish king to restrain somewhat the arrogance of the Teutonic Order. In Alexander the characteristic virtues of the Jagielllos, patience and generosity, degenerated into slothfulness and extravagance. Frequently he was too poor to pay the expenses of his own table. But he never felt at home in Poland, and bestowed his favour principally upon his fellow-countrymen, the most notable of whom was the wealthy Lithuanian magnate Michael Glinkys, who justified his master's confidence by his great victory over the Tatars at Kleck (August 5, 1500), the news of which was brought to Alexander on his deathbed.

See V. Cerny, The Reigns of John Albert and Alexander Jagielle (Pol.) (Cracow, 1882).

ALEXANDER, the name of eight popes—

ALEXANDER I, was bishop of Rome from about 106 to 115. He has been identified, without any foundation, with Alexander, a martyr of the Via Nomentana, whose day is the 3rd of May.

ALEXANDER II. (Anselmo Baggio), pope from 1061 to 1073, was a native of Milan. As bishop of Lucca he had been an energetic coadjutor with Hildebrand in endeavouring to suppress simony, and to enforce the celibacy of the clergy. His election, which Hildebrand had arranged in conformity with the decree of 1059 (see Nicholas II.), was not sanctioned by the imperial court of Germany. This court, faithful to the practice observed by it in the preceding elections, nominated another candidate, Cadalus, bishop of Parma, who was proclaimed at the council of Basel under the name of Honorius II., marched to Rome, and for a long time jeopardized his rival's position. At length, however, he was abandoned by the Germanic court and deposed by a council held at Mantua; and Alexander's position remained unchallenged. Alexander was succeeded by his associate Hildebrand, who took the title of Gregory VII.

ALEXANDER III. (Orlando Bandinelli), pope from 1159 to 1181, was a Siennese, and as a teacher of canon law in Bologna composed the Stroma or the Summa Magistri Rolandi, one of the earliest commentaries on the Decretum Gratiani. In October 1159 Eugenius III. created him cardinal deacon SS. Cosmae and Damiani; later he became cardinal priest of St. Mark's. Probably about this time he composed his Sentences, based on his Introductio ad theologiam of Abelard. In 1159, however, he became papal chancellor, and was the leader of the cardinals opposed to Frederick Barbarossa. On the 7th of September 1159 he was chosen the successor of Adrian IV., a minority of the cardinals, however, electing the cardinal priest Octavian, who assumed the name of Victor IV. This antipope, and his successors Paschal III. (1164-1168) and Callixtus III. (1185-1199), had the imperial support; but after the defeat of Legnano, Barbarossa finally (in the peace of Venice, 1177) recognized Alexander as pope. On the 13th of March 1178 Alexander issued a bull to Rome, which he had hitherto been compelled to leave twice, namely, from 1162 until the 23rd of November 1165, and again in 1167. The first period he spent in France, the latter chiefly in Gaeta, Benevento, Anagni and Venice. In March 1179 Alexander held the third Lateran synod, a brilliant assemblage, reckoned by the Roman church as the eleventh ecumenical council; its acts embody several of the pope's proposals for the betterment of the condition of the church, among them the present law requiring that no one may be elected pope without the votes of two-thirds of the cardinals. This synod marks the summit of Alexander's power. Besides checkmating Barbarossa, he had humbled Henry II. of England in the affair of Thomas Becket, he had confirmed the right of Alphonsino I. of Portugal to the crown, and even as a fugitive had enjoyed the favour and protection of Louis VII. of France. Nevertheless, soon after the close of the synod the Roman republic forced Alexander to leave the city, which he never re-entered; and on the 29th of September 1179 some nobles set up the antipope Innocent III. By the judicious use of money, however, Alexander got him into his power, so that he was deposed in January 1180. In a council held at Mantua the 3rd of August 1181 Alexander IV. (Rinaldo), pope from 1254 to 1261, was, like Innocent III. and Gregory IX., a member of the family of the
counts of Segni. His uncle Gregory IX, made him cardinal deacon in 1227 and cardinal bishop of Ostia in 1231. On the death of Innocent IV. he was elected pope at Naples on the 12th of December 1254. He is described as a stout man, kindly, cheerful, but of no great brilliancy. He succeeded Innocent IV. as guardian of Conradin, the last of the Hohenstaufen, committee with him his benefice on probation, but on the 29th of July he consented against him and bitterly opposed Conradin's uncle Manfred. Alexander fulminated with excommunication and interdict against the party of Manfred, but in vain; nor could he enlist the kings of England and Norway in a crusade against the Hohenstaufen. Rome itself became too Ghibelline for the pope, who withdrew to Viterbo, where he died on the 25th of May 1261. His pontificate was signalized by efforts to unite the Greek and Latin churches, by the establishment of the Inquisition in France, by favours shown to the mendicant orders, and by an attempt to organize a crusade against the Tatars.

The registers of Alexander IV. are published by Bourel de la Roncière and others in the Bibliothèque des Écoles françaises d' Athènes et de Rome, Paris, 1895 ff.

(A. W. W. K.)

ALEXANDER V. (Peter Philargèse), pope 1409-1410, was born in Crete of unknown parents and entered the order of St. Francis, for which, as for the other mendicant orders, he later manifested his affection in a striking manner. He was a member in turn of the universities of Oxford and Paris, and finally settled in France, where he was known as Pere de la Roncière. In 1392, at the request of Gian Galeazzo Visconti, he became bishop, first of Piacenza, then of Vincenza, then of Novara, and afterwards archbishop of Milan. On being created cardinal by Innocent VII. he devoted all his energies from 1408 onwards to the realization of the union of the church, in spite of the two rival popes. He was one of the promoters of the council of Pisa, and after that assembly had declared Gregory XII. and Benedict XIII. deposed, the cardinals assembled in concilave thought they could not do better than crown with the tiara this cosmopolitan prelate, who had an equal mastery of the Latin and Greek languages, and was renowned not only for his learning in theology but for his affability (June 26, 1409). As a matter of fact, the only effect of this election was to aggravate the schism by adding a third to the number of rival pontiffs. During his short reign of ten months Alexander V.'s aim was to extend his obedience with the assistance of France, and, notably, of the duke Louis II. of Anjou, upon whom he conferred the investiture of the kingdom of Sicily, together with the title of gonfalonier of the church. He proclaimed and promised rather than effected a certain number of reforms: the abandonment of the rights of "spoil" and "pensions"; the re-establishment of the system of canonical elections in the cathedral churches and principal monasteries, &c.

But death came upon him almost without warning at Bologna, in the night of the 3rd-4th May 1410. A rumour went about that he had been poisoned by the cardinal Baldassarre Cossa, impatient to be his successor, who succeeded him in fact under the name of John XXIII. The crime has, however, never been proved, though a Milanese physician, who performed the task of dissecting the corpse of Peter Philargèse, seems to have thought that he found traces of poison.

(A. V.)

ALEXANDER VI. (Rodrigo Borja Borgia) (1431-1503), born in 1431 at Granada, the seat of the most notorious of the corrupt and secular popes of the Renaissance. He was born (January 1, 1431) at Xativa, near Valencia in Spain, and his father's surname was Lanzol or Llanol; that of his mother's family, Borgia or Borja, was assumed by him on the elevation of his maternal uncle to the papacy as Calixtus III. (April 8, 1458). He studied law at Bologna, and after his uncle's election he was created successively bishop, cardinal and vice-chancellor of the church, an act of nepotism characteristic of the age. He served in the Curia under five popes and acquired much administrative experience, influence and wealth, although no great power; he was economical in his habits; on occasion he displayed great splendour and lived in a fine palace. His manners were agreeable and his appearance fascinating, but, like many other prelates of the day, his morals were far from blameless, his two dominant passions being greed of gold and love of women, and he was devotedly fond of the children whom his mistresses bore him. Although ecclesiastical corruption was then at its height, his riotous mode of life called down upon him a very severe reprimand from Pope Pius II., who succeeded Calixtus III. in 1455. On his many mistresses the one whom his passion lasted longest was a certain Vannozza (Giovanna) dei Cattani, born in 1442, and wife of three successive husbands. The connexion began in 1470, and she bore him many children whom he openly acknowledged as his own: Giovanni, afterwards duke of Gandia (born 1474), Cesare (born 1476), Lucrezia (born 1478), and Goffredo or Giufre (born 1481 or 1482). His other children—Girolamo, Isabella and Pier Luigi—were of uncertain parentage. Before his elevation to the papacy Cardinal Borgia's passions for Vannozza somewhat diminished, and she subsequently led a very frugal life. Few of the signs by which she was known was film by the beautiful Giulia Farnese (Giulia Bella), wife of an Orsini, but his love for his children by Vannozza remained as strong as ever and proved, indeed, the determining factor of his whole career. He lavished vast sums on them and loaded them with every honour. A characteristic instance of the corruption of the papal court is the fact that Borgia's daughter Lucrezia (see BORGIA, LUCREZIA) lived with her mistress Giulia, who bore him a daughter Laura in 1492.

On the death of Pope Innocent VIII. the three likely candidates for the Holy See were Cardinals Borgia, Ascanio Sforza, and Giulio della Rovere; the last two competitors elected by the immense sums of money spent on bribery, and Borgia by his great wealth succeeded in buying the largest number of votes, including that of Sforza, and to his intense joy he was elected on the 10th of August 1492, assuming the name of Alexander VI. Borgia's elevation did not at the time excite much alarm, except in some of the cardinals who knew him, and at first his reign was marked by a strict administration of justice and an orderly method of government in satisfactory contrast with the anarchy of the previous pontificate, as well as by great outward splendour. But it was not long before his passionate desire for endowing his relatives at the expense of the church and his neighbours became manifest. For this object he was ready to commit any crime and to plunge all Italy into war. Cesare, then a youth of sixteen and a student at Pisa, was made archbishop of Valencia, his nephew Giovanni received a cardinal's hat, and for the duke of Gandia and Giufre the pope proposed to carve fiefs out of the papal states and the kingdom of Naples. Among the fiefs destined for the duke of Gandia were Cervetri and Anguillara, lately acquired by Virginio Orsini, head of that powerful and turbulent house, with the pecuniary help of Ferdinand of Aragon. King of Naples (Don Ferrante), who, by powerful influence and the largesse of his court, brought the latter into conflict with Alexander, who determined to revenge himself by making an alliance with the king's enemies, especially the Sforza family, lords of Milan. In this he was opposed by Cardinal della Rovere, whose candidature for the papacy had been backed by Ferdinand. Della Rovere, feeling that Rome was a dangerous place for him, fortified himself in his bishopric of Ostia at the Tiber's mouth, while Ferdinand allied himself with Florence, Milan, Venice, and the pope formed a league against Naples (April 25, 1493) and prepared for war. Ferdinand appealed to Spain for help; but Spain was too anxious to keep her good terms with the pope to obtain a title over the newly discovered continent of America and could not afford to quarrel with him.

Alexander meditated great marriages for his children. Lucrezia had been married to the Spaniard Don Gaspar de Proeda, but on her father's elevation to the papacy the union was annulled, and in 1493 she was married to Giovanni Sforza, lord of Pesaro, the ceremony being celebrated at the Vatican with unparalleled magnificence. But in spite of the splendours of the court, the condition of Rome became every day more deplorable. The city swarmed with Spanish adventurers, assassins, prostitutes and informers; murder and robbery were committed with impunity, heretics and Jews were admitted to the city on payment of bribes, and the pope himself shamelessly cast aside all show of decorum, living a purely secular and

POPEs
immoral life, and indulging in the chase, dancing, stage plays and indecent orgies. One of his boon companions was Jem, the brother of the sultan Bayezid, detained as a hostage fraction.

The general political outlook in Italy was that of the gloomiest, and the country was on the eve of the catastrophe of foreign invasion. At Milan Lodovico Sforza (il Moro) ruled, nominally as regent for the youthful duke Gian Galeazzo, but really with a view to making himself master of the state. He made many alliances to secure his position, but fearing himself isolated he sought help from Charles VIII. of France, and as the king of Naples threatened to come to the aid of Gian Galeazzo, who had married his grand-daughter, he encouraged the French king in his schemes for the conquest of Naples. Alexander carried on a diplomatic policy, always ready to seize opportunities to aggrandize his family. But through the intervention of the Spanish ambassador he made peace with Naples in July 1493 and also with the Orsini; the peace was cemented by a marriage between the pope's son Giuifre and Doña Sancha, Ferdinand's grand-daughter. In order to dominate the Sacred College more completely he created twelve new cardinals, among them his own son Cesare, then only eighteen years old, and Alessandro Farnese, the brother of Giulia Bella, one of the pope's mistresses, creations which caused much scandal. On the 25th of January 1494 Ferdinand died and was succeeded by his son Lodovico. Charles VIII. of France, infatuated with Alexander, drew him to his side and authorized him to pass through Rome ostensibly on a crusade against the Turks, without mentioning Naples. But when the French invasion became a reality he was alarmed, recognized Alfonso as king, and concluded an alliance with him in exchange for various fiefs to his sons (July 1494). Preparations for defence were made; a Neapolitan army was to advance through the Romagna and attack Milan, while the fleet was to seize Genoa; but both expeditions were badly conducted and failed, and on the 8th of September Charles crossed the Alps and joined Lodovico il Moro at Milan. The papal states were in a turmoil, and the powerful Colonna faction seized Ostia in the name of France. Charles rapidly advanced southward, and after a short stay in Florence set out for Rome (November 1494). Alexander appealed to Ascanio Sforza for help, and even to the sultan. He tried to collect troops and put Rome in a state of defence, but his position was most insecure, and the Orsini offered to admit the French to their castles. This decision depressed the pope to come to terms, and on the 31st of December Charles entered Rome with his troops. Charles was accustomed to the Colonna, who had been his tool in the past, and now he ordered the Colonna to summon a council, but he won over the bishop of St Malo, who had much influence over the king, with a cardinal's hat, and agreed to send Cesare, as legate, to Naples with the French army, to deliver Jem to Charles and to give him Civitavecchia (January 16, 1495). On the 28th Charles departed for Naples with Jem and Cesare, but the latter escaped to Spoleto. Neapolitan resistance collapsed; Alfonso fled and abdicated in favour of his son Ferdinand II., who also had to fly abandoned by all, and the kingdom was conquered with surprising ease. But a reaction against Charles soon set in, for all the powers were alarmed at his success, and on the 31st of March a league between the pope, the emperor, Venice, Lodovico il Moro and Ferdinand of Spain was formed, ostensibly against the Turks, but in reality to expel the French from Italy. Charles had himself crowned king of Naples on the 12th of May, but a few days later began his retreat northward. He encountered the allies at Forono, and after a drawn battle cut his way through them and was back in France by November; Ferdinand II. with Spanish help was reinstated at Naples soon afterwards. The expedition, if it produced no memorable result in Italy, became the turning point of the Italian political system and the country's incapacity for resistance.

Alexander availed himself of the defeat of the French to break the power of the Orsini, following the general tendency of all the princes of the day to crush the great feudalatories and establish a centralized despotism. Virginio Orsini, who had been captured by the Spaniards, died a prisoner at Naples, and the pope confiscated his property. But the rest of the clan still held out, and the papal troops sent against them by Gudobaldo duke of Urbino and the duke of Gandia were defeated at Soriano (January 1497). Peace was made through venetian mediation, the Orsini paying 50,000 ducats in exchange for their conquered lands; the duke of Urbino, whom they had captured, was left by the pope to pay his own ransom. The Orsini still remained very powerful, and Alexander could count on none but his 3000 Spaniards. His only success had been the capture of Ostia and the submission of the Francophile cardinals Colonna and Savelli.

Now occurred the first of those ugly domestic tragedies for which the house of Borgia remained famous. On the 14th of June the duke of Gandia, lately created duke of Benevento, was found murdered in his cell. His corpse was found in the Tiber. Alexander, overwhelmed, with grief, shut himself up in St. Angelo, and then declared that the reform of the church would be the sole object of his life henceforth—a resolution which he did not keep. Every effort was made to discover the assassin, and suspicion fell on various highly placed personages. Suddenly the rumour spread about that Cesare, the pope's second son, was the author of the deed, and although the inquiries then ceased and no conclusive evidence has yet come to light, there is every probability that the charge was well founded. No doubt Cesare, who contemplated quitting the church, was inspired by jealousy of the pope's position, but a violent death, while he was in the prime of life, and without a definite cause having happened, his death was regarded with great alarm in Rome, and even his father quailed before him. As he needed funds to carry out his various schemes, the pope began a series of confiscations, of which one of the victims was his own secretary, in order to enrich him. The process was a simple one: any cardinal, nobleman or official who was known to be rich would be accused of some offence; imprisonment and perhaps murder followed at once, and then the confiscation of his property. The disorganization of the Curia was appalling, the sale of offices became a veritable scandal, the least opposition to the Borgia was punished with death, and even in that corrupt age the state of things shocked public opinion. The story of Alexander's relations with Savonarola is narrated under the latter heading; it is sufficient to say here that the pope's hostility was due to the friar's outspoken invective against papal corruption and to his appeals for a General Council. Alexander, although he could not get Savonarola into his own hands, browbeat the Florentine government into condemning the reformer to death (May 23, 1498). The pope was unable to maintain order in his own dominions; the Venetians had been defeated in the Colle di Val d'Arno, and although they were victorious in the second battle of Pavia, after much fighting they made peace on a basis of alliance against the pope. Thus further weakened, he felt more than ever that he had only his own kin to rely upon, and his thoughts were ever turned on family aggrandizement. He had annulled Lucrezia's marriage with Sforza in 1497, and, unable to arrange a union between Cesare and the daughter of Frederick, king of Naples (who had succeeded Ferdinand II. the previous year), he induced the latter by threats to agree to a marriage between the duke of Biscaglia, a natural son of Alfonso II., and Lucrezia. Cesare, who renounced his cardinalate, was sent on a mission to France at the end of the year, bearing a bull of divorce for the new king Louis XII., in exchange for which he obtained the duchy of Valentinois (hence his title of Duca Valentino) and a promise of material assistance in his schemes to subjugate the feudal princedoms of Romagna; he married a princess of Navarre. Alexander hoped that Louis's help would be more profitable to his house than that of Charles had been, and in spite of the remonstrances of Spain and of the Sforza, he allied himself with France in January 1499 and was joined by Venetia. By the autumn Louis was in Italy and successfully forced Ferdinand from his dominions. In 1500 he was able to consolidate his possessions still further, now that French success seemed assured, the pope determined to deal drastically with Romagna, which although nominally under papal rule was divided up into a number of practically independent lordships on which Venice, Milan and Florence cast hungry eyes. Cesare, nominated gonfaloniere of the Church, and strong in French favour, proceeded to attack the turbulent cities one by one (for detail see BORJA, CESARE). But the
expulsion of the French from Milan and the return of Lodovico Sforza interrupted his conquests, and he returned to Rome early in 1500. This year was a jubilee year, and crowds from the whole world flocked to the city from all parts of the world bringing money for the purchase of indulgences, so that Alexander was able to furnish Cesare with funds for his enterprise. In the north the pendulum swung back once more and the French reoccupied Milan in April, causing the downfall of the Sforzas, much to Alexander's gratification. But there was no end to the Vatican tragedies, and in July the duke of Biscaglia, whose existence was no longer advantageous, was murdered by Cesare's orders; this left Lucrezia free to contract another marriage. The pope, ever watchful of his enemies, next created a new cardinals' college, the members of which he received 120,000 ducats, and fresh conquests for Cesare were considered. But while a crusade was talked of, the real object was central Italy, and in the autumn Cesare, favoured by France and Venice, set forth with 10,000 men to complete his interrupted enterprise. The local despots of Romagna were dispossessed and an administration was set up, which, if tyrannical and cruel, was at least orderly and strong, and aroused the admiration of Machiavelli (q.v.). On his return to Rome (June 1501) he was created duke of Romagna. Louis XII, having succeeded the aged Francis I, concerted plans with Alexander, and as well as to conclude a treaty with Spain for the division of the Neapolitan kingdom, which was ratified by the pope on the 25th of June, Frederick being formally deposed. The French army proceeded to invade Naples, and Alexander took the opportunity, with the help of the Orsini, to reduce the Colonna to obedience. In his absence he left Lucrezia as regent, offering the astounding spectacle of a pope's natural daughter in charge of the Holy See. Shortly afterwards he induced Alfonso d'Este, son of the duke of Ferrara, to marry her, thus establishing her as heiress to one of the most important principalities in Italy (January 1502); this time there was no doubt for mainstay support of Borgia's enemies. Alexander's diplomacy, however, turned the tide, and Cesare, in exchange for promising to assist the French in the south, was given a free hand in central Italy. A new danger now arose in the shape of a conspiracy against him on the part of the deposed despots, the Orsini and some of his own condottieri. At first the papal troops were defeated and things looked black for the house of Borgia. But a promise of French help at once forced the confederates to come to terms, and Cesare by an act of treachery seized the regicides at Senigallia, and put Oliverotto da Fermo and Vitellozzo Vitelli to death (Dec. 31, 1502). As soon as Alexander heard the news he decoyed Cardinal Orsini to the Vatican and cast him into a dungeon, where he died. His goods were confiscated, his aged mother turned into the street and numbers of other members of the clan in Rome were arrested, while Giuffre Borgia led an expedition into the Campagna and seized their castles. Thus the two great houses of Orsini and Colonna, who had long fought for predominance in Rome and often flouted the pope's authority, were subjugated, and a great step achieved towards consolidating the Borgia's position. Cesare then returned to Rome, where his father wished him to make Giuffre in reproducing the last Orsini stronghold; this for some reason he was unwilling to do, much to Alexander's annoyance, but he eventually marched out, captured Ceri and made peace with Giulio Orsini, who surrendered Bracciano.

Three more high personages fell victims to the Borgia's greed this year, viz. Cardinal Michiel, who was poisoned in April, J. da Santa Croce, who had helped to seize Cardinal Orsini, and Troches or Trucco, one of the family's most faithful assassins; all these murders brought immense sums to the pope. About Cardinal Ferrari's death there is more doubt; he probably died of fever, but the pope immediately confiscated his goods.

The war between France and Spain for the possession of Naples dragged on, and Alexander was ever intriguing, ready to ally himself with whichever power promised at the moment most advantageous terms. He offered to help Louis on condition that Sicily be given to Cesare, and then offered to help Spain in exchange for Siena, Pisa and Bologna. Cesare was preparing for another expedition into central Italy in July 1503, when, in the midst of all these projects and negotiations, both he and his father were taken ill with fever. The occurrence was of course kept from the pope, who would have created new cardinals, although quite without foundation, being merely due to malaria, at that time very prevalent in Rome. On the 18th of August Alexander died at the age of 72. His death was followed by scenes of wild disorder, and Cesare, being himself ill, could not attend to business, but sent Don Michelotto, his chief brave, to seize the pope's treasures before the demise was publicly announced. When the body was exhibited to the people the next day it was in a shocking state of decomposition, which of course strengthened the suspicion of poison. At the funeral a brawl occurred between the soldiers and Cesare's guards, and Cesare, having been made too short the body without the mitre was swung between the crowd, and covered with an oil-cloth. Alexander's successor on the chair of St Peter was Francesco Todeschini-Piccolomini, who assumed the name of Pius III.

Alexander VI. has become almost a mythical character, and countless legends and traditions are attached to his name. As a matter of fact he cannot be regarded in any sense as a great man. His career shows no great political ideas, and none of his actions indicate genius. His one thought was family aggrandizement, and while it is unlikely that he meditated making the future Napoleon, it is true that he gave himself completely to his family's interest. He seized his temporal estates to his children as though they belonged to him. The secularization of the church was carried to a pitch never before dreamed of, and it was clear to all Italy that he regarded the papacy as an instrument of worldly schemes with no thought of its religious aspect. During his pontificate the church was brought to its lowest level of degradation. The condition of his subjects was deplorable, and if Cesare's rule in Romagna was an improvement on that of the local tyrants, the people of Rome have seldom been more oppressed than under Alexander. It was he who gave the first real impetus to the general unrest in Italy and the foreign invasion; but he was ever ready to profit by them. Even if we do not accept all the stories of his murders and poisonings and immoralities as true, there is no doubt that his greed for money and his essentially vicious nature led him to commit a great number of crimes. For many of his misdeeds his terrible son Cesare was responsible, but of others the pope cannot be acquitted. The one pleasing aspect of his life is his patronage of the arts, and in his days a new architectural era was initiated in Rome with the coming of Bramante, Raphael, Michelangelo and Pitturichio all working for him, and a curious contrast, characteristic of the age, is afforded by the fact that a family so steeped in vice and crime could take pleasure in the most exquisite works of art.

BIBLIOGRAPHY.—The chief contemporary authorities for this reign are: the diary of Alexander's master of ceremonies, Johannes Burchardus, edited by L. Thuasne (Paris, 1883-1884), which is characterized by accuracy and extraordinary candour often amounting to gross indecency; the dispatches of Giustiniani, the Venetian ambassador, edited by P. Villari (Florence, 1876), which show great insight and are based on the most accurate information; and Paolo Cappelli's "Diarii" in E. Alberi's Relazioni, series ii., iii. Among modern works the most important is O. Seibt's Geschicht der Stadt Rom (3rd ed., Stuttgart, 1881), a work of immense research and admirable synthesis, giving a very unfavourable view of the Borgia; A. von Reumont's Geschichte der Stadt Rom (Berlin, 1867-1870), also a valuable book; M. Creighton's History of the Papacy (London, 1897) is very learned and accurate, but the author is more lenient towards Alexander; F. Gregorovius's Lucaestia Borgiae (Stuttgart, 1874) contains a great deal of information about the Borgia family; P. Villari's Machiavelli (English translation, new ed., 1892) deals with the subject at some length. Of the Catholic writers
ALEXANDER I.  

L. Pastor, *Geschichte der Päpste* (Freiburg i. B. 1886) should be consulted, for although the author tries to extenuate the pope to some extent, on the whole he is fair.

ALEXANDER VII. (Fabio Chigi), pope from 1655 to 1667, was born at Siena on the 13th of February 1599. He was successively inquisitor at Malta, vice-legate at Ferrara and nuncio in Cologne (1639-1651). Though expected to take part in the negotiations which led in 1648 to the peace of Westphalia, he refused to deliberate with heretics, and protested against the treaties when completed. Innocent X. subsequently made him cardinal secretary of state. When Innocent died, Chigi, the candidate favoured by Spain, was elected pope on the 7th of April 1655. The claveh believed he was strongly opposed to the nepotism then prevalent. In the first year of his reign Alexander VII. forbade his relations even to visit Rome; but in 1656 he gave them the best-paid civil and ecclesiastical offices, also palaces and princely estates. Alexander disliked business of state, preferring literature and philosophy; a collection of his Latin poems appeared at Paris in 1656 under the title *Philomastiki Labores Juveniles.* He also encouraged architecture, and in particular constructed the beautiful colonnade in the piazza of St Peter's. He favoured the Jesuits, especially in their conflict with the Jansenists, forbade in 1661 the translation of the Roman Missal into French, and in 1665 canonized Francis of Sales. His pontificate was marked by protracted controversies with France and Portugal. He died on the 22nd of May 1667.

ALEXANDER VIII. (Pietro Ottoboni), pope from 1667 to 1669, was born in 1610 of a noble Venetian family, was created cardinal, and then successively bishop of Brescia and duxia. The ambassador of Louis XIV. succeeded in procuring his election on the 6th of October 1669 as successor to Innocent XI.; nevertheless, after months of negotiation Alexander finally condemned the declaration made in 1682 by the French clergy concerning the liberties of the Gallican church. Charities on a large scale and unbounded nepotism exhausted the papal treasury. He bought the books and manuscripts of Queen Christina of Sweden for the Vatican library. Alexander condemned in 1690 the doctrines of so-called philosophic sin, taught in the Jesuit schools. He died on the 1st of February 1691.

ALEXANDER I. (Aleksander Pavlovich) (1777-1825), emperor of Russia, son of the grand-duke Paul Petrovich, afterwards Paul I., and Maria Fedorovna, daughter of Frederick Eugene of Württemberg, was born on the 28th of December 1777. The strange contradictions of his character make Alexander one of the most interesting as he is one of the most important figures in the history of the 19th century. Autocrat and "Jacobin," man of the world and mystic, he was to his contemporaries a riddle which each read according to his own temperament. Napoleon thought him a "shiftz Byzantine," and called him the "Talma of the North," as ready to play any conspicuous part. To Metternich he was a madman to be humoured. Castlereagh, writing of him to Lord Liverpool, gives him credit for "grand qualities," but adds that he is "suspicious and undecided." His complex nature was, in truth, the outcome of the complex character of his early environment and education. Reared in the free-thinking atmosphere of the court of Catherine II. he had imbibed from his Swiss tutor, Frédéric César de Laharpe, the principles of Rousseau's gospel of humanity; from his military governor, General Soltikov, the traditions of Russian autocracy which had inspired him with his own passion of military parade, and taught him to combine a theoretical love of mankind with a practical contempt for men. These contradictory tendencies remained with him through life, revealed in the fluctuations of his policy and influencing through him the fate of the world. Another element in his character discovered itself when in 1801 he mounted the throne over the body of his murdered father: a mystic melancholy liable at any moment to issue in extravagant action. At first, indeed, this exercised but little influence on the emperor's life. Young, emotional, impressionable, well-meaning and egotistic, Alexander displayed from the first an intention of playing a great part on the world's stage, and plunged with all the ardour of youth into the task of realizing his political ideals. While retaining for a time the old ministers who had served and overthrown the emperor Paul, one of the first acts of his reign was to appoint a secret committee, calledironically the "Comité du salut public," consisting of young and enthusiastic friends of his own—Victor Gavovich Kochubej, Nikolai Nikoloevich Novosilsou, Alexander Alexandrovich Strogonov and Adam Czartoryskis—to draw up a scheme of internal reform. Their aims, inspired by their admiration for English institutions, were far in advance of the possibilities of the time, and even after they had been raised to regular ministerial positions but little of their programme could be realized. For Russia was not ripe for liberty; and Alexander, the disciple of the revolutionist Laharpe, was—as he himself said—but a "happy accident" on the throne of the tsars. He spoke, indeed, bitterly of "the state of barbarism in which the country had been left by the traffic in men." "Under Paul," he said, "three thousand peasants had been given away like a bag of diamonds. If civilization were more advanced, I would abolish this slavery, if it cost me my head." But the universal corruption, he complained, had left him no men; and the filling up of the government offices with Germans and other foreigners merely accentuated the sullen resistance of the "old Russians" to his reforms. That Alexander's reign, which began with so large a promise of amelioration, ended by riveting still tighter the chains of the Russian people was, however, due less to the corruption and backwardness of Russian life than to the defects of the tsar himself. His love of liberty, though sincere, was in fact unreal. It flattered his vanity to pose before the world as the dispenser of benefits; but his theoretical liberalism was mated with an autocratic will which brooked no contradiction. "You always want to instruct me!" he exclaimed to Derzhavin, the minister of justice, "but I am the autocratic emperor, and I will this, and nothing else!" "He would gladly have agreed," wrote Adam Czartoryskis, "that every one should be free, if every one had freely done only what he wished." Moreover, with this masterful temper was joined an infirmity of purpose which ever let "I dare not wait upon I would," and which seized upon any excuse for postponing measures the principles of which he had publicly approved. The codification of the laws initiated in 1801 was never carried out during his reign; nothing was done to improve the intolerable status of the Russian peasantry; the constitution drawn up by Speranski, and passed by the emperor, remained unsigned. Alexander, in fact, who, without being consciously tyrannical, possessed in full measure the tyrant's characteristic distrust of men of ability and independent judgment, lacked also the first requisite for a reforming sovereign: confidence in his people; and it was this want that vitiated such reforms as were actually realized. He perfected the programme of the outlying provinces of his empire; and the Russians noted with open murmers that, not content with governing through foreign instruments, he was conferring on Poland, Finland and the Baltic provinces benefits denied to themselves. In Russia, too, certain reforms were carried out; but they could not survive the suspicious interference of the autocrat and his officials. The newly created council of ministers, and the senate, endowed for the first time with certain theoretical powers, became in the end but the slavish instruments of the tsar and his favourites of the moment. The elaborate system of education, culminating in the creation of the universities, including St Petersburg, St Petersburg, St Petersburg, St Petersburg, St Petersburg, the educational system of the provinces, was overloaded with cost, and never realized. He surrounded himself with foreign ministers. Vilin, Kazan and Kharkov, was strangled in the supposed interests of "order" and of orthodoxy piety; while the military colonies which Alexander proclaimed as a blessing to both soldiers and state were forced on the unwilling peasantry and army with pitiless cruelty. Even the Bible Society, through which the emperor in his later mood of evangelical zeal proposed to bless his people, was conducted on the same ruthless lines. The Roman archbishop and the Orthodox metropolitans were forced to serve on its committee side by side with Protestant pastors, and village popes, trained to regard any tampering with the letter of

1 Savary to Napoleon, Nov. 4, 1807. Tatschell, p. 226.
the traditional documents of the church as mortal sin, became
the unwitting instruments for the propagation of what they
regarded as works of the devil.

Such an imagination was, however, more strongly
touched by the great questions of European politics than by
attempts at domestic reform which, on the whole, wounded his
pride by proving to him the narrow limits of absolute power.
On the morrow of his accession he had reversed the policy of
Paul, denounced the League of Neutrals, and made peace with
England (April 1801), at the same time opening negotiations
with Austria. Soon afterwards at Memel he entered into a
close alliance with Prussia, not as he boasted from motives of policy,
but in the spirit of true chivalry, out of friendship for the young
knight of the burning heart and his disinterestedness. The develop-
ment of this alliance was interrupted by the short-lived peace of
October 1801; and for a while it seemed as though France and
Russia might come to an understanding. Carried away by the
enthusiasm of Laharpe, who had returned to Russia from Paris,
Alexander began openly to proclaim his admiration for French
institutions and for the person of Bonaparte. Soon, however,
came a change. Laharpe, after a new visit to Paris, presented to
the tsar his Reflections on the True Nature of the Consulship for
Life, which, as Alexander said, tore the veil from his eyes, and
revealed, was not to be only a departure in France, but the uni-
versal process by which the most famous tyrant the world has produced.” His disillusion-
ment was completed by the murder of the duc d’Enghien. The
Russian court went into mourning for the last of the Condés, and
diplomatic relations with Paris were broken off.

The events of the war that followed belong to the general
history of Europe; but the tsar’s attitude throughout is personal
to himself, though pregnant with issues momentous for the
world. In opposing Napoleon, “the oppressor of Europe and
the disturber of the world’s peace,” Alexander in fact already
believed himself to be fulfilling a divine mission. In his instruc-
tions to his envoy, Count Lopukhin, he summed up his
considerations in the following words: “In my love of my
fatherland elaborated the motives of his policy in language which appealed
as little to the common sense of Pitt as did the later treaty of
the Holy Alliance to that of Castlereagh. Yet the document is
of great interest, as in it we find formulated for the first time in
an official dispatch those exalted ideals of international policy
which were to play so conspicuous a part in the affairs of the
world at the close of the revolutionary epoch, and issued at the
end of the 19th century in the Rescript of Nicholas II.1 and
the conference of the Hague. The outcome of the war, Alexander
argued, was to enable the tsar to make France his ally, and
thus to realize the universal triumph of “the sacred rights of humanity.” To attain
this it would be necessary “after having attached the nations to
their government by making these incapable of acting save in
the greatest interests of their subjects, to fix the relations of the
states amongst each other on more precise rules, and such as it is
to their interest to respect.” A general treaty was to become
the basis of the relations of the states forming “the European
Confederation”; and this, though “it was no question of realiz-
ing the dream of universal peace, would attain some of its results if,
at the conclusion of the general war, it was possible to establish
on clear principles the prescriptions of the rights of nations.” “Why could not one submit to it,” the tsar continued,
“the positive rights of nations, assure the privilege of neutrality,
insert the obligation of never beginning war until all the resources
which the mediation of a third party could offer have been
exhausted, having by this means brought to light the respective
grievances, and tried to remove them? It is on such principles as
these that one could proceed to a general pacification, and give
birth to a league of which the stipulations would form, so to
speak, a new code of the last of nations, which, sanctioned by the
greater part of the nations of Europe, would without difficulty
become the immutable rule of the cabinets, while those who
should try to infringe it would risk bringing upon themselves
the forces of the new union.”2

Meanwhile Napoleon, little deterred by the Russian autocrat’s
youthful idealogy, never gave up hope of detaching him from
the coalition. He had no sooner entered Vienna in triumph than
opened negotiations with him; he resumed them after Austerlitz.
Russia and France, he urged, were “geographical allies”; there-
was, and could be, between them no true conflict of interests;
together they might rule the world. But Alexander was still
determined “to persist in the system of disinterestedness in
respect of all the states of Europe which he had thus far followed,”
and he again allied himself with Prussia. The campaign of
Jena and the battle of Eylau followed; and Napoleon, though still
intent on the Russian alliance, stirred up Poles, Turks and
Russians to break the treaty. But whereas Russia herself, headed by
the tsar’s brother the海滨-nomad

want anything for myself," he said to the French ambassador, "therefore the world is not large enough to come to an understanding on the affairs of Poland, if it is a question of its restoration." The treaty of Vienna, which added largely to the grand-duchy of Warsaw, he complained had "ill required him for his loyalty," and he was only mollified for the time by Napoleon's public declaration that he had no intention of restoring Poland, and by a convention, signed on the 4th of January 1810 but not ratified, aboliishing the Polish name and orders of chivalry.

But if Alexander suspected Napoleon, Napoleon was no less suspicious of Alexander; and, partly to test his sincerity, he sent an almost peremptory request for the hand of the grand-duchess Anne, the tsar's youngest sister. After some little delay Alexander returned a polite refusal, on the plea of the princess's tender age and the objection of the dowager empress to the marriage. Napoleon's answer was to refuse to ratify the convention of the 4th of January, and to announce his engagement to the archduchess Marie Louise in such a way as to lead Alexander to suppose that the two marriage treaties had been negotiated simultaneously. From this time the relation between the two emperors gradually became more and more strained. The annexation of Oldenburg, of which the duke was the tsar's uncle, to France in December 1810, added another to the personal grievances of Alexander against Napoleon; while the ruinous reaction of "the continental system" on Russian trade made it impossible for the tsar to maintain a policy which was Napoleon's chief motive for the alliance. An acid correspondence followed, and ill-concealed armaments, which culminated in the summer of 1812 in Napoleon's invasion of Russia. Yet, even after the French had passed the frontier, Alexander still protested that his personal sentiments towards the emperor were unaltered; "but," he added, "God Himself cannot undo the past." It was the occupation of Moscow and the desecration of the Kremlin, the sacred centre of Holy Russia, that changed his sentiment for Napoleon into passionate hatred. In vain the French emperor, within eight days of his entry into Moscow, wrote to the tsar a letter, which was one long cry of distress, revealing the desperate straits of the Grand Army, and appealed to "any remnant of his former sentiments." Alexander returned no answer to these "fanaronnades". "No more peace with Napoleon!" he cried, "He or I, I or He: we cannot longer reign together!"

The campaign of 1812 was the turning-point of Alexander's life; and its horrors, for which his sensitive nature felt much of the responsibility, overset still more a mind never too well balanced. At the burning of Moscow, he declared afterwards, his own soul had found illumination, and he had realized once for all the divine revelation to him of his mission as the peacemaker of Europe. He tried to calm the unrest of his conscience by correspondence with the leaders of the evangelical revival on the continent, and sought for omens and supernatural guidance in texts and passages of scripture. It was not, however, according to his own account, till he met the Baroness de Krüdener—a religious adventuress who made the conversion of princes her special mission—at Basel, in the autumn of 1813, that his soul found peace. From this time a mystic piety became the avowed force of his political, as of his private actions. Madame de Krüdener, and her colleague, the evangelist Empayatz, became the confidants of the emperor's most secret thoughts; and during the campaign that ended in the occupation of Paris the imperial prayer-meetings were the oracle on whose revelations hung the fate of the world.

Such was Alexander's mood when the downfall of Napoleon left him the most powerful sovereign in Europe. With the memory of Tilsit still fresh in men's minds, it was not unnatural that to cynical men of the world like Metternich he merely seemed to be disguising "under the language of evangelical abnegation" vast and perilous schemes of ambition. The puzzled powers were, in fact, the more inclined to be suspicious in view of other, and seemingly inconsistent, tendencies of the emperor, which yet seemed all to point to a like disquieting conclusion. For Madame de Krüdener was not the only influence behind the throne; and, though Alexander had declared war against the Revolution, Laharpe was once more at his elbow, and the catchwords of the gospel of humanity were still on his lips. The very proclamations which denounced Napoleon as "the genius of evil," denounced him in the name of "liberty," and of "enlightenment." A monstrous intrigue was suspected to the alliance of the eastern autocrat with the Jacobinism of all Europe, which would have issued in the substitution of an all-powerful Russia for an all-powerful France. At the congress of Vienna Alexander's attitude accentuated this distrust. Castlereagh, whose single-minded aim was the restoration of "a just equilibrium" in Europe, reproached the tsar to his face for a "conscience" which suffered him to imperil the concert of the powers by keeping his hold on Poland in violation of his treaty obligation.

Yet Alexander was sincere. Even the Holy Alliance, the pet oppining of his plotters, does not deserve the sinister reputation it has hitherto obtained. To the other powers it seemed, at best, "verbiage" and "exalted nonsense," at worst an effort of the tsar to establish the hegemony of Russia on the goodwill of the smaller signatory powers. To the Liberals, then and afterwards, it was clearly a hypocritical conspiracy against freedom. Yet to Alexander himself it seemed the only means of placing the "confederation of Europe" on a firm basis of principle and, so far from its being directed against liberty he declared roundly to all the signatory powers that "free constitutions were the logical outcome of its doctrines." Europe, in fact, owed much to this time of Alexander's exalted temper. During the period when his influence was supreme, the fateful years, that is, between the Moscow campaign and the close of the congress of Aix-la-Chapelle, it had been used largely in the interests of moderation and liberty. To him mainly it was due that France was saved from dismemberment, and received a constitution which, to use his own words, "united crown and representatives of the people in a sense of common interests." By his wise intervention Switzerland was saved from violent reaction, and suffered to preserve the essential gains of the Revolution. To his proactivity, it was due that the weak beginnings of constitutional freedom in Germany were able for a while to defy the hatred of Austria. Lastly, whatever its ultimate outcome, the constitution of Poland was, in its inception, a genuine effort to respond to the appeal of the Poles for a national existence.

From the end of the year 1818 Alexander's views began to change. A revolutionary conspiracy among the officers of the guard, and a foolish plot to kidnap him on his way to the congress of Aix-la-Chapelle (q.v.), are said to have shaken the foundations of his Liberalism. At Aix he came for the first time into intimate contact with Metternich, and the astute Austrian was swift to take advantage of the psychological moment. From this time dates the ascendancy of Metternich over the mind of the Russian emperor and in the councils of Europe. It was, however, no case of sudden conversion. Though alarmed by the revolutionary agitation in Germany, which culminated in the murder of his agent, the dramatist Kotzebue (q.v.), Alexander approved of Castlereagh's protest against Metternich's policy of "the governments contracting an alliance against the peoples," as formulated in the Carlsbad decrees, 1819, and deprecated any intervention of Europe to support "a league whose sole object is the absurd pretensions of absolute power." He still declared his belief in "free institutions, though not in such as are forced from feebleness, nor contracts ordered by popular leaders from their
sovereign, nor constitutions granted in difficult circumstances to tide over a crisis. "Liberty," he maintained, "should be confined within just limits. And the limits of liberty are the principles of order."1

It was the apparent triumph of the principles of disorder in the revolutions of Naples and Piedmont, combined with increasingly disquieting symptoms of discontent in France, Germany and among his own people, that completed Alexander's conversion. In the seclusion of the little town of Troppau, where in October of 1829 the powers met in conference, Metternich found an opportunity for cementing his influence over Alexander which he did not fail to avail of amidst the turmoil and feminine intrigues of Vienna and Aix. Here, in confidence begotten of friendly chats over afternoon tea, the disillusioned autocrat confessed his mistake. "You have nothing to regret," he said sadly to the exulant chancellor, "but I have!"2 The issue was momentous. In January Alexander had still upheld the ideal of a free confederation of the European states, symbolized by the Holy Alliance, against the policy of a dictatorship of the great powers, symbolized by the Quadruple Treaty; he had still protested against the claims of collective Europe to interfere in the internal life of the subject states. On the 12th of November he signed the Troppau Protocol, which consecrated the principle of intervention and wrecked the harmony of the concert. (See Troppau, Congress of.)

At Laibach, whither in the spring of 1831 the congress had been adjourned, Alexander first heard of the revolt of the Greeks. From this time until his death his mind was torn between his anxiety to realize his dream of a confederation of Europe and his traditional mission as leader of the Orthodox crusade against the Turks. At first, under the careful nursing of Metternich, the former motive prevailed. He struck the name of Alexander Ypsilanti from the Russian army list, and directed his foreign minister, Count Capo d'Istria, himself a Greek, to disavow all sympathy of Russia with his enterprise; and, next year, a deputation of the Greeks of the Morea on its way to the congress of Verona was turned back by his orders on the road. He made, indeed, some effort to reconcile the principles at conflict in his mind. He offered to surrender the claim, successfully asserted when the sultan had been excluded from the Holy Alliance and the affairs of the Ottoman empire from the deliberations of Vienna, that the affairs of the East were the "domestic concerns of Russia," and to march into Turkey, as Austria had marched into Naples, "as the mandatory of Europe."3 Metternich's opposition to this, illogical, but natural from the Austrian point of view, first opened his eyes to the true character of Austria's attitude towards his ideals. Once more in Russia, far from the fascination of Metternich's personality, the immemorial spirit of his people drew him back into itself; and when, in the autumn of 1825, he took his dying emperor for change of air to the south of Russia, in order—as all Europe supposed—to place himself at the head of the great army concentrated near the Ottoman frontiers, his language was no longer that of "the peace-maker of Europe," but of the Orthodox tsar determined to take the interests of his people and of his religion "into his own hands." Before the momentous issue could be decided, however, Alexander died at Taganrog on the 1st of December (November 18, O.S.) 1825, "crushed," to use his own words, "beneath the terrible burden of a crown" which he had more than once declared his intention of resigning. A report, current at the time and often revived, affirmed that he did not in fact die. By some it is supposed that a mysterious hermit named Pomichi, who lived at Tomsk until 1870 and was treated with peculiar deference by successive tsars, was none other than Alexander.4

Modern history knows no more tragic figure than that of Alexander. The brilliant promise of his early years; the haunting memory of the crime by which he had obtained the power to realize his ideals; and, in the end, the terrible legacy he left to Russia: a principle of government which, under lofty pretensions, veiled a tyrant supported by spies and secret police; an uncertain succession; an army perverted by organized disaffection; an armed Poland, whose hunger for liberty the tsar had whetted but not satisfied; the quarrel with Turkey, with its alternative of war or humiliation for Russia; an educational system rotten with official hypocrisy; a Church in which conduct counted for nothing, orthodoxy and ceremonial observance for everything; economical and financial conditions scarce recovering from the verge of ruin; and, lastly, that curse on the Russian federative spirit, the idea of a grand-duke as a political power, the son of the Grand Duchess of Taganrog,岖 she swelled to her little grand-duchess, died on the 12th of May 1858; and their common sorrow drew husband and wife closer together. Towards the close of his life their reconciliation was completed by the wise charity of the emperor in sympathizing deeply with him over the death of his beloved daughter by Madame Narishkine.

(3 vols., London, 1873), but the above is the best available source of information, but the references in footnotes are often wanting in precision, and it has no index.

ALEXANDERII (1581–1881), emperor of Russia, eldest son of Nicholas I., was born on the 29th of April 1818. His early life gave little indication of his subsequent activity, and up to the moment of his accession in 1855 no one ever imagined that he would be known to posterity as a great reformer. In so far

as he had any decided political convictions, he seemed to be animated with that reactionary spirit which was predominant in Europe at the time of his birth, and continued in Russia to the end of his father’s reign. In the period of thirty years during which he was heir-apparent, the moral atmosphere of St. Petersburg was very unfavourable to the development of any originality of thought, or character. It was a time when the power of government on martinet principles, under which all freedom of thought and all private initiative were as far as possible suppressed vigorously by the administration. Political topics were studiously avoided in general conversation, and books or newspapers in which the most keen-scented press-censor could detect the least odour of political or religious free-thinking were strictly prohibited. Criticism of existing authorities was regarded as a serious offence. The common policeman, the insignificant scribe in a public office, and even the actors in the “imperial” theatres, were protected against public censure as effectually as the government itself; for the whole administration was considered as one and indivisible, and an attack on the humblest representative of the imperial authority was looked on as an indirect attack on the fountain from which that authority flowed. Such was the moral atmosphere in which young Alexander Nikolaeiehich grew up to manhood. He received the education commonly given to young Russians of good family at that time—a smattering of a great many subjects, and a good practical acquaintance with the chief modern European languages. Like so many of his countrymen, he displayed the subversive ideas current in Western Europe, and this quality caught up even peculiarities of dialect. His ordinary life was that of an officer of the Guards, modified by the ceremonial duties incumbent on him as heir to the throne. Nominally he held the post of director of the military schools, but he took little personal interest in military affairs. To the disappointment of his father, in whom the military instinct was ever predominant, he showed no love of soldiering, and gave evidence of a kindliness of disposition and a tender-heartedness which were considered out of place in one destined to become a military autocrat. These tendencies had been fostered by his tutor Zhukovsky, the amiable humanitarian poet, who had made the Russian public acquainted with the literature of the German romantic school, and they remained with him all through life, though they did not prevent him from being severe in his official position when he believed severity to be necessary. In 1841 he married the daughter of the grand-duke Louis II. of Hesse, Maximilienne Wilhelmine Marie, thenceforward known as Maria Alexandrovna, who bore him six sons and two daughters. He did not travel much abroad, for his father, in his desire to exclude Holy Russia from the subversive ideas current in Western Europe, disapproved foreign tours, and could not consistently encourage in his own family what he tried to prevent among the rest of his subjects. He visited England, however, in 1839, and in the years immediately preceding his accession he was entrusted with several missions to the courts of Berlin and Vienna. On the 2nd of March 1855, during the Crimean War, he succeeded to the throne on the death of his father.

The first year of the new reign was devoted to the prosecution of the war, and after the fall of Sevastopol, to negotiations for peace. Then began a period of radical reforms, recommended by public opinion and carried out by the autocratic power. The rule of Nicholas, which had sacrificed all other interests to that of making Russia an irresistibly strong military power, had been tried by the Crimean War and found wanting. A new system must, therefore, be adopted. All who had any pretensions to enlightenment declared loudly that the country had been exhausted and humiliated by the war, and that the only way of restoring it to its proper position in Europe was to develop its natural resources and to reform thoroughly all branches of the administration. The government found, therefore, in the educated classes a new-born public spirit, anxious to assist it in any work of reform that it might think fit to undertake. Fortunately for Russia the autocratic power was now in the hands of a man who was impressionable enough to be deeply influenced by the spirit of the time, and who had sufficient prudence and practical common-sense to prevent his being carried away by the prevailing excitement into the dangerous region of Utopian dreaming. Unlike some of his predecessors, he had no grand, original schemes of his own to impose by force on unwilling subjects, and no pet crotches to lead his judgment astray; and he instinctively looked with a suspicious, critical eye on any scheme which more immediately and deeply affected the people recommended. These traits of character, together with the peculiar circumstances in which he was placed, determined the part which he was to play. He moderated, guided and in great measure realized the reform aspirations of the educated classes. Though he carefully guarded his autocratic rights and privileges, and obstinately resisted all efforts to push him farther than he felt inclined to go he acted for several years somewhat like a constitutional sovereign of the continental type. At first he moved so slowly that many of the impatient, would-be reformers began to murmur at the unnecessary delay. In reality not much time was lost. Soon after the conclusion of peace important changes were made in the legislation concerning industry and commerce, and the new freedom thus accorded produced a large number of limited liability companies. At the same time plans were formed for constructing a great network of railways, partly for the purpose of developing the natural resources of the country, and partly for the purpose of increasing its powers of defence and attack. Then it was found that further progress was blocked by a great obstacle, the existence of serfdom; and Alexander II. showed that, unlike his father, he meant to grapple boldly with the difficult and dangerous problem. Taking advantage of a petition presented by the Polish landed proprietors of the Lithuanian provinces, praying that their relations with the serfs might be regulated in a more satisfactory way—meaning in a way more satisfactory for the proprietors—he authorized the formation of committees “for ameliorating the condition of the peasants,” and laid down the principles on which the amelioration was to be effected. This was a decided step and it was followed by one still more significant. Without consulting his ordinary advisers, his majesty ordered the minister of the interior to send a circular to the provincial governors of European Russia, containing a copy of the instructions forwarded to the governor-general of Lithuania, praising the supposed generous, patriotic intentions of the Lithuanian landed proprietors, and suggesting that perhaps the landed proprietors of other provinces might express a similar desire. The hint was taken, of course, and in all provinces where serfage existed emancipation committees were formed. The deliberations at once raised a host of questions, the answers to which were not merely a humanitarian question capable of being solved instantaneously by imperial ukaz. It contained very complicated problems affecting deeply the economic, social and political future of the nation. Alexander II. had little of the special knowledge required for dealing successfully with such problems, and he had to restrict himself to choosing between the different measures recommended to him. The main point at issue was whether the serfs should become agricultural labourers dependent economically and administratively on the landlords, or should be transformed into independent proprietors. The emperor gave his support to the latter project, and the Russian peasantry accordingly acquired rights and privileges such as are enjoyed by no other peasantry in Europe. In the numerous other questions submitted to him he began by consulting carefully the conflicting authorities, and while leaning as a rule rather to the side of those who were known as “Liberals,” he never went so far as they desired, and always sought some middle course by which conflicting interests might be reconciled. On the 3rd of March 1861, the sixth anniversary of his accession, the emancipation law was signed and published. Other reforms followed in quick succession during the next five or six years: army and navy organization, a new judicial administration on the French model, a new penal code and a greatly simplified system of civil and criminal procedure, an elaborate scheme of local self-government for the rural districts and the large
towns, with elective assemblies possessing a restricted right of taxation, and a new rural and municipal police under the direction of the minister of the interior. These new institutions were incomparably better than the old ones which they replaced, but they did not work such miracles as inexperienced enthusiasts expected. Comparisons were made, not with the past, but with an ideal state of things which never existed in Russia or elsewhere. Hence arose a general feeling of disappointment, which acted on different natures in different ways. Some of the enthusiasts sank into a sceptical, reactionary frame of mind; while others, with deeper convictions or capable of more lasting excitement, forebore the failure to the effect that some measures and compromises had been adopted by the government. Thus appeared in the educated classes two extreme groups: on the one hand, the discontented Conservatives, who recommended a return to a more severe disciplinarian régime; and on the other, the discontented Radicals, who would have been satisfied with nothing less than the adoption of a thoroughgoing socialistic programme. Between the two extremes stood the discontented Moderates, who indulged freely in grumbling without knowing how the unsatisfactory state of things was to be remedied. The government, in its wisdom, adopted the medium course, which, with its sound common-sense and dislike of exaggeration, held the balance fairly between the two extremes; but long years of uninterrupted labour, anxiety and disappointment weakened his zeal for reform, and when radicalism assumed more and more the form of secret societies and revolutionary agitation, he felt constrained to adopt severe repressive measures.

The revolutionary agitation was of a very peculiar kind. It was confined to a section of the educated classes, and emanated from the universities and higher technical schools. At the beginning of the reform period there had been much enthusiasm for scientific as opposed to classical education. Russia required, it was said, not classical scholars, but practical, scientific men, capable of developing her natural resources. The government, in accordance with this view, had encouraged scientific studies until it discovered to its astonishment that there was some mysterious connexion between natural science and revolutionary tendencies. Many of the young men and women, who were supposed to be qualifying as specialists in the various spheres of industrial and commercial enterprise, were in reality devoting their time to considering how human society in general, and Russian society in particular, might be improved. The emperor, with his sound perception of the latest physiological, biological and sociological principles. Some of these young people wished to put their crude notions immediately into practice, and as their desire to make gigantic socialist experiments naturally alarmed the government, their activity was opposed by the police. Many of them were arrested and imprisoned or exiled to distant provinces, but the revolutionary work was continued with unabated zeal. Thus arose a struggle between the youthful, hot-headed partisans of revolutionary physical science and the zealous official guardians of political order—a struggle which has made the strange term Nihilism (p. e.) a familiar word not only in Russia but also in western Europe. The movement gradually assumed the form of terror, and aimed at the assassination of prominent officials, and even of the emperor himself, and the natural result was that the reactionary tendencies of the government were strengthened.

In foreign policy Alexander II. showed the same qualities of character as in internal affairs, ever trying prudently to steer a middle course. When he came to the throne a peace policy was imposed on him by circumstances. The Crimean war was still going on, but as there was no doubt as to the final issue, and the country was showing symptoms of exhaustion, he concluded peace with the allies as soon as he thought the national honour had been satisfied. Prince Gorchakov could then declare to Europe, "La Russie ne boude pas; elle se recueille"; and for fifteen years he avoided foreign complications, so that the internal strength of the country might be developed, while the national pride and ambition received a certain satisfaction by the expansion of Russian influence and domination in Asia. Twice, indeed, during that period the chancellor ran the risk of provoking war. The first occasion was in 1863, when the Western powers seemed inclined to intervene in the Polish question, and the Russian chancery declared categorically that no interference would be tolerated. The second occasion was during the Franco-German War of 1870-71, when the cabinet of St Petersburg boldly declared that it considered itself no longer bound by the Black Sea clause of the treaty of Paris. On both these occasions hostilities were averted. Not so on the next occasion, when Russia abandoned her attitude of recueillement. When the Eastern question was raised in 1875 by the insurrection of Herzegovina, Alexander II. had no intention of allowing the Balkan provinces to remain unoccupied, as he was waiting for an opportunity of recovering the portion of Bessarabia which had been ceded by the treaty of Paris, and he perceived in the disturbed state of Eastern Europe a possibility of obtaining the desired rectification of frontier, but he hoped to effect his purpose by diplomatic means in conjunction with Austria. At the same time he was anxious to obtain for the Christians of Turkey some amelioration of their condition, and to give thereby some satisfaction to his own subjects. As autocratic ruler of the nation which had long considered itself the defender of the Eastern Christians, he was prepared to make great sacrifices, but he hoped, and he was not disappointed, that these sacrifices would be less than if the Tsar had been compelled to depend on the help of other powers. The Austrian government, indeed, was reported to be unwilling to follow the lead of Russia, and Russia had to act alone. The diplomatic pressure failed and war became inevitable. During the campaign he displayed the same perseverance and the same moderation that he had shown in the emancipation of the serfs. To those who began to despair of success, and advised him to conclude peace on any terms so as to avoid greater disasters, he turned a deaf ear, and brought the campaign to a successful conclusion; but when his more headstrong advisers urged him to insist on terms which would probably have produced a conflict with Great Britain and Austria, he resolved, after some hesitation, to make the requisite concessions. In this resolution he was influenced by the discovery that he could not rely on the expected support of Germany, and the discovery made him waver in his devotion to the German alliance, which had been the main pivot of his foreign policy; but he realized that his attachment to the emperor William prevented him from adopting a hostile attitude towards the empire he had helped to create.

The patriotic excitement produced by the war did not weaken the revolutionary agitation. The struggle between the Terrorists and the police authorities became more and more intense, and attempts at assassination became more and more frequent. Alexander II. succumbed by degrees to the mental depression produced originally by the disappointments which he experienced in his home and foreign policy; and in 1880, when he had reigned twenty-five years, he entrusted to Count Loris-Melikov a large share of the executive power. In that year the empress died, and a few weeks afterwards he married secretly a Princess Dolgorukii, with whom he had already entertained intimate relations for some years. Early in 1881, on the advice of Count Loris-Melikov, he determined to try the effect of some moderate liberal reforms on the revolutionary agitation, and for this purpose he caused a ukaz to be prepared creating special commissions, composed of high officials and private personages who should prepare reforms in various branches of the administration. On the very day on which this ukaz was signed—18th of March 1881—he fell a victim to a Nihilist plot. When driving in one of the central streets of St Petersburg, near the Winter Palace, he was mortally wounded by the explosion of some small bombs and died a few hours afterwards.

(D. M. W.)

ALEXANDER III. (1845-1894), emperor of Russia, second son of Alexander II., was born on the 10th of March 1845. In natural disposition he bore little resemblance to his soft-hearted, liberal-minded father, and still less to his refined, philosophical, sentimental, chivalrous, yet cunning grand-uncle Alexander I., who
coveted the title of “the first gentleman of Europe.” With high culture, exquisite refinement and studied elegance he had no sympathy and never affected to have any. Indeed, he rather gloried in the idea of being of the same rough texture as the great majority of his subjects. His straightforward, abrupt manner savoured sometimes of gruffness, while his direct, unadorned method of expressing himself harmonized well with his rough-hewn, immobile features and somewhat sluggish movements. His education was not fitted to soften these peculiarities. During the first twenty years of his life he had no prospect of succeeding to the throne, because he had an elder brother, Nicholas, who seemed of a fairly robust constitution. Even when this elder brother showed symptoms of delicate health it was believed that his life might be indefinitely prolonged by proper care and attention, and precautions had been taken for the succession by his betrothal with Princess Dagmar of Denmark. Under these circumstances the greatest solicitude was devoted to the education of Nicholas as cesarevich, whereas Alexander received only the perfunctory and inadequate training of an ordinary prince of that period, which did not go much beyond primary and secondary instruction, practical acquaintance with French, English and German, and a certain amount of drill. When he became heir-apparent by the death of his elder brother in 1865, he began to study the principles of law and administration under Professor Pobédonostsef, who did not succeed in awakening in his pupil a love of abstract studies or prolonged intellectual exertion, but who influenced the character of his reign by instilling into his mind the belief that zeal for Eastern Orthodoxy ought, as an essential facet of Russian patriotism, to be counteracted by every right-minded tsar. His elder brother when on his deathbed had expressed a wish that his affianced bride, Princess Dagmar of Denmark, should marry his successor, and this wish was realized on the 6th of November 1866. The union proved a most happy one and remained unclouded to the end. During those years when he was heir-apparent—1865 to 1881—he did not play a prominent part in public affairs, but he allowed it to become known that he had certain ideas of his own which did not coincide with the principles of the existing government. He deprecated what he considered undue foreign influence in general, and German influence in particular, and hesitated to adopt the image of genuine national principles in all spheres of official activity, with a view to realizing his ideal of a homogeneous Russia—homogeneous in language, administration and religion. With such ideas and aspirations he could hardly remain permanently in cordial agreement with his father, who, though a good patriot according to his lights, had strong German sympathies, often used the German language in his private relations, occasionally ridiculed the exaggerations and eccentricities of the Slavophils, and had an aversion to Russian policy on the Prussian alliance. The antagonism first appeared publicly during the Franco-

German War, when the tsar supported the cabinet of Berlin and the cesarevich did not conceal his sympathies with the French. It reappeared in an intermittent fashion during the years 1875–1879, when the Eastern question produced so much excitement in all ranks of Russian society. At first the cesarevich was more Slavophil than the government, but his phlegmatic nature preserved him from many of the exaggerations indulged in by others, and any of the prevalent popular illusions he may have imbibed were soon dispelled by personal observation in Bulgaria, where he commanded the left wing of the invading army. The Bulgarians had been represented in St Petersburg and Moscow not only as martyrs but also as saints, and a very little personal experience sufficed to correct the error. Like most of his brother officers he could not feel any very great affection for the “little brothers,” as the Bulgarians were then commonly called, and he was constrained to admit that the Turks were by no means so black as they had been painted. He did not, however, scandalize the believers by any public expression of his opinions, and did not in the least make himself conspicuous in any way during the campaign. Never consulted on political questions, he devoted himself to his military duties and fulfilled them in a conscientious and unobtrusive manner. After many mistakes and disappoint-

ments, the army reached Constantinople and the treaty of San Stefano was signed, but much that had been obtained by that important document had to be sacrificed at the congress of Berlin. Prince Bismarck failed to do what was confidently expected of him. In return for the Russian support, which had enabled him to create the German empire, it was thought that he would help Russia to solve the Eastern question in accordance with her own interests, but to the surprise and indignation of the cabinet of St Petersburg he confined himself to acting the part of “honest broker” at the congress, and shortly afterwards he ostentatiously contracted an alliance with Austria for the express purpose of counteracting Russian designs in Eastern Europe. The cesarevich could point to these results as confirming the views he had expressed during the Franco-German War, and he drew from them the practical conclusion that for Russia the best thing to do was to recover as quickly as possible from her temporary exhaustion and to prepare for future contingencies by a radical scheme of military and naval reorganization. In accordance with this conviction, he suggested that certain reforms should be introduced. During the campaign in Bulgaria he had found by painful experience that grave disorders and gross corruption existed in the military administration, and after his return to St Petersburg he had discovered that similar abuses existed in the naval department. For these abuses, several high-placed personages—among others two of the grand-dukes—were believed to be responsible, and he called his father’s attention to the subject. His representations were not favourably received. Alexander II. had lost much of the reform zeal which distinguished his father’s reign, and there no longer the energy required to undertake the task suggested to him. The consequence was that the relations between father and son became more strained. The latter must have felt that there would be no important reforms until he himself succeeded to the direction of affairs. That change was much nearer at hand than was commonly supposed. On the 13th of March 1881 Alexander II. was assassinated by a band of Nihilists, and the autocratic power passed to the hands of his son. In the last years of his reign, Alexander II. had been much exercised by the spread of Nihilist doctrines and the increasing number of anarchistic conspiracies, and for some time he had hesitated between strengthening the hands of the executive and making concessions to the widespread political aspirations of the educated classes. Finally he decided in favour of the latter course, and on the very day of his death he signed a ukaz, creating a number of consultative commissions which might have been easily transformed into an assembly of notables. Alexander III. determined to adopt the opposite policy. He at once cancelled the ukaz before it was published, and in the manifesto announcing his accession to the throne he very clearly understood that he had no intention of limiting or weakening the autocratic power which he had inherited from his ancestors. Nor did he afterwards show any inclination to change his mind. All the internal reforms which he initiated were intended to correct what he considered as the too liberal tendencies of the previous reign, so that he left behind him the reputation of a sovereign of the retrograde type. In his opinion Russia was to be saved from anarchical disorders and revolutionary agitation, not by the parliamentary institutions and so-called liberalism of western Europe, but by the three principles held by the elder generation of the Slavophils systematically recommended—nationality, Eastern Orthodoxy and autocracy. His political ideal was a nation containing only one nationality, one language, one religion and one form of administration; and he did his utmost to prepare for the realization of this ideal by imposing the Russian language and Russian schools on his German, Polish and Finnish subjects, by fostering Eastern Orthodoxy at the expense of other confessions, by persecuting the Jews and by destroying the remnants of German, Polish and Swedish institutions in the outlying provinces. In the other provinces he sought to contrive where he considered the excessive liberalism of his father’s reign. For this purpose he clipped the feeble wings of the zemstvo, an elective local
administration resembling the county and parish councils in England, and placed the autonomous administration of the peasant communes under the supervision of landed proprietors appointed by the government. At the same time he sought to strengthen and centralize the imperial administration, and to bring it more under his personal control. In foreign affairs he was eminently a man of peace, and at all partisan of the doctrine of peace at any price, and he followed the principle that the best means of averting war is to be well prepared for it. Though indignant at the conduct of Prince Bismarck towards Russia, he avoided an open rupture with Germany, and even revived for a time the Three Emperors' Alliance. It was only in the last years of his reign, when M. Katkov had acquired a certain influence over him, that he adopted towards the cabinet of Berlin a more hostile attitude, and even then he confined himself to keeping a large quantity of troops near the German frontier, and establishing cordial relations with France. With regard to Bulgaria he exercised similar self-control. The efforts of Prince Alexander and afterwards of Stamboloff to destroy Russian influence in the principality excited his indignation, but he persistently vetoed all proposals to intervene by force of arms. In Central Asian affairs he followed the traditional policy of gradually extending Russian domination without provoking a conflict with Great Britain, and he never allowed the bellicose partisans of a forward policy to get out of hand. As a whole his reign cannot be regarded as one of the eventful English history, but it is one on which he acted with distinction under his hard unsympathetic rule the country made considerable progress. He died at Livadia on the 1st of November 1894, and was succeeded by his eldest son, Nicholas II. (D. M. W.)

ALEXANDER I. (c. 1078–1124), king of Scotland, was the fourth son of Malcolm Canmore by his wife (St) Margaret, grand-niece of Edward the Confessor. On the death of his brother Edgar in 1107 he succeeded to the Scottish crown; but, in accordance with Edgar's instructions, he inherited only a part of its possessions. By a partition, the motive of which is not quite certain, the districts south of the Forth and Clyde were erected into an earldom for Alexander's younger brother, David. Alexander, dissatisfied, sought to obtain the whole, but without success. A curious combination of the fierce warrior and the pious churchman, he manifested the one aspect of his character in his ruthless suppression of an insurrection in his northern dominion (thus gaining for himself the title of "the Fierce"), the other in his munificent foundation of bishoprics and abbeys. Among the latter were those of Scone and Inchcolm. His strong championship of the independence of the Scottish church involved him in struggles with both the English and the Roman church, but in the latter he espoused the cause of his cousin King Haakon, against the French archbishop of York, and was consecrated bishop of York on the 27th of April 1124, and was succeeded by his brother, David L.

ALEXANDER II. (1109–1249), king of Scotland, son of William the Lion and Ermengarde of Beaumont, was born at Haddington in 1108, and succeeded to the kingdom on the death of his father in 1124. The year after his accession the clans MacWilliam and MacHeth, inveterate enemies of the Scottish crown, broke into revolt; but the insurrection was speedily quelled. In the same year Alexander joined the English barons in their struggle against John, and led an army into England in support of their cause; but on the conclusion of peace after John's death between his youthful son Henry III. and the French prince Louis, the Scottish king was included in the pacification. The reconciliation thus effected was further strengthened by the marriage of Alexander to Henry's sister Joanna in 1221. The next year was marked by the subjection of the hitherto semi-independent district of Argyll. A revolt in Galloway in 1235 was crushed without difficulty; nor did an invasion attempted soon afterwards by its exiled leaders meet with any better fortune. Soon afterwards a claim for homage from Henry of England drew forth of Alexander his counter-claim to the northern English counties. The dispute was settled by peace was concluded in 1237. A threat of invasion by Henry in 1243 for a time interrupted the friendly relations between the two countries; but the prompt action of Alexander in anticipating his attack, and the disinclination of the English barons for war, compelled him to make peace next year at Newcastle. Alexander now turned his attention to securing the Western Isles, which still owned a nominal dependence on Norway. Negotiations and purchase were successively tried but without success. Alexander was "persuaded to seduce Ewen, the son of Duncan, Lord of Argyll, from Norway", and made him his Norwegian king. Ewen refused his overtures, and Alexander sailed forth to compel him. But on the way he was seized with fever at Kerrera, and died there on the 8th of July 1249.

ALEXANDER III. (1241–1285), king of Scotland, son of Alexander II. by his second wife Mary de Coucy, was born in 1241. At the age of eight years the death of his father called him to the throne. The years of his minority were marked by an embittered struggle for the control of affairs between two rival parties, the one led by Walter Comyn, earl of Menteith, the other by Alan Durward, the justiciar. The form was in the ascendant during the early years of the reign. At the marriage of Alexander to Margaret of England in 1251, Henry III. seized the opportunity to demand from his son-in-law homage for the Scottish kingdom, but the claim was refused. In 1255 an interview between the English and Scottish kings at Kelso resulted in the deposition of Menteith and his party in favour of their opponents. But though disgraced, they still retained great influence; and two years later, seizing the person of the king, they compelled their rivals to consent to the erection of a regency-representative of both parties. On attaining his majority in 1262, Alexander declared his intention of resuming the projects on the Western Isles which had been cut short by the death of his father thirteen years before. A formal claim was laid before the Norwegian king Haakon. Not only was this unsuccessful, but next year Haakon replied by a formidable invasion. Sailing round the west coast of Scotland he halted off Arran, where negotiations were opened. These were arbitrarily prolonged by Alexander until the autumn storms should begin. At length Haakon, weary of delay, attacked, only to encounter a terrific storm which greatly damaged his ships. The battle of Largs, fought next day, was indecisive. But even so Haakon's position was hopeless. Baffled he turned homewards, but died on the way. The Isles now lay at Alexander's feet, and in 1266 Haakon's successor concluded a treaty by which the Isle of Man and the Western Isles were ceded to Scotland in return for a money payment, Orkney and Shetland alone being retained. Towards the end of Alexander's reign, the death of all his three children within a few years made the question of the succession one of pressing importance. In 1284 he induced the Estates to recognize as his heir-presumptive his grand-daughter Margaret, daughter of John, as next in the line of succession. But the desire for war and the heir led him to contract a second marriage. But all such hopes were defeated by the sudden death of the king, who was killed by a fall from his horse in the dark while riding to visit the queen at Kinghorn on the 16th of March 1285.

ALEXANDER (ALEXANDER OBRENOVIICH) (1876–1903), king of Servia, was born on the 14th of August 1876. On the 6th of March 1889 his father, King Milan, abdicated and proclaimed him king of Servia under a regency until he should attain his majority at eighteen years of age. King Alexander, on the 13th of April 1890, being then in his seventeenth year, made his notable coup d'état, proclaimed himself of full age, dismissed the regents and their government, and took the royal authority into his own hands. His action was popular, and was rendered still more so by his appointment of a radical ministry. In May 1894 King Alexander, by another coup d'état, abolished the liberal constitution of 1889 and restored the conservative one of 1860. His attitude during the Turco-Greek war of 1897 was one of strict neutrality. In 1898 he appointed his father commander-in-chief of the Servian army, and from that time, or rather from his return to Servia in 1894 until 1900, ex-King Milan was regarded as the de facto ruler of the country. But while, during the summer of 1900, Milan was away from Servia taking waters in Carlsbad, and making arrangements to secure the hand of a German princess for his son, and while the
premier, Dr Vladan Dyorevich, was visiting the Paris Universal Exhibition, King Alexander suddenly announced to the people of Servia his engagement to Mme Draga Maslin, a widow, formerly a lady-in-waiting to Queen Natalie. The projected union aroused great opposition at first. Ex-King Milan resigned his post; so did the government; and King Alexander had great difficulty in forming a new cabinet. But the opposition subsided somewhat, as the publication of Tsar Nicholas's congratulations to the king on his engagement and of his acceptance to act as the principal witness at the wedding. The marriage was then duly celebrated on the 5th of August 1900. Still this union was unpopular and weakened the position of King Alexander in the army and the country. He tried to reconcile political parties by granting from his own initiative a liberal constitution (April 6, 1901), introducing for the first time in the constitutional history of Servia the system of two chambers (skupština and senate). This did in a certain measure reconcile the political parties, but did not reconcile the army, which, already dissatisfied with the king's marriage, became still more so at the rumours that one of the two unpopular brothers of Queen Draga, Lieutenant Nicodiye, was to be proclaimed heir-apparent to the throne. Meanwhile the independence of the senate and of the council of state caused growing irritation to King Alexander, which led him to another coup d'état. He suspended (March 1903) the constitution for half an hour, time enough to publish the decrees by which the old senators and councillors of state were dismissed and replaced by new ones. This arbitrary act naturally increased the dissatisfaction in the country. The general impression was that inasmuch as the senate was packed with men devoted to the royal couple, and inasmuch as the government obtained a large majority at the general elections, King Alexander would not hesitate any longer to proclaim Queen Draga's brother as the heir to the throne. Apparently to prevent this, but in reality to replace Alexander Obrenovich by Peter Karageorgevich, a military conspiracy was organized. The conspirators penetrated into the palace and savagely murdered King Alexander and Queen Draga in the early morning of the 11th of June 1903.

ALEXANDER, son of Nummius, Greek rhetorician, flourished in the first half of the second century A.D. In addition to general treatises on rhetoric, he wrote a special work Ἑκατεοῦν τῶν τῆς διανοιῶν καὶ τῆς λέξεως σχήματων, of which only an abridgment is extant; later epitomes were made in Latin by Aquila Romanus and Julius Rufinius under the title De Figuris Sententiarum et Eloquiorum. Another epitome was made in the fourth century by a Christian for use in Christian schools, containing additional examples from Gregory of Nazianzus.

Text in Spengel, Rhetor Graeca (1773).

ARCHIBALD (1772–1851), American Presbyterian divine, was born, of Scottish-Irish descent, in that part of Augusta county which is now Rockbridge county, Virginia, on the 17th of April 1772. After completing his preliminary education in the little school at Lexington, Virginia, which later developed into Washington and Lee University, he came under the influence of the religious movement known as the "great revival" (1789-1799) and devoted himself to the study of theology. Licensed to preach in 1791, he was engaged for several years as an itinerant Presbyterian preacher in his native state, and acquired during this period the facility in extemporaneous speaking for which he was remarkable. He was president of Hampden-Sidney College from 1796 to 1807, with a short intermission (1801-1802), and in 1807 became pastor of Pine Street Church, Philadelphia. In 1812 he became first professor in the newly established Presbyterian Theological Seminary at Princeton, New Jersey, where he remained until his death at Princeton on the 22nd of October 1851, filling successively the chairs of didactic and polemic theology (1812–1840), and pastoral and polemic theology (1840–1851). He married, in 1802, Janetta Waddel, the daughter of the celebrated blind preacher, James Waddel (1730–1821), whose eloquent services in William Wirt's Letters of a British Spy (1803). Dr. Archibald wrote a considerable number of theological works, which had a large circulation. Among these may be mentioned his Brief Outline of the Evidences of the Christian Religion (1835), which passed through several editions, and was translated into various languages; The Canon of the Old and New Testament Asserted; or the Bible Complete without the Apocrypha and Unrevised Traditions (1830); A History of the Israelitish Nation (1852), and Outlines of Moral Science (1852), the last two being published posthumously.

See the biography (New York, 1854) by his son James A. Alexander.

ALEXANDER, Francis (1800–1881), American portrait-painter, was born in Windham county, Connecticut, in February 1800. Brought up on a farm, he taught himself the use of colours, and in 1820 went to New York City and studied painting with Alexander Robertson. He spent the winters of 1831 and 1832 in Rome, and then for nearly a decade he lived in Boston, Massachusetts, where he had considerable vogue, and where in 1834 he painted a portrait of Charles Dickens. One of his first portraits is that of Mrs Fletcher Webster in the Boston Museum of Fine Arts. He died in 1881 in Florence.

ALEXANDER, George (1858–1936), English actor, whose family name was Samson, was born in Reading on the 10th of June 1858, the son of a Scottish manufacturer. He went into business in London after leaving school, but having acted as an amateur he determined to make the stage his profession. His first appearance was at Nottingham in 1879, and after some seasons of provincial experience he made his first London appearance as Caliban in De Deei's Two Jews in 1881, transferring into the Lyceum. He was selected by W. S. Gilbert to continue Mary Anderson in Comedy and Tragedy, returned for a time to the Lyceum, where he was Irving's principal associate, especially as Faust (1886) and Macbeth (1888); and, after starting successfully under his own management at the Avenue Theatre in 1890 with Dr Bll, in 1891 became manager of the St James's Theatre. There he produced a number of successful plays, notably Oscar Wilde's Lady Windermere's Fan and The Importance of Being Earnest, Pinero's Second Mrs Tanqueray, The Princess and the Butterfly, His House in Order and The Thunderbolt; C. Haddon Chamberlain's The Idler; H. A. Jones's Masqueraders; Alfred Sutor's John Clayle's Honour and The Builder of Bridges; Carton's Liberty Hall and The Tree of Knowledge; Anthony Hope's Prisoner of Zenda and Rupert of Hentzau; and Stephen Phillips's Poalo and Francesca, himself playing the leading parts with great distinction. In 1900 he was elected a member of the London County Council as a municipal reformer, but continued to act regularly at the St James's.

ALEXANDER, Sir James Edward (1803–1885), British soldier and traveller, was born on the 16th of October 1803, at the Elysian Fields, to the British army in 1825. As aide-de-camp to the British envoy to Persia, he was an eye-witness of the fighting in the war between Persia and Russia (1826), and in 1829 was present in the Balkans during the Russo-Turkish war. In 1832–1834 he was in Portugal during the Miguelete war, and in 1835 served in the Kaffir war in South Africa as aide-de-camp to Sir Benjamin D'Urban. Subsequently he conducted an exploring expedition into Namaqualand and Damaraland, and was knighted for his services (1838). From 1841 to 1855 he served in Canada, proceeding thence to the Crimea, and in 1862 held an important command in New Zealand during the Maori war. He retired from the service in 1877, and in 1881 was given the honorary rank of general. He was largely responsible for the preservation and transfer to England of Cleopatra's Needle in 1877. His varied experiences provided material for a large number of books, among which were Travels from India to England (1837); Transatlantic Sketches (1833); An Expedition of Discovery into the Interior of Africa (1838); Passages in the Life of a Soldier (1857); Incidents of the Maori War (1865). He was also the author of a Life of Field-Marshal the Duke of Wellington (1840). He died on the 11th of April 1885, and was buried in Westminster Abbey.

ALEXANDER, John White (1856–1896), American painter, was born in Allegheny, Pennsylvania, on the 7th of October
ALEXANDER—ALEXANDER BALAS

1856. He was left an orphan when very young, became an illustrator for *Harper’s Magazine*, studied in Europe, became a pupil of the Royal Academy at Munich, and also worked in Venice, in Holland and in Paris, where he attracted much attention by his exhibition at the Salon of two female portraits entitled “Gris” and “Noir.” He became a member of the Société Nationale des Beaux Arts (Paris), of the National Academy of Design (New York), of the International Society (London), and of the Vienna and Munich Societies of Painters. In 1901 he was made a Chevalier of the Legion of Honour. He executed decorative panels for the Congressional Library, Washington, D.C., and a large decoration for the Carnegie Institute, Pittsburgh, Pennsylvania; and his works include numerous paintings, portraits, etchings, etc.

ALEXANDER, JOSEPH ADDISON (1809–1860), American biblical scholar, the third son of Archibald Alexander, was born in Philadelphia, Pennsylvania, on the 24th of April 1809. He graduated at the College of New Jersey (now Princeton University) in 1826, having devoted himself especially to the study of Hebrew and other oriental languages, and from 1830 to 1833 was adjunct professor of ancient languages and literature there. In 1834 he became an assistant to Dr Charles Hodge, professor of oriental and biblical literature in the Princeton Theological Seminary, and in 1838 became associate professor of oriental and biblical literature there, succeeding Dr Hodge in that chair in 1840 and being transferred in 1851 to the chair of biblical and ecclesiastical history, and in 1859 to that of Hellenistic and New Testament literature, which he occupied until his death at Princeton on the 28th of January 1860. Alexander was a remarkable linguist and exegete. He had been ordained as a Presbyterian minister in 1839, and was well known for his pulpit eloquence. He was the author of *The Earlier Prophecies of Isaiah* (1846), *The Later Prophecies of Isaiah* (1847), and an abbreviation of these two volumes, *Isaiah Illuminated and Explained* (3 vols., 1850), commentaries on *Acts* (2 vols., 1857), *Mark* (1858) and *Matthew* (1860), and two volumes of *Sermons* (1860). See *The Life of Joseph A. Alexander* (2 vols., 2nd ed., New York, 1875) by his nephew, Henry C. Alexander.

His brother, JAMES WADDELL ALEXANDER (1804–1859), born in Louisa county, Virginia, on the 13th of March 1804, was a famous Presbyterian preacher. He graduated at the College of New Jersey in 1820, studied theology in the Princeton Seminary, and was pastor of a Presbyterian church in Charlotte county, Virginia. He was transferred to the First Presbyterian church in Trenton, New Jersey, in 1830–1832. From 1833 to 1844 he was professor of belles-lettres and Latin language and literature in the College of New Jersey, from 1844 to 1849 was pastor of the Duane Street Presbyterian church in New York City, from 1849 to 1851 was professor of ecclesiastical history, church government and sacred rhetoric in the Princeton Theological Seminary, and from 1851 until his death, at Red Sweet Springs, Virginia, on the 31st of July 1859, was pastor of the Fifth Avenue Presbyterian church in New York City. He wrote numerous magazine articles and published a number of books, including *The American Mechanic and Workingman* (2 vols., 1847), a collection of papers on mechanics first printed under the pseudonym of “Charles Quill”), *Thoughts on Family Worship* (1847), *Sacramental Addresses* (1848), *The Revival and its Lessons* (1850), *Thoughts on Preaching* (1867), *Faith* (1862), and many juvenile books for Sunday-school libraries.

See Forty Years’ Familiar Letters of James W. Alexander (2 vols., New York, 1860), edited by Dr John Hall (1806–1894) of Trenton, N. J.

ALEXANDER, WILLIAM (1824— ), Protestant archbishop of Armagh and primate of all Ireland, was born at Londonderry on the 13th of April 1824 and educated at Tonbridge Grammar School and Brasenose College, Oxford. After holding several livings in the north of Ireland he was made bishop of Derry and Raphoe in 1867, and was elevated to the primacy in 1896. He was Bampton lecturer in 1876. An eloquent preacher and the author of numerous theological works, he is best known to literature as a master of dignified and animated verse. His poems were collected in 1857 under the title of *St Augustine’s Holiday, and other Poems*. His wife, Cecilia Francis Humphreys (1818–1895), wrote some tracts in connexion with the Oxford movement, but is famous as the author of “Jesus calls us o’er the tumult,” “There is a green hill far away” and other well-known hymns (nearly four hundred in all). A collection of her verse was published in 1896.

ALEXANDER, WILLIAM LINDSAY (1808–1884), Scottish divine, was born at Leith on the 24th of August 1808. He was educated at the universities of St Andrews and Edinburgh, where he gained a lasting reputation for classical scholarship. He entered Glasgow Theological Academy under Ralph Wardlaw in September 1837, but in December of the same year he left to become classical tutor at the Blackburn Theological Academy (afterwards the Lancashire Independent College). At Blackburn he stayed till 1834, lecturing on biblical literature, metaphysics, Greek and Latin. After short visits to Germany and London he was invited in November 1834 to become minister of North College Street church (afterwards Argyle Square), Edinburgh, an independent church which had arisen out of the evangelical movement associated with the Haldanes. He deliberately put aside the ambition to become a pulpit orator in favour of the practice of biblical exposition, which he invested with a singular charm and impressiveness. In 1836 he became one of the editors of the *Congregational Magazine*, to which he contributed articles on biblical literature and theology and on the “voluntary” controversy. In 1840 he delivered the Congregational Lecture in London on the “Connexion and Harmony of the Old and New Testaments.”

Alexander took an active part in the “voluntary” controversy which ended in the Disruption, but he also maintained broad and liberal views of the personal relations between different bodies of the Christian church. In 1845 he visited Switzerland with the special object of inquiring into the religious life of the churches there. He published an account of his journey in a book, *Switzerland and the Swiss Churches*, which led to an interchange of correspondence between the Swiss and Scottish churches. In 1845 he received the degree of D.D. from the university of St Andrews. In 1861 he undertook the editorship of the third edition of Kitto’s *Biblical Encyclopaedia* with the understanding that the whole work should be thoroughly revised and brought up to date. In January 1870 he became one of the committee of Old Testament revisers, and by his thorough biblical scholarship rendered exceptional service to the board; he enjoyed the work and devoted much time to it for the next fourteen years. In 1877 he became principal of the Edinburgh Theological Hall, a position which he held, in spite of many tempting offers of preferment elsewhere, until his death on the 20th of December 1884.

See his *Life and Work* by James Ross (1887).

ALEXANDER AETOLUS, of Pleuron in Aetolia, Greek poet and man of letters, the only representative of Aetolian poetry, cultivated about 280 B.C. When living in Alexandria he was commissioned by Ptolemy Philadephos to arrange the tragedies and satyric dramas in the library; some ten years later he took up his residence at the court of Antigonus Gonatas, king of Macedonia. His reputation as a tragic poet was so high that he was allotted a place in the Alexandrian tragic Pleiad; we only know the title of one play (Astragalistae). He also wrote short epics, epigrams and elegies, the considerable fragments of which show learning and eloquence.

Meineke, *Athenaeum Alexandrinum* (1854); Bergk, *Poetae Lyrici Graeci* (St. Louis, 1852).
king Demetrius Soter in 150 B.C. Being now undisputed master of Syria, he abandoned himself to a life of debauchery. Demetrius Soter's son profited by the opportunity to regain the throne. Ptolemy Philometor, who was Alexander's father-in-law, went over to his side, and Alexander was defeated in a pitched battle near Antioch in Syria. He fled for refuge to a Nabataean prince, who murdered him and sent his head to Ptolemy, who had been mortally wounded in the engagement.

**ALEXANDER CORNELIUS**, Greek grammarian, surnamed Polonius, was the descendant of an old Athenian family (Muller, surnamed Apelt, d'Aphr. Gk. Gk.). He was educated at Athens to the art of rhetoric, and was afterwards appointed the tutor of the son of the great Socrates. After the death of Socrates, he continued his education at Pergamum, and was at last called to Rome, where he obtained the favor of the emperor Augustus, to whom he was recommended by Cicero. He was much admired by the emperor, and was made the tutor of his son, who, on his death, succeeded to the throne. He continued in this station till the death of Augustus, and then retired to Athens, where he lived in retirement till his death. He was the author of several works, the most famous of which is his History of Greece, which was translated into Latin by Polybius.

**ALEXANDER JANNAEUS**, king of the Jews, succeeded his brother Aristobulus in 103 B.C. and died in 76 B.C. His first act was the murder of one of his brothers who claimed the throne, and his reign was disgraced by the cruelties that he perpetrated in order to retain his position. (See Jews and Pharisees.)

**ALEXANDER NEVSKY, SAINT** (1220–1263), grand-duc of Vladimir, was the second son of the grand-duc of Yaroslav. His childhood and youth were spent at Great Novgorod, whither his father sent him to rule (1228) with some guardian boyars. In 1230 he married Alexandra, daughter of Prince Bryachislav of Polotsk. At an early age he distinguished himself in constant warfare with the Germans, Swedes and Lithuanians, who tried to wrest Novgorod and Pskov from Russia while she was still suffering from the effects of the terrible Tatar invasion. The most notable of these battles, whereby he won his honorific epithet of Nevsky (i.e. of the Neva), was fought on the banks of the Neva (July 15, 1240), against the famous Swedish statesman, Birger Jarl, whom he utterly defeated, besides wounding him with his lance. In the following years, Alexander, in common with the Order of the Sword, succeeded in captivating Pskov; but Alexander recovered it in 1242, advanced into Livonia, and on the 5th of April killed the knights on the ice of Lake Peipus and compelled them in the ensuing peace to renounce all their conquests. He also prevented the Swedes (in 1250) from settling in South Finland. On the death of his father (1246) Alexander and his younger brother Andrew went on a two years' journey into Mongolia to obtain their earls, or letters of investiture, from the Grand Khan, who, on his death, disposed of the fate of all the Russian princes. He returned (1250) as grand-duc of Kiev and Novgorod, while to Andrew was given the far more important grand-duchy of Vladimir. In 1252, however, the Tatars themselves expelled Andrew and placed Alexander on the throne of Vladimir. Alexander henceforth did his best for his country by humbling himself before the Tatars so as to give them no pretext for ravaging the land again. Most of his spare money he devoted to the ransom of the numerous Russian captives detained at the Golden Horde. But the men of Novgorod, in their semi-independent republic, continued (1255–1257) to give the grand-duke trouble, their chief grievance being the imposition of a Tatar tribute, which they only submitted to in 1259 on the rumour of an impending Tatar invasion. In 1262 the Tatar tribute was felt so grievously all over Russia that preparations were made for a general insurrection, and Alexander, who knew that an abortive rebellion would make the yoke heavier, was obliged to go to the Horde in person to prevent the Tatars from again attacking Russia. He stayed at Sarai, their Volgan capital, all the winter, and not only succeeded in obtaining a mitigation of the tribute, but also the abolition of the military service previously rendered by the Russians to the Tatars. This was his last service to his country. He died on his way home from the Horde, and in the words of his contemporary, the metropolitan Cyril, "with him the sun of Russia set." The Orthodox Church has canonized the ruler who gave his whole life for Russia and the Orthodox faith. His relics, discovered in 1380, were in 1724 translated by Peter the Great from Vladimir to St. Petersburg.

See Sergei Mikhailovich Solovev, History of Russia (Russ. 2nd ed., St. Petersburg, 1897, vol. 3).

(R. N. B.)

**ALEXANDER OF APHRODISIAS**, pupil of Aristocles of Messene, the most celebrated of the Greek commentators on the writings of Aristotle, and styled, by way of pre-emience, *Alexanderus Philosophus* ("the Philosopher") was a great scholar and orator in Caria. He came to Athens towards the end of the 2nd century A.D., became head of the Lyceum and lectured on peripatetic philosophy. The object of his work was to free the doctrine from the syncretism of Ammonius and to reproduce the pure doctrine of Aristotle. Commentaries by Alexander on the following works of Aristotle are still extant:—the *Analytica Priora*, i; the *Topica*; the *Meteorologiae*; the *De Sensu*; and the *Metaphysica*, i-iv., together with an abridgment of what he wrote on the remaining books of the *Metaphysica*. His commentaries were greater or less esteemed among the Arabs, who translated many of them. There are also several original writings by Alexander still extant.

The most important of these are a work *On Fate*, in which he argues against the Stoic doctrine of necessity; and one *On the Soul*, in which he contends that the undeveloped reason in man is material (νοετός ἄνθρωπός) and inseparable from the body. He argued strongly against the doctrine of immortality. He identified the active intellect (νοετός τοιχίκος), through whose agency the potential intellect in man becomes actual, with God. Several of Alexander's works were published in the Aldine edition of Aristotle, Venice, 1495-1498; his *De Fato* and *De Anima* were printed along with the works of Themistius at Venice (1534); the former work, which has been translated into Latin by Grotius and also by Schultheiss, was edited by J.C. Orelli, Zürich, 1824; and his commentaries on the *Metaphysica* by H. Bonitz, Berlin, 1847. J. Nourisson has treated of Alexander's doctrine of fate (*De la liberté et du hasard*, Paris, 1870). In the early Renaissance his doctrine of the soul's mortality was adopted by P. Pomponazzi against the Thomists and the Averroists.

**ALEXANDER OF HALES** (ALEXANDER HALENSIS), surnamed Doctor IREFFRAGABILIS, *Theologorum Monarcha* and *Fons Vitae*, a celebrated English theologian of the 13th century, was born in Gloucestershire. Trained in the monastery of Hales he was early raised to an archdeaconry. He went, like most of the scholars of his day, to study at Paris, where he took the degree of doctor and became celebrated as a teacher. He is generally held that he taught Bonaventura, Duns Scotus and Thomas Aquinas, but a comparison of dates makes it clear that the two latter could not have been his pupils and that the statement about Bonaventura is open to doubt. In 1222 (or 1221, see Denifle, *Chartul. Univers. Paris*, Paris, 1889, i. 135) Alexander entered the order of Minorite Friars and thenceforward lived in strict seclusion. He refused, however, to renounce his degree of doctor, and was first of his order who continued to bear that title after initiation. He died in 1245 and was buried in the convent of the Cordeliers at Paris. His most celebrated work was the *Summa Theologica* (Nuremberg, 1494; Paris, 1502, 1517; Cagnan, 1761), undertaken by the orders of Pope Innocent IV. and approved by Alexander IV., on the report of seventy learned theologians, as a system of instruction for all the schools in Christendom. The form is that of question and answer, and the method is rigidly scholastic. Of small intrinsic value, it is interesting partly as the first philosophical contribution of the Franciscans who were afterwards to take a prominent part in medieval thought (see *Scholasticism*), and partly as the first work based on a knowledge of the whole Aristotelian *corpus* and the Arabian commentators.

See Wadding, *Script. ord. minor.* (Rome, 1560); for his method
ALEXANDER OF TRALLES—ALEXANDERSBAD

ALEXANDER THE PAPHLAGONIAN, a celebrated impostor and worker of false oracles, was born at Abonouteichos (see INSEBOLI) in Paphlagonia in the early part of the 2nd century A.D. The vivid narrative of his career given by Lucian might be taken as fictitious but for the corroboration of certain coins of the emperors Lucius Verus and Marcus Aurelius (J. H. Eckhel, Doctrina Numismatica sive Pratica Historiae Nummorum) in the Library of a statue of Alexander, said by Athenagoras (Apologet. c. 26) to have stood in the forum of Parium. After a period of instruction in medicine by a doctor who also, according to Lucian, was an impostor, he succeeded in establishing an oracle of Aesculapius at his native town. Having circulated a prophecy that the son of Apollo was to be born again, he contrived that there should be found in the foundations of the temple of Aesculapius, then in course of construction at Abonouteichos, an egg in which a small live snake had been placed. In an age of superstition no people so great a reputation for oracle as the Paphlagonians, and Alexander had little difficulty in convincing them of the second coming of the god under the name of Glycon. A large tame snake with a false human head, wound round Alexander’s body as he sat in a shrine in the temple, gave “autophones” or oracles unasked, but the usual methods practised were those of the numerous oracle-mongers of the time, of which Lucian gives a detailed account, the opening of sealed inquiries by heated needles, a neat plan of forging broken seals, and the giving of vague or meaningless replies to difficult questions, coupled with a lucrative blackmailing of those whose inquiries were unprofitable. The reputation of the oracle, which was in origin medical, spread, and with it grew Alexander’s skilled plans of organized deception. He set up an “intelligence bureau” in Rome, instituted mysteries like those of Eleusis, from which his particular enemies the Christians and Epicureans were alike excluded as “profane,” and celebrated a mystic marriage, between himself and the moon. During the plague of A.D. 166 a verse from the oracle was used as an amulet and was inscribed over the doors of houses as a protection, and an oracle was sent, at Marcus Aurelius’ request, by Alexander to the Roman army on the Danube during the war with the Marcomanni, declaring that victory would follow on the throwing of two lions alive into the river. The result was a great disaster, and Alexander had recourse to the old quibble of the Delphic oracle to Croesus for an explanation. Lucian’s own close investigations into Alexander’s methods of fraud led to a serious attempt on his life. The whole account gives a graphic description of the inner working of one among the many new oracles that were springing up at this period. Alexander had remarkable beauty and the striking personality of the successful charlatan, and his schemes were so clearly conceived that he was able to overcome all obstacles and get his organization. His income is said by Lucian to have reached an enormous figure. He died of gangrene of the leg in his seventeenth year.

See Lucian, Αλεξάνδρου τῆς Παφλαγονίας; Samuel Dill, Roman Society from Nero to Marcus Aurelius (1904); and F. Gregorovius, The Emperor Hadrian, trans. by M. E. Robinson (1898).

ALEXANDERS (botanical name, Smyrnium olsatrum, natural order Umbelliferae), a stout herbaceous plant with a flowered, much-branched stem 1-5 ft. high, and large compound leaves with broad shining stalks, and broad, flat, strap-like leaflets. The small yellow flowers are borne in compound umbels. The plant is a native of the Mediterranean region, and was formerly cultivated as a pot-herb. It is now found apparently wild in Great Britain and Ireland, growing in waste places, especially near the sea and amongst ruins. In England the plant is sometimes popularly termed "Alexander"; in North America Thaspium aureum is sometimes called "Alexanders." "Alexander’s foot," botanical name Anacyclus Pyrethrum, is the pellitory of Spain.

ALEXANDERSBAD, a watering-place of Germany, in the kingdom of Bavaria, romantically situated on the Fichtelgebirge, 3020 ft. above the sea. Its waters, which are ferruginous and largely charged with carbonic acid gas, are of use in nervous and rheumatic conditions.

See E. Milward, Traillianus Reviuscens (London, 1734).

ALEXANDER SEVERUS (Marcus Aurelius Severus Alexander) (208-235), Roman emperor from A.D. 222 to 235, was born at Arca Caesarea in Palestine on the 1st of October 208. His father, Gessius Marcellus, held office more than once as an imperial procurator; his mother, Julia Mamaea, was the daughter of Julia Maesa and the aunt of Helogabalus. His original name was Bassianus, but he changed it in 221 when his grandmother, Maesa, persuaded the emperor Helogabalus to adopt his cousin as successor and create him Caesar. In the next year, on the 11th of March, Helogabalus was murdered, and Alexander was proclaimed emperor by the Praetorians and accepted by the senate. He was then a mere lad, amiable, well-meaning, but entirely under the dominion of his mother, a woman of many virtues, who surrounded him with wise counsellors, watched over the development of his character and improved the tone of the administration, but on the other hand was inordinately jealous, and, combining force with parsimony, while neither she nor her son had a strong enough hand to keep tight the reins of military discipline. Mutinies became frequent in all parts of the empire; to one of them the life of the jurist and praetorian prefect Ulpius was sacrificed; another compelled the retirement of Dio Cassius from his command. On the whole, however, the reign of Alexander was prosperous till he was summoned to the East to face the new power of the Sassanians (see Persia: History). Of the war that followed we have various accounts; Mompson lends to that which is least favourable to the Romans. According to Alexander’s own despatch to the senate he gained great victories. At all events, though the Persians were checked for the time, the conduct of the Roman army showed an extraordinary lack of discipline. The emperor returned to Rome and celebrated a triumph (233), but next year he was called to face German invaders in Gaul, where he was slain (on the 18th or 19th of March 235), together with his mother, in a mutiny which was probably led by Maximinus, a Thracian legionary, and at any rate secured him the throne. Alexander was the last of the great line of emperors. After his death, and as long as his name and example were remembered, the influence of his mother, he did much to improve the morals and condition of the people. His advisers were men like the famous jurist Ulpian, the historian Dio Cassius and a select board of sixteen senators; a municipal council of fourteen assisted the city prefect in administering the affairs of the fourteen districts of Rome. The luxury and extravagance that had formerly been so prevalent at the court were put down; the standard of the coinage was raised; taxes were lightened; literature, art and science were encouraged; the loan offices that served the people, loan offices were instituted for lending money at a moderate rate of interest. In religious matters Alexander preserved an open mind. In his private chapel he had busts of Orpheus, Abraham, Apollonius of Tyana and Jesus Christ. It is said that he was desirous of erecting a temple to the founder of Christianity, but was dissuaded by the pagan priests. There is no doubt that, had Alexander’s many excellent qualities been supported by the energy and strength of will necessary for the government of a military empire, he would have been one of the greatest of the Roman emperors.

See Lampridius, Alexander Severus; Dio Cassius xxviii. 30, lxviii. 17, lxxv. 1; Herodian vi. 1-18; Porrath, Der Kaiser ALEX. Sever. (1876); Pauly-Wissowa, Realencyclopädie, ii. 2526 foll. (Groebe); monograph by R. V. Nind Hopkins, Cambridge Historical Essays, No. xiv. (1907).
disorders. In the neighbourhood is the Lusenburg (or Lux-
burg), so called after a visit paid by Queen Louise of Prussia in
1805, a hill covered by majestic granite rocks, commanding a
grand view of the whole range of the Fichtelgebirge.

ALEXANDRE, NOËL (NAUTALI ALEXANDER) (1639-1724),
French theologian and ecclesiastical historian, was born at
Rouen on the 10th of January 1639. In his 15th year he joined
the Dominicans, and shortly after his ordination was ap-
pointed professor of philosophy at the convent of Saint-Jacques in
Paris. The success of his subsequent lectures at the Sorbonne
led to his selection by Colbert as tutor to his son, Jacques Nicolas
Colbert, afterwards archbishop of Nantes. Alexandre's election to
the degree of doctor in divinity from the Sorbonne in 1675 and
for twelve years taught philosophy, theology and ecclesiastical
law to the members of the Saint-Jacques community. He
played a prominent part in ecclesiastical affairs and preached
several times before Louis XIV., who granted him an annual
pension of 800 livres, and in the general assemblies of the French
bishops. He became provincial of his order in 1706, but was
banished to Châteleraut in 1709 for having subscribed to the
Cas de conscience (1703), and was deprived of his pension in
1713 for expressing his opposition to the ecclesiastical
primacy. He died in Paris on the 21st of August 1724, having lost his sight
some time before owing to his strenuous literary activity. His
numerous works are still much valued by ecclesiastical students.
His best-known work, the Selecta historiae ecclesiasticae capita,
et in loca ejusdem insignia dissertationes historicae, chronologicae,
dogmaticae (26 vols., Paris, 1676-1680), was placed on the Index
by Innocent XI., on account of his bold defence of the Gallican
claims. In 1689 he brought out at Paris his history of the Old
Testament: Selecta historiae Veteris Testamenti capita, &c., in
6 vols. Of the numerous editions of Alexandre's ecclesiastical
history the best is that of P. J. D. Mansi, which contains many
valuable notices and additions (11 vols., Lucca, 1749) and has
been frequently reprinted. Alexandre's principal contribution
to theological literature is his Theologia dogmatica et moralis
secundum ordinem catechismi concilii Tridentini (10 vols., Paris,
1694), in which he clearly shows himself a disciple of the Thomist
school.

See Catalogue complet des ouvrages du Père Alexandre (Paris, 1716);
Quétif-Echard, Scripores ordinis praedescalorum (Paris, 1719-1721),
t. ii, p. 810; and full bibliography in A. Vacant, Dic. de théologie
(scholarly article by F. Mandonnet, cols. 769-772).

ALEXANDRETTA, or ISKANDERUN (medISKANDERUAN), a town
of N. Syria, situated in the N.E. angle of the Levantine
Mediterranean on the S.E. of the gulf to which it gives a title.
About 10,000, two-thirds Moslem. Iskanderun preserves
the name, but probably not the exact site, of Alexandria ad
Ixxum, founded by Alexander in 332 B.C., about 23 m. S. of the
scene of his victory, to supersede Myriandrus as key of the
Syrian Gates (Bellan Pass). The importance of the place ever
since has been derived from its relation to this pass, the easiest
approach to the open ground of N. Syria of which Antioch and
Aleppe have been the successive capitals; and this relation
has prevailed over the extreme unhealthiness of the site, which
lies on marshy deltaic ground, screened by the horseshoe of
Elma Dagh from all purifying influences of N. and E. winds.
As the main outlet for the overland trade from Bagdad and India,
whose importance was great until the establishment of the
Egyptian overland route, the place was a great resort, first of
Genoese and Venetian merchants, then of those of West and
North European nations. The British Levant (Turkey) Company
maintained an agency and factory here for 200 years, till 1825,
in spite of appalling mortality among its employés. Alexander-
dretta is still the main port for the Aleppo district, to which a
good chaussee leads over the Bellan Pass, and it has a considerable
export trade in tobacco, silk, cereals, liquors, textiles. The
health of the place has improved with the draining of the marshes
and the provision of a better supply of water, but still leaves
much to be desired. The wealthier inhabitants have summer
residences at Bellan near the summit of the pass, long a strong-
hold of freebooting Dere Beye and the scene of the victory
won by Ibrahim Pasha in 1832, which opened Cilicia to his
advance. There are resident consuls of all the principal powers,
and the port is well served by coasting steamers under European
and Ottoman flags. The distance by road to Aleppo has been
shortened to about 70 m., and Antakia (Antioch) is about 45 m.
distant by a branch of the same chaussee.

(D. G. H.)

ALEXANDRIA (Arab. Asskendaria), a city and chief seaport
of Egypt, and for a thousand years from the foundation
of the city on the site of the island of Pharos in the
Mediterranean or Pillar of Heracle (Antioch) in 30
12° N., 30° 15' E., and 129 m. by rail N.W. of Cairo. The
ancient Canopic mouth of the Nile (now dry) was 12
E.

I. The Modern City.—The city is built on the strip of land
which separates the Mediterranean from Lake Mareotis (Marriot),
and on a T-shaped peninsula which forms harbours east and
west. The stem of the T was originally a mole leading to an
island (Pharos) which formed the cross-piece. In the course
of centuries this mole has been silted up and is now an isthmus
half a mile wide. One part of the modern city is built.
The cape at the northern end of the peninsula is Ras el-Tin (Cape
of Figi); the eastern cape is known as Pharois or Kait Bay.
South of the town—between it and Lake Mareotis—runs the
Mahmudiya canal, which enters the western harbour by a series of locks.

The customs house and chief warehouses are by the western
harbour, but the principal buildings of the city are in the east
and south-east quarters. From the landing-stage, by the
customs house, roads lead to the Place Mehmet Ali, the centre
of the life of the city and the starting-point of the electric tram-
ways. The place, usually called the Grand Square, is an oblong
open space, tree-lined, in the centre of which there is an equestrian
statue of the prince after whom it is named. The square is faced
with handsome buildings mainly in the Italian style. The most
important are the law courts, exchange, Ottoman bank,
English church and the Abbas Hilmi theatre. A number of
short streets lead from the square to the eastern harbour. Here
a sea wall, completed in 1905, provides a magnificent drive and
promenade along the shore for a distance of about 3 m.

In building this quay a considerable area of foreshore was
claimed and an evil-smelling beach done away with. From the
south-western corner of the rue Sherif Pasha—in which
are the principal shops—and the rue Tewfik Pasha lead to the
boulevard, or rue, de Rosette, a long straight road with a general E. and
W. direction. In it are the Zizinia theatre and the municipal
palace (containing the public library); the museum lies up a
short street to the N. Opened in 1895 this museum possesses
an important collection of Egyptian, Greek and Roman anti-
quities, found not only in the city but in all Lower Egypt and
the Fayum. The western end of the boulevard leads to the Place
Ibrahim, often called Place Ste Catherine, from the Roman
Catholic church at its S.E. side. In a street running S. from the
boulevard to the railway station is the mosque of Nebi Daniel,
containing the tombs of Said Pasha and other members of the
khedivial family. Immediately E. of the mosque is Kom ed-
Dik, garrisoned by British troops, one of several forts built for
the protection of the city. Except Kom ed-Dik the forts have
not been repaired since the bombardment of 1882. Equally
obsolete is the old line of fortifications which formerly marked
the limits of the city south and east and has now been partly
demolished. Throughout the central part of Alexandria the
streets are paved with blocks of lava and lighted by electricity.

The north quarter is mainly occupied by natives and Levans.
The narrow winding streets and the Arab bazaars present
an Oriental scene contrasting with the European aspect of the
district already described. This Arab quarter is traversed by
the rue Ras el-Tin, leading to the promontory of that name.
Here, overlooking the harbour, is the khedivial yacht club
(built 1903) and the palace, also called Ras el-Tin, built by
Mehemet Ali, a large but not otherwise noteworthy building.
In the district between the Grand Square and the western
harbour, one of the poorest quarters of the city, is an open space
with Fort Caffarelli or Napoleon in the centre. This quarter has been pierced by several straight roads, one of which, crossing the Mahmudiya canal by the Pont Neuf, leads to Gabbari, the most westerly part of the city and an industrial and manufacturing region, possessing asphalt works and oil, rice and paper mills. The northeastern (the fish and water area) is furnished wholesale dealers in cotton, wool, sugar, grain and other commodities.

In the southern part of the city are the Arab cemetery, "Pompey's Pillar" and the catacombs. "Pompey's Pillar," which stands on the highest spot in Alexandria, is nearly 90 ft. high, including the pedestal. The shaft is of red granite and is beautifully polished. Nine feet in diameter at the base, it tapers to eight feet at the top. The catacombs, a short distance S.W. of the pillar, are hewn out of the rocky slope of a hill, and are an elaborate series of chambers adorned with pillars, statues, religious symbols and traces of painting (see below, Ancient City). Along the northern side of the Mahmudiya canal, which here passes a little S. of the catacombs, are many fine houses and gardens (Moharrem Bey quarter), stretching eastward for a considerable distance, favourite residences of wealthy citizens.

A similar residential quarter has also grown up on the N.E., where the line of the old fortifications has become a boulevard. The district extending outside the E. fortifications, in the direction of Hadra, has been laid out with fine avenues, and contains numerous garden-cafés and pleasure resorts. Thence roads lead to the E. suburb known generally as Ramleh, which stretches along the canal having a local railway. It begins E. of the racecourse with Sidi Gabr, and does not end till the khedivial estates E. of San Stefano are reached, some 5 m. E. All this space is filled with villas, gardens and hotels, and is a favourite summer resort not only of Alexandrians but also of Cairoenses.

The eastern bay is rocky, shallow and exposed, and is now used only by native craft. The harbour is on the W. of Pharos and partly formed by a breakwater (built 1871-1873 and prolonged 1906-1907), 2 m. long. The breakwater starts opposite the promontory of Ras et-Tin, on which is a lighthouse, 130 ft. above the sea, built by Mehmet Ali. Another breakwater starts from the Gabbari side, the opening between the two works being about half a mile. A number of scattered rocks lie across the entrance, but through them two fairways have been made, one 600 ft. wide and 35 ft. deep, the other 300 ft. wide and 30 ft. deep. The enclosed water is divided into an outer and inner harbour by a mole, 1000 yds. long, projecting N.W. from the southern shore. The inner harbour covers 464 acres. It is lined for 2½ m. by quays, affording accommodation for ships drawing up to 28 ft. The outer harbour (1400 acres water area) is a lighthouse, 130 ft. above the sea, subsidence, 1020 ft. long, and with quays and jetties along the Gabbari foreshore. Their construction was begun in 1906.

Alexandria is linked by a network of railway and telegraph lines to the other towns of Egypt, and there is a trunk telephone line to Cairo. The city secured in 1906 a new and adequate water-supply, modern drainage works having been completed the previous year. Being the great entrepôt for the trade of Egypt, the city is the headquarters of the British chamber of commerce and shipping, and the merchant and companies engaged in the development of the Suez Canal. About 97½% of the exports and imports of the country pass through the port, though the completion, in 1904, of a broad-gauge railway connecting Cairo and Port Said deflected some of the cotton exports to the Suez Canal route. The staple export is raw cotton, the value of which is about 80% of the exports. The principal imports are manufactured cotton goods and other textiles, machinery, timber and coal. The value of the trade of the port increased from £30,000,000 in 1900 to £46,000,000 in 1906. In the same period the tonnage of the ships entering the harbour rose from 2,375,000 to 3,605,000. Of the total trade Great Britain supplies from 30 to 40% of the imports and takes over 50% of the exports. Among the exports sent to England are the great majority of the 80,000,000 eggs annually shipped (see also Egypt: Commerce).

The population of the city (1907) was 332,246 or including the suburbs, about 400,000. The foreigners numbered over 90,000. The majority of these were Greeks, Italians, Syrians, Armenians and other Levantines, though almost every European and Oriental nation is represented. The predominant languages spoken, besides the Arabic of the natives, are Greek, French, English and Italian. The labouring population is mainly Egyptian; the Greeks and Levantines are usually shopkeepers or petty traders. In its social life Alexandria is the most progressive and occidental of all the cities of North Africa, with the possible exception of Algiers.

II. The Ancient City.—The Greek Alexandria was divided into three regions: (1) the Jews’ quarter, forming the north-east portion of the city; (2) Rhacotis, on the west, occupied chiefly by Egyptians; (3) Brucheum, the Royal or Greek quarter, formed by the most magnificent portion of the city. In Roman times Brucheum was enlarged by the addition of an official quarter, making up the number of four regions in all. The city was laid out as a gridiron of parallel streets, each of which had an attendant subterranean canal. Two main streets, lined with colonnades and said to have been each about 300 ft. wide, intersected in the centre of the city, close to the point where rose the Sema (or Soma) of Alexander (i.e. his Mausoleum). This point is very near the present mosque of Nebi Daniel; and the line of the great east-west "Canopic" street only slightly diverged from that of the modern Boulevard de Rosette. Traces of its pavement and canals have been found near the Rosetta, but better remains of streets and canals were exposed in 1859 by the German excavators outside the E. fortifications, which lie well within the area of the ancient city.

Alexandria consisted originally of little more than the island of Pharos, which was joined to the mainland by a mole nearly a mile long and called the Heptastadium. The end of this abutted on the land at the head of the present Grand Square, where rose the "Moon Gate." All that now lies between that point and the modern Ras-et-Tin quarter is built on the silt which gradually formed the oblong triangular portion of the city, which represents all that is left of the island of Pharos, the site of the actual lighthouse having been weathered away by the sea. On the east of the mole was the Great Harbour, now an open bay; on the west lay the port of Eunostos, with its inner basin Kibotos, now vastly enlarged to form the modern harbour.

In Strabo's time, (latter half of 1st century B.C.) the principal buildings were as follows, enumerated as they were to be seen from a ship entering the Great Harbour. (1) The Royal Palaces, filling the N.E. angle of the town and occupying the promontory of Lochias, which shut in the Great Harbour on the east. Lochias, the "Aphrodite;" the "Pharilion," and Kibotos, "Upper Pharos," on the west, together with the palaces, the "Private Port" and the island of Antihrussos. There has been a land subsidence here, as throughout the N. Delta and indeed all the N.E. coast of Africa; and on calm days the foundations of buildings may be seen, running out far under sea, near the Pharillon. Search was made for relics of these palaces by German explorers in 1898-1899, but without much success. (2) The Great Theatre, on the modern Hospital Hill near the Ramleh station. This was used by Caesar as a fortress, where he stood a siege from the city mob against the B.C. "Mosque of the Pharaohs," and was called the "Temple of the Sea God," close to the theatre and in front of it. (4) The Timonium built by Antony. (5, 6, 7) The Emporium (Exchange), Apostases (Magazines) and Navalia (Docks), lying west of (4), along the sea-front as far as the mole. Behind the Emporium rose (8) the Great Caesareum, by which stood the two great obelisks, later known as "Cleopatra’s Needles," and now removed to New York and London. This temple became in time the Patriarchal Church, some remains of which have been discovered: but the actual Caesareum, so far as not eroded by the waves, lies under the houses lining the new sea-wall. (9) The Gymnasium and (10) the Palaestra are both inland, near the great canal street (Boulevard de Rosette) in the eastern half of the town, but on sites not determined. (11) The Temple of Saturn: site unknown. (12) The Mausolea of Alexander (Soma) and the Ptolemies in one ring-fence, near the point of intersection of
the two main streets. (13) The Museum with its library and theatre in the same region; but on a site not identified. (14) The Serapeum, the most famous of all Alexandria temples. Strabo tells us that this stood in the west of the city; and recent discoveries go far to place it near "Pompey's Pillar" (see above), which, however, was an independent monument erected to commemorate Diocletian's siege of the city. We know the names of a few other public buildings on the mainland, but nothing as to their position. On the eastern point of the Pharos island stood the next Lighthouse of the Seven Wonders of the World; it was 400 ft. high. The first Ptolemy began it, and the second completed it, at a total cost of 800 talents. It is the prototype of all lighthouses (q.v.) in the world. A temple of Hephaestus also stood on Pharos at the head of the mole. In the Augustan age the population of Alexandria was estimated at 300,000 free folk, in addition to an immense number of slaves.

III. History.—Founded in 332 B.C. by Alexander the Great, Alexandria was intended to supersede Naucratis (q.v.) as a Greek centre in Egypt, and to be the link between Macedonia and the rich Nile Valley. If such a city as the Egyptian coast, there was only one possible site, behind the screen of the Pharos island and removed from the silt thrown out by Nile mouths. An Egyptian townlet, Rhacotis, already stood on the shore and was a resort of fishermen and pirates. Behind it (according to the Alexandrian treatise, known as pseudo-Callisthenes) five native villages scattered along the strip between Lake Mareotis and the sea. Alexander occupied Pharos, and had a walled city marked out by Deinocrates on the mainland to include Rhacotis. A few months later he left Egypt for the East and never returned to his city; but his heart was deeply entombed there. His viceroy, Cleomenes, continued the creation of Alexandria. The Heptastadium, however, and the mainland quarters seem to have been mainly Ptolemaic work. Inheriting the trade of ruined Tyre and becoming the centre of the new commerce between Europe and the Arabian and Indian East, the city grew less than a century to be larger than Carthage; and for some centuries more it had to acknowledge no superior but Rome. It was a centre not only of Hellenism but of Semitism, and the greatest Jewish city in the world. There the Septuagint was produced. There the Ptolemies, in order to fasten the development of their museum into the leading Greek university; but they were careful to maintain the distinctness of its population into three nations, "Macedonian" (i.e. Greek), Jew and Egyptian. From this division arose much of the later turbulence which began to manifest itself under Ptolemy Philopater. Nominally a free Greek city, Alexandria retained its senate to Roman times; and indeed the judicial functions of that body were restored by Septimius Severus, after temporary abolition by Augustus. The city passed formally under Roman jurisdiction in 58 B.C., according to the will of Ptolemy Alexander; but it had been under Roman influence for more than a hundred years previously. There Julius Caesar dallied with Cleopatra in 47 B.C. and was mobbed by the rabble; there his example was followed by Antony, for whose favour the city paid dear to Octavian, who placed over it a prefect from the imperial household. Alexandria seems from this time to have regained its old prosperity, commanding, as it did, an important granary of Rome. This latter fact, doubtless, was one of the chief reasons which induced Augustus to place it directly under the imperial power. In A.D. 215 the emperor Caracalla visited the city; and, in order and without any insulting satire, the inhabitants had made upon him, he commanded his troops to put to death all youths capable of bearing arms. This brutal order seems to have been carried out even beyond the letter, for a general massacre was the result. Notwithstanding this terrible disaster, Alexandria soon recovered its former splendour, and for some time longer was esteemed the first city of the world after Rome. Even as its main historical importance had formerly sprung from pagan learning, so now it acquired fresh importance as a centre of Christian theology and church government. There Arias was formulated and there Athanasius, the great opponent of both heresy and pagan reaction, worked and triumphed. As native influences, however, began to reassert themselves in the Nile valley, Alexandria gradually became an alien city, more and more detached from Egypt; and, losing much of its commerce as the peace of the empire broke up during the 3rd century A.D., it declined fast in population and splendour. The Brucheum and Jewish quarters were desolate in the 5th century, and the central monuments, the Soma and Museum, fallen to ruin. On the other hand, Alexandria soon seems to have centred in the vicinity of the Serapeum and Caesareum, both became Christian churches: but the Pharos and Heptastadium quarters remained populous and intact. In 616 it was taken by Chosroes, king of Persia; and in 640 by the Arabs, under 'Amr, after a siege that lasted fourteen months, during which Heraclius, the emperor of Constantinople, did not send a single ship to its assistance. Notwithstanding the losses that the city had sustained, 'Amr was able to write to his master, the caliph Omar, that he had taken a city containing '4000 palaces, 4400 baths, 12,000 dealers in fine oil, 40,000 gardeners, 400,000 Jews who pay tribute, 4000 theatre foundations which amused' (Ancient History).

The story of the destruction of the library by the Arabs is first told by Bar-Hebraeus (Abulfaragius), a Christian writer who lived six centuries later; and it is of very doubtful authority. It is highly improbable that even of the 700,000 volumes collected by the Ptolemies remained at the time of the Arab conquest, when the various calamities of Alexandria from the time of Caesar to that of Diocletian are considered, together with the disgraceful pillage of the library in A.D. 583 under the rule of the Christian bishop, Theophilus, acting on Theodosius' decree concerning the "Monasteries in the East" (Ancient History). The story of Abulfaragius runs as follows:—

John the Grammian, a famous Periætatic philosopher, being in Alexandria at the time of its capture, and in high favour with 'Amr, begged that he would give him the royal library. 'Amr told him that it was not in his power to grant such a request, but promised to write to the caliph for his consent. Omar, on hearing the report of his general, is said to have replied that if those books contained the same doctrine with the Koran, they could be of no use, since the Koran contained all necessary truths; but if they contained anything contrary to that book, they ought to be destroyed; and therefore, whatever their contents were, he ordered them to be burnt. Pursuant to this order, they were distributed among the public libraries of the day, a number of which were large in the city, where, for six months, they served to supply the fires.

Shortly after its capture Alexandria again fell into the hands of the Greeks, who took advantage of 'Amr's absence with the greater portion of his army. On hearing what had happened, however, 'Amr returned, and quickly regained possession of the city. About the year 646 'Amr was deprived of his government by the caliph 'Othman. The Egyptians, by whom 'Amr was greatly beloved, were so much dissatisfied by this act, and even showed such a tendency to revolt, that the Greek emperor determined to make an effort to reduce Alexandria. The attempt proved perfectly successful. The caliph, perceiving his mistake, immediately restored 'Amr, who, on his arrival in Egypt, drove the Greeks within the walls of Alexandria, but was only able to capture the city after a most obstinate resistance by the defenders. This so exasperated him that he completely demolished its fortifications, although he seems to have spared the lives of the inhabitants as far as lay in his power. Alexandria now rapidly declined in importance. The building of Cairo in 969, and, above all, the discovery of the route to the East by the Cape of Good Hope in 1488, nearly ruined its commerce; the canal, which supplied it with Nile water, became blocked; and although it remained a principal Egyptian port, at which most European visitors in the Mameluke and Ottoman periods landed, we hear little of it until about the beginning of the 19th century.

[Alexandria figured prominently in the military operations of Napoleon's Egyptian expedition of 1798. The French troops stormed the city on the 2nd of July 1798, and it remained in their hands until the arrival of the British expedition of 1801. The battle of Alexandria, fought on the 21st of March of that}
year, between the French army under General Menou and the British expeditionary corps under Sir Ralph Abercromby, took place near the ruins of Nicopolis, on the narrow spit of land between the sea and Lake Aboukir, along which the British forces had to bring the badly wounded in the action of Aboukir on the 8th and Mandora on the 13th. The British position on the night of the 20th extended across the isthmus, the right resting upon the ruins of Nicopolis and the sea, the left on the lake of Aboukir and the Alexandria canal. The line faced generally south-west towards the city, the reserve division under Major-General (Sir) John Moore on the right, the Guards brigade in the centre, and three other brigades on the left. In second line were two brigades and the cavalry (dismounted). On the 21st the troops were under arms at 5 A.M., and began to the French attack and drive in the front. The French army now moved forward with great rapidity in their usual formation of columns. The brunt of the attack fell upon the command of Moore, and in particular upon the 28th (Gloucestershire Regiment). The first shock was repulsed, but a French column penetrated in the dark between two regiments of the British and a confused fight ensued in the ruins, in which the 42nd (Black Watch) captured a colour. The front and rear ranks of the 28th were simultaneously engaged, and the conduct of the regiment won for it the distinction of winning bravely both at the back of the head-dress of its comrades. Other regiments which assisted in the overthrow of the French column were the 23rd, 40th, and 59th. In a second attack the enemy's cavalry inflicted severe losses on the 42nd. Sir Ralph Abercromby was here engaged in personal conflict with some French dragons, and about this time received a mortal wound, though he remained on the field and in command to the end. The attack on the centre was repulsed by the cool and steady fire of the Guards, and the left wing maintained its position with ease, but the French cavalry for the second time came to close quarters with the reserve. Abercromby might have gained his point if no troops at the back of his troops had charge of the cavalry, but had these men wounded by the sabre. Part of the French losses, which were disproportionately heavy, were caused by the gunboats which lay close inshore and cannonaded the left flank of the French columns, and by a heavy naval gun which was placed in battery near the position of the 28th. The forces engaged on this day were approximately 14,000 British to about 20,000 French, and the losses were:—British, 1,468 killed, wounded and missing, including Abercromby (who died on the 21st), Moore and three other generals wounded; French, 1,160 killed and (?) 3000 wounded. The British subsequently advanced upon Alexandria, which surrendered on the 31st of August.

During the anarchy which accompanied Ottoman rule in Egypt from first to last, Alexandria sank to a small town of about 4000 inhabitants; and it owed its modern renascence solely to Mehemet Ali, who wanted a deep port and naval station for his viceregal domain. He restored its water communication with the Nile by making the Mahmuiliya canal, finished in 1820; and he established at Rayut El-Tin his favourite residence. The old Eunoussy port became the port, and a flourishing city arose on the old Pharois island and the Heptastadium district, with outlying suburbs and villa residences along the coast eastwards and the Marecotis shore. Being the starting-point of the "overland route" to India, and the residence of the chief foreign consuls, it quickly acquired a European character and attracted not only Frank residents, but great numbers of Greeks, Jews and Syrians. There most of the negotiations between the powers and Mehemet Ali were conducted; thence started the Egyptian naval expeditions to Crete, the Morea and Syria; and thither sailed the ships of Alexandria. Hence issued also the war with Turkey in 1828. It was then threatened by hostile fleets, the Greek in 1827 and the combined British, French and Russian squadrons in 1828. The latter withdrew on the viceroy's promise that Ibrahim should evacuate the Morea. The fortifications were strengthened in 1841, and remained in an antiquated condition until 1882, when they were renovated by Arabi Pasha. Alexandria was connected with Cairo by railway in 1856. Much favoured by the earlier viceroys of Mehemet Ali's house, and removed from the Mameluke troubles, Alexandria was the real capital of Egypt till Said Pasha died there in 1863; Ismail came into power. Though this prince continued to develop the city, giving it a municipality in 1866 and new harbour works in 1871-1878, he developed Cairo still more; and the centre of gravity definitely shifted to the inland capital. Fate, however, again brought Alexandria to the front. After a mutiny of soldiers there in 1881, the town was greatly excited by the arrival of an Anglo-French fleet in May 1882, and on the 11th of June a terrible riot and massacre took place, resulting in the death of four hundred Europeans. Since satisfaction was not given for this and the forts were strengthened at the instigation of Arabi Pasha, the war minister, the British admiral, Sir Beauchamp Seymour (afterwards Lord Alchester), sent an ultimatum on the 10th of July and opened fire on the forts the next day. They were demolished, but as no troops were landed immediately a fresh riot and massacre ensued. As Arabi did not submit, a British military expedition landed at Alexandria on the 10th of August, the sequel being the British occupation of the whole country, the history of which is set forth under Egypt.

Since the restoration of tranquillity and the establishment of greater political and economic conditions in the Nile valley, Alexandria has greatly expanded. As the British consul report for 1904 says, "Building... for residential and other purposes proceeds with almost feverish rapidity. The cost of living has doubled and the price of land has risen enormously." On the E. and S.E. a new town of handsome houses, gardens and boulevards has been called into existence, in the arrangement of which the controlling influence of the municipality is evident (see Modern City above).

IV. Antiquities.—Persistent efforts have been made to explore the ancient remains in and near Alexandria. Encouragement and help have been given by the local Archaeological Society, and by many individuals, notably Greeks justly proud of a city which is one of the glories of their national story. The past and present directors of the museum have been enabled from time to time to carry out systematic excavations when opportunity offered; Mr D. G. Hogarth made tentative researches on behalf of the Egypt Exploration Fund and the Society for the Promotion of Hellenic Studies in 1895; and a German expedition worked for two years (1898-1899). But two difficulties face the would-be excavator in Alexandria. First, since the great and growing modern town stands right over the ancient one, it is almost impossible to find any considerable space in which to dig, except at enormous cost. Second, the general subsidence of the coast has sunk the lower-lying parts of the ancient town under water. Unfortunately the spaces still most open are the low grounds to N.E. and S.W., where it is practically impossible to get below the Roman strata.

The most important results were those achieved by Dr G. Botti, late director of the museum, in the neighbourhood of "Pompey's Pillar," where there is a good deal of open ground. Here the structures of a large building or group of buildings have been exposed, which are perhaps part of the Serapeum. Hard by immense catacombs and columbaria have been opened which may have been appendages of the temple. These contain one

1 This municipality was superseded by a new municipal body, with extensive powers, created in 1890.
very remarkable vault with curious painted reliefs, now lighted by electricity and shown to visitors. The objects found in these researches are in the museum, the most notable being a great basalt bull, probably once an object of cult in the Serapeum. Other catacombs and tombs have been opened in Kom es-Shugafa Hadra (Roman) and Ras et-Tin (painted). The Germans found remains of a Ptolemaic colonnade and streets in the north-east of the city, but little else. Mr Hogarth explored part of an immense brick structure under the mound of Kom ed-Dik, which may have been part of the Panum, the Mausolea or a Roman fortress. The making of the new foreloaf led to the dredging up of remains of the Patriarchal Church; and the foundations of modern buildings are seldom laid without some objects of antiquity being discovered. The wealth underground is doubtless immense; but, despite all efforts, there is not much for antiquarians to see in Alexandria outside the museum and the neighbourhood of "Pompey's Pillar." The native tomb-robers, well-sinkers, dredgers and the like, however, come upon valuable objects from time to time, which find their way into private collections.

tiones ad historiam Egypti Provinciae Romanae (1885); G. Lumbroso, L'Età del tempo dei Greci e dei Romani (1882); H. Klepert, Zur Territorialgeschichte Alexandries (1904).

ALEXANDRIA, a city of Madison county, Indiana, U.S.A., about 46 m. N.E. of Indianapolis. Pop. (1890) 715; (1900) 7221 (1900 foreign-born); (1910) 5006. Alexandria is served by the Cincinnati, Cleveland, Chicago & St Louis, and the Lake Erie & Western railways, and by the Indiana Union Traction System (electric). In the city is a Carnegie library and Beulah Park (24 acres), the latter belonging to the Northern Indiana Holiness Association, which there holds summer camp-meetings. The city is in a rich farming country, which produces Indiana corn, oats and wheat; and is in the Indiana natural gas region, to which fact it owes its rapid growth as a manufacturing centre. It is one of the principal seats of the glass industry in Indiana—plate glass, lamp chimneys, mirrors, &c., being manufactured here—and also has mineral wool factories and paper mills. The municipality owns and operates the water-works and the gas-lighting plant. Alexandria was founded in 1836 and was chartered as a city in 1893.

ALEXANDRIA, a city of Louisiana, U.S.A., capital of Rapides Parish, on the S. bank of the Red river in almost the exact geographical centre of the state. Pop. (1890) 2061; (1900) 5645 (3742 negroes); (1910) 11,213. The city is served by the Louisiana Railway & Navigation Company, the St Louis, Watkins & Gul, the Texas & Pacific, the Louisiana & Arkansas, the Southern Pacific, the Chicago, Rock Island & Pacific, and the Missouri Pacific railways. The Red river is navigable to Alexandria during the entire year. Alexandria is on a level plain in the centre of the Louisiana long-leaf pine forests, in which pine is interspersed with various hardwoods. The forests stretch on all sides within a radius of 75 m. In the immediate vicinity of the city, on the Red river, cotton, sugar, alfalfa and garden vegetables are cultivated; south of the Red river is a peculiarly rich farming country watered by Bayou Rapides and Bayou Bacuf. Near the city is the Louisiana Asylum for the Insane. The principal industries are cotton-pressing and the manufacture of lumber and of cotton-seed products; sugar and molasses, artificial ice, mineral waters and brick are other manufactures. The city owns and operates the water-works and electric-lighting plant; the water-supply is derived from artesian wells. Alexandria was named in honour of Alexander Fulton, on whose grant from Spain the first settlement was made in 1785; it was first incorporated as a town in 1818 and received a city charter in 1834. In the spring of 1863 a Union fleet under Admiral David D. Porter, operating on the Red river, co-operated with land forces under General N. P. Banks in pushing the Confederates westward. Alexandria was occupied on the 7th of May 1863, but the troops were soon withdrawn for the Port Hudson attack. On the 16th of March 1864 it was again occupied by the Union forces, who made it the point of concentration for another land and naval expedition against E. Kirby Smith and Shreveport. After the check of this expedition and its abandonment, Alexandria was again occupied on the 12th of May, when the city was almost entirely burned. The Union gunboats, which had passed up the river toward Shreveport at high water, were caught in its decline above the falls at Alexandria, but they were saved by a splendid piece of engineering (a dam at the falls), constructed by Lieutenant-Colonel Joseph Bailey (1827–1867), who for this service received the thanks of Congress and the brevet of brigadier-general of volunteers.

ALEXANDRIA, a town of Rumania, situated among the rich corn-lands of the Teleorman department, on the right bank of the river Audea (a After) Pop. (1900) 13,675. It is a coach station on the largest of the Turkey-red dyeing establishments in the Vale of Leven. The public buildings include a public hall, the mechanics' institute with library and lecture-hall, an institute for men, with library and recreation rooms, a similar institution for women, banks and other important commercial offices. Pop. (1891) 7796; (1901) 8007. Alexandria is connected with Bonhill, on the opposite bank of the river, by a bridge which replaced in 1868 one bought three years earlier by the county council from the Smollett family, who have been closely associated with the district since the time of Sir James Smollett, the well-known medical writer. The largest of the Turkey-red dyeing establishments in the valley. Population (1891) 3843; (1901) 3333. Jamestown, about 1 m. to the north-east of Alexandria, with a station on the Forth & Clyde railway from Balloch to Stirling (North British), contains some of the largest cotton-printing works in Scotland. Population (1891) 1668; (1901) 2080.

ALEXANDRIA, a city and a port of entry of Alexandria county, Virginia, U.S.A., on the W. bank of the Potomac river, 6 m. below Washington, D.C., with which it is connected by a ferry. Pop. (1890) 14,535; (1900) 14,528, of whom 4533 were negroes; (1910, census), 15,329. Alexandria is served by the Baltimore & Ohio, the Chesapeake & Ohio, the Southern and the Washington Southern railways; by the Washington, Alexandria & Mount Vernon electric railway; and by several lines of river and coasting steamboats. It is a quaint, old-fashioned city, with quiet, shady streets, and a number of buildings dating back to the 18th century; of these the most interesting is the old Christ Church in which George Washington and Robert E. Lee worshipped. The city has a public library. About 23 m. W. of Alexandria is the Protestant Episcopal Theological Seminary in Virginia, opened here in 1823 and chartered in 1834; in 1906–1907 the Seminary had a faculty of 7 and 46 students. Alexandria is a distributing and jobbing centre for the north-east counties of Virginia. Among its manufactures are fertilizers, bottles, carbonated beverages, flour, beer, shoes, silk thread, aprons, brooms, leather, bricks, and tiling and structural iron. The total value of its factory product in 1905 was $2,186,658. The municipality owns and operates its gas-lighting plant. Alexandria, first known as Belhaven, was named in honour of John Alexander, who in the last quarter of the 17th century had bought the land on which
ALEXANDRIAN SCHOOL

The intellectual movement so originated extended over a long period of years. If we date its rise from the 4th century B.C., at the time of the fall of the Seleucids and the foundation of the Graeco-Macedonian empire, we must look for its final dissolution in the 7th century of the Christian era, at the time of the fall of Alexandria and the rise of the Mahommedan power. But this very long period falls into two divisions. The first, extending from about 360 to 30, includes the time from the foundation of the Ptolemaic dynasty to its final subjugation by the Romans; the second extends from 30 to A.D. 642, when Alexandria was destroyed by the Arabs. The characteristic features of these divisions are very clearly marked, and their difference affords an explanation of the variety and vagueness of meaning attaching to the term "Alexandrian," which signifies that the intellectual activity was of a purely literary and scientific nature. It was an attempt to continue and develop, under new conditions, the old Hellenic culture. This direction of effort was particularly noticeable under the early Ptolemies, Alexandria being then almost the only home in the world for pure literature. During the last century and a half before the Christian era, the school, as it might be called, began to break up and to lose its individuality. This was due partly to the state of government under some of the later Ptolemies, partly to the formation of new republics in the Mediterranean, and partly to the fall of Alexandria and the growing division of the Mediterranean Sea into commercial branches. The position of Alexandria as the leading city which has been so long held by the state of Egypt, has fallen, and its political influence is now divided between the Alexanrians and the Sais. The new intellectual movement was not in the old direction—had, indeed, nothing in common with it. With its characteristic largely determined by Jewish elements, and even more by contact with the dogmas of Christianity, this second Alexandrian school resulted in the speculative philosophy of the Neo-Platonists and the religious philosophy of the Gnostics and early church fathers.

There appear, therefore, to be at least two definite significations of the title Alexandrian School; or, rather, there are two Alexandrian schools, distinct both chronologically and in substance. The one is the Alexandrian school of poetry and science, the other the Alexandrian school of philosophy. The term "Alexandrian school," as used in this country, may be explained as meaning a body of men united by learning or study or purpose, such as the Academics or Peripatetics, the Stoics or Epicureans. These consisted of a company united by holding in common certain speculative principles, by having the same theory of things. There was nothing at all corresponding to this among the Alexandrians. In literature their activities were directed to the most diverse objects; they have only in common a certain spirit or form. There was among them no definite system of philosophy. Even in the later schools of philosophy proper there is found a community rather of tendency than of definite result or of fixed principles.

I. Literature.—The general character of the literature of the school appears as the necessary consequence of the state of affairs brought about by the fall of Greek nationality and independence. The great works of the Greek mind had formerly been the products of a fresh life of nature and perfect freedom of thought. All their hymns, epics and histories were bound up with their individuality as a free people. But the Macedonian conquest at Chaeroneia brought about a complete dissolution of this Greek life in all its relations, private and political. The full, genial spirit of Greek thought vanished when freedom, with which it was interwoven, was lost; and literature, whose originality was found at Alexandria in learned research, extended and multifarious knowledge. Amply provided with means for acquiring information, and under the watchful care of a great monarch, the Alexandrians readily took this new direction in literature. With all the great objects removed which could excite a true spirit of poetry, they devoted themselves to minute researches in all sciences subordinate to literature proper. They
ALEXANDRIAN SCHOOL

Dramatic poetry appears to have flourished to some extent. There are still extant three or four varying lists of the seven great dramatists who composed the Pleiad of Alexandria. Their works, perhaps not unfortunately, have perished. A ruder kind of drama, the amoebae verse, or bucolic mime, developed into the only pure stream of genial poetry found in the Alexandrian School, the *Idyls* of Theocritus. The name of these poems preserves their original idea; they were *pictures* of fresh country life.

The most interesting fact connected with this Alexandrian poetry is the powerful influence it exercised on Roman literature. That literature, especially in the Augustan age, is not to be thoroughly understood without due appreciation of the character of the Alexandrian school. The historians of this period were numerous and prolific. Many of them, e.g. Cleitarchus, devoted themselves to the life and achievements of Alexander the Great. The best-known names are those of Timaeus and Polybius.

Before the Alexandrians had begun to produce original works, they had been directed towards *theses* or masterpieces of ancient Greek literature. If that literature was to be a power in the world, it must be handed down to posterity in a form capable of being understood. This was the task begun and carried out by the Alexandrian critics. These men did not merely collect works, but sought to arrange them, to subject the texts to criticism, and to explain any allusion or reference in them which at a later date might become obscure. The complete philological examination of any work consisted, according to them, of the following processes: *ἀναθέως*, arrangement of the text; *ἀναγωγή*, settlement of accents; *ἐπίστωσις*, theory of forms, *ἐπιστημονικόν* explanation either of words or things; and finally, *κρίσις*, judgment on the author and his work, including all questions as to authenticity and integrity. To perform their task adequately required from the critics a wide circle of knowledge; and from this requirement sprang the sciences of grammar, prosody, lexicography, mythology and archaeology. The service rendered by these critics is invaluable. To them we owe not merely the possession of the greatest works of Greek intellect, but the possession of them in a readable state. The most celebrated critics were Zenodotus; Aristophanes of Byzantium, to whom we owe the theory of Greek accents; Crates of Mallus; and Aristarchus of Samothrace, confessedly the core of the school of criticism. Others were Lycophron, Callimachus, Eratosthenes and many of a later age, for the critical school long survived the literary. Dionysius Thrax, the author of the first scientific Greek grammar, may also be mentioned. These philological labours were of great indirect importance, for they led immediately to the study of the natural sciences, and in particular to a more accurate knowledge of geography and history. Considerable attention began to be paid to the ancient history of Greece, and to all the myths relating to the foundation of cities and states. A large collection of such curious information is contained in the *Bibliothecae* of Apollodorus, a pupil of Aristarchus who flourished in the 2nd century B.C. Eratosthenes was the first to write on mathematical and physical geography; he also first attempted to draw up a chronological table of the Egyptian kings and of the historical events of Greece. The sciences of mathematics, astronomy and medicine were also cultivated with assiduity and success at Alexandria, but they can scarcely be said to have their origin there, or in any strict sense to form a part of the peculiarly Alexandrian literature. The founder of the mathematical school was the celebrated Euclid (Eucleides); among his scholars were Archimedes; Apollonius of Perga, author of a treatise on *Conic Sections*. Eratosthenes, to whom we owe the first measurement of the earth; and Hipparchus, the founder of the epicyclical theory of the heavens, afterwards called the *Ptolemaic* system, from its most famous expositor, Claudius Ptolemaeus. Alexandria continued to be celebrated as a school of mathematics and science long after the Christian era. The science of medicine had distinguished representatives in Herophilus and Erasistratus, the two first great anatomists.

ALEXANDRIA TROAS—ALEXANDRINE VERSE

Mahaffy, Greek Life and Thought from the Age of Alexander to the Roman Empire; Coust, La Poésie alexandrienne; and especially von Soden, Geschichte der griechischen Literatur in der Alexandrinerzeit. Nicolai’s Griechische Literaturgeschichte, though somewhat out of date, is useful for bibliography.

II. Philosophy.—Although it is not possible to divide literature with anything like the same definiteness, and although the intellectual life of Alexandria, particularly as applied to science, long survived the Roman conquest, yet at that period the school, which for some time had been gradually breaking up, seems finally to have succumbed. The later productions in the field of pure literature bear the stamp of Rome rather than of Alexandria. But in that city for some time past there had been various forces secretly working, and these, coming in contact with great spiritual changes in the world around, produced a second outburst of intellectual activity, which is generally known as the Alexandrian school of philosophy. The doctrines of this school were a fusion of Eastern and Western thought, and combined in varying proportions the elements of Hellenistic and Jewish philosophy. Traces of this eclectic tendency are discoverable as far back as 280 B.C., but for practical purposes the dates of the school may be given as from about 30 B.C. to A.D. 529. The city of Alexandria had gradually become the neutral ground of Europe, Asia and Africa. Its population, then as at the present day, was a heterogeneous collection of all races. Alexander had planted a colony of Jews who had increased in number until at the beginning of the Christian era they occupied two-fifths of the city and held some of the highest offices. The contact of Jewish theology with Greek speculation became the great problem of thought. The Jewish ideas of divine authority and their transcendental theories of conduct were peculiarly attractive to the Greek thinkers who found no inspiration in the dry intellectualism into which they had fallen (see NEO-PYTHAGOREANISM). At the same time the Jews of the Dispersion had to some extent shaken off the exclusiveness of their old political relations and were prepared to compare and contrast their old territorial theologies. Greek philosophers who visited the city came to consider the results of their intellectual inheritance they found that they had sufficient common ground for the initial compromise. Thus the Hellenistic doctrine of personal revelation could be combined with the Jewish tradition of a complete theology revealed to a special people. The result was the application of a purely philosophical system to the somewhat vague and unorganized corpus of Jewish theology. The matter was Jewish, the arrangement Greek. According to the relative predominance of these two elements arose Gnosticism, the Patriotic theology, and the philosophical schools of Neo-Pythagoreanism, Neo-Platonism, and eclectic Platonism.

The members of the school may be enumerated under three heads. (1) The beginnings of the eclectic spirit are, according to some authorities, discernible in the Septuagint (280 B.C.) (see Frankel, Historisch-kritische Studien zur Septuaginta, 1841), but the first concrete exemplification is found in Aristobulus (c. 160 B.C.). So far as the Jewish succession is concerned, the great name is that of Philo in the first century of our era. He took Greek metaphysical theories, and, by the allegorical method, interpreted them in accordance with the Jewish Revelation. He dealt with (a) human life as expounded in the relative relations of Man and God, (b) the Divine nature and the existence of God, and, (c) the great Logos doctrine as the explanation of the relation between God and the material universe. From these three arguments he developed an elaborate theosophy which was a syncretism of oriental mysticism and pure Greek metaphysic, and may be regarded as representing the climax of Jewish philosophy. (2) The first purely philosophical phenomenon of the Alexandrian school was Neo-Pythagoreanism, the second and last Neo-Platonic philosophy. In the accounts given of the schools to special devoted to them, it is sufficient here to say that their doctrines were a synthesis of Platonism, Stoicism and the later Aristotelianism with a leaven of oriental mysticism which gradually became more and more important. The world to which they spoke had begun to demand a doctrine of salvation to satisfy the human soul. They endeavoured to deal with the problem of good and evil. They therefore devoted themselves to examining the nature of the soul, and taught that its freedom consists in communion with God, to be achieved by absorption in a sort of ecstatic trance. This doctrine reaches its height in Plotinus, after whom it degenerated into magic and theory in its unorganized form with the theurgy of Christianity. Finally this pagan theosophy was driven from Alexandria back to Athens under Plutarch and Proclus, and occupied itself largely in purely historical work based mainly on the attempt to re-organize ancient philosophy in conformity with the system of Plotinus. This school ended under Damascius when Justinian closed the Athenian schools (A.D. 529). (3) The eddies of Neo-Platonism had a considerable effect on certain Christian thinkers about the beginning of the 3rd century. Among these the most important were Clement of Alexandria and Origen. Clement, as a scholar and theologian, proposed to unite the mysticism of Neo-Platonism with the practical spirit of Christianity. He combined the principle of pure living with that of free thinking, and held that instruction must have regard to the mental capacity of the hearer. The compatibility of Christian and later Neo-Platonic ideas is evidenced by the writings of Synesius, bishop of Ptolemais, and though Neo-Platonism eventually succumbed to Christianity, it had the effect, through the writings of Clement and Origen, of modifying the tyrannical fanaticism and ultra-dogmatism of the early Christian writers.
episodical Alexandrines with the vers communis of his tragedies and so introduced them into drama. It was Ronsard, however, who made the verse popular, and gave it vogue in France. From his time it became the recognized vehicle for all great poetry, and the regulation of its pauses became more and more strict. The following is an example of the verse as used by Racine—

Où suis-je? qu’ai-je fait? || que dois-je faire encore?
Quel transport me saisit? || quel chagrin me dévore?

Two inexorable laws came to be established with regard to the pauses. The first is, that each line should be divided into two equal parts, the sixth syllable always being on a word. In the earlier use of this metre, on the contrary, it frequently happened that the sixth and seventh syllables belonged to the same word. The other is that, except under the most stringent conditions, there should be none of what the French critics call enjamment, that is, the overlapping of the sense from one line on to the next. Ronsard completely ignored this rule, which was after his time settled by the authority of Malherbe. The latest school of French prosody has given great attention to the breaking up of the Alexandrine, which no longer possesses the rigidity of authoritative form which it held until about 1880, but is often used with a licence no less than when Ronsard wrote.

Michael Drayton, who was twenty-two years of age when Ronsard died, seemed to think that the Alexandrine might be as pleasing to English as it was to French ears, and in this metre he wrote a long poem in twenty-four books called the Polyolbion. The metre, however, failed to catch the English ear. The principal English measure is a line of ten syllables, and the Alexandrine is used only occasionally to give it variety and weight. In ordinary English heroic verse it is but rarely introduced; but in the favourite narrative metre, known as the Spenserian, it comes in regularly as the concluding line of each stanza. In English usage, moreover, it is to be observed that there is no fixed rule as to the position of the pause, though it is true that most commonly the pause occurs at the end of the sixth syllable. Spenser is very free in shifting the pause about; and though the later poets who have used this stanza are not so free, yet, with the exception of Shenstone and of Byron, they do not scruple to obliterate all pause between the sixth and seventh syllables. Thus Thomson (Castle of Indolence, i. 43)—

And music lent new gladness to the morning air.

The danger in the use of the Alexandrine is that, in attempting to give dignity to his line, the poet may only produce heaviness, incurring the sneer of Pope—

A needless Alexandrine ends the song.

That, like a wounded snake, drags its slow length along.

The Alexandrine was the dominant metre in Dutch poetry from the 16th to the middle of the 17th century, and about the time of its introduction to Holland it was accepted in Germany by the school of Opitz. In the course of the 17th century, after being used without rhyme by Seckendorf and others, it formed a transitional station on the route to German blank verse, and has since then been rarely employed, except occasionally in rhymed comedy.

ALEXANDRISTS, the name given to those philosophers of the Renaissance, who, in the great controversy on the subject of personal immortality, adopted the explanation of the De Anima given by Alexander of Aphrodiasia. According to the orthodox Thomism of the Roman Catholic Church, Aristotle rightly regarded reason as a faculty of the individual soul. Against this, the Averroists, led by Agostino Nifo (g.v.), introduced the modifying theory that universal reason in a sense individualizes itself in each soul and then absorbs the active reason into itself again. These two theories respectively evolved the doctrine of individual and universal immortality, or the absorption of the individual into the eternal One. The Alexandrists, led by Pietro Pomponazzi, boldly assailed these beliefs and denied that either was rightly attributed to Aristotle. They held that Aristotle considered the soul as a material and therefore a mortal entity which operates during life only under the authority of universal reason. Hence the Alexandrists denied the possibility of immortality in every shape or form. Since the soul is organically connected with the body, the dissolution of the latter involves the extinction of the former.

ALEXANDRITE, a variety of chrysoberyl (g.v.) discovered in the Urals in 1833, on the day set apart for celebrating the majority of the cesarevich, afterwards the tsar, Alexander II., in whose honour the stone was named by Nils Gustaf Nordenskiöld, of Helsingfors. It is remarkable for being strongly dichroic, generally appearing dark green by daylight and raspberry-red by candle-light, or by daylight transmitted through the stone. As red and green are the military colours of Russia, the mineral became highly popular as a gem-stone. The dark green crystals are usually cloudy and cracked, and grouped in triplets presenting a pseudo-hexagonal form. Alexandrite was found originally in the emerald-mine of Takovaya, east of Ekaterinburg in the Urals, and afterwards in the gold-bearing sands of the Sanarka in the southern Urals. Subsequently it was discovered in greater abundance in the Urals, and in China. An imitation of Ceylon has been found also in Tasmania. Some of the Ceylon alexandrites exhibit, when suitably cut, the Cat's-eye chatoyancy, whence it has been called alexandrite cat's-eye.

ALEXANDRIST, ALEXANDRINE, or ALEXANDRINES, or ALEXANDRINES, a transitional metre, often rhymed, used by Ronsard, and which is in common use in French poetry. It is formed of six feet, three feet of three syllables and three feet of two syllables. It is used occasionally with rhyme, but more often in blank verse, in the construction of mottoes, and of motto verses in alphabets. The regular form is seven lines. But six lines are rather common. The Alexandrine was introduced into English poetry by Drayton, who used it in his Polyolbion. The metre is sometimes called by his name, and the time of his life, also the Polyolbion metre.
ALEXISBAD—ALEXIOUS

immediately popular and was translated into several languages, including English. It was followed by *Schloß Avalon* (1837), with regard to which the author adopted the same tactics and achieved success. These historical novels, however, were of considerable literary merit, and would doubtless have achieved popularity even without the borrowed plumage. Shortly after wards Häring published a number of successful short stories (*Gesammelte Novellen, 4 vols., 1830–1831), some books of travel, and in the novels *Das Haus Dasterweg* (1835) and *Zwölf Nächte* (1838) showed for a while a leaning towards the "Young German" school. In *Cobannis* (1832), however, a story of the time of Frederick the Great, he entered the field of patriotic-historical romance, in which he so far excelled as to have earned himself the title of "the faithful Geschichtsmacher" ("the reliable historian", the Mark). From 1840 onwards he published at short intervals a series of romances, each dealing with some epoch in the history of Brandenburg. Among them may be especially noted *Der Roland von Berlin* (1840), *Der falsche Waldemar* (1842), *Die Hosen des Herrn von Bredow* (1846–1848), *Ruhe ist die erste Bürgerpflicht* (1852), *Isegrim* (1854) and *Dorothee* (1856). In all these the author shows himself as a keen observer of men and things; the characters, situations and natural surroundings are excellently delineated, and the patriotic feeling which pervades the novel is admirably employed, not only for the purpose of glorifying himself in the field of criminology by commencing in 1842, in conjunction with the publicist, Julius Eduard Hitzig (1780–1849), the publication of *Der neue Ptolema* (continued by A. Vollert, 36 vols., Leipzig, 1842–1865; new edition, 24 vols., Leipzig, 1866–1881), a collection of criminal anecdotes culled from all nations and all times. This publication attained great popularity, and is of-day of psychological interest and value. His *Gesammelte Werke* were published in 20 volumes (Berlin, 1874); the *Vaterländische Romane* separately in 8 volumes (Berlin, 1881, 1882), and, since the expiry of the copyright in 1901, in many cheap reprints. *C. W. Alexis* Erinnerungen, edited by M. Ewert (1900), and *Emden, Falken, Patronymik, Julian Schmidt* (Neue Bilder aus dem geistigen Leben des Zeitgenossen, 1787–1900, 5 parts, 1898), are invaluable works.

ALEXISBAD, a spa of Germany, in the duchy of Anhalt, lying along the Harz mountains, 1000 ft. above the sea, on the railway from Gnernrode to Harzeperg. Pop. 1000. It is celebrated for its medicinal waters, of which the Alexisbrunner, a ferruginous spring, is the chief. The Selke and Brocken streams supply the baths, which are of use in feminine disorders. The place was founded in 1810 by Duke Alexis of Anhalt-Bernburg. ALEXIS I. (1048–1118), emperor of the East, was the third son of John Comnenus, nephew of Isaac Comnenus, emperor 1057–1059. His father declined the throne of the abdication of Isaac, who was accordingly succeeded by four emperors of other families between that date and 1081. Under one of these emperors, Romanus Diogenes (1067–1071), he served with distinction against the Seljuk Turks. Under Michael Parapinces (1071–1078) and Nicophorus Botanites (1078–1081) he was also employed, along with his elder brother Isaac, against rebels in Asia Minor, Thrace and in Epirus (1071). The success of the Comneni roused the jealousy of Botanites and his ministers, and the Comneni were almost compelled to take up arms in self-defence. Botanites was forced to abdicate and retire to a monastery, and Isaac declined the crown in favour of his younger brother Alexis, who then became emperor in the 33rd year of his age. His long reign of nearly 37 years was full of difficulties (see ROMAN EMPIRE, LATER). At the very outset he had to meet the formidable attack of the Normans (Robert Guiscard and his son Bohemund), who took Dyrhachium and Corfu, and laid siege to Larissa in Thessaly. The Norman danger ended for the time with Robert Guiscard’s death (1085) and the conquests were recovered. He had next to repel the invasions of Patzinaks (Petchenege) and Kumans in Thrace, with whom the Manichaean sects of the Paulicians and Bogomilians made common cause; and thirdly, he had to cope with the fast-growing power of the Turks in Asia Minor. Above all he had to meet the difficulties caused by the arrival of the warriors of the First Crusade, which

had been in a great degree initiated owing to the representations of his own ambassadors, though the help which he wanted from the West was simply mercenary forces and not the immense hosts which arrived to his congratulations. The first part, under Peter the Hermit, he got rid of by sending them on to Asia Minor, where they were massacred by the Turks (1096). The second and much more serious host of warriors, led by Godfrey of Bouillon, he conducted also into Asia, promising to supply them with provisions in return for an oath of homage, and by their victories recovered for the Empire a number of important cities and islands—Nicaea, Chios, Rhodes, Smyrna, Ephesus, Philadelphia, Sardis, and in fact most of Asia Minor (1097–1099). This is ascribed as a credit to his policy and (continued (see ALEXIUS III. CANGEN, especially as it shows the last touches of his pen. But to his treachery and falseness, but during the last twenty years of his life he lost much of his popularity. They were marked by persecution of the followers of the Paulician and Bogomilian heresies (one of his last acts was to burn Basilius, a Bogomilian leader, with whom he had engaged in a theological controversy), by renewed struggles with the Turks (1110–1117), by anxieties as to the succession, which his wife Irene wished to alter in favour of her daughter Anne’s husband, Nicephorus Bryennius for whose benefit the special title panhyperbasesthai (i.e. as it were "pious king") was bestowed. It was only under his son that the Empire, even in his dying hours. He deserves the credit of having raised the Empire from a condition of anarchy and decay at a time when it was threatened on all sides by new dangers. No emperor devoted himself more laboriously or with a greater sense of duty to the task of ruling. Authorities.—*Zonaras, viii. 27–39; Anna Commena’s Life; see also Du Cange, *Familiae Byzantinae*; Friedrich Wilken, *Rerum ab Alexio I. Ioanne, Manuele et Alexio II. Comnenorum Romanorum* Byzantinorum imperatoribus gestorum, *libri iv. Commentatio* (Heidelberg, 1811); Finlay, *History of Greece* (vol. iii., Oxford, 1877); Gibbon, *Decline and Fall of the Roman Empire*, edited with notes, *ii. B. Burne*. There are many works which treat of the last Comneni. The best are cited: F. Chalandon, *Essai sur le règne d’Alexis Ier Comnène* (1900).

ALEXIUS II. (COMNENUS) (1167–1183), emperor of the East, was the son of Manuel Comnenus and Maria, daughter of Raymund, prince of Antioch, and was born at Constantinople on the 10th of September 1167. On Manuel’s death, Maria, who had been immured in a convent under the name of Xenè, had herself proclaimed regent (1179–1182), and handing over her son to evil counsellors, who encouraged him in every vice, supported the government of Alexius the protosebastos (nephew of Manuel), who was supposed to be her lover. The young Alexius and his friends now tried to form a party against the empress mother and the protosebastos; and his sister Maria, wife of Caesar John, stirred up riots in the streets of the capital. Their party was defeated (May 2, 1182), but Andronicus Comnenus took a barbarous massacre of the Latins in Constantinople, which he made no attempt to stop. He allowed Alexius to be crowned, but forced him to consent to the death of all his friends, including his mother, his sister and the Caesar, and refused to allow him the smallest voice in public affairs. The betrothal in 1180 of Alexius with Agnes, daughter of Louis VII of France, a child of nine, was quashed, and he was married to Irene, daughter of Andronicus. The latter was now formally proclaimed as co-emperor, and not long afterwards, on the pretext that his rule was injurious to the Empire, he caused Alexius to be strangled with a bow-string (October 1183). (J. B. B.)

ALEXIUS III. (ANGELUS), emperor of the East, was the second son of Andronicus Angelus, nephew of Alexius I. In 1195, while his brother Isaac II. was away hunting in Thrace, he was proclaimed emperor by the troops; he captured Isaac at Stagira in Macedonia, put out his eyes, and kept him henceforth a close prisoner, though he had been redeemed by him from captivity at Antioch and loaded with promises. To compensate for this crime, and to confirm his position as emperor, he had to scatter money

I. 19

5
so lavishly as to empty his treasury, and to allow such licentiousness to the officers of the army as to leave the Empire practically defenceless. He consummated the financial ruin of the state. The empress Euphrosyne tried in vain to sustain his credit and his court; Vatazas, the favourite instrument of her attempts at reform, was assassinated by the emperor’s orders. Eastward the Empire was overrun by the Turks; from the north Bulgarians and the Vlachs descended unchecked to ravage the plains of Macedonia and Thrace; while Alexius squandered the public treasure on his palaces and gardens. Soon he was threatened by a new and yet more formidable danger. In 1202 the Western princes assembled at Venice, bent on a new crusade. To them Alexius, son of the deposed Isaac, made appeal, promising as a crowning bribe to heal the schism of East and West if they would help him to depose his uncle. The crusaders, whose objective had been Egypt, were persuaded to set their course for Constantinople, before which they appeared in June 1203, proclaiming the emperor Alexius IV. and summoning the capital to depose his uncle. Alexius III., sunk in debauchery, took no efficient measures to resist. His son-in-law, Lascaris, who was the only one to do anything, was defeated at Scutari, and the siege of Constantinople began. On the 17th of July the crusaders, the aged doge Dandolo at their head, scaled the walls and took the city by storm. During the fighting and carnage that followed Alexius hid in the palace, and finally, with one of his daughters, Irene, and such treasures as he could collect, got into a boat and escaped to Develin in Thrace, leaving his wife, his other daughters and his sons to the fate of the victors. Isaac, drawn from his prison and robed once more in the imperial purple, received his son in state.

Shortly afterwards Alexius made an effort in conjunction with Murtzuphlos (Alexius V.) to recover the throne. The attempt was unsuccessful and, after wandering about Greece, he surrendered with Euphrosyne, who had meanwhile joined him, to Boniface of Montferrat, then master of a great part of the Balkan peninsula. Leaving his protection he sought shelter with Michael, despot of Epirus, and then repaired to Asia Minor, where his son-in-law Lascaris was holding his own against the Latins. Alexius, joined by the sultan of Iconium (Konich), now demanded the crown of Lascaris, and on his refusal marched against him. Lascaris, however, defeated and took him prisoner. Alexius was relegated to a monastery at Nicaea, where he died on some date unknown.

Authorities.—Nicetas Acominatus, George Acropolites, Nicephorus Gregoras; and the sources for the Fourth Crusade (see Crusades). (J. M. B.)

ALEKSIUS V., eastern Roman emperor, was proclaimed emperor on the 5th of February 1204, during the siege of Constantinople by the Latins (Fourth Crusade). His name was Alexius Ducas Murtzuphlos, and he was a constituent of the imperial house of the Angeli. His elevation was the result of a revolution in the city against Isaac II. and Alexius IV. He conducted the defence with great bravery till it became hopeless (April 12), whereupon he fled. He would then have made common cause with Alexius III. against the Latins, but was blinded by that ex-monarch and fell into the hands of the crusaders, who put him to death by casting him from the top of the tower of Alexius as their victors.

ALEKSIUS MIKHAILOVICH (1659-1679), tsar of Muscovy, the son of Tsar Michael Romanov and Eudoxia Streshnevaya, was born on the 9th of March 1630. A youth at his father’s death (1645), he was committed to the care of the boyar Boris Ivanovich Morozov, a shrewd and sensible guardian, sufficiently enlightened to recognize the needs of his country, and by no means inaccessible to Western ideas. Morozov’s foreign policy was pacificatory. He secured the truce with Poland and carefully avoided complications with the Porte. His domestic policy was severely equitable, and aimed at relieving the public burdens by limiting the privileges of foreign traders and abolishing a great many useless and expensive courts and institutions. On the 17th of January 1648 he procured the marriage of the tsar with Maria Miloslavskaya, himself marrying her sister, Anna, ten days later. The Miloslavskies were typical self-seeking 17th century boyars, whose extortion made them generally detested. In May 1648 the people of Moscow rose against them, and the young tsar was compelled to dismiss both them and their patron Morozov. The successful issue of the Moscow riots was the occasion of disquieting disturbances all over the tsardom culminating in dangerous rebellions at Pskov and Great Novgorod, with which the government was so unable to cope that they surrendered, and the tsar, granting the malcontents their own terms. One man only had displayed equal tact and courage at Great Novgorod, the metropolitan Nikon (g.v.), who in consequence became in 1651 the tsar’s chief minister. In 1653 the weakness and disorder of Poland, which had just emerged, bleeding at every pore, from the savage Cossack war, encouraged Alexius to attempt to recover from her secular rival the old Russian lands. On the 1st of October 1653 a national assembly met at Moscow to sanction the war and find the means of carrying it on, and in April 1654 the army was blessed by Nikon (now patriarch). The campaign of 1654 was an uninterrupted triumph, and scores of towns, including the important fortress of Smolensk, fell into the hands of the Muscovites. In January 1655 the rout of Ochmatov arrested their progress; but in the summer of the same year, the sudden invasion by Charles X. of Sweden for the moment swept the Polish state out of existence; the Muscovites, unopposed, quickly appropriated nearly everything which was not already occupied by the Swedes, and when at last the Poles offered to negotiate, the whole grand-duchy of Lithuania was the least of the advantages of Alexius. Solely for Poland, the tsar and the king of Sweden now quarrelled over the apportionment of the spoil, and at the end of May 1656 Alexius, stimulated by the emperor and the other enemies of Sweden, declared war against her. Great things were expected of the Swedish war, but nothing came of it. Dorpat was taken, but countless multitudes were lost in vain before Riga. In the meantime Poland had so far recovered herself as to become a much more dangerous foe than Sweden, and, as it was impossible to wage war with both simultaneously, the tsar resolved to rid himself of the Swedes first. This he did by the peace of Kardis (July 2, 1656), whereby Muscovy retroceded all her conquests. The Polish war dragged on for six years longer and was then concluded by a truce, nominally for thirteen years, which proved the most durable of treaties. By the truce of Andrusovo (February 11, 1667) Vitebsk, Polotsk and Polish Livonia were restored to Poland, but the infinitely more important Smolensk and Kiev remained in the hands of the Muscovite together with the whole eastern bank of the Dnieper. This truce was the achievement of Athanasy Orduin-Nashchokin, the first Russian chancellor and diplomatist in the modern sense, who after the disgrace of Nikon became the tsar’s first minister till 1670, when he was superseded by the equally able Artamon Matveyev, whose beneficent influence prevailed to the end of the reign. It is the crowning merit of the ever amiable and courteous tsar Alexius that he discovered so many great men (like Nikon, Orduin, Matveyev, the best of Peter’s predecessors) and suitably employed them. He was not a man of superior strength of character, or he would never have submitted to the dictation of Nikon. But, on the other hand, he was naturally, if timorously, progressive, or he would never have encouraged the great reforming boyarovtsev. His education was necessarily narrow; yet he was learned in his way, wrote verses, and even began a history of his own times. His last years, notwithstanding the terrible rebellion of Stenka Razin, were deservedly tranquil. By his first consort he had thirteen children, of whom two sickly sons and eight healthy daughters survived him. By his second consort, Natalya Narishkina, he had two children, the tsarevich Peter and the tsarevna Natalya.

ALEKSIUS PETROVICH (1690-1718), Russian tsarevich, the sole surviving son of Peter I. and Eudoxia Lopukhina, was born on the 19th of February 1690. The young tsar married the boyarinya Lopukhina at his mother’s command. We know
nothing of the bride except that she was beautiful, modest and "brought up in the fear of the Lord. She would, doubtless, have made a modest curtesie of the pre-Petrine period, but unfortunately, she was not fit wife for such a vagabond of genius as Peter the Great. From the first her society bored Peter unaccountably, and, after the birth of their second short-lived son Alexander, on the 3rd of October 1691, he practically deserted her.

The young Alexius was ignored by his father till he was nine years old. Peter was a rare and unwelcome guest in his own family, and a son who loved his mother could have little affection for a father who had ever been that mother's worst persecutor. From his sixth to his ninth year Alexius was educated by the diffuse and pedantic Vyazemsky, but after the removal of his mother to Moscow, Monasch, one of the chief librarians of the Russian library, was confided to the care of learned foreigners, who taught him history, geography, mathematics and French. In 1703 Alexius was ordered to follow the army to the field as a private in a bombardier regiment. In 1704 he was present at the capture of Narva. At this period the preceptors of the tsarevich had the highest opinion of his ability; but, unfortunately, it was not the sort of ability that his father could make use of. He was essentially a student, with strong leanings towards archaeology and ecclesiology. A monastic library was the proper place for this gentle emotional dreamer and, to tell the truth, the character of the prince was better suited to a career in intellectual toil than to the strenuous activity of his abnormally energetic father. He liked neither the labour itself nor its object. Yet Peter, not unnaturally, wished his heir to dedicate himself to the service of new Russia, and demanded from him unceasing labour in order to maintain the brand-new state at the high level of greatness to which it had been raised. Painful relations between father and son, quite apart from the personal antipathies already existing, were therefore inevitable. It was an additional misfortune for Alexius that his father should have been too busy to attend to him just as he was growing up from boyhood to manhood. He was left in the hands of reactionary boyars and priests, who encouraged him to hate his father and wish for the death of the tsar-antichrist. His confessor, Yakov Ignatiev, whom he promised to obey as "an angel and apostle of God," was his chief counsellor in these days.

In 1708 Peter sent Alexius to Smolensk to collect provender and recruits, and thence to Moscow to fortify it against Charles XII.

At the end of 1709 he went to Dresden for twelve months for finishing lessons in French and German, mathematics and fortification, and, his education completed, he was married, greatly to the distress and unsatisfaction of his tutor, Wolfenbüttel, whose sister espoused, almost simultaneously, the heir to the Austrian throne, the archduke Charles. The wedding was celebrated at Toruń on the 14th of October 1711, in the house of the queen of Poland, and three weeks later the bridegroom was hurried away by his father to Thorn to superintend the provisioning of the Russian troops in Poland. For the next twelve months Alexius was kept constantly on the move. His wife joined him at Thorn in December, but in April 1712 a peremptory ukaz ordered him off to the army in Pomerania, and in the autumn of the same year he was forced to accompany his father on a tour of inspection through Finland. Evidently Peter was determined to tear his son away from a life of indolent ease. Immediately on his return from Finland Alexius was dispatched by his father to Staraya Russa and Ladoga to see to the building of new ships. This was the last commission entrusted to him. On his return to the capital Peter, in order to see what progress his son had made in mechanics and mathematics, asked him to draw something of a technical nature for his inspection. Alexius, in order to escape such an ordeal, resolved, what was not easy, to become an aide-de-camp of the chief aide-de-camp. A pistol-shot. In no other way could the tsarevich have offended his father so deeply. He had behaved like a cowardly recruit who mutinates himself to escape military service. After this, Peter seemed for a time to take no further interest in Alexius. He left him entirely to himself. He employed him no more.

He no longer pressed him to attend public functions. Alexius rejoiced at this welcome change, but he had cause rather to fear it. It marked the deepening of a hatred which might have been overcome. Alexius was evidently consoling himself with the reflection that the future belonged to him. He was well aware that the mass of the Russian nation was on his side. Nearly all the prelates were devoted to him. Equally friendly were the great boyar families. All Alexius had to do was to sit still, keep out of his father's way as much as possible and await the natural course of events. But with Peter the present was everything. He could not afford to leave anything to chance. All his life long he had been working incessantly with a single object—the regeneration of Russia. What if his successor refused to tread in his father's footsteps or, still worse, tried to destroy his achievements? By some such process of reasoning as this must the idea of changing the succession be considered. To be sure, Alexius and his father Peter I, have first occurred to the mind of Peter the Great. Nevertheless he made one last effort to reclaim his son. On the 22nd of October 1715 Alexius' consort, the princess Charlotte, died, after giving birth to a son, the grand-duke Peter, afterwards Peter II. On the day of the funeral Peter addressed to Alexius a stern letter of warning and remonstrance, urging him no longer to resemble the slothful servant in the parable, and threatening to cut him off, as though he were a gangrenous swelling, if he did not acquiesce in his father's plans. But it was now that Alexius freed himself from the servility which had clung to him for so long. He wrote a reply to his father, offering to renounce the succession in favour of his baby half-brother Peter, who had been born the day after the princess Charlotte's funeral. As if this were not enough, in January 1716 he wrote to his father for permission to become a monk. Still Peter did not despair. On the 26th of August 1716 he wrote to Alexius from abroad urging him, if he desired to remain tsarevich, to join him and the army without delay. Rather than face this ordeal Alexius fled to Vienna and placed himself under the protection of his brother-in-law, the emperor Charles VI., who sent him for safety first to the Tyrolean fortress of Ahrenberg, and finally to the castle of San Elmo at Naples. He was accompanied throughout his journey by his mistress, the Finnish girl Afroswa. That the emperor sincerely sympathized with Alexius, and suspected Peter of harbouring murderous designs against his son, is plain from his confidential letter to George I. of England, whom he consulted on this delicate affair.

Peter's agitation was extreme. The flight of the tsarevich to a foreign potentate was a reproach and a scandal. He must be recovered and brought back to Russia at all hazards. This difficult task was accomplished by Count Peter Tolstoi, the husband of the tsar's sister-in-law, and accomplice of the tsarevich's servants; but it was not without a struggle. Though he was, Alexius would only consent to return on his father solemnly swearing, "before God and His judgment seat," that if he came back he should not be punished in the least, but cherished as a son and allowed to live quietly on his estates and marry Afroswa. On the 31st of January 1718 the tsarevich reached Moscow. Peter had already determined to institute a most searching inquisition in order to get at the bottom of the mystery of the flight. On the 18th of February a "confession" was extorted from Alexius which implicated most of his friends, and he then publicly denounced the succession to the throne in favour of the baby grand-duke Peter Petrovich. A horrid reign of terror ensued, in the course of which the ex-tsarsita Eudoxia was dragged from her monastery and publicly tried for alleged adultery, while all who had in any way befriended Alexius were impaled, broken on the wheel and otherwise lingeringly done to death. All this was done to terrorize the reactionaries and isolate the tsarevich. In April 1718 fresh confessions were extorted from Alexius, now utterly broken and half idiotic with fright. Yet even now there were no actual facts to go upon. Most subtle and cunning as Peter's agents were, not even they had not been, perhaps never would be, translated into practice. The worst that could be brought against him was that he had wished his father's death. In the eyes of Peter, his son was now a self-convicted and most dangerous traitor, whose life was forfeit. But there was no getting over the fact that his father had sworn "before the Almighty and His judgment seat" to pardon him and let him live in peace if he returned to Russia. From Peter's
point of view the question was, did the enormity of the tsarevich's crime absorb the tsar from the oath which he had taken to spare the life of this prodigal son? This question was solemnly submitted to a grand council of prelates, senators, ministers and other dignitaries on the 13th of June 1718. The clergy left the matter to the tsar's own decision. The temporal dignitaries declared the evidence to be insufficient and suggested that Alexius should be examined by torture. Accordingly, on the 19th of June, the weak and ailing tsarevich received twenty-five strokes with the knout (as then administered nobody ever survived thirty), and on the 24th fifteen more. It was hardly possible that he could survive such treatment; the natural inference is that he was not intended to survive it. Anyway, he expired two days later in the guardhouse of the citadel of St Petersburg, two days after the senate had condemned him to death for insubordination against his father, and for hoping for the co-operation of the common people and the armed intervention of his brother-in-law, the emperor. This shameful sentence was the outcome of mingled terror and obsequiousness. Abominable, unnatural as Peter's conduct to his unhappy and innocent son undoubtedly was, there is no reason to suppose that he ever regretted it. He argued that a single worthless life stood in the way of the regeneration of Russia, and he therefore deliberately removed it.

ALFANI, DOMENICO, Italian painter, was born at Perugia towards the close of the 15th century. He was a contemporary of Raphael, with whom he studied in the school of Perugino. The two artists lived on terms of intimate friendship, and the influence of the more distinguished of the two is so clearly traceable in the works of the other, that these have frequently been attributed to Raphael. Towards the close of his life Alfani gradually changed his style and approximated to that of the later Florentine school. The date of his death, according to some, was 1546; but others say he was alive in 1553. Pictures by Alfani may be seen in collections at Florence and in several churches in Perugia.

ALFELD, a town of Germany, in the Prussian province of Hanover, 10 m. W. of Hildesheim, on the river Leine and the Hanover-Cassel main line of railway. Pop. (1900) 4900. It has a handsome church with twin spires, and training colleges for schoolmasters and theological candidates. Its industries are flourising, and embrace paper-making, agricultural machine-work, iron-founding and flax-spinning.

ALFIERI, VITTORIO, Count (1749-1803), Italian dramatist, was born on the 17th of January 1749 at Asti in Piedmont. He lost his father in early infancy; but he continued to reside with his mother, who married a second time, till his tenth year, when he was placed at the academy of Turin. After he had passed a twelvemonth at the academy, he went on a short visit to a relation who dwelt at Coni; and during his stay there he made his first poetical attempt in a sonnet chiefly borrowed from lines in Ariosto and Metastasio, the only poets he had at that time read. When thirteen years of age he was induced to begin the study of civil and canonical law; but the attempt only served to disgust him with every species of application and to increase his relish for the perusal of French romances. By the death of his uncle, who had hitherto taken some charge of his education and conduct, he was left, at the age of fourteen, to enjoy without control his vast paternal inheritance, augmented by the recent accession of his uncle's fortune. He now began to attend the riding-school, where he acquired that rage for horses and equestrian exercise which continued to be one of his strongest passions till the close of his existence.

After some time spent in alternate fits of extravagant dissipation and ill-directed study, he was seized with a desire of traveling; and having obtained permission from the king, he departed in 1766, under the care of an English preceptor. Restless and unquiet, he posted with the utmost rapidity through the towns of Italy; and his improvement was such as was to be expected from his mode of travelling and his previous habits. Hoping to find in foreign countries some relief from the tedious and ennui with which he was oppressed, and being anxious to become acquainted with the French theatre; he proceeded to Paris. But he appears to have been completely dissatisfied with everything he had seen in France and the remembrance of his life was devoted to augment than diminish. In Holland he became deeply enamoured of a married lady, who returned his attachment; but he was soon obliged to accompany her husband to Switzerland. Alfieri, whose feelings were of the most impetuous description, was in despair at this separation, and returned to his own country in the utmost anguish and despondency of mind. While under this depression of spirits he was induced to seek alleviation from works of literature; and the perusal of Plutarch's *Lives*, he read with profound emotion, inspired him with an enthusiastic passion for freedom and independence. Under the influence of this rage for liberty he recommenced his travels; and his own gratification, in the absence of freedom among the continental states, appears to have been derived from contemplating the wild and sterile regions of the north of Sweden, where gloomy forests, lakes and precipices conspired to excite those sublime and melancholy ideas which were congenial to his disposition. Everywhere his soul felt as if confined by the bonds of society; he panted for something more free in government, more elevated in sentiment, more devoted in love and more perfect in friendship. In search of this ideal world he passed through various countries more with the rapidity of a courier than of one who travels for amusement or instruction. During a journey to London he engaged in an intrigue with a married lady of high rank; and having been detected, the publicity of a rencontre with the injured husband, and of a divorce which followed, rendered it expedient and desirable for him to quit England. He then visited Spain and Portugal, where he became acquainted with the Abbe Caluso, who remained through life the most attached and estimable friend he ever possessed. In 1777 Alfieri returned to France; and lived in Paris for a time with the Abbé Tournefort, and Turinetti di Prie, whom he loved with his usual ardent, and who seems to have been as undeserving of a sincere attachment as those he had hitherto adored. In the course of a long attendance on his mistress, during a malady with which she was afflicted, he one day wrote a dialogue or scene of a drama, which he left at her house. On a difference taking place between them the piece was returned to him, and being retouched and extended to five acts, it was performed at Turin in 1775, under the title of *Cleopatra*.

From this moment Alfieri was seized with an insatiable thirst for the composition of verse and drama, and the remainder of his life was devoted to its attainment. His first two tragedies, *Filippo* and *Polinesie*, were originally written in French prose; and when he came to versify them in Italian, he found that, from his Lombard origin and long intercourse with foreigners, he expressed himself with feebleness and inaccuracy. Accordingly, with the view of improving his Italian style, he went to Tuscany and, during an alternate residence at Florence and Siena, he completed his *Filippo* and *Polinesie*, which were originally written in French prose; and when he came to versify them in Italian, he found that, from his Lombard origin and long intercourse with foreigners, he expressed himself with feebleness and inaccuracy. Accordingly, with the view of improving his Italian style, he went to Tuscany and, during an alternate residence at Florence and Siena, he completed his *Filippo* and *Polinesie*, and conceived the plan of various other dramas. While thus employed he became acquainted with the countess of Albany, who then resided with her husband at Florence. For her he formed an attachment which, if less violent than his former loves, appears to have been more permanent. With this motive to remain at Florence, he could not endure the chains by which his vast possessions bound him to Piedmont. He therefore resigned his whole property to his sister, the countess Cumiana, reserving an annuity which scarcely amounted to a half of his original revenues. At this period the countess of Albany, urged by the ill-treatment she received from her husband, sought refuge in Rome, where she at length received a hope to live apart from her tormentor. Alfieri followed the countess to that capital, where he completed fourteen tragedies, four of which were now for the first time printed at Siena.

At length, however, it was thought proper that, by leaving Rome, he should remove the aspersions which had been thrown on the object of his affections. During the year 1783 he
therefore travelled through different states of Italy, and published six additional tragedies. The interests of his love and literary glory had not diminished his rage for horses, which seems to have been at least the third passion of his soul. He came to England solely for the purpose of purchasing a number of these animals, which he carried with him to Italy. On his return he learned that the countess of Albany had gone to Colmar in Alsace, where he joined her, and resided with her under the same roof during the rest of his life. They chiefly passed their time between Alsace and Paris, but at length took up their abode entirely in that metropolis. While here, Alfieri made arrangements with Didot for an edition of his tragedies, but soon after forced by the storms of the revolution. He recrossed the Alps with the countess, and finally settled at Florence. The last ten years of his life, which he spent in that city, seem to have been the happiest of his existence. During that long period his tranquillity was only interrupted by the entrance of the Revolutionary armies into Florence in 1799. Though an enemy of kings, the aristocratic feeling of Alfieri rendered him also a decided foe to the principles and leaders of the French Revolution; and he rejected with the utmost contempt those advances which were made with view to bringing him over to that cause. The concluding years of his life were laudably employed in the study of the Greek literature and in perfecting a series of comedies. His assiduous labour on this subject, which he pursued with his characteristic impetuosity, exhausted his strength, and brought on a malady for which he would not adopt the prescriptions of his physicians, but obstinately persisted in employing remedies of his own. His disorder rapidly increased, and he died on the 8th of October 1803.

The character of Alfieri may be best appreciated from the portrait which he has drawn of himself in his own Memoirs of his Life. He was evidently of an irritable, impetuous and almost ungovernable temper. Pride, which seems to have been a ruling sentiment, may account for many apparent inconsistencies of his character. But his less amiable qualities were greatly softened by the cultivation of literature. His application to study gradually tranquilized his temper and softened his manners, leaving him at the same time in perfect possession of those good qualities which he had inherited from nature—a warm and disinterested attachment to his family and friends, united to a generosity, vigour and elevation of character, which rendered him not unworthy to embley in his dramas the actions and sentiments of Grecian heroes.

It is to his dramas that Alfieri is chiefly indebted for the high reputation he has attained. Before his time the Italian language, so harmonious in the Sonnets of Petrarch and so energetic in the Commedia of Dante, had been invariably languid and prosaic in dramatic dialogue. The pedantic and inanimate tragedies of the 16th century were followed, during the iron age of Italian literature, by dramas of which extravagance in the sentiments and improbability in the action were the chief characteristics. The prodigious success of the Merope of Massfet, which appeared in the commencement of the 18th century, may be attributed more to a comparison with such productions than to intrinsic merit. In this degradation of tragic taste the appearance of the tragedies of Alfieri was perhaps the most important literary event that had occurred in Italy during the 18th century. On these tragedies it is difficult to pronounce a judgment, as the taste and system of the author underwent considerable change and modification during the intervals which elapsed between the three periods of their publication. An excessive harshness of style, an aspersion of sentiment and total want of poetical ornament are the characteristics of his first four tragedies, Filippo, Polinice, Antigone and Virginia. These faults were in some measure corrected in the sixth tragedies which he gave to the world some years after, and in those which he published along with Saul, the drama which enjoyed the greatest success of all his productions—a popularity which may be partly attributed to the severe and unadorned manner of Alfieri being well adapted to the patriarchal simplicity of the age in which the scene of the tragedy is placed. But though there be a considerable difference in his dramas there are certain observations applicable to them all. None of them are his own invention. They are founded either on mythological fable or history; most of them had been previously treated by the Greek dramatists or by Seneca. Rosmundo, the only one which could be supposed of his own contrivance, and which is certainly the least happy effusion of his genius, is partly founded on the eighteenth novel of the third part of Bandello and partly on Prevost's Mémoires d’un homme de qualité. But whatever subject he chooses, his dramas are always formed on the Grecian model and breathe a freedom and independence worthy of an Athenian poet. Indeed, his Agide and Bronte may be rather considered oratorical declamations and dialogues of liberty and perils. The unities of time and place are not so scrupulously observed in his as in the ancient dramas; but he has rigidly adhered to a unity of action and interest. He occupies his scene with one great action and one ruling passion, and removes from it every accessory event or feeling. In this excessive zeal for the observance of unity he seems to have forgotten that its charm consists in producing a common relation between multiple feelings, and not in the bare exhibition of one, divested of those various accompaniments which give harmony to that species of a drama. Consistently with that austere and simple manner which he considers the true spirit of the dramatic composition, he excluded from his scene all coups de théâtre, all philosophical reflexions, and that highly ornamented versification which had been so assiduously cultivated by his predecessors. In his anxiety, however, to avoid all superfluous ornament, he has stripped his dramas of the embellishments of imagination; and for the harmony and flow of poetical language he has substituted, even in his best performances, a style which, though correct and pure, is generally harsh, elaborate and abrupt; often strained into unnatural energy or condensed into facetious conciseness. The chief excellence of Alfieri consists in powerful delineation of dramatic character. In his Filippo he has represented, almost with the masterly touches of Tacitus, the sombre character, the dark mysterious counsels, the suspensa semper et obscura verba, of the modern Tiberius. In Polinice, the characters of the rival brothers are beautifully contrasted; in Maria Stuarda, that unfortunate queen is represented unsuspicious, impatient of contradiction and violent in her attachments. In Mira, the character of Cinio is perfect as a father and king, and Cecri is a model of a wife and mother. In the representation of that species of mental alienation where the judgment has perished but traces of character still remain, he is peculiarly happy. The insanity of Saul is skilfully managed; and the horrid joy of Orestes in killing Aegisthus rises finely and naturally to madness in finding that, at the same time, he had inadvertently slain his mother.

Whatever may be the merits or defects of Alfieri, he may be considered as the founder of a new school in the Italian drama. His country hailed him as her sole tragic poet; and his successors in the same path of literature have regarded his bold, austere and rapid manner as the genuine model of tragic composition. Besides his tragedies, Alfieri published during his life many sonnets, five odes on American independence and the poem of Etruria, founded on the assassination of Alexander L., duke of Florence. Of his prose works the most distinguished for animation and eloquence is the Pamegryc on Trajan, composed in a transport of indignation at the supposed feehlessness of Pliny's eulogium. The two books entitled La Turinide and the Essays on Literature and Government are remarkable for elegance and vigour of style, but are too evidently imitations of the manner of his M. de Voltaire. His Antiquities of Rome, which was written at the same time with his Defence of Louis XVI., comprehends an historical and satirical view of the French Revolution. The posthumous works of Alfieri consist of satires, six political comedies and the Memoirs of his Life—a work which will always be read with interest, in spite of the cold and languid gravity with which he delineates the most interesting adventures and the strongest passions of his agitated life.

ALFORD—ALFRED THE GREAT

Life of Alferi, by Centofanti (Florence, 1842); Vita, Giorraali, Lettre di Alferi, by Tenai (Florence, 1861); Vittorio Alferi, by Antonini and Cognetti (Turin, 1898).

ALFORD, HENRY (1810-1871), English divine and scholar, was born in London on the 7th of October 1810. He came of a Somersetshire family, which had given five consecutive generations of clergymen to the Anglican church. Alford’s early years were passed with his widowed father, who was curate of Steeple Ashton in Wiltshire. He was an extremely precocious lad, and before he was ten had written several Latin odes, a history of the Jews and a series of homiletic outlines. After a parochial school course he went up to Cambridge in 1827 and entered Christ’s College. In 1832 he was 34th wrangler and 8th classic, and in 1834 was made fellow of Trinity. He had already taken orders, and in 1835 began his eighteen years’ tenure of the vicarage of Wymeswold in Leicestershire, from which seclusion the twice-repeated offer of a colonial bishopric failed to draw him. He was Hulsean lecturer at Cambridge in 1841-1842, and steadily built up a reputation as scholar and preacher, which would have been enhanced but for his discursive ramblings in the fields of mystics and minor magazines. In September 1853 Alford removed from Quebec Chapel to which he had charge and cultured congregation. In March 1857 Viscount Palmerston advanced him to the deanship of Canterbury, where, till his death on the 12th of January 1871, he lived the same strenuous and diversified life that had always characterized him. The inscription on his tomb, chosen by himself, is “Diversiorum Viatoris Hierosolymam Pretiosissimi.”

ALFORD was a not inconconsiderable artist, as his picture-book, The Riviera (1870), shows, and he had abundant musical and mechanical talent. Besides editing the works of John Donne, he published several volumes of his own verse, The School of the Heart (1835), The Abbot of Muchelney (1841), and a number of hymns, the best-known of which are “Forward! be our watchword,” “Come, ye thankful people, come,” and “Ten thousand times ten thousand.” He translated the Odyssey, wrote a well-known manual of idiom, A Plea for the Queen’s English (1863), and was the first editor of the Contemporary Review (1866-1870). His chief fame, however, rests upon his monumental edition of the New Testament in Greek (4 vols.), which occupied him from 1841 to 1861. In this work he first brought before English students a careful collation of the readings of the chief MSS. and the researches of the ripest continental scholarship of his day.Philological rather than theological in character, it marked an epochal change from the old homiletic commentary, and though more recent research, patriarchal and papyrological, has largely changed the method of New Testament exegesis, Alford’s work is still a quarry where the student can dig with a good deal of profit.

His Life, written by his widow, appeared in 1873 (Rivington).

A. J. G.

ALFRED, or ALFRED, known as The Great (848-899), king of England, was born in 848 at Wantage, and was the fourth son of King Æthelwulf and his first wife (Osburh). He seems to have been a child of singular attractiveness and promise, and stories of his boyhood were remembered. At the age of five (853) he was sent to Rome, where he was confirmed by Leo IV., who is also stated to have “hallowed him as king.” Later writers interpreted this as an anticipatory crowning in preparation for his ultimate succession to the throne of Wessex. That, however, could not have been foreseen in 853, as Alfred had three elder brothers living. It is probably to be understood either of investiture with the consular insignia, or possibly with some titular royalty such as that of the under-kingdom of Kent. In 855 Alfred again went to Rome with his father Æthelwulf, returning towards the end of 856. About two years later his father died. During the short reigns of his two eldest brothers, Æthelbald and Æthelberht, nothing is heard of Alfred. But with the accession of the third brother Æthelred (866) the public life of Alfred begins, and he enters on his great work of delivering England from the Danes. It is in this reign that Asser applies to Alfred the unique title of secundarius, which seems to indicate a position analogous to that of the Celtic tanist, a recognized successor, closely associated with the reigning prince. It is probable that this arrangement was definitely sanctioned by the witenagemot, to guard against the danger of a disputed succession should Æthelred fall in battle. In 868 Alfred married Ealhswith, daughter of Æthelred Mucil, who is called ealdorman of the Gains, an unidentified district. The same year the two brothers marched northward, to relieve the unsuccessful Essex of the pressure of the Danes. For nearly two years Wessex had a republic, but at the end of 870 the storm burst; and the year which followed has been rightly called “Alfred’s year of battles.” Nine general engagements were fought with varying fortunes, though the place and date of two of them have not been recorded. A successful skirmish at Englefield, Berks (December 31, 870), was followed by a severe defeat at Reading (January 4, 871), and this, four days later, by the brilliant victory of Ashdown, near Compton Beauchamp in Shrivehampton Hundred. On the 22nd of January the English were again defeated at Basing, and on the 22nd of March at Marton, Wilts, the two unidentified battles having perhaps occurred in the interval. In April Æthelred died, and Alfred succeeded to the whole burden of the contest. While he was busied with his brother’s exequies, the Danes defeated the English in his absence at an unnamed spot, and once more in his presence at Wilton in May. After this peace was made, and for the next five years the Danes were occupied in other parts of England, Alfred merely keeping a force of observation on the frontier. But in 876 part of the Danes managed to slip past him and occupied Wareham; whence, early in 877, urged on by treacherous negotiations, they made a dash westwards and seized Exeter. Here Alfred blockaded them, and a relieving fleet having been scattered by a storm, the Danes had to submit and withdrew to Mercia. But in January 878 they made a sudden swoop on Chippenham, a royal villa in which Alfred had been keeping his Christmas, and most of the people they reduced, except the King Alfred, and he with a little band made his way . . . by wood and swamp, and after Easter he . . . made a fort at Athelney, and from that fort kept fighting against the foe” (Chron.). The idea that Alfred, during his retreat at Athelney, was a helpless fugitive rests upon the foolish legend of the cakes. In reality he was organizing victory. By the middle of May his preparations were complete and he moved out of Athelney, being joined on the way by the levies of Somerset, Wilts and Hants. The Danes on their side moved out of Chippenham, and the two armies met at Edington in Wiltshire. The result was a decisive victory for Alfred. The Danes submitted. Guthrum, the Danish king, and twenty-nine of his chief men accepted baptism. By the next year (879) not only Wessex, but Mercia, west of Walling Street, was cleared of the invader. This is the arrangement known as the peace of Wedmore (878), though no document embodying its provisions is in existence. And though for the present the north-eastern half of England, including London, remained in the hands of the Danes, in reality the tide had turned, and western Europe was saved from the danger of becoming a heathen Scandinavian power. For the next few years there was peace, the Danes being kept busy on the continent. A landing in Kent in 884 or 885, though unsuccessfully repelled, encouraged the East Anglian Danes to revolt. The measures taken by Alfred to repel this revolt culminated in the capture of London in 885 or 886, and the treaty known as Alfred and Guthrum’s peace, whereby the boundaries of the treaty of Wedmore (with which this is often confused) were materially modified in Alfred’s favour. Once more for a time there was a lull; but in the autumn of 892 (893) the final storm burst. The Danes, finding their position on the continent becoming more and more precarious, crossed to England in two divisions, amounting in the aggregate to 3,309 sail, and entrenched themselves, the larger body at Appledore and the lesser under Haesten at Milton in Kent. The fact that the new invaders brought their wives and children with them shows that this was no mere raid, but a deliberate

1 Where alternative dates are given the later date is that of the Saxon Chronicle. But the evidence of the Continental Chronicle makes it probable that the Saxon Chronicle is one year in advance of the true chronology in this part.
attempt, in concert with the Northumbrian and East Anglian Danes, to conquer England. Alfred, 893 (894), took up a position whence he could observe both forces. While he was negotiating with Haesten the Danes at Appleford broke out and struck north-westwards, but were overtaken by Alfred's eldest son, Edward, and defeated in a general engagement at Farnham, and driven to take refuge in Thorney Island in the Hertfordshire Colne, where they were blockaded and ultimately compelled to surrender. They then fell back on Essex, and after suffering another defeat at Benfleet coalesced with Haesten's force at Shoebury. Alfred had been on his way to the southern half of the island are clearer. They obstructed the river so as to prevent the egress of the Danish ships. The Danes realized that they were out-maneuvered. They struck off north-westwards and wintered at Bridgenorth. The next year, 896 (897), they abandoned the struggle. Some retired to Northumbria; some to East Anglia; those who had no connexion in England withdrew to the continent. The long campaign was over. The result testifies to the confidence inspired by Alfred's character and generalship, and to the efficacy of the militia and the fyrdr of national militia into two parts, relieving each other at fixed intervals, so as to ensure continuity in military operations; (2) the establishment of fortified posts (burgs) and garrisons at certain points; (3) the enforcement of the obligations of homage on all owners of five hides of land, thus giving the king a nucleus of highly equipped troops. After the final dispersal of the Danish invaders Alfred turned his attention to the increase of the navy, and ships were built according to the king's own designs, partly to repress the ravages of the Northumbrian and East Anglian Danes on the coasts of Wessex, partly to prevent the landing of fresh hordes. This is not, as often asserted, the beginning of the English navy. There had been earlier naval operations under Alfred. One naval engagement was certainly fought under Ethelfulf (851), and earlier ones, possibly in 833 and 840. Nor were the new ships a great success, as we hear of themgrounding in action and foundering in a storm. Much, too, was needed in the way of civil re-organization, especially in the districts ravaged by the Danes. In the parts of Mercia acquired by Alfred, the shire system seems now to have been introduced for the first time. This is the one great truth in the legend that Alfred was the inventor of shires, hundreds and tithings. The finances also would need careful attention; but the subject is obscure, and we cannot accept Asser's description of Alfred's appropriation of his revenue as more than an ideal sketch. Alfred's care for the administration of justice is testified both by history and legend; and the title "protector of the poor" was his by unquestioned right. Of the action of the witenagemot we do not hear very much under Alfred. That he was anxious to respect its rights is conclusively proved, but both the circumstances of the time and the character of the king would tend to throw more power into his hands. The legislation probably belongs to the later part of the reign, after the pressure of the Danes had relaxed. The details of it cannot be discussed here. Asser speaks grandiosely of Alfred's relations with foreign powers, but little definite information is available. He certainly corresponded with Elias III., the patriarch of Jerusalem, and probably sent a mission to India. Embassies to Rome conveying the English aims to the pope were fairly frequent; while Alfred's interest in foreign countries is shown by the inscriptions which he made in his translation of Orosius. His relations to the Celtic princes was shown when, in late the year 896, he made the Danes. The Danes, and the practical extinction of the knowledge of Latin among the clergy. The translation of Gregory's Pastoral Care bears eloquent testimony. It was to remedy these evils that he established a court school, after the example of Charles the Great; for this he imported scholars like Grimbald and John the Saxon from the continent and Asser from South Wales; for this, above all, he put himself to school, and made the series of translations for the instruction of his clergy and people, most of which still survive. These belong unquestionably to the last part of his reign, not improbably to the last four years of it, during which the chronicles are almost silent. Apart from the lost Handwroth or Encheiridion, which seems to have been merely a commonplace-book kept by the king, the earliest work to be translated was the Dialogues of Gregory, a book enormously popular in the middle ages. In this case the translation was made by Alfred's great friend Wærferth, bishop of Worcester, the king merely furnishing a preface. The next work to be undertaken was Gregory's Pastoral Care, especially for the benefit of the clergy. In this Alfred keeps very close to his original; but the introduction which he prefixed to it is one of the most interesting documents of the reign, or indeed of English history. The next two works taken in hand were historical, the Universal History of Orosius and Bede's Ecclesiastical History of the English People. The priority should probably be assigned to the Orosius, but the point has been much debated. In the Orosius, by omissions and additions, Alfred so remodels his original as to produce an almost new work; in the Bede the author's text is closely adhered to, no additions being made, though most of the documents and some other less interesting matters are omitted. Of late years doubts have been raised as to Alfred's authorship of the Bede translation. But the sceptics cannot be regarded as having proved their point. We come now to what is in many ways the most interesting of Alfred's works, his translation of Boethius' Consolation of Philosophy, the most popular philosophical manual of the middle ages. Here again Alfred deals very freely with his original and though the late Dr G. Scheppe showed that many of the additions to the text are to be traced not to Alfred himself, but to the glosses and commentaries which he used, still there is much in the work which is solely Alfred's and highly characteristic of his genius. It is in the Boethius that the oft-quoted sentence occurs: "My will was to live worthily as long as I lived, and after my life to leave to them that should come after, my memory in good
works." The book has come down to us in two MSS. only. In one of these the poems with which the original is interspersed are rendered into prose, in the other into alliterating verse. The authorship of the latter has been much disputed; but probably they also are by Alfred. Of the authenticity of the work as a whole there has never been any doubt. The last of Alfred's works, to which he gave a fitting epitaph for the noblest of English kings. "Therefore he seems to me a very foolish man, and very wretched, who will not increase his understanding while he is in the world, and ever wish and long to reach that endless life where all shall be made clear."

Besides these works of Alfred's, the Saxon Chronicle almost certainly, and a Saxon Martyrology, of which fragments only exist, probably owe their inspiration to him. A prose version of the first fifty Psalms has been attributed to him; and the attribution, though not proved, is perfectly possible. How Alfred passed to "the life where all things are made clear" we do not know. The very year is uncertain. The arguments on the whole are in favour of 900. The day was the 26th of October. Allike for what he did and for what he was, there is none to equal Alfred in the whole line of English sovereigns; and no monarch in history ever deserved more truly the epithet of Great.

BIBLIOGRAPHY.—The chief original authorities for the reign of Alfred are the so-called Life by Asser (best edition by W. H. Stevenson, Cherson, 1905); and the Saxon Chronicles (text and notes by Earle and Plummer, 2 vols., Clar. Press, 1892–1899; parallel translation, The Anglo-Saxon Chronicle, 2 vols., 1861–1863, translation alone, Joseph Stevenson in Church Historians of England, vol. ii., 1853). The above sketch is based mainly on C. Plummer's Life and Times of Alfred the Great (Clar. Press, 1902). Of earlier biographies, the one by Bede is still of considerable value: (Bede, The Ecclesiastical History of the English People, trans. by Thorpe (Bohn, 1853).) Eng. trans. by Thorpe (Bohn, 1853).) Of recent works mention may be made of Alfred the Great, Chapters on his Life and Times, by various authors, edited by Alfred Bowker (1899); Earle, The Alfred Jewel (Clar. Press, 1901).

ALFRED ERNEST ALBERT, duke of Saxe-Coburg and Gotha, and duke of Edinburgh (1844–1900), second son and fourth child of Queen Victoria, was born at Windsor Castle on the 6th of August 1844. In 1856 it was decided that the prince, in accordance with his own wishes, should enter the navy, and a separate establishment was accordingly assigned to him, with Lieutenant Sowell, R. E., as governor. He passed a most creditable examination for midshipman in August 1858, and was appointed to the "Euryalus," at once began to work hard at the practical part of his duties. In 1859 he accompanied, while on this ship, he paid an official visit to the Cape, and made a very favourable impression both on the colonials and on the native chiefs. On the abdication of Otto, king of Greece, in 1862, Prince Alfred was chosen by the whole people to succeed him, but political conventions of long standing rendered it impossible for the British government to accede to their wishes. The prince therefore remained in the navy, and was promoted lieutenant on the 24th of February 1863 and captain on the 23rd of February 1866, being then appointed to the command of the "Galatea." On attaining his majority in 1865 the prince was created duke of Edinburgh, 1st of January, 1866, with an annuity of £15,000 granted by parliament. While still in command of the "Galatea" the duke started from Plymouth on the 24th of January 1867 for his voyage round the world. On the 11th of June 1867 he left Gibraltar and reached the Cape on the 24th of July, and landed at Glenelg, South Australia, on the 31st of October. Being the first English prince to visit Australia, the duke was received with the greatest enthusiasm. During his stay of nearly five months he visited Adelaide, Melbourne, Sydney, Brisbane and Tasmania; and it was on his second visit to Sydney that, while attending a public picnic at Castlefield in aid of the Sailors' Home, an Irishman named O'Farrell shot him in the back with a revolver. The wound was fortunately not dangerous, and within a month the duke was able to resume command of his ship and return home. He reached Spithead on the 26th of June 1868, after an absence of seventeen months. The duke's next voyage was to India, where he arrived in December 1869. Both there and at Hong Kong, which he visited on the way, he was the first British prince to set foot in the country. The native rulers of India vied with one another in the magnificence of their entertainments during the duke's stay there. On 27th April 1870 the duke, on the occasion of the visit of the duke to the grand-duchess Marie Alexandrovna, only daughter of Alexander II., emperor of Russia, was celebrated at St Petersburg, and the bride and bridegroom made their public entry into London on the 12th of March. The duke still devoted himself to his profession, showing complete mastery of his duties and unusual skill in naval tactics. He was promoted rear-admiral on the 30th of December 1878; vice-admiral, 10th of November 1882; admiral, 18th of October 1887; and received his baton as admiral of the Fleet, 3rd of June 1893. He commanded the Channel fleet, 1883–1884; the Mediterranean fleet, 1886–1889; and was commander-in-chief at Davenport, 1890–1893. He always paid the greatest attention to his official duties and was most efficient as an admiral.

On the death of his uncle, Ernest II., duke of Saxe-Coburg and Gotha, on the 22nd of August 1893, the vacant duchy fell to the duke of Edinburgh, for the prince of Wales had renounced his right to the succession. At first regarded with some coldness as a "foreigner," he gradually gained popularity, and by the time of his death, on the 30th of July 1900, he had completely won the good opinion of his subjects. The duke was exceedingly fond of music and an excellent violinist, and took a prominent part in establishing the Royal College of Music. He was also a keen collector of glass and ceramic ware, and his collection, valued at half a million of marks, was presented by his widow to the "Veste Coburg," near Coburg. When he became duke of Saxe-Coburg he surrendered his English allowance of £15,000 a year, but the £10,000 granted in addition by parliament on his marriage he retained in order to keep up Clarence House. The duke had one son, who died unmarried on the 6th of February 1899, and four daughters. The third daughter, Princess Alexandra Louise Olga Victoria, was in 1893 the betrothed princess of the hereditary prince Ernest of Hohenlohe-Langenburg, who became regent of the duchy of Coburg during the minority of the deceased duke's nephew, the young duke of Albany, to whom the succession fell.

(G. F. B.)

ALFRED, a village in the township of Alfred, Allegany county, New York, U.S.A., about 75 m. S.W. of Buffalo. Pop. of the township, including the village (1900), 1615; (1910 U.S. census) 1590. Pop. of the village (1900) 735; (1910 U.S. census) 739. The township is served, at Alfred station, by the Erie railway. The village, which is connected by stage with the station, is situated at the junction of two valleys and commands delightful views of mountain scenery. On the west slope of Pine Hill is Alfred University (co-educational), which embraces
a college (non-acctarian), an academy (non-acctarian) and a theological seminary (Seventh-Day Baptist). Closely associated with it also, and under the management of the university trustees, is the New York State School of Clay-Working and Ceramics (1906), one of the most efficient schools of the kind in the country. In 1908 the legislature of New York appropriated $80,000 for the establishment of a state school of agriculture in connexion with the university. The institution had its beginning in 1836 in a private school. This developed into an academy, which in 1843 was incorporated as Alfred Academy and Teachers' Seminary; in 1857 the university was chartered under its present name. The principal industry of the village is the manufacture of roofing tiles. The township of Alfred lies within the territory held by Robert Morris in 1791. He sold it in the same year to a company resident in London, England. Their agent sold most of it to settlers and, it is said, named the township, when it was organized in 1806, in honour of Alfred the Great. The first settlement within its present limits was made in 1807. For several years most of the settlers were Seventh-Day Baptists, and in 1812 they organized a church here. The village of Alfred was chartered in 1857.

J. S. Minard, Allegany County and its People (Alfred, 1896).

ALFRED, a market town in the mid-parliamentary division of Derbys, Eng. Pop. N. E. of Derby and rail. Pop. of urban district (1901) 17,955. It lies at a considerable elevation above the valley of a small stream tributary to the Derwent. The church of St Martin is Early English and later. The neighbourhood abounds in ironworks, collieries, quarries and potteries, and is thickly populated. To the north-east of Alfred are South Normanton (pop. 5170), Blackwell (4144) and Tibshelf (3432); to the north Shirlston (3929), to the south Ironville and other busy industrial villages. The foundation of Alfred is traditionally ascribed to King Alfred.

ALFURUS (Alfred, Horatius), a term of no ethnological value, which the Malays to all the uncivilized non-Mahomedan peoples in the eastern portion of the Malay Archipelago. Its origin is uncertain, but its meaning is "wild" or "uncivilized." The term is not restricted to the aborigines, but is far more frequently used to describe the tribes of Malay blood.

ALGAE. The Latin word alga seems to have been the equivalent of the English word "seaweed," and probably stood for any or all of the species of plants which form the "wrack" of a seashore. The word "Algae" appears to have been employed in botanical classification as the name of a class, an arbitrary limitation had to be set to its signification, and this was not always in keeping with its original meaning. The absence of differentiation into root, stem and leaf which prevails among seaweeds, seems, for example, to have led Linnaeus to employ the term in the Genera Plantarum for a sub-class of Cryptogamia, the members of which presented this character in a greater or less degree. Of the fifteen genera included by Linnaeus among algae, not more than six—viz. Chaeta, Fucus, Ulva and Convera, and in part Tremella and Byssus—would to-day, in any sense in which the term is employed, be regarded as algae. The excluded genera are distributed among the liverworts, lichens and fungi; but notwithstanding the great advance in knowledge since the time of Linnaeus, the difficulty of deciding what limits to assign to the group seems to be designated Algae still remains. It arises from the fact that algae, as generally understood, do not constitute a homogeneous group, suggesting a descent from a common stock. Among them exist, as will be seen hereafter, many well-marked but isolated classes. Their instruction in the larger group is generally felt to be a matter of convenience rather than the expression of a belief in their close inter-relationship. Efforts are therefore continually being made by successive writers to exclude certain outlying sub-groups, and to reserve the term Algae for a central group reconstituted on a more natural basis within narrower limits.

It is perhaps desirable, in an article like this, to treat of algae in the widest possible sense in which the term may be used, an indication being at the same time given of the narrower senses in which it has been proposed to employ it. Interpreted in this way, the place of algae in the vegetable kingdom may be shown by means of a table—

<table>
<thead>
<tr>
<th>The Vegetable Kingdom</th>
<th>Cryptogamia</th>
<th>Thallophyta</th>
<th>Myxomycetes</th>
</tr>

<td></td>
<td>Gymnosperms</td>
<td>Angiosperms</td>
</tr>
</tbody>
</table>

Algae in this wide sense may be briefly described as the aggregate of those simpler forms of plant life usually devoted, like the rest of the Thallophyta, of differentiation into root, stem and leaf; but, unlike other Thallophyta, possessed of a colouring matter; by means of which they can use the atmospheric carbonic acid. A more important distinction, the occasional absence of this colour in species, or groups of species, with, in other respects, algal affinities. Such aberrant forms are to be regarded in the same light as Cuscuta and Orobancheae, for example, among Phanerogams. As these non-green plants do not cease to be classed with other Phanerogams, so must the forms in question be retained among algae. In all cases the loss of the colouring matter is associated with an incapacity to take up carbon from so simple a compound as carbonic acid.

It might be mentioned here that the whole group of the Fungi (q.v.) and many thousands of species, is now generally regarded as having been derived from algae, and the system of classification of fungi devised by Brefeld is based upon this belief. The similarity of the morphological characters of one group of fungi to those of certain algae has earned for it the name Phycocyanets or alga-fungi.

Further discussion of the general characters of algae will be deferred in order to take a brief survey of the subdivisions of the group. For this purpose there will be adopted the classification of algae into four sub-groups, founded on the nature of the colouring matters present in the plants:

I. Cyanophyceae, or Blue-green Algae.

II. Chlorophyceae, or Green Algae.

III. Phaeophyceae, or Brown Algae.

IV. Rhodophyceae, or Red Algae.

The merits and demerits of this system will appear during the description of the characters of the members of the several subdivisions.

I. CYANOPHYCEAE—This group derives its name from the circumstance that the cells contain in addition to the green colouring matter, chlorophyll, a blue-green colouring matter to which the term phycocyanin has been applied. To the eye, however, members of this group present a similar variety of colour, and the distinctions among them are based on the structure of the cell which is structural and not often obvious. The thallus may be unicellular or multicellular. When unicellular, it may consist of isolated cells, but more commonly the cells are held together in a common jelly (Chroococcaceae) derived from the outer layers of the cell-wall. The multicellular species consist of filaments, branched or unbranched, which arise by the repeated divisions of the cells in parallel planes, no formation of mucilage occurring in the dividing walls. Such filaments may not give rise to mucilage on the
lateral surface either, in which case they are said to be free; when mucilage does occur on the lateral wall, it appears as the sheath surrounding either the single filament, or a sheaf of filaments of common origin. The mucilage may also form an embedding substance similar to that of Chroococaceae, in which the filaments lie parallel or radiate from a common centre (Rivulariaceae). The cells of the filament may be all alike, and growth may occur equally in all parts (Oscillatoraceae); or certain cells (heterocytes) may become marked off by their larger size and the transparency of the contents in which case growth may still be distributed equally throughout (Nostoc), or the filament may be attached where the heterocyte arises, and grow out at the opposite extremity into a fine hair (Rivulariaceae). An African form (Camptotatoria), devoid of heterocytes and hair-like at both extremities, has recently been described. Branching has been described as “false” and “true.” The former arises when a filament in a sheath, either in consequence of growth in length beyond the capacity of the sheath to accommodate it, with that of the higher plants. It is said to be derived by a minute chalazal cell, which is the spindle and the differentiation of chromosomes. It is further stated by Olive that the chromosomes undergo longitudinal fission, and that for the same species the same number of chromosomes appear at each division. If, when the periphery of the sheath, which is a hollow sphere in spherical cells, and either a hollow cylinder or barrel-shaped body in filamentous forms, must be regarded as the single chromatophore of the Cyanophyceae cell. But what precisely is the nature of the central mass is still uncertain. Some investigators, such as R. Hegler, F. G. Kohl and E. W. Olive, claim that this body is a true nucleus comparable

or because of the decay of a cell, becomes interrupted by breaking, and the free ends slip past one another. “True” branching arises only by the longitudinal division of a cell of a filament into the lateral outgrowth of one of the cells resulting from the division (Sirosporaceae).

The nature of the contents of the cells of Cyanophyceae has given rise to considerable controversy. The cells are for the most part exceedingly minute, and are not easy to free from their colouring matters, so that investigation has been attended with great difficulty. Occupied by these algae do perhaps the lowest grade of plant life, it is a matter of interest to ascertain whether a nucleus or chromatophore is differentiated in their cells, or whether the functions and properties of these bodies are diffused throughout the whole protoplast. It is certain that the centre of the cell, which is usually non-vacuolated, is occupied by protoplasm of different properties from the peripheral region; and A. Fischer has further established the fact that the peripheral mass, which is a hollow sphere in spherical cells, and either a hollow cylinder or barrel-shaped body in filamentous forms, must be regarded as the single chromatophore of the Cyanophyceae cell. But what precisely is the nature of the central mass is still uncertain. Some investigators, such as R. Hegler, F. G. Kohl and E. W. Olive, claim that this body is a true nucleus comparable
Chlorophyceae, variously magnified.

A. Chlamydomonas sp., unicellular; chr., chromatophore; p., pyrenoid; n., nucleus; p.v., pulsating vacuoles; e.s., eyespot.
B. Volvox sp., with a, antheridia, and o, oogonia.
C. Pandorina sp., a 16-celled colony.
D. Hydrodictyon, a single mesh surrounded by 6 cells.
E. Micrastera sp., showing H-pieces in the wall.
F. Entoderma sp., endophytic in Ectocarpus.
G. Coleochaete sp., growing as a plate.
H. Oedogonium sp., intercalated growth by insertion of new piece(a) leaving caps.
K. Struvia sp., showing branches forming a net-work.
L. Caulerpa sp., showing portion of axis with leaf-like and root-like appendages.
M. Chara sp., axis with leaf-like appendages and a branch.
M*. Chara sp., apical region.
N. Batrydium, a simple siphonaceous alga with root-like attachment.
O. Acteobulbus Mediterraneus, mushroom-like calcareous siphonaceous alga.

Dermatophyton grows on the carapace of the tortoise and Trichophillus in the hairs of the sloth. Certain Protococcales and Confluvalias exist as the gamidia of the lichen-thallus. The thallus is of more varied structure in this group than in any other.

In the simplest case it may consist of a single cell which may remain free during the whole of the greater part of its existence, or be loosely aggregated together within a common mucilage, or be held together by the adhesion of the cell-walls at the surface of contact. These aggregations or colonies, as they are termed, may assume the form of a plate, a ring, a solid sphere, a hollow sphere, a perforate sphere, a closed net, or a simple or branched filament. It is not easy in all cases to draw a distinction between a colony of plants and a multicellular individual. In a Volvox sphere, for example, there is a marked protoplasmic continuity between all the cells of the colony. The Ulvaceae, the thallus of which consists of laminae, one or more cells thick, or hollow tubes, probably represent a still more advanced stage in the passage of a colony into a multicellular plant. Here there is some amount of localization of growth and distinction of parts. It is only in such cases as Volvox and Ulvaceae that there is any pretension to the formation of a true parenchyma within the limits of the Chlorophyceae. In the whole series of the Confluvalias, the thallus consists of filaments branched or unbranched, attached at one extremity, and growing almost wholly at the free end. The branches end in fine hairs in Chaetophoraceae. In Coleochaetaceae the branches are often welded into a plate, simulating a parenchyma. In all Conjugatae and most Protococcales, and in the bulk of the Confluvalias, the thallus consists of a cell or cells, the protoplast of which contains a single nucleus. In Hydrodictyaceae, Cladophoraceae, Sphaeropleaceae and Gomontiaceae this is no longer the case. Instead of a single relatively large nucleus, each cell is found to contain many small nuclei, and is spoken of as a coenocyte. This character becomes still more pronounced in the large group of the Siphonales. Valoniacae and Dasycladaceae are partially separate, but elsewhere no cellulosic partitions occur, and the thallus is more or less the continuous tube from which the group is named. Yet the siphonaceous algae may assume great variety of form and reach a high degree of differentiation. - Protosiphon and Betridium, on the one hand, are minute vesicles attached to muddy surfaces by rhizoids; Caulerpa, on the other, presents a remarkable instance of the way in which the same external morphology as that of cormophytes has been reached by a totally different internal structure. Many Siphonales are encrusted with lime like Corallina among Red Algae. Penicillus is brush-like, Halimeda and Cymopolia are jointed. Actebulbus has much the same external form as an expanded Cephalis, Neomeris simulates the fertile shoot of Equisetum with its densely packed whorled branches, and in Microdictyon, Anadyomene, Struvea and Boodlea the branches, spreading in one plane, become bound together in a more or less close network. Characeae are separated from other Chlorophyceae by a long interval, and present the highest degree of differentiation of parts known among Green Algae. Attached to the bottom of pools by means of rhizoids, the thallus of Characeae grows upwards by means of an apical cell, giving off whorled appendages at regular intervals. The appendages have a limited growth; but in connexion with each whorl there arise, singly or in pairs, branches which have the same unlimited growth as the main axis. There is thus a close approach to the external morphology of the higher plants. The streaming of the protoplasm, known elsewhere among Chlorophyceae, is a conspicuous feature of the cells of Characeae.
ANDO ALGAE

388

In motility, Euchlorophyceae, are these rings single or are they a pair of stellate masses, the rays of which branch peri-
pherally; in Oedogonium they are longitudinally-disposed anasto-
mosing bands; in Desmidiales plates with irregular margins; in Clado-
porales or Trichomata, peritrichous ciliation; in Vaucheriaceae, beaded, occurring in immense numbers. Embedded in the chromatophore, much in the same way as the nucleus is embedded in the cytoplasm, and in the same way as the carapace is embedded in the carapace of crustaceans. When colonized, the thallus is not known only in Banglades and Nematocera among Rhodophyceae, but are of frequent occurrence among Chlorophyceae, excepting Characeae. Sometimes several pyrenoids occur in each chloroplast, and in Euchlorophyceae two or three are common. Each chloroplast contains pyrenoid at all, as in Cladophora. The pyrenoid seems to be of protod nature and gelatinous consistency, and to arise as a derivative of the pyrenoid of the previous generation by division. When carbon-assimilation is active, starch-granules crowd upon the surface of the pyrenoid and completely obscure it from view.

Special provision for vegetative multiplication is not common among Chlorophyceae. Volvox and Caulerpa among Siphonophyceae, detach portions of their thallus, which are capable of independent growth. In Caulerpa no other means of multiplication is as yet known. In Characeae no fewer than four methods of vegetative reproduction have been recognized. The beaked cyst is formed when the cell is undergoing division. Such beaked cysts are used to make the spores, but they are in no cases detached has been adduced as an evidence of affinity with Bryophyta, which, as a class, are distinguished by their reproductive methods.

With regard to true reproduction, which is characterized by the formation of special cells, the group Euchlorophyceae is characterized by the production of zoospores (G. zoos, animal, oopak, seed); the term zoospore is of much etymological interest. Such ciliary motion is known in the adult condition of the cells of Volvoxaceae, but where this is not the case the reproductive cells are formed in zoosporangia or sporangia. The zoospore is a pyriform mass of naked protoplasm, the beak end of which where the cilia arise is devoid of colouring matter. A reddish-brown body, known as the eyespot, is usually situated near the limits of the hyaline portion, and in the protoplast contractile vacuoles similar to those of lower animals have been occasionally detected. The movement of the zoospore is effected by the lashing of the cilia and is in the direction of the beak, while the zoospore slowly rotates on its own axis. The zoospore escapes from the parent cell through a pit (Botrydium and Hydrodictyon only one is present; in certain species of Cladophora four; in Dictyosiphon a chapelet, in Cladophora a ring of many cilia. The so-called zoospore of Vaucheria is a coenocyte covered over with paired cilia corresponding in position to nuclei lying below. In all other cases zoospores are uninucleate bodies. Zoospores arise in cells of ordinary size and form termed zoosporangia. In uninuclear forms (Vaucheria) the thallus becomes transformed into a zoosporangium at the reproductive stage. In the zoosporangia of Oedogonium, Tetraspora and Coleochaete the content is thrown into a single large zoospore. In most of these the repeated division seems to take place, and the final number is represented by some power of two. In coenocytic forms the zoospore would seem to arise simultaneously, probably because many nuclei and zoospores escape from the parent cell at one time. It is in the degeneration of the sporangial wall (Chaeotoma), or by a pore (Cladophora), a slit (Pediasrium), or a circular fracture (Oedogonium). Zoospores are of two kinds: (1) Those which come to rest and germinate to form a new plant; these are asexual and are zoospores proper. (2) Those which are unable to germinate of themselves, but fuse with another cell, the product giving rise to a new individual; these are sexual and are zoogametes (G. zoos, animal, and yann, yaveth, husband, wife). When two similar zoogametes fuse, the process is conjugation, and the product a zygospore (G. yvde, yoke). Usually, however, only one of the fusing cells is a zoogamete, the other being a much larger resting cell. If the zoogamete, the zoogamete male, is called an antherozoid or spermatozoid, and arises in an antheridium; the larger gamete is an oosphere and arises in an oogonium. The fusion of the zoogametes and the zygospore is the zygospore. Reproduction by conjugation is also known as isogamy, by fertilization as oogamy. When zoospores come to rest, a new cell is formed and germination ensues at once. When zoospores and oospores are produced a new cell-wall is formed, but a long period of rest ensues. All investigation goes to show that an essential part of sexual union is the fusion of the two nuclei concerned. It is interesting to know, on the authority of Oedogonium, that the conjugation is sexual without fertilization; in Vaucheria, there is a retrogression of all the included nuclei but one. That the antherozoid of Vaucheria contains a single nucleus has been shown.

From a comparison of those Euchlorophyceae which have been most closely investigated, it appears probable that sexual reproduc-
tive cells have in the course of evolution arisen as the result of specialization of ordinary reproductive cells. Thus the oogamous reproduction has arisen as the result of differentiation of the two conjugating cells into the smaller male gamete and the larger male gamete. It would further appear that Oogonial
of three layers, the outer of which is furnished with spiracular pro-
ominences of various forms. In Zygnemataceae there is no dissolution of
the filaments, but the whole contents of one cell pass over by
means of a conjugation-tube into the cavity of a cell of a neighbour-
ing filament, where the zygospore is formed by the fusion of the two
to conjugation; and as two segments are cut off in the case of the
active gamete, and only one in the case of the passive gamete, there
is a corresponding difference of size, marking another step in the
second conjugation. In Coleochaetium, although no cell-division
takes place, the gametes consist of a portion only of the contents of
a cell, and this is regularly the case in Mesocarpaciaceae, which occupy
the position of an appendage among Conjugatae. Some Zygnemataceae
and Mesocarpaciaceae form either a short conjugation tube, or none at
all, but the filaments approach each other by a knee-like bend, and the
zygospore is formed at the point of contact, often being partially
contained within the wall of the parent-cell. It will be seen that in
some cases the nuclei of the gametes remain distinct in the zygos-
spore for a considerable time after conjugation. It is probable that
in all cases nuclear fusion takes place sooner or later. In Zygnem-
ataceae and Mesocarpaciaceae the zygospore, after a period of rest,
germinates, to form a new filamentous colony; in Desmidiaceae its
contents divide on germination, and thus give rise to two or more
DesmidiaGametes which fail to conjugate sometimes assume the
appearance of zygospores and germinate in due course. They are
known as azygospores.

The reproduction of Characeae is characterized by a pronounced
ogonary, the reproductive organs being the most highly differen-
tiated among Chlorophyceae. The antheridia and oogonia are
formed at the nodes of the appendages. The oogonium, seated on
a single cell, is surrounded by an investment consisting of five spirally
wound cells, from the projecting ends of which segments are cut off,
constituting the so-called stigma. The oosperm is not differentiated
within the wall of the oogonium, but certain cells known as "wendungs-
zellen", the significance of which has given rise to much speculation,
are cut off from the basal portion of the parent-cell during its
development. The antheridia are spherical orange-coloured bodies of
very complex structure. The antherozoid is a spirally-coiled thread
of pseudopodium furnished at one end with a pair of clila. This cell
resembles the antherozoids of Bryophyta and certain Pteridophyta
than any known among other algae. The fertilized egg charged with
food reserves rests for a considerable period, surrounding itself with
the whole having assumed a reddish-brown colour. On germination
it gives rise to a row of cells in which short (nodal) and long (inter-
odal) cells alternate. From the first node arise rhizoids; from the
second a lateral bud, which becomes the new plant. This process
of germination, which intervenes between the oosperm and the
adult form, is the proembryo. It will be remembered that in Musc.
the sex cells somewhat similarly gives rise to protonemata, from
which the adult plant is produced as a new plant. In Characeae
there is anther or more embryonic branches of Characeae, one of the means of vegetative
reproduction already referred to, are so called because they repeat
the characters of the proembryo.

Before leaving the Chlorophyceae, it should be mentioned that
the genus Volvox has been included by some zoologists (Büttschli,
for example) among Flagellata; on the other hand, certain green
flagellates, such as Euglena, are included by some botanists (for
example, van Tieghem) among unicellular plants. A similar un-
certainty exists with reference to certain groups of Phaeophyceae,
and the matter will thus arise again.

A census of the Chlorophyceae is furnished below:

1. Conafflaveae—12 families, 77 genera, 1021 species.
2. Siphonemia—9 families, 26 genera, 271 species.
3. Oedogonia—2 families, 32 genera, 342 species.
4. Conjugatae—2 families, 33 genera, 1296 species.
5. Characeae—2 families, 6 genera, 181 species.

(Engler and Prantl's 'Phanzenfamilien,' 1892.)

II. PHAEOPHYCÉ.—The Phaeophyceae are distinguished by the
possession of a brown colouring matter, phycophaein, in addition to
celluloid. They consist of the following groups:—Phaeosporae,
Phaeosporeae, Dictyotaceae, Cryptomonaecae, Peridiniaceae
and Diatomaceae. Of these the first three include multicellular
plants, some of them of great size; the last three are unicellular
organisms, with l differentiation of the flagellum on bining the
process occurring in common with the rest excepting the possession
of brown colouring matter. Fucales and Phaeosporeae are doubtless
closely allied, and to these Dictyotaceae may be joined, though
the relation of the latter is less close. They constitute the Euphaeophyceae, and
will be dealt with in the next place.

Euphaeophyceae are almost exclusively marine, growing on rocks
and stones on the coast, or epiphytic upon other algae. In tides
seas they range from the limits of high water to some distance
beyond the low-water line. On the British coasts zones are observ-
able in passing from high to low water mark, characterized by the
prevalence of different species; thus,—Pelvetia canaliculata, Laminaria
lucus sessilis, Laminaria digitata, Fucus vesicularis, Laminaria
digitata. Some species are minute filamentous plants, requiring the
microscope for their detection; others, like Lessonia, are considerable
bulky or, like Mericotheca, of considerable length. In Fucaceae,
Dictyotaceae, and in Laminariaceae and Sphaerocarpicaceae,
among Phaeosporeae, the thallus consists of a true parenchyma;
elsewhere it consists of free filaments, or filaments so compacted
as to form the so-called Cartilagineae and Desmidioseae, to form
parenchyma. In Fucaceae and Laminariaceae the inner tissue is
differentiated into a conducting system. In Laminariaceae the in-
fusion of the ends of conducting cells gives rise to the so-called

mann; I1 from Vibes, by permission of Anna Sonnenschein and Co.; I2, D, Y from Ottmanns, by permission of Gustav Fischer.))
trumpet-hyphae. In *Nereocystis* and *Macrocystis* a zone of tubes occurs, which present the appearance of sieve-tubes even to the eventual obliteration of the perforations by a callus. While there is a general tendency in the group to form pseudoparenchymatous structures, in *Fucus*, in *Alaria*, and in *digitata* there are also glands secreting a plentiful mucilage. Secondary growth in thickness is effected by the tangential division of superficial cells. The most fundamental external feature, however, is the distinct, biconvex, dorsiventral thallus. In *Laminariaeaceae* there is a distinction of stipe and blade. The blade is centrally-ribbed in *Alaria* and laterally-ribbed in *Macrocystis*. It is among the Sargassaceae that the greatest amount of sexual reproduction is known. In *Fucus vesiculosus* they arise in lateral pairs; in *Asparagaleum* they are single and median; in *Macrocystis* one vesicle arises at the base of each thallus segment; in *Sargassum* and *Halidrys* the vesicles arise on special branches. They serve to buoy up the plant when attached to the seafloor, but they are more probably used for the spread of the gregarious species. When such plants are detached they are enabled to float for great distances, and the great Sargasso Sea of the North Atlantic Ocean is probably only renewed by the constant advent of plants detached from the shores of the Caribbean Sea and Gulf of Mexico.

Growth in length is effected in a variety of ways. In *Dictyota*, Sphacelaria, *Phaeospora*, and in some of the Ectocarpaceae, the cell is divided longitudinally, and first it is a biconvex lens, from which segments are continually cut off parallel to the posterior surface; and in the second an elongated dome, from which segments are cut off by a transverse wall. While, however, in *Dictyota* the product of the subsequent division in the segment enlarges with each subdivision, the divisions in the cylindrical segment of Sphacelariaeae are such that the whole product after subdivision, however many cells it may consist of, does not exceed the former segment as cut off from the apical cell. In *Dictyotaceae* the apical cell occasionally divides longitudinally, and thus the dichotomous branching is provided for. In some Sphacelarioideae the portion of the thallus that divides longitudinally is divided into subsegments of the apical cell itself. In Fucaceae an apical cell is situated at the surface of the thallus in a slit-like depression at the apex. From this cell segments are cut off in three or four lateral oblique planes.

A peculiar manner of growth in length is that to which the term trichothallic has been applied. It may readily be observed that in the hair-like branches of Ectocarpaceae, the point at which most rapid division occurs is situated near the apex, while *maresia* and *Arthrocladia*, for example, it is found that the thallus ends in a tuft of such hairs, each of them growing by means of an independent cellular system. In *Fucus* the ends of the hairs behind the growing region become agglutinated together into a solid cylindrical pseudo-parenchymatous axis. In *Culteria* the laminated thallus is formed in the same way. The intercalated growth, however, is not the case of *Ectocarpus*. In *Taonia*, *Phaeospora* is observed by Berthold in *Ectocarpus siliculosus* and *Scytoastaphon lomentarius* in 1880; and these observations have been recently confirmed in the case of the former species by Sauvageau, and in the case of *Phaeospora*. In *Phaeospora*, the potential gametes may, failing conjugation, germinate directly, like the zoospores derived from unilocular sporangia. The ascospores of *Ectocarpus globosa*, in the case of *Dityostylus hirpudoi*, is no doubt to be ascribed to error. It would thus seem that the explanation of the existence of two kinds of sporangia—unilocular and plurilocular, among Phaeosporae, lies in the fact that unilocular sporangia are for asexual reproduction, and that plurilocular sporangia are gametangia—potential or actual. It must however be remembered that so important a generalization as this is not yet established upon a sufficient number of examples. Moreover, for the important family of the Laminariaceae only unilocular sporangia are known to occur; and for many species of other families, only one type of sporangium has hitherto been observed. The four species—*Ectocarpus siliculosus*, *Giffordia secunda*, *Culteria multifida* and *Phaeospora globosa*—can be taken to represent, within the Phaeosporae, successive steps in the advance from isogamy to oogamy or ascogamy.
Phaeophyceae, variously magnified.

A. Halopteris, apical region.
B. Chordaria sp., apical region showing so-called trichothallic growth.
C. Dictyota sp., apical cells immediately after dichotomy.
D. Caldaria sp., margin of thallus showing trichothallic growth.

The brown colouring matter which is added to chlorophyll is identical with phycoeaxin; two varieties of it have been termed phycoeaxin and peridinol. Certain species, such as Gymnodinium spirale, are colourless and therefore saprophytic in their method of nutrition. Multiplication takes place in some cases by the endogenous formation of zoospores; the organism having come to rest; in others by longitudinal division, when the organism is still motile. No method of sexual reproduction is known with certainty. The Cryptomonadaceae also are unicellular, and live free or in colonies. Each cell contains a flattened chromatophore of a brown or yellow colour. Hydrurus forms a branched gelatinous colony attached to stones in mountain streams. Chromophytum forms an eight-celled colony. Both plants multiply solely by means of zoospores. The Cryptomonadaceae and Chromulineae are motile through the greater part of their life. Cryptomonas, when dividing in a mucilage after encystment, recalls the condition in Gloeocystis. In Synura and Chromulina the cells form a spherical motile colony recalling Volvocaceae. Chromulina is uniciliate, and is contained in a hyaline capsule. Like the Peridiniaceae, the Cryptomonadaceae have been included among Flagellata. They have no close affinity with Euphacophyceae. Such colonial forms as Hydrurus and Phaeocystis are supposed, however, to indicate a stage in the passage to the multicellular condition.

Diatomaceae have long been recognized as plants. Together with Peridiniaceae they constitute the bulk of marine plankton, and thus play an important part in the support of marine animal life. They exhibit striking adaptations in these circumstances to the floating habit. (See Diatomaceae.)

A census of Phaeophyceae is given below:—

1. Cyclosphorine (Fucaceae) — 4 families, 32 genera, 347 species.
2. Tetrasporine (Dictyotaceae) — 1 family, 17 genera, 130 species.
3. Phaeacozoneae (Phaeophoraceae) — 24 families, 143 genera, 571 species.
(De Toni's Sylloge Algarum.)

4. Peridiniales — 3 families, 32 genera, 167 species.

5. Cryptomonadaceae (including Chrysomonadaceae) — 2 families, 28 genera, 50-60 species.
6. Bacillariales (Diatomaceae) — about 150 genera and 5000 species, fossil and recent.

(Engler and Prantl's Pflanzenfamilien.)

IV. Rhodophyceae, or Florideae.—The members of this group are characterized by the possession of a red colouring matter, phycoerythrin, in addition to chlorophyll. There is, however, a considerable amount of difference in the shades of red which mark different species. The brightest belongs to those species which grow near low-water mark, or under the shade of larger algae at higher levels; species which grow near high-water mark are usually of so dark a hue that they are easily mistaken for brown seaweeds. Rhodophyceae are mostly marine, but not exclusively so. Thora, Lema, U. Tomoy, Stenocladia, Batrachostemum, Balbisia are genera belonging entirely to fresh water; and Bangia, Chaetetofia, Caloglossa, Brotyschis and Deloetis contain each one or more freshwater species. Most of the larger species of marine Rhodophyceae are attached by means of a disc to rocks, stones or shells. Many are epiphytic on other algae, more especially the larger Phaeophyceae and Rhodophyceae. As in the case of epiphytic brown seaweeds, the rhizoids of the epiphyte often penetrate the substance of the supporting alga. Some Red Algae find a home in the gelatinous substance of Fluita, Alcyonidium and other polyzoa, only emerging for the formation of the reproductive organs. Some are perforating algae and burrow into the substance of molluscan shells, in company with certain Green and Blue-green Algae. Some species belonging to the families Squamariaeae and Corallineae grow attached through their whole length and breadth, and are often encrusted with lime. The forms which grow away from the substratum vary greatly in external configuration. In point of size the largest cannot rival the larger Brown Algae, while the majority require the aid of the microscope for their investigation.

No unicellular Rhodophyceae are known, although a flagellate organism, Rhodomonas, has recently been described as possessed
of the same red colouring matter. If the sub-group, Bangiaceae, be excluded, they may be said to consist exclusively of branched filaments. The thallus consists of a single cell, from which successive segments are cut off by means of a transverse wall. The segment so cut off does not usually divide and becomes an independent cell, the covering material and the wall which passes through the organic axis of the cell. New cells may be cut off laterally, which become the apical cells of branches. When the new cells grow no further, but constitute a palisading row, this condition is the parenchyma, or leghinge, which is reached when the characteristic species of Polysiphonia, the "siphons" of which may be regarded as one-celled branches. To the law that no subsequent transverse division takes place in segments cut off, there are a few exceptions, in the calcareous genus Corallina, in the pliable joints of which intercalated division occurs; and, second, the Niphellidae, in which, moreover, the true cortical division is replaced by a lateral division, lin the walls of the so-called depressions. Like the Fungi, therefore, the Red Algae consist for the most part of branched filaments, even where the thallus appears massive to the eye, and, as in the case of Fungi, this fact is not inconsistent with a great variety of external morphology. In the great majority the thallus is obviously filamentous, as in some species of Callithamnion. In other species of that genus an apparent cortication arises by the downward growth of rhizoids, which are retailed with a gelatinous wall of the axial cells. In Batrachospermum the whole system of branches is retained within a different gelatinous substance derived from the outer layers of the cell-walls. In other cases the cortication arises as the result of the growth of the cell (in Helminthora). In such cases as Lemaone, the terminal cells of the lateral branches form a superficial layer which has all the appearance of a parenchyma when viewed from the surface. In Chermisia and another genus, the cortical axis is a hollow filament, with an axial filament, but of several, the growth of which is co-ordinated to form a septated tube. The branching of the thallus, which meets the new cells to it, and the co-ordination of lateral divisions, when such a lateral branch overtops the main axis whose growth has become limited, as in Placodium and Dasya, a symposium is formed. For the most part the branching is monopodial. Besides the differentiation into holofase and shoot, and into branches of limited and branches of unlimited growth, there appear superficial structures of the nature of hairs. These are for the most part developed in the so-called fruticellulae, cells cut off from the outer cells of the pseudo-cortex, or from the cortical cells of branches when the filaments are free. Among Rhodomelaceae, hair-like structures of a higher order are known. These arise from the fruticellulae, the fruticellulae themselves having an apical point, and the lateral branches assume the form of leaves. In the compact thallii a secondary development often takes place by the growth of rhizoid-like internal filaments. They present a hypha-like appearance, according to an excellent study of Constance, since the development is so difficult in such compact species to distinguish between superficial cells, whose chief function is assimilation, subapical cells charged with reduction, and cells engaged in the devolution of elaborated material from part to part.

An interesting feature of the minute anatomy of Eufluorideae, as the Red Algae, exclusive of the Bangiaceae, have been termed, is the existence of the so-called, Floridean pit. When a cell divides it is found that there remains in the middle of the new wall a single large circular pit, which persists throughout the life of the cells, becoming more and more conspicuous with the progress of the thickening of the wall. These pits serve to indicate the genetic relationship of adjacent cells, when they form a compact pseudo-parenchyma, notwithstanding the fact that somewhat smaller secondary pits appear later in the development of the cell. Communication has been observed in the delicate membrane closing the pit.

Vegetative multiplication occurs only sparingly in Rhodophyceae. Melobesia callithamnoides gives rise to multicellular propagula; Corallina corallina is said to give rise to new individuals, by detaching portions of the thallus from the base of which new attachment organs have already arisen. The spores of Monospora are by some regarded as unicellular propagula. Reproduction is both asexual and sexual. It is noteworthy that although all the members of the group are aquatic no zoospores are produced, a negative character common to them and the Blue-green Algae. As a rule the asexual organs are known as monosporia and Polysiphonia byssoides both kinds of sexual organs are formed. In a number of species the same condition occurs, and in some cases the asexual cells may occur in conjunction with either the male or female sexual cells. Asexual cells are termed tetraspores on account of the usual occurrence of four in each sporangium. What may be termed monosporia, bispores and octospores, however, are not unknown. The sporangia may be terminal or intercalary. When they are confined to special branches such branches are spoken of as sporangia. In those cases in which the transverse division of the contents of a sporangium, when they are arranged tetrahedrally, or they may arise by two successive divisions, in which case they are termed bispores. The latter case is considered rare. When the sporangium is in a row or cruciate when the second divisions are at right angles to the first or tetrahedral when the second divisions are at right angles to the first and also to one another. Tetraspores are at first naked, but soon become enveloped in a special envelope. Many cases of male sexual cells are produced singly in the terminal cells of branches. They are spoken of as spermatia. Great numbers of antheridia are usually crowded together, when the part is distinguishable by the abundance of the gelatinous material, the antheridia being distinguished from the surface in the cases of Dictyota and other genera. When, however, they pass over its surface through an open communication set up at the point of contact. The nucleus then passes down the trichogyne and fuses within the oostoma with another nucleus from the opposite part of the thallus. The trichogyne, however, always reaches the surface. The first effect of fertilization is the occurrence of the trichogyne from the fertilized cell. Oocytes, is due to the formation of a characteristic cell of the Florideaceae. The carpogonium germinates forthwith, drawing its nourishment almost wholly from the parent plant. The ultimate product in all cases is a number of carpospores, but before the stage is reached the development is different in different subgroups. In Batrachospermum filaments arise from the carpogonium on all sides; in Cystosoria and Scenica on one side only; in Helminthora, the thallus occurs in a number of species which, from the close relation of the Rhodoid Gelfideae, the single filament arising from the carpogonium grows back into the tissue and passes up the cells of the axis and larger branches, after which the end-cells give rise to carpospores and a diffused cystocarp is formed. In the whole group of the Cryptonemales the parasitism becomes more marked still. The filaments arising from the carpogonium grow into long thin tubes, which fuse with each other, and thus by giving rise to iso-iso to sporogenous filaments, several of which may form the product of one fertilized female cell. In Naccaria, one of the Gelfideae, it is observable that the ooblastema filament, as the tube or fairly for the most part within the thallus, and is almost completely with a cell contiguous to the carpogonium before giving rise to the foraging filaments already referred to. This is also the case among Cryptonemiales, in which the entire axis of a highly specialized auxiliary cell in the neighbourhood of the carpogonium is a characteristic feature. In the Gigartinales it is already differentiated previous to fertilization; in Rhodymeniales it arises subsequent to fertilization. In the Gigartinales the filaments which arise from the auxiliary cell may spread and give rise to isolated tufts of sporogenous filaments, as in the Cryptonemiales. In the Rhodymeniales a single tuft arises directly from the auxiliary cell. The carpospores are in all cases bright red masses of protoplasm when first discharged. They soon acquire a cell-wall, and germinate without a period of rest. When the cystocarps or generally referred to as the "cystocarps", and the base of the cystocarp is marked by a swelling of the substance. When the cystocarp is produced externally, it may form a berry-like mass without an envelope, in which case it is known as a ferrule. In Rhodymeniales there is a special urn-shaped envelope surrounding the sporogenous filaments. This is a ceratiomum. The attachment of the cell of an ooblastema filament to a cell of the thallus may be effected by means of a minute pore, or the two cells may fuse their contents into one protoplasmic mass. In the latter case, and especially where the union is with a special auxiliary cell, it is of importance to know what happens to the nuclei of the two cells. In the case of some genera, no fusion of nuclei takes place, in the case of other genera the union there occurred a fusion of nuclei similar to that which occurs in the sexual union of two cells. He found his generalization to a large extent upon the observation that in the case of the ooblastema cell the contents of the nucleus can be detected in the fused mass. Oltmanns has recently re-investigated the phenomena in this plant, among others, and has shown that the nucleus of the cell which is being preyed upon recedes to the wall and generally atrophies. The nucleus of the ooblastema filament dominates the
k. Nemalion sp., carpogonial and antheridial branches.
L. Batrachospermum sp., trichogyne with spermatia attached; carpospores arising from fertilized carpogonium.
M. Polyphysantium sp., antheridium.
N. Conantinae sp., with flattened leaf-like appendages.
O. Diodactinae coccinea, fusion of ooblastema filaments with auxiliary cells; a is an axial cell in transverse section with four appendages.
P. Callithamnion corymbosum, a joint cell with carpogonial branch and a, b, two auxiliary cells.
Q. Callicrithamnion corymbosum, fusion of products of fertilization with auxiliary cells, the nuclei of which a and b retire to the wall.
R. Polysiphonia sp., section through young cystocarp.

After this survey of the four groups comprised under Algae it is easier to indicate the variations in the limits of the class as defined by different authorities. To consider the Cyanophyceae first, either the marked contrast in the method of nutrition of the generally colourless Bacteriaceae to that of the blue-green Cyanophyceae is regarded as sufficient ground for excluding Bacteriaceae from algae altogether, notwithstanding their acknowledged morphological affinity with Cyanophyceae, or, in recognition of the incongruity of effecting such a separation, the whole group of the Schizophyta—that is to say, the Cyanophyceae in the narrow sense, together with Bacteriaceae, is included or excluded altogether. Again, while Conjugatae may be shut out from Chlorophyceae as an independent group co-ordinate with them in rank, the Characeae constitute so aberrant a group that it has even been proposed to raise them as Charophyta to the dignity of a main division co-ordinate with Thallophyta. Similarly, while Diatomaceae may be excluded from among Phaeophyceae, though retained among algae, the Cryptonodinaceae and Ceramiales, like Euglenia and other Chlorophyceae, may be excluded from Thallophyta and ranged among the flagellate Protozoa. It is doubtful, however, whether the conventional distinction between plants and animals will continue to be urged; and the suggestion of Haeckel that a class Protista should be established to receive the forms exhibiting both animal and plant affinities has much
to recommend it on phylogenetic grounds. To adopt a figure, it is probable that the sources from which the two streams of life—animal and vegetable—spring may not be separable by a well-defined watershed at all, but consist of a great level upland, in which the waterways anastomose. Finally, while Chlorophyceae and Phaeophyceae exhibit important affinities, the Rhodophyceae are so distinct that the term "algae" cannot be made to include them, except when used in its widest sense. It has been well said that the attempt to classify plants according to their natural affinities is an attempt to construct phylogeny, for them the genealogical tree by which their relationships can be traced. Algae are, however, so heterogeneous a class, of which the constituent groups are so inadequately known, that it is at present futile to endeavour thus to exhibit their pedigree. A synoptical representation of the present state of knowledge would be expressed by a network rather than by a tree. The following table is an adaptation of a scheme devised by Klebs, and indicates the inter-relationships of the various constituent groups. The area included in the thick boundary line represents algae in the widest sense in which the term is used, and the four included areas the four main subdivisions. A continuous line indicates a close affinity, and a dotted line a doubtful relationship.

In comparing algae with the great archegoniate series which has doubtless sprung from them, it is natural to inquire to what extent, if any, they present evidence of the existence of the marked alternation of generations which dominates the life-history of the higher plants. Turning first to the Rhodophyceae, both on account of the high place which they occupy among algae and also the remarkable uniformity in their reproductive processes, it is clear that, as is the case among Archegoniatae, the product of the sexual act never germinates directly into a plant which gives rise to the sexual organs. Even among Bangiaceae the carpospores arise from the fertilized cell by division, while in all other Rhodophyceae the oospore, as it may be called, gives rise to a filamentous structure, varying greatly in its dimensions, epiphytic, and to a large extent parasitic upon the egg-bearing parent plant, and in the end giving rise to carpospores in the terminal cells of certain branches. This is the invariable condition of the tetrasporangia of Bryophyta, where the sporogony arising from the oospore is epiphytic and partially parasitic upon the female plant, and always culminates in the production of spores. Not even Riccia, with its rudimentary sporogonium, has so simple a corresponding stage as Bangia, for, while there is some amount of sterile tissue in Riccia, in Bangia the oospore completely divides to form carpospores. Excluding Bangiaceae, however, from consideration, the Euflorideae present in the product of the development of the oospore like Bryophyta a structure partly sterile and partly fertile. There is, nevertheless, this important difference between the two cases. While the spore of Bryophyta on germination gives rise to the sexual plant, the carpospore of the alga may give rise on germination to a plant bearing a second sort of asexual cells, viz. the tetraspores, and the sexual plant may only be reached after a series of such plants have been successively generated. It is possible, however, that the tetrasporangial formation should be regarded as comparable with the prolific vegetative reproduction of Bryophyta, and in favour of this view there is the fact that the tetraspores originate on the thallus in a different way from carpospores with which the spores of Bryophyta are in the first place to be considered; moreover, in certain Nemalionales the production of tetraspores does not occur, and the term is referred to does not arise in such cases. Altogether it is difficult on morphological grounds to resist the conclusion that Florideae present the same fundamental phenomenon of alternation of generations as prevails in the higher plants. It is by means of the cytological evidence, however, that this problem will finally be solved. As is well known, the dividing nuclei of the cells of the sporophyte generation of the higher plants exhibit a double number of chromosomes, while the dividing nuclei of the cells of the gametophyte generation exhibit the single number. In a fern-plant, for example, which is a sporophyte, every karyokinesis divulgates the double number, while in the prothallium, which is the gametophyte generation, the single number appears. The doubling process is provided by the act of fertilization, where an antherozoid with the single number of chromosomes fuses with an oosphere also with the single number to provide a fertilized egg with the double number. The reduction stage, on the other hand, is the first division of the mother-cell of the spore. From egg to spore-mother-cell is sporophyte; from spore-mother-cell to gametophyte. And since this rule has been found to hold good for all the archegoniate series and also for the flowering plants where, however, the gametophyte generation has become so extremely reduced as to be only with difficulty discerned, it is natural that when alternation of generation is stated to occur in any group of Thallophyta it should be required that the cytological evidence should support it.

The genus Nemalion has been recently investigated by Wolfe with the object of examining the cytological evidence. He finds that eight chromosomes appear in karyokinesis in the ordinary thallus cells, but sixteen in the gonimoblast filaments derived from the fertilized carposporon. Eight chromosomes appear again in the ultimate divisions which give rise to the carpospores. Upon the evidence it would seem therefore that so far as Nemalion is concerned an alternation occurs comparable with that existing in the lower Bryophyta where the sporophyte is relatively small, being attached to and to some extent parasitic upon the gametophyte. Nemalion is, however, one of those Florideae in which tetraspores do not occur. What is the case with those Florideae which have been described as triramous? If the sporophyte generation is confined to the cystocarp, is the tetrasporiferous plant, as has been suggested, merely a potential gametophyte reproducing by a process analogous to the bud-formation of the Bryophyta? In answer to this question a recent writer, Yamanouchi, states in a preliminary communication that he has found that in Polysiphonia violacea the germinating carpospores exhibit forty chromosomes, and the germinating tetraspores twenty chromosomes. From this it would seem that in this plant reduction takes place in the tetrasporangial mother-cell, and that the sporophyte generation of Bryophyta, which alternate with sexual plants. Novel as this result may seem, the tetraspores of Florideae become hereby comparable with the tetraspores of Dietotylo, to which reference will be made hereafter. But it is clear that it becomes on this view increasingly difficult to explain the occasional occurrence of tetraspores on male, female and monocious plants or the role of the carpospores in the life-cycle of Florideae. The results of future research on the cytology of the group will be awaited with interest.

Among Phaeophyceae it is well known that the oospore of Fucaceae germinates directly into the sexual plant, and there is thus only one generation. Moreover, it is known that the reduction in the number of chromosomes which occurs at the initiation of the gametophyte generation in Pteridophyta occurs
in the culminating stage of *Fucus*, where the oogonium is separated from the stalk-cell, so that unless it be contended that the *Fucus* is really a sporophyte which does not produce spores, and that the gametophyte is represented merely by the oogonium and antheridium, there is no semblance of alternation of generation in this case. The only case among Phaeophyceae which has been considered to point to the existence of such a phenomenon is *Cutteria*. Here the asexual cells are borne upon the so-called *Algaonias* or *repans* and the sexual cells upon the plants themselves as in *Cutteria*. The spores of the *Algaonias* form are known to give rise to sexual plants, and the oospore of *Cutteria* has been observed to grow into rudimentary *Algaonias*. Latterly, however, as the result of the cytological investigations of Mottert and Lloyd Williams, great advance has been made in our knowledge of the conditions existing in *Dictyota*. Mottert first observed that a reduction in the number takes place in the mother-cells of the tetraspore. It will be remembered that, as in most Florideae, the male, female and asexual plants are distinct in this genus. Mottert's observation has been confirmed by Lloyd Williams, who has shown, moreover, that the single nucleus is comparable to the *apogamic* case in the tetraspore. In *Sphaeroplea* it is only at this stage that zoospores are formed at all; but in most cases, such as *Oedogonium*, *Ulothrix*, *Coleochaete*, similar zoospores are produced again and again upon the thallus, and the product of the oospore may be regarded as merely a first brood of a series. It has been held by some, however, that the first brood corresponds to the sporophyte generation of the higher plants, and that the rest of the cycle is the gametophyte generation. Were the case of *Sphaeroplea* to stand alone, the phenomenon might perhaps be regarded as an alternation of generations, but still only comparable with the case of *Bangia*, and not the case of the Florideae. But it is difficult to apply such a term at all to those cases in which there intervene between the oospore and the next sexual stage a series of generations, the zoospores of which are all precisely similar.

The difficulty of tracing the relationships of algae is largely due to the inadequacy of our knowledge of the conditions under which they pass through the critical stages of their life-cycle. Of the thousands of species which have been distinguished, relatively few have been traced from spore to spore, as the flowering plants have been observed from seed to seed. The aquatic habit of most of the species and the minute size of many of them are difficulties which do not exist in the case of most seed-plants. From the analogy of the higher plants observers have justly argued that when they have seen and marked the characters of the reproductive organs they have found the plant at the stage when it exhibits its most noteworthy features, and they have named and classified the species in accordance with these observations. While even in such cases it is obvious that interesting stages in the life of the plant may escape notice altogether, in the cases of those plants the reproduction of which is unknown, and which have been named and placed on the analogy of the vegetative parts alone, there is considerable danger that a plant may be named as a distinct species which is only a stage in the life of another distinct and perhaps already known species. To take an example, *Lemanea* and *Batrachospermum* are Florideae which bear densely-whorled branches, but which, on the germination of the carpospore, give rise to a laxly-filamentous, somewhat irregularly-branched plant, from which the ordinary sexual plants arise at a later stage. This filamentous structure has been attributed to the genus *Chononaisia*, which it greatly resembles, especially when, as is said to be the case in *Batrachospermum*, it bears similar monospores. The true *Chononaisia*, however, bears its own sexual organs as well as monospores. To the specific identity of *Haplopora globosa* and *Scaphospora speciosa*, and of *Cutteria multifida* and *Algaonias repans*, reference has already been made. Again, many Green Algae—some unilayer, like *Sphaerella* and *Chlamydomonas*; some colonial forms, like *Volvox* and *Hormitollia*; some even filamentous forms, like *Ulothrix* and *Stigeoclonium*—are known to pass into a condition resembling that of *Palmaella*, and referred to on this ground.

It is, on the other hand, a danger in the opposite sense to conclude that all *Chononaisia* species are stages in the life-cycle of other plants, and, similarly, that all irregular colonial forms, like *Palmaella*, represent phases in the life of other Green Algae. Long ago Kätzing went so far as to express the belief that the lower algae were all capable of transformations into higher forms, even into moss-protonemata. Later writers have also thought that in all four groups of algae transformations of a most far-reaching character occur. Thus Borzi finds that *Protdoruma* passes through stages represented by *Protococcus*, *Characium*, *Dactylococcus* and *Sciadium*. Klebs has, however, recently canvassed the conclusions of both these investigators; and as the result of his own observations declares that algae, so far from being as polymorphic as they have been described, vary only within relatively narrow limits, and present on the whole as great fixity as the higher plants. It certainly supports his view to discover, on subjecting to a careful investigation *Botrydium granulatum*, a siphonaceous alga whose varied forms had been described by R. Stafafinski and M. Wronin, that these authors had included in the life-cycle stages of a second alga described previously by Kätzing, and now described afresh by Klebs as *Protosiphon botryoides*. In *Botrydium* the chromatophores are small, without pyrenoids, and oil-drops are present; in *Protosiphon* the chromatophores form a net-work with pyrenoids, and the contents include starch. Klebs insists that the only solution of such problems is the subjection of the algae in question to a rigorous method of pure culture. It is interesting to learn that G. Sen, pursuing the methods described by Klebs, has confirmed Chodat's observation of the passage of *Raphidium* into a *Dactylococcus*-stage, although he was unable to observe further metamorphosis. He has also seen *Pleurococccus viridis* dividing so as to form a filament, but has not succeeded in seeing the formation of zoospores as described by Chodat. While, therefore, there is much evidence of a negative character against the existence of an extensive polymorphism among algae, some amount of metamorphosis is known to occur. But until the conditions under which a particular transformation takes place have been ascertained and described, so that the observation may be repeated by other investigators, scant credence is likely to be given to the more extreme polymorphistic views.

In comparison with the higher plants, algae exhibit so much simplicity of structure, while the conditions under which they grow are so much more readily controlled, that they have frequently been the subject of physiological investigation with a view chiefly to the application of the results to the study of the higher plants. (See PLANTS: Physiology of.) In the literature of vegetable physiology there has thus accumulated a great body of facts relating not only to the phenomena of reproduction, but also to the life history of algae. With reference to their chemical physiology, the gelatinization of the cell-wall, which is so marked a feature, is doubtless attributable to the occurrence along with cellulose of pectic compounds. There is, however, considerable variation in the nature of the membrane in different species; thus the cell-wall of *Oedogonium*, treated with sulphuric acid and iodine, turns a bright blue, while the colour is very faint in the case of *Spirogyra*, the wall of which is said to consist for the most part of pectose. While starch occurs commonly as a cell-content in the majority of the Green Algae no trace of it occurs in *Vaucheria* and some of
spheric nitrogen is fixed by the agency of Green Algae in the soil. (For the remarkable symbiosis between algae and fungi see Fungus and Lichens.)

Most algae, particularly Phaeophyceae and Rhodophyceae, spend the whole of the life-cycle immersed in water. In the case of the freshwater algae, however, belonging to the Chlorophyceae and Cyanophyceae, although they required to be immersed during the vegetative period, the reproductive cells are often capable of resisting a considerable degree of desiccation, and in this condition are dispersed through great distances by various agencies. Again, as is well known, many species of marine algae growing in the region between the limits of high and low water are so constituted that they are capable of living either in the water or on the land. It is remarkable of characteristic algae at different levels constituting the zones to which reference has already been made, is probably in part an expression of the fact that different species vary in the capacity to resist desiccation from exposure. Thus Laminaria digitata, which characterizes the lowest zone, is only occasionally exposed at all, and then only for short periods of time. On the other hand, Postelia concilculata, which marks the upper belt, is exposed for longer periods, and during neap tides may not be reached by the. water for many days. Algae of more delicate texture than either Fucaceae or Laminariaceae also occur in the region exposed by the ebb of the tide, but these secure their exemption from desiccation either by retaining water in their meshes by capillary attraction, as in the case of Pilayella, or by growing among the tangles of the larger Fucaceae, as in the case of Polyphysis fastigata, or by growing in dense masses on rocks, as in the case of Laurencia pinnatifida. Such a species as Delesseria sanguinea or Callophylis laciniosa would on the contrary run great risk by exposure for even a short period. A few algae approach the ordinary terrestrial plants in their capacity to live in a sub-aerial habitat subject only to such occasional supplies of water as is afforded by the rainfall. Of this nature are some of the species of Vauclaria. A very few species, like Chrooleps, which grows on rock surfaces, are comparable with the land plants which have been termed xerophilous.

The great majority of the aquatic algae, both freshwater and marine, are attached plants. Some, however, are wanderers, either swimming actively with the aid of cilia, or floating inertly as the result of a specific weight closely similar to that of the surrounding water. The quantitative estimate of the amount of this flora has revealed its enormous aggregate amount and therefore its great importance in the economy of oceanic and lacustrine animal life. The organisms constituting this plankton are mostly unicellular, often aggregated together in colonies, and the remarkable structure which they exhibit has added a new chapter to the story of adaptation to environment. The families Diatomeae, Peridiniaceae and Protococceae are best represented in the pelagic plankton, while in addition the Volvocaceae are an important element in freshwater plankton.

The great majority of algae, however, grow like land-plants attached to a substratum, and to these the term benthos is now generally applied. While the root of land-plants serves for the double purpose of attachment and the supply of water, it is attachment only that is usually sought in the case of algae. Immersed as they usually are in a medium containing in solution the inorganic substances which they require for their nutrition, the absorption of these takes place throughout their whole extent. The elaborate provision for the conduct of water from part to part which has played so important
a role in the morphological development of land plants is entirely wanting in algae, such conducting tissues as do exist in the larger Phaeophyceae and Rhodophyceae serving rather for dance to leaching fungoides being a remarkable feature of the algae, in which there is a tendency toward elaboration of organic substance, and being thus comparable with the phloem of the higher plants. The attachment organ of algae is thus more properly called a holdfast, and is found to be of very varied structure. It generally takes the form of a single flattened disc as in the Fucaceae, or a group of finger-like processes as in Laminariaceae, or a tuft of filaments as in many instances. When the attachment is in sand or mud, it often shows the appearance of a true root as in Chara or Catenella. It is clear that where the bottom of a lake or sea consists of oozy mud or shifting sand, it is impossible for algae to grow without some such advantage as a firm stand. This may often be observed in sand covered with vegetation like an oasis in a desert. The rapidity with which walls, piles and pontoons—stone, wood and iron—become covered with marine plants is well known, while the discovery of some effective means of preventing the fouling of the bottoms of ships by the growth of algae would be hailed as a boon by shipowners. While rocks and boulders are the favoured situation for the growth of marine algae, those which readily disintegrate, like the coarser sandstones, are naturally less favoured than the harder rocks. When an algae is found growing in sheltered coves or on the beach may often be observed to stand covered with vegetation like an oasis in a desert. The rapidity with which walls, piles and pontoons—stone, wood and iron—become covered with marine plants is well known, while the discovery of some effective means of preventing the fouling of the bottoms of ships by the growth of algae would be hailed as a boon by shipowners. It is not, however, the British coast a favourite collecting ground for the smaller red and brown epiphytes. Endophytes a distinction must be made between those which occupy the cell-wall only and those which perforate the cells, bringing about their destruction. There can be little doubt that in some cases the epiphyllous approaches parasitism. In one case described by Kuckuck the chromatops of the infesting algae are absent, a circumstance which points to a complete parasitism. Allusion has already been made to the peculiar habit of the shell-boring algae.

In many algae certain branches of limited growth bear a remarkable resemblance to leaves. The Characeae among freshwater algae and the Sargassaceae among marine algae might be cited as examples. Surveying the whole range of algae life, Olmann distinguishes bush-forms, whip-forms, net-forms, leaf-forms, sack-forms, darting barbs, and rounded processes. The similarity of outline in many species to that of trees and shrubs will strike any one who examines algae mounted for the herbarium. Cladophora and Bryopsis among monosiphonous forms, Chara, Polydictyon, Ceramium and Cystosira among larger algae, are illustration of this. The whip-forms are represented by Spirogyra, Chlozophora, Scytosiphon, Nemalion, Himanthalia and Chorda. Net-forms are found in Hydrodictyton and Microdictyton. The leaf-forms are very varied and owe their existence to the advantage accruing from the exposure of a large surface to the influence of the light. In some cases such as Delesseria, Neurymenia, Fucus, Alaria, Ulva, Porphyra, etc., are leaf-like with a rigidity varying from a flabby lamina to the thin and pliable. Agarum, Claudea and Struwea are leaf-forms which are perforated like Aldrovanda among flowering plants. Enteromorpha, Asperoococcus and Adenocystis are sack-forms. Dorsi-ventral algae are rare. Leptolinid and resistentoides being a remarkable resemblance to a leafy liverwort. In the next group of forms the simplest are crusts attached to the substratum throughout their extent, and growing at the margin. Such are Myrionema, Ralfsia, Melobesia and Hildebrandia. Others are attached throughout their extent, but also grow vertical filaments so as to form a velvety pile. Such are Coleochaete, Ochlochaete, Elachistes, Ascoscyoc and Rhododerms. Peyssonella squamaria, Melobesia lichenoides, Leathesia disformis are forms which are not attached throughout but grow in plates like the foliaceous lichens. When it is sought to consider algae with a view to the correlation of the external form to the conditions of life, a subject the study of which under the name of ecology has been latterly pursued with great success among land plants, it is difficult as yet to arrive at generalizations which are trustworthy. Among land plants, as is well known, similarity of environment has often called forth similar adaptations among plants of widely separated families. The similarity of certain xerophilous Euphorbiaceae to Cactaceae is a ready illustration of this phenomenon. From what has been already said it is evident that among algae also strikingly similar forms will be found. The infesting algae of a rocky shore may be cast upon the beach and thus found in the sand. Compare, for example, the blue-green Gloeocystis with the green Gloeaostis, the red Batrachocystis with the green Draparnaldia, the red Corallina with the green Cymopolia, the green Enteromorpha with the brown Asperoococcus, the green Ulva with the red Porphyra, the red Nemalion with the brown Castagnea, and so on. But on the one hand similar forms seem to grow often under different conditions, while on the other hand different forms flourish under the same conditions. The conceivable variations in the conditions which would count in algal life are wondrously manifold.

The algal life has often been wanting to resist injury from surf or current. The vesicles of Fucaceae and Laminariaeae prevent the sinking of the bulkier forms. But why certain Fucaceae favour certain zones in the littoral region, why certain epiphytes are confined to certain hosts, why Red and Brown Algae are not better represented in fresh water or Green Algae in salt,—these are problems to which it is difficult to find a ready answer. Algae cannot be regarded as directly important in the industry of the sea. On the coasts of Europe marine algae detached by the annual gales are commonly carted on to the land as a convenient manure. Porphyra laciniata and Rhodymenia palmata are locally used as food, the latter being known as dulse. Agar-agar is a gelatinous substance derived from an eastern species of Grateludia. The ash of seaweeds, known in Scotland as kelp, and in Brittany as varec, was formerly used as a source of iodine to a greater extent than is at present the case. Excepting where the thallus is impregnated with silica, as in Diatomaceae, or carbonate of lime, as in Corallineaceae, Characeae and some Siphonales, it is perhaps not surprising that algae should not have been extensively preserved in the fossil form. Considering, however, that it is generally believed that Bryophyta and vascular plants are descended from an algal ancestry, it is natural to suppose that, prior to the luxuriant vegetable growths of the Carboniferous period, there must have existed an age of algae. It was doubtless this expectation that has led to the description of a number of Silurian and Devonian remains as algae upon which account is taken in the character of these. The geological record is, as perhaps is to be expected, exceedingly poor, except as regards the calcareous Siphonales, which are well represented at various horizons, from the Silurian to the Tertiary; even the Diatomaceae, which are found in great quantities in the Tertiary deposits, do not occur at all earlier than the chalk. It is believed, however, that the Devonian fossil, Nematothecys, is a Laminarian algae, but it is not until the late Secondary and
the Tertiary formations that fossil remains of algae become frequent. (See Palaeobotany.)

The subjoined list includes the larger standard works on algae, together with a number of works to which reference is made in this article. For a detailed account of the principal litte works, see the 'Bibliotheca Phycologica' in de Toni’s Sylloge Algarum, vol. i. (1886), with the addendum thereto in vol. iv. (1897) of the same work.

ALGARDI, ALESSANDRO (1600-1654), Italian sculptor, was born at Bologna in 1602. While he was attending the school of the Caracci his preference for the plastic art became evident and he placed himself under the instruction of the sculptor Conventi. At the age of twenty he was brought under the notice of Duke Ferdinand of Mantua, who gave him several commissions. He was also much employed about the same period by jewellers and others in modelling in gold, silver and ivory. After a short residence in Venice he went to Rome in 1625 with an introduction from the duke of Mantua to the pope’s nephew, Cardinal Ludovisi, who employed him for a time in the restoration of ancient statues. The death of the duke of Mantua left him to his own resources, and for several years he earned a precarious maintenance from these restorations and the commissions of goldsmiths and diamond cutters. In 1645 he went to Padua, where he first worked in marble, a colossal statue of San Filippo Neri, with kneeling angels. Immediately after, he produced a similar group representing the execution of St Paul, for the church of the Barnabite Fathers in Bologna. These works, displaying great technical skill, though with considerable exaggeration of expression and attitude, at once established Algarotti’s reputation and other commissions followed in rapid succession. The turning point in Algarotti’s fortune was the accession of Innocent X., of the Bolognese house of Farnelli, to the papal throne in 1644. He was employed by Camillo Farnelli, nephew of the pontiff, to design the Villa Doria Pamphili outside the San Pancrazio gate. The most important of Algarotti’s other works were the monument of Leo XI., a bronze statue of Innocent X. for the capitoline, and above all, La Fuega d’Attilia, the largest aro-relievo in the world, the two principal figures being about 10 ft. high. In 1650 Algarotti met Velasquez, who obtained some interesting orders for his Italian companion in Spain. Thus there are four chimney-pieces by Algarotti in the palace of Aranjuez, where also the figures on the fountain of Neptune were executed by him. The Augustinian monastery at Salamanca was restored and a bronze statue of the count de Monterrey, which was also the work of Algarotti. From an artistic point of view, he was most successful in his portrait-statues and groups of children, where he was obliged to follow nature more closely. In his later years he became very avaricious and amassed a great fortune. He died in Rome on the 10th of June 1654.

ALGAROTH, POWDER OF, a basic chloride of antimony. It is obtained by the action of 2 parts of hydrochloric acid on 1 part of the Veronese physician Victor Algarotus about the end of the 17th century. Its composition is probably Sb2O3Cl, but it may be prepared by the addition of much water to a solution of antimony chloride; a bulky amorphous precipitate being formed, which, on standing, gradually becomes crystalline. It is soluble in hydrochloric acid and tartaric acid, but insoluble in alcohol. On its composition and preparation see E. Péliger, Annalen, 1847, xv., 380; L. Schmied, Chem. News, 1869, clxxv., 314; and W. E. Maclvor, Chem. News, 1875, xxvii., 229.

ALGAROTTI, FRANCESCO, COUNT (1712-1764), Italian philo-
sopher and writer on art, was born on the 11th of December 1712 at Venice, and died at Pisa in 1764. He studied at Rome and Bologna, and at the age of twenty went to Paris, where he enjoyed the friendship of Voltaire and produced his great
ALGARVE

work Neuentianismo per le dame, a work on optics. Voltaire called him his cher cygne de Pojone. Returning from a journey to Russia, he met Frederick the Great who made him a count of Prussia (1740) and court chamberlain (1747). Augustus III. of Poland honoured him with the title of councillor. In 1756, after seven years' residence partly in Berlin and partly in Dresden, he returned to Italy, living at Venice and then at Pisa, where he died on the 3rd of May 1764. Frederick the Great erected to his memory a monument on the Campo Santo at Pisa. He was a man of wide knowledge, a connoisseur in art and music, and the friend of most of the leading authors of his time. His chief work on art is the Saggi sopra le belle arti ("Essays on the Fine Arts"). Among his other works may be mentioned Poemi, Travels in Russia, Essay on Painting, Correspondence.

The best complete edition with biography was published by D. Michelesi (1791-1794).

ALGARVE, or ALGARVES, an ancient kingdom and province in the extreme S. of Portugal, corresponding with the modern administrative district of Faro, and bounded on the N. by Alentejo, E. by the Spanish province of Huelva, and S. and W. by the Atlantic Ocean. Pop. (1900) 255,191; area, 1937 sq. m. The greatest length of the province is about 85 m. from E. to W.; its average breadth is about 22 m. from N. to S. The Serra de Malhão and the Serra de Monchique extend in the form of a crescent across the northern part of the province, and, sweeping to the south-west, terminate in the lofty promontory of Cape St Vincent, the south-west extremity of Europe. This headland is famous as the scene of many sea-fights, notably the defeat inflicted on the Spanish fleet in February 1797 by the British under Admiral Jervis, afterwards Earl St Vincent. Between the mountainous tracts in the north and the southern coast stretches a narrow plain, watered by numerous rivers flowing southward from the hills. The coast is fringed for 30 m. from Quarteira to Tavira, with long sandy islands, through which there are six passages, the most important being the Ria Formosa, between Faro and Olhão. The navigable estuary of the Guadiana divides Algarve from Huelva, and its tributaries water the western districts. From the Serra de Malhão flow two streams, the Silves and Odelouca, which unite and enter the Atlantic below the town of Silves. In the hilly districts the roads are bad, the soil unsuited for cultivation, and the inhabitants few. Flocks of goats are reared on the mountain-sides. The level country along the southern coast is more fertile, and produces in abundance grapes, figs, oranges, lemons, olives, almonds, aloes, and even plantains and dates. The land is, however, not well suited for the production of cereals, which are mostly imported from Spain. On the coast the people gain their living in great measure from the fisheries, tunny and sardines being caught in considerable quantities. Salt is also made from sea-water. There is no manufacturing or mining industry of any importance. The harbours are bad, and almost the whole foreign trade is carried on by ships of other nations, although the inhabitants of Algarve are reputed to be the best seamen and fishermen of Portugal. The chief exports are dried fruit, wine, salt, tunny, sardines and anchovies. The only railway is the Lisbon-Faro main line, which passes north-eastward from Faro, between the Monchique and Malhão ranges. Faro (11,780), Lagos (8291), Loulé (22,478), Monchique (7345), Olhão (10,000), Silves (9687) and Tavira (12,175), the chief towns, are described in separate articles.

The name of Algarve is derived from the Arabic, and signifies a land lying to the west. The title "king of Algarve," held by the kings of Portugal, was first assumed by Alphonso III., who captured Algarve from the Moors in 1253.

ALGOU, or ALCOU, the name now given to a comparatively small district forming the south-western corner of Bavaria, and belonging to the province of Swabia and Neuburg, but formerly applied to a much larger territory, which extended as far as the Danube on the N., the Inn on the S. and the Lech on the W. The Algou Alps contain several lofty peaks, the highest of which is Mädelegabel (8681 ft.). The district is celebrated for its cattle, milk, butter and cheese.

ALGEBRA (from the Arab. al-jabr wa'l-muqâbala, transposition and removal [of terms of an equation], the name of a treatise by Mahommed ben Musa al-Khowarizmi), a branch of mathematics which may be defined as the generalization and extension of arithmetic.

The subject-matter of algebra will be treated in the following article under three divisions:—A. Principles of ordinary algebra; B. Special kinds of algebra; C. History. Special phases of the subject are treated under their own headings, e.g. Algebraic Forms; Binomial; Combinatorial Analysis; Determinants; Equation; Continued Fraction; Function; Groups, Theory of; Logarithm; Number; Probability; Series.

A. PRINCIPLES OF ORDINARY ALGEBRA

1. The above definition gives only a partial view of the scope of algebra. It may be regarded as based on arithmetic, or as dealing in the first instance with formal results of the laws of arithmetical number; and in this sense Sir Isaac Newton gave the title Universal Arithmetick to a work on algebra. Any definition, however, must have reference to the state of development of the subject at the time when the definition is given.

2. The earliest algebra consists in the solution of equations. The distinction between algebraical and arithmetical reasoning then lies mainly in the fact that the former is in a more condensed form, while the latter is based on the use of algebraic symbols, which are only used as a kind of shorthand for verbal expressions. This form of algebra was extensively studied in ancient Egypt; but, in accordance with the practical tendency of the Egyptian mind, the study consisted largely in the treatment of particular cases, very few general rules being obtained.

3. For many centuries algebra was confined almost entirely to the solution of equations; one of the most important steps being the enunciation by Diophantus of Alexandria of the laws governing the use of the minus sign. The knowledge of these laws, however, does not imply the existence of a conception of negative quantities. The development of symbolic algebra by the use of general symbols to denote numbers is due to Franciscus Vieta (François Viète, 1540–1603). This led to the idea of algebra as a generalized arithmetic.

4. The principal step in the modern development of algebra was the recognition of the meaning of negative quantities. This appears to have been due in the first instance to Albert Girard (1595–1632), who extended Vieta's results in various branches of mathematics. His work, however, was little known at the time; and later was overshadowed by the greater work of Descartes (1596–1650).

5. The main work of Descartes, so far as algebra was concerned, was the establishment of a relation between arithmetical and geometrical measurement. This involved not only the geometrical interpretation of negative quantities, but also the idea of continuity; this latter, which is the basis of modern analysis, leading to two separate but allied developments, viz. the theory of the function and the theory of limits.

6. The great development of all branches of mathematics in the two centuries following Descartes has led to the term algebra being used to cover a great variety of subjects, many of which are really only ramifications of arithmetic, dealt with by algebraical methods, while others, such as the theory of numbers and the general theory of series, are outgrowths of the application of algebra to arithmetic, which involve such special ideas that they must properly be regarded as distinct subjects. Some writers have attempted unification by treating algebra as concerned with functions, and Comte accordingly defined algebra as the calculus of functions, arithmetic being regarded as the calculus of values.

7. These attempts at the unification of algebra, and its separation from other branches of mathematics, have usually been accompanied by an attempt to base it, as a deductive science, on certain fundamental laws or general rules; and this has tended to increase its difficulty. In reality, the variety of algebra corresponds to the variety of phenomena. Neither
mathematics itself, nor any branch or set of branches of mathematics, can be regarded as an isolated science. While, therefore, the logical development of algebraic reasoning must depend on certain fundamental relations, it is important that the early study of the subject these relations should be introduced gradually, and not in an isolated and theoretically analytical acquaintance with the phenomena with which they are concerned.

8. The extension of the range of subjects to which mathematical methods can be applied, accompanied as it is by an extension of the range of study which is useful to the ordinary worker, has led in the latter part of the 19th century to an important reaction against the specialization mentioned in the preceding paragraph. This reaction has taken the form of a return to the alliance between algebra and geometry (§8), on which modern analytical geometry is based; the alliance, however, is designed not only with the application of graphical methods to particular cases rather than to general expressions. These applications are sometimes treated under arithmetic; sometimes under algebra; but it is more convenient to regard graphs as a separate subject, closely allied to arithmetic, algebra, mensuration and analytical geometry.

9. The association of algebra with arithmetic on the one hand, and with geometry on the other, presents difficulties, in that geometrical measurement is based essentially on the idea of continuity, while arithmetical measurement is based essentially on the idea of discontinuity; both ideas being equally matters of intuition. The difficulty first arises in elemental mensuration, where it is partly met by associating arithmetical and geometrical measurement with the cardinal and the ordinal aspects of number respectively (see Arithmetic). Later, the difficulty recurs in an acute form in reference to the continuous variation of a function. Reference to a geometrical interpretation seems at first sight to throw light on the meaning of a differential coefficient; but closer analysis reveals new difficulties, due to the geometrical interpretation itself. One of the most recent developments of algebra is the algebraic theory of number, which is devised with the view of removing these difficulties. The harmony between arithmetical and geometrical measurement, which was disturbed by the Greek geometers on the discovery of irrational numbers, is restored by an unlimited supply of the causes of disturbance.

10. Two other developments of algebra are of special importance. The theory of sequences and series is sometimes treated as a part of elementary algebra; but it is more convenient to regard the simpler cases as isolated examples, leading up to the general theory. The treatment of equations of the second and higher degree introduces temporary and complex numbers, the theory of which is a special subject.

11. One of the most difficult questions for the teacher of algebra is the stage at which, and the extent to which, the ideas of a negative number and of continuity may be introduced. On the one hand, the modern developments of algebra began with these ideas, and particularly with the idea of a negative number. On the other hand, the lateness of occurrence of any particular mathematical idea is usually closely correlated with its intrinsic difficulty. Moreover, the ideas which are usually formulated at an early stage are incomplete; and, if the incompleteness of an idea is not realized, operations in which it is implied are apt to be purely formal and mechanical. What are called negative numbers in arithmetic, for instance, are not really negative numbers but negative quantities (§27 (i)); and the difficulties incident to the ideas of continuity have already been pointed out.

12. In the present article, therefore, the main portions of elementary algebra are treated in one section, without reference to the separate branch of algebra which is considered generally in two separate sections. These three sections may therefore be regarded as to a certain extent concurrent. They are preceded by two sections dealing with the introduction to algebra from the arithmetical and the graphical sides, and are followed by a section dealing briefly with the developments mentioned in §§ 9 and 10 above.

13. Order of Arithmetical Operations.—It is important, before beginning the study of algebra, to have a clear idea as to the meanings of the symbols used to denote arithmetical operations.

(i.) Additions and subtractions are performed from left to right. Thus $3 + 2 + 4 + 5 = 16$, $7 - 2 + 9 = 14$. The first 3 is added to 16, the result, and 2 added to the new result.

(ii.) The above operation is performed with 1 lb as the unit of counting, and the process would be the same with any other unit; e.g. we should perform the same process to find $35 + 25 - 75 + 23$. Hence we can separate the numbers from the common unit, and replace $3 - 5 + 7 - 2 = 15 - 7 + 2$, the additions and subtractions being then performed by means of an addition-table.

(iii.) Multiplications, or operations represented by $\times$, are performed from right to left. Thus $2 \times 3 \times 7 \times 11$ means 5 times 3 times 7 times 1 lb; i.e. it means that 1 lb is to be multiplied by 7, the result by 3, and the new result by 5. We may regard this as meaning the same as $5 \times 3 \times 7 \times 1$, since 7 lb itself means $7 \times 1$ lb, and the lb is the unit in each case. But it does not mean the same as $5 \times 21$ lb, though the two are equal, i.e. give the same result (see §23).

This rule as to the meaning of $\times$ is important. If it is intended that the first number is to be multiplied by the second, a special sign such as $\times$ should be used. The sign $\times$ means that the quantity or number preceding it is to be divided by the quantity or number following it.

(v.) The use of the solidus / separating two numbers is for convenience of printing fractions or fractional numbers. Thus $16/5$ does not mean $16 + 1/5$.

(vi.) Any compound operation not coming under the above descriptions is to have its meaning made clear by brackets, the use of a pair of brackets indicating that the expression between them is to be treated as a whole. Thus we should not write $8 \times (7+6)$, but $(8 \times 7)+6$, or $8 \times (7+6)$. The sign $\times$ coming before, or immediately after, a bracket may be omitted; e.g. $8 \times (7+6)$ may be written $8 \times 13$.

This rule as to using brackets is not always observed, the convention sometimes adopted being that multiplications or divisions are to be performed before additions or subtractions. The convention is even pushed to such an extent as to make “$4 \times 3$ of $7 + 5$” mean “$4 \times (3 \times 7) + 5$”, though it is not clear what “Find the value of $4 \times (3 \times 7)$ times $7 + 5$” would then mean. There are grave objections to an arbitrary rule of this kind, the chief being the useless waste of mental energy in remembering rules.

(vii.) The only exception that may be made to the above rule is that an expression involving multiplication-dots only, or a simple fraction written with the solidus, may have the brackets omitted for additions or subtractions, provided the figures are so spaced as to prevent misunderstanding. Thus $8 \times (7+6)+3$ may be written $8+7+6+3$, and $8+7+6+3$ may be written $8+7+6+3$. But $3+3$ should be written $(3+3)/2.4)$, not $3.5/2.4$.

14. Latent Equations.—The equation exists, without being shown as an equation, in all those elementary arithmetical processes which come under the head of inverse operations; i.e. processes which consist in obtaining an answer to the question “Upon what has a given operation to be performed in order to produce a given result?” or to the question “What operation of a given kind has to be performed on a given quantity or number in order to produce a given result?”

(i.) In the case of subtraction the second of these two questions is perhaps the simpler. Suppose, for instance, that we wish to know how much will be left off 10s. after spending 3s., how much has been spent out of 10s. if 3s. is left. In either case we may put the question in two ways: (a) What must be added to 3s. in order to produce 10s., or (b) To what must 3s. be added in order to produce 10s. If the answer to the question is $X$, we have either

(a) $10s. = 3s. + X$, $X = 10s. - 3s.$, or
(b) $10s. = X + 3s.$, $X = 10s. - 3s.$
(ii.) In the above case the two different kinds of statement lead to arithmetical formulae of the same kind. In the case of division we get two kinds of arithmetical formula, which, however, may be regarded as requiring a single kind of numerical process in order to determine the final result:—

(a) If 24d. is divided into 4 equal portions, how much will each portion be?

Let the answer be $X$; then

$$24d. = 4X,$$

$x = 6$ of 24d.

(b) Into how many equal portions of 6d. each may 24d. be divided?

Let the answer be $x$; then

$$24d. = x \times 6d., \therefore x = 24d. \div 6d.$$

(iii.) Where the direct operation is evolution, for which there is no commutative law, the two inverse operations are different in kind.

(a) What would be the dimensions of a cubical vessel which would exactly hold 125 litres; a litre being a cubic decimetre?

Let the answer be $X$; then

$$125 \text{ c.dm.} = X^3, \therefore X = \sqrt[3]{125} \text{ c.dm.}$$

(b) To what power must 5 be raised to produce 125?

Let the answer be $x$; then

$$125 = 5^x \therefore x = \log_5{125}$$

15. With regard to the above, the following points should be noted.

(1) When we require to know a quantity, it is simplest to deal with this quantity as a whole. In (i.), for instance, we want to find the amount by which 10s. exceeds 35s., not the number of shillings in this amount. It is true that we obtain this result by subtracting 3 from 10 by means of a subtraction-table (concrete or ideal); but this table merely gives the generalized results of a number of operations of addition or subtraction performed with concrete units. We must count with something; and the successive summations obtained by the addition of successive units are in fact numerical quantities, not numbers.

Whether this principle may legitimately be extended to the notation adopted in (iii.) (a) of § 14 is a moot point. But the present tendency is to regard the early association of arithmetical with linear measurement as important; and it seems to follow that we may properly (at any rate at an early stage of the subject) multiply a length by a length, and the product again by another length, the practice being dropped when it becomes necessary to give a strict definition of multiplication.

(2) The results may be stated briefly as follows, the more usual form being adopted under (iii.) (a):—

(i.) If $A = B + X$, or $= X + B$, then $A = A - B$.

(ii.) (a) If $A = m \times X$, then $X = \frac{A}{m}$.

(b) If $A = x \times M$, then $x = \frac{A}{M}$.

(iii.) (a) If $n = x$, then $x = \sqrt[n]{n}$.

(b) If $n = a^2$, then $x = \log_a{a}$.

The important thing to notice is that where, in any of these five cases, one statement is followed by another, the second is not to be regarded as obtained from the first by logical reasoning involving such general axioms as that "if equals are taken from equals the remainders are equal"; the fact being that the two statements are merely different ways of expressing the same relation. To say, for instance, that $X$ is equal to $A - B$, is the same thing as to say that $X$ is a quantity such that $X$ and $B$, when added, make up $A$; and the above five statements of necessary connexion between two statements of equality are in fact nothing more than definitions of the symbols—

$$+, \cdot, ^\frac{1}{n}, \sqrt[n]{n}, \text{ and } \log_a$$

An apparent difficulty is that we use a single symbol to denote the result of the two different statements in (i.) (a) and (i.) (b) of § 14. This is due to the fact that there are really two kinds of subtraction, respectively involving counting forwards (complementary addition) and counting backwards (ordinary subtraction); and it suggests that it may be wise not to use the one symbol to represent the result of both operations until the commutative law for addition has been fully grasped.

16. In the same way, a statement as to the result of an inverse operation is really, by the definition of the operation, a statement as to the result of a direct operation. If, for instance, we state that $A = X - B$, this is really a statement that $X = A + B$.

Thus, corresponding to the results under § 15 (2), we have the following:

(1) Where the inverse operation is performed on the unknown quantity or number:

(i.) If $A = X - B$, then $X = A + B$.

(ii.) (a) If $M = \frac{A}{n}$, then $X = m \times M$.

(b) If $m = X + M$, then $X = m \times M$.

(iii.) (a) If $a = \sqrt[n]{x}$, then $x = a^n$.

(b) If $p = \log_a{a}$, then $x = a^p$.

(2) Where the inverse operation is performed with the unknown quantity or number:

(i.) If $B = A - X$, then $A = B + X$.

(ii.) (a) If $m = A + X$, then $A = m - X$.

(b) If $M = \frac{A}{n}$, then $A = m \times M$.

(iii.) (a) If $p = \log_a{m}$, then $m = a^p$.

(b) If $X = \sqrt[n]{n}$, then $n = a^p$.

In each of these cases, however, the reasoning which enables us to replace one statement by another is of a different kind from the reasoning in the corresponding cases of § 15. There we proceeded from the direct to the inverse operations; i.e. so far as the nature of arithmetical operations is concerned, we launched out on the unknown. In the present section, however, we return from the inverse operation to the direct; i.e. we rearrange our statement in its simplest form. The statement, for instance, that $32 - x = 25$, is really a statement that $32$ is the sum of $x$ and $25$.

17. The five equalities which stand first in the five pairs of equalities in § 15 (2) may therefore be taken as the main types of a simple statement of equality. When we are familiar with the treatment of quantities by equations, we may ignore the units and deal solely with numbers; and (ii.) (a) and (ii.) (b) may then, by the commutative law for multiplication, be regarded as identical. The five processes of deduction then reduce to four, which may be described as (i.) subtraction, (ii.) division, (iii.) (a) taking a root, (iii.) (b) taking logarithms. It will be found that these (and particularly the first three) cover practically all the processes legitimately adopted in the elementary theory of the solution of equations; other processes being sometimes liable to introduce roots which do not satisfy the original equation.

18. It should be noticed that we are still dealing with the elementary processes of arithmetic, and that all the numbers involved in §§ 14-17 are supposed to be positive integers. If, for instance, we are told that $15 = \frac{3}{2}$ of $(x - 2)$, what is meant is that (1) there is a number $n$ such that $x = n + 2$, (2) there is a number $r$ such that $n = 4$ times $r$, and (3) $r = 3$ times $v$. From these statements, working backwards, we find successively that $r = 5$, $u = 20$, $x = 22$. The deductions follow directly from the definitions, and such mechanical processes as "clearing of fractions" find no place ($§ 21$ (ii.). The extension of the methods to fractional numbers is part of the establishment of the laws governing these numbers ($§ 27$ (ii.).)

19. Expressed Equations.—The simplest forms of arithmetical equations arise out of abbreviated solutions of particular problems. In accordance with § 15, it is desirable that our statements should be statements of equality of quantities rather than of numbers; and it is convenient in the early stages to have a distinctive notation, e.g. to represent the former by capital letters and the latter by small letters.

As an example, take the following. I buy 2 lb of tea, and have 6s. 8d. left out of 10s.; how much per lb did tea cost?

(1) In ordinary language we should say: Since 6s. 8d. was left, the amount spent was 10s. - 6s. 8d., i.e. was 3s. 4d. Therefore 2 lb of tea cost 3s. 4d. Therefore 1 lb of tea cost 1s. 8d.

(2) The first step towards arithmetical reasoning in such a case is the introduction of the sign of equality. Thus we say:—

Cost of 2 lb tea = 6s. 8d. = 10s.

Cost of 2 lb tea = 10s. - 6s. 8d. = 3s. 4d.

Cost of 1 lb tea = 1s. 8d.
(3) The next step is to show more distinctly the unit we are dealing with (in addition to the money unit), viz. the cost of 1 lb tea. We write:

\[ (2 \times \text{cost of 1 lb tea}) + 8 \times 6s. = 10s. \]

\[ 2x \times \text{cost of 1 lb tea} = 10s. - 6s. = 3s. 4d. \]

\[ \text{Cost of 1 lb tea} = 1s. 8d. \]

(4) The stage which is introductory to algebra consists merely in replacing the unit "cost of 1 lb tea" by a symbol, which may be a letter or a mark such as the mark of interrogation, the asterisk, &c. If we denote this unit by X, we have

\[ (2xX) + 8 \times 6s. = 10s. \]

\[ 2X = 10s. - 6s. = 3s. 4d. \]

\[ X = 1s. 8d. \]

20. Notation of Multiples.—The above is algebraic. The only thing which it is necessary to import from algebra is the notation by which we write 2X instead of \( 2 \times X \) or \( 2 \times X \). This is rendered possible by the fact that we can use a single letter to represent a single number or numerical quantity, however many digits are contained in the number.

It must be remembered that, if \( a \) is a number, \( 3a \) means 3 times \( a \), not a times 3; the latter must be represented by \( a \times 3 \) or \( a^3 \).

The number by which an algebraical expression is to be multiplied is called its coefficient. Thus in \( 3a \) the coefficient of \( a \) is 3. But in \( 3a \), the coefficient of \( 4a \) is 3, while the coefficient of \( a \) is 3.

21. Equations with Fractional Coefficients.—As an example of a special form of equation we may take

\[ \frac{1}{2} + \frac{3}{4} = 10. \]

(i.) There are two ways of proceeding.

(a) The statement is that (1) there is a number \( u \) such that \( x = 2u \). (2) there is a number \( u \) such that \( x = 3u \), and (3) \( u + v = 10u \).

We may therefore conveniently take as our unit, in place of \( x \), a number \( y \) such that

\[ x = 6y. \]

We then have

\[ 3y + 2y = 10, \]

whence

\[ y = 10, \quad y = 2, \quad x = 6y = 12. \]

(b) We can collect coefficients, i.e. combine the separate quantities or numbers expressed in terms of \( x \) as unit into a single quantity or number so expressed, obtaining

\[ \frac{x}{2} = 10. \]

By successive stages we obtain \( \frac{x}{2} = 2, \quad x = 12 \); or we may write at once \( x = \frac{1}{50} \text{ of } 10 \times 6 \) or \( 10 \times 12 \). The latter is the more advanced process, implying some knowledge of the laws of fractional numbers, as well as an application of the associative law \( (\frac{26}{2}) \)

(ii.) Perhaps the worst thing we can do, from the point of view of intelligibility, is to "clear of fractions" by multiplying both sides by 6. It is no doubt true that, if \( x^3 + x^4 = 10 \), then \( x^3 + 2x + 6 = 10 \); and similarly if \( \frac{x}{x} + \frac{x}{x} = 10 \), then \( \frac{x}{x} + 2x = \frac{x}{x} \); but the fact, however interesting it may be, is of no importance for our present purpose. In the method (a) above there is indeed a multiplication by 6; but it is a multiplication arising out of subdivision, not out of repetition (see Arithmetic), so that the total \( (\text{viz. } 10) \) is unaltered.

22. Arithmetical and Algebraical Treatment of Equations.—The following will illustrate the passage from arithmetical to algebraical reasoning. "Coal costs 3s. a ton more this year than last year. If 4 tons last year cost 104s., how much does a ton cost this year?"

If we write X for the cost per ton this year, we have

\[ 4X = 3s. = 104s. \]

From this we can deduce successively \( X = 26s. \), \( X = 29s. \). But, if we transform the equation into

\[ 4X - 12s. = 104s. \]

we make an essential alteration. The original statement was with regard to \( X - 3s. \) as the unit; and from this, by the application of the distributive law \( (\frac{26}{2}) \), we have passed to a statement with regard to \( X \) as the unit. This is an algebraical process.

In the same way, the transition from \( x^2 + 4x^2 = 21 \) to \( x^2 + 4x + 4 = 25 \), or from \( x + 2 \) to \( x + 2 = 25 \), is arithmetical; but the transition from \( x^2 + 4x + 4 = 25 \) to \( (x + 2)^2 = 25 \) is algebraical, since it involves a change of the number we are thinking about.

Generally, we may say that algebraic reasoning in reference to equations consists in the alteration of the form of a statement rather than in the deduction of a new statement; i.e. it cannot be said that "If \( A = B \), then \( E = F \)" is arithmetical, while "If \( C \) and \( E = F \)" is algebraic. Algebraic treatment consists in replacing either of the terms \( A \) or \( B \) by an expression which we know from the laws of arithmetic to be equivalent to it. The subsequent reasoning is arithmetical.

23. Sign of Equality.—The various meanings of the sign of equality \( (=) \) must be distinguished.

(i.) \( 4 \times 3 \text{ lb.} = 12 \text{ lb.} \)

This states that the result of the operation of multiplying 3 lb by 4 is 12 lb.

(ii.) \( 4 \times 3 \text{ lb.} \times 3 = 3 \times 4 \times 3 \)

This states that the two operations give the same result; i.e. that they are equivalent.

(iii.) \( A \text{'s share} = \frac{5}{8} \), or \( 3 \text{ times } A \text{'s share} = 15 \).

Either of these is a statement of fact with regard to a particular quantity; it is usually called an equation, but sometimes a conditional equation, the term "equation" being then extended to cover (i.) and (ii.).

This is a definition of \( x^2 \); the sign \( = \) is in such cases usually replaced by \( = \).

This is usually regarded as being, like (ii.), a statement of equivalence. It is, however, only true if \( x \) is equivalent to \( 12d. \), and the correct statement is then

\[ 18 \times 12d. = 24d. = 28. \]

If the operator \( \frac{1}{12} \) is omitted, the statement is really an equation, giving \( x \) in terms of \( 1d. \) or vice versa.

The following statements should be compared:

\[ X = A \text{'s share} = \frac{1}{3} \times 10 = \frac{1}{3} \times 5 = \frac{1}{3} \times 15. \]

In each case, the first sign of equality comes under (iv.) above, the second under (ii.), and the fourth under (i.); but the third sign comes under (i.) in the first case (the statement being that \( \frac{1}{3} \text{ of } 15 \) and under (ii.) in the second.

It will be seen from (v.) that the application of algebra to equations consists in the interchange of equivalent expressions, and therefore comes under (i.) and (ii.). We replace \( 4x + 3 \), for instance, by \( 4x - 4 \), because we know that, whatever the value of \( x \) may be, the result of subtracting 3 from it and multiplying the remainder by 4 is the same as the result of finding \( 4x \) and 4 separately and subtracting the latter from the former.

A statement such as (ii.) or (iii.) is sometimes called an identity. The two expressions whose equality is stated by an equation or an identity are its members.

24. Use of Letters in General Reasoning.—It may be assumed that the use of letters to denote quantities or numbers will first arise in dealing with equations, so that the letter used will in each case represent a definite quantity or number; such general statements as those of §§ 15 and 16 being deferred to a later stage. In addition to these, there are cases in which letters can usefully be employed for general arithmetical reasoning.

(i.) There are statements, such as \( A + B = B + A \), which are particular cases of the laws of arithmetic, but need not be expressed as such. For multiplication, for instance, we have the statement that, if \( P \) and \( Q \) are two quantities, containing respectively \( p \) and \( q \) of a particular unit, then \( p \times Q = q \times P \); or the more abstract statement that \( p \times q = q \times p \).

(ii.) The general theory of ratio and proportion requires the use of general symbols.

(iii.) The general statement of the laws of operation of fractions is perhaps best deferred until we come to fractional numbers, when letters can be used to express the laws of multiplication and division of such numbers.

(iv.) Variation is generally included in text-books on algebra, but apparently only because the reasoning is general. It is part of the general theory of quantitative relation, and in its elementary stages is a suitable subject for graphical treatment (§ 31).
25. Preparation for Algebra.—The calculation of the values of simple algebraical expressions for particular values of letters involved is a useful exercise, but its tediousness is apt to make the subject repulsive. What is more important is to verify particular examples of general formulae. These formulae are of two kinds: (a) the general properties, such as \(m(a+b) = ma + mb\), on which algebra is based, and (b) particular formulae such as \((a-o)(a+o) = a^2-o^2\). Such verifications are of value for two reasons. In the first place, they lead to an understanding of what is meant by the use of brackets and by such a statement as \(5(7+2) = 3.7+3.2\). This does not mean (cf. § 23) that the algebraic result of performing the operation \(3(7+2) = 3.7+3.2\); it means that if we convert \(7+2\) into the single number 9 and then multiply by 3 we get the same result as if we converted 3 and 7 into 27 and 6 respectively and added the results. In the second place, particular cases lay the foundation for the general formula.

Exercises in the collection of coefficients of various letters occurring in a complicated expression are usually performed mechanically, and are probably of very little value.

(i.) The fundamental laws of arithmetic (q.v.) should be constantly borne in mind, though not necessarily stated. The following are some special points.

(a) The commutative law and the associative law are closely related, and it is best to establish each law for the case of two numbers before proceeding to the general case. In the case of addition, for instance, suppose that we are satisfied that \(a+b+c+d+e\) we may take any two, as \(b\) and \(c\), together (association) and interchange them (commutation). Then we have \(a+b+c+d+e = a+c+b+d+e\). Thus any pair of adjoining numbers can be interchanged, so that the numbers can be arranged in any order.

(b) The important form of the distributive law is \(m(A+B) = ma+mb\). The form \((m+n)A = ma+na\) follows at once from the fact that \(A\) is the unit with which we are dealing.

(c) The fundamental properties of subtraction and of division are that \(A-B+B = A\) and \(mX\frac{1}{m}\) of \(A = \lambda\), since in each case the second operation restores the original quantity with which we started.

The elements of the theory of numbers belong to arithmetic. In particular, the theorem that if \(m\) is a factor of \(a\) and of \(b\) it is also a factor of \(pa+qb\), where \(p\) and \(q\) are any integers, is important in reference to the determination of greatest common divisor and to the elementary treatment of continued fractions.

Graphical methods are useful here (§ 34 (iv.)). The law of relation of successive convergents to a continued fraction involves more advanced methods (see § 42 (iii.) and CONTINUED FRACTION).

(iii) There are important theorems as to the relative value of fractions; e.g.

(a) If \(\frac{a}{b} > \frac{c}{d}\), then each \(\frac{pa}{qb} > \frac{pc}{qd}\).

(b) \(\frac{a+n}{b+n}\) is nearer to \(\frac{a}{b}\) than \(\frac{a}{b}\); and, generally, if \(\frac{a}{b} > \frac{c}{d}\), then \(\frac{pa+qd}{pb+qc}\) lies between the two. (All the numbers are, of course, positive.)

27. Negative Quantities and Fractional Numbers.—(i.) What are usually called "negative numbers" in arithmetic are in reality not negative numbers but negative quantities. If a person has to receive 7s. and pay 5s., with a net result of 2s., the order of the operations is immaterial. If he pays first, he then has -5s. This is sometimes treated as a debt of 5s.; an alternative method is to recognize that our zero is really arbitrary, and that in fact we shift it with every operation of addition or subtraction. But when we say "-5s." we mean "(-5s.)", not "-5s."; the idea of (-5) as a number with which we can perform such operations as multiplication comes later (§ 40).

(ii.) On the other hand, the conception of a fractional number follows directly from the use of fractions, involving the subdivision of a unit. We find that fractions follow certain laws corresponding exactly with those of integral multipliers, and we are therefore able to deal with the fractional numbers as if they were integers.

28. Miscellaneous Developments in Arithmetic.—The following are matters which really belong to arithmetic; they are usually placed under algebra, since the general formulae involve the use of letters.

(i.) Arithmetical Progressions such as \(2, 5, 8, \ldots\) — The formula for the \(r\)th term is easily obtained. The problem of finding the sum of \(r\) terms is aided by graphic representation, which shows that the terms may be taken in pairs, working from the outside to the middle; the two cases of an odd number of terms and an even number of terms may be treated separately at first, and then combined by the ordinary method, viz. writing the series backwards.

In this, as in almost all other cases, particular examples should be worked before obtaining a general formula.

(ii.) The law of indices (positive integral indices only) follows at once from the definition of \(a^1, a^2, a^3, \ldots\) as abbreviations of \(a.a, a.a.a, a.a.a.a, \ldots\), or (by analogy with the definitions of \(2, 3, 4, \ldots\) themselves) of \(a.a, a^2, a^3, \ldots\). Successively.

The treatment of roots and of logarithms (all being positive integers) belongs to this subject; \(a = \sqrt[n]{a} \quad n = \log\sqrt[n]{a}\) being the inverses of \(a = a^n\) (cf. §§ 15, 16). The theory may be extended to the case of \(a = 1, n = 0\); so that \(a^a = a.a.a.a, a^0 = 1\), \(a^1 = a, a^2 = a^2\) means \(a\), \(a^3\) means \(1\) (there being then none of the multipliers \(a\)).

The terminology is sometimes confused. In \(n = a^a, a\) is the root or base, \(p\) is the index or logarithm, and \(n\) is the power or antilogarithm. Thus \(a, a^2, a^3, \ldots\) are the first, second, third, \ldots powers of \(a\). But \(a^p\) sometimes incorrectly described as "\(a\) to the power \(p\);" the power being thus confused with the index or logarithm.

(iii.) Scales of Notation lead, by considering, e.g., how to express in the scale of 10 a number whose expression in the scale of 8 is 2222222, to

(iv.) Geometrical Progressions.—It should be observed that the radix of the scale is exactly the same thing as the root mentioned under (ii.) above; and it is better to use the term "root" throughout. Denoting the root by \(a\), and the number 2222222 in this scale by \(N\), we have

\[ N = 2222222. \]

Thus by adding 2 to \(a\) we can subtract \(N\) from \(aN + 2\), obtaining

\[ \text{the number } \frac{20000000}{a}. \]

and from this we easily pass to the general formula for the sum of a geometrical progression having a given number of terms.

(v.) Permutations and Combinations may be regarded as arithmetical recreations; they become important algebraically in reference to the binomial theorem (§§ 41, 44).

(vi.) Surds and Approximate Logarithms.—From the arithmetical point of view, surds present a greater difficulty than negative quantities and fractional numbers. We cannot solve the equation \(7X = 45\); but we are accustomed to transactions of lending and borrowing, and we can therefore invent a negative quantity -3s. such that \(-3s + 3s = 0\). We cannot solve the equation \(7X = 45\); but we are accustomed to subdivision of units, and we can therefore give a meaning to \(X\) by inventing a unit \(\frac{1}{7}\), such that \(7\times\frac{1}{7} = 1\), and can thence pass to the idea of fractional numbers. When, however, we come to the equation \(a = 5\), where we are dealing with numbers, not with quantities, we have no concrete facts to assist us. We can, however, find a number whose square shall be as nearly equal to \(a\) as we please, and it is this number that we treat algebraically as \(\sqrt{a}\).

We may take it to (say) 4 places of decimals; or we may suppose it to be taken to 1000 places. In actual practice, surds mainly arise out of mensuration; and we can then give an exact definition by graphical methods.

When, by practice with logarithms, we become familiar with the correspondence between additions of length on the logarithmic scale (a slide-rule) and multiplication of numbers in the natural scale (including fractional numbers), \(\sqrt{a}\) acquires
a definite meaning as the number corresponding to the extremity of a length \(x\), on the logarithmic scale, such that 5 corresponds to the extremity of 90. The concrete fact required to enable us to pass arithmetically from the conception of a fractional number to the conception of a surd is the fact of performing calculations by means of logarithms.

In the same way we regard \(\log ax\), not as a new kind of number, but as an approximation.

(vii.) The use of fractional indices follows directly from this parallelism. We find that the product \(a^{m} \times a^{n} = a^{m+n}\); and, by definition, the product \(\sqrt[3]{a} \times \sqrt[3]{a} \times \sqrt[3]{a} \) is equal to \(a\). This suggests that we should write \(\sqrt[3]{a} = a^{1/3}\); and we find that the use of fractional indices in this way satisfies the laws of integral indices. It should be observed that, by analogy with the definition of a fraction, \(a^{p/q}\) is mean \((a^{p})^{1/q}\), not \((a^{p/q})^{1/q}\).

II. Graphical Introduction to Algebra.

29. The science of graphics is closely related to that of mensuration. While mensuration is concerned with the representation of geometrical magnitudes by numbers, graphics is concerned with the representation of numerical quantities by geometrical figures, and particularly by lengths. An important development, covering such diverse matters as the equilibrium of forces and the algebraic theory of complex numbers (§66), has relation to cases where the numerical quantity has direction as well as magnitude. There are also cases in which graphics and mensuration are used jointly; a variable numerical quantity is represented by a graph, and the principles of mensuration are then applied to determine related numerical quantities. General aspects of the subject are considered under MENSURATION; VECTOR ANALYSIS; INFINITESIMAL CALCULUS.

30. The elementary use of graphic methods is qualitative rather than quantitative; i.e., it is for purposes of illustration and suggestion rather than for purposes of deduction and exact calculation. We start with related facts, and adopt a particular method of visualizing the relation. One of the relations most commonly illustrated in this way is the time-relation; the passage of time being associated with the passage of a point along a straight line, so that equal intervals of time are represented by equal lengths.

31. It is important to begin the study of graphics with concrete cases rather than with the tracing values of an algebraic function. Simple examples of the time-relation are the number of scholars present in a class, the height of the barometer, and the reading of the thermometer, on successive days. Another useful set of graphics comprises those which give the relation between the expressions of a length, volume, &c., on different systems of measurement. Mechanical, commercial, economic and statistical facts (the latter usually involving the time-relation) afford numerous examples.

32. The ordinary method of representation is as follows. Let \(X\) and \(Y\) be the related quantities, their expressions in terms of selected units \(A\) and \(B\) being \(x, y\), so that \(X = xa\), \(Y = y\). For graphical representation we select units of length \(L\) and \(M\), not necessarily identical. We take a fixed line \(OX\), usually drawn horizontally; for each value of \(X\) we measure a length or abscissa \(ON\) equal to \(xL\), and draw an ordinate \(NP\) at right angles to \(OX\) and equal to the corresponding value of \(y\). The assemblage of ordinates \(NP\) is then the \(graph\) of \(Y\).

The series of values of \(X\) will in general be discontinuous, and the graph will then be made up of a succession of parallel and (usually) equidistant ordinates. When the series is theoretically continuous, the theoretical graph will be a continuous figure of which the lines actually drawn are ordinates. The upper boundary of this figure will be a line of some sort; it is this line, rather than the figure, that is sometimes called the "graph." It is better, however, to treat this as a secondary meaning. In particular, the equality or inequality of values of two functions is more readily grasped by comparison of the lengths of the ordinates of the graphs than by inspection of the relative positions of their bounding lines.

33. The importance of the bounding line of the graph lies in the fact that we can keep it unaltered while we alter the graph as a whole by moving \(OX\) up or down. We might, for instance, read temperature from \(60^\circ\) instead of from \(0^\circ\). Thus we form the conception, not only of a zero, but also of the arbitrariness of position of this zero (cf. §27 (i.)); and we are assisted to the conception of negative quantities. On the other hand, the alteration in the direction of the bounding line, due to alteration in the unit of measurement of \(Y\), is useful in relation to geometrical projection.

This, however, applies mainly to the representation of values of \(Y\). \(Y\) is represented by the length of the ordinate \(NP\), so that the representation is cardinal; but this ordinate really corresponds to the point \(N\), so that the representation of \(X\) is ordinal. It is therefore only in certain special cases, such as those of simple time-relations (e.g. "\(x\) is aged 40, and \(k\) is aged 26; when \(j\) will be twice as old as \(k^2\)?"), that the graphic method leads without arithmetical reasoning to the properties of negative values. In other cases the continuation of the graph may constitute a dangerous extrapolation.

34. Graphic representation thus rests on the principle that equal numerical quantities may be represented by equal lengths, and that a quantity \(m\) may be represented by a length \(ml\), where \(A\) and \(L\) are the respective units; and the science of graphics rests on the converse property that the quantity represented by \(pL\) is \(pA\), i.e. that \(PA\) is determined by finding the number of times that \(L\) is contained in \(pL\). The graphic method may therefore be used in arithmetic for comparing two particular magnitudes of the same kind by comparing the corresponding lengths \(P\) and \(Q\) measured along a single line \(OX\) from the same point \(O\).

(i.) To divide \(P\) by \(Q\), we cut off from \(P\) successive portions each equal to \(Q\), till we have a piece \(R\) left which is less than \(Q\). Thus \(P = IQ + R\), where \(k\) is an integer.

(ii.) To continue the division we may take as our new unit a submultiple of \(Q\), such as \(Q/r\), where \(r\) is an integer, and repeat the process. We then get \(P = IQ + OR + Q + S = (k + m + r)L + Q + S\), where \(S\) is less than \(Q/r\). Proceeding in this way, we may be able to express \(P/Q\) as the sum of a finite number of terms \(k + m + r + n + \ldots\); or, if \(r\) is not suitably chosen, we may not. If, e.g. \(r = 10\), we get the ordinary expression of \(P/Q\) as an integer and a decimal; but, if \(P/Q\) were equal to \(1/3\), we could not express it as a decimal with a finite number of figures.

(iii.) In the above method the choice of \(r\) is arbitrary. We can avoid this arbitrariness by a different procedure. Having obtained \(R\), which is less than \(Q\), we now repeat with \(Q\) and \(R\) the process that we adopted with \(P\) and \(Q\); i.e. we cut off from \(Q\) successive portions each equal to \(R\). Suppose we find \(Q = kR + T\), then we repeat the process with \(R\) and \(T\); and so on. We thus express \(P/Q\) in the form of a continued fraction, \(k + m + r + n + \ldots\), which is usually written, for conciseness, \(k + 1\) \(\frac{1}{s + 1}\) \(\frac{1}{t + 1}\) &c., or \(k + 1\) \(s + 1\) \(t + 1\) &c.

(iv.) If \(P\) and \(Q\) can be expressed in the forms \(PL\) and \(QL\), where \(p\) and \(q\) are integers, \(R\) will be equal to \((p - q)\), which is both less than \(PL\) and less than \(QL\). Hence the successive remainders are successively smaller multiples of \(L\), but still integral multiples, so that the series of quotients \(k, s, t, \ldots\) will ultimately come to an end. Moreover, if the last divisor is \(mL\), then it follows from the theory of numbers (§26 (i.)) that \((a) u\) is a factor of \(p\) and of \(q\), and \((b)\) any number which is a factor of \(p\) and \(q\) is also a factor of \(u\). Hence \(u\) is the greatest common measure of \(p\) and \(q\).

35. In relation to algebra, the graphic method is mainly useful in connexion with the theory of limits (§§ 48, 61) and the functional treatment of equations (§60). As regards the latter, there are two classes of cases. In the first class come equations in a single unknown; here the function which is equal to zero is the \(Y\) whose values for different values of \(X\) are traced.
and the solution of the equation is the determination of the points where the ordinates of the graph are zero. The second class of cases comprises equations involving two unknowns; here we have to deal with two graphs, and the solution of the equation is the determination of their common ordinates.

Graphical methods also enter into the consideration of irrational numbers (§ 65).

III. Elementary Algebra of Positive Numbers.

36. Monomials.—(i.) An expression such as \(a_1a_2a_3a_4\), denoting that a series of multiplications is to be performed, is called a monomial; the numbers (arithmetical or algebraical) which are multiplied together being its factors. An expression denoting that two or more monomials are to be added or subtracted is a monomial or polynomial, each of the monomials being a term of it. A monomial consisting of two or of three terms is a binomial or a trinomial.

(ii.) By means of the commutative law we can collect like terms of a monomial, numbers being regarded as like terms. Thus the above expression is equal to \(a_1a_2b_1c_1\), which is, of course, equal to other expressions, such as \(a_1b_2a_3\). The numerical factor \(a\) is called the coefficient of \(a_1b_1c_1\) (§ 20); and, generally, the coefficient of any factor or of the product of any factors is the product of the remaining factors.

(iii.) The multiplication and division of monomials is effected by means of the law of indices. Thus \(a_1a_2b_1c_1 = a_1a_2b_1c_1\), since \(b_2 = 1\). It must, of course, be remembered (§ 23) that this is a statement of arithmetical equality; we call the statement an “identity,” but we do not mean that the expressions are the same, but that, whatever the numerical values of \(a\), \(b\), and \(c\) may be, the expressions give the same numerical result.

In order that a monomial containing \(a^n\) as a factor may be divisible by a monomial containing \(a^m\) as a factor, it is necessary that \(p\) should not be greater than \(m\).

(iv.) In algebra we have a theory of highest common factor and lowest common multiple, but it is different from the arithmetical theory of greatest common divisor and least common multiple. We disregard numerical coefficients, so that by the H.C.F. or L.C.M. of \(a\) and \(b\) we mean the H.C.F. or L.C.M. of \(a\) and \(b\) and \(a\) and \(c\). The H.C.F. is then an expression of the form \(a^n\), where \(q, r, s\) have the greatest possible values consistent with the condition that each of the given expressions shall be divisible by \(a^n\). Similarly the L.C.M. is of the form \(a^n\), where \(q, r, s\) have the least possible values consistent with the condition that \(a^n\) shall be divisible by each of the given expressions. In the particular case it is clear that the H.C.F. is \(a^n\) and the L.C.M. is \(a^n\).

The extension to multinomials forms part of the theory of factors (§ 51).

37. Products of Multinomials.—(i.) Special arithmetical results may often be used to lead up to algebraical formulae. Thus a comparison of numbers occurring in a table of squares

\[
\begin{array}{c|c}
1^2 & 1 \\
2^2 & 4 \\
3^2 & 9 \\
\end{array}
\]

suggests the formula \((A+a)^2 = A^2 + 2Aa + a^2\). Similarly the equalities

\[
\begin{align*}
99 \times 101 &= 9999 = 10000 - 1 \\
98 \times 102 &= 9996 = 10000 - 4 \\
97 \times 103 &= 9991 = 10000 - 9
\end{align*}
\]

lead up to \((A-a)(A+a) = A^2 - a^2\). These, with \((A-a)^2 = A^2 - 2Aa + a^2\), are the most important in elementary work.

(ii.) These algebraical formulae involve not only the distributive law and the law of signs, but also the commutative law. Thus \((A+a)(A-a) = A^2 - a^2\), \(a(A+a) = AA + aA + aA = aa + Aa + Aa\); and the grouping of the second and third terms as \(2Aa\) involves treating \(Aa\) and \(aa\) as identical. This is important when we come to the binomial theorem (§ 41, and cf. § 54 (i)).

(iii.) By writing \((A+a)^2 = A^2 + 2Aa + a^2\) in the form \((A+a)^2 = A^2 + (2Aa + a^2)\), we obtain the rule for extracting the square root in arithmetic.

(iv.) When the terms of a multinomial contain various powers of \(x\), and we are specially concerned with \(x\), the terms are usually arranged in descending (or ascending) order of the indices; terms which contain the same power being grouped so as to give a single coefficient. Thus \(x^5 - x^3 + 2x^2 + 5x + 7\) would be written \(-x^5 + (2 + 5 + 7)x^2 + 0x + 7\). It is not necessary to regard \(-x^5\) as a negative number; all that is meant is that \((-x^5)\) has to be subtracted.

(v.) When we have to multiply two multinomials arranged according to powers of \(x\), the method of detached coefficients enables us to omit the powers of \(x\) during the multiplication. If any power is absent, we treat it as present, but with coefficient 0. Thus, to multiply \(x^2 + 2x + 4\) by \(2x^2 - 4\), we write the process

\[
\begin{align*}
+1 &+0 &-2 &+1 \\
+2 &+0 &+4 \\
+2 &+0 &+0 &+0 \\
+4 &+0 &+8 &+4 \\
+7 &+0 &+8 &+4
\end{align*}
\]

giving \(2x^4 + 2x^3 + 18x^2 + 30x + 56\) as the result.

38. Construction and Transformation of Equations.—(i.) The statement of problems in equational form should precede the solution of equations.

(ii.) The solution of equations is effected by transformation, which may be either arithmetical or algebraical. The principles of arithmetical transformation follow from those stated in §§ 15-18 by replacing \(X, a, b, m, n, a, b\) by any expressions involving or not involving the unknown quantity or number and representing positive numbers or (in the case of \(X, a, b\) and \(m\)) positive quantities. The principle of algebraic transformation has been stated in § 22; it is that if \(A = B\) is an equation (i.e. if either or both of the expressions \(A\) and \(B\) involves \(x\), and \(A\) and \(B\) are arithmetically equal to \(B\) for the particular value of \(x\) which we require), and if \(B = C\) is an identity (i.e. if \(B\) and \(C\) are expressions involving \(x\) which are different in form but are arithmetically equal for all values of \(x\)), then the statement \(A = C\) is an equation which is true for the same value of \(x\) for which \(A = B\) is true.

(iii.) A special rule of transformation is that any expression may be transposed from one side of an equation to the other, provided its sign is changed. This is the rule of transposition. Suppose, for instance, that \(P + Q - R + S = T\). This may be written \((P + Q) - R + S = T\); and this statement, by definition of the sign ~, is the same as the statement that \((P + Q) - R = T + S\). Similarly the statements \(P + Q - R - S = T\) and \(P + Q = T + R - S\) are the same. These transformations are purely arithmetical. To transpose a term which is not the last term on either side we must first use the commutative law, which involves an algebraical transformation. Thus from the equation \(P + Q - R + S = T\) and the identity \(P + Q - R + S = P - R + S + Q\) we have the equation \(P + Q + S + Q = T\), which is the same statement as \(P + R + S = T + Q\).

(iv.) The procedure is sometimes stated differently, the transposition being regarded as a corollary from a general theorem that the roots of an equation are not altered if the same expression is added to or subtracted from both members of the equation. The objection to this (cf. § 21 (ii.) is that we do not need the general theorem, and that it is unwise to cultivate the habit of laying down a general law as a justification for an isolated action.

(v.) An alternative method of obtaining the rule of transposition is to change the zero from which we measure. Thus from \(P + Q - R + S = T\) we deduce \(P + Q - R + S = T - P\). If instead of measuring from zero we measure from \(P\), we find \(Q - R + S = T - P\). The difference between this and (iv) is that we transpose the first term instead of the last; the two methods corresponding to the two cases under (i.) of § 15 (a).

(vi.) In the same way, we do not lay down a general rule
that an equation is not altered by multiplying both members by the same number. Suppose, for instance, that \( \frac{2}{3}(x+1) = \frac{3}{4}(x-2) \). Here each member is a number, and the equation may, by the commutative law for multiplication, be written \( \frac{2}{3}(x+1) = \frac{3}{4}(x-2) \).

This means that, whatever unit \( A \) we take, \( \frac{2}{3}(x+1) = \frac{5}{3} \) \( A \) and \( \frac{4}{5}(x-2) \) are equal. We therefore take \( A \) to be 15, and find that \( 6(x+1) = 20(x-2) \). Thus, if we have an equation \( P=Q \), where \( P \) and \( Q \) are numbers involving fractions, we can clear of fractions, not by multiplying \( P \) and \( Q \) by a number \( m \), but by applying the equal multiples \( P \) and \( Q \) to a number \( m \) as unit. If the \( P \) and \( Q \) of our equation were quantities expressed in terms of a unit \( A \), we should state the equation in terms of a unit \( A/m \), as explained in §§ 18 and 21. (i.)

(vii.) One result of the rule of transposition is that we can transpose all the terms in \( x \) to one side of equation, and all the terms not containing \( x \) to the other. An equation of the form \( ax=b \), where \( a \) and \( b \) do not contain \( x \), is the standard form of simple equation.

(viii.) The quadratic equation is the equation of two expressions, monomial or multinomial, none of the terms involving any power of \( x \) except \( x \) and \( x^2 \). The standard form is usually taken to be

\[ ax^2+bx+c=0, \]

from which we find, by transformation,

\[ (2ax+b)^2=b^2-4ac, \]

and thence

\[ x=\frac{-b\pm\sqrt{b^2-4ac}}{2a}. \]

This only gives one root. As to the other root, see § 47 (iii.).

39. Fractional Expressions.—An equation may involve a fraction of the form \( \frac{P}{Q} \), where \( Q \) involves \( x \).

(i.) If \( P \) and \( Q \) can (algebraically) be written in the forms \( RA \) and \( SA \) respectively, where \( A \) may or may not involve \( x \), then \( \frac{P}{Q} = \frac{RA}{SA} = \frac{R}{S} \), provided \( A \) is not 0.

(ii.) In an equation of the form \( \frac{P}{Q} = \frac{U}{V} \), the expressions \( P \), \( Q \), \( U \), and \( V \) are usually numerical. We then have \( \frac{P}{Q} \cdot \frac{Q}{V} = \frac{U}{V} \), or \( PV = UQ \), as in § 38 (vi.). This is the rule of cross-multiplication.

(iii.) The restriction in (i.) is important. Thus \( \frac{x^2-1}{x+2} = \frac{(x-1)(x+1)}{x+2} \), except when \( x = -1 \). For this latter value it becomes \( \frac{3}{x} \), which has no direct meaning, and requires interpretation (§ 60).

40. Powers of a Binomial.—We know that \( (a+b)^n = a^n + \binom{n}{1}a^{n-1}b + \binom{n}{2}a^{n-2}b^2 + \cdots \), where \( n \) is a non-negative integer.

In the same way we have \( (A+a)^n = A^n + \binom{n}{1}A^{n-1}a + \binom{n}{2}A^{n-2}a^2 + \cdots \). So the multinomial equivalent to \( (A+a)^n \) has the same coefficients as the multinomial equivalent to \( (a+b)^n \), but with signs alternately + and -.

The multinomial which is equivalent to \( (A=a)^n \), and has its terms arranged in ascending powers of \( a \), is called the expansion of \( (A=a)^n \).
Theorem 1. \( n(r) = (n-r+1)(n-r+2)\ldots n \) (1)

Hence the formula (2) is also true for the \( n \)th power of \( A+a \). But it is true for the 1st and the 2nd powers; therefore it is true for the 3rd; therefore for the 4th; and so on. Hence it is true for all positive integral powers of \( n \).

(iii.) The product 1, 2, 3 \ldots \( r \) is denoted by \( r! \) or \( r \), and called factorial \( r \). The form \( r! \) is better for printing, but the form \( r \) is more convenient for ordinary use. If we denote \( n(n-1) \ldots (n-r+1) \) (\( r \) factors) by \( n^r \), then \( n(r) = n^r / r! \).

(iv.) We can write \( n_0 \) in the more symmetrical form

\[
\frac{n^r}{r!} = n(r) = n^r \cdot \frac{1}{r!}.
\]

which shows that

\[
\frac{n^r}{r!} = n(r) = n^r \cdot \frac{1}{r!}.
\]

We should have arrived at this form in (i.) by considering the selection of terms in which there are to be two large and three small letters, the large letters being written down first. The terms can be built up in 5! ways; but each will appear \( 3! \) times.

(v.) Since \( n(r) \) is an integer, \( n^r \) is divisible by \( r! \); i.e. the product of any \( r \) consecutive integers is divisible by \( r! \) (see § 42 (ii.)).

(vi.) The product \( r! \) arises in (i.) by the successive multiplicaton of \( r \), \( r-1 \), \( r-2 \) \ldots . In practice the successive factorials \( 1! \), \( 2! \), \( 3! \) \ldots are supposed to be obtained successively by introduction of new factors, so that

\[
r! \cdot r! = (r-1)! \cdot (r-1)! \ldots \cdot 1!
\]

Thus in defining \( r! \) as 1, 2, 3 \ldots \( r \) we regard the multiplications as taking place from left to right; and similarly in \( n^r \). A product in which multiplicatons are taken in this order is called a continued product.

(vii.) In order to make the formula (5) hold for the extreme values \( n_0 \) and \( n_0 \) we must adopt the convention that

\[
\frac{n^0}{0!} = 1
\]

This is consistent with (7), which gives \( t = 1.0 \). It should be observed that, for \( r = 0 \), (4) is replaced by

\[
(n-1)^0 = n_0 \cdot n_0 \cdot \frac{1}{0!}.
\]

and similarly, for the final terms, we should note that

\[
\frac{n^0}{0!} = 1
\]

(viii.) If \( u \) denotes the term involving \( a \) in the expansion of \( (A+a)^n \), then \( u(n+1) = (n+1)(n+2)\ldots n \). This decreases as \( r \) increases; its value ranging from \( nA/A \) to \( a/A \). If \( nA/A \) the terms will decrease from the beginning; if \( nA/A \), the terms will increase up to the end; if \( a/A \), the terms will first increase up to a greatest term (or two consecutive equal greatest terms) and then decrease.

(ix.) The position of the greatest term will depend on the relative values of \( A \) and \( a \); if \( a/A \), it will be near the beginning. Advantage can be taken of this, when \( n \) is large, to make approximate calculations, by omitting terms that are negligible.

(a) Let \( S \), denote the sum \( u_0 + u_1 + \ldots + u_r \), this sum being taken so as to include the greatest term (or terms); and let \( u_{r+1} = u_{r+2} = \ldots = u_r = 0 \). Then the sum of the remaining terms \( u_0 + u_1 + \ldots + u_r \) is less than \( (1 + 1)^n - (r+1)! \), which is less than \( n(r)/r! \), and therefore \( (A+a)^n \) lies between \( S \) and \( S + u_{r+1} \). We can therefore stop as soon as \( u_{r+1} \) becomes negligible.

(b) In the same way, for the expansion of \( (A-a)^n \), let \( \sigma \), denote \( u_0 + u_1 + \ldots + u_r \). Then, provided \( \sigma \) includes the greatest term, it will be found that \( (A-a)^n \) lies between \( \sigma + n \), and \( \sigma + r \).

For actual calculation it is most convenient to write the theorem in the form

\[
(A+a)^n = A^n(1 + \frac{a}{A})^n = A^n + \frac{n}{a/A} \cdot A^{n-1} \left(1 - \frac{1}{2} \frac{a}{A} \right) \ldots A^2 \cdot \frac{n}{2! a/A} \ldots A \ldots
\]

where \( x = a/A \); thus the successive terms are obtained by successive multiplication. To apply the method to the calculation of \( N^n \), it is necessary that we should be able to express \( N \) in the form \( A+a \) or \( A-a \), where \( a \) is small in comparison with \( A \), \( A^n \) is easy to calculate and \( a/A \) is convenient as a multiplier.

42. The reasoning adopted in § 41 (ii.) illustrates two general methods of procedure. We know that \( (A+a)^n \) is equal to a multinomial of \( n+1 \) terms with unknown coefficients, and we require to find these coefficients. We therefore represent them by separate symbols, in the same way that we represent the unknown quantity in an equation by a symbol. This is the method of undetermined coefficients. We then obtain a set of equations, and by means of these equations we establish the required result by a process known as mathematical induction. This process consists in proving that a property involving \( p \) is true when \( p \) is any positive integer by proving (1) that it is true when \( p = 1 \), and (2) that if it is true when \( p = n \), where \( n \) is any positive integer, then it is true when \( p = n+1 \). The following are some further examples of mathematical induction.

(i) By adding successively 1, 3, 5 \ldots we obtain 1, 4, 9 \ldots This suggests that, if \( n_0 \) is the sum of the first \( n \) odd numbers, then \( n_0 = n^2 \). Assume this true for \( n_0 \). Then

\[
\sum_{k=1}^{n} (2k-1) = n(n+1)/2
\]

This is by hypothesis, \( n^2 \) is divisible by \( p! \).

(b) Let us assume that the product of every set of \( p \) consecutive integers is divisible by \( p! \), and let us try to prove that the product of every set of \( p+1 \) consecutive integers is divisible by \( (p+1)! \). Denote the product \( n(n+1) \ldots (n+p-r) \) by \( n^r \). Then the assumption is that, whatever positive integral value \( n \) may have, \( n^r \) is divisible by \( p! \).

Thus, if \( n-1 \) is divisible by \( (p-1)! \), \( n^r \) is divisible by \( (p+1)! \).

(2) This is divisible by \( (p+1)! \).

(3) Therefore \( n^r \) is divisible by \( (p+1)! \), whatever positive integral value \( n \) may have.

(c) Thus, if the theorem of § 41 (v.) is true for \( r = p \), it is true for \( r = p+1 \). But it is true for \( r = 1 \). Therefore it is true generally.

(iii.) Another application of the method is to proving the law of formation of consecutive convergents, to a continued fraction (see CONTINUED FRACTIONS).

43. Binomial Coefficients.—The numbers denoted by \( n_0 \) in § 41 are the binomial coefficients, shown in the table in § 40; \( n_0 \) being the \( r \)-th number in the \( (n-r) \)-th row. They have arisen as the coefficients in the expansion of \( (A+a)^n \); but they may be considered independently as a system of numbers defined by (1) of § 41. The individual numbers are connected by various relations, some of which are considered in this section.

(i) From (4) of § 41 we have

\[
n(c) = (n-1)(n-2)(n-3)\ldots (c)
\]

Changing \( n \) into \( n-1 \), \( n-2 \), \ldots and adding the results,

\[
n(c) = (n-2)(n-3)(n-4)\ldots (c)
\]

In particular,

\[
n(r) = (n-r)(n-r-1)(n-r-2)\ldots (n-r-1)
\]

Similarly, by writing (4) in the form

\[
n(c) = (n-1)(n-2)(n-3)\ldots (c)
\]

changing \( n \) and \( r \) into \( n-1 \) and \( r-1 \), repeating the process, and adding, we find, taking account of (9),

\[
n(c) = (n-1)(n-2)(n-3)\ldots (c)
\]

(ii) It is therefore more convenient to rearrange the table of § 40 as shown below, on the left; the table on the right giving the key to the arrangement.

\[
\begin{array}{cccc}
1 & 1 & 1 & 1 \\
1 & 2 & 3 & 4 \\
2 & 4 & 6 & 8 \\
4 & 8 & 12 & 16 \\
\end{array}
\]

\[
\begin{array}{cccc}
1 & 1 & 1 & 1 \\
1 & 2 & 3 & 4 \\
2 & 4 & 6 & 8 \\
4 & 8 & 12 & 16 \\
\end{array}
\]
Here we have introduced a number \( a_0(n) \) given by
\[ a_0(n) = \frac{(n-1)!}{(n-1)!} \]
which is consistent with the relations in (i.). In this table any number is equal to the sum of the numbers which lie horizontally above it in the preceding column, and the difference of any two numbers in a column is equal to the sum of the numbers horizontally between them in the preceding column.

The coefficients in the expansion of \((A+2)\) for any particular value of \( n \) are obtained by reading diagonally upwards from left to right from the \((n+1)\)th number in the first column.

(iii.) The table might be regarded as constructed by successive applications of (g) and (h); the initial data being (16) and (10). Alternatively, we might consider that we start with the first diagonal row (downwards from the left) and construct the remaining diagonal rows by successive applications of (15). Constructed in this way, the successive diagonal rows, commencing with the first, give the \( \text{figure} \) numbers of the first, second, third, . . . order. The \((r+1)\)th figure number of the \( r \)th order, i.e. the \((r+1)\)th number in the \( r \)th diagonal row, is \( n(n+1) \ldots (n+r-1)/r! = n^r/r! \); this may, by analogy with the notation of \( \text{§41} \), be denoted by \( n_r \). Then we have
\[ (n+1)_{r+1} = (n+1)_{r+1} + (n-1)_r \]
(iv.) By means of (17) the relations between the binomial coefficients in the form \( r(n) \) may be replaced by others with the coefficients expressed in the form \( r(n) \). The table in (ii.) may be written
\[
\begin{align*}
1(n) & = 1 \quad 1(1) \\
2(n) & = 3 \quad 1(2) \quad 1(3) \\
3(n) & = 1 \quad 2(4) \quad 1(4) \\
4(n) & = 3 \quad 2(5) \quad 3(6) \\
5(n) & = 1 \quad 2(7) \quad 1(8) \\
& \quad \ldots \ldots \ldots \\
& \quad & & \ldots \ldots \ldots
\end{align*}
\]
and so on.

The most important relations are
\[ n_r = n(n-1) + (n-1)_r \quad (19) \]
\[ n_{r+1} = (n-1)_r + (n-2)_r + \ldots + (n-r)_r \quad (20) \]

(v.) It should be mentioned that the notation of the binomial coefficients, and of the continued products such as \( n(n-1) \ldots (n-r+1) \), is not settled. Some writers, for instance, use the symbol \( n_r \) in place, in some cases, of \( n_r \), and, in other cases, of \( n^r \). It is convenient to retain \( n_r \) to denote \( x^n/r! \), so that the consistent notation
\[ x^n = x^n/r! \quad n_r = n^r/r! \quad n_{r+1} = n^{r+1}/r! \]

The binomial theorem for positive integral index may then be written
\[ (x+y)^n = \sum_{r=0}^{n} \binom{n}{r} x^{n-r} y^r \]

This must not be confused with the use of suffixes to denote particular terms of a series or a progression (as in § 41 (vi.) and (ix.)).

44. Permutations and Combinations.—The discussion, in § 41 (i.), of the number of terms of a particular kind in a particular product, forms part of the theory of \( \text{combinatorial analysis} \) (g.\text{c}), which deals with the grouping and arrangement of individuals taken from a defined stock. The following are some particular cases; the proof usually follows the lines already indicated. Certain of the individuals may be distinguishable from the remainder of the stock, but not from each other; these may be called a type.

(i.) A permutation is a linear arrangement, read in a definite direction of the line. The number \( (\pi_p) \) of permutations of \( p \) individuals out of a stock of \( n \), all being distinguishable, is \( n^p \). In particular, the number of permutations of the whole stock is \( n! \).

If \( a \) of the stock are of one type, \( b \) of another, \( c \) of another, . . . , the number of distinguishable permutations of the whole stock is \( n!/(a!b!c! \ldots) \).

(ii.) A combination is a group of individuals without regard to arrangement. The number \( (\text{C}_p) \) of combinations of \( r \) individuals out of a stock of \( n \) has in effect been proved in § 41 (ii.) to be \( n_r \). This property enables us to establish, by simple reasoning, certain relations between binomial coefficients. Thus (4) of § 41 (ii.) follows from the fact that, if \( A \) is any one of the \( n \) individuals, the \( A \) group of \( r \) consist of \( A \) are not distinguishable, which contain \( A \) and \( n-r \), which do not contain \( A \). Similarly, considering the various ways in which a group of \( r \) may be obtained from two stocks, one containing \( n \) and the other containing \( m \), we find that
\[ n \times m = m \times n \]

which gives
\[ (n+m)(n+m)(n+m)(n+m) = (n+n)(n+n)(n+n)(n+n) \]

If \( r \) is greater than \( m \) or \( n \) (though of course not greater than \( m+n \)), some of the terms in (22) and (23) will be zero.

(iv.) Other developments of the theory deal with distributions, partitions, &c. (see \( \text{COMBINATORIAL ANALYSIS} \).)

(v.) The theory of probability (g.\text{c}) also comes under this head. Suppose that there are a number of arrangements of \( r \) terms or elements, the first of which is \( a \) or not-\( A \), the second is \( b \) or not-\( B \), the third is \( c \) or not-\( C \), and so on. If, out of every \( N \) cases, where \( N \) may be a very large number, \( a \) is \( A \) in \( N \) cases and not-\( A \) in \((1-p)N \) cases, where \( p \) is a fraction such that \( pN \) is an integer, then \( p \) is the probability of \( r \) and \( p \) of occurrence of \( A \). We may consider that we are dealing always with a single arrangement \( abc \ldots \) and that the number of times that \( a \) is made \( A \) bears to the number of times that \( a \) is made not-\( A \) the ratio of \( p \) to \((1-p) \); or we may consider that there are \( N \) individuals, for \( pN \) of which the \( \text{attribute} \) is \( A \), while for \((1-p)N \) it is not \( A \). If, in this latter case, the proportion of cases in which \( b \) is \( B \) to cases in which \( b \) is not-\( B \) is the same for the group of \( pN \) individuals in which \( a \) is \( A \) as for the group of \((1-p)N \) in which \( a \) is not-\( A \), then the frequencies of \( A \) and of \( B \) are said to be independent; if this is not the case they are said to be correlated. The possibilities of \( a \), instead of being \( A \) and not-\( A \), may be \( A_1, A_2, \ldots \), each of these having its own frequency; and similarly for \( b, c, \ldots \). If the frequency of each \( A \) is independent of the frequency of each \( B \), then the attributes \( a \) and \( b \) are independent; otherwise they are correlated.

45. Application of Binomial Theorem to Rational Integral Functions.—An expression of the form \( a x^n + a x^{n-1} + \ldots + c_n \), where \( c_0, c_1, \ldots \) do not involve \( x \), and the indices of the powers of \( x \) are all positive integers, is called a rational integral function of \( x \) of degree \( n \). If we represent this expression by \( f(x) \), the expression obtained by changing \( x \) into \( x + h \) is \( f(x+h) \); and each term of this may be expanded by the binomial theorem. Thus we have
\[
\begin{align*}
f(x+h) &= a x^n + a x^{n-1} + h + (n-1) a x^{n-2} \frac{h^2}{2!} + \ldots + a x^{n-2} + (n-1)(n-2) a x^{n-3} \frac{h^3}{3!} + \ldots + a x^{n-2} + (n-1)(n-2)(n-3) a x^{n-4} \frac{h^4}{4!} + \ldots + \& \ldots + a x^{n-2} + (n-1)(n-2)(n-3)(n-4) a x^{n-5} \frac{h^5}{5!} + \ldots + \& \ldots + a x^{n-2} + (n-1)(n-2)(n-3)(n-4)(n-5) a x^{n-6} \frac{h^6}{6!} + \ldots + \& \ldots + a x^{n-2} + (n-1)(n-2)(n-3)(n-4)(n-5)(n-6) a x^{n-7} \frac{h^7}{7!} + \ldots + \& \ldots \end{align*}
\]

It will be seen that the expression in curled brackets in each line after the first is obtained from the corresponding expression in the preceding line by a definite process; viz. \( x \) is replaced by

\[ a x^{n-1} \]
except for $r = 0$, when $a^0$ is replaced by 1. The expressions obtained in this way are called the first, second, etc., derived functions of $f(x)$. If we denote these by $f_1(x), f_2(x), \ldots$, so that $f_r(x)$ is obtained from $f_{r-1}(x)$ by the above process, we have

$$f(x + h) = f(x) + f_1(x)h + f_2(x)h^2/2! + \ldots + f_r(x)h^r/r! + \ldots$$

This is a particular case of Taylor's theorem (see Infinitesimal Calculus).

46. Relation of Binomial Coefficients to Summation of Series.

(i.) The sum of the first $n$ terms of an ordinary arithmetical progression $(a + b, a + 2b, \ldots, a + nb)$ is $\frac{n}{2}(2a + (n - 1)b) = na + \frac{n(n - 1)b}{2} = a_1 + a_2 + b$. Comparing this with the table in § 43 (iv), and with formula (21), we see that the series expressed by the summation of two, viz. $a + a + \ldots$ and $b + b + b + \ldots$; for the first series we multiply the table (i.e. each number in the table) by $a$, and for the second series we multiply it by $b$, and the terms and their successive sums are given for the first series by the first and the second columns, and for the second series by the second and the third columns.

(ii.) In the same way, if we multiply the table by $c$, the sum of the first $n$ numbers in any column is equal to the $nth$ number in the following column. Thus we get a formula for the sum of $n$ terms of a series such as

$$2.4.6.8 + \ldots + 6.8.10.12 + \ldots$$

This cannot be summed directly by the above method. But the $nth$ term is $(3n - 1)(3n + 2) = 9n^2 - n - 2$. The sum of $n$ terms is therefore $(\frac{3}{4}n^3 + \frac{1}{2}n^2 - \frac{1}{2}n)$.

(iv.) Generally, let $N$ be any rational integral function of $n$ of degree $r$. Then, since $n+1$ is also a rational integral function of $n$ of degree $r$, we can find a coefficient $c_r$ not containing $n$, and such as to make $N - c_r n^r$ contain no power of $n$ higher than $n^{r-1}$. Proceeding in this way, we can express $N$ in the form $c_r n^r + c_{r-1} n^{r-1} + \ldots + c_1 n + c_0$, where $c_r, c_{r-1}, \ldots$ do not contain $n$, and whence we can obtain the sum of the numbers found by putting $n = 1, 2, 3, \ldots n$ successively in $N$. These numbers constitute an arithmetical progression of the $rth$ order.

(v.) A particular case is that of the sum $1^r + 2^r + 3^r + \ldots + n^r$, where $r$ is a positive integer. It can be shown by the above reasoning that this can be expressed as a series of terms containing descending powers of $n$, the first term being $n^{r+1}/(r+1)$. The most important cases are

$$1^2 + 2^2 + \ldots + n^2 = \frac{1}{6} n^3 + B_1 (r + 1) n^{r-1} - B_1 (r + 1) n^{r-1} + \ldots$$

where $B_1, B_2, \ldots$ are certain numbers known as Bernoulli's numbers, and the terms in the bracket, after the first, have signs alternately and -. The values of the first ten of Bernoulli's numbers are

$$B_1 = \frac{1}{6}, B_2 = 0, B_3 = 0, B_4 = \frac{1}{30}, B_5 = 0, B_6 = \frac{1}{42}, B_7 = 0, B_8 = \frac{1}{30}, B_9 = -\frac{5}{66}, B_{10} = \frac{1}{28}.$$
dividend and divisor are rational integral functions of some
expression such as \( x \) which we regard as the root of the notation
(§ 28 (iv)), and are arranged in descending or ascending powers
of \( x \). If \( P \) and \( M \) are rational integral functions of \( x \), arranged in
descending powers of \( x \), the division of \( P \) by \( M \) is complete when
we obtain a remainder \( R \) whose degree (§ 45) is less than that of \( M \). If \( R = 0 \), then \( M \) is said to be a factor of \( P \).

The highest common factor (or common factor of highest degree)
of two rational integral functions of \( x \) is therefore found in the
same way as the G.C.M. in arithmetic; numerical coefficients of
the factor as a whole being ignored (cf. § 36 (iv)).

52. Relation between Roots and Factors. — (i) If we divide the
monomial

\[ P = p_0 x^n + p_1 x^{n-1} + \ldots + p_n \]

by \( x - a \), according to algebraic division, the remainder is

\[ R = P_0 + p_1 a^{-1} + \ldots + p_n a^{-n} \]

This is the remainder-theorem; it may be proved by induction.

(ii) If \( x = a \) satisfies the equation \( P = 0 \), then \( p_0 a^n + p_1 a^{n-1} + \ldots + p_n a^{-n} = 0 \); and therefore the remainder when \( P \) is divided by \( x - a \) is 0, i.e. \( x - a \) is a factor of \( P \).

(iii) Conversely, if \( x = a \) is a factor of \( P \), then \( p_0 a^n + p_1 a^{n-1} + \ldots + p_n a^{-n} = 0 \); i.e. \( x = a \) satisfies the equation \( P = 0 \).

(iv) Thus the problems of determining the roots of an equation
\( P = 0 \) and of finding the factors of \( P \), when \( P \) is a rational integral function of \( x \), are the same.

(v) In particular, the equation \( P = 0 \), where \( P \) has the value in (i), cannot have more than \( n \) different roots.

The consideration of cases where two roots are equal belongs to
the theory of equations (see EQUATION).

(vi) It follows that, if two multinomials of the \( n \)th degree
in \( x \) have equal values for more than \( n \) values of \( x \), the cor-
responding coefficients are equal, so that the multinomials are
equal for all values of \( x \).

53. Negative Indices and Logarithms. — (i) Applying the general
principles of §§ 47-49 to indices, we find that we can interpret \( X^{-m} \) as being such that

\[ x^m X^{-m} = x^m \]

in the same way we interpret \( X^{m/n} \) as meaning \( 1/X^{m/n} \).

(ii) This leads to negative logarithms (see LOGARITHM).

54. Laws of Algebraic Form. — (i) The results of the addition,
subtraction and multiplication of multinomials (including
monomials as a particular case) are subject to certain laws which
are analogous to those in arithmetic (§ 26 (ii)) but differ from
them in relating, not to arithmetical value, but to algebraic
form. The commutative law in arithmetic, for instance, states that
\( a + b \) and \( b + a \) are equal. The corresponding law of form
states that \( a + b \) and \( b + a \) are identical, where \( a \) and \( b \) are any
multinomials. Thus \( a(b+c) \) and \( (b+c)a \) give the same result,
though it may be written in various ways, such as \( ab + ac \)
\( + ba + bc \). In the same way the associative law is that \( A(BC) \)
and \( (AB)C \) give the same formal result.

These laws can be established either by tracing the individual
terms in a sum or a product or by means of the general theorem in
§ 26 (vi).

(i) One result of these laws is that, if we have obtained any
formula involving a letter \( a \), we can replace \( a \) by a multi-
nomial. For instance, having found that \( (x + a)^2 = x^2 + 2ax + a^2 \),
we can deduce that \( (x + b + c)^2 = (x + b + c)^2 \). This is
an identity. From this it follows that \( -a + b \) and \( -b + a \) are
identical, where \( a \) and \( b \) are any multinomials.

(ii) Another result is that we can equate coefficients of like
powers of \( x \) in two multinomials obtained from the same
expression by different methods of expansion. For instance, by
equating coefficients of \( x^r \) in the expansions of \( 1 + x)^{n+1} \) and
of \( (1+x)^n \) we obtain (22) of § 44 (ii).

(iii) On the other hand, the method of equating coefficients
of multinomials is often applied without the assumption of these
laws. In § 41 (ii), for instance, the coefficient of \( A^n x^r \) in the expansion of
\( (A + x) (A + x)^{n-1} \) has been called \( \binom{n}{r} \); and it has then been
shown that \( \binom{n}{r} = \binom{n-1}{r-1} + \binom{n-1}{r} \). This does not involve any
made as small as we please by taking $r$ large enough, so that we can make $S_n$ approximate as closely as we please to $(1+x)^n$.

(iv) To assimilate this to the binomial theorem, we extend the definition of $n_{(i)}$ in (i) of §41 (i), so as to cover negative integral values of $n$; and we then have

\[ (m-r)_{(i)} = (m)_{(i)} - (m-1)_{(i)} + \ldots - (m-r)_{(i)} \]

so that, if $m = n$, $S_n = 1 + a_1x + a_2x^2 + \ldots + a_rx^r$.

(v) The further extension to fractional values (positive or negative) of $n$ depends in the first instance on the establishment of a method of algebraical evolution which bears the same relation to arithmetical evolution (calculation of a surd) as algebraical division bears to arithmetical division. In calculating $\sqrt[2]{x}$, for instance, we proceed as if $x = \ldots \ldots$ were the exact square of some number of the form $a_0 + \sqrt[2]{c}$, etc., so that $(1 + x_1x + x_2x^2 + \ldots)$ shall be identical with $X$.

The application of the method to the calculation of $(1+x)^n$, when $n = \frac{p}{q}$, $q$ being a positive integer and $p$ a positive or negative integer, involves, as in the case where $n$ is an integer, the separate consideration of the form of the coefficients $b_1, b_2, \ldots$ of the numerical value of $1 + x_1x + x_2x^2 + \ldots$.

(vi) The definition of $n_{(i)}$, which has already been extended in (iv), above, has to be further extended so as to cover fractional values of $n$, positive or negative. Certain relations still hold, the most important being (29) of §44 (ii), which holds whatever the values of $m$ and of $n$ may be; $r$, of course, being a positive integer. This may be proved either by induction or by the method of §52 (vi). The relation, when written in the form (28), is known as \textit{Vandermonde's theorem}. By means of this theorem it can be shown that, whatever the value of $n$ may be, $$(1+(\sqrt[2]{p})x + (\sqrt[2]{q})x^2 + \ldots + (\sqrt[2]{q})x^r)_{(i)} = 1 + p_1x + p_2x^2 + \ldots + p_rx^r$$

(vii) The comparison of the numerical value of $1 + n_{(i)}x^n + \ldots + n_{(i)}x^r$, when $n$ is fractional, with that of $(1+x)^n$, involves advanced methods (§64). It is found that this expression can be used for approximating to the value of $(1+x)^n$, provided that $|x| < 1$; the results are as follows, where $u_i$ denotes $n_{(i)}x^n$ and $S_n$ denotes $u_0 + u_1 + u_2 + \ldots + u_r$.

(a) If $n > 1$, then, provided $r > 1$,

(1) If $1 > x > 0$, $(1+x)^n$ lies between $S_n$ and $S_{n+1}$;

(2) If $0 < x < 1$, $(1+x)^n$ lies between $S_n$ and $S_{n+1}/(1-x)$.

(b) If $n < 1$, the successive terms will either constantly decrease (numerically) from the beginning or else increase up to a greatest term (or two equal consecutive greatest terms) and then constantly decrease. If $S_n$ is taken so as to include the greatest term (or terms), then,

(1) If $1 > x > 0$, $(1+x)^n$ lies between $S_n$ and $S_{n+1}$;

(2) If $0 < x < 1$, $(1+x)^n$ lies between $S_n$ and $S_{n+1}/(1-x_{(i)}/u_i)$.

The results in (b) apply also if $n$ is a negative integer.

(viii) In applying the theorem to concrete cases, conversion of a number into a continued fraction is often useful. Suppose, for instance, that we require to calculate $(23/13)^4$. We want to express $(23/13)^2$ in the form $a/b$, where $b$ is nearly equal to $1$. We find that \[ \frac{1}{\log_2(23/13)} = 32.376767 = \log_2(2.5533) = \log_2(40/17) \]

nearly; and hence that $(23/13)^2 = (40/17)(1 + 1063/3515200)$, which can be calculated without difficulty to a large number of significant figures.

(ix) The extension of $n_{(i)}$, and therefore of $n_{(i)}x^n$, to negative and fractional values of $n$, enables us to extend the applicability of the binomial coefficients to the summation of series (§64 (ii)). Thus the $n$th term of the series $2, 5, 8, 11, \ldots$ in §64 (ii) is $18(-2/3)^n$; formula (20) of §44 (iv) holds for the extended coefficients, and therefore the sum of $n$ terms of this series is $18(-1/3)^{18} - 18(-2/3)^{17} = 3n^2 + 6n + 1$. In this way we get the general rule that, to find the sum of $n$ terms of a series, the $r$th term of which is $(a+rb)(a+rb+1) \ldots (a+r+rb-1)$, we divide the product of the $p+1$ factors which occur either in the $r$th or in the $(n+1)$th term by $p+1$, and by the common difference of the factors, and add to a constant, whose value is found by putting $n = 0$.

57. \textit{Generating Functions}.—The series $1 - m_{12}x + m_{13}x^2 + \ldots$ obtained by dividing $1 + a_1x + a_2x^2 + \ldots$ by $(1+x)$, or the terms $1 + (p_1x + p_2x^2 + \ldots)$ obtained by taking the root of $1 + p_1x + p_2x^2 + \ldots$, is an \textit{infinite series}, i.e. a series whose successive terms correspond to the numbers $1, 2, 3, \ldots$. It is often convenient, as in §56 (ii) and (vi), to consider the mode of development of such a series, without regard to arithmetical calculation; i.e. to consider the relations between the coefficients of powers of $x$, rather than the values of the terms themselves. From this point of view, the function which, by algebraical operations on $1 + a_1x + a_2x^2 + \ldots$, produces the series, is called \textit{its generating function}. The generating functions of the two series, mentioned above, for example, are $(1+x)^n$ and $(1+x)^p$. In the same way, the generating function of the series $1 + 2x + 3x^2 + 4x^3 + \ldots$ is $(1-x)^{-1}$.

Considered in this way, the relations between the coefficients of the powers of $x$ in a series may sometimes be expressed by a formal equality involving the series as a whole. Thus $$(1 + x + x^2 + \ldots)(1 + x^2 + x^4 + \ldots) = 1 + 2x + 3x^2 + \ldots$$

In the same way (21) of §43 (iv) leads to such relations as

$$1 + 3x + 6x^2 + \ldots, \quad 1 + 2x + 3x^2 + \ldots, \quad 1 + 2x + 3x^2 + \ldots$$

The relation of which to (30) is obvious.

An application of the method is to the summation of a \textit{recurring series}, i.e. a series $a_0 + a_1x + a_2x^2 + \ldots$ whose coefficients are connected by a relation of the form $p_0x + p_1x^2 + \ldots + p_2x^2 + \ldots = 0$, where $p_0, p_1, \ldots$ are independent of $x$ and of $r$.

58. \textit{Approach to a Limit}.—There are two kinds of approach to a limit, which may be illustrated by the series forming the expansion of $(x+h)^n$, where $n$ is a negative integer and $2h > 2x$.

(i) Denote $n_{(i)}x^n$ by $u$, and $u_n + u_{n+1} + \ldots u_r$ by $S_n$. Then (§56 (iii)) $(x+h)^n$ lies between $S_n$ and $S_{n+1}$, and provided $S_n$ includes the numerically greatest term, $|S_{n+1} - S_n|$ constantly decreases as $r$ increases, and can be made as small as we please by taking $r$ large enough. Thus by taking $r = 0, 1, 2, \ldots$ we have a sequence $S_0$, $S_1$, $S_2$, \ldots (i.e. a succession of numbers corresponding to the numbers $1, 2, 3, \ldots$) which possesses the property that, by starting far enough in the sequence, the range of variation of all subsequent terms can be made as small as we please, but $(x+h)^n$ always lies between the two values determining the range. This is expressed by saying that the sequence converges to $(x+h)^n$ as its limit; it may be stated concisely in any of the three ways,

$$(x+h)^n = \lim (x+h)^n(x+h)^n + n_{(i)}x^n + (x+h)^n + \ldots = \lim S_n = (x+h)^n.$$
the greatest (numerically). Then \((x-h)^n-S_n/k^n\) lies between \(n_1h^2x^{n-1}+\) and \(n_1h^2x^{n-1}+\) and the difference between these can be made as small as we please by taking \(k\) small enough. Thus we can say that the limit of \((x-h)^n-S_n/k^n\) is \(n_1h^2x^{n-1}\); but the approach to this limit is of a different kind from that considered in (i.), and its investigation involves the idea of continuity.

V. Continuity.

59. The idea of continuity must in the first instance be introduced from the graphical point of view; arithmetical continuity being impossible without a considerable extension of the idea of number (§ 65). The idea is utilized in the elementary consideration of a differential coefficient; and its importation into the treatment of certain functions as continuous is therefore properly associated with the infinitesimal calculus.

60. The first step consists in the functional treatment of equations. Thus, to solve the equation \(ax^2+bx+c=0\), we consider, not merely the value of \(x\) for which \(ax^2+bx+c=\)= 0, but the value of \(ax^2+bx+c\) for every possible value of \(x\). By graphical treatment we are able, not merely to see why the equation has usually two roots, and also to understand why there is in certain cases only one root (i.e., two equal roots) and in other cases no root, but also to see why there cannot be more than two roots.

Simultaneous equations in two unknowns \(x\) and \(y\) may be treated in the same way, except that each equation gives a functional relation between \(x\) and \(y\). ("Indeterminate equations" belong properly to the theory of numbers.)

61. From treating an expression involving \(x\) as a function of \(x\) which may change continuously when \(x\) changes continuously, we are led to regard two functions \(x\) and \(y\) as changing together, so that (subject to certain qualifications) to any succession of values of \(x\) or of \(y\) there corresponds a succession of values of \(y\) or of \(x\); and thence, if \((x, y)\) and \((x+h, y+k)\) are pairs of corresponding values, we are led to consider the limit (§ 58 (ii.)) of the ratio \(h/k\) \(\frac{h}{k}\) when \(h\) and \(k\) are made indefinitely small. Thus we arrive at the differential coefficient of \(f(x)\) as the limit of the ratio \(f(x+h)-f(x)\) to \(\theta\) when \(\theta\) is made indefinitely small; and this gives an interpretation of \(nx^n\) as the derived function of \(x^n\) (§ 45).

This conception of a limit enables us to deal with algebraic expressions which assume such forms as \(\frac{0}{0}\) for particular values of the variable (§ 39 (iii.)). We cannot, for instance, say that the fraction \(\frac{\frac{h}{h}}{\frac{h}{h}}\) is arithmetically equal to \(x+1\) when \(x=1\), as well as for other values of \(x\); but we can say that the limit of the ratio \(\frac{h}{h}\) to \(\frac{h}{h}\) when \(x\) becomes indefinitely nearly equal to \(1\) is the same as the limit of \(x+1\).

On the other hand, if \(f(y)\) has a definite and finite value for \(x=x\), it must not be supposed that this is necessarily the same as the limit which \(f(y)\) approaches when \(y\) approaches the value \(x\), though this is the case with the functions with which we are usually concerned.

62. The elementary idea of a differential coefficient is useful in reference to the logarithmic and exponential series. We know that \(\log_2n(1+\theta) = \log_2n+\log_2(1+\theta)\), and inspection of a table of logarithms shows that, when \(\theta\) is small, \(\log_2(1+\theta)\) is approximately equal to \(\lambda\), where \(\lambda\) is a certain constant, whose value is \(4.34\ldots\). If we took logarithms to base \(\alpha\), we should have

\[
\log_\alpha(1+\theta) = \log_\alpha\times\lambda\theta,
\]

approximately. If therefore we choose a quantity \(\epsilon\) such that

\[
\log\times\lambda\theta = \epsilon,
\]

which gives (by more accurate calculation)

\[
\epsilon = 2.71828\ldots,
\]

we shall have

\[
\lim(log_2(1+\theta))/\theta = 1,
\]

and conversely

\[
\lim[\epsilon(\theta+\epsilon)]/\theta = \epsilon.
\]

The deduction of the expansions

\[
\log(1+x) = x - \frac{1}{2}x^2 + \frac{1}{3}x^3 - \ldots,
\]

where \(\epsilon = 1 + x + x^2/2 + x^3/3 + \ldots\),

is then more simply obtained by the differential calculus than by ordinary algebraic methods.

63. The theory of inequalities is closely connected with that of maxima and minima, and therefore seems to come properly under this head. The more simple properties, however, only require the use of elementary methods. Thus to show that the arithmetic mean of \(n\) positive numbers is greater than their geometric mean (i.e., than the \(n\)th root of their product) we show that if any two are unequal their product may be increased, without altering their sum, by making them equal, and that if all the numbers are equal their arithmetic mean is equal to their geometric mean.

VI. Special Developments.

64. One case of convergence of a sequence has already been considered in § 58 (i.). The successive terms of the sequence in that case were formed by successive additions of terms of a series; the series is then also said to converge to the limit which is the limit of the sequence.

Another example of a sequence is afforded by the successive convergents to a continued fraction of the form \(a_0+a_1+a_2+\ldots\), where \(a_0, a_1, a_2, \ldots\) are integers. Denoting these convergents by \(P_0/Q_0, P_1/Q_1, P_2/Q_2, \ldots\), they may be regarded as obtained from a series \(P_0/Q_0, P_1/Q_1, P_2/Q_2, \ldots\); the successive terms of this series, after the first, are alternately positive and negative, and consist of fractions with numerators \(x\) and denominators continually increasing.

Another kind of sequence is that which is formed by introducing the successive factors of a continued product; e.g., the successive factors on the right-hand side of Wallis's theorem

\[
\pi = \frac{2\times2}{1\times3} \cdot \frac{4\times4}{3\times5} \cdot \frac{6\times6}{5\times7} \ldots
\]

A continued product of this kind can, by taking logarithms, be replaced by an infinite series.

In the particular case considered in § 58 (i.) we were able to examine the approach of the sequence \(S_0, S_1, S_2, \ldots\) to its limit \(X\) by direct examination of the value of \(X-S_n\). In most cases this is not possible; and we have first to consider the convergence of the sequence or of the series which it represents, and then to determine its limit by indirect methods. This constitutes the general theory of convergence of series (see Series).

The word "sequence," as defined in § 58 (i.), includes progressions such as the arithmetical and geometrical progressions, and, generally, the succession of terms of a series. It is usual, however, to confine it to those sequences (e.g., the sequence formed by taking successive sums of a series) which have to be considered in respect of their convergence or non-convergence.

In order that numerical results obtained by summing the first few terms of a series may be of any value, it is usually necessary that the series should converge to a limit; but there are exceptions to this rule. For instance, when \(n\) is large, \(n\) is approximately equal to \((\sqrt{n})/(\sqrt{n})\); the approximation may be improved by Stirling's theorem

\[
\log_2\log_2\cdots + n\log(n-1) + \log n = \log(2\times2) + n\log n + \frac{B_1}{2}-\frac{B_2}{12} + \frac{B_3}{3}+\cdots + \frac{(-1)^{n-1}B_{n}}{1\cdot 2\cdot n} + \cdots
\]

where \(B_1, B_2, \ldots\) are Bernoulli's numbers (§ 46 (v.)), although the series is not convergent.

65. Consideration of the binomial theorem for fractional index, or of the continued fractions involving a sum, or of theorems such as Wallis's theorem (§ 64), shows that a sequence in every term of which is rational, may have as its limit an irrational number, i.e., a number which cannot be expressed as the ratio of two integers.

These are isolated cases of irrational numbers. Other cases arise when we consider the continuity of a function. Suppose, for instance, that \(y=x^2\); then to every rational value of \(x\) there corresponds a rational value of \(y\), but the converse does not hold. Thus there appear to be discontinuities in the values of \(y\).

The difficulty is due to the fact that number is naturally not
continuous, so that continuity can only be achieved by an artificial development. The development is based on the necessity of being able to represent geometrical magnitude by arithmetical magnitude; and it may be regarded as consisting of three stages. Taking any number \( n \) to be represented by a point on a line at distance \( n \) from a fixed point \( O \), where \( L \) is a unit of length, we start with a series of points representing the integers 1, 2, 3, ... This series is of course discontinuous. The next step is to suppose that fractional numbers are represented in the same way. This extension produces a new series of points; but in the original integral series each number had a definite number next to it, on each side, except 1, which began the series. But in the new series there is no first number, and no number can be said to be next to any other number, since, whatever two numbers we take, others can be inserted between them. On the other hand, this new series is not continuous; for we know that there are some points on the line which represent surds and other irrational numbers, and these numbers are not contained in our series. We therefore take a third step, and obtain theoretical equality by introducing as many different points, each point on the line from the beginning of the series, unless it does not represent a rational number, represents something which may be called an irrational number.

This insertion of irrational numbers (with corresponding negative numbers) requires for its exact treatment certain special methods, which form part of the algebraic theory of number, and are dealt with under Number.

66. The development of the theory of equations leads to the amplification of real numbers, rational and irrational, positive and negative, by imaginary and complex numbers. The quadratic column of \( \sqrt{2} \), for instance, has no real root; we may treat the roots as being \( +\sqrt{2} - 1 \) and \( -\sqrt{2} - 1 \), which solves the laws of arithmetic and emerges into reality under the condition \( \sqrt{2} - 1 = 1 = -1 \). Expressions of the form \( b + c + 1 \) and \( a + b + 1 \), where \( a \) and \( b \) are real numbers, are then described as imaginary and complex numbers respectively; the former being a particular case of the latter.

Complex numbers are conveniently treated in connexion not only with the theory of equations but also with analytical trigonometry, which suggests the graphic representation of \( a+b \sqrt{-1} \) by a line of length \((a^2+b^2)^{1/2}\) drawn in a direction different from that of the line along which real numbers are represented.

B. Special kinds of algebra

1. A special algebra is one which differs from ordinary algebra in the laws of equivalence which its symbols obey. Theoretically, no limit can be assigned to the number of possible algebras; the varieties actually known, however, for the most part, the same signs of operation, and differ among themselves principally by their rules of multiplication.

2. Ordinary algebra developed very gradually as a kind of shorthand, devised to abbreviate the discussion of arithmetical problems and the statement of arithmetical facts. Although the distinction is one which cannot be ultimately maintained, it is convenient to classify the signs of algebra into symbols of quantity (usually figures or letters), symbols of operation, such as +, ×, and symbols of distinction, such as brackets. Even when the formal evolution of the symbols was fairly to indicate it, it is often found that its symbols of quantity invariably stood for numbers, and that its symbols of operation were restricted to their ordinary arithmetical meanings. It could not escape notice that one and the same symbol, such as \( (a-b) \), or even \( (a-b) \), sometimes did and sometimes did not admit of arithmetical interpretation, according to the values attributed to the letters involved: This led to a prolonged controversy on the nature of negative and imaginary quantities, which was ultimately settled in a very curious way. The progress of analytical geometry led to a geometrical interpretation both of negative and also of imaginary quantities; and when a "meaning" or, more properly, an interpretation, had thus been found for the symbols in question, a reconsideration of the old algebraic problem became inevitable, and the true solution, now so obvious, was eventually obtained.

It was at last realized that the laws of algebra do not depend for their validity upon any particular interpretation, whether arithmetical, geometrical or other; the only question is whether these laws do or do not involve any logical contradiction. When this fundamental truth had been fully grasped, mathematicians began to inquire whether algebras might not be discovered which obeyed laws different from those obtained by the generalization of arithmetic.

The answer to this question has been so manifest as to be almost embarrassing. All that can be done here is to give a sketch of the more important and independent special algebras at present known to exist.

3. Although the results of ordinary algebra will be taken for granted, it is convenient to give the principal rules upon which it is based. They are:

\[ a+b+c=a+c+b \quad (A) \]
\[ a+b-b+a=a \quad (B) \]
\[ a+b=b+a \quad (C) \]
\[ a+b+c=a+c+b \quad (D) \]
\[ a+b=a+c \quad (E) \]
\[ a+b=a+b \quad (F) \]

These formulae express the associative and commutative laws of the operations + and \( x \), the distributive law of \( x \), and the definitions of the inverse symbols \(-a\) and \(-b\), which are assumed to be unambiguous.

The symbols of ordinary algebra do not necessarily denote numbers; they may, for instance, be interpreted as operations of which the addition is the analog of \( + \). Evolution and involution are usually regarded as operations of ordinary algebra; this leads to a notation for powers and roots, and a theory of irrational algebraic quantities analogous to that of irrational numbers.
4. The only known type of algebra which does not contain arithmetical elements is substantially due to George Boole. Although originally suggested by formal logic, it is most simply interpreted as an algebra of regions in space. Let \( i \) denote a definite region of space; and let \( a, b, \&c. \) stand for definite parts of \( i \). Let \( a+b \) denote the region made up of \( a \) and \( b \) together (the common part, if any, being reckoned only once), and let \( a\times b \) or \( ab \) mean the region common to \( a \) and \( b \). Then \( a+a=a \cdot a \cdot a \cdot a \cdot a \); hence numerical coefficients and indices are not required. The inverse symbols \( -a \) are ambiguous, and in fact are rarely used. Each symbol \( a \) is associated with its supplément \( \bar{a} \) which satisfies the equations \( a+\bar{a}=i \), \( a \cdot \bar{a}=0 \), the latter of which means that \( a \) and \( \bar{a} \) have no region in common. Finally, there is a law of absorption expressed by \( a \cdot ab=a \). From every proposition in this algebra a reciprocal one may be deduced by interchanging \( + \) and \( \times \), and also the symbols \( o \) and \( i \). For instance, \( x+y=x+y \) and \( xy=x(y-z) \) are reciprocal. The operations \( + \) and \( \times \) obey all the ordinary laws \( a, b, c (§ 3) \).

5. A point \( P \) in space may be associated with a (real, positive, or negative) numerical quantity \( a \), called its weight, and denoted by the symbol \( a \). The sum of two weighted points \( aA, bB \) is, by definition, the point \( (a+b)G \), where \( G \) divides \( AB \) so that \( AG=BG=b.a \). It can be proved by geometric means that

\[
(a+\beta+b+c+y)+P=(a+\beta+b+c+y)P
\]

where \( P \) is in fact the centroid of masses \( a, b, c \) placed at \( A, B, C \) respectively. So, in general, if we put

\[
aA+bB+cC+\ldots+X
\]

where \( a, b, c, \ldots \) are, in fact, equivalent to a set of homogeneous co-ordinates of \( P \). For constructions in a fixed plane three points of reference are sufficient. It is remarkable that Möbius employs the symbols \( AB, ABC, \) etc., in his ordinary geometrical sense as lengths, areas and volumes, except that he distinguishes their sign; thus \( AB=-BA, ABC=-ACB, \) and so on. If he had happened to think of them as “products,” he might have anticipated Grassmann’s discovery of the extensive calculus. From a mere formal point of view, we have in the barycentric calculus a set of “special symbols of quantity or “extraordinary” A, B, C, \&c., which combine with each other by means of operations \( + \) and \( - \) which obey the ordinary rules, and with ordinary algebraic quantities by operations \( \times \) and \( \div \), also according to the ordinary rules, except that division by an extraordinary is not used.

6. A quaternion is best defined as a symbol of the type

\[
g=\sum a_i\epsilon_i=\sum a_i\epsilon_i=\sum a_i\epsilon_i
\]

where the \( \epsilon_i \) are independent extraordinary and ordinary algebraic quantities, which may be called the co-ordinates of \( g \). The sum and product of two quaternions are defined by the formulae

\[
\Sigma a_i+\Sigma b_i=\Sigma (a_i+b_i), \\
\Sigma a_i\times \Sigma b_i=\Sigma (a_i b_i)
\]

where the products \( \epsilon_i\epsilon_j \) are further reduced, according to the following multiplication table, in which, for example, the second line is to be read

\[
e_0e_0=e_0, e_1e_0=-e_0, e_1e_1=e_0, e_1e_2=-e_2
\]

and, similarly for \( e_2, e_3 \). The effect of these definitions is that the sum and the product of two quaternions are also quaternions; that addition is associative and commutative; and that multiplication is associative and distributive, but not commutative. Thus \( e_0e_0=-e_0e_0 \) and if \( q, q’ = \) any two quaternions, \( qq’ \) is generally different from \( q’q \). The symbol \( e_0 \) behaves exactly like 1 in ordinary algebra; Hamilton writes \( i, j, k, k \) instead of \( e_0, e_1, e_2, e_3 \), and in this notation all the special rules of operation may be summed up by the equalities

\[
P^2=-P, ijk=-1.
\]

Putting \( q=a+b+\gamma j+\delta k \), Hamilton calls \( a \) the scalar part of \( q \), and denotes it by \( S(q) \); he also writes \( V(q) \) for \( \beta+i+j+\delta k \), which is called the vector part of \( q \). Thus every quaternion may be written in the form \( q=S(q)+V(q) \), where either \( S(q) \) or \( V(q) \) may separately vanish; so that ordinary algebraic quantities (or scalars, as we shall call them) and pure vectors may each be regarded as special cases of quaternions.

The equations \( q^2=q \) and \( q^2=q \) are satisfied by the same quaternion, which is denoted by \( q^2=q \). On the other hand, the equations \( q^2=q \) and \( q^2=q \) have, in general, different solutions. It is the value of \( y \) which is generally denoted by \( q^2=q \); a special symbol for \( z \) is desirable, but has not been established. If we put \( q^2=q^2 \), then \( q^2 \) is called the conjugate of \( q \), and the scalar \( q^2=q^2 \) is called the norm of \( q \) and \( q \). With this notation the values of \( x \) and \( y \) may be expressed in the forms

\[
x=qR/|q|, \quad y=qR/|q|
\]

which are free from ambiguity, since scalars are commutative with quaternions. The values of \( x \) and \( y \) are different, unless \( V(q^2)=0 \).

The basis of the calculus the co-ordinates of a quaternion are usually assumed to be numerical; when they are complex, the quaternion is further distinguished by Hamilton as a bi-quaternion. Clifford’s bi-quaternions are quantities \( q=\gamma \cdot r \), where \( q, \gamma \) are quaternions, and \( \gamma \) are symbols (commutative with quaternions) obeying the laws \( \gamma^2=\xi, \gamma \gamma=1, \gamma^2=\xi^2=0 \) (for quaternion). The quaternion is a general division algebra.

7. In the extensive calculus of the \( n \)th category, we have, first of all, \( n \) independent “units,” \( e_1, e_2, \ldots, e_n \). From these are derived symbols of the type

\[
A_1=a_1e_1+a_2e_2+\ldots+a_ne_n=\Sigma a_i e_i
\]

which we shall call extensive quantities of the first species (and, when necessary, of the \( n \)th category). The co-ordinates \( a_1, \ldots, a_n \) are scalars, and in particular applications may be restricted to real or complex numerical values. If \( B_1=\Sigma b_i \), there is a law of addition expressed by

\[
A_1+B_1=\Sigma (a_1+b_i)=A_1+A_1
\]

this law of addition is associative as well as commutative. The inverse operation is free from ambiguity, and, in fact,

\[
A_1-B_1=\Sigma (a_1-b_i)
\]

To multiply \( A_1 \) by a scalar, we apply the rule

\[
eA_1=A_1e_1=\Sigma (a_i e_i)
\]

and similarly for division by a scalar.

All this is analogous to the corresponding formulae in the barycentric calculus and in quaternions; it remains to consider the multiplication of two or more extensive quantities. The binary products of the units \( e_i \) are taken to satisfy the equalities

\[
e_i^2=0, \quad e_i e_j=-e_j e_i
\]

this reduces them to \( 2^n \) distinct values, exclusive of zero. These values are assumed to be independent, so we have \( n(n-1) \) derived units of the second species or order. Associated with these new units there is a system of extensive quantities of the second species, represented by symbols of the type

\[
A_2=\Sigma a_i E_i, \quad [E_1, E_2, \ldots, E_{n(n-1)}]
\]

where \( E_i, E_j, \&c. \) are the derived units of the second species. If \( A_2=\Sigma a_i E_i, B_1=\Sigma b_i E_i \), the distributive law of multiplication is preserved by assuming

\[
A_2B_i=\Sigma (a_i b_i)E_i
\]

it follows that \( A_2 B_i=B_i A_2 \), and that \( A_2=0 \).

By assuming the truth of the associative law of multiplication, and taking account of the reducing formulae for binary products,
we may construct derived units of the third, fourth \ldots nth species. Every unit of the rth species which does not vanish is the product of r different units of the first species; two such units are independent unless they are permutations of the same set of primary units \( e_t \), in which case they are equal or opposite according to the usual rule employed in determinants. Thus, for instance,

\[
(\epsilon_1 e_2) = \epsilon_1 e_2 = \epsilon_2 e_1, \quad (\epsilon_1 e_2 e_3) = \epsilon_1 e_2 e_3 = \epsilon_3 e_1 e_2;
\]

and, in general, the number of distinct units of the rth species in the n'th category \( r < n \) is \( C_{n,r} \). Finally, it is assumed that in the \( n \)th category \( e_1 e_2 \ldots e_n = 1 \), the suffixes being in their natural order.

Let \( A = \Sigma A e_t^0 \) and \( B = \Sigma B e_t^0 \) be two extensive quantities of species \( r \) and \( s \); then if \( r + s < n \), they may be multiplied by the rule

\[
A B = \Sigma(\epsilon_t) e_t^0 E^0 \]

where the products \( E^0 e_t^0 \) may be expressed as derived units of species \( r + s \). The product \( B A \) is equal or opposite to \( A B \), according as \( rs \) is even or odd. This process may be extended to the product of three or more factors such as \( A B C \); provided that \( r + s + t < n \) does not exceed \( n \). The law is associative; thus, \((A B) C = A(B C)\). But the commutative law does not always hold; thus, indicating species, as before, by extensive quantities, the product \( A B C \) is equal to \( (-1)^{rs+st+tr} C B A \), with analogous rules for other cases.

If \( r + s > n \), a product such as \( E e_t \) worked out by the previous rules, comes out to be zero. A characteristic feature of the calculus is that a meaning can be attached to a symbol of this kind by adopting a new rule, called that of regressive multiplication, as distinguished from the foregoing, which is progressive. The new rule requires some preliminary explanation. If \( E \) is any extensive unit, there is one other unit \( E' \), and only one, such that the (progressive) product \( E E' = 1 \). This unit is called the supplement of \( E \), and denoted by \( E' \). For example, when \( n = 4 \),

\[
i_1 e_2 e_3 e_4, \quad i_2 e_3 e_4, \quad i_3 e_4, \quad = i_4, \]

and so on. Now when \( r + s > n \), the product \( E E' \) is defined to be that unit of which the supplement is the progressive product \( E E' \). For instance, if \( n = 4 \), \( E = e_3 e_2, \ E' = e_2 e_3 \), we have

\[
E E' = (-i_3 e_2), \quad (-i_2 e_3) = i_4 = i_4 e_1 e_2 e_3 e_4,
\]

consequently, by the rule of regressive multiplication,

\[
i_3 e_2 e_3 e_4 = i_4 e_1 e_2 e_3 e_4 = E e_t.
\]

Applying the distributive law, we obtain, when \( r + s > n \),

\[
A B = E E' E, \quad G B E = (E E') E, \quad A B C = (E E') C,
\]

where the regressive products \( E e_t \) are to be reduced to units of species \( r + s - n \) by the foregoing rule.

If \( A = \Sigma A e_t e_t \), then, by definition, \( A A = \Sigma A e_t e_t \), and hence

\[
A(B + C) = A B + A C,
\]

Now this is formally analogous to the distributive law of multiplication; and in fact we may look upon \( A B \) as a particular way of multiplying \( A \) and \( B \) (not \( A \) and \( B \)). The symbol \( A B \), from this point of view, is called the inner product of \( A \) and \( B \), as distinguished from the outer product \( I A B \). An inner product may be either progressive or regressive. In the course of reducing such expressions as \( (A B) C, (A B) (C D E) \) and the like, where a chain of multiplications has to be performed in a certain order, the multiplications may be all progressive, or all regressive, or partly, one, partly the other. In the first two cases the product is said to be pure, in the third case mixed. A pure product is associative; a mixed product, speaking generally, is not.

The outer and inner products of two extensive quantities \( A, B, \ldots \) are in many ways analogous to the quaternion symbols \( V a b \) and \( S a b \). As in quaternions, so in the extensive calculus, there are numerous formulae of transformation which enable us to deal with extensive quantities without expressing them in terms of the primary units. Only a few illustrations can be given here. Let \( a, b, c, d, e, f \) be quantities of the first species in the fourth category; \( A, B, \ldots \) quantities of the third species in the same category. Then

\[
(a b c d) = (a b)(c d) + (a c)(d b) + (a d)(b c) = (a c b)(d a) + (a b d)(c a) + (a d c)(b a) = (a d c b)(a b c d),
\]

and these may be compared and contrasted with such quaternion formulae as

\[
S(V a V b) = S a V b - S b V a,
\]

\[
S a b c = S a S b - S b S a - S c S d + S d S c,
\]

where \( a, b, c, d \) denote arbitrary vectors.

8. An \( n \)-tuple linear algebra (also called a complex number system) deals with quantities of the type \( A = 2 a e_t \) derived from \( n \) species units \( e_1, e_2, \ldots, e_n \). The sum and product of two quantities are defined in the first instance by the formulae

\[
2a + 2b = 2(a + b), \quad 2a e_t = 2(a e_t), \quad 2(b e_t) = 2(e_t b a),
\]

so that the laws \( A, B, C \) of \( \S 3 \) are satisfied. The binary products \( e_t e_s \) however, are expressible as linear functions of the units \( e_t \) by means of a "multiplication table" which defines the special characteristics of the algebra in question. Multiplication may or may not be commutative, and in the same way it may or may not be associative. The types of linear associative algebras, not assumed to be commutative, have been enumerated (with some omissions) up to sextuple algebras inclusive by B. Peirce. Quaternions afford an example of a quadruple algebra of this kind; ordinary algebra is a special case of a duplex linear algebra. If, in the extensive calculus of the \( n \)th category, all the units (including \( 1 \) and the derived units \( E \)) are taken to be homologous instead of being distributed into species, we may regard it as a \((2^n - 1)\)-tuple linear algebra, which, however, is not wholly associative. It should be observed that, while the use of special units, or extraordinarys, in a linear algebra is convenient, especially in applications, it is not indispensable. Any linear quantity may be denoted by a symbol \( a, a_2, \ldots, a_n \) in which only its scalar coefficients occur; in fact, the special units only serve, in the algebra proper, as \( s m b r a \) or regulators of certain operations on scalars (see \( \text{NUMBER} \)). This idea finds fuller expression in the algebra of matrices, as to which it must suffice to say that a matrix is a symbol consisting of a rectangular array of scalars, and that matrices may be combined by a rule of addition which obeys the usual laws, and a rule of multiplication which is distributive and associative, but not, in general, commutative. Various special algebras (for example, quaternions) may be expressed in the notation of the algebra of matrices.

9. In ordinary algebra we have the disjunctive law that if \( a b = 0 \), then either \( a = 0 \) or \( b = 0 \). This applies also to quaternions, but not to extensive quantities, nor is it true for linear algebras in general. One of the most important questions in investigating a linear algebra is to decide the necessary relations between \( a \) and \( b \) in order that this property may be satisfied.

10. The algebras distinguished up to this point may be considered as independent in the sense that each of them deals with a class of symbols of quantity more or less homogeneous, and a set of operations applying to them all. But when an algebra is used with a particular interpretation, or even in the course of its formal development, it frequently happens that new symbols of operation are, so to speak, superposed upon the algebra, and are found to obey certain formal laws of combination of their own. For instance, there are the symbols \( \Delta, \Sigma, \Delta \Sigma, E \) used in the calculus of finite differences; Aронхоль's method in the calculus of invariants; and the like. In such cases these subsidiary algebras, as they may be called, are inseparable from the applications in which they are used; but in any attempt at a natural classification of algebra (at present a hopeless task), they would have to be taken into account. Even in ordinary algebra the notation for powers and roots disturbs the symmetry of the rational theory; and when a schoolboy illegitimately extends the distributive law by writing \( (a + b) = (a + b) \), he is unconsciously emphasizing this want of complete harmony.
ALGEBRA

H. Grassmann, Die lineare Ausdehnungslehre (Leipzig, 1844).

C. History

Various derivations of the word "algebra," which is of Arabian origin, have been given by different writers. The first mention of the word is to be found in the title of a work by Mahommed ben Musa al-Khwarizmi (Hovarezmi), who flourished about the beginning of the 9th century. The full title is ilm al-Jabr wa'l-Mugabala, which contains the ideas of restitution and comparison, or opposition and comparison, or resolution and equation, jebr being derived from the verb jabara, to reunite, and mugabala, to make equal. (The root jabara is also met with in the word algebrista, which means a "bone-setter," and is still in common use in Spain.) The same derivation is given by Lucas Pacioli (Luca Pacioli), who reproduces the phrase in the transliterated form algebrea e almucabala, and ascribes the invention of the art to the Arabinians.

Other writers have derived the word from the Arabic particle al (the definite article), and jebr, meaning "man." Since, however, Geber happened to be the name of a celebrated Moorish physician who flourished in the 11th and 12th centuries, it has been supposed that he was the founder of algebra, which has since perpetuated his name. The evidence of Peter Ramus (1515-1572) on this point is interesting, but he gives no authority for his singular statements. In the preface to his Arithmeticae libri duo et totidem Algebrae (1560) he says: "The name Algebra is Syriac, signifying the art or doctrine of an excellent man. For Geber, in Syriac, is a name applied to men, and is sometimes a term of honour, as master or doctor among us. There was a certain learned mathematician who sent his algebra, written in the Syriac tongue, to Diophantus of Alexandria, to obtain that name, algebrabala, that is, the book of dark or mysterious things, which others would rather call the doctrine of algebra. To this day the same book is in great estimation among the learned in the oriental nations, and by the Indians, who cultivate this art, it is called algebrabala and al-geber; though the name of the author himself is not known." The uncertain nature of these statements, and the plausibility of the preceding explanation, have caused philologists to accept the derivation from al and jabara.

Robert Recorde in his Whetstone of Witte (1557) uses the variant algebra, while John Dee (1527-1608) affirms that algebra, and not algebra, is the correct form, and appeals to the authority of the Arabian Avicenna.

Although the term "algebra" is now in universal use, various other appellations were used by the Italian mathematicians during the Renaissance. Thus we find Pacioli calling it l'Arte Magiore; diita dal vulgo la Regula de la Cosa over Algebre e Almucabala. The name l'arte magiore, the greater art, is designed to distinguish it from l'arte minore, the lesser art, a term which he applied to the modern arithmetic. His second variant, la regula de la cosa, appears to have been common in use in Italy, and the word cosa was preserved for several centuries in the forms cosina, cosic or algebraic, cositt or algebraist, &c. Other Italian writers termed it la Regula rei et census, the rule of the thing and the product, or the root and the square. The principle underlying this expression is probably to be found in the fact that it measured the limits of their attainments in algebra, for they were unable to solve equations of a higher degree than the quadratic or square.

Franciscus Vieta (François Viète) named it Speciæ Arithmeticæ, on account of the species of the quantities involved, which he represented symbolically by the various letters of the alphabet. Sir Isaac Newton introduced the term Universal Arithmetic, since it is concerned with the doctrine of operations, not affected on numbers, but on general symbols.

Notwithstanding these and other idiosyncratic appellations, European mathematicians have adhered to the older name, by which the subject is now universally known.

It is difficult to assign the invention of any art or science definitely to any particular age or race. The few fragmentary records, which have come down to us from past civilizations, make the task of determining the regalia difficult, and the study of the underlying doctrine, and the omission of a science or art does not necessarily imply that the science or art was unknown. It was formerly the custom to assign the invention of algebra to the Greeks, but since the decipherment of the Rhind papyrus by Eisenlohr this view has changed, for in this work there are distinct signs of an algebraic analysis. The particular problem—a heap (hau) and its seventh makes 19—is solved as we should now solve a simple equation; but Ahmes varies his methods in other similar problems. This discovery carries the invention of algebra back to about 1700 B.C., if not earlier.

It is probable that the algebra of the Egyptians was of a most rudimentary nature, for otherwise we should expect to find traces of it in the works of the Greek geometers, of whom Thales of Miletus (640-546 B.C.) was the first. Notwithstanding the profusion of writers and the number of the writings, all attempts at extracting an algebraic analysis from their geometrical theorems and problems have been fruitless, and it is generally conceded that their analysis was geometrical and had little or no affinity to algebra. The first extant work which approaches to a treatise on algebra is that called De Mondatae et Quadratum Libri V, by the Arabian mathematician, who flourished about A.D. 350. The original, which consisted of a preface and thirteen books, is now lost, but we have a Latin translation of the first six books and a fragment of another on polygonal numbers by Xylander of Augsburg (1575), and Latin and Greek translations by Gaspar Bachet de Mersiac (1621-1670). Other editions have been published, of which we may mention Pierre Fermat's (1670), T. L. Heath's (1885) and F. Tannery's (1883-1885). In the preface to this work, which was published in 1621, the author affirms, "Algebra is the delight of men, naming the square, cube and fourth powers, dynamis, cubus, dynamodinimus, and so on, according to the sum in the indices. The unknown he terms arithmos, the number, and in solutions he marks it by the final s; he explains the generation of powers, the rules for multiplication and division of simple quantities, but he does not treat of the addition, subtraction, multiplication and division of compound quantities. He then proceeds to discuss various artifices for the simplification of equations, giving methods which are still in common use. In the body of the work he displays considerable ingenuity in reducing his problems to simple equations, which admit either of direct solution, or fall into the class known as indeterminate equations. This latter class he discussed so assiduously that they are often known as Diophantine problems, and the methods of resolving them as the Diophantine analysis (see Equation, Indeterminate). It is
ALGEBRA

difficult to believe that this work of Diophantus arose spontaneously in a period of general stagnation. It is more than likely that he was indebted to earlier writers, whom he omits to mention, and whose works are now lost; nevertheless, but for this work, we should be led to assume that algebra was almost, if not entirely, unknown to the Greeks.

The Romans, who succeeded the Greeks as the chief civilized power in Europe, failed to set store on their literary and scientific treasures; mathematics was all but neglected; and beyond a few improvements in arithmetical computations, there are no material advances to be recorded.

In the chronological development of our subject we have now to turn to the Orient. Investigation of the writings of Indian mathematicians has shown that the most fundamental and arithmetical of algebra was accomplished between the Greek and Indian minds, the former being pre-eminently geometrical and speculative, the latter arithmetical and mainly practical. We find that geometry was neglected except in so far as it was of service to astronomy; trigonometry was advanced, and algebra improved far beyond the attainments of Diophantus.

The earliest Indian mathematician of whom we have certain knowledge is Aryabhata, who flourished about the beginning of the 6th century of our era. The fame of this astronomer and mathematician rests on his work, the Aryabhattiyam, the third chapter of which is devoted to mathematics. Gausses an eminent astronomer, mathematician and scholiast of Bhaskara, quotes this work and makes separate mention of the cuttaca ("pulveriser"), a device for effecting the solution of indeterminate equations. Henry Thomas Colebrooke, one of the earliest modern investigators of Hindu science, presumes that the treatise of Aryabhata extended to determinate quadratic equations, indeterminate equations of the first degree, and probably of the second. An astronomical work, called the Surya-siddhanta ("knowledge of the Sun") is, of uncertain age and probably belonging to the 4th or 5th century, was considered of great merit by the Hindus, who ranked it only second to the work of Brahmagupta, who flourished about a century later. It is of great interest to the historical student, for it exhibits the influence of Greek science upon Indian mathematics at a period prior to Aryabhata. After an interval of about a century, during which mathematics attained its highest level, there flourished Brahmagupta (b. A.D. 598), whose work entitled Brahma-sphuta-siddhanta ("The revised system of Brahma") contains the algebraic ideas which we have already referred to as the Hindu-Arabic system. The Arabic historians mention that it was made by Cridhara, the author of a Ganita-sara ("Quintessence of Calculation"), and Padmanabha, the author of an algebra.

A period of mathematical stagnation then appears to have possessed the Indian mind for an interval of several centuries, for the works of the next author of any moment stand but little in advance of Brahmagupta. We refer to Bhaskara Acarya, whose work the Siddhanta-ciromani ("Diadem of an Astronomical System"), written in 1150, contains two important chapters, the Lilawati ("the beautiful [science or art]") and Viga-ganita ("root-extraction") which are given up to arithmetic and algebra. English translations of the mathematical chapters of the Brahma-siddhanta and Siddhanta-ciromani by H. T. Colebrooke (1817), and of the Surya-siddhanta by E. Burgess, with annotations by W. D. Whitney (1886), may be consulted for details.

The question as to whether the Greeks borrowed their algebra from the Hindus or vice versa has been the subject of much discussion. There is no doubt that there was a constant traffic between Greece and India, and it is more than probable that an exchange of ideas would be the result of such contacts. Moritz Cantor suspects the influence of Diophantine methods, more particularly in the Hindu solutions of indeterminate equations, where certain technical terms are, in all probability, of Greek origin. However this may be, it is certain that the Hindu algebraists were far in advance of Diophantus. The deficiencies of the Greek symbolism were partially remedied; subtraction was denoted by placing a dot over the subtractand; multiplication, by placing bhā (an abbreviation of bhāsita, the "product") after the factors; division, by placing the divisor under the dividend; and square root, by inserting ka (an abbreviation of karana, irrational) before the quantity. The unknown was called yādākāra, and if there were several, the first took this appellation, and the others were designated by the names of colours; for instance, x was denoted by yā and y by kā (from kālabha, black).

A notable improvement on the ideas of Diophantus is to be found in the fact that the Hindus recognized the existence of two roots of a quadratic equation, but the negative roots were considered to be inadequate, since no interpretation could be found for them. It is also supposed that they anticipated discoveries of the solutions of higher equations. This was first made in the study of indeterminate equations, a branch of analysis in which Diophantus excelled. But whereas Diophantus aimed at obtaining a single solution, the Hindus strove for a general method by which any indeterminate problem could be resolved. In this they were completely successful, for they obtained general solutions for the equations

\[ ax^2 + by^2 = c, \]

\[ xy = ax + by + c, \]

(reverse) of Leonhard Euler) and

\[ y^2 = ax^2 + b. \]

A particular case of the last equation, namely,

\[ y^2 = ax^2 + 1, \]

sorely taxed the resources of modern algebraists. It was proposed by Pierre de Fermat to Bernhard Pacquet de la Hire, who in his letter to John Wallis and Lord Brunsen jointly obtained a tedious solution which was published in 1658, and afterwards in 1668 by John Pell in his Algebra. A solution was also given by Fermat in his Relation. Although Pell had nothing to do with the solution, posterity has termed the equation Pell's Equation, or, when more rightly it should be the Hindu Problem, in recognition of the mathematical attainments of the Brahmans.

Hermann Hankel has pointed out the readiness with which the Hindus passed from number to magnitude and vice versa. Although this transition from the discontinuous to the continuous is not truly scientific, yet it materially augmented the development of algebra, and Hankel affirms that if we define algebra as the application of arithmetical operations to both rational and irrational numbers or magnitudes, then the Brahmans are the real inventors of algebra.

The integration of the scattered tribes of Arabia in the 7th century by the stirring religious propaganda of Mahomet was accompanied by a meteoric rise in the intellectual powers of a hitherto obscure race. The Arabs became the custodians of Indian and Greek science, and when the Abbasids, Bagdad became the centre of scientific thought; physicians and astronomers from India and Syria flocked to their court; Greek and Indian manuscripts were translated (a work commenced by the Caliph Mamun (833-835) and ably continued by his successors); and in about a century the Arabs were placed in possession of the vast stores of Greek and Indian learning. Euclid's Elements were first translated in the reign of Harrun-al-Rashid (786-809), and revised by the order of Mamun. But these translations were regarded as imperfect, and it remained for Tobit ben Korra (836-901) to produce a satisfactory edition. Ptolemy's Almagest, the works of Apollonius, Archimedes, Diophantus and portions of the Brahma-siddhanta, were also translated. The first notable Arabian mathematician was Mahommed ben Musa al-Khwarizmi, who flourished in the reign of Mamun. His treatise on algebra and arithmetic (the latter part of which is only extant in the form of a Latin translation, discovered in 1657) contains nothing that was unknown to the Greeks and Hindus; it exhibits methods allied to those of both races, while the Greek element predominated. The part of the algebra is called al-jabr wa'l-muqābala, and the arithmetical begins with "Spoken has Algoritmi," the name Khwarizmi or Hovarezmi having passed into the word Algoritmi, which has been further transformed into the modern words algorithm and algorit, signifying a method of computing.

Tobit ben Korra (836-901), born at Harran in Mesopotamia, an accomplished linguist, mathematician and astronomer,
rendered conspicuous service by his translations of various Greek authors. His investigation of the properties of amicable numbers (q.v.) and of the problem of trisecting an angle, are of importance. The Arabians more closely resembled the Hindus than the Greeks in the choice of studies; their philosophers blended speculative dissertations with the more progressive study of medicine; their mathematicians neglected the subtleties of the conic sections and Diophantine analysis, and applied themselves more particularly to perfect the system of numerals (see NUMERAL), arithmetic and astronomy (q.v.). When it was thus accomplished that whereas was made in algebra, the talents of the race were bestowed on astronomy and trigonometry (q.v.). Fahri des al Karhi, who flourished about the beginning of the 11th century, is the author of the most important Arabic work on algebra. He follows the methods of Diophantus; his work on indeterminate equations has no resemblance to the Indian methods, and contains nothing that cannot be gathered from Diophantus. He solved quadratic equations both geometrically and algebraically, and also of the form \(x^n + ax^{n-1} + \ldots + b = 0\); he also proved certain relations between the sum of the first \(n\) natural numbers, and the sum of their squares and cubes.

Cubic equations were solved geometrically by determining the intersections of conic sections. Archimedes' problem of dividing a sphere by a plane into two segments having a prescribed ratio, was first expressed as a cubic equation by Al Mahani, and the first solution was given by Abu Gafar al Hazin. The determination of the side of a regular heptagon which can be inscribed or circumscribed to a given circle was reduced to a more complicated equation which was first successfully resolved by Abul Gud. The method of solving equations geometrically was considerably developed by Omar Khayyam of Khurasan, who flourished in the 11th century. This author questioned the possibility of solving cubics by pure algebra, and biquadratics by geometry. His first contention was not disproved until the 15th century, but his second was disposed of by Abu Wefa (940–998), who succeeded in solving the forms \(x^3 = a\) and \(x^4 + ax^2 = b\).

Although the foundations of the geometrical resolution of cubic equations are to be ascribed to the Greeks (for Euclides assigns to Menaeachmus two methods of solving the equation \(x^3 = a\) and \(x^3 + ax^2 = b\)), yet the subsequent development by the Arabs must be regarded as one of their most important achievements. The Greeks had succeeded in solving an isolated example; the Arabs accomplished the general solution of numerical equations.

Considerable attention has been directed to the different styles in which the Arabian authors have treated their subject. Moritz Cantor has suggested that at one time there existed two schools, one in sympathy with the Greeks, the other with the Hindus; and that, although the writings of the latter were first studied, they were rapidly discarded for the more perspicuous Grecian methods, so that, among the later Arabian writers, the Indian methods were practically forgotten and their mathematics became essentially Greek in character.

Turning to the Arabs in the West we find the same enlightened spirit; Cordova, the capital of the Moorish empire in Spain, was as much a centre of learning as Bagdad. The earliest known Spanish mathematician is Al Madshritti (d. 1007), whose fame rests on a dissertation on amicable numbers, and on the schools which were founded by his pupils at Cordova, Dania and Granada. Gahir ben Allah of Sevilla, commonly called Geber, was a celebrated astronomer and apparently skilled in algebra, for it has been supposed that the word "algebra" is compounded from his name.

When the Moorish empire began to wane the brilliant intellectual gifts which they had so abundantly nourished during three or four centuries became enfeebled, and after that period they failed to produce an author comparable with those of the 7th to the 11th centuries.

In Europe the decline of Rome was succeeded by a period, lasting several centuries, during which the sciences and arts were again promulgated by the political nations occupied the greatest intellects, and the only progress to be recorded is in the art of computing or arithmetic, and the translation of Arabic manuscripts. The first successful attempt to revive the study of algebra in Christendom was due to Leonardo of Pisa, an Italian merchant trading in the Mediterranean. His travels and mercantile experience had led him to conclude that the Hindu methods of computing were in advance of those then in general use, and in 1202 he published his Liber Abaci, which treats of both algebra and arithmetic. In this work, which is of great historical interest, since it was published about two centuries before the art of printing, the student is taught how to solve for rational or irrational, but of imaginary roots of equations whether positive or negative, of equations whose rational roots were very small, and he admits his inability to resolve the so-called
irreducible case) (see Equation). Fundamental theorems in the theory of equations are to be found in the same work. Clearer ideas of imaginary quantities and the "irreducible case" were subsequently published by Bombelli, in a work of which the dedication is dated 1572, though the book was not published until 1579.

Contemporaneously with the remarkable discoveries of the Italian mathematicians, algebra was increasing in popularity in Germany, France and England. Michael Stifel and Johann Scheubelius (Scheibl) (1494-1570) flourished in Germany, and although unacquainted with the work of Cardan and Tartalea, their writings are noteworthy for their pungency and the introduction of complete symbolism for quantities and operations. Stifel introduced the sign (+) for addition or a positive quantity, which was previously denoted by plus, piu, or the letter p. Subtraction, previously written as minus, mene or the letter m, was symbolized by the sign (−) which is still in use. The square root he denoted by (v), whereas Paciolus, Cardan and others used the letter R.

The first treatise on algebra written in English was by Robert Recorde, who published his arithmetic in 1543, and his algebra entitled The Whetstone of Witte, which is the second part of Arithmetike de cionte, of the second book of the same. This work was written in the form of a dialogue, closely resembles the works of Stifel and Scheubelius, the latter of whom he often quotes. It includes the properties of numbers; extraction of roots of arithmetical and algebraical quantities, solutions of simple and quadratic equations, and a fairly complete account of surds. He introduced the sign (=) for equality, and the terms binomial and residual. Of other writers who published works about the end of the 16th century, we may mention Jacques Peletier, or Jacobus Peletarius (De occulta parte Numerorum, quam Algebra vocant, 1538); Petrus Ramus (Arithmeticæ Libri duo et totidem Algebrae, 1560), and Christoph Clavius, who wrote on algebra in 1580, though it was not published until 1608. At this time also flourished Simon Stevinus (Stevin) of Bruges, who published an arithmetic in 1585 and an algebra shortly afterwards. These works possess considerable originality, and contain many new improvements in algebraic notation; the unknown (res) is denoted by a small circle, in which he places an integer corresponding to the power. He introduced the terms multimonial, trinomial, quadrinomial, &c., and considerably simplified the notation for decimals.

About the beginning of the 17th century, two mathematical works by Francisca Vieta were published, which were afterwards collected by Franz van Schooten and republished in 1646 at Leiden. These works exhibit great originality and mark an important epoch in the history of algebra. Vieta, who does not avail himself of the discoveries of his predecessors—the negative roots of Cardan, the revised notation of Stifel and Stevin, &c.—introduced or popularized many new terms and symbols, some of which are still in use. He denotes quantities by the letters of the alphabet, retaining the vowels for the unknown and the consonants for the knowns; he introduced the vinculum and among others the terms coefficient, affirmative, negative, pure and affected equations. He improved the methods for solving equations, and devised geometrical constructions with the aid of the conic sections. His method for determining approximate values of the roots of equations is far in advance of the Hindu method as applied by Cardan, and is identical in principle with the methods of Sir Isaac Newton and W. G. Horner.

We have next to consider the works of Albert Girard, a Flemish mathematician. This writer, after having published an edition of Stevin's works in 1622, published in 1629 at Amsterdam, a small tract on algebra which shows a considerable advance on the work of Vieta. Girard is inconsistent in his notation, sometimes following Vieta, sometimes Stevin; he introduced the new symbols f for greater than and $\leq$ for less than; he follows Vieta in using the plus (+) for addition, he denotes subtraction by Recorde's symbol for equality (−), and he had no sign for equality but wrote the word out. He possessed clear ideas of indices and the generation of powers, of the negative roots of equations and their geometrical interpretation, and was the first to use the term imaginary roots. He also discovered how to sum the powers of the roots of an equation.

Passing over the invention of logarithms (q.v.) by John Napier, and their development by Henry Briggs and others, the next author of moment was an Englishman, Thomas Harriot, whose algebra (Artis analyticae praxis) was published posthumously by Walter Warner in 1631. Its great merit consists in the complete notation and symbolism, which avoided the cumbersome expressions of the earlier algebraists, and reduced the art to a form closely resembling that of to-day. He follows Vieta in assigning the vowels to the unknown quantities and the consonants to the known, but instead of using capitals, as with Vieta, he employs the small letters; equality he denotes by Recorde's symbol, and he introduced the signs > and < for greater than and less than. His principal discovery is concerned with equations, which he showed to be derived from the continued multiplication of as many simple factors as the highest power of the unknown, and he was thus enabled to deduce relations between the coefficients and various functions of the roots. Mention may also be made of his chapter on inequalities, in which he proves that the arithmetical mean is always greater than the geometrical mean.

Oughtred, a contemporary of Harriot, published an algebra, Clavis mathematicae, simultaneously with Harriot's treatise. His notation is based on that of Vieta, but he introduced the sign X for multiplication, : for continued proportion, : : for proportion, and denoted ratio by one dot. This last character has since been entirely restricted to multiplication, and ratio is now denoted by two dots (.). His symbols for greater than and less than (≠ and <) have been completely superseded by Harriot's signs.

So far the development of algebra and geometry had been mutually independent, except for a few isolated applications of geometrical constructions to the solution of algebraical problems. Certain minds had long suspected the advantages which would accrue from the unrestricted application of algebra to geometry, but it was not until the advent of the philosopher René Descartes that the co-ordination was effected. In his famous Geometria (1637), which is really a treatise on the algebraic representation of geometric theorems, he founded the modern theory of analytical geometry (see Geometry), and at the same time he rendered signal service to algebra, more especially in the theory of algebraical fractions. 

The mode of expressing the square root of a negative number has been much discussed: some have held that the square root of the negative unity is the same as the square root of the positive unity, but he differs from that writer in retaining the first letters of the alphabet for the known quantities and the final letters for the unknowns.

The 17th century is a famous epoch in the progress of science, and the mathematics in no way lagged behind. The discoveries of Johann Kepler and Bonaventura Cavalieri were the foundation upon which Sir Isaac Newton and Gottfried Wilhelm Leibnitz erected that wonderful edifice, the Infinitesimal Calculus (q.v.). Many new fields were opened up, but there was still continual progress in pure algebra. Continued fractions, one of the earliest examples of which is Lord Brouncker's expression for the ratio of the circumference to the diameter of a circle (see Circles), were elaborately discussed by John Wallis and Leonhard Euler; the convergence of series treated by Newton, Euler and the Bernoullis; the binomial theorem, due originally to Newton and subsequently expanded by Euler and others, was used by Joseph Louis Lagrange as the basis of his Calcul des Fonctions. Diophantine problems were revived by Gaspar Bachet, Pierre Fermat and Euler; the modern theory of numbers was founded by Fermat and developed by Euler, Lagrange and others; and the theory of probability was attacked by Blaise Pascal and Fermat, their work being subsequently expanded by James Bernoulli, Abraham de Moivre, Pierre Simon Laplace and others. The germs of the theory of determinants are to be found in the works of Leibnitz; Étienne Bézout utilized them in 1764 for expressing the result obtained by the process of elimination known by his name, and since restated by Arthur Cayley.

In recent times many mathematicians have formulated other kinds of algebras, in which the operators do not obey the laws of
ordinary algebra. This study was inaugurated by George Peacock, who was one of the earliest mathematicians to recognize the symbolic character of the fundamental principles of algebra. About the same time, D. F. Gregory published a paper on the real nature of symbolical algebra. In Germany the work of Karl Friedrich Gauss, and the formulation of various systems of vector analysis by Sir William Rowan Hamilton, Hermann Grassmann and others, followed. These algebras were essentially geometrical, and it remained, more or less, for the American mathematician Benjamin Peirce to devise systems of pure symbolic algebras; in this work he was ably seconded by his son Charles S. Peirce. In England, multiple algebra was developed by James Joseph Sylvester, who, in company with Arthur Cayley, expanded the theory of matrices, the germs of which are to be found in the writings of Hamilton (see above, under (B); and QUATERNIONS).

The preceding summary shows the specialized nature which algebra has assumed since the 17th century. To attempt a historical account of the development of the various theories of algebra in this article is inappropriate, and we refer the reader to the separate articles. References.—The history of algebra is treated in all historical works on mathematics in general (see MATHEMATICS: References). Greek algebra can be specially studied in T. L. Heath's Diophantus. See also John Wallis, Opera Mathematica (1653-1699), and Charles Hutton, Mathematical and Philosophical Dictionary (1815), article "Algebra." (C. E. *)

ALGEBRAIC FORMS. The subject-matter of algebraic forms is to a large extent connected with the linear transformation of algebraical polynomials which involve two or more variables. The theories of determinants and of symmetric functions and of the algebra of differential operations have an important bearing upon this comparatively new branch of mathematics. They are the chief instruments of research, and have themselves much benefited by being so employed. When a homogeneous polynomial is transformed by general linear substitutions as hereafter explained, and is then expressed in the original form with new coefficients affecting the new variables, certain functions of the new coefficients and variables are numerical multiples of the same functions of the original coefficients and variables. The investigation of the properties of these functions, as well for a single homogeneous set of forms, and as well for one as for many series of variables, is included in the theory of invariants. As far back as 1773 Joseph Louis Lagrange, and later Carl Friedrich Gauss, had met with simple cases of such functions, George Boole, in 1841 (Camb. Math. Journ. iii. pp. 1-20), made important steps, but it was not till 1845 that Arthur Cayley (Coll. Math. Papers, i. pp. 80-94, 95-112) showed by his calculus of hyper-determinants that an infinite series of such functions might be obtained systematically. The subject was carried on over a long series of years by himself, J. J. Sylvester, G. Salmon, L. O. Hesse, S. H. Aronhold, C. Hermite, Francesco Brioschi, R. F. A. Clebsch, P. Gordon, &c. The year 1868 saw a considerable enlargement of the field of operations. This arose from the study by Felix Klein and Sophus Lie of a new theory of groups of substitutions; it was shown that there exists an invariant theory connected with every group of linear substitutions. The invariant theory then existing was classified by them as appertaining to "finite continuous groups." Other "Galois" groups were defined whose substitution coefficients have fixed numerical values, and in particular the theory connected with the theory of equations. Arithmetical groups, connected with the theory of quadratic forms and other branches of the theory of numbers, which are termed "discontinuous," and infinite groups connected with differential forms and equations, came into existence, and also particular linear and higher transformations connected with analysis and geometry. The effect of this was to co-ordinate many branches of mathematics and greatly to increase the number of workers. The subject of transformation in general has been treated by Sophus Lie in the classical work Theorie der Transformationsgruppen. The present article is merely concerned with algebraical linear transformations. Two methods of treatment have been carried on in parallel lines, the unsymmetrical and the symbolic; both of these originated with Cayley, but he with Sylvester and the English school have in the main confined themselves to the former, whilst Aronhold, Clebsch, Gordan, and the continental schools have principally restricted themselves to the latter. The two methods have been conducted so as to be in constant touch, though the nature of the results obtained by the one differs much from those which flow naturally from the other. Each has been singularly successful in discovering new lines of advance and in encouraging the other to renewed efforts. P. Gordan first proved that for any system of forms there exists a finite number of covariants, in terms of which all others are expressible as rational and integral functions. This enabled David Hilbert to produce a very simple unsymmetrical proof of the same theorem. So the theory of the forms appertaining to a binary form of unrestricted order was first worked out by Cayley and P. A. MacMahon by unsymmetrical methods, and later G. E. Stroh, from a knowledge of the results, was able to verify and extend the results by the symbolic method. The partition method of treating symmetrical algebra is one which has become singularly successful in indicating new paths of advance in the theory of invariants; the important theorem of expressibility is, directly we exclude unity from the partitions, a theorem concerning the expressibility of covariants, and involves the theory of the reducible forms and of the syzygies. The theory brought forward has not yet found a place in any systematic treatise in any language, so that it has been judged proper to give a fairly complete account of it.

I. THE THEORY OF DETERMINANTS. Let there be given \(n^2\) quantities

\[
\begin{align*}
& a_1, a_2, a_3, \ldots, a_n \ 
& a_{11}, a_{12}, a_{13}, \ldots, a_{1n} 
& a_{21}, a_{22}, a_{23}, \ldots, a_{2n} 
& \vdots \quad \vdots \quad \vdots \quad \vdots 
& a_{n1}, a_{n2}, a_{n3}, \ldots, a_{nn}
\end{align*}
\]

and form from them a product of \(n\) quantities

\[
\prod_{k=1}^{n} \prod_{\ell=1}^{k} a_{\ell k}
\]

where the first suffixes are the natural numbers 1, 2, 3, \ldots, \(n\) taken in order, and \(a, b, \gamma, \ldots\) is some permutation of these \(n\) numbers. This permutation by a transposition of two numbers, say \(a, b\) is called singular if \(a, b, \gamma, \ldots\) is the same as \(b, a, \gamma, \ldots\); that is to say, if the permutation can be reduced to the form 1, 2, 3, \ldots, \(n\). Let \(k\) such transpositions be necessary; then the expression

\[
\left(\prod_{k=1}^{n} \prod_{\ell=1}^{k} a_{\ell k}\right) \prod_{p=1}^{k} (-1)^{p} a_{p 1} a_{p 2} \ldots a_{p n}
\]

the sum being first taken over all permutations of the \(n\) numbers, is called the determinant of the \(n^2\) quantities. The quantities \(a_{11}, a_{22}, \ldots, a_{nn}\) are called the elements of the determinant; the term \((-1)^{p} a_{p 1} a_{p 2} \ldots a_{p n}\) is called a member of the determinant, and there are evidently \(n!\) members corresponding to the \(n!\) permutations of the \(n\) numbers 1, 2, 3, \ldots, \(n\) and the determinant is usually written

\[
\begin{vmatrix}
& a_1 & a_2 & \ldots & a_n \\
& a_{11} & a_{12} & \ldots & a_{1n} \\
& a_{21} & a_{22} & \ldots & a_{2n} \\
& \vdots & \vdots & \ddots & \vdots \\
& a_{n1} & a_{n2} & \ldots & a_{nn}
\end{vmatrix}
\]

the square array being regarded the matrix of the determinant. A matrix has in many parts of mathematics a significance apart from its evaluation as a determinant. A theory of matrices has been constructed by Cayley in connexion particularly with the theory of linear transformation. The matrix consists of \(n\) rows and \(n\) columns. Each row as well as each column supplies one and only one element to each member of the determinant. Consideration of the definition of the determinant shows that the value is unaltered when the suffixes in each element are transposed. Theorem.—If the determinant is transformed so as to read by columns as it formerly did by rows its value is unchanged. The leading number of the determinant is \(a_{11} a_{22} \ldots a_{nn}\), and corresponds to the principal diagonal of the matrix.

We write frequently

\[
\Delta = \sum_{i=1}^{n} a_{1i} j_{1i} = \sum_{j=1}^{n} a_{j1} i_{1j} = a_{11} a_{22} \ldots a_{nn}
\]

If the first two columns of the determinant be transposed the

The elementary theory is given in the article DETERMINANT.
expression for the determinant becomes \( \Sigma (-) a_\alpha B_\beta a_{\beta+1} ... a_{\alpha+n}, \) viz. 
\( a \) and \( \beta \) are transposed, and it is clear that the number of transpositions necessary to convert the permutation \( a_{\alpha+1} ... a_{\alpha+n} \) to the natural order is decreased by one. Hence the transposition of columns merely changes the sign of the determinant. Similarly it is shown that the transposition of any two rows or of any two columns merely changes the sign of the determinant.

**Theorem.—**Interchange of any two rows or of any two columns merely changes the sign of the determinant.

**Corollary.—**If any two rows or any two columns of a determinant be identical, the determinant is zero.

**Minors of a Determinant.**—From the value of \( \Delta \) we may separate those members which contain a particular element \( a_\alpha \) as a factor, and we have the portion \( a_\alpha A_\alpha A_\alpha \); the cofactor of \( a_\alpha \) is called the minor of order \( \alpha \) of the determinant.

Now \( a_1 A_1 = a_1 a_2 a_3 a_4 a_5 a_6 \), wherein \( a_1 \) is not to be changed, but the second sufixes in the product \( a_2 a_3 a_4 a_5 a_6 \) assume all permutations, the number of transpositions necessary determining the sign to be afixed to the member.

Hence \( a_1 A_1 = a_1 a_2 a_3 a_4 a_5 a_6 \), where the cofactor of \( a_1 \) is clearly the determinant obtained by erasing the first row and the first column.

Hence \( A_1 = a_1 a_2 a_3 a_4 a_5 a_6 \), proceeding according to the elements of the first row and the corresponding minors.

Similarly we have a development proceeding according to the elements contained in the \( k^{\text{th}} \) row and the \( k^{\text{th}} \) column. No member of a determinant can involve more than one element from one row. Hence we have the development

\[
\Delta = a_1 A_1 + a_2 A_2 + a_3 A_3 + a_4 A_4 + a_5 A_5 + a_6 A_6
\]

This theory enables the evaluation of a determinant by successive reduction of the orders of the determinants involved.

**Example.**

\[
\begin{pmatrix}
1 & 0 & 3 \\
0 & 5 & 3 \\
1 & 3 & 6
\end{pmatrix}
\]

The determinant vanishes identically; we have by development according to the elements of the first row

\[
a_1 A_1 + a_2 A_2 + a_3 A_3 + a_4 A_4 = 0
\]

and, in general, since

\[
a_1 a_1 + a_2 a_2 + a_3 a_3 + a_4 a_4 = \Delta
\]

if we suppose the \( k^{\text{th}} \) and \( k^{\text{th}} \) rows identical,

\[
a_1 A_1 + a_2 A_2 + a_3 A_3 + a_4 A_4 = 0
\]

and proceeding by columns instead of rows,

\[
a_1 A_1 + a_2 A_2 + a_3 A_3 + a_4 A_4 = 0
\]

identical relations always satisfied by these minors.

If in the first relation of (A) we write \( a_1 = b_1 + c_1 + d_1 + ... \) we find that \( \Sigma A_1 b_1 + \Sigma A_2 c_1 + \Sigma A_3 d_1 + ... \), so that it breaks up into a sum of determinants, and we also obtain a theorem for the addition of determinants which have \( n - 1 \) rows in common. If we multiply the elements of the second row by an arbitrary magnitude \( k \), and add to the corresponding elements of the first row, \( \Delta \) becomes \( \Sigma A_1 b_1 + \Sigma A_2 c_1 + \Sigma A_3 d_1 + ... \) showing that the value of the determinant is unchanged. In general we can prove in the same way that

**Theorem.**—The value of a determinant is unchanged if we add to the elements of any row or column the corresponding elements of the other rows or other columns respectively each multiplied by an arbitrary magnitude, such magnitude remaining constant in respect of the elements in a particular row or a particular column.

**Observation.**—Every factor common to all the elements of a row or of a column is obviously a factor of the determinant, and may be taken outside the determinant.

\[
\begin{pmatrix}
1 & a & a^2 \\
1 & b & b^2 \\
1 & c & c^2
\end{pmatrix}
\]

The minor \( A_1 \) is \( a \Delta a_{\alpha+1} \) and is itself a determinant of order \( n - 1 \).

The product of any two rows or of any two columns will be obtained by detaching the minor of a determinant is a minor also of \( \Delta \) of order \( n - 2 \). It will be \( A_1 A_2 = a_1 a_2 a_3 a_4 a_5 a_6 \), and will be obtained by detaching the elements \( A_1 a_2 \) and \( A_2 a_2 \) and the columns containing the elements \( A_1 a_2 \) this was originally the second row and the \( a^{\text{th}} \) column of \( \Delta \); the \( a^{\text{th}} \) row of \( \Delta \) is the \( a^{\text{th}} \) row of \( A_2 a_2 \) according to \( \Sigma a_2 \) and the \( a^{\text{th}} \) column of \( \Delta \) is the \( a^{\text{th}} \) row of \( A_2 a_2 \) according to \( k_{\alpha} \). Hence, if we denote the number of transpositions necessary to bring the succession \( r^s \) into ascending order of magnitude, the sign to be attached to the determinant arrived at by erasing the \( a^{\text{th}} \) row and \( a^{\text{th}} \) column from \( \Delta \) in order produce \( A_3 a_3 \) to be added to the power of \( T_1 \). Similarly proceeding to the minors of order \( n - 3 \), we find that

\[
A_4 = \begin{pmatrix}
a_1 \end{pmatrix}
\]

where the determinant factor is given by the four points in which the deleting lines intersect. This determinant and that associated with \( A_2 \) are termed corresponding determinants. Similarly \( \rho \) lines of deletion intersecting in \( \rho \) points yield corresponding determinants of \( \rho \) and \( \rho \) respectively. Recalling the formula

\[
\Delta = a_1 A_1 + a_2 A_2 + a_3 A_3 + ... + a_n A_n
\]

it will be seen that if \( A_k \) of the constant of \( A_1 \) involving corresponding determinants. Since \( A_1 \) is a determinant we similarly obtain

\[
A_k = a_1 A_1 + a_2 A_2 + a_3 A_3 + ... + a_k A_k + a_{k+1} A_{k+1} + a_{k+2} A_{k+2} + ... + a_n A_n
\]

and hence

\[
\Delta = \Sigma a_i A_i
\]

where \( i \geq k \), and as before

\[
\Delta = a_1 A_1 + a_2 A_2 + a_3 A_3 + ... + a_k A_k
\]

an important expansion of \( \Delta \).

Similarly

\[
\Delta = \Sigma a_i A_i
\]

and the general theorem is manifest, and yields a development in a sum of products of corresponding determinants. If the \( k^{\text{th}} \) column be identical with the \( k^{\text{th}} \) the determinant \( \Delta \) vanishes identically; hence if \( j \) be not equal to \( i \), \( h \) or \( r \),

\[
0 = \Delta
\]

Similarly, by putting one or more of the deleted rows or columns equal to rows or columns which are not deleted, we obtain, with Laplace, a number of identities between products of determinants of complementary orders.

**Multiplication.**—From the theorem given above for the expansion of a determinant as a sum of products of pairs of corresponding determinants it will be plain that the product of \( \Delta = (a_1 a_2, a_{12}) \) and \( D = (b_1 b_2, b_{12}) \) may be written as a determinant of order \( 2n \), viz.

\[
\begin{pmatrix}
1 & a_1 & a_2 & a_{12} & 1 \\
0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0
\end{pmatrix}
\]

Multiply the 1st, 2nd, ... \( n^{\text{th}} \) rows by \( b_1 b_2 b_3 b_4 b_5 b_6 b_7 b_8 \) respectively, and
add to the $(n+1)^{th}$ row by $b_1, b_2, \ldots, b_n$, and add to the $(n+2)^{th}$ row by $b_n, b_{n-1}, \ldots, b_1$, and add to the $(n+3)^{th}$ row, &c. Then becomes
\[\begin{align*}
a_1b_1 + a_1b_2 + \cdots + a_1b_n &+ a_2b_1 + a_2b_2 + \cdots + a_2b_n + \cdots + a_nb_1 + a_nb_2 + \cdots + a_nb_n \\
a_1b_1 + a_1b_2 + \cdots + a_1b_n &+ a_2b_1 + a_2b_2 + \cdots + a_2b_n + \cdots + a_nb_1 + a_nb_2 + \cdots + a_nb_n \\
&\vdots \\
a_1b_1 + a_1b_2 + \cdots + a_1b_n &+ a_2b_1 + a_2b_2 + \cdots + a_2b_n + \cdots + a_nb_1 + a_nb_2 + \cdots + a_nb_n
\end{align*}\]
and all the elements of $D$ become zero. Now by the expansion theorem the determinant becomes
\[\det A = (-1)^{n+1} \det C = (-1)^{2n+1} \det C = -\det C.
\]
We thus obtain for the product a determinant of order $n$. We may say that, in the resulting determinant, the element in the $i^{th}$ row and $k^{th}$ column is obtained by multiplying the elements in the $k^{th}$ row of the first determinant severally by the elements in the $i^{th}$ row of the second, and has the expression
\[a_{i1}b_1 + a_{i2}b_2 + \cdots + a_{in}b_n.
\]
and we obtain other expressions by transforming either or both determinants so as to read by columns as they formerly did by rows.

Remark.—In particular the square of a determinant is a determinant of the same order $(a_{ij}a_{kl})$, such that $b_i = b_j$; it is for this reason termed symmetrical.

The Adjoint or Reciprocal Determinant arises from $\Delta = (a_{ij}a_{kl})$, by substituting for each element $a_{ij}$ the corresponding minor $A_{ij}$ so as to form $D = (A_{ij}A_{kl}) \cdots A_{ij})$. If we form the product $\Delta D$ by the theorem for the multiplication of determinants we find that the element in the $i^{th}$ row and $j^{th}$ column of the product is
\[\det A_{i1} + \det A_{i2} + \cdots + \det A_{in},
\]
the value of which is zero when $k = i$, and $\Delta$ when $k = j$. Hence the product determinant has the principal diagonal elements each equal to $\Delta$ and the remaining elements zero. Its value is therefore $\Delta^2$ and we have the identity
\[D = \Delta \Delta D = \det A.
\]
It can now be proved that the first minor of the adjoint determinant, say $B_{i1}$, is equal to $\Delta^2$. Hence the expressions for the first, second and third systems of elements  
\[B_{i1} = \Delta^2 \Omega_{i1},
\]
In general it can be proved that any minor of order $p$ of the adjoint is equal to the complementary of the corresponding minor of the original multiplied by the $(p-1)^{th}$ power of the original determinant.

Theorem.—The adjoint determinant is the $(n-1)^{th}$ power of the original determinant. The adjoint determinant will be seen subsequently to present itself in the theory of linear equations and in the theory of linear transformation.

Determinants of Special Forms.—It was observed above that the square of a determinant when expressed as a determinant of the same order is such that its elements have the property expressed by $a_{ij} = a_{ij}$. Such determinants are called symmetrical. A determinant is also symmetrical, viz, such that $A_{ij} = A_{ji}$, for the determinant got by suppressing the $i^{th}$ row and $k^{th}$ column differs only by an interchange of rows and columns from that got by suppressing the $k^{th}$ row and $i^{th}$ column. If any symmetrical determinant vanish and be bordered as shown below
\[\begin{vmatrix}
a_{11} & a_{12} & a_{13} & \cdots & a_{1n} \\
a_{21} & a_{22} & a_{23} & \cdots & a_{2n} \\
0 & 0 & 0 & \cdots & 0 \\
0 & 0 & 0 & \cdots & 0 \\
0 & 0 & 0 & \cdots & 0 \\
\end{vmatrix}
\]
It is a perfect square when considered as a function of $\lambda_1$, $\lambda_2$, $\lambda_3$. For since $A_{11}A_{22} - A_{12}A_{21} = A_{11}A_{22}$ we have a number of relations similar to $A_{11}A_{22} = A_{12}A_{21}$, and either $A_{11} = + \sqrt{A_{11}A_{22}}$ or $- \sqrt{A_{11}A_{22}}$ for all different values of $r$ and $s$. Now the determinant has the value
\[\det A = \det A + \det A = \det A + 2\sqrt{A_{11}A_{22}} + 2\sqrt{A_{11}A_{22}}
\]
and the problem is to express the coefficients of $\Delta$ in terms of three independent quantities.

In general in space of $n$ dimensions we have $n$ substitutions similar to
\[x_1 = a_{11}x + a_{12}y + \cdots + a_{1n}z,
\]
and we have to express the $n\theta$ coefficients in terms of $\Delta(n-1)$ independent quantities, which must be possible, because
\[X^2 + X^1 + \cdots + X^1 + X^1 + \cdots + \cdots + X^1
\]
where $b_i = b_i$ for all values of $r$ and $s$. There are then $n(n-1)$ quantities $b_i$. Let the determinant of the $b$ be $A_b$ and $B_b$, the minor corresponding to $b_i$. We can eliminate the quantities $b_i$, $b_{i+1}$, $\ldots$, and obtain $n$ relations
\[\Delta X_i = (2b_1 - \Delta) \Delta x + 2b_2 X_1 + 2b_3 X_2 + \cdots
\]
and from these another equivalent set
\[\Delta x_1 = (2b_1 - \Delta) x + 2b_2 X_1 + 2b_3 X_2 + \cdots
\]
and now writing
\[2b_1 - \Delta = a_{11} = a_{11} = a_{11},
\]
we have a transformation which is orthogonal, because $\Sigma X = x^2$ and the elements $a_{11}, a_{11}$ are functions of the $n(n-1)$ independent quantities $b$. We may therefore form an orthogonal transformation in association with the leading diagonal elements, for the $n(n-1)$ quantities $b$ are clearly arbitrary.

For the second order we may take
\[\Delta = \begin{vmatrix} -1 & 1 \\ 1 & -1 \end{vmatrix} = 1 + \lambda^2,
\]
and the adjoint determinant is the same; hence
\[(1 + \lambda^2) \Delta = (1 - \lambda^2) \Delta = 2 \Delta x^1 + (1 - \lambda^2) \Delta x^1.
\]
Similarly, for the $3^{rd}$ order, we take
\[\Delta = \begin{vmatrix} -1 & 1 & 1 \\ 1 & -1 & 1 \\ 1 & 1 & -1 \end{vmatrix} = 1 + \lambda^3 + \mu^3 + \nu^3,
\]
and the adjoint is
\[\Delta = \begin{vmatrix} 1 & \nu & -\lambda \\ \lambda & 1 & -\mu \\ \mu & \lambda & 1 \end{vmatrix} = 1 + \lambda^3 + \mu^3 + \nu^3,
\]
leading to the orthogonal substitution
\[\Delta x_1 = (1 - \lambda^2) \Delta x^1 + 2(\mu \lambda - \nu) \Delta x^2,
\]
\[\Delta x_2 = (1 - \lambda^2) \Delta x^2 + 2(\nu \lambda - \mu) \Delta x^3
\]
\[\Delta x_3 = (1 - \lambda^2) \Delta x^3 + 2(\mu \lambda - \nu) \Delta x^1,
\]
Functional determinants were first investigated by Jacobi in a work De Determinantibus Functionalibus. Suppose $n$ independent variables $y_1, y_2, \ldots, y_n$, each of which is a function of $n$ independent variables $z_1, z_2, \ldots, z_n$. From the differential coefficients of the $y$'s with regard to the $x$'s we form the functional determinant

Resultants.
When we are given k homogeneous equations in k
i variables, the
variables or k non-homogeneous equations in k
equations being independent, it is always possible to derive from
them a single equation R = o, where in R the variables do not
"
reappear. " R is" a function "of the coefficients which is called the
sultant
or
eliminant
of the k equations, and the process by
"
which it is obtained is termed elimination." We cannot combine
the equations so as to eliminate the variables unless on the supposition that the equations are simultaneous, i.e. each of them satisfied
by a common system of values; hence the equation R = o is derived
on this supposition, and the vanishing of R expresses the condition
that the equations can be satisfied by a common system of values
assigned to the variables.

and by elimination we obtain the resultant

which reads by columns as the former determinant reads by rows, and is therefore identical with the former. E. Bézout's method gives the resultant in the form of a determinant of order \(m n\) or \(n\), according as \(m \geq n\). As modified by Cayley it takes a very simple form. He forms the equation

which can be satisfied when \(f\) and \(\phi\) possess a common factor. He first divides \(f\) by \(\phi\) and then, reducing it to the degree \(m - 1\) in both \(x\) and \(x'\), he then forms \(m\) equations by equating to zero the coefficients of the various powers of \(x\); these equations involve the powers \(x, x', x^2, x'^2, \ldots\) of \(x\) and regarding these as the unknown coefficients, the resultant is reached in the form of a determinant of order \(m + n\). Ex. gr. Put

\[
\begin{vmatrix}
 x^4 + ax^3 + bx^2 + cx + d & 0 \\
 0 & x^4 + ax^3 + bx^2 + cx + d
\end{vmatrix} = 0;
\]

dividation by \(x - x'\) the three equations are formed

and hence the resultant

which is a symmetric determinant.

Case of Three Variables.—In the next place we consider the results of three homogeneous polynomials in three variables. We can prove that if the three equations be satisfied by a system of values of \(x\) and \(x'\), the same system will also satisfy the Jacobian or functional determinant. For if \(u, v, w\) be the polynomials of order \(m, n, p\) respectively, the Jacobian is \((u, v, w)\), and by Euler's theorem of homogeneous functions

we have, by differentiating

or

Hence the resultant of all values also causes \(\frac{\partial J}{\partial x'}\) to vanish in this case; and by symmetry \(\frac{\partial J}{\partial x}, \frac{\partial J}{\partial y}, \frac{\partial J}{\partial z}\) all vanish.

The proof being of general application we may state that a system of values which causes the vanishing of \(k\) polynomials in \(k\) variables causes the vanishing of the Jacobian determinant and in particular when the forms are of the same degree, the vanishing also of the differential coefficients of the Jacobian in regard to each of the variables.

There is no occasion here in discussing the resultant by the method of symmetric functions. Taking two of the equations

we find that, eliminating \(x\), the resultant is a homogeneous function of \(y\) and \(z\) of degree \(k\); substituting this to zero and solving for the ratio of \(y \) to \(z\) we obtain \(m n\) solutions, but if it involves \(y\) and \(z\), given by any solution, be substituted in each of the two equations, they will possess a common factor which gives a value of \(x\) which, com-
II. The Theory of Symmetric Functions

Consider $n$ quantities $a_1, a_2, a_3, \ldots, a_n$. Every rational integral function of these quantities, which does not alter its value however the $n$ suffixes $1, 2, 3, \ldots, n$ be permuted, is a rational integral symmetric function of the quantities. If we write a product which is separated $(1 + a_1 a_2 a_3 \cdots + a_{n-1} a_n + a_1 + a_2 + a_3 + \cdots + a_{n-1} a_n)$, $a_1, a_2, \ldots, a_n$ are called the elementary symmetric functions.

The general monomial symmetric function is

$$\sum_{\sigma} \mu_1^{a_{\sigma(1)}} \mu_2^{a_{\sigma(2)}} \cdots \mu_n^{a_{\sigma(n)}}$$

the summation being for all permutations of the indices which result in different terms. The function is written $(n, \mu_1, \mu_2, \ldots, \mu_n)$. For brevity, and repetitions of numbers in the bracket are indicated by exponents, so that $(\mu_1 \mu_2 \mu_3)$ is written $(\mu_1^3 \mu_2^2 \mu_3)$. The weight of the function is the sum of the numbers in the bracket, and the degree the highest of those numbers.

Ex. gr. The elementary functions are denoted by $(1), (1^2), (1^3), \ldots$, and are all of the first degree, and are of weights $1, 2, 3, \ldots$ respectively.

Remark. In this notation $(0) = \sum_{\sigma} \mu_1^{a_{\sigma(1)}} \mu_2^{a_{\sigma(2)}} \cdots \mu_n^{a_{\sigma(n)}} = (\mu_1^a \mu_2^{a-1} \mu_3^{a-2} \cdots)$, and $(n, \mu_1^{a_1} \mu_2^{a_2} \cdots \mu_n^{a_n})$ is simply $(n^{a_1} a_2^{a_2} \cdots n^{a_n})$. The binomial coefficients appear, in fact, as symmetric functions, and this is frequently of importance.

The order of the numbers in the bracket $(\mu_1, \mu_2, \ldots, \mu_n)$ is immaterial; we may therefore always place them, as is most convenient, in descending order of magnitude; the numbers then constitute an ordered partition of the weight $w$, and the leading number denotes the degree.

The sum of the monomial functions of a given weight is called the homogeneous-product-sum or complete symmetric function of that weight; it is denoted by $h_n$; it is connected with the elementary functions by the formula

$$\sum_{\sigma} \mu_1^{a_{\sigma(1)}} \mu_2^{a_{\sigma(2)}} \cdots \mu_n^{a_{\sigma(n)}} = 1 + h_1 + h_2 + h_3 + \cdots$$

which remains true when the symbols $a$ and $h$ are interchanged, as is obvious at once by writing $-x$ for $x$. This proves, also, that in any formula connecting $a_1, a_2, \ldots, a_n$ with $h_1, h_2, \ldots, h_n$, the symbols $a$ and $h$ may be interchanged.

Ex. gr. from $h_n = a_1! - a_2$ we derive $a = h - e$.

The function $\Sigma_{\tau} \mu_1^{b_{\tau(1)}} \mu_2^{b_{\tau(2)}} \cdots \mu_n^{b_{\tau(n)}}$ being as above denoted by a partition of the weight, viz. $(\mu_1 \mu_2 \cdots \mu_n)$, it is necessary to bring under view other functions associated with the same series of numbers; such, for example, as

$$\sum_{\tau} \mu_1^{b_{\tau(1)}} \mu_2^{b_{\tau(2)}} \cdots \mu_n^{b_{\tau(n)}} = (\mu_1^{b_{\tau(1)}} \mu_2^{b_{\tau(2)}} \cdots \mu_n^{b_{\tau(n)}})$$

The expression just written is in fact a partition of a partion, and to avoid confusion of language will be termed a separation of a partition. A partition is separated into separations so as to produce a separation of the partition by writing down a set of partitions, each separate partition in its own brackets, so that when all the parts of these partitions are reassembled in a single bracket the ordered partition is separated. It is convenient to write the distinct partitions or separations in descending order as regards weight. If the successive weights of the separations $w_1, w_2, w_3, \ldots$ be enclosed in a bracket we obtain a partition of the weight $w$ which appertains to the separated partition. This partition is termed the specification of the separation. The degree of the separation is the sum of the degrees of the component separations. A separation is the symbolic representation of a product of monomial symmetric functions. A partition $(\mu_1 \mu_2 \cdots \mu_n)$ can be separated in the manner $(\mu_1 \mu_2 \cdots \mu_n) = (\mu_1 \mu_2 \cdots \mu_n)$, and we may take the general form of a partition to be $(\mu_1 \mu_2 \cdots \mu_n)$ and that of a separation $(J) = (J) = (J) = (J)$ when $J_1, J_2, J_3, \ldots$ denote the distinct separations involved.

Theorem. The function symbolized by $(n)$, viz. the sum of the $n^{th}$ powers of the quantities, is expressible in terms of functions which are symbolized by separations of any partition $(n^1 n^2 n^3 \cdots)$ of the number $n$. The expression is

$$(-1)^{n-1} n^{(n)} = \sum_{\tau} (-1)^{n-1} \mu_1^{b_{\tau(1)}} \mu_2^{b_{\tau(2)}} \cdots \mu_n^{b_{\tau(n)}}$$

$(J) = (J) = (J) = (J)$ being a separation of $(n^1 n^2 n^3 \cdots)$ and the summation being in regard to all such separations. For the particular case

$$(-1)^{n-1} (n) = \sum_{\tau} (-1)^{n-1} \mu_1^{b_{\tau(1)}} \mu_2^{b_{\tau(2)}} \cdots \mu_n^{b_{\tau(n)}}$$

the product on the right involving a factor for each of the quantities $a_1, a_2, \ldots, a_n$ and $\mu$ being arbitrary.

Multiplying out the right-hand side and comparing coefficients, we have

$$X_1 = (1),$$
$$X_2 = (2^1),$$
$$X_3 = (3^1 + 2^2),$$
$$X_4 = (4^1 + 3^2 + 2^3 + 1^4),$$
$$X_5 = (5^1 + 4^2 + 3^3 + 2^4 + 1^5),$$

the summation being for all partitions of $m$. (continued...
The Differential Operators.—Starting with the relation

$$(1 + a_i t)(1 + a_2 t)...(1 + a_n t) = 1 + a_1 t + a_2 t^2 + ... + a_n t^n$$

multiply each side by $1 + \mu t$, thus introducing a new quantity $\mu$;

so that if $f(a_1, a_2, ... , a_n) = f$, a rational integral function of the elementary functions, is converted into

$$f(t, \mu t, \mu a_1, \... , \mu a_n) = f + \mu d_1 f + \mu^2 d_2 f + \...$$

where

$$d_1 = \frac{\partial f}{\partial t}, \quad d_2 = \frac{\partial^2 f}{\partial t^2}, \quad \...$$

and $d_i$ denotes, not $s$ successive operations of $d_1$, but the operator of order $s$ obtained by raising $d_1$ to the $s$th power symbolically as in Taylor's theorem in the Differential Calculus.

Write also $1 + \frac{t}{\sqrt{3}} = D$, so that

$$f(a_1 + \mu, a_2 + \mu, ... , a_n + \mu) = f + \mu d_1 f + \mu^2 d_2 f + ...$$

The introduction of the quantity $\mu$ converts the symmetric function $(\lambda_1 \lambda_2 ... \lambda_n)$ into

$$(\lambda_1 \lambda_2 ... \lambda_n) = \mu^1 (\lambda_1 \lambda_2 ... \lambda_n) + \mu^2 (\lambda_2 \lambda_3 ... \lambda_n) + \mu^3 (\lambda_3 \lambda_4 ... \lambda_n) + ...$$

Hence, if $f(a_1, a_2, ... , a_n) = (\lambda_1 \lambda_2 ... \lambda_n)$,

$$(\lambda_1 \lambda_2 ... \lambda_n) + \mu^1 (\lambda_2 \lambda_3 ... \lambda_n) + \mu^2 (\lambda_3 \lambda_4 ... \lambda_n) + ... = (1 + \mu^1 + \mu^2 + \mu^3 + ... ) (\lambda_1 \lambda_2 ... \lambda_n)$$

Comparing coefficients of like powers of $\mu$ we obtain

$$D\lambda_1 (\lambda_2 \lambda_3 ... \lambda_n) = (\lambda_2 \lambda_3 ... \lambda_n)$$

while $D_1 (\lambda_2 \lambda_3 ... \lambda_n) = 0$ unless the partition $(\lambda_2 \lambda_3 ... \lambda_n)$ contains a part $s$. Further, if $D_1 ... D_{s-1}$ denote successive operations of $D_1$ and $D_{s-1}$,

$$D_1 ... D_{s-1} (\lambda_2 \lambda_3 ... \lambda_n) = (\lambda_s ... \lambda_n)$$

and the operations are evidently commutative.

Also $D_1^e D_2^e D_3^e ... (p_1^e p_2^e ...)$ is $1$, and the law of operation of the operators $D$ upon a monomial symmetric function is clear.

We have obtained the equivalent operations

$$(a^1 + \mu^1 a^2 + \mu^2 a^3 + ...$ = $\exp \mu d_1$$

where $\exp$ denotes (by the rule over $\exp$) that the multiplication of operators is symbolic as in Taylor's theorem. $d_i$ denotes, in fact, an operator of order $s$, but we may transform the right-hand side so that we are only concerned with the successive performance of linear operations. For this purpose write

$$a_0 = a_0 + a_1 + a_2 + ...$$

It has been shown (vide "Memoir on Symmetric Functions of the Roots of Systems of Equations," Phil. Trans. 1890, p. 490) that

$$\exp (\lambda^1 ... \lambda^i ... ... + \lambda^s ... ) = \exp (\lambda^1 ... \lambda^i ... ... + \lambda^s ... )$$

the multiplication on the respective operators, provided that

$$\exp (\lambda_1^1 ... \lambda_1^i ... ... + \lambda_1^s ... ) = 1 + \lambda_1^1 ... \lambda_1^i ... ... + \lambda_1^s ... ,$$

$q$ being an undetermined algebraic quantity.

Hence we derive the particular cases

$$\exp \mu d_i = \exp (\mu d_i + \lambda_1^1 ... \lambda_1^i ... ... + \lambda_1^s ... )$$

and we can express $D_i$ in terms of $d_i$, $d_2$, $...$, products denoting successive operations, by the same law which expresses the elementary function $a_i$ in terms of the sums of powers $s_i$, $s_2$, $...$. Further, we can express $D_i$ in terms of $D_1$, $D_2$, $...$, by the same law which expresses the power function $s_i$ in terms of the elementary functions $s_1$, $s_2$, $...$,

Operation of $D_i$ upon a Product of Symmetric Functions.—Suppose $f$ to be a product of symmetric functions $\phi_{s_1} ... \phi_{s_m}$. If in the identity

$$f = \phi_{s_1} ... \phi_{s_m}$$

we introduce a new root $a$ we change $a$ into $a + \mu a$, and we obtain

$$(1 + a_1 t + a_2 t^2 + ... + a_n t^n)$$

and now expanding and equating coefficients of like powers of $\mu$

$$D_1 f = \sum (D_1 \phi_{s_1}) ... \phi_{s_m} + \sum (D_2 \phi_{s_1}) ... \phi_{s_m} + ...$$

and

$$D_2 f = \sum (D_2 \phi_{s_1}) ... \phi_{s_m} + \sum (D_3 \phi_{s_1}) ... \phi_{s_m} + ...$$

the summation in a term covering every distribution of the operators of the type presenting itself in the term.

Writing these results

$$D_1 f = D_0 f,$$

$$D_2 f = D_0 f + D_1 f,$$

$$D_3 f = D_0 f + D_1 f + D_2 f,$$

and
we may write in general
\[ D_f = 2D(p_1p_2p_3\ldots) f, \]
the summation being for every partition \( p_1p_2p_3\ldots \) of \( s \), and
\[ D_{(p_1p_2p_3\ldots)} f = \{ (D_f)_{p_1} \} \{ (D_f)_{p_2} \} \{ (D_f)_{p_3} \} \ldots f. \]

Ex. gr. To operate with \( D_0 \) upon \( (219) \), we have
\[ D_{(219)} f = (219)(1) + (219)(1), \]
and hence

\[ Application to Symmetric Function Multiplication. \]
An example will explain this. Suppose we wish to find the coefficient of \( (231) \) in the product \( (21)(21)(3). \)
Write
\[ (21)(21)(1^3) = \ldots + A(222)(1) + \ldots; \]
then
\[ D_2 D_3 (21)(21)(1^3) = A; \]
every other term disappearing by the fundamental property of \( D_r \). Since
\[ D_2 (21)(21)(1^3) = (21^2)(1^3), \]
we have:
\[ D_2 D_3 (21)(21)(1^3) = A; \]
and since
\[ D_2 D_3 (21)(21)(1^3) = A, \]
we obtain the following equation
\[ \lambda_1 \lambda_2 \lambda_3 + \lambda_1 \lambda_1 \lambda_2 + \lambda_1 \lambda_1 \lambda_2 = 0. \]

Further, let
\[ 1 + b_1x + b_2x^2 + b_3x^3 + \ldots + b_mx^m = (1 + a_1x)(1 + a_2x)(1 + a_3x)(1 + a_mx); \]
so that
\[ 1 + a_1x + a_2x^2 + a_3x^3 + \ldots + a_mx^m = e^{a_1x}; \]
and
\[ 1 + a_1x + a_2x^2 + \ldots + a_mx^m = e^{a_1x}; \]
and, by multiplication,
\[ \Pi (1 + a_1x + a_2x^2 + \ldots) = \Pi (1 + b_1x + b_2x^2 + \ldots + b_mx^m) \]
\[ = e^{a_1x+a_2x^2+a_3x^3+\ldots+amxm}. \]

Denote by brackets \( (\ldots) \) and \( [\ldots] \) symmetric functions of the quantities \( a_1, a_2, \ldots, a_m \) respectively. Then
\[ (a_1 + a_2 + a_3 + \ldots) = (1 + a_1x)(1 + a_2x)(1 + a_3x)(1 + a_mx); \]
and, by multiplication,
\[ \Pi (1 + a_1x + a_2x^2 + \ldots) = \Pi (1 + b_1x + b_2x^2 + \ldots + b_mx^m) \]
\[ = e^{a_1x+a_2x^2+a_3x^3+\ldots+amxm}. \]

Expanding the right-hand side by the exponential theorem, and then expressing the symmetric functions of the \( a_i, a_2, \ldots, a_m \) which arise, in terms of the \( b_1, b_2, \ldots, b_m \), we obtain by comparison with the middle series the symbolic representation of all symmetric functions in brackets \( (\ldots) \) appertaining to the quantities \( a_1, a_2, \ldots, a_m \). To obtain particular theorems the quantities \( a_1, a_2, a_3, \ldots \) are auxiliaries which are at our entire disposal. Thus to obtain Stroh's theorem of seminvarianten put

\[ b_1 = a_1 + a_2 + \ldots + a_m = 1 + 0; \]
we then obtain the expression of non-unitary symmetric functions of the quantities \( a_1, a_2, \ldots, a_m \) as functions of differences of the symbols \( a, a_1, \ldots \)

\[ edge_0 \]

Expansion in the right-hand side by the exponential theorem, and then expressing the symmetric functions of the \( a_i, a_2, \ldots, a_m \) which arise, in terms of the \( b_1, b_2, \ldots, b_m \), we obtain by comparison with the middle series the symbolic representation of all symmetric functions in brackets \( (\ldots) \) appertaining to the quantities \( a_1, a_2, \ldots, a_m \). To obtain particular theorems the quantities \( a_1, a_2, a_3, \ldots \) are auxiliaries which are at our entire disposal. Thus to obtain Stroh's theorem of seminvarianten put

\[ b_1 = a_1 + a_2 + \ldots + a_m = 1 + 0; \]
we then obtain the expression of non-unitary symmetric functions of the quantities \( a_1, a_2, \ldots, a_m \) as functions of differences of the symbols \( a_i, a_1, \ldots \)

\[ edge_0 \]

The coefficient of \( a_i a_j a_k \ldots \) being \( \frac{1}{b_1 b_2 b_3 \ldots} \). The operators
\[ a_o = a_1 a_2 a_3 \ldots, \quad a_2 a_3 a_4 \ldots \quad a_o + 2a_2 a_3 \ldots \]
are seen to be \((1, 0; 1, 1)\) and \((1, 1; 1, 1)\) respectively. Also the operator of the Pure Reciprocants (see Sybester Lectures on the New Theorem of Reciprocants, Oxford, 1888) is

\[ (4, 1; 2, 1) = \frac{1}{2} (a_3 a_4 - 10 a_3 a_4 a_5 + 6 a_3 a_4 a_5 a_6 + \ldots) \]

It will be noticed that

\[ (\mu, \nu; m, n) = (1, 0; m, n) + (0, 1; m, n). \]

The importance of the operator consists in the fact that taking any two operators of the system

\[ (\mu, \nu; m, n) = (1, 0; m, n) + (0, 1; m, n); \]
the operator equivalent to

\[ (\mu, \nu; m, n) = (1, 0; m, n) + (0, 1; m, n) \]

and, being the "alternant" of the two operators, is also an operator of the same system. We have the theorem

\[ (\mu, \nu; m, n) = (1, 0; m, n) + (0, 1; m, n); \]
where

\[ \mu_1 = (m_1 + m_2 - 1) \left( \frac{1}{\mu} (m_1 + n_2) - \frac{1}{\mu} (m_1 + n_2) \right) \]

and

\[ n_1 = m_1 + n_2 - 1, \]

and we conclude that "alternation" of the operators of the system form a "group." It is thus possible to study simultaneously all the theories which depend upon operations of the group.

Symmetric Representation of Symmetric Functions. Denote the elementary symmetric functions by

\[ a_1, a_2, a_3, \ldots \]

...; at pleasure; then, taking \( n \) equal to \( w \), we may write

\[ a_1 + a_2 a_3 + a_1 a_3 a_5 + \ldots = (1 + p_1)(1 + p_2)(1 + p_3) \ldots \]

where

\[ a_1 = \sum \left( p_1 p_2 \ldots p_n \right) a_1 \]

Further, let

\[ 1 + b_1 x + b_2 x^2 + \ldots + b_m x^m = (1 + a_1 x)(1 + a_2 x)(1 + a_3 x) \ldots + (1 + a_m x); \]

so that

\[ 1 + a_1 x + a_2 x^2 + a_3 x^3 + \ldots = (1 + a_1 x)(1 + a_2 x)(1 + a_3 x)(1 + a_m x); \]

and, by multiplication,

\[ \Pi (1 + a_1 x + a_2 x^2 + \ldots) = \Pi (1 + b_1 x + b_2 x^2 + \ldots + b_m x^m) \]

\[ = e^{a_1x+a_2x^2+a_3x^3+\ldots+amxm}. \]
and we see further that \((\sigma_1 + \sigma_2 + ... + \sigma_n)^{\frac{1}{2}}\) vanishes identically unless \(k \equiv 0 \mod m\). If \(m \equiv 0\) finite and
\[
1 + b_x + b_x^2 + ... = (1 + b_x)(1 + a_x) = \text{const} = \sigma_1 = \sqrt{\text{const}} = ...
\]
we have the symbolic identity
\[
\sigma_1 \sigma_2 \sigma_3 \sigma_4 = \sum \sigma_1 \sigma_2 \sigma_3 \sigma_4
\]
and
\[
(\sigma_1 \sigma_2 \sigma_3 \sigma_4)^n = (p_{ij} + p_{ik} + p_{jl} + p_{jk})^n.
\]
Instead of the above symbols we may use equivalent differential operators. Thus let
\[
\delta_a = \alpha_a \delta_a + 2a_1 \alpha_a + 3a_2 \alpha_a + ...
\]
and let \(a, b, c, \ldots\) be equivalent quantities. Any function of differences of \(a, b, c, \ldots\) being formed, the expansion being carried out, an operand of \(a, b, c, \ldots\) being taken and \(b\) and \(c\) being subsequently put equal to a, a non-unitary symmetric function will be produced.

Ex. gr. (4) \(a_1 = a_2 = a_3 = 0\) \(a_1 = 1\), and this is the same as
\[
\sigma_1 = \sigma_2 = \sigma_3 = \sigma_4 = 0
\]
and let \(\sigma_1\) be an elementary function. Any function of differences of \(\delta_a\), \(\delta_b\), \(\delta_c, \ldots\) being formed, the expansion being carried out, an operand of \(\delta_a\) or of \(\delta_b\) or \(\delta_c, \ldots\) being taken and \(\delta_b\) and \(\delta_c, \ldots\) being subsequently put equal to a, a non-unitary symmetric function will be produced.

The whole theory of these forms is consequently contained implicitly in the operation \(\delta_a\).

Symmetric Functions of Several Systems of Quantities.—It will suffice to consider two systems of quantities as the corresponding theory for three or more systems is obtainable by an obvious enlargement of the nomenclature and notation.

Taking the systems of quantities to be
\[
a_{11}, a_{22}, a_{33}, \ldots, b_1, b_2, b_3, \ldots,
\]
we start with the fundamental relation
\[
(1 + a_{11} + b_1)(1 + a_{22} + b_2)(1 + a_{33} + b_3) = \text{const} = (1 + a_{11})(1 + a_{22})(1 + a_{33}) + \ldots + a_{11} a_{22} a_{33} + ...
\]
As shown by Schläfli, this equation may be directly formed and exhibited as the resultant of the two given equations, and an arbitrary linear non-homogeneous equation in two variables. The right-hand side may also be written
\[
1 + 2a_{12} + 2a_{13} + 2a_{23} + 2a_{12} a_{23} + 2a_{12} a_{13} + 2a_{13} a_{23} + 2a_{12} a_{13} a_{23} + ...
\]
and the most general symmetric function to be considered is
\[
2a_{12} a_{13} a_{23} a_{12} a_{13} a_{23} = (\text{perm} a_{12} a_{13} a_{23})
\]
conveniently written in the symbolic form
\[
(\text{perm} a_{12} a_{13} a_{23}) = (\text{perm} a_{12} a_{13} a_{23})
\]
Observe that the summation is in regard to the expressions obtained by permuting the \(n\) suffixes \(1, 2, 3, \ldots, n\). The weight of the function is bipartite and consists of the two numbers \(2p, 2q\); the symbolic expression of the symmetric function is a partition into bipartite (multipartite) of the bipartite (multipartite) number \(\Sigma_{pq}\).

Each part of the partition is a bipartite number, and in representing the partition it is convenient to indicate repetitions of parts by power symbols. In this notation the fundamental relation is written
\[
(1 + a_{11} + b_1)(1 + a_{22} + b_2)(1 + a_{33} + b_3) = 1 + (1 + a_{11})(1 + a_{22})(1 + a_{33}) + (1 + a_{11})(a_{22} a_{33}) + (1 + a_{22})(a_{11} a_{33}) + (1 + a_{33})(a_{11} a_{22}) + (a_{11} a_{22} a_{33}) + ...
\]
where in general \(a_{pq} = (a_{pq} + a_{qp})\). All symmetric functions are expressible in terms of the quantities \(a_{pq}\) in a rational integral form; from this property they are termed elementary functions; further they are said to be single-unitary since each part of the partition denoting \(a_{pq}\) involves but a single unit.

The number of partitions of a bipartite function \(p_{pq}\) into exactly \(\mu\) bipartite is given (after Euler) by the coefficient of \(q_{\mu1}^{\mu1} q_{\mu2}^{\mu2} \ldots\) in the expansion of the generating function
\[
s = 1 + a_{11} + a_{12} + a_{13} + a_{22} + a_{23} + a_{33} = q_{\mu1} \sum (\sum a_{12} a_{13} a_{23} \ldots a_{12} a_{13} a_{23}) = \text{const} = 1 + a_{11} a_{12} a_{13} + a_{22} a_{23} a_{33} + ...
\]

The rule over \(\text{exp}\) will serve to denote that \(\mu_{12} + \mu_{13} + \mu_{23} + \mu_{12} \mu_{13} + \mu_{12} \mu_{23} + \mu_{13} \mu_{23} + \mu_{12} \mu_{13} \mu_{23} + \mu_{12} \mu_{13} \mu_{23} + \ldots\) is converted into
\[
\text{exp}(\text{perm} a_{12} a_{13} a_{23})
\]
where \(d_0 = \sum d_{a_{12} a_{13} a_{23}}\).

The rule over \(\text{exp}\) will serve to denote that \(\mu_{12} + \mu_{13} + \mu_{23} + \mu_{12} \mu_{13} + \mu_{12} \mu_{23} + \mu_{13} \mu_{23} + \mu_{12} \mu_{13} \mu_{23} + \mu_{12} \mu_{13} \mu_{23} + \ldots\) is converted into
\[
\text{exp}(\text{perm} a_{12} a_{13} a_{23})
\]
where \(d_0 = \sum d_{a_{12} a_{13} a_{23}}\).

Vienna Transactions, t. iv. 1852.
vanish. From the above $D_{pq}$ is an operator of order $pq$, but it is convenient for some purposes to obtain its expression in the form of a number of terms, each of which denotes $pq$ successive linear operations; to accomplish this write

$$d_{pq} = \sum \alpha_{i_{pq}+1} \frac{d}{d}$$

and note the general result

$$\exp \left( m_{p} + m_{q} \right) = \exp \left( \exp \left( m_{p} + m_{q} \right) \right)$$

where the multiplications on the left- and right-hand sides of the equation are symbolic, and the same symbol, provided that $m_{pq}, M_{pq}$ are quantities which satisfy the relation

$$\exp \left( M_{pq} \right) = 1 + \exp \left( m_{pq} \right) + \exp \left( m_{pq} \right)^{2} + ...$$

or

$$M_{pq} = \left( 1 + \exp \left( m_{pq} \right) + \exp \left( m_{pq} \right)^{2} + ... \right)^{1/\exp \left( m_{pq} \right);}$$

and the result is thus

$$\exp \left( \left( m_{p} + m_{q} \right) \right) = \exp \left( \exp \left( m_{p} + m_{q} \right) \right)$$

and thence

$$\mu_{pq} = \left( 1 + \exp \left( m_{pq} \right) + \exp \left( m_{pq} \right)^{2} + ... \right)^{1/\exp \left( m_{pq} \right)};$$

$$\log \left( 1 + \mu_{pq} \right) = \mu_{pq} - \frac{\mu_{pq}^{2}}{2} + \frac{\mu_{pq}^{3}}{3} - ...$$

From these formulas we deduce two important relations, viz.

$$\left( - \frac{z_{pq}^{2}}{p^{q!}} \right) d_{pq} = \sum_{x_{1} = 1}^{q} \left( - \frac{z_{pq}^{2}}{p^{q!}} \right) d_{pq}$$

and

$$\left( - \frac{z_{pq}^{2}}{p^{q!}} \right) d_{pq} = \sum_{x_{1} = 1}^{q} \left( - \frac{z_{pq}^{2}}{p^{q!}} \right) d_{pq}$$

the last written relation having, in regard to each term on the right-hand side, to do with $z_{pq}^{2}$ successive linear operations. Recalling the formulation above which connect $\phi_{pq}$ and $d_{pq}$, we see that $d_{pq}$ and $D_{pq}$ are in co-relation with these quantities respectively, and may be said to be operations which correspond to the partitions ($pq$), (Gordan) respectively. We might conjecture from this observation that every partition is in correspondence with some operation; this is found to be the case, and it has been shown (loc. cit. p. 493) that the operation

$$1 \frac{d}{d_{pq}} = c \frac{d}{d_{pq}} + c \frac{d}{d_{pq}}$$

corresponds to the partition ($pq$) and ($pq$). The partitions being taken as denoting symmetric functions we have complete correspondence between the algebra of quantities and operation, and from any algebraic formula we can deduce many operations on the partition. This fact is of extreme importance in the theory of algebraic forms, and is easily and realizable whatever the number of the systems of quantities under discussion.

We may remark the particular result

$$\left( - \frac{z_{pq}^{2}}{p^{q!}} \right) d_{pq} = \sum_{x_{1} = 1}^{q} \left( - \frac{z_{pq}^{2}}{p^{q!}} \right) d_{pq}$$

contains the solution of the partial differential equation $d_{pq} = 0$ which does not consist of one part of the partition of the biweight $pq$ amongst its parts.

$$d_{pq} = \frac{d}{d_{pq}} - \frac{d}{d_{pq}}$$

the solutions of the partial differential equation $d_{pq} = 0$ are the single bipart forms, omitting $\phi_{pq}$, and we have seen that the solutions of $D_{pq} = 0$ are those monomial functions in which the part $pq$ is absent.

One more relation is easily obtained, viz.

$$d_{pq} = \frac{d}{d_{pq}}$$

III. THE THEORY OF BINARY FORMS

A binary form of order $n$ is a homogeneous polynomial of the nth degree in two variables. It may be written in the form

$$a_{n}x_{n} + bx_{n} + ...$$

or in the form

$$a_{n}x_{n} + ... + a_{n-k}x_{n-k} + \cdots + a_{0}$$

which Cayley denotes $\left( a_{0}, b_{0}, c_{0}, \ldots \right) \left( x_{1}, x_{2} \right)$... being a notation for the successive binomial coefficients $n, n(n-1), \ldots$ Other forms are

$$a_{n}x_{n} + ... + a_{n-k}x_{n-k} + \cdots + a_{0}$$

and

$$a_{n}x_{n} + ... + a_{n-k}x_{n-k} + \cdots + a_{0}$$

the binomial coefficients $\left( a_{0}, b_{0}, c_{0}, \ldots \right)$ being replaced by $a(x)$, and

$$a_{n}x_{n} + ... + a_{n-k}x_{n-k} + \cdots + a_{0}$$

the special convenience of which will appear later. For present purposes the form will be written

$$a_{n}x_{n} + ... + a_{n-k}x_{n-k} + \cdots + a_{0}$$

the notation adopted by German writers; the literal coefficients have a rule placed over them to distinguish them from unbracketed coefficients which are at once replaceable by any other coefficients; the coefficients $a_{0}, a_{1}, a_{2}, \ldots, a_{n}$ are in number arbitrary. If the form, sometimes termed a quantic, be made to zero the $n+1$ coefficients are evidently independent, but in practice one can be made unity by division and the equation is to be regarded as one of the determination of the ratio of the variables.

If the variables of the quantic $f(x_{1}, x_{2})$ are subjected to the linear transformation

$$x_{1} = a_{01}x_{1} + a_{11}x_{2} + a_{21}x_{2}$$

$\xi_{1}, \xi_{2}$ being new variables replacing $x_{1}$ and $x_{2}$ and the coefficients $a_{01}, a_{11}, a_{21}$, $a_{02}, a_{12}, a_{22}$, term the coefficients of substitution (or of transformation), being constants, we arrive at a transformed quantic

$$f(\xi_{1}, \xi_{2}) = a_{00}x_{00} + ... + a_{0n}x_{0n} + a_{0n-1}x_{0n-1} + \cdots + a_{01}x_{01}$$

in the new variables which is of the same order as the original quantic; the new coefficients $a_{00}, a_{11}, a_{22}, \ldots$ are linear functions of the original coefficients, and also linear functions of products, of the coefficients of substitution, of the nth degree.

By solving the equations of transformation we obtain

$$r_{1} \phi_{1} = a_{11} \phi_{1} + a_{12} \phi_{2} + \cdots + a_{1n} \phi_{n}$$

where $r_{1} = a_{11} \phi_{1} + a_{12} \phi_{2} + \cdots + a_{1n} \phi_{n}$

$r$ is termed the determinant of substitution or modulus of transformation; we assure $x_{1}$ to be independent, so that $r$ must differ from zero.

In the theory of forms we seek functions of the coefficients and variables of the original quantic which, save as to a power of the modulus of transformation, are equal to the like functions of the coefficients and variables of the transformed quantic. We may have such a function which does not involve the variables, viz.

$$F(a_{0}, a_{1}, a_{2}, \ldots) = r^{-F(a_{0}, a_{1}, a_{2}, \ldots)}$$

the function $F(a_{0}, a_{1}, a_{2}, \ldots)$ is then said to be an invariant of the quantic of the quantic under linear transformation. If, however, $F$ involve as well the variables, viz.

$$F(a_{0}, a_{1}, a_{2}, \ldots) = r^{-F(a_{0}, a_{1}, a_{2}, \ldots)}$$

the function $F(a_{0}, a_{1}, a_{2}, \ldots, x_{1}, x_{2})$ is said to be a covariant of the quantic. The expression "invariant functions" includes both invariants and covariants, and frequently also other analogous functions which will be met with. Occasionally the word "invariants" includes covariants; when this is so it will be implied by the text. Invariant functions will be found to be homogeneous functions alike of the coefficients and of the variables. Instead of a single quantic we may have several

$$f(a_{0}, a_{1}, a_{2}, \ldots, x_{1}, x_{2}), \phi(b_{0}, b_{1}, b_{2}, \ldots, x_{1}, x_{2})$$

which have different coefficients, the same variables, and are of the same or different order. We may transform them all by the same substitution, so that they become

$$f(\alpha_{1}, \alpha_{2}, \alpha_{3}, \ldots, x_{1}, x_{2}), \phi(\beta_{0}, \beta_{1}, \beta_{2}, \ldots, x_{1}, x_{2})$$

If we are to find

$$f(a_{0}, a_{1}, a_{2}, \ldots, b_{0}, b_{1}, b_{2}, \ldots) = r^{-F(a_{0}, a_{1}, a_{2}, \ldots, x_{1}, x_{2})}$$

for all $x_{1}, x_{2}$,
the function $f$, on the right which multiplies $r$, is said to be a
simultaneous invariant or covariant of the system of quantic.
This notion is fundamental in the present theory because we will
find that one of the most valuable artifices for finding invariants
of a single quantic is first to find simultaneous invariants of several
different quantics, and subsequently to make all the quantics
identical. Moreover, instead of having one pair of variables $x_1$, $x_2$
we may have several pairs $y_1$, $y_2$, $z_1$, $z_2$, ... in addition, and transform
each pair into a new pair by substitutions, having the same
coefficients $a_{ii}$, $a_{ij}$, $a_{ji}$, $a_{jj}$ and arrive at functions of the original
coefficients and variables (of one or more quantics) which possess the above-
described invariant property. An intricate quantic of the system
may be of the same or different degrees in the pairs of variables
which it involves, and these degrees may vary from quantic to
quantic of the system. Such quantics have been termed by Cayley
multivariate.

Symbolic Form.—Restricting consideration, for the present, to
binary forms in a single pair of variables, we must introduce the
symbolic form of Aronhold, Clebsch and Gordan; they write the form

$$ (a_{ii}x_1 + a_{ij}x_2)^n = a_{ii}^n x_1^n + \left(\binom{n}{1} a_{ii}^{n-1} a_{ij} x_1^{n-1} x_2 + \ldots + a_{ij}^n x_2^n \right) $$

where $a_{ii}$, $a_{ij}$ are umbrae, such that

$$ a_{ii}, a_{ij}, a_{ji}, a_{jj} $$

are symmetrical representations of the real coefficients $\tilde{a}_i$, $\tilde{a}_j$,
and in general $a_{ii}$ is the symbol for $\tilde{a}_i$. If we restrict
ourselves to this set of symbols we can uniquely pass from a product
of real coefficients to the symbolic representation of such product,
but we cannot uniquely, from the symbols recover the real form.
This is clear because we can write

$$ a_{ii} a_{jj} a_{ij} a_{ji} = a_{ii} a_{jj} a_{ij} a_{ji} $$

while the same product of umbrae arises from

$$ a_{ii} a_{jj} a_{ij} a_{ji} = a_{ii} a_{jj} a_{ij} a_{ji} $$

Hence it becomes necessary to have more than one set of umbrae,
so that we may have more than one symmetrical representation
of the same real coefficients. We consider the quartic to have any
number of equivalent representations $a_{ii} = b_{ii} = c_{ii} = \ldots$. So that

$$ a_{ii} = a_{ii} \quad a_{ij} = a_{ij} \quad a_{jj} = a_{jj} \quad a_{ji} = a_{ji} $$

Ex. gr. We write

$$ \tilde{a}_{ii} = a_{ii}^n \tilde{a}_{ij}^n \tilde{a}_{ji}^n \tilde{a}_{jj}^n $$

and so on whenever we require to represent a product of real
coefficients symbolically; we then have a one-to-one correspondence
between the products of real coefficients and their symbolic forms.
If we have a function of degree $s$ in the coefficients, we may select
any $s$ sets of umbrae for use, and having made a selection we may
when only one quartic is under consideration at any time permute
the sets of umbrae in any manner without altering the true
significance of the symbolism. Ex. gr. To express the function $\tilde{a}_{ii} \tilde{a}_{jj} - \tilde{a}_{ij} \tilde{a}_{ji}$
which is the discriminant of the binary quadratic $\tilde{a}_{ii} \tilde{x}_1^2 + 2\tilde{a}_{ij} \tilde{x}_1 \tilde{x}_2 + \tilde{a}_{jj} \tilde{x}_2^2$
we pass to the symbolic form

$$ a_{ii} a_{jj} a_{ij} a_{ji} = \phi(\tilde{a}), $$

where

$$ a_{ii} = a_{ii} a_{ii} + a_{ii} a_{ij} \quad a_{ii} = a_{ii} a_{ij} + a_{ij} a_{jj} $$

We pass to the symbolic form

$$ A^2 = a_{ii} a_{jj} a_{ij} a_{ji} = \phi(\tilde{a}), $$

by writing for

$$ a_{ii} a_{jj} a_{ij} a_{ji} $$

then

$$ A^2 = a_{ii}^2 a_{jj}^2 a_{ij}^2 a_{ji}^2 = a_{ii}^2 a_{jj}^2 $$

and therefore

$$ A^2 = a_{ii}^2 a_{jj}^2 a_{ij}^2 a_{ji}^2 = a_{ii}^2 a_{jj}^2 $$

so that

$$ A^2 = a_{ii}^2 a_{jj}^2 a_{ij}^2 a_{ji}^2 = a_{ii}^2 a_{jj}^2 $$

whence $A$, $A_i$ become $a$, $a_j$ respectively and

$$ \phi(\tilde{a}) = \phi(a_{ii} a_{jj} a_{ij} a_{ji}) $$

The practical result of the transformation is to change the umbrae
$\tilde{a}_i$, $\tilde{a}_j$ into the umbrae

$$ a_{ii} = a_{ii} + a_{ij} \quad a_{jj} = a_{jj} + a_{ji} $$

respectively.

By similarly transforming the binary $n$th form $\tilde{a}_n$ we find

$$ A^2 = a_{ii}^2 a_{jj}^2 a_{ij}^2 a_{ji}^2 = a_{ii}^2 a_{jj}^2 $$

the umbrae $A$, $A_i$, $A_j$ are expressed in terms of the umbrae $a_{ii}$, $a_{ij}$
by the formulae

$$ A = a_{ii} + a_{jj} \quad A_i = a_{ii} + a_{ij} \quad A_j = a_{jj} + a_{ji} $$

We gather that $A$, $A_i$, $A_j$ are transformed to $a$, $a_i$, $a_j$ in such wise that
the determinant of transformation reads by rows as the original
determinant reads by columns, and that the modulus of the transforma-
tion is, as before, $(\lambda a)$. For this reason the umbrae $A$, $A_i$, $A_j$
are said to be congradient to $x_i$, $x_j$. If we solve the equations
connecting the original and transformed umbrae we find

$$ A = a_{ii} + a_{jj} \quad A_i = a_{ii} + a_{ij} \quad A_j = a_{jj} + a_{ji} $$

and we find that, except for the factor $(\lambda a) = -a_i - a_j$, and $a_i + a_j$
are transformed to $-A_i$ and $-A_j$, by the same substitutions as $x_i$ and $x_j$
are transformed to $x_i$ and $x_j$. For this reason the umbrae $-a_i$, $a_j$
are said to be congradient to $x_i$ and $x_j$. We frequently meet with con-
gradient and congradient quantities, and we have in general the
following definitions:—1. "If two equally numerous sets of quan-
tics $x_i, y_i, z_i, \ldots$, $x_i', y_i', z_i', \ldots$ are such that whenever one set $x_i, y_i, z_i$,
expressed in terms of new quantities $x_i', y_i', z_i', \ldots$, the second set
$x_i, y_i, z_i$ is expressed in terms of other new quantities $x_i', y_i', z_i', \ldots$
by the same scheme of linear substitution the two sets are said to
be congradient quantities." (2) "Two sets of quantities $x_i, y_i, z_i, \ldots$
are said to be congradient when the linear substitutions for the first set are

$$ x = \lambda x_i + \mu_i y_i + \nu_i z_i + \ldots $$

and these are associated with the following formulae appertaining to the
second set,

$$ x' = \lambda x_i + \mu_i' y_i + \nu_i' z_i + \ldots $$

wherein it should be noticed that new quantities are expressed in
terms of the old, as regards the latter set, and not vice versa."
we find
\[ \left( \frac{d}{dx} \cdot \frac{d}{dy} \cdot \frac{d}{dz} \right)^n = \left( \lambda_1, \lambda_2, \lambda_3, \ldots \right) \left( \frac{d}{dx} \cdot \frac{d}{dy} \cdot \frac{d}{dz} \right)^n. \]

Observe the notation, which is that introduced by Cayley into the theory of matrices which he himself created.

Just as coegrediency leads to a theory of covariants, so contraegrediency leads to a theory of contravariants. If \( a \), \( b \), \( c \), \( x \), \( y \), \( z \) be expressed in terms of new variables \( X \), \( Y \), \( Z \) \( \ldots \); and if \( \xi, \eta, \zeta \ldots \) be quantities cocontragredient to \( x, y, z \ldots \); there are found to exist functions of \( \xi, \eta, \zeta \ldots \) and of the coefficients in \( u \), which need, at most, be simplified by powers of the modulus to be made equal to the same functions of \( X, Y, Z \ldots \) of the transformed coefficients of \( u \); such functions are called contravariants of \( u \). There also exist functions, which involve both sets of variables as well as the coefficients of \( u \), possessing the per property; such have been termed mixed concomitants, and, they like covariants, may appertain as well to a system of forms as to a single form.

As between the original and transformed quantic we have the umbral relations
\[ A_1 = a_1 A_2 + a_2 A_3, \quad A_2 = \mu a_1 + \mu a_3, \]
and for a second form
\[ B_1 = b_1 B_2 + b_2 B_3, \quad B_2 = \mu b_1 + \mu b_3. \]

The original forms are \( a_2, b_2 \) and we may regard them either as different forms or as equivalent representations of the same form. In other words, \( a, b \) may be regarded as different or alternative symbols to \( A, B \).

\[(AB)(AB) = A_2 B_2 A_3 B_3 = (a_2)(b_2); \]
and, from the definition, \( ab \) possesses the invariant property. We cannot, however, say that it is an invariant unless it is expressible in terms of the real coefficients. Since \( ab = a_1 b_1 + a_2 b_2 + a_3 b_3 \), this may be the case in linear; and may be expressed by powers of the modulus to be made equal to one another and \( ab \) vanishes. A single linear form has, in fact, no invariant. When either of the forms is of an order higher than the first \( (ab) \), as not being expressible in terms of the actual coefficients of the form, may not be an invariant and has no significance. Introducing now other sets of symbols \( C, D \ldots \); \( c, d \ldots \) we may write
\[ (ABC)(ABC) = (abc)(abc) \]
so that the symbolic product
\[ (ab)(ac)(bc)^k \]
possesses the invariant property. If the forms be all linear and different, the function is an invariant, viz. the \( k \)th power of that appertaining to \( a_2 \) and \( b_2 \) multiplied by the \( k \)th power of that appertaining to \( a_1 \) and \( c_1 \) and so forth, being sum to the different quantities of \( a_2 b_2 \) and \( a_1 c_1 \ldots \) may be supposed identical, any symbolic expression involving the factor \( a_1 a_2 b_1 b_2 \ldots \) is zero. Notice, therefore, that the symbolic product \( (ab)(ac)(bc)^n \) may be always viewed as a simultaneous invariant of a number of different linear forms \( a_1, b_1, c_1 \ldots \), in order that \( (ab)(ac)(bc)^n \) may be a simultaneous invariant of a number of different forms \( a_2, b_2, c_2 \ldots \), where \( n_1, n_2, n_3 \ldots \) may be the same or different, it is necessary that every product of umbrae which arises in the expansion of the symbolic product be of degree \( n_1 \); in \( a_2, b_2; \) in the case of \( b_2, c_2 \) of degree \( n_2 \); and so on. For these only will the symbolic product be replaceable by a linear function of products of real coefficients. Hence the condition is
\[ i + j + k = n_1, \quad i + j + k = n_2 \ldots \]

If the forms \( a_2, b_2, c_2 \ldots \) be identical the symbols are alternative, and provided that the form does not vanish it denotes an invariant of the single form \( a_2 \).

There may be a number of forms \( a_2, b_2, c_2 \ldots \), and we may suppose such identities between the symbols that on the whole only two, three, or more of the sets of umbrae are not equivalent; we will then obtain invariants of two, three, or more sets of binary forms. The symbolic expression of a covariant is equally simple, because we see at once that since \( A_2, B_2, C_2 \ldots \) are equal to \( a_2, b_2, c_2 \ldots \) respectively, the linear forms \( a_2, b_2, c_2 \ldots \) possess the invariant property, and we may write
\[ (ABC)(ABC) = (abc)(abc) \]
and assert that the symbolic product
\[ (ab)(ac)(bc)^n \]
possesses the invariant property. It is always an invariant or covariant appertaining to a number of different linear forms, and as before it may vanish if two such linear forms be identical. In general it will be simultaneous covariant of the different forms \( a_2, b_2, c_2 \ldots \) if
\[ i + j + k = n_2 \ldots \]

It will also be a covariant if the symbolic product be factorizable into portions each of which satisfies these conditions. If the forms be identical the sets of symbols are ultimately equated, and the form, provided it does not vanish, is a covariant of the form \( a_2 \).

The expression \( (ab) \) properly appertains to a quartic; for a quadratic it may also be written \( (ab) \), and would denote the square (in the discriminant) of the factor. For the quartic \( (ab) = a_1 b_1 + a_2 b_2 + a_3 b_3 + a_4 b_4 \)
and, transforming to the real form,
\[ (ab) = a_1 b_1 + a_2 b_2 + a_3 b_3 + a_4 b_4 \]
the simultaneous invariant; and now, putting \( b = a \), we obtain twice the Hessian
\[ (ab) = a_1 b_1 + a_2 b_2 + a_3 b_3 + a_4 b_4 \]
It will be shown later that all invariants, single or simultaneous, are expressible in terms of symbolic products. The degree of the covariant in the coefficients is equal to the number of different symbols \( a, b, c \ldots \) that occur in the symbolic expression; the degree in the discriminant of the quartic is \( a_1 a_2 a_3 a_4 \) and the weight of the coefficient of the leading term \( x_1 x_2 x_3 x_4 \) is equal to \( i + j + k - n \).

In an invariant with \( m, n \) powers of \( a \) and \( b \), respectively, the invariants of the \( w \)th power of the \( \omega \)th degree of the \( \omega \)th order of the covariant is \( a_1 a_2 a_3 a_4 \) and the weight of the coefficient of the leading term \( x_1 x_2 x_3 x_4 \) is equal to \( i + j + k - n - 2w \).

Similarly.

For the purpose of manipulating symbolic expressions it is necessary to be in possession of certain simple identities which connect certain symbolic products. From the three equations
\[ a_2 = a_1 x_2 + a_3 x_3, \quad b_2 = b_1 x_2 + b_3 x_3, \quad c_2 = c_1 x_2 + c_3 x_3 \]
we find by eliminating \( x_1 \) and \( x_2 \) the relation
\[ a_2 b_2 c_2 = (a_1 b_1 c_1) x_2 = 0 \]
Each term on the right-hand side may be shown by permutation of a, b, c to be the symbolic representation of the same covariant; they are equivalent symbolic products, and we may accordingly write
\[ 2(ac)(bc) = (ab) \text{transvectant} y \]

a relation which shows that the form on the left is the product of the two covariants
\[ (ab) a_e - b_x = 0 \quad \text{and} \quad c_z. \]

The identities are, in particular, of service in reducing symbolic products to standard forms. Any symbolic expression may be always so transformed that the power of any determinant factor \((ab)\) is even. For we may in any product interchange a and b without altering its signification; therefore
\[ (ab)^m = (ab)^m - \text{transvectant} y \]

where \(\phi_1\) becomes \(\phi_2\) by the interchange, and hence
\[ (ab)^m = \frac{1}{2}(ab)^{m-1} \phi_1 + \frac{1}{2}(ab)^{m-1} \phi_2 \]

and identity (1) will always result in transforming \(\phi_1\) to \(\phi_2\) so as to make it divisible by \((ab)\).

Ex. gr.,
\[ (ab) (ac) c_b = -(ab)(bc) a_c = \]
\[ = \frac{1}{2}(ab) c_b a_c = \frac{1}{2}(ab) c_b. \]

so that the covariant of the quadratic on the left is half the product of the quadratic itself and its own invariant. To obtain the corresponding theorem concerning the general form of even order we multiply throughout by \((ab)^m a b c\) and obtain
\[ (ab)^m c_b = \frac{1}{2}(ab)^{m-1} (\phi_1 + \phi_2) \]

Paying attention merely to the determinant factors there is no form with one factor since \((ab)\) vanishes identically. For two factors the standard form is \((ab)^2\); for three factors \((ab)^3 (ac)\); for four factors \((ab)^2 (ac)^2\); for five factors \((ab)^4 (ac)^2\); and for six factors \((ab)^2 (ac)^2 (cd)^2\), and \((ab)(cd)(ef)\) if it is a useful exercise for the reader to interpret the corresponding covariants of the general quantic, to show that some of them are simple powers or products of other covariants of lower degrees and order.

The Polar Process.—The \(\mu\)th polar of \(a_x^\mu\) with regard to \(y\) is
\[ a_x^\mu a_y - a_y^\mu a_x, \]

i.e. \(\mu\) of the symbolic factors of the form are replaced by \(\mu\) others in which new variables \(y_1, y_\mu\) replace the old variables \(x_1, x\mu\). The operation of taking the polar results in a symbolic product, and the repetition of the process in regard to new cognate sets of variables results in symbolic forms. It is therefore an invariant process. All the forms obtained are invariants in regard to linear transformations, in accordance with the same scheme of substitutions, of the several sets of variables.

An important associated operation is
\[ \frac{\partial}{\partial y} \frac{\partial}{\partial x} \]

which, operating upon a polar, causes it to vanish. Moreover, its operation upon any invariant form produces an invariant form.

Every symbolic product, involving several sets of cognate variables, can be expressed as a sum of terms, each of which is a polar multiplied by a product of powers of the determinant factors (xy), (xy), (xy),...

Transvection.—We have seen that \((ab)\) is a simultaneous invariant of the two different linear forms \(a_x, b_y\); and we observe that \((ab)\) is equivalent to
\[ \frac{\partial f}{\partial x} \frac{\partial f}{\partial y} \frac{\partial f}{\partial x} \frac{\partial f}{\partial y} \]

where \(f = a_x, \phi = b_y\).

If \(f = a_x, \phi = b_y\) be any two binary forms, we generalize by forming the function
\[ \frac{(m-n)}{m} \frac{(m-n)}{n} \frac{\partial f}{\partial x} \frac{\partial f}{\partial x} \frac{\partial f}{\partial x} \frac{\partial f}{\partial x} \]

This is called the \(k^\text{th}\) transvection of \(f\) over \(\phi\); it may be conveniently denoted by \((f, \phi)^k\).

Observing that
\[ (a_x^\mu b_y^\mu)^k = (ab)^m a_x b_y - a_x b_y \quad \text{it is clear that the} \quad (ab) \quad \text{transvection is a simultaneous covariant of the two forms.} \]

It has been shown by Gordan that every symbolic product is expressible as a sum of transvectants. If \(m > n\) there are \(n + 1\) transvectants corresponding to the values 0, 1, ..., \(n\) of \(k\); if \(m = n\) we have the product of the two forms, and for all values of \(k > n\) the transvectants vanish. In general we may have any two forms
\[ \phi_1 = (\phi_1 + \phi_2) \quad \psi_1 = (\psi_1 + \psi_2) \]

\(\phi_1, \psi_1, \phi_2, \psi_2\) being the umbrâ, as usual, and for the \(k^\text{th}\) transvection we have
\[ (\phi_1^2, \psi_1^2)^k = (\phi_1^2) \phi_2^k + \psi_2^k \]

a simultaneous covariant of the two forms. We may suppose \(\phi_1^2, \psi_1^2, \phi_2^2, \psi_2^2\) to be any two covariants appertaining to a system, and the process of transvection supplies a means of proceeding from them to other covariants.

The two forms \(a_x^2, b_y^2\) or \(\phi_1^2, \psi_1^2\) may be identical; then we have the \(k^\text{th}\) transvection of a form over itself which may, or may not, vanish identically; and, in the latter case, is a covariant of the single form. It is obvious that, when \(k\) is uneven, the \(k^\text{th}\) transvection of a form over itself does vanish. We have seen that transvection is equivalent to the performance of partial differential operations upon the two forms, but, practically, we may regard the process as merely substituting \((ab)^k\) for \(a_x^k, b_y^k\) respectively in the symbolic product subjected to transvection. It is essentially an operation performed upon the product of two forms. If, then, we require the transvectants of the two forms \(f + J f, f + \mu f\), we take their product
\[ f^2 + \lambda f + \mu f + \lambda f^2 + \mu f^2 \]

and the \(k^\text{th}\) transvection is simply obtained by operating upon each term separately, viz.
\[ (f, \phi)^2 + \lambda (f, \phi)^2 + \mu (f, \phi)^2 + \lambda (f, \phi)^2 + \mu (f, \phi)^2 \]
and, moreover, if we require to find the \(k^\text{th}\) transvection of one linear system of forms over another we have merely to multiply the two systems, and take the \(k^\text{th}\) transvection of the separate products.

The process of transvection is connected with the operations \(\Omega\); for
\[ (f, \phi)^2 = f^2 + \phi^2 \]
\[ \text{or} \]
\[ \phi^2 + f^2 \text{ or } (f, \phi)^2 = \]

so also is the polar process, for since
\[ f_2 = a_x b_y - a_y b_x \]
if we take the \(k^\text{th}\) transvection of \(f_2\) over \(\phi_2\), regarding \(y_1, y_2\) as the variables,
\[ (f_2, \phi_2)^k = (ab)^{m-n} b_y^k \]

or the \(k^\text{th}\) transvection of the \(k^\text{th}\) polars, in regard to \(y\), is equal to the \(k^\text{th}\) transvection of the forms. Moreover, the \(k^\text{th}\) transvection \((ab)^{m-n} b_y^k\) is derivable from the \(k^\text{th}\) polar of \(a_x^m\), viz. \(a_x^m b_y^k\), by substituting for \(y_1, y_2\) the cognate quantities \(b_x, -a_x\) and multiplying by \(b^k\).

First and Second Transvectants.—A few words must be said about the first two transvectants as they are of exceptional interest. Since, if \(f = a_x^m, \phi = b_y^k\),
\[ (f, \phi)^2 = \frac{m}{m} \frac{m}{m} \frac{\partial f}{\partial x} \frac{\partial f}{\partial x} \frac{\partial f}{\partial x} \frac{\partial f}{\partial x} \]
the first transvection differs but by a numerical factor from the Jacobian or functional determinant, of the two forms. We can find an expression for the first transvection of \((f, \phi)^2\) over another form \(\psi\).

For
\[ (m+n)(f, \phi)^2 = \mu f_1 + \mu f_2 + \mu f_3 + \mu f_4 \]
and, if \(f, \phi = f_1, f_2, f_3, f_4\),
\[ f_1 f_2 = a_x b_y - a_y b_x \]

Put \(m = n = 1\) for \(n\), and multiply through by \((ab)\); then
\[ (f, \phi)^1 = (ab)^{m-n} a_x b_y - b_x a_y \]

Multiply by \(e^{k-1}\) and for \(y_1, y_2\) write \(e^{\mu} - \mu e^{\mu} - \mu e^{2\mu} + \mu e^{3\mu}\), then the right-hand side becomes
\[ (ab)(bc) a_x b_y - b_x a_y \quad \text{of which the term, writing} \]
\[ f_1 = \psi, \]

is
\[ a_x e^{2\mu} b_y e^{2\mu} (ab) (bc) a_x b_y = \]
\[ = \frac{e^{2\mu}}{} (bc) a_x b_y - b_x a_y \]

and, if \((f, \phi)^1 = \psi\),
\[ (f, \phi)^1 = e^{2\mu} a_x b_y - b_x a_y \]

and, if \((f, \phi)^1 = \psi\).
and this, on writing \( a_n - c_i \) for \( y_n, y_k \), becomes

\[
(kc)^n - c_v = \left\{ (f, \phi) \right\}^n
\]

and hence it appears that the first transvectant of \((f, \phi)\) over \(\psi\) is always expressible by means of forms of lower degree in the coefficients wherever each of the forms \(f, \phi, \psi\) is of higher degree than the first in \(x_n, x_k\).

The second transvectant of a form over itself is called the Hessian of the form. It is

\[
\left( f(f) \right)^n = (ab)^n - b^{2n-2} = H^{m-n} = H;
\]

universally so, it is a numerical multiple of the determinant \(\Delta x_1^2 \cdots x_n^2\). It is also the first transvectant of the differential coefficients of the form with regard to the variables, viz.

\[
\frac{\partial f}{\partial x_i} \frac{\partial f}{\partial x_j} \cdots \frac{\partial f}{\partial x_k} = 1 \text{ in } (n-1) = H;
\]

and there is a remarkable theorem which states that if \(H = 0\) and \(n = 2, 3, 4\) the original form can be exhibited as a form in 1, 2, 3 variables respectively.

The Form \( f + \lambda \phi \).—An important method for the formation of covariants is connected with the form \( f + \lambda \phi \), where \( f, \phi \) are of the same order in the variables and \(\lambda\) is an arbitrary constant. If the invariants and covariants of this composite quartic be formed, we obtain functions of \(\lambda\) such that the coefficients of the various powers of \(\lambda\) are simultaneous invariants of \( f, \phi \). In particular, if \(\phi\) is a covariant of \( f \), we obtain in this manner covariants of \( f \).

The Partial Differential Equations:—It will be shown later that such covariants may be studied by restricting attention to the leading coefficient, viz. that affecting \(x^e\), where \(e\) is the order of the covariant.

An important fact, discovered by Cayley, is that the coefficients, and also the complete covariants, satisfy certain partial differential equations which suffice to determine them, and to ascertain many of their properties. These equations can be arrived at in many ways; the method here given is due to Gordan. \(\lambda_1, \lambda_2, \mu_1, \mu_2\) being as usual the coefficients of substitution, let

\[
\lambda_1 \frac{\partial}{\partial x_1} + \lambda_2 \frac{\partial}{\partial x_2} + \mu_1 \frac{\partial}{\partial x_1} + \mu_2 \frac{\partial}{\partial x_2} = D_{\lambda_1 \lambda_2 \mu_1 \mu_2} = D_{x_x}
\]

be linear operators. Then if \( f, g \) be the original and transformed forms of an invariant

\[
\omega = (f^m g^n)
\]

be the weight of the invariant.

Operation upon \( f \) results as follows:

\[
D_{\lambda_1 \lambda_2} f = w f; D_{\mu_1 \mu_2} f = 0;
\]

The first and fourth of these indicate that \((\lambda^m)^n\) is a homogeneous function of \(\lambda_1, \lambda_2\), and of \(\mu_1, \mu_2\) separately, and the second and third arise from the fact that \((\lambda^m) \) is defined to vanish by both \(D_{\lambda_1} \) and \(D_{\mu_1} \).

Since

\[
J = F(X_1, X_2, \ldots, X_n), \text{ where } X_k = a_{k1} \text{ and } a_{ki},
\]

we find that the results are equivalent to

\[
\sum \left( D_{\lambda_1 \lambda_2} X_1 \right) \frac{\partial X_1}{\partial x_k} = w J; \sum \left( D_{\mu_1 \mu_2} X_2 \right) \frac{\partial X_2}{\partial x_k} = 0;
\]

\[
\sum \left( D_{\lambda_1 \lambda_2} X_1 \right) \frac{\partial X_1}{\partial x_k} = 0; \sum \left( D_{\mu_1 \mu_2} X_2 \right) \frac{\partial X_2}{\partial x_k} = w J.
\]

According to the well-known law for the changes of independent variables. Now

\[
D_{\lambda_1 \lambda_2} X_k = (\lambda_k) X_k; D_{\lambda_1 \lambda_2} X_k = a_{k1} X_k; \]

so we obtain

\[
\sum \left( n - k \right) a_{k1} \frac{\partial X_k}{\partial x_k} = \sum \left( k \right) a_{k1} \frac{\partial X_k}{\partial x_k} = 0;
\]

\[
\sum \left( n - k \right) a_{k1} \frac{\partial X_k}{\partial x_k} = w J; \sum \left( k \right) a_{k1} \frac{\partial X_k}{\partial x_k} = w J;
\]

and hence, transforming from \( a \) to \( x \), we obtain the first equation

\[
\omega = \sum \left( \left( - k \right) a_{k1} \frac{\partial X_k}{\partial x_k} \right)
\]

and this, on writing \(a_n - c_i\) for \(y_n, y_k\), becomes

\[
\left( k^c \right)^n - c_v = \left\{ (f, \phi) \right\}^n
\]

and therefore the values are such that \(J = j, \omega = \omega_j\). Hence

\[
\frac{\partial x_1}{\partial x_k} + \left( \frac{\partial x_2}{\partial x_k} \right) + \cdots + \left( \frac{\partial x_n}{\partial x_k} \right) = w J.
\]

The system of equations satisfied by an invariant. The fourth shows that every term of the invariant is of the same weight.

Moreover, if we add the first to the fourth we obtain

\[
\sum a_{k1} \frac{\partial X_k}{\partial x_k} = \sum a_{k1} \frac{\partial X_k}{\partial x_k} = 0.
\]

The second and third are those upon the solution of which the theory of the invariant may be said to depend. An instantaneous deduction from the relation \(w = c^m\) has been the use of even orders possessing only invariants of even degree in the coefficients. The two operators

\[
\omega = \sum a_{k1} \frac{\partial X_k}{\partial x_k} + (n - 1) a_{k1} \frac{\partial X_k}{\partial x_k} + \cdots + a_{k1} \frac{\partial X_k}{\partial x_k}.
\]

The Evectant Process.—If we have a symbolic product, which contains the symbol \(a\) only in determinant factors such as \((ab)\), we may write \(x_{a1} = x_{a2} = \ldots = x_{an}\) and thus obtain a product in which \((ab)\) is replaced by \(b_{x} (ac) \) and so on. In particular, when the product denotes an invariant we may transform each of the symbols \(a, b, \ldots, z\) in succession, and take the sum of the resultant products; we thus obtain a covariant which is called the first evectant of the original invariant.

The second evectant is obtained by similarly operating upon all the symbols remaining which only occur in determinant factors, and so on for the higher evectants.

Ex. gr. From \((ac)^3 (bd)(ad)(bc)\) we obtain

\[
(bd)^3 (bc) (b^2 c^2) - (ad)^3 (ad) (a^2 d^2) = \omega_d (a^2 d^2) \text{ the first evectant;}
\]

and hence \(a^2 d^2\) is the second evectant; in fact the two evectants are to numerical factors \(prb\), the cubic covariant \(Q\) and the square of the original cubic.
of the second pair; so that the condition for the existence of such common factor must be the same in the two cases. A leading proposition states that, if an invariant of $a^n$ and $b^n$ be considered as a form in the variables $\lambda$ and $\mu$ and an invariant of the latter be taken, the result will be a combination of $a^p$ and $b^p$. The idea can be generalized as to have regard to ternary and higher forms each of the same order and of the same number of variables.

For further information see Gordan, Vorlesungen über Invariantentheorie, Bd. ii. § 6 (Leipzig, 1887); E. B. Elliott, Algebra of Quantics, Art. 264 (Oxford, 1895).

Associated Forms.—A system of forms, such that every form appertaining to the binary form is expressible as a rational and integral function of the members of the system, is difficult to obtain. If, however, we specify that all forms are to be rational, but not necessarily integral functions, a new system of forms arises which is easily obtainable. A binary form of order $n$ contains $n$ independent constants, three of which by linear transformation can be given determinate values; the remaining $n-3$ coefficients, together with the determinant of transformation, give us $n-2$ parameters, and in consequence one relation must exist between any $n-1$ invariants of the form, and fixing upon $n-2$ invariants every other invariant is a rational function of its members. Similarly regarding $x_1, x_2$ as additional parameters, we see that every covariant is expressible as a rational function of $n$ fixed covariants. We can so determine these invariants that every other covariant is expressed in terms of them by a fraction whose denominator is a power of the binary form.

First observe that with $f_1 = a_1 b^n, \ldots, f_n = a_0 a_n b^n$, we find

$$\psi = (a_1 b^n)^{a_1} \cdot \ldots \cdot (a_n b^n)^{a_n},$$

and that hence every symbolic product is equal to a rational function of common invariants for the fraction whose denominator is a power of $f$. Making the substitution in any symbolic product the only determinate factors that present themselves in the numerators are of the form $(a_1 b^n), (a_2 b^n), \ldots$ and every symbol finally appears in the form.

$$\psi = \left(\frac{a_1}{a_2}\right)^{a_3} \cdot \ldots \cdot \left(\frac{a_{n-1}}{a_n}\right)^{a_n}.$$

')(x*+y+z'>)xyz

Passing on to the ternary quartic we find that the number of
ground forms is apparently very great. Gordan (Math. Ann. xvii.
217-233), limiting himself to a particular case of the form, has
determined 54 ground forms, and G. Maisano (Batt. G. xix. 198-237,
1881) has determined all up to and including the 5th degree in the
coefficients.

The system of two ternary quadratics consists of 20 forms; it
has been investigated by Gordan (Clebsch-Lindemann's Vorlesungen
i.
288, also Math. Ann. xix. 529-552); Perrin (S. M. F. Bull, xviii.
1-80, 1-890); Rosanes (Math. Ann. vi. 264); and Gerbaldi (Annali
161-196).

Ciamberlini has found a system of 127 forms appertaining to three
ternary quadratics (Batt. G. xxiv. 141-157).
A. R. Forsyth has discussed the algebraically complete sets of
ground forms of ternary and quaternary forms (see Amer. J. xii. 1-60,
He proves,
by means of the six linear partial differential equations satisfied

the expression in brackets being the -well-known invariant of a*,
the vanishing of which expresses the condition that the form may
break up into two linear factors, or, geometrically, that the conic
may represent two right lines. The complete system consists of
the form itself and this invariant.
The ternary cubic has been investigated by Cayley, Aronhold,
Hermite, Brioschi and Gordan. The principal reference is to
Gordan (Math. Ann. i. 00-128, 1869, and vi. 436-512, 1873). The
complete covariant and contravariant system includes no fewer
than 34 forms; from its complexity it is desirable to consider the
cubic in a simple canonical form; that chosen by Cayley was

He

individuals.

Bibliographical references to ternary forms are given

by Forsyth

Clebsch,
16) and by Cayley (Amer. J. iv., 1881).
and Math. Ann. t. v., established the important result that in the
case of a form in n variables, the concomitants of the form, or of
a system of such forms, involve in the aggregate n I classes of

(Amer. J.

xii. p.


variables. For instance, those of a ternary form involve two classes which may be geometrically interpreted as point and line coordinates in a plane; those of a quaternion form involve three classes which may be geometrically interpreted as point, line and plane coordinates in space.

IV. Enumerating Generating Functions

Professor Michael Roberts (Quart. Math. J. iv.) was the first to remark that the study of covariants may be reduced to the study of their leading coefficients, and that from any relations connecting the latter are immediately derivable the relations connecting the former. It has been shown above that a covariant, in general, satisfies four partial differential equations. Two of these show that the leading coefficient of any covariant is an isotropic and homogeneous function of the coefficients of the symbol; the remaining two may be regarded as operators which cause the vanishing of the covariant. These may be written, for the binary $n$th:

$$\sum a_{nk} d \frac{d}{dx} = 0;$$

or in the form

$$\sum (n-k)a_{nk} d \frac{d}{dx} = 0;$$

where

$$a_{nk} = \frac{n!}{(n-k)!k!}.$$  

Let a covariant of degree $e$ in the variables, and of degree $\theta$ in the coefficients (the weight of the leading coefficient being $w$ and $n^e-2w = e$), be

$$C_{e,\theta} + \sum_{i=1}^{e-1} C_{i,\theta} l^i.$$  

Operating with $-x_i \frac{d}{dx}$ we find $C_0 = 0$; that is to say, $C_0$ satisfies one of the two partial differential equations satisfied by an invariant. It is for this reason called a seminvariant, and every seminvariant is the leading coefficient of a covariant. The whole theory of invariants of binary form depends upon the solutions of the equation $\Omega = 0$. Before discussing these it is best to transform the binary form by substituting $1 l_{ao}, 2 l_{ao}, 3 l_{ao}, \ldots, n l_{ao}$ for $a_1, a_2, a_3, \ldots, a_n$, respectively; it then becomes

$$a_{e,\theta} + \sum_{i=1}^{e-1} a_{i,\theta} l^i + x_1 l_1 x_2 l_2 \ldots + n l_{ao} x_{ao},$$

and it takes the simpler form

$$a_{e,\theta} l_{ao} + a_{e-1,\theta} l_{ao-1} + \ldots + a_{1,\theta} l_{ao}.$$  

One advantage we have obtained is, that if we now write $a_0 = 0$, and substitute $a_{-1}$ for $a_{-1}$, when $e > 0$, we obtain

$$a_{e,\theta} l_{ao} + a_{e-1,\theta} l_{ao-1} + \ldots + a_{1,\theta} l_{ao},$$

which is the form of $\Omega$ for a binary $(e - 1)$th.

Having eliminated each such a seminvariant by unity, we obtain another seminvariant of the same degree, and of weight $w - \theta$, appertaining to the $(e - 1)$th. Also, if we increase each in a seminvariant we obtain terms, free from $a_0$ of some seminvariant of degree $0$ and weight $w - \theta$. Ex. gr. from the invariant $a_1 l_{ao} + a_2 l_{ao} + a_4 l_{ao}$ of the quartic the diminishing process yields $a_1 l_{ao} + a_2 l_{ao}$, the leading coefficient of the Hessian of the cubic, and the increasing process leads to $a_2 l_{ao} + a_4 l_{ao}$ which only requires the addition of $a_2 l_{ao} + a_4 l_{ao}$ to become a seminvariant of the sextic. A more important advantage, springing from the new form of $\Omega$, arises from the fact that if

$$\sum (n-k)a_{nk} d \frac{d}{dx} = 0;$$

the sums of powers $\sum a_{nk} d \frac{d}{dx} = 0$ all satisfy the equation $\Omega = 0$. Hence, excluding $a_0$ we may, in partition notation, write down the fundamental solutions of the equation, viz.

$$a_0(2), (3), (4), (n),$$

and say that with $a_0$ we have an algebraically complete system. Every symmetric function denoted by partitions, not involving the figure unity (say a non-unitary symmetric function), which remains unchanged by any increase of $n$, is also a seminvariant, and we may take if we please another fundamental system, viz.

$$a_0(2), (3), (5), (6),$$

Observe that, if we subject any symmetric function (here $p_{1,2}$) to the diminishing process, it becomes $\frac{p_{1,2}}{p_{1,2} + p_{2,1}}$. Next consider the solutions of $\Omega = 0$ which are of degree $\theta$ and weight $w$. The general term in a solution involves the product $a_{nk} l_{ao} + a_{nk} l_{ao} + \ldots + a_{nk} l_{ao}$ where $X_1 = x_1 + x_2 + \ldots + x_n$; the number of such terms that may appear depends upon the number of partitions of $e$ into $\theta$ or fewer parts limited not to exceed $n$ in magnitude. Let this number be denoted by $(\omega; \theta, n)$. In order to obtain the seminvariantants we would write down the $(\omega; \theta, n)$ terms each associated with a literal coefficient; if we now operated with $a_{nk}$ we obtain a linear function of $(\omega-1; \theta, n)$ products, for the vanishing of which the literal coefficients must satisfy $(\omega-1; \theta, n)$ linear equations; hence (with $\omega = 1, \theta = n$), $(\omega-1; \theta, n)$ linear equations. This theory is due to Cayley; its validity depends upon showing that the $(\omega-1; \theta, n)$ linear equations may be assumed arbitrarily, and the number of linearly independent solutions of $\Omega = 0$, of the given degree and weight, is precisely $(\omega; \theta, n)-(\omega-1; \theta, n)$.

Hence $(\omega; \theta, n)-(\omega-1; \theta, n)$ are given by the coefficient of $a_{\omega \theta}$ in the fraction

$$1 = a_0(1 - a_{1 \theta} - a_{2 \theta} - \ldots - a_{e \theta})$$

and since this expression is unaltered by the interchange of $n$ and $\theta$ we prove Hermite’s Law of Reciprocity, which states that the algebraic forms of degree $\theta$ for the $n$’th are equinumerous with those of degree $n$ for the $\theta$’th.

The degree of the covariant in the variables is $e = n - 2w$; consequently we are only concerned with positive terms in the developments and $(\omega; \theta, n)-(\omega-1; \theta, n)$ will be negative unless $n - 2w \geq 0$. It is convenient to enumerate the seminvariants of degree $0$ and order $e = n - 2w$ by a generating function; so, in the first written generating function for seminvariants, write $\frac{1}{z^2}$ for $z$ and $\frac{1}{a^2}$ for $a$; we obtain

$$(\omega; \theta, n)-(\omega-1; \theta, n)$$

in which we have to take the coefficient of $a_{\omega \theta}$, the expansion being in ascending powers of $a$. As we have to do only with that part of the expansion which involves positive powers of $a$, we must try to isolate that portion, say $A(\omega)$.

For $n = 2$ we can prove that the complete function may be written

$$A(\omega) = \frac{1}{a^2}$$

and this is the reduced generating function which tells us, by its denominator factors, that the complete system of the quadratic is composed of the form itself, $1 l_{ao}$ shown by $a_2$, and of the Hessian of degree order 2, $o$ shown by $a^2$.

Again, for the cubic, we can find

$$A(\omega) = \frac{1}{a^3}$$

where the ground forms are indicated by the denominator factors, viz.: these are the cubic itself of degree order 1, 3; the Hessian of degree order 2, 2; the cubi-covariant of degree order 3, 3, and the quartic invariant of degree order 4, 0. Further, the numerator factor establishes that these are not all algebraically independent, but are connected by a syzygy of degree order 6, 6.

Similarly for the quartic

$$A(\omega) = \frac{1}{a^4}$$

establishing the 5 ground forms and the syzygy which connects them.

The process is not applicable with complete success to quintic and higher orders binary forms. This arises from the circumstance that the simple syzygies between the ground forms are not all independent, but are connected by second syzygies, and these again by third syzygies, and so on; this introduces new denominators which have not been completely overcame. As regards invariants a little further progress has been made by Cayley, who established the two generating functions for the quintic

$$1 = a^5$$

and for the sextic

$$1 = a^6$$

Accounts of further attempts in this direction will be found in Cayley’s Memoirs on Quaternics (Collected Papers), in the papers of Sylvester and Franklin (Amer. J. I.-iv.), and in Elliott’s Algebra of Quaternics, chap. viii.

Perpetuants.—Many difficulties, connected with binary forms of finite order, disappear altogether when we come to consider the
form of infinite order. In this case the ground forms, called also permutants, have been enumerated and actual representative seminvariant forms established. Putting $r$ equal to $\infty$, in a generating function obtained by using the fact that the function, which enumerates the asyzygetic seminvariants of degree $\theta$, is

$$\frac{1}{1-x^{r}+x^{2r}+x^{3r}+...+x^{\theta r}}$$

that is to say, of the weight $\omega$, we have one form corresponding to each non-unitary partition of $\omega$ into the parts $2, 3, 4, \ldots \theta$. The extraordinary advantage of the transformation of $\Omega$ to association with non-unitary symmetric functions is now apparent; for we may take, as representative forms, the symmetric functions which are symbolically denoted by the partitions referred to. *Ex. gr.*, of degree 3 weight 8, we have the two forms $(z^{2}a^{2})$, $a(z^{2})$. If we wish merely to enumerate those whose partitions contain the figure $\theta$, and do not therefore contain any power of $\theta$ as a factor, we have the generator

$$\frac{z^{2}}{1-z^{2}+z^{4}-z^{6}}$$

If $\theta=2$, every form is obviously a ground form or permutant, and the series of forms is denoted by $(z^{2})$, $(z^{4})$, $(z^{6})$, $(z^{8})$, ..., and obviously $i^{}\times \ldots +<r$ portion of some dictionary which is asyzygetic but not so in the case of $\theta=3$. Similarly, if $\theta=3$, every form $(z^{3}a^{2})$ is a permutant. For these two cases the permutants are enumerated by

$$\frac{1}{1-z^{3}} \text{ and } \frac{1}{1-z^{2}}$$

respectively.

When $\theta=4$, it is clear that no form, whose partition contains a part 3, can be reduced; but every form, whose partition is composed of the parts 4 and 2, is by elementary algebra reducible by means of permutants of degree 2. These latter forms are enumerated by

$$\frac{1}{1-z^{2}} \text{ and } \frac{1}{1-z^{4}}$$

and the general form of permutants is $(z^{4}a^{2} z^{6}a^{2} z^{8})$.

When $\theta=5$, the reducible forms are connected by syzygies which there is some difficulty in enumerating. Sylvester, Cayley and MacMahon succeeded, by a laborious process, in establishing the generators for $\theta=6$, and $\theta=6$, viz.

$$\frac{1}{1-z^{2}} \text{ and } \frac{1}{1-z^{4}} \text{ and } \frac{1}{1-z^{6}}$$

the but the best method of procedure is that of Stroh which we are about to explain.

Method of Stroh.—In the section on "Symmetric Functions," it was noted that Stroh considers

$$(a_{0}+a_{1}z^{2}+a_{2}z^{4}+...+a_{\theta}z^{2\theta})$$

where $a_{0}+a_{1}+...+a_{\theta}=0$ and $a_{0}+a_{1}+...+a_{\theta}=a_{\theta}$ symbolically, to be the fundamental form of seminvariant of degree $\theta$ and weight $\omega$; he observes that every form of this degree and weight is a linear function of such symbolic expressions. We may write

$$(1+z)(1+z^{2})(1+z^{4})\ldots (1+z^{2\theta})=1+A_{2}z^{2}+A_{4}z^{4}+...+A_{2\theta}z^{2\theta}$$

If we expand the symbolic expression by the binomial theorem, and remember that any symbolic product $a_{0}a_{1}a_{2}...a_{\theta}$ retains the same value, however the suffixes be permuted, we shall obtain a sum of terms, such as $a_{0}a_{1}a_{2}...a_{\theta}$ $z^{s_{1}+s_{2}+...+s_{\theta}}$, which in real form is $a_{0}a_{1}a_{2}...a_{\theta}$ $S_{1}'S_{2}'...S_{\theta}'$...; and, if we express $S_{1}'S_{2}'...$ in terms of $A_{0}$, $A_{2}$, $A_{4}$, and arrange the whole as a linear function of products of $A_{0}$, $A_{2}$, ..., each coefficient will be a seminvariant, and the aggregate of the coefficients will give us the complete asymptotic system of the given degree and weight. When the proper degree $\theta$ is $< \omega$ a factor $a_{\theta-9}$ must be of course understood.

*Ex. gr.*

$$\frac{1}{1-z^{2}}(a_{0}+a_{1}z^{2}+a_{2}z^{4}+...+a_{\theta}z^{2\theta})=a_{0}+a_{1}z^{2}+a_{2}z^{4}+...+a_{\theta}z^{2\theta}$$

In general the coefficient, of any product $A_{0}A_{2}A_{4}...A_{2\theta}$, will have, as coefficient, a seminvariant which, when expressed by partitions, will have as leading partition (preceding in dictionary order all others) the partition $(\gamma_{2} \gamma_{4} \gamma_{6} \ldots \gamma_{2\theta})$. Now the symbolic expression of the seminvariant can be expanded by the binomial theorem so as to be exhibited as a sum of products of seminvariants, of lower degrees if $\alpha_{0}+\alpha_{2}+...+\alpha_{2\theta}$ can be broken up into any two portions

$$(\alpha_{0}+\alpha_{2}+...+\alpha_{2\theta})=(\alpha_{1}+\alpha_{3}+...+\alpha_{2\theta})+(\alpha_{0}+\alpha_{2}+...+\alpha_{2\theta})$$

such that $\alpha_{1}+\alpha_{3}+...+\alpha_{2\theta}=0$, for then

$$a_{1}+a_{3}+...+a_{2\theta}=0$$

and each portion raised to any power denotes a seminvariant.

Stroh assumes that every reducible seminvariant can in this way be reduced. The existence of such a relation, as $\alpha_{0}+\alpha_{2}+...+\alpha_{2\theta}=0$, necessitates the vanishing of a certain function of the coefficients $A_{0}, A_{2}, ...$, and we can omit one of these coefficients which can be eliminated from the expanding form and no seminvariant, which appears as a coefficient to such a product (which may be the whole or only a part of the complete product, with which the seminvariant is associated), will be capable of reduction. *Ex. gr.* for $\theta=2$, $(a_{0}+a_{2}z^{2})$; either or $v_{2}$ will vanish if $\alpha_{0}+\alpha_{2}=A_{0}=0$; but every term, in the development, is of the form $(222...A_{3}A_{5})$ and therefore vanishes; so that none are left to undergo reduction. Therefore every form of degree 2, except of course that one whose weight is zero, is a permutant. The generating function is

$$k^{2}=1-z^{2}$$

For $\theta=3, (a_{0}+a_{2}+a_{3}z^{3})$; the condition is clearly $\alpha_{0}+\alpha_{2}+\alpha_{3}=A_{0}=0$, and since every seminvariant, of proper degree 3, is associated, as coefficient, with a product containing $A_{0}$, all such are permutants. The general form is $(z^{3}a^{2})$ and the generating function

$$k^{2}=1-z^{2}$$

For $\theta=4, (a_{0}+a_{2}+a_{3}+a_{4}z^{4})$; the condition is $\alpha_{0}+\alpha_{2}+\alpha_{3}+\alpha_{4}+\alpha_{5}+...+\alpha_{4}=0$; and we can determine the lowest weight of a permutant; in the quantities $\sigma$ is

$$2\sigma+(2\sigma)^{2}+(2\sigma)^{3}+...+\frac{1}{2}(2\sigma)^{\frac{3}{2}}=2\sigma^{\frac{3}{2}}-1=2\sigma^{\frac{3}{2}}-1.$$
The general term of a seminvariant of degree $\theta$, $\theta'$ and weight $w$ will be

$$a_0 a_\theta^2 a_{\theta'} + a_1 a_\theta a_{\theta'} + \cdots + a_n,$$

where $a_i = \delta_{\theta+\theta', \theta}$.

The number of such terms is the number of partitions of $w$ into $\theta+\theta'$ parts, the part magnitudes, in the two portions, being limited not to exceed $\theta$ and $\theta'$ respectively. Denote this number by $\delta(\theta, \theta', w) \equiv \delta(\theta+\theta')$. The number of linearly independent seminvariants of the given type will then be denoted by

$$\delta(\theta, \theta', w) \equiv \delta(\theta+\theta')$$

and will be given by the coefficient of $\delta(\theta+\theta')$ in

$$1 - a_0 - a_1 z - a_2 z^2 - \cdots = 1 - b_0 - b_1 z - b_2 z^2 - \cdots$$

that is, by the coefficient of $z^w$ in

$$1 - \theta z - \theta' z^2 - \cdots = 1 - \theta z - \theta' z^2 - \cdots = 1 - \theta z - \theta' z^2 - \cdots = 1 - \theta z - \theta' z^2 - \cdots$$

which preserves its expression when $\theta$ and $\theta'$ and $\theta$ and $\theta$ are separately or simultaneously interchanged.

Taking the first generating function, and writing $a=a_0$, $b=a_1$, $c=a_2$, $\cdots$ for $a$, $b$ and $c$ respectively, we obtain the coefficient of $a_0 a_{\theta} a_{\theta'}$ in

$$1 - a_0 - a_1 z - a_2 z^2 - \cdots = 1 - b_0 - b_1 z - b_2 z^2 - \cdots,$$

the unreduced generating function which enumerates the coefficients of degrees $\theta$, $\theta'$ in the coefficients and order in the variables. Thus, for two linear forms, $p=q=1$, we find

$$1 - a_0 - b_0 z = 1 - a_0 - b_0 z,$$

the positive part of which is

$$1 - a_0 - \frac{a_0}{z} = 1 - a_0 - \frac{a_0}{z}$$

establishing the ground forms of degree-order (1; 1; 1), (1; 1; 1), (1; 1; 1), (1; 1; 0), viz.:—the linear forms themselves and their Jacobian $J_a$. Similarly, for a linear and a quadratic, $p=1$, $q=2$, and the reduced form is found to be

$$1 - a_0 z^2 \frac{a_0}{z} = 1 - a_0 z^2 \frac{a_0}{z},$$

where the denominator factors indicate the forms themselves, their Jacobian, the invariant of the quadratic and their resultant; connected, as shown by the numerator, by a syzygy of degrees $1, 2, 3$.

The complete theory of the perpetuants appertaining to two or more forms of infinite order has not yet been established. For two forms the seminvariants of degrees $1, 1$ are enumerated by

$$1 - a_0 = 1 - a_0$$

and the only one which is reducible is $a_0 b_0$ of weight zero; hence the perpetuants of degrees $1, 1$ are enumerated by

$$1 - a_0^{-1} - a_0^{-1} = 1 - a_0^{-1} - a_0^{-1}$$

and the series is evidently

$$a_0 b_0 = a_0 b_0,$n

one for each of the weights $1, 2, 3, \cdots$ ad infinitum.

For the degrees $1, 2$, the asyzygetic forms are enumerated by

$$1 - a_0^{-1} - a_0^{-1} = 1 - a_0^{-1} - a_0^{-1}$$

and the actual forms for the first three weights are

$$a_0 b_0 = a_0 b_0,$n

amongst these forms are included all the asyzygetic forms of degrees $1, 1$, multiplied by $a_0 b_0$, and all the perpetuants of the second binary form multiplied by $a_0 b_0$; hence we have to subtract from the generating function

$$\frac{1}{1 - a_0 z^2 \frac{a_0}{z}}$$

and obtain the generating function of perpetuants of degrees $1, 2$.

The first perpetuant is the last semivariant written, viz.:

$$a_0 b_0 (a_0 b_0 - 2 a_0 b_0 - a_0 b_0 - a_0 b_0)$$

or, in partition notation,

$$a_0 b_0 (a_0 b_0 - 2 a_0 b_0 - a_0 b_0 - a_0 b_0).$$

and in this form it is at once seen to satisfy the partial differential equation. It is important to notice that the expression

$$(\theta + \theta')(\theta + \theta') - (\theta + \theta')(\theta + \theta') + (\theta + \theta')(\theta + \theta') - \cdots = (\theta + \theta')(\theta + \theta')$$

denotes a seminvariant, if $\theta + \theta'$, be neither of them unity, for, after operation, the terms destroy one another in pairs: when $\theta = 0$, $(\theta + \theta')$ must be taken to denote $\theta$ and so for $\theta'$. In general it is a seminvariant of degrees $\theta$, $\theta'$, and weight $\theta + \theta'; z$; to this there is an exception, viz., when $\theta = 0$, or when $\theta = 0$, the corresponding partial degrees are $1$ and $1$. When $\theta = 0$, or we have the general perpetuant of degrees $1$. There is a still more general form of seminvariant; we may instead of $\theta, \theta'$ any collections of non-unitary integers not exceeding $\theta, \theta'$ in magnitude respectively, Ex. gr.

$$(2\theta z^2 + \theta' z^3)^2 - (2\theta z^2 + \theta' z^3)^2 - (2\theta z^2 + \theta' z^3)^2$$

is a seminvariant, and since these forms are clearly enumerated by

$$1 - a_0^{-1} - a_0^{-1} = 1 - a_0^{-1} - a_0^{-1}$$

an expression which also enumerates the asyzygetic seminvariants, we may regard the form, written, as denoting the general form of asyzygetic seminvariant; a very important conclusion. For the case in hand, from the simplest perpetuant of degrees $1, 2$, we derive the perpetuants of weight $w$

$$a_0 b_0 = a_0 b_0,$n

and

$$a_0 b_0 = a_0 b_0,$n

as a series of $\frac{1}{w-2}$ or of $\frac{1}{w-1}$ forms according as $\theta$ is even or

un even. Their number for any weight $w$ is the number of ways of composing $w-3$ with the parts $1, 2$, and thus the generating function is verified. We cannot, by this method, easily discuss the perpetuants of degrees $2, 2$, because a syzygy presents itself as early as weight $2$. It is better now to proceed by the method of Stroth.

We have the symbolic expression of a seminvariant.

$$a_0 b_0 = a_0 b_0,$n

where

$$a_0 b_0 = a_0 b_0,$n

and

$$a_0 b_0 = a_0 b_0,$n

One proceeding as we did in the case of the single binary form we find that for a given total degree $\theta + \theta'$, the condition which expresses reducibility is of total degree $2\theta + 2\theta' - 2$ in the coefficients $\theta$ and $\theta'$; combining this with the knowledge of the generating function of asyzygetic forms of degrees $\theta, \theta'$, we find that the perpetuants of these degrees are enumerated by

$$2\theta + 2\theta' - 2 = 1$$

and this is true for $\theta + \theta' = 2$ as well as for other values of $\theta + \theta'$ (compare the case of the single binary form).

Observe that, if there are more than two binary forms, the weight of the simplest perpetuant of degrees $\theta$, $\theta'$, ..., is $2\theta + 2\theta' - n - 1$, as can be seen by reasoning of a similar kind.

To obtain information concerning the actual forms of the perpetuants, write

$$(1 + a_0 b_0)(1 + a_0 b_0)...(1 + a_0 b_0) = 1 + A_1 A_2 A_3 + \cdots + A_2 A_3 A_4 A_5$$

and

$$(1 + a_0 b_0)(1 + a_0 b_0)...(1 + a_0 b_0) = 1 + B_1 B_2 B_3 + \cdots + B_2 B_3 B_4 B_5$$

where

$$A_1 + B_1 = 0.$$n

For the case $\theta = 0$, $\theta' = 1$, the condition is

$$a_0 b_0 = a_0 b_0,$n

which since $A_1 + B_1 = 0$, is really a condition of weight unity. For $w = t$ the form is $A_0 A_1 + A_2$, which we may write $a_0 b_0 = a_0 b_0 = a_0 b_0 = a_0 b_0 = a_0 b_0 = a_0 b_0 = a_0 b_0 = a_0 b_0 = a_0 b_0$. The remaining perpetuants, enumerated by $\frac{1}{w-2}$, have been set forth above.

For the case $\theta = 1$, $\theta' = 2$, the condition is

$$a_0 b_0 = a_0 b_0,$n

and the simplest perpetuant, derived directly from the product $A_0 B_2$, is $(1 + a_0 b_0)^2$; the remainder of those enumerated by

$$1 - \theta z - \theta' z^2$$

may be represented by the form

$$(1 + a_0 b_0)(1 + a_0 b_0)...(1 + a_0 b_0) = A_1 A_2 A_3 B_4 B_5$$

where

$$A_1 + B_1 = 0.$$n

To represent the simplest perpetuant, of weight $7$, we may take as base either $A_0 B_2 B_3$ or $A_0 B_2 B_3$ and since $A_1 + B_1 = 0$ the former is equivalent to $A_0 A_1 B_2$ and the latter to $A_0 A_1 B_2$; so that we have,
apparently, a choice of four products. \( A^2B_3 \) gives \((2^4)(21) = (21) (21) \), and \( A_2B_2(2^2)(21) = (21) (21) \); these two merely differ in sign; and similarly \( A^2B_3 (2^2)(21) \) yields \((2^2)(21) - (2^2)(21) \), and that due to \( A_2B_3 \) merely differs from it in sign. We will choose from the forms in such manner that the product of letters \( A \) is either a power of \( A \), or does not contain \( A \); this rule leaves us with \( A^2B_3 \) and \( A_2B_3 \); of these forms we will choose that one which in letters \( B \) is earliest in ascending dictionary order; this is \( A_2B_3 \), and our earliest permutation is

\[
(2^3)(21) = (21)(21),
\]

the general form and the alphabet form enumerated by the generating function

\[
\frac{1}{(1-z)(1-z^2)} = \left( \frac{1}{1-z} - \frac{1}{1-z^2} \right).
\]

For the case \( \theta = 1 \), \( \theta' = 3 \), the condition is

\[
s_1r_1r_2(r_1 + r_2)(r_1 + r_2)(r_1 + r_2)(r_1 + r_2). \]

The calculation results in

\[
A_3B_3 - A_2B_3 + A_1B_3 - A_1B_3 = 0.
\]

The simplest permutation of weight \( 7 \); and taking the general form enumerated by the generating function

\[
\frac{1}{1-z - z^2 - z^3} = \left( \frac{1}{1-z} - \frac{1}{1-z^2} - \frac{1}{1-z^3} \right).
\]

For the case \( \theta = 2 \), \( \theta' = 3 \), the condition is

\[
s_2r_2r_3(r_2 + r_3)(r_2 + r_3)(r_2 + r_3). \]

The simplest permutation of weight \( 7 \); and taking the general form enumerated by the generating function

\[
\frac{1}{1-z - z^2 - z^3} - \frac{1}{1-z^2 - z^3} = \left( \frac{1}{1-z} - \frac{1}{1-z^2} - \frac{1}{1-z^3} \right).
\]

For the case \( \theta = 2 \), \( \theta' = 4 \), the condition is

\[
s_3r_3r_4(r_3 + r_4)(r_3 + r_4)(r_3 + r_4)(r_3 + r_4). \]

The calculation results in

\[
A_3B_3 + A_2B_3 + A_1B_3 - A_1B_3 = 0.
\]

The simplest permutation of weight \( 7 \); and taking the general form enumerated by the generating function

\[
\frac{1}{1-z - z^2 - z^3} - \frac{1}{1-z^2 - z^3} = \left( \frac{1}{1-z} - \frac{1}{1-z^2} - \frac{1}{1-z^3} \right).
\]

The fundamental fact that he discovered was the invariance of \( x^2 + 2 \cos \omega y + y^2 \), viz.

\[
x^2 + 2 \cos \omega y + y^2 = X^2 + 2 \cos \omega Y + Y^2,
\]

which from it appears that the Boolean invariants of \( ax^2 + 2bxy + cy^2 \) are nothing more than the full invariants of the simultaneous quadratics

\[
ax^2 + 2bxy + cy^2,
\]

the word invariant including here covariant. In general the Boolean system, of the general \( n^2 \), is coincident with the simultaneous system of the \( 2n \) and the quadratic \( x^2 + cy^2 \).

Orthogonal System. In particular, if we consider the transformation from one pair of rectangular axes to another pair of rectangular axes we obtain an orthogonal system which we shall now briefly inquire into. We have

\[
\cos \omega = \cos \omega = \sin \omega x_1 = \sin \omega x_1 = \cos \omega x_1 = \cos \omega x_1 = \sin \omega x_1 = \sin \omega x_1,
\]

with modulus unity. This is called the direct orthogonal substitution, because the sense of rotation from the axis of \( x_1 \) to the axis of \( X_1 \) is the same as that from the origin of \( x_1 \) to that of \( x_1 \). If the sense of rotation be opposite we have the skew orthogonal substitution

\[
\cos \omega = \sin \omega x_1 = \sin \omega x_1 = \cos \omega x_1 = \cos \omega x_1 = \sin \omega x_1 = \sin \omega x_1 = \cos \omega x_1 = \cos \omega x_1 = \sin \omega x_1 = \sin \omega x_1 = \cos \omega x_1,
\]

with modulus unity. This is called the skew orthogonal substitution, because the sense of rotation from the axis of \( x_1 \) to the axis of \( X_1 \) is the same as that from the origin of \( x_1 \) to that of \( x_1 \). If the sense of rotation be opposite we have the skew orthogonal substitution

\[
\cos \omega = \sin \omega x_1 = \sin \omega x_1 = \cos \omega x_1 = \cos \omega x_1 = \sin \omega x_1 = \sin \omega x_1 = \cos \omega x_1 = \cos \omega x_1 = \sin \omega x_1 = \sin \omega x_1 = \cos \omega x_1,
\]

with modulus unity. This is called the skew orthogonal substitution, because the sense of rotation from the axis of \( x_1 \) to the axis of \( X_1 \) is the same as that from the origin of \( x_1 \) to that of \( x_1 \). If the sense of rotation be opposite we have the skew orthogonal substitution

\[
\cos \omega = \sin \omega x_1 = \sin \omega x_1 = \cos \omega x_1 = \cos \omega x_1 = \sin \omega x_1 = \sin \omega x_1 = \cos \omega x_1 = \cos \omega x_1 = \sin \omega x_1 = \sin \omega x_1 = \cos \omega x_1,
\]

with modulus unity. This is called the skew orthogonal substitution, because the sense of rotation from the axis of \( x_1 \) to the axis of \( X_1 \) is the same as that from the origin of \( x_1 \) to that of \( x_1 \). If the sense of rotation be opposite we have the skew orthogonal substitution

\[
\cos \omega = \sin \omega x_1 = \sin \omega x_1 = \cos \omega x_1 = \cos \omega x_1 = \sin \omega x_1 = \sin \omega x_1 = \cos \omega x_1 = \cos \omega x_1 = \sin \omega x_1 = \sin \omega x_1 = \cos \omega x_1,
\]

with modulus unity. This is called the skew orthogonal substitution, because the sense of rotation from the axis of \( x_1 \) to the axis of \( X_1 \) is the same as that from the origin of \( x_1 \) to that of \( x_1 \). If the sense of rotation be opposite we have the skew orthogonal substitution

\[
\cos \omega = \sin \omega x_1 = \sin \omega x_1 = \cos \omega x_1 = \cos \omega x_1 = \sin \omega x_1 = \sin \omega x_1 = \cos \omega x_1 = \cos \omega x_1 = \sin \omega x_1 = \sin \omega x_1 = \cos \omega x_1,
\]
Consider the binary \( n^4 \), \((a_1x_1 + a_2x_2)^4 = a_4^n \), and the direct substitution
\[ x_1 = \lambda X_1 - \mu X_2, \quad x_2 = X_1 + \lambda X_2, \]
where \( \lambda^2 + \mu^2 = 1; \lambda, \mu \) replacing cos \( \theta \), sin \( \theta \) respectively. In the notation
\[ a_4 = a_1x_1 + a_2x_2, \]
observe that
\[ a_4 = a_1^4 + a_2^4, \]
Suppose that
\[ a_4 = 2x_1 x_2 \]
is transformed into
\[ A_4 = B_4 = C_4 = \cdots \]
then of course \((AB) = (ab)\) the fundamental fact which appertains to the general linear substitution; now here we have additional and equally fundamental facts; for since
\[ A_1 = a_1^2 + a_2^2, \quad A_2 = a_1^2 + a_2^2, \quad A_4 = a_1^4 + a_2^4; \]
\[ (A_1) = a_1^4 + a_2^4, \quad (A_2) = a_1^4 + a_2^4; \]
\[ (X_1) = x_1^2 + x_2^2, \quad (X_2) = x_1^2 + x_2^2; \]
showing that, in the present theory, \( a_1, a_2, a_3, a_4 \) possess the invariant property.

The general form of covariant is therefore
\[ (ab)^4 (ac)^4 (bc)^4 a_1^4 a_2^4 a_3^4 a_4^4 \]
\[ (x_1) = x_1^2 + x_2^2 a_1^2 + a_2^2 a_3 + a_4 = \cdots \]
\[ = (ab)^4 (ac)^4 (bc)^4 a_1^4 a_2^4 a_3^4 a_4^4 \]
\[ (X_1) = x_1^2 + x_2^2 a_1^2 + a_2^2 a_3 + a_4 = \cdots \]
If this be of order \( e \) and appertain to an \( n^e \).

viz., the symbols \( a, b, c, \ldots \) must each occur \( n \) times. It may denote a simultaneous orthogonal invariant form of orders \( n_1, n_2, n_3, \ldots \); the symbols must then present themselves \( n_1, n_2, n_3, \ldots \), times respectively. The number of different symbols \( a, b, c, \ldots \) denotes the degree \( \theta \) of the covariant in the coefficients. The coefficients of the covariants are homogeneous, but not in general isobaric functions, of the coefficients of the original form or forms. Of the above general form of covariant there are important transformations due to the symbolic identities:
\[ (ab)^4 = a_1^4 + a_2^4 \]
\[ (x_1) = x_1^2 + x_2^2 a_1^2 + a_2^2 a_3 + a_4 = \cdots \]
as a consequence any even power of a determinant factor may be expressed in terms of the other symbolic factors, and any uneven power may be expressed as the product of its first power and a function of the other symbolic factors.

Hence in the above general form of covariant we may suppress some of the exponents
\[ b_1, b_2, b_3, b_4, b_5, \ldots \]
if the determinant factors to be, each of them, either zero or unity. Or, if we please, we may leave the determinant factors untouched and consider the exponents \( i_1, i_2, i_3, i_4, i_5, \ldots \), to be each of them, either zero or unity. Or, lastly, we may leave the exponents \( b, j, k, l, \ldots \), untouched and consider the product
\[ a_1^{i_1} a_2^{i_2} a_3^{i_3} a_4^{i_4} \]
to be reduced either to the form \( g^n \), where \( g \) is a symbol of the series \( a, b, c, \ldots \), or to a power of \( x_4 \).

To assist us in handling the symbolic products we have not only the identity
\[ (ab)^2 = (bc) a_1 + (ac) b_2 = 0, \]
but also
\[ (ab)^2 = (ac) + (bc) a_1 a_2 + (ac) b_2 = 0, \]
and many others which may be derived from these in the manner which will be familiar to students of the works of Aronhold, Clebsch and Gordan. Previous to continuing the general discussion it is useful to have before us the orthogonal invariants and covariants of the binary linear and quadratic forms.

For the linear forms \( a_1 x_1 + a_2 x_2 \), \( a_3 = a_4 = a_5 = a_6 = a_7 = a_8 = a_9 \), there are four fundamental forms
\[ (i.) \quad a_3 = a_2x_1 + a_6x_2 \]
\[ (i) \quad a_3 = a_2x_1 + a_6x_2 \]
\[ (ii.) \quad (x_1) = a_1^2 + a_2^2 a_3 \]
\[ (ii) \quad (x_1) = a_1^2 + a_2^2 a_3 \]
\[ (iii.) \quad (x_1) = a_1^2 + a_2^2 a_3 \]
\[ (iv.) \quad (x_1) = a_1^2 + a_2^2 a_3 \]
respectively. Every other concomitant is a rational integral function of these four forms. The linear covariant, obviously the Jacobian of \( a_3 \), and \( x_1 \) is the line perpendicular to \( a_3 \), and the vanishing of the quadriinvartant \( a_4 \) is the condition that \( x_1 \) passes through one of the circular points at infinity. In general any pencil of lines, connected with the line \( a_3 \), by descriptive or metrical properties, has for its equation a rational integral function of the four forms equated to zero.

For the quadratic \( a_2x_1^2 + 2a_3x_1x_2 + a_2x_2^2 \), we have
\[ a_4 = a_2 + 2a_3 + a_2 = \cdots \]

This is the fundamental system; we may, if we choose, replace \((ab)\) by \(a_3 = a_2 + 2a_3 + a_2\).

There is no linear covariant, since it is impossible to form a symbolic product which will contain \( x_1 \) and at the same time appertain to a quadratic. (v.) is the Jacobian; geometrically it denotes the bisectors of the angles between the lines \( a_2 \) or, as we may say, the common harmonic conjugates of the lines \( a_2 \) and \( a_2 \).

The linear invariant \( a_4 \) is such that, when equated to zero, it determines the lines \( a_2 \) as harmonically conjugate to the lines \( x_1 \); or, in other words, it is the condition that \( a_2^2 \) may denote lines at right angles.

and sustained a reverse; but on the 12th he again attacked the enemy, whose fleet was double his own strength, and inflicted on them a complete defeat. The important international conference on Moroccan affairs, which resulted in an agreement between France and Germany, was held at Algeciras from the 16th of January to the 7th of April 1906. (See MOROCCO.)

**ALGER OF LIÈGE—ALGERIA**

**ALGER OF LIÈGE** (d. 1131), known also as Alger of Cluny and Algerus Magister, a learned French priest who lived in the first half of the 12th century. He was a canon of the church of St. Bartholomew at Liège, his native town, and was then appointed (c. 1100) to the cathedral church of St. Lambert. He declined many offers from German bishops and finally retired to the monastery of Cluny, where he died about 1131 at a great age, and was reputed to be a man of charity and intelligence. His History of the Church of Liège, and many of his other works, are lost. The most important of those still extant are: 1. *De Misericordia et Justitia*, a collection of biblical and patristic extracts with a commentary (an important work for the history of church law and discipline), which is to be found in the *Anecdota* of Martène, vol. v. 2. *De Sacramentis Corporis et Sanguinis Domini*; a treatise, in three books, against the Berengarian heresy, highly commended by Peter of Cluny and Erasmus. 3. *De Gratia et Libri Arbitrio*, given in B. Per's *Anecdola*, vol. iv. (See further *Collectio Vet.* of Angelo Malo, vol. ix. p. 371.)

**ALGER, RUSSELL ALEXANDER** (1836-1907), American soldier and politician, was born in Lafayette township, Medina county, Ohio, on the 27th of February 1836. Left an orphan at an early age, he worked on a farm to pay his expenses at Richfield (Ohio) Academy, was a schoolmaster for two winters, and, having studied law in the meantime, was admitted to the bar in 1859. He began practice at Cleveland, Ohio, but early in 1860 he removed to Michigan, where he abandoned his profession and engaged in the lumber business. Enlisting in a Michigan cavalry regiment in September 1861, he rose from captain to colonel, distinguished himself in the Gettysburg campaign and under Sheridan in the Shenandoah Valley, and in 1864 and 1865 respectively received the brevets of brigadier-general and major-general of volunteers. After the war he invested extensively in pine lands in Michigan, and accumulated a large fortune in the lumber business. In 1864 he was elected governor of Michigan on the Republican ticket, serving from 1885 to 1887. In 1889-1890 he was commander-in-chief of the Grand Army of the Republic. From 1897 to 1899 he was secretary of war in President McKinley's cabinet. His administration of the war department during the Spanish-American War was severely criticized for extravagance in army contracts, for unpreparedness, and for general inefficiency, charges which he answered in his *The Spanish-American War* (1901). The extent of his personal responsibility is at least uncertain. In 1902 he was appointed by the governor of Michigan, and in 1903 was elected by the state legislature, as United States senator to complete the unexpired term of James McMillan (1838-1902). He died at Washington, D.C., on the 24th of January 1907.

**ALGERIA** (Algérie), a country of North Africa belonging to France, bounded N. by the Mediterranean, W. by Morocco, S. by the Sahara and E. by Tunisia. The boundaries, however, are in part not accurately determined. Algeria extends for about 690 m. along the coast, and stretches inland from 320 to 360 m., lying between 2° 16' W. and 8° 50' E., and 33° and 37° N. It is divided, politically, into three departments—Oran in the west, Algiers in the centre and Constantine in the east. Its area is 184,474 sq. m., exclusive of the dependent Saharan regions, which have an area of some 750,000 sq. m. (see SAHARA, TUAT, &c.).

**Physical Features.**—The character of the Algerian coast is severe and inhospitable. The western half is bordered by a hilly rampart, broken only here and there, in the bays where the larger streams find their outlet, by flat and sandy plains. Between Delys and Philippeville high mountains rise almost sheer from the sea, leaving only a narrow strip of beach. East of Philippeville the mountains recede from the coast, and the rampart of hills reappears. Only between Bona and La Calle is the general character of the sea-board low and sandy. Save near the towns and in the cultivated district of Kabylie, the coast is bare and uninhabited; and in spite of numerous indentations, of which the most important going from west to east are the Gulf of Oran, the Gulf of Algeciras, the Bay of Algiers, and the gulfs of Bougie, Stora and Bona, there are few good harbours. From time immemorial, indeed, this coast has had an evil reputation among mariners, quite apart from the pirates who for centuries made it the base of their depredations. A violent current, starting from the Straits of Gibraltar, runs southward along the shore, hurls back from the headlands, is deflected to the west. In summer the east wind brings dense and sudden fogs; while in winter the northerly gales blow straight into the mouths of the harbours. In these circumstances navigation is especially perilous for sailing craft. The terrors of this "savage sea and inhospitable shore," once described by Sallust, have, however, been greatly mitigated by the introduction of steam, the improvement of the harbours, and the establishment by the French government of an excellent system of lighthouses.

The coast ranges from sea to country falls naturally into three divisions, clearly distinguished by their broad physical characteristics. The healthy, and on the whole fertile coast region, from 50 to 100 m. in width, is known, as in Morocco and Tunisia, as the Tell (Arabic for "hill"). It is a mountainous country intersected with rocky canons and fertile valleys, which occasionally broaden out into alluvial plains like that of the Shelif, or the Metija near Algiers, or those in the neighbourhood of Oran and Bona. Behind the Tell is a lofty table-land with an average elevation of 1000 ft., consisting of vast plains, for the most part arid or covered with sparse grass, in the depressions of which are great salt lakes and swamps (Arabic, *skat*) fed by streams which can find no outlet to the sea through the encircling hills. To the south this region is divided by the Great Atlas from the deserts of the Sahara, with its oases, in which the boundary of Algeria is lost.

The country is traversed by lofty ranges of the Atlas system, which run nearly parallel to the coast, and rise in places over 7000 ft. These are commonly divided into two leading chains, distinguished as the Great1 and Little Atlas. The Great, or Saharan Atlas contains the highest peaks in the country. The chief ranges are Ksour and Amara in the west and the Aures in the east. The peak of Tellia, the highest point in Algeria, in the Aures range, has a height of 7611 ft. In the Amar are Jebel Ksel (6594 ft.) and Tuilla Makna (6561 ft.). The Little Atlas, otherwise the Tell or Maritime Atlas, lies between the sea and the Saharan Atlas, and is composed of many distinct ranges, generally of no great elevation and connected by numerous transverse chains forming extensive table-lands and elevated valleys. The principal ranges of the Little Atlas—from west to east—are the Tiemcen (5500 ft.); the Warsenis (with Kef Sidi Omar, 6500 ft.); the Tifni (4900 ft.); the Jurfara, with the peak of Lalla Kedjii (7542 ft.) and Mount Babor (6447 ft.); and the Mejerdja (3700 ft.), which extends into Tunisia. The Jurfara range, forming the background of the plains between Algiers and Bougie, extends through the district of Kabylie, with which for grandeur of scenery no other part of Algeria can compare. South of the Jurfara and separated from it by the valley of the Sahel, is the Biban range with a famous double pass of the same name, through which alone access is gained to the highlands beyond. The Bibans or *Portes de fer* (Iron Gates) consist of two defiles with stupendous walls of rock, by which erosion have assumed the most fantastic shapes. In the case of the *Petite porte* the walls in some places are not more than twelve feet apart. The Dahra range (see MOSTAGANEM) overlooks the sea, and is separated from the Warsenis by the valley of the Shelif (see ATLAS MOUNTAINS, SAHARA and TUAT).

The rivers are numerous but the majority are short. Most

1 The name "Great" Atlas is more correctly applied to the main range in Morocco.
of them rise in the mountains near the coast, and rush down through deep and rocky channels. During the rainy season they render communication between different parts of the country extremely difficult. The most important river, both from its length and volume, is the Shelif. It rises on the northern slopes of the Amur mountains and flows N.E. across the high plateau, piercing the little Atlas between the Warsenis and Tiferi ranges. It then turns W. and reaches the Mediterranean at the eastern end of the Gulf of Arzew. The Shelif, which has many tributaries, is about 430 m. long. The Seybuse (about 150 m. long), formed by the union of several small streams in the department of Constantine, runs through a fertile valley and reaches the Mediterranean near Bona. The Sahel (about 100 m. long), which contains the greatest body of water after the Shelif, rises in the department of Algiers near Aumale, and flows for the most part N.E. to its mouth near Bougie. The Kebir or Rummel—the river is known by both names—is formed by the union of several small streams south of Constantine, and flows past that town N.W. 140 m. to the sea. Among the less important rivers which empty into the Mediterranean are the Macta, the Talma, the Harrach and the Mazafra. The Macta, but 3 m. long, enters the sea in the Gulf of Arzew, some 25 m. W. of the mouth of the Shelif. It is formed by the Habra (140 m.) and the Sig (130 m.), which rise in the Amur mountains and flowing north unite in a marshy plain, whence issues the Macta. On the lower courses of the Habra and the Sig, barrages have been built for irrigation purposes. The Habra barrage holds 38,000,000 cubic metres; that on the Sig 18,000,000. The Talma (about 100 m.) rises in a large cavern in the mountains south of Tlemcen and flows N.E. to the sea at Rachgun. It has many affluents; the largest, the Isser (70 m.), joins it on the east bank about 30 m. above its mouth. The Harrach (40 m.), a picturesque stream, enters the Mediterranean in the Bay of Algiers. The Mazafra (90 m.) crosses the plains S.W. of Algiers, reaching the sea N. of Kolea. The Mejerda and its affluent the Mellegue, rivers of Tunisia (q.v.), have their rise in Algeria, in the mountainous country east of Constantine. None of these rivers is navigable. Besides these there are a number of streams in the interior, but they are usually dry except in the rainy season.

Algeria abounds in extensive salt lakes and marshes. Of the lakes in the northern part of the country near the coast the principal are,—the Fexara, 14 m. S.W. of Bona; Sebkha and El Melah, south of Oran; and three small lakes in the immediate vicinity of La Calle. In the high plateaux are the Shat-el-Gharbi or Western Shat, the Shat-el-Shergui or Eastern Shat, the Zarhez-Gharbi and the Zarhez-Shergui, the Shat-el-Hodna and a number of others. South of the Jebel Aures is another series of salt lakes closely connected with the Shat-el-Jerid (of Tunisia). The chief of these is the Shat Melfir. There are a number of warm mineral springs, containing principally salts of lime, used with success by both Arabs and Europeans in several kinds of disease.

One of the most remarkable groups of springs is near Guelma, in the department of Constantine. There are two principal sources. Their waters unite in one stream whose course is marked by gigantic limestone cones, some of which are 36 ft. high. The water, which is at boiling point, falls into natural basins of a creamy white colour, formed by the deposit of carbonate of lime. The springs are known to the Arabs as Hammam Meskutin (the "accursed baths"). The name and the cones are accounted for by a legend which represents that at this spot lived a sheikh who, finding his sister too beautiful to be married to anyone else, determined to espouse her himself. While the marriage festivities were being celebrated the judgment of Heaven descended on the guilty pair; fire came from below; the water became hot and the sheikh and his sister were turned into stone. Within a mile of Hammam Meskutin are ferruginous and sulphureous springs.

[Geology.—The geology of Algeria has been worked out in considerable detail by French geologists. Rocks of Archean and Palaeozoic ages contribute only a small share, but there is a
very complete sequence of formations from the Lias to those of recent date. An interesting and orderly petrological sequence of Tertiary igneous rocks has been determined. Archean rocks form the cores of the ancient crystalline masses within the littoral zone from Algiers to Bona. They consist of gneiss, mica-schist, quartzites, crystalline limestones and conglomerates. Primary deposits are doubtfully represented by the detached fragments of unfossiliferous strata of Traras, Blida and east of Oranville. Carboniferous and Permian strata are possibly represented by some black and grey micaceous shales with beds of coal in the Jurjura. At Jebel-kahar and west of Traras, Pomel attributes certain conglomerates, red sandstones and purple and green shales to the Permian. The rocks of Secondary and Tertiary ages have been profoundly affected by the Alpine movements, and are thrown into a series of complex folds, so that in numerous instances their stratigraphy is imperfectly understood. The gypsiferous and siliferous marls of Shellata, Suk Abras and Ain Nessl have yielded Triassic fossils. Triassic rocks are considered to be present in Constantine and in the Jurjura. Rhaetic beds (Infra Lias), consisting of dolomites and siliceous limestones, have been recognized at Saida. The lower and middle divisions of the Jurassic, composed of massive limestones more or less siliceous and overlain by the marls and highly fossiliferous limestones of the Upper Lias, play an important part in the constitution of the chief mountains of the Tell. In south Oman they determine the principal axes of the mountain ranges. The Inferior Cretaceous rocks include the Neocomian and Gault (Albian and Aptian) suborders, and the flint of the Tell and the Gault are developed in the Tell. In the south the Albian subdivision of the Gault is alone represented. Rocks of Upper Cretaceous age are represented in all their stages. The Cenomanian presents two distinct facies. North of the Atlas it belongs to the European type, in the south it contains a fauna of oysters and sea-urchins belonging to the facies "africano-syrian" of Zittel. There is a continuous transition between the Senonian and Danian, proving that the Algerian region did not participate in the immersion which occurred in Provence and in the Corbières of southern France during the Danian epoch. The Lower Eocene rocks contain the chief phosphatic deposits of Algeria, those of the Tell region being the best known. Certain species of nummulites, which are very common, distinguish the various subdivisions of the Eocene. The highest beds, consisting of quartzites, shales, marls and sandstones with the remains of fucoids, are found in the Jurjura and Shella. The Oligocene period consists of a marine phase confined to the littoral zone of Kabylie, and of a continental phase occupying vast areas composed of lacustrine, alluvial, gypsiferous marls, sandstones and conglomerates. The deposits of the Oligocene formation obtains its greatest development in Oran and is much expanded in the Tell. At the close of the Lower Miocene period (beds with Ostrea crassissima) great modifications in the relief and limits of the Algerian formations took place. Hitherto marine conditions were confined to the littoral; in Middle Miocene times (Helvetian) the sea broke in and spread in a south-east direction in the form of long ramified fjords but did not extend as far as the Sahara. To the Pliocene period the marine deposits of the Sahel of Algiers and of the Sahel Jijelli must be attributed; also the lacustrine marls and limestone of the basin of Constantine, and the ancient alluviums of the basins and depressions which bear no relation to the existing valleys. Among the Tertiary volcanic rocks those of acid types (granites, granulites) were the first to appear and are developed latitudinally; rocks of intermediate type (dacies, andesites) characterize the Miocene and early Pliocene periods; while the basic rocks (ophites, elacleite syenites and basalts) attained their maximum in later Pliocene and Quaternary times. Their development, feeble as compared with the acid rocks, is meridional. The Quaternary period includes an older stage containing fragments of fossils from the underlying formations; a later stage containing the bones of Hipparions, Elephas, Rhinoceros, Camelus, Equus; and finally the vast accumulations of sand which began to be formed in prehistoric times. The broad platforms of the hamada are covered with Quaternary deposits. (W. G.**) 

Climate.—Although Algeria enjoys a warm climate, the temperature varies considerably in different parts, according to the elevation and configuration of the country. Along the coast the weather is very mild, the thermometer rarely falling to freezing-point even in winter. The coldest month is January, the hottest August. The mean annual temperature in the coastal plain is 61° F. The coldest months prevail from December to March, and rain is not uncommon during other months also, excepting June, July, August and September, which are very hot and rainy. The average annual fall is 20 in. On the mountains and the high plateaus the winter is often very severe; snow lies for six months on the higher peaks of the Kabyl mountains. On the plateaus the temperature passes from one extreme to the other, and rain seldom falls. (For the climate of the Saharan region see Sahara.) Throughout Algeria, especially in the summer, there is a great difference between day and night temperature, notably in the mountain districts. Between May and September the sirocco, or hot wind of the desert, sweeps at intervals over the country, impregnating the air with fine sand; but in general, with the exception of the vicinity of the marshes, the climate is healthy. Its salubrity has been increased by the draining of many marshes in the neighbourhood of the larger towns.

Fauna and Flora.—The fauna of Algeria resembles that of the Mediterranean system generally, though many animals once common to South Europe and North Africa—such as the lion, panther, hyena and jackal—are now extinct in Europe. Lions, formerly plentiful, have disappeared, and leopards and panthers are rare; but jackals, hyenas and Algerian apes are not uncommon. Wild boars are found in the oak forests, and brown bears in the uplands. In the south are various species of antelope and wolf. Red deer (Cervus elaphus barbarus), which differ from the typical European species only in the fact that the second horn is absent from their antlers, a peculiarity which they share with the red deer of Spain and Corsica, are still found in the forest of Beni Salah in the department of Constantine, but are being exterminated by forest fires and poaching Arabs. Of domestic animals the camel and sheep are the most important. The chief wealth of the Arab tribes of the plateaus consists in their immense flocks of sheep. The horses and mules of Algeria are noted; and the native cattle are an excellent stock on which to graft the better European varieties. Of birds, eagles, vultures, hawks, owls and quails are common; snipe, curlews, plovers, storks and herons frequent the marshy parts; and the ostrich the desert. Partridges and woodcocks are fairly common. Among the reptiles are various species of serpents, tortoises, turtles, lizards, &c. Locusts are common and sometimes do great mischief. Scorpions are the most common in the dry regions. Algerian prawns, especially those of Bona, are large and of a delicate flavour. Of the twenty-one species of freshwater fish, five are peculiar to the country, but none is of much economic value save the barbel and eel. A species of trout is found in the streams near Collo, but in none of the other rivers.

The flora of Algeria consists of about 3000 species, of which some 450 are indigenous to the country, 100 being peculiar to the Sahara. The flora of the Tell is South European in character. The agave and prickly pear, the myrtle, the olive and the dwarf palm grow luxuriantly; and the fields are covered with narcissus, irises and other flowers of very bright hues, geraniums, and the like, bloom throughout the winter. The flora of the high plateaus consists chiefly of grasses, notably various kinds of alfalfa or esparto, and aromatic herbs. In the Saharan oases the characteristic tree is the date palm—"the king of the desert." Over 11,000 sq. m. of the mountainous country near the coast are covered with forests of various species of oak, pine, fir, cedar, elm, ash, maple, olive, many of them of gigantic size, and other trees; and on the slopes of the mountains up to 3800 ft. above the sea the fig is common. Its fruit forms one of the staple articles of food among the Kabylee. Cork and carob trees are also very common. A magnificent conifer, the Atlantic
pinsapo (Abies Pinsapo), is found on the heights round Bougie. The forests suffer great damage from fires, occasioned in part by the custom of burning up the grass every autumn, and in part by incendiarism. In 1902 alone, according to the British consular report, "at a moderate estimate the number of trees damaged or destroyed might be put down at 6,000,000." Forestry is a state-protected industry, the government owning over 20 per cent of the woodland. The chief tree with this commercial value is the cork, and the stripping of the bark is under official supervision. The first cork harvest was gathered in 1890, when 14,747 cwt. were sold for £1361. Since that date the yield has been very great. Another tree of great commercial value is the soap tree (Sapindus saponaria), introduced into the country in 1845 and grown extensively in low-lying lands near the coast.

Inhabitants.—Algeria had in 1906 a population of 5,231,850, consisting of a medley of European, Eastern and African races.

The census showed that in addition to French settlers and their descendants (278,976) there were 117,745 Spaniards (most of whom are found in the department of Oran), 33,153 Italians (chiefly in the department of Constantine), 64,645 Jews, 6217 Maltese, and smaller communities of British, Germans, Levantines and Greeks. There were, moreover, 170,444 naturalized French citizens, mainly of Spanish and Italian origin. (These figures are exclusive of 73,799 persons counted apart, as not enjoying municipal rights. In the 73,799 the troops, French and native, are included). The total European population, in which category are reckoned the Jews, other than those of Mzab, was 680,762. Compared with the census of 1901 the figures of 1906 showed a decrease of 14,000, French, 36,000 Spaniards and 5000 Italians, but an increase of nearly 100,000 in the foreigners naturalized. Of other races: (1) The Berbers (q.v.) constitute 75% of the entire population. The Kabyles (q.v.), a division of the Berbers, occupy chiefly the more mountainous parts of the Tell, but some live in the plains and valleys. (2) Arabs, a numerous class, are found principally in the south. (3) The so-called "Moors," generally of mixed blood, inhabit the towns and villages near the sea-coast. (4) Negroes, originally brought from the interior and sold as slaves, are now found chiefly in the towns, where they serve as labourers and domestic servants. (5) Mzabites (q.v.) or Beni-Mzab, a distinct branch of the Berber race, are for the most part engaged in petty trade, and are distinguished by their sleeveless coats of many colours. (6) A few Tuareg (q.v.), another division of the Berbers, are among the nomads found in the Algerian Sahara. The Kabyles, Mzabites, Tuareg, Arabs and Moors all profess Mahomedanism, but they are only among the Arabs that their tenets are held in any purity. The census of 1906 gave the number of the native population at 4,447,440. There were also 28,639 non-European foreigners in the country.

The Turks, though for a considerable period the dominant race, were never very numerous in Algeria. The majority of them were repatriated by the French. The Kululgis, descendants of Turks by native women—once a distinct race noted for their energy, bravery and pride—have almost ceased to exist as a separate people, being merged in the Moors. Jews have long been settled in Algeria. Some are supposed to have fled thither when expelled from Cyrenaica in the reign of the emperor Hadrian. There are said to have been 200 in 142. The purely "African" Jew is now found only in the extreme south of the country. In the towns the "native" Jews have intermarried with later arrivals from Europe. A remarkable feast is kept annually by the Algerian Jews to commemorate the defeat by the Turks of the emperor Charles V.'s attempt to capture Algiers (1541). The Jews, who enjoyed religious freedom under the Mahomedans, believed that the success of the Spaniards would lead to their own persecution.

Chief Towns.—The chief towns are Algiers, the capital and principal seaport, with a population (1900), including Mustapha and other suburbs, of 154,049; Oran (190,499); a western seaport and capital of the department of the same name, and Constantine (46,866), an inland town, capital of the department of Constantine. Besides Algiers and Oran the principal seaports are Bona (36,004), Mostaganem (19,528), Philippeville (16,539), Bougie (10,419), Cherchel (4733) and La Calle (2774). Inland, besides Constantine, are the important towns of Tlemcen (24,662), Sidi-bel-Abbes (24,494), Mascara (15,958) and Blida (16,866). In the Sahara are Biskra (4218), El Wadi (750), Tissemsilt (2007) and Warga (3579). All these places are separately noticed.

Nemours (1229) is a seaport near the Morrocan frontier, which formerly bore an Arabic name pregnant with its history—Jamaa-el-Ghazaut ("rendezvous of the pirates"). The surrounding country is rich in mineral wealth. Arzeu (3083) occupies a site on the western side of the gulf of the same name. It has a good harbour, is the outlet for the produce of several fertile valleys, and the starting-point of a railway which penetrates into the Sahara. This railway passes Salda (9256), 106 m. south of Arzeu, one of the capitals of Abd-el-Kader, and serves to bring down from the high plateaux their rich crops of esparto grass. Four miles S.E. of Arzeu is a Berber village, where are interesting ruins of a Roman settlement, identified by some authorities as the Portus Magnus of Pliny; other authorities claim Oran as occupying the site of Portus Magnus. In the vicinity are the famous quarries of Numidian marbles. Tenes (3176) is a seaport situated about 100 m. east of Arzeu on the site of the Phoenician town, afterwards the Roman colony, of Carteina. Outside the town to the west is a public garden in which the remains of the remains of the ancient town have been discovered. Tenes and Algiers are Tipasa (q.v.) and Castigelone (1634), formerly called Bu-Ismaiil, both pleasant watering-places. Five miles inland west of Castiglione is Kolea (2032), a town dating from 1550 and originally peopled by Moslem refugees from Spain. It was destroyed by earthquake in 1825 and has been rebuilt largely in European style. It contains the koubba of a celebrated marabout, Sidi Embarek, who lived in the 17th century. Dellys (3473), 50 m. by sea E. of Algiers, has a small harbour sheltered from the W. and N.W. winds only. It is a walled town regularly laid out, built by the French on the site of the Roman Ruscurium, the western ramparts of which may still be seen. Jijelli (4578), on the eastern side of the Gulf of Bougie, occupies the site of the Roman colony of Igilgilis. The old town, built on a rocky peninsula, was completely destroyed by earthquake in 1856. A new town arose eastward of the former site, which is now restored as a citadel. Twenty miles by sea west of Philippeville is Collo (2258), a city of considerable importance during the Roman occupation. It was the Kollops Magnus of Ptolemy.

A little more than three miles S.W. by rail from Algiers is Buirarik (the "hanging well"); pop. 950. A thoroughly French town, it dates from 1835, when General Drouet d'Urton established there an entrenched camp on a hillock in the midst of a pestilential swamp. Soon afterwards Marshal Clausel began to build a regular city, which was at first called Medina Clausel in his honour. The draining of the site and neighbourhood was a costly undertaking, and was only accomplished by the sacrifice of many lives. The town, surrounded by vast orchards and farms, is now one of the most flourishing in the country; and the most important market in the colony for the produce of the "Meadows" (q.v.). Sixty-three miles S.W. of Algiers is Medea (4030)—supposed to stand on the site of a Roman town—finedly situated on a plateau 3000 ft. above the sea. It is surrounded by a wall pierced by five gates. An ancient aqueduct is built into the eastern side of the wall. The town, which was chosen by the Turks as capital of the beylik of Titeri, is now French in character. Miliana (3991), which occupies the site of the Roman Miliana, lies about midway between Blida and Orleansville, is 2400 ft. above the sea, and is built on a plateau of the Zakkar mountains, commanding magnificent views of the valley of the Tiflet. It possesses a few remains of antiquity. An Old Moorish minaret has been turned into a clock tower. The town, which is walled, has been rebuilt by the French. The chief streets are bordered by trees and have streams of water
running down either side. Hammam R’Ihna to the N.E. of Miliana, noted from the time of the Romans for its thermal springs, occupies a Suberosque position 1800 ft. above the sea. Being the only place within easy distance of western Europe where patients can take with safety a course of baths during the winter months, it has become a resort of invalids. Orleånsville (3510), on the extensive plain of the Shelif, 130 m. S.W. by rail from Algiers, and 132 m. N.E. from Oran, is an important military station. The basilica of St Reparatus, discovered in 1843, was allowed to be used as a public stable and has been completely destroyed. There was in it a beautiful mosaic of which, fortunately, drawings exist. From it this appears that the town was built in the 4th century and the bishop, bishop of the diocese, was buried in it in 475. Orleånsville occupies the site of the Roman Castellum Tingitanum. Ninety miles S.W. of Bougie is Aumâlé (2350), a town and military post established by the French in 1846 on the site of the ancient Autia. The Roman town was founded in the reign of Augustus, and it flourished for two centuries before it disappeared from history. Out of the materials of the ancient city the Turks built a fort, which at the time of the French occupation was itself a heap of ruins. Setif (12,261), the site of the ancient Colonia Tingitanum and Bougie which was reached by rail W. of Constantine. It stands 3573 ft. above the sea and is the junction of several great lines of communication. Its market is attended by Kabyles, Arabs of the plateau and people from the Sahara. The town has been entirely rebuilt in the French style. Most of the Roman ruins, even those existing at the time of the French occupation (1839), have disappeared. The walls of the Roman city, restored probably by the Byzantines, have been incorporated in the French walls, which are pierced by four gates. Batina (5270), a walled town 3350 ft. above the sea, 50 m. S. of Constantine, by the railway to Biskra, commands the passage of the Aures mountains by which the nomads of the Sahara were wont to enter the Tell. Its importance rests on the site of the ancient position. On the railway between Constantine and Bona and 76 m. from the latter, is Guelma (658), the Roman Kalama, finely situated on the right bank of the Seybuse. The French occupied the place in 1836 and built their town out of the Roman ruins. Thirty miles S.E. of Guelma is Suk Abras (7692), a station on the railway to Tunis, identified with the Roman city Tagaste, the birthplace of St Augustine. Towns in the Sahara — On the southern slopes of the Great Atlas, 2437 ft. above the sea, looking out on the Saharan desert, and 200 m. in a straight line S.W. of Algiers, is Ghardaia (pop. 7868), the capital of the Mzab country, annexed by France in 1882. This country consists of seven oases, five in close proximity and two isolated. The town of Ghardaia (in the local documents Tagharet), is situated on a mosque-crowned hill in the middle of the Wadi Mzab, 1755 ft. above the sea. Ghardaia, which is divided by walls into three quarters, is built of limestone and the houses are in terraces above one the other. The central quarter is the home of the ruling tribe, the Beni-Mzab. The eastern quarter belongs to the Jews, of whom there are about 300 families; the western is occupied by the Medabia, Arabs from the Jebel Amur. The gardens belong exclusively to the Beni-Mzab. According to native accounts the town was founded about the middle of the 16th century. Aghrem Baba Saad, a small ruined town to the west of Ghardaia, is the fortified post in which the Beni-Mzab took refuge when the Turks under Salah Rais (about 1555) attempted unsuccessfully to subjugate the country. Next to Ghardaia the most important Mzabite town is Beni-Isguen (pop. 4916), an active trading centre. Guerrara, one of the two isolated oases, 37 m. N.E. of Ghardaia, contains a flourishing commercial town with 1912 inhabitants.

The caravan route south from Ghardaia brings the traveller, after a journey of 130 m., to the oasis and town of El Golea (pop. about 2500). The town consists of three portions—the citadel on a limestone hill, the upper and the lower town—separated by irregular plantations of date trees. The place is an important station for the caravan trade between Algeria and the countries to the south. It was occupied by the French under General Gallifet in 1873. El Golea was originally a settlement of the Zenata Berbers, by whom it was known as Taoret, and there is still a considerable Berber element in its population. The full Arab name is El Golea el Menâ'ia, or the ‘little forest of the desert’. Archaeology.—Algeria is rich in prehistoric memorials of man, especially in megalithic remains, of which nearly every known kind has been found in the country. Numerous flints of paleolithic type have been discovered, notably at Tlemçen and Kolea. Near Jelfa, in the Great Atlas, and at Mecheria-Sfa (‘ford of the flat stones’), a peninsula in the valley of the river Mina not far from Tiaret in the department of Oran, are vast numbers of megalithic monuments. In the Kubr-er-Rumia—\textsuperscript{1} grave of the Roman lady—\textsuperscript{1} Romans being used by the Arabs to designate strangers. The monument is found in the region of Ghardaia and Biskra. It possesses a remarkable series of sepulchral monuments. The Kubr-er-Rumia—best known by its French name, \textit{Tomeau de la Chrétienne}, tradition making it the burial-place of the beautiful and unfortunate daughter of Count Julian—is near Kolea, and is known to be the tomb of the Mauretanic king Juba II. and of his wife Cleopatra Selene, daughter of Cleopatra, queen of Egypt, and Mark Antony. It is built on a hill 756 ft. above the sea. Resting on a lower platform, 200 ft. square, is a circular stone building surrounded by a pyramid. Originally the monument was about 130 ft. in height, but it has been wantonly damaged. Its height is now 100 ft. 8 in.: the cylindrical portion 36 ft. 6 in., the pyramid 64 ft. 2 in. The base, 105 ft. in diameter, is ornamented with 60 engaged Ionic columns. The capitals of the columns have disappeared, but their design is preserved among the drawings of James Bruce, the African traveller. In the centre of the tomb are two vaulted chambers, reached by a spiral passage or gallery 6½ ft. broad, about the same height and 489 ft. long. The sepulchral chambers are separated by a short passage, and are cut off from the gallery by a circular wall, and measured by a single slab which can be moved up and down by levers, like a portcullis. The larger of the two chambers is 144 ft. long by 11 ft. broad and 11 ft. high. The other chamber is somewhat smaller. The tomb was early violated, probably in search of treasure. In 1555 Salah Rais, pasha of Algiers, set men to work to pull it down, but the records say that the attempt was given up because big black wasps came from under the stones and stung them to death. At the end of the 18th century Baba Mahammed tried vain to batter down the tomb with artillery. In 1866 it was explored by order of the emperor Napoleon III., the work being carried out by Adrian Berbrügger and Oscar MacCarthy. The Medrassen is a monument similar to the Kubr-er-Rumia, but older. It was built about 150 n.c. as the burial-place of the Numidian kings, and is situated 35 m. S.W. of Constantine. The form is that of a truncated cone, placed on a cylindrical base, 105 ft. in diameter. It is 60 ft. high. The columns encircling the cylindrical portion are stunted and much broader at the base than the top; the capitals are Doric. Many of the columns, 60 in number, have been much damaged. When the sepulchral chamber was opened in 1873 by Bauchet, a French engineer officer, clear evidence was found that at some remote period the tomb had been rifled and an attempt made to destroy it by fire. The Jedars (Arab. “walls” or “buildings”) are in the department of Oran. The name is given to a number of sepulchral monuments placed on hill-tops. A rectangular or square podium is in each case surmounted by a pyramid. The tombs date from the 5th to the 7th century of the Christian era, and lie in two distinct groups between Tiaret and Frenda, a distance of 35 m. Tiaret (pop. 5778), an ancient town modernized by the French, can be reached by railway from Mostaganem. Near
Frenda (2623), which has largely preserved its old Berber character, are numerous dolmens and prehistoric rock sculptures.

Algeria contains many Roman remains besides those mentioned and is also rich in monuments of Saracenic art. For a description of the chief antiquities see the separate town articles, including, besides those already cited, Lambessa, Tebessa, Tipasa and Timgad.

Agriculture.—Ever since the time of the Romans Algeria has been noted for the fertility of its soil. Over two-thirds of the inhabitants are engaged in agricultural pursuits. More than 7,500,000 acres are devoted to the cultivation of cereals. The Tell is the grain-growing land. Under French rule its productivity has been largely increased by the sinking of artesian wells in districts which only required water to make them fertile. Of the crops raised, wheat, barley and oats are the principal cereals. A great variety of vegetables and of fruits, especially the orange, is exported. A considerable amount of cotton was grown during the American Civil War, but the industry afterwards declined. In the early years of the 20th century efforts to extend the cultivation of the plant were renewed. A small amount of cotton is also grown in the southern oasis. Large quantities of cotton are exported.

Algiers is devoted to the cultivation of cereals. The cultivation of cotton was attacked (1883) despite precautionary measures, but in the meantime the worth of their wines had been proved. In 1850 less than 2000 acres were devoted to the grape, but in 1878 this had increased to over 42,000 acres, which yielded 7,436,000 gallons of wine. Despite bad seasons and ravages of insects, cultivation extended, and in 1895 the vineyards covered 300,000 acres, the produce being 88,000,000 gallons. The area of cultivation in 1905 exceeded 400,000 acres, and in that year the amount of wine produced was 157,000,000 gallons. By that time the limits of profitable production had been reached in many parts of the country. Practically the only foreign market for Algerian wine is France, which in 1905 imported about 110,000,000 gallons.

Fishery is a flourishing but not a large industry. The fish caught are principally sardines, bonito, smelts and sprats. Fresh fish are exported to France, dried and preserved fish to Spain and Italy. Coral fisheries exist along the coast from Bona to Tunis.

Minerals.—Algeria is rich in minerals, found chiefly in the department of Constantine, where iron, lead and zinc, copper, calamine, antimony and mercury mines are worked. The most productive are those of iron and zinc. Lignite is found in the department of Algiers and petroleum in that of Oran. Immense phosphate beds were discovered near Tebessa in 1891. They yielded 313,500 tons in 1905. Phosphate beds are also worked near Setif, Guelma and Ain Beida. There are more than 300 quarries which produce, amongst other stones, onyx and beautiful white and red marbles. Algerian onyx from Ain Tekbalet was used by the Romans, and many ancient quarries have been found near Kleber in the department of Oran, some being certainly those from which the long-lost Numidian marbles were taken. Salt is collected on the margins of the skats.

Shipping and Commerce.—The carrying trade between Algeria and France is confined, by a law passed in 1889, to French bottoms. The largest port is Algiers, after which follow Oran, Philippeville and Bona. There is a considerable coasting trade. The average number of vessels entering and clearing Algerian ports each year has been, since 1890, about 4000, with a total tonnage of some 6,500,000. In the coasting trade some 12,000 small vessels are engaged. Under French administration the commerce of Algeria has greatly developed. The total imports and exports at the time of the French occupation (1830) did not exceed £175,000. In 1850 the figures had reached £5,000,000; in 1868, £32,000,000; in 1880, £17,000,000; and in 1890, £20,000,000. From this point progress was slower and the figures varied considerably year by year. In 1905 the total value of the foreign trade was £24,500,000. About five-sixths of the trade is with or via France, into which country several Algerian goods have been admitted duty-free since 1851, and all since 1867. French goods, except sugar, have been admitted into Algeria without payment of duty since 1835.

The chief exports are sheep and oxen, most of which are raised in Morocco and Tunisia, and horses; animal products, such as wool and skins; wine, cereals (rye, barley, oats), vegetables, fruits (chiefly figs and grapes for the table) and seeds, esparto grass, oils and vegetable extracts (chiefly olive oil), iron ore, zinc, natural phosphates, timber, cork, crin végétal and tobacco. Of these France takes fully three-quarters. The import of wool exceeds the export. Sugar, coffee, machinery, metal work of all kinds, clothing and notions are largely imported. Of these by far the greater part comes from France. The British imports consist chiefly of coal, cotton fabrics and machinery.

Communications.—Algeria possesses a railway system covering over 2000 m. A decree of 1857 granted to the Paris- Lyons Company the right to construct a line linking Algiers with Oran (266 m.) and Constantine (290 m.) and shorter lines joining the seaports to the trunk line, notably Philippeville to Constantine (54 m.). These lines were opened between 1862 and 1871, but it was not until 1879 that a general scheme for railway construction was created. A trunk line runs from the frontier of Morocco at Lalla Magnah, 44 m. W. of Tlemcen, across the Tell to the Tunisian frontier, whence it is continued to the city of Tunis; while traverse railways connect the seaports with the trunk line and with towns to the south, the Philippeville line being continued to Biskra. From Arzeu a line goes south across the plateaus and crossing the Ksar range at a height of 4211 ft. enters the Sahara. Passing Ain Sefra and Figgig (372 m. from Arzeu) the line is continued towards Tuat. The normal gauge of the railways is 4 ft. 8½ in.; a few "light lines" have a gauge of 3 ft. 3 in. Algeria is also traversed by a network of roads constructed by the French, of which the routes nationales alone are 2000 m. in length. There are complete postal and telegraphic facilities in all parts of the colony save the Saharan Territories, and cable communication with France.

Central Government.—By the Turks the country was divided into four provinces—Algiers and Titeri in the centre and south, Constantine in the east and Mascara or Oran in the west. The last three were governed by beyas dependent upon the representative of the Porte resident at Algiers. The Turkish governors were in the 17th century replaced by dais (see below, History). The French rule was at first (1830) purely military. In 1834 the post of governor-general was created. Under the direction of the ministry of war that officer exercised nearly all the executive power. At the same time a civil administration and consultative council were formed. The principle of unity of authority was set aside by the second republic in 1848, when many of the public services were attached to the corresponding ministries in Paris, and the departments organized on the metropolitan model by division into arrondissements and communes and by placing a prefect at their head. Under Napoleon III. the governor-generalship was abolished, the governor of Algeria and the colonies being created (24th of June 1858), and the whole administration conducted from Paris. At the same time the powers of the prefects were augmented and each department given a general council. This arrangement was not of long duration. By decree of the 24th of November 1860, the ministry of Algeria and the colonies was abolished and the office of governor-general re-established with increased powers. This régime, strongly military in its type, ended with the fall of the second empire. After a
brief transitional period, a decree of the 29th of March 1871 placed at the head of Algeria a civil governor-general and gave the control in Paris to the ministry of the interior. In 1876, on the initiative of General Chanzy, then governor-general, that official was accorded the right to correspond direct with all the ministers in Paris. This concession led, however, to the diminu-
tion of the authority of the governor-general, whose powers were; step by step, absorbed by the various ministries in France. It had its logical end in the system adopted in 1881 and known as the rattachement. Under this system the plan of 1845 was carried out more completely, every department of state being placed under one or other of the ministries in Paris, whilst the governor-
general became little more than an ornamental personage. After lasting fifteen years the rattachement was, with the approval of the legislature, abrogated by decree dated the 31st of December 1896. The opposing principle, that of concentrating power in the hands of the governor-general, was re-affirmed, but in practice was modified by the retention of the direction from Paris of a few of the public services. The decree of 1896, which was of a provisional character, was replaced by another, dated the 23rd of August 1898, defining the powers of the governor-general under the new scheme. By a law of the 15th of December 1900, Algeria was constituted a legal personality, with power to own goods, contracts a naval division, and a decree of 1901 placed the customs department, until then directed from Paris, under the control of the governor-general, whose hands were also strengthened in various minor matters.

It will be seen that the form of government is entirely dependent on the will of France. The French chambers alone possess the legislative power, though in the absence of express legislation the head of the state have the force of law. To the legislature in Paris Algeria elects three senators and six deputys (one senator and two deputys for each department). The franchise is confined to "citizens" in which category the native Jews are included by decree of the 24th of October 1870. The Mahommedans, who number nearly eight-ninths of the population, are not, however, "citizens" but "subjects," and consequently have not the vote. They can, however, acquire "citizenship" at their own request, by placing themselves absolutely under the civil and political laws of France (decreed of 1865, confirmed in 1870). The number of Mahommedans who avail themselves of this rule is very small; naturalizations do not exceed an average of thirty persons a year. For certain specified objects, financial and municipal, Mahommedans are, however, permitted to exercise the franchise.

The actual form of government may be summarized thus:—

At the head of the administration in Algeria is a governor-
general, who exercises control over all branches, civil and military, of the administration, except the services of justice, public instruction and worship (as far as concerns Europeans) and the treasury. He corresponds directly with the other Barbar states; draws up the budget, and contracts loans on behalf of the colony. The governor-general is assisted by:

(1) The Council of Government, a purely advisory body, composed entirely of high officials;

(2) A Superior Council, composed partly of elected and partly of nominated members, including representatives of the Mahommedans. Its duty is to deliberate upon all administrative matters, including the budget, and it possesses certain powers over the finances;

(3) The Financial Delegations (created by decree in 1898), an elective body whose duty is to investigate all matters affecting taxation and to vote the budget. The delega-
tions are represented in the rural community; (b) taxpayers, being citizens other than "colonists," i.e. the urban community; (c) the Mahom-
medan population. The last section is partly elective and partly nominated. A proportion of the members of the delegations are elected to the superior council.

Local Government:—The departments, presided over by pre-
flects, are divided into territoires civils and territoires du com-
mandant. In the regions under civil administration the local organization closely resembles that of France. The country is divided into arrondissements and communes, with most of the apparatus of self-government enjoyed by the corresponding units in France. The canton (in France a judicial area) has, however, no existence in Algeria. In the territoires du commandant, which are the districts farthest from the coast, and in which the European population is small, the prefect is replaced by a high military officer, who exercises all the functions of a prefect.

The prefect of each department is assisted by a general council, consisting of members elected by the citizens and of nominated representatives of the Mahommedan population. The powers of the council correspond to those of the councils in France. Communes are of three kinds: (1) those with full powers, (2) mixed, (3) native. In those of the first kind, modeled on the French communes, the Mahommedans possess the municipal franchise. The "mixed" communes are under an administrator nominated by the governor-general and assisted by a municipal council composed of Europeans and natives. These communes are large areas, each containing several towns or villages. In the territoires du commandant the mixed commune is presided over by a military officer who fulfills the duties of mayor. Native communes are organized on the same plan as those last mentioned. There will be seen that communes do not correspond with areas, but are administrative units. The unit among the Mahommedans is the dawar, a tribal division administered by a cadi. The communes with full powers have each for centre a town with a considerable European population.

By decree of the 14th of August 1905, the frontier between Saharan territory dependent on Algeria and that attached to French West Africa was laid down. The Algerian Sahara was divided into four territories, officially named Tuggurt, Ghadaria, Ain Sefra and the Saharan Oases (Touat, Guara and Tidikelt). The governor-general represents the territories in civil affairs; the budget is distinct from that of Algeria and an annual sub-
vention is provided by France.

Finance.—Revenue is derived chiefly from direct taxation, customs and monopolies. The heaviest item of expenditure chargeable on the Algerian budget is on public works, posts and telegraphs and agriculture. Algeria has had a budget distinct from that of France since 1901. This budget includes all the expenses of Algeria save the cost of the army (estimated at £2,000,000 yearly) and the guarantee of interest on the railway loans, which are paid by the state. The Algerian budget for 1906 showed revenue and expenditure balancing at £4,282,000. The country has a debt (1905), including capital, annuities and interest, of some £3,400,000.

Defence.—The military force constitutes the XIX. army corps of the French army. There are in addition a territorial army reserve and a special body of troops, largely Arab, for the defence of the Saharan territory. The troops quartered in Algeria exceed 50,000. The defence of the coast is provided by the French navy.

Land Tenure.—The colonization of Algeria by the French has been greatly hampered by the system of land tenure which they found in force. Except among the Kabyles, private property in land was unknown. Amongst the Arabs, lands were either held in common by a whole tribe, under a tenure known as the arch or sabegha, or sometimes, especially in the towns, under a modified form of freehold (melk) by the family. At the same time the boundaries of property were ill defined and difficult to determine. This system made it impossible for the colonists to obtain land by lawful transfer. The only lands at the outset available for settlement were, in fact, the confiscated domains of the day. The obvious solution of the difficulty was to encourage the free movement of real estate by substituting private ownership for the traditional system. Before doing this, however, it was necessary to define the limits of tribal properties already existing—a work of great difficulty—with a view to their ultimate division, and at the same time to guard against any premature traffic in the rights.
of Arabs in the lands about to be divided. A sénatus-consulte of 1863 laid the basis for the change in the land system by providing (1) for the delimitation of the territory of each tribe, (2) for the repartition of the territory thus delimited among newly formed tribal divisions (douars or communes), and (3) for the recognition of private ownership by the issue of title deeds for such individual or family property (medîk) as already existed. The purpose of this excellent law, which would have laid firmly the basis for gradual change, was defeated by the impatience of the French colonists. At the instance of their representatives in the chambers it was abandoned in 1870, and was not revived till seventeen years later. A law was passed in 1873, and amended in 1887, legalizing the immediate conversion of tribal and family property into private freehold. The result has been disappointing. For the most part, the Arab tribes have been reluctant to avail themselves of their new powers, and where they have done so the hasty reversal of the traditions of centuries has proved demoralizing to the natives, without any sufficient equivalent in the way of healthy French colonization. The main profit has been reaped by Jewish usurers.

The state domains were exhausted by 1870, but were again replenished by the large confiscations which followed the Arab revolt of 1871. Government lands were originally given free to applicants, but with a provisional and insecure title, which made it impossible for poor colonists to borrow money on their land. This was modified by a law of 1874. But ultimately, the results not being satisfactory, the precedent of Australia was followed, and by a law of 1880 domain lands were sold publicly at a fixed price. This had the effect of attracting more and a better class of immigrants, but was none the less reversed in 1881.

In September 1904, a new scheme, intended to attract more European settlers, was adopted. The lands of the state—other than woods and brushwoods situated in the plains, valleys, and brushwoods situated in the plains, were offered for colonization, to be disposed of (1) by sale at a fixed price, (2) by auction, and (3), in certain cases, by agreement. Purchasers were to be Frenchmen, or Europeans naturalized as French citizens, who had never held "colony lands"; and they were obliged, under pain of forfeiture, either to take up residence themselves on their property within six months and to live on it and exploit it for a period of ten years, or else to place on the land another family fulfilling the same conditions. The purchaser farmed the land himself and made satisfactory progress, the period of obligatory residence was reduced to five years. When the interests of colonization required it, free gifts of land might be made; in which case the grantee must himself exploit his concession. In no case might land acquired under this scheme be let to natives until after the expiration of ten years.

For the purpose of creating villages, land was put at the disposal of societies or individuals, who undertook to people them with immigrants fulfilling the same conditions as independent settlers. Two-thirds of the villagers were to be French immigrants, the other third Frenchmen or naturalized Frenchmen already settled in Algeria. To favour the establishment of special industries, the governor-general was given power to authorize the introduction of foreign instead of French immigrants. The societies or individuals undertaking village settlements must do so from philanthropic motives, inasmuch as within two years of the founding of a village, the land, under pain of forfeiture to the state, must be transferred gratuitously to the villagers. As will be seen, settlement on the land by Europeans is hampered by restrictive laws, especially by the stringent regulations as to residence.

Justice.—Two judicial systems exist in Algeria—native and French. Native courts decide suits between Mahommedans. From the decision of the cadis appeal lies to the French courts. The French system provides, for civil cases, a court of first instance in each of the sixteen arrondissements into which the country is divided. A court of appeal sits at Algiers. There are also tribunals of commerce and justices of the peace with extensive jurisdiction. The criminal courts are organized as in France. Trial by jury has been introduced; but as natives are not allowed to act as jurymen this has often led to serious miscarriages of justice and to excessive severities. Whilst modifications of the law required special legislation or decree, it has been legally decided that all laws in force in France before the conquest of the country (i.e., those anterior to the 22nd of July 1834) are in force in Algeria. In practice the courts allow themselves wide latitude in applying this principle.

Education.—The system of education is complicated by the co-existence of Mahommedan and Christian communities. Before the arrival of the French two kinds of instruction were given, reading and writing being taught in the ordinary schools for, as higher education—largely theological—in medressas (colleges), usually attached to the chief mosques. Attempts by the French to improve the education of the natives were at first marked by hesitation and long periods in which little or nothing was done. The provision for the instruction of the European and Jewish population was also inadequate. In 1883 a law was passed for the reorganization of the systems in force, and primary instruction was made compulsory for Europeans and Jews, whilst in the case of Mahommedans discretion was in the establishment of schools was vested in the governor-general.

Attempts are made to assimilate the Mahommedan population by means of Franco-Arab primary and secondary schools, which supplement the purely French and purely Arab establishments of the same character. These attempts meet with little success, owing in part to racial prejudice and in part to the indifference of the Arabs to education. Few Moslems attend the secondary schools. Purely Mahommedan higher schools exist at Algiers, Tlemçen and Constantine. From these establishments the ranks of native clerics are recruited; there is one secondary school for Moslem girls. The education provided for Europeans resembles in most respects that given in France. (The lycées at Algiers, Oran and Constantine are open to Mahommedans, but few take advantage of them.) Besides the government schools there are establishments conducted by clerics and laymen. The best girls' schools are generally those kept by nuns. At Algiers there is an establishment with faculties of law, medicine and pharmacy, science and letters. At Oran is a college for European girls. The scholars attending primary schools number about 150,000 (over 100,000 being Europeans and some 50,000 Jewish) and those at secondary schools about 6000. (P. R. C.)

History

From a geographical point of view Algeria, together with Morocco and Tunisia, from which it is separated only by artificial and purely political frontiers, forms a distinct country, which it is convenient to designate by the name of Africa Minor. Both historically and geographically, Africa Minor belongs much more to the Mediterranean world than to the African. All the foreign invaders who successively established their dominion over this country either crossed the Mediterranean or followed its shores. The Phoenicians, the Romans, the Vandals, the Byzantines, the Arabs, the Turks and the French, all came from the east or from the north. The history of Africa Minor is the history of all those foreigners who have successively endeavoured to exploit this land, the history of their divers civilizations struggling against an ever-renewed barbarism. The political divisions of Africa Minor have changed many times, i.e., as the country has no natural centre, many towns have aspired to play the rôle of capital. The rivalry of these towns is intimately connected with the struggles and insurrections which have stained the land with blood. The existing division viz., Morocco, Algeria and Tunisia—dates back to the time of the Turkish dominion. It is since that time only that the expression Algeria has been in use.

At the beginning of the 16th century the native dynasties
ALGERIA

which divided Africa Minor between them—the Marindites at Fez, the Abd-el-Wahid at Tlemçen, and the Hafides at Tunis—were without strength and without authority. Two nations, then at the height of their power, Spain and Turkey, disputed the empire of the Mediterranean. The Spaniards took Mers-el-Kebir (1502), Oran (1509), and Bougie and Tripoli (1510). Two Turkish corsairs, Arouj and his brother, Khair-ed-Din (otherwise known as Barbarossa), at first established in the island of Jerba and afterwards at Jijelli, disputed with the Spaniards the dominion of the country. Arouj seized Algiers (1516); Khair-ed-Din, succeeding him in 1518, did homage for his conquest to the sultan at Constantinople, who named him beylerbey and sent him soldiers (1519). Then began the struggle of the Turks with Spain. In 1541 the emperor Charles V. undertook a great expedition against Algiers. He succeeded in landing, and proceeded to attack the town. But during the night of the 26th of October a violent storm destroyed a great part of his fleet. His provisions and his ammunition were lost, his army was compelled to retreat with considerable loss, and the emperor had to re-embark with the remnant of his troops. This check completely discouraged the Spaniards and assured success to the Turks. The Spanish garrisons established in the coast towns, badly paid and left without reinforcements, had difficulty in defending themselves. In the end, the only towns the Spaniards retained on the Algerian coast were Oran and Mers-el-Kebir. These two towns, taken by the Turks in 1542 and retaken by the Spaniards in 1572, were finally abandoned in 1791.

Under the Turkish dominion Algeria had originally at its head a beylerbey resident at Algiers. He controlled three beys:—

Barbarry corsairs.

the bey of Titeri in the south, the bey of the east at Constantine, and the bey of the west who resided at Mascara and afterwards at Oran. These three beys existed till 1636. The beylerbeyes were replaced in 1587 by pashas sent triennially by the Porte. But the authority of these pashas, strange to say, was almost without extent, and extremely precarious. They found themselves, in fact, in conflict with two forces, which in principle were in their service, but which in reality held the power—the taifé des reis, otherwise called the corporation of the corsairs (see BARBARY PIRATES), and the janissaries, a kind of military democracy in which each member was promoted according to seniority. In 1669 the corsairs drove out the pasha, and put into his place a dey elected by themselves. After some fruitless attempts Turkey ceased to send pashas to Algiers—where they were not allowed even to land—and thus recognized the de facto independence of this singular republic. The authority of the deys, moreover, was scarcely more solid than that of the pashas. They trembled before the janissaries, who from the 18th century elected and deposed them at their pleasure.

The relations which the European powers were able to maintain with northern Africa were at that time difficult and uncertain. Ships trading in the Mediterranean were seized by the corsairs, who pillaged the coasts of Europe, carried off their captives to Algiers, and destroyed the fishing and commercial settlements founded by the Marseillais on the shores of Africa. The Christian governments either uttered useless and impotent complaints at Constantinople, or endeavoured to negotiate directly with Algiers, as in the case of the negotiations of Sanson Napoleon during the ministry of Richelieu. More rarely their patience became exhausted, and ships were sent to bombard this nest of pirates. Two naval demonstrations were made by France during the reign of Louis XIV., one by Abraham Duquesne in 1688, and the other by Marshal Jean d’Estrees in 1688, but these repressive measures were too intermittent to produce a durable effect.

In 1815 at the congress of Vienna, and in 1818 at the congress of Aix-la-Chapelle, the powers endeavoured to concert measures to put an end to the Barbary piracy. Nevertheless the naval demonstrations made by Lord Exmouth in 1816, and by a combined English and French squadron in 1819, remained equally fruitless. But the result which the European powers in concert had been unable to achieve, was brought about by the accidental circumstances which led France to undertake alone an expedition against Algiers.

Some difficulties had arisen between France and the dey of Algiers with reference to the debts contracted to Bacri and Busnach, two Algerine Jews who had supplied corn to the French government under the Directory. This question of interest would not have been sufficient in itself to bring about a rupture, but the situation became acute when the dey, Hussein, struck the French consul, Deval, on the face with his fly-flap (April 30, 1827). Thereupon the port of Algiers was blockaded. The minister of war, the duc de Clermont-Tonnere, would have gone further, but the president of the council, the comte de Villepôe, opposed the sending of an expedition, while in the Martignac ministry M. de la Ferronays, minister of foreign affairs, was bent upon negotiating. It needed a second insult—the firing on "La Providence," a vessel carrying a flag of truce, in the harbour of Algiers (August 3, 1829)—to spur the French government to further action than an ineffectual blockade. An expedition against Algiers was then decided upon, and Marshal de Bourmont, the minister of war, himself took the command. On the 14th of June 1830 the French troops landed at Sidi-Ferruch. On the 19th of June they beat the enemy at Staoueli. On the 4th of July the fort de l’Empereur was blown up. On the 5th of July Algiers capitulated. Some days later the dey was deported, as well as the greater part of the janissaries. Those who were not marched away were conveyed immediately to Asia Minor; the rest had permission to remain, but in fact they left the country soon afterwards.

Meanwhile the revolution of July 1830 had broken out in France. The new government found itself very much embarrassed by the situation bequeathed by the Restoration. The more serious section in parliament were frankly opposed to the idea of conquering or of colonizing Algeria; on the other hand, popular sentiment was hostile to evacuation. The French government—fearing to displease the other powers by following with the Trois-Rivières the path opened by the ruptures with Persia and Turkey—was deterred in particular by its engagements towards England, yet conscious that the only means of putting an end to the piracy was to remain—decided provisionally in favour of that intermediate system, called restricted occupation, which consisted in occupying merely the principal seaports and awaiting events. The Algerians extricated the government from its difficulty by attacking the French troops, who were obliged to defend themselves. The natives gained some successes, and it became necessary to avenge the honour of the flag. In this gradual manner were the French led to conquer Algeria.

General Bertrand Clausel, who succeeded Marshal de Bourmont, was one of the few men who at that period dreamed of conquering and colonizing Algeria. His enthusiastic confidence knew no obstacles. If the dey had left, the three beys remained. With the feeble resources at his disposal Clausel undertook an expedition against Bu-Meyrag, the bey of Titeri, took from him Blida and Medea, dismissed him, replaced him by a successor devoted to France, and returned to Algiers after having left a garrison in Medea. Then, not having the means of directly extending the rule of France to the east or west, Clausel devised a system of protectorates. He negotiated directly with the bey of Tunis with a view to installing as beys at Oran and Constantine Tunisian princes who recognized the authority of France. But the events which were taking place in Europe made it imperative to send home a part of the army of Africa, and Medea had to be evacuated. At the same time the negotiations set on foot with the bey of Tunis were censured by the government, and General Clausel was recalled (February 1831).

The period of uncertainty was prolonged under his successors, General Pierre Bertheloté (February 1831 to September 1831; A. J. M. R. Savary, duc de Rivery (December 1831 to March 1833), General Avizard (March to April 1833), and General Voirlot (April 1833 to September 1834). The French, not yet certain whether or not they would retain Algeria, remained on the defensive. They occupied only the three towns of Algiers, Bona and Oran, with their suburbs, where their situation was moreover singularly precarious. The Arabs would pillage
the suburbs and run away. Sometimes they cut off supplies by casing to bring provisions to the market, but the French were not to be turned aside by such tactics.

At Algiers the energies of the French were devoted to protecting themselves against the incursions of the Hafitas. This was sufficient to absorb the attention of the general-in-chief, who left the guardianship of the east and west to the initiative of the generals established at Bona and Oran. At Bona, where General Monk d’Uzer was in command till 1836, things went fairly well. At once firm and conciliatory, he had been able to attach to the French cause the natives whom the cruelty of Ahmed, bey of Constantine, had alienated. The occupation of Bougie by General Camille Alphonse Trézel in October 1833 gave the French a footing at another point of this eastern province. But at Oran, where General Desmichels had succeeded General P. F. X. Boyer in the spring of 1833, their situation was much less favourable. There the French had found a redoubtable adversary in the young Abd-el-Kader, who had been proclaimed amir at Mascara in 1832.

A man of rare intelligence, a fearless horseman and an eloquent orator, Abd-el-Kader had acquired a great reputation by his prowess. He was the heir of a line of amirs which had already hitherto been divided, and he infused new spirit into their resistance. For fifteen years he held the French in check, treating on terms of equality with their government. Moreover, the treaty which General Desmichels had the weakness to sign with him on the 24th of February 1834 greatly improved his position. In pursuance of this treaty, French officers were to represent their country at the court of the amir; while the amir on his part was represented in the three French coast towns, Oran, Arzew and Mostaganem, by vakils who immediately began to act as masters of the natives. Such was the situation at the period when, the French having at last resolved to keep Algeria, the ordinance of the 22nd of July 1834 laid down the bases of the political and administrative organization of the “French possessions in the north of Africa,” at the head of which was placed a governor-general. But this date (July 22, 1834), very important from a judicial point of view, is much less so from a historical point of view. The position of the first governor-general, Jean Baptiste Drouet d’Erlof (1765–1844), remained fully as precarious as that of his predecessor. During this time the power of Abd-el-Kader increased. Master of the province of Oran, he crossed the Sheli at the approach of the natives, the people flocking to witness his progress as that of an emperor. He entered Miliana and Medea, where he installed beys of his own choice. All the western part of Algeria belonged to him. General Trézel, who had succeeded General Desmichels at Oran, resolved to march against the amir, but was defeated on the banks of the Macta (June 1835). This defeat shook public opinion. Drouet d’Erlof was recalled and replaced by Marshal Clausel.

In short, five years after the capitulation of Algiers, the French dominion extended as yet over only six coast towns. Clausel, who returned with the same colonial ambitions as in 1830, resolved to conquer the interior of the country. He marched against the amir, defeated him and entered Mascara. Then he proceeded to deliver the inhabitants of Tlemçen, who had been attacked by Abd-el-Kader, and there he left a garrison. Turning towards the east, Clausel organized at Bona the first expedition against Constantine. This failed, and the only result of it was the occupation of Guelma. Clausel was recalled and replaced by General C. M. D. Damrémont (February 1837). The task of maintaining the position of France was then left to Marshal Clausel, Thomas Robert Bugeaud (1784–1849), acting independently in the west, and Damrémont, who directed all his efforts towards the east. By the signature of the celebrated treaty of the Tafna (June 1, 1837), Bugeaud made peace with Abd-el-Kader. In return for a vague recognition of the sovereignty of France in Africa, this treaty gave up to the amir the whole of western Algeria. France reserved to herself only Oran and its environs, Mazagran, Algiers and the Metjia; she gave up Tlemçen and the Titeri beylik. This was a triumph for Abd-el-Kader, who regarded the peace as but a truce which would allow him time to gain strength to resume the war under more favourable conditions.

Damrémont, on his part, directed a second expedition on Constantine. The town was taken, but Damrémont was killed (October 1837). Marshal Sylvain Charles Valée (1772–1846), who replaced him, founded Philippeville to serve as a seaport for the region of Constantine, occupied Jijel, and at the head of the expeditionary column returned from Constantine to Algiers by the interior, passing through Setif and les Portes de fer. Abd-el-Kader maintained that the French had thrust up to the treaties of Tafna, and began the war again. For two years his power had been intensified. A large hierarchy of khalifas, aghas and caids obeyed him. He had a regular army of 8000 infantry and 2000 cavalry, without counting 50,000 gousas (bodies of Arab horsemen) brought by the khalifas. He was well furnished with war material, possessing magazines and arsenals in the heart of the Tell. He had attacked and subdued all who were not willing to recognize his authority. Under his influence old rivalries were effaced; at his voice all the tribes joined in the holy war. On the 18th of November 1839, when he was driven from Miliana by Marshal Valée, the injured Hafitahs had already devastated the Metjia. Marshal Valée marched against Abd-el-Kader, and at first gained some successes: the French occupied Cherchel, Medea and Miliana. But at the end of 1840 Valée was recalled and replaced by Bugeaud, who adopted totally different tactics. The system of Marshal Valée had been the defensive: he multiplied the fortified posts in order to draw the enemy to a spot chosen beforehand. Bugeaud resolutely adopted the offensive, reduced the weight carried by the soldiers in order to increase the mobility of his troops, and carried the war into the province of Oran, from which Abd-el-Kader drew his principal resources. One after the other, all the magazines of the amir—those at Takdempt, Boghar, Taza, Saïda and Sebdu—were taken and destroyed. In the spring of 1843 the duc d’Aumale had an opportunity of surprising the smola (camp) of Abd-el-Kader near Taguin. This was a serious blow for the amir, whose determination to continue the contest was, however, as strong as ever. He took refuge in Morocco, and induced that power to declare war on the French on the pretext that they would not give up the frontier post of Lalla-Maghnia. Morocco was soon vanquished. While one sultan, the invincible Tindaghe and Mogador, Bugeaud gained the victory of the Ily (August 1844). Morocco signed a treaty of peace at Tangier on the 10th of September 1844.

The struggle, however, was not ended. Islam made a supreme effort in Algeria. The Dahra and the Wansenis rose at the voice of a fanatic called Bu-Maza (“the goat man”), a Khawan of the order of the Mouley-Taleb. Elsewhere other “masters of the hour,” false Bu-Mazas, rose. Abd-el-Kader reappeared in Algeria, which he overran with a rapidity which baffled all pursuit. He beat the French at Sidi Brahim, raided the tribes of the Tell Oranais which had abandoned him, penetrated as far as the borders of the Metjia, and reached the Jurafa, where he endeavoured to rouse the Kabyles. But his eloquence offended the narrow and cramping particularism of those little democratic cities, deaf to the sentiment of the common interest. From that time he played a losing game. He returned toward the west, penetrating farther and farther to the south. Badly received by the great aristocratic family of the Walid-ssid-Sheikh, he re-entered Morocco, but the emperor of that country, dreading his influence and fearing disquietude in the French, drove him out. This was the end. On the 23rd of December 1847 Abd-el-Kader surrendered to General Lamoricière in the plains of Sidi-Brahim. His adversary, Bugeaud, was there no longer. Having failed to persuade the French government to adopt his plans of military colonization, he had retired in June 1847 and had been replaced by the duc d’Aumale.

The surrender of Abd-el-Kader marks the end of the period of the conquest. It is true that Great Kabylia had to be subdued only ten years later, and that terrible insurrections still had to
be quelled. But at the end of the reign of Louis Philippe the essential work was accomplished. All that remained was to complete and to secure it.

Under the second republic Algeria was governed successively by Generals L. E. Cavaignac (February to April 1848), N. A. T. Changarnier (April to September 1848), V. Charon (September 1848 to October 1850), and A. H. d'Hautpoul (October 1850 to December 1851). The policy followed at this period consisted in assimilating Algeria to France. Important efforts were made to attract French colonists to the country, the colonization of Algeria appearing as a means towards the extinction of pauperism in the mother-country. This point of view suggested numerous projects, as chimerical as they were generous; two millions sterling (50 million francs) were expended with a view to installing Parisian unemployed workmen as colonists, but this attempt failed miserably. The most remarkable military events of this period were (1) the siege and destruction of the oasis of Zaatcha, where the inhabitants, displeased by an altercation in the tax on palms, rose at the voice of a fanatic named Bu-Zian; (2) the ineffectual campaign of Marshal Saint Arnaud in Little Kabylia, where the tribes rose at the instigation of Bu-Magla ("the mule man") in 1851.

Marshal J. L. C. A. Randon (1795-1871), named governor-general of Algeria after the coup d'état, had at first to repress in the south a rising of a new "master of the hour," Mahomet ben Abdallah, the sheik of Wargla. A column seized Laghouat (El Aghuat) in December 1853. Si-Hamza, leader of the Wargla, seized Bi-Sidi-Sheikh, and drove Randon into France, in command of a base-born agitator, pursued him and seized Wargla (1853). In 1854 General Desvauex entered Tuggurt. Henceforth matters remained quiet in the region of the Sahara, and Marshal Randon turned his efforts towards Kabylia. Neither the Romans nor the Turks had been able to subdue this square mountainous tract, of which Bougie, Setif, Aumale and Delys form the four corners. But in two months (May to June 1857) Marshal Randon made himself master of it, and built in the heart of this country Fort Napoleon (now Fort National), "the thorn in the side of Kabylia," whose batteries commanded all the Kabyle villages of the region.

In 1858 the creation of a "ministry of Algeria and of the colonies" brought about the resignation of Marshal Randon. The administrative headquarters of Algeria was then transferred from Algiers to Paris. The ministry of Algeria was entrusted first to Prince Napoleon, and afterwards to the marquis J. N. S. P. de Chassellou-Laubat (1803-1873). But this office, created at the least prematurely, soon disappeared without causing any regrets. This ephemeral régime lasted from the 24th of June 1858 to the 30th of October of the same year. On the 24th of November 1850 transferred the services from Paris back to Algiers, and re-established the functions of governor-general, which were exercised at the end of the second empire first by Marshal Pélissier, duc de Malakoff (December 1850 to September 1864) and then by Marshal MacMahon, duc de Magenta (September 1864 to July 1870). At this period the conception of the Arab kingdom was prevalent. The emperor Napoleon III., in a celebrated letter, wrote that he was as much the emperor of the Arabs as the emperor of the French. Algeria was considered as a kind of great military fief, and the officers who ruled there commonly took the side of the native chieftains against the civil population. European colonization, hampered by the ill-will of the Arab bureaux, then made little progress.

It was at this period that the great insurrection of the Walid-sidi-Sheikh broke out in the Sud Oranais. This powerful family had lived up to that time on a good understanding with France; Si-Hamza, chief of the elder branch, had remained until his death (1861) a faithful ally of France.

Thanks to him, the security of the southern frontier was assured. But after his death his son, Si-Sliman, imbued with anti-French sentiments, revolted in 1864 and massacred the Beaufreêtre column. Several years were occupied in quelling the insurrection. Compelled to guard themselves on the south against the Walid-sidi-Sheikh, the French realized how much they lost by not having the support of these great chieftains. They then accepted the services offered to them by Si-Sliman-ben-Kadour, chief of the younger branch of the Walid-sidi-Sheikh, who maintained tranquillity in the Sud Oranais during the great insurrection of Kabylia in 1871.

The causes of this insurrection were manifold, and, moreover, interdependent: the injury done to the military prestige of France by its defeats in Europe; the fall of the imperial government, in which, in the eyes of the natives, the authority of France was incarnate; and the insults offered with impunity in the streets by the civil population to the officers, who were loved and respected by the Arabs, at the same time that the decree of Adolphe Crémieux accorded to the Algerian Jews the rights of French citizens. The great native chiefs, bewildered and disquieted, thought themselves menaced. The insurrection was inevitable. Mokrani, bach-agha of the Mejana, whom the imperial Government had loaded with favours, gave the signal. He had an interview with El Haddad, the sheik of the Kkuans, the religious confederation of Sidi-Abd-er-Rahman, whose influence was great, and having secured his support in April 1871, Mokrani proclaimed the holy war. At the bidding of El Haddad the whole of Kabylia rose, and numbers of French colonists were massacred; the columns of Colonel Céré and General F. G. Sausser had to engage in numerous fights. The death of the bach-agha at the battle of Sufiat, the submission of the Sheikh El Haddad, and finally the arrest of Bu-Meyrag, brother of Mokrani, marked the end of the declining stages of the insurrection, which was completely repressed by 1871. A heavy war contribution was imposed upon the rebels and their lands were sequestered. The Beni-Manassir, who rose almost at the same time in the Dahra, were subdued soon after. Subsequently the native population of the Algerine Tell remained quiet, the massacre of the colonists at Margueritte many years later being a local and isolated movement.

Under the third republic Algeria was governed successively by Admiral L. H. de Gueydon (March 1871 to June 1873), General A. E. A. Chanzy (June 1873 to February 1879), J. P. L. Albert Grévy (March 1879 to November 1884), T. Limar (November 1885 to April 1891), Jules Cambon (April 1891 to September 1897), Louis Lépine (September 1897 to August 1898), E. J. Laferrière (August 1898 to October 1900), Charles Jonnart (October 1900 to June 1901), A. J. P. Révoil (June 1901 to April 1903), and again Jonnart. During the first years of the new régime a keen reaction was produced against the political system of the imperial government in Africa. The civil territory was considerably enlarged at the expense of the military. An effort was made to attract French colonists to Algeria by giving them free land. Some lands were granted in particular to natives of Alsace-Lorraine, who preferred to retain French nationality after the war.

Peasants from the south of France, whose vines had been destroyed by the phylloxera, crossed the Mediterranean and established in Algeria an important vineyard. This double current of immigration notably increased the French population of North Africa. The tendency then was to treat Algeria as a piece of France. This assimilative policy attained its culminating point in the so-called decrees of rattachement (1881), in pursuance of which each ministerial department in France was made responsible for Algerine affairs which came by their nature within its jurisdiction.

After a great inquiry held in 1892 by a senatorial committee a reaction was produced in France against this excessive assimilation. The system of rattachement was in great part abandoned, and decentralization was obtained by augmenting the powers of the governor-general, and by granting to Algeria legal personality and a special budget (see above, Central Government). These reforms appear to have given satisfaction to Algerian opinion. Profoundly troubled as Algeria was in the last years of the 19th century by the anti-Semitic agitation, which occasioned frequent changes of governors, it appears to-day to have turned aside from sterile political struggles to interest itself exclusively in the economic development of the country.

The movement of expansion towards the south was continued
under the third republic. In 1873 General G. A. Gallifet entered El Golea. In 1882 the oasis of Mzab was annexed. In the Sud Orleans an insurrection, fomented by a marabout named Bu-Amama, broke out in 1881, and the insurgents massacred the European labourers engaged in the collection of alfalfa (or esparto) grass. But soon the French columns re-established peace, and Bu-Amama had to take refuge in Morocco. In 1883 Si-Hamza, chief of the elder branch of the Waldj-sidi-Sheikh, made his submission, and since then that family has remained devoted to France.

The attempts at penetration into the extreme south, abandoned after the massacre by Tuareg of a mission sent in 1881, under Colonel Paul Flatters, to study the question of railway communication with Senegal, were begun again in 1890, in which year the British government recognized the western Sahara as within the French sphere. Since then military stations and scientific and commercial exploration have increased. But the results of these efforts remained inconclusive until the spring of 1900, when the French authorities decided to occupy the oases of Gourara, Tuat and Tidjikila. This being as-yet-shrouded by March 1901, the conquest of the Algerine Sahara was from that time completed, and nothing any longer hindered the attempts to join Algeria and the Sudan across the Sahara. (A. Gr.)

Trabut, Histoire de l'Algérie et de la Tunisie, depuis 1798, sous l'empire (5 vols., 1892-1900), on agriculture and the fauna; Arthur Girault, Principes de colonisation et de législation coloniale, Tome iii. ch. i.-viii. (3rd ed., Paris, 1908), containing valuable bibliographies of works relating to legislation, jurisprudence, etc.; Jules Duval, L'Algérie et ses colonies françaises (Paris, 1877), The Statistique générale de l’Algérie is published periodically by the Algerian government. The British Foreign and Colonial Office publishes annual Reports on the Trade, with R. Lambert Playfair’s Handbook for Travellers in Algeria (Murray’s Handbooks), corrected to 1902, as a capital guide to the country, as is also Algérie et Tunisie (Paris, 1906), in the Guides-jeunesse series. For geology, see the successive volumes of the Geological Survey of Great Britain’s Comptes rendus (i.-viii., 1888-1903). The Statistique générale de l’Algérie has been supplemented by the Statistique générale de l’Algérie (La Haye, 1907). The French government has published, Extrait du dictionnaire géographique de l’Algérie (20 vols., 1844-1853), which contains the results of investigations made in 1840-1842. D. Deport and X. Coppolani, Description géologique du Bassin méditerranéen (Paris, 1902), and G. Delescluse, Histoire de l’Algérie. domaine géographique des confins (Algiers, 1898), have special reference to the Islamic sects in Algeria. Stéphane Galliss’s Les monuments antiques de l’Algérie (2 vols., Paris, 1901), one of the official series of publications of the Délégation des Antiquités de l’Empire, is an authoritative and finely illustrated work on the antiquities of Algeria. For archaeology see also the bibliography in Africa, Roman.

The best elementary work on the history of Algeria is that of Cat., La petite histoire de l’Algérie (Algiers, 1889). For more profound researches consult: (a) for the Turkish period: H. D. Gramont, Histoire d’Alger sous la domination turque (1887); Mercier, Histoire de l’Afrique septentrionale (1888-1891); Eugène Plantet, Correspondance des desy d’Alger avec la cour de France (1890-1892); Paul Masson, Histoire des établissements et du commerce français dans l’Afrique barbarese (1903); General Paure-Biguet, Histoire de l’Afrique septentrionale sous la domination musulmane (Dijon, 1905). (b) for the French period: Camille Rousset, La Conquête d’Algérie (8th ed., 1892). Les Commencements d’une conquête: l’Algérie de 1830 à 1840, with atlas (1887); and La Conquête de l’Algérie, 1841-1857, with atlas (1889); Pelissier, Annales algériennes (1884); Leon Rochez, Trente-deux ans à travers l’Islam (1884-1887); Colonel Trabut, Histoire d’algerie (Algiers, 1892). R. Rittis, La révolution de l’Algérie (1882) (1891).

The best general maps are those of the Carte de l’Algérie, in numerous sheets, on the scale of 1:50,000; published by the geographical section of the Ministry of War (Paris).

ALGERO, a seaport and episcopal see on the W. coast of Sardinia, in the province of Sassari, 21 m. S.W. by rail from the town of Sassari. Pop. (1901) 10,779. The see was founded in 1503, but the cathedral itself dates from the 12th century, though it has been reconstructed. The town was strongly fortified by medieval walls, which have to some extent been demolished. It was originally founded by the Doria family of Genoa about 1192, but was occupied by the house of Aragon in 1354, who held it successfully against various attacks until it fell to the house of Savoy with the rest of Sardinia in 1720. Catalanian is still spoken here. Charles V. visited Alghero on his way to Africa in 1541. The coral and fishing industries are the most important in Alghero, but agriculture has made some progress in the district, which produces good wine. There is a large penal establishment containing over 700 convicts. Seven miles to the W.N.W. is the fine natural harbour of Porto Conte, secure in all weather, and on the W. of this harbour is the Cape Caccia, with two stalactite grottos, the finest of which, the Grotta di Nettuno, is accessible only from the sea. The important prehistoric necropolis of Anghelu Ruju was excavated in 1904 (0 m. N. of Alghero (Notizie degli Scavi, 1904, 301 seq.).

ALGIDUS MONS, a portion of the ridge forming the rim of the larger crater of the Allian volcano (see ALBANUS MONS) and more especially the eastern portion, traversed by a narrow opening (now called the Cava d’Aglio) of which the Via Latina took advantage, and which frequently appears in the early military history of Rome. That a distinct town existed (Dion. Hal. x. 21, xi. 3) on the mountain is improbable; there must have been a fortified post, but the extensive castle on the hill (Maschio d’Ariano) to the south of the Via Latina is entirely medieval, a fact which has not been recognized by some topographers.

ALGIERS (Fr. Alger, Arab. Jenin, i.e. The Islands), capital and largest city of Algeria, North Africa, seat of the governor-general, of a court of appeal, and of an archbishop and bishop of the French XIX. corps d’armée. It is situated on the west side of a bay of the Mediterranean, to which it gives its name, in 36° 47' N., 3° 4' E., and is built on the slopes of the Sahel, a chain of hills parallel to the coast. The view of the city from the sea is one of great beauty. Seen from a distance it appears like a succession of dazzling white terraces rising from the water’s edge. The houses being seemingly embowered in the luxuriant verdure of the Sahel, the effect is imposing and picturesque, and has given rise to the Arab comparison of the town to a diamond set in an emerald frame. The city consists of two parts; the modern French town, built on the level ground by the seashore, and the ancient city of the depsys, which climbs the steep hill behind the modern town and is crowned by the kasbah or citadel, 400 ft. above the sea. The kasbah forms the apex of a triangle of which the quays form the base.

Extending along the front of the town is the boulevard de la République, a fine road built by Sir Morton Peto on a series of arches, with a frontage of 3700 ft., and bounded on one side by handsome buildings, whilst a wide promenade overlooks the casablanca, the principal streets of the city meet in the place du Gouvernement, the rue Bab Azoun (Gate) and other roads leading from the centre of the boulevard to the quay 40 ft. below. On the quay are the landing-stages, the coach-house and the railway station. At the southern end of the boulevard de la République is the square de la République, formerly the place Bresson, in which is the municipal theatre; at the other extremity of the boulevard is the place du Gouvernement, which is planted on three sides with a double row of plane trees and is the fashionable resort for evening promenade. The principal streets of the city meet in the place du Gouvernement, the rue Bab Azoun (Gate) which goes north to the site of the old arsenal demolished in 1900; the rue de la Marine which leads to the ancient harbour, and in which are the two principal mosques. A large part of the modern town lies south of the square de la République; in this quarter are the law courts, hotel de ville, post office and other public buildings. The streets in the modern town are regularly laid out; several are graded on both sides.

The old town presents a strong contrast to the new town. The streets are narrow, tortuous and inaccessible to carriages. They often end in a cul-de-sac. The principal street is the rue de la Kasbah, which leads up to the citadel by 497 steps. The
afforded striking confirmation of an incident recorded by a Spanish Benedictine named Haedo, who published a topography of Algeria in 1612. Haedo sets forth that a young Arab who had embraced Christianity and had been baptized with the name of Gerimono was captured by Moorish corsairs in 1569 and taken to Algiers. The Arabs endeavoured to induce Gerimono to renounce Christianity, but as he steadfastly refused to do so he was condemned to death. Bound hand and foot he was thrown alive into a mould in which a block of concrete was about to be made. The block containing his body was built into an angle of the Fort of the Twenty-four Hours, then under construction. In 1853 the Fort of the Twenty-four Hours was demolished, and in the angle specified by Haedo the skeleton of Gerimono was found. The bones were interred at St. Philippe. Into the mould left by the saint's feet, liquid plaster of Paris was run, and a perfect model obtained, showing the features of the youth, the cords which bound him, and even the texture of his clothing. This model is now in the museum at Mustapha (see below).

Algeria possesses a college with schools of law, medicine, science and letters. The college buildings are large and handsome. There is also a lyceum in which the instruction is similar to that given in France, and in which Christians, Jews and Mahomedans are educated together. The museum (a state institution), formerly housed in the same building as the library, was transferred in 1867 to a new building in the suburb of Mustapha Superieur. In the museum are some of the ancient sculptures and mosaics discovered in Algeria, together with medals and Algerian money. New buildings, to contain specimens of Moslem art, were added in 1903.

The port of Algiers is sheltered from all winds. There are two harbours, both artificial—the old or northern harbour and the southern or Agha harbour. The northern harbour covers an area of 354 acres. The depth at the entrance is 72 to 108 ft., and in port from 36 to 66 ft. Two government dry docks are available for merchant vessels. The quays cover 18,000 sq. yds. There are three jetties and a mole, east to west. Within this harbour is the small harbour of the deys, now transformed into a wet dock. An opening in the south jetty affords an entrance into Agha harbour, constructed in Agha Bay. This harbour is formed by the projection of a mole, 2,500 ft. in length, from the eastern jetty of the old harbour. It provides extensive quayage with a minimum depth of water of 28 ft. Agha harbour has also an independent entrance on its southern side. Algiers is the chief coal station in the Mediterranean, having become so largely at the expense of Gibraltar. In other respects the trade resembles that of other Algerian ports (see Algeria). The inner harbour was begun in 1518 by Khaïr-ed-Dîn (see History, below), who, to accommodate his pirate vessels, caused the island on which was built Fort Penon to be connected with the mainland by a mole. The lighthouse which occupies the site of Fort Penon was built in 1844. Work on the northern harbour was begun in 1836, on the southern in 1904. Algiers maintains communication with Marseilles by a quick service of steamers, which run the 497 miles across the Mediterranean in twenty-eight to thirty hours. The journey between Algiers and Paris, from which it is distant 1,051 miles, is accomplished in about forty-five hours.

Algiers was a walled city from the time of the deys until the close of the 16th century. The French, after their occupation of the city (1830), built a rampart, parapet and ditch, with two terminal forts, Bab Azoum to the south and Bab-el-Oued to the north. The forts and part of the ramparts were demolished at the beginning of the 20th century, when a line of forts occupying the heights of Bou Zarea (at an elevation of 1300 ft. above the sea) took their place.

Owing to the mildness of its climate Algiers has become a favourite resort for those seeking to escape the rigours of a European winter. The city is well supplied with water and its sanitary state is good. The mistral of the Riviera is entirely absent from Algiers, but in summer the city occasionally suffers from the sirocco or desert wind. The environs of Algiers are noted for their beauty and healthiness. Of the suburbs the most...
ALGOA BAY—ALGOL

picturesque is Mustapha Supérieur, about 2 m. from the centre of the city on the slopes of the hills to the south. Here are the summer palace of the governor-general, many fine Moorish and French villas and luxurious hotels, all surrounded by beautiful gardens. Its own, Oran being the chief port of the Algerian coast, where there is an English club. Mustapha Inférieur is built on the lower slopes of the hills. Farther to the south is the large Jardin d’Essai, containing five avenues of palms, planes, bamboos, and magnolias. Notre-Dame d’Afrique, a church built (1858–1872) in a mixture of the Roman and Byzantine styles, is conspicuously situated, overlooking the sea, on the shoulder of the Bu Zarea hills, 2 m. to the north of the city. Above the altar is a statue of the Virgin depicted as a black woman. The church also contains a solid silver statue of the archangel Michael, belonging to the confraternity of Neapolitan fishermen. Beyond Notre-Dame d’Afrique is the beautiful Valley of the Consuls, very little changed since the time of the deys. (The valley was in those days the favourite residence of the consuls.) At the Petit Séminaire, on the site of the old French consulate, Cardinal Lavigerie died (1897).

In 1906 the population of the commune of Algiers was 154,049; the population municipale, which excludes the garrison, prisoners, &c., was 145,286. Of this total 138,240 were living in the city proper or in Mustapha. Of the inhabitants 105,908 were Europeans. French residents numbered 50,906, naturalized Frenchmen 23,158, Spaniards 12,354, Italians 7,563, Maltese 865, and other Europeans (chiefly British and Germans) 1562, besides 12,400 Jews. The remainder of the population—all Mahomedans—are Moors, Arabs, Berbers, Negroes, with a few Turks. The vast majority of the Europeans are Roman Catholics. Most of the naturalized French citizens are of Spanish or Italian origin.

History.—In Roman times a small town called Icosium existed on what is now the marine quarter of the city. The rue de Marple follows the line of a Roman street. Roman cemeteries existed near the ruined houses, and the Bishops of Icosium—which was created a Latin city by Vespasian—are mentioned as late as the 5th century. The present city was founded in 1444 by Bulukkin b. Zeiri, the founder of the Zeïrid-Sanhaja dynasty, which was overthrown by Roger II. of Sicily in 1148 (see FATIMITES). The Zeïrids had before that date lost Algiers, which in 1159 was occupied by the Almohades, and in the 13th century came under the dominion of the Abd-el-Wahid, sultans of Tlemcen. Nominally part of the sultanate of Tlemcen, Algiers had a large measure of independence under Abbé Arouj in 1254. Great war at this time was fought against the Spaniards and Bishops of Icosium, who were then under the dominion of the Abd-el-Wahid. The latter of the frontiers, subsequently known as the Penon, had been occupied by the Spaniards as early as 1302. Thereafter a considerable trade grew up between Algiers and Spain. Algiers, however, continued of comparatively little importance until after the expulsion from Spain of the Moors, many of whom sought an asylum in the city. In 1316, following their occupation of Oran and other towns on the coast of Africa, the Spaniards fortified the Penon. In 1316 the amir of Algiers, Selim b. Toumi, invited the brothers Arouj and Khair-ed-Din (Barbarossa) to expel the Spaniards. Arouj came to Algiers, caused Selim to be assassinated, and seized the town. Khair-ed-Din, succeeding Arouj, drove the Spaniards from the Penon (1350) and was the founder of the pashalik, afterwards deylik, of Algeria. Algiers from this time became the chief seat of the Barbary pirates. In October 1541 the emperor Charles V. sought to capture the city, but a storm destroyed a great number of his ships, and his army of some 30,000, chiefly Spaniards, was defeated by the Algerians under their pasha, Hassan. Repeated attempts were made by various European nations to subdue the pirates, and in 1816 the city was bombarded by a British squadron under Lord Exmouth, assisted by Dutch men-of-war, and the corsair fleet burned. The piracy of the Algerians was renewed and continued until 1830. On the 4th of July in that year a French army under General de Bourmont attacked the city, which capitulated on the following day (see ALGERIA, History).

ALGOA BAY, a wide, shallow bay of South Africa, 436 m. E. from the Cape of Good Hope, bounded W. by Cape Recife, E. by Cape Padre. St Croix Island in the bay is in 33° 47' S. 25° 46' E. On this island Bartholomew Diaz made his second landing in South Africa some time after the 3rd of February 1488, and from the cross which he is thought to have erected on it the island gets its name. Algol Bay was the landing-place of the British emigrants to the eastern province of Cape Colony in 1820. At a spot 6 m. N.E. of Cape Recife these emigrants founded a town, Port Elizabeth (q.v.), its harbour being sheltered from all winds save the S.E. By seafarers “Algol Bay” is used as synonymous with Port Elizabeth.

ALGOL, the Arabic name (signifying “the Demon”) of β Persei, a star of the second magnitude, noticed by G. Montanari in 1669 to fluctuate in brightness. John Goodricke established in 1782 the periodicity of its change in about 26.21 days, and suggested its cause in recurring eclipses by a large dark satellite. Their intermittent character prompted the supposition. The light of Algol remains constant during close up to 56 hours; then declines in 6½ hours (approximately) to nearly one-fourth its normal amount, and is restored by sensibly the same gradations. The amplitude of the phase is 1.1 magnitude; and the absence of any stationary interval at minimum proves the eclipse to be partial, not annular. Its conditions were investigated from photometric data, by Professor E. C. Pickering in 1880; and their realization found and proved by Dr H. C. Vogel's spectroscopic measures in 1885. Previously to each obscuration, the star was found to be moving rapidly away from the earth; its velocity then diminished to zero pari passu with the loss of light, and reversed its direction during the process of recovery. Algol, in fact, travels at the rate of 26.3 miles a second round the centre of gravity of the system which it forms with an invisible companion, while the two together approach the sun with an unvarying speed of 3.3 miles per second. The elements of this disparate pair, calculated by Dr Vogel on the somewhat presumable supposition that its dark and bright members are of equal mean density, are as follows:—

| Diameter of Algol | 1,061,000 English miles. |
| Diameter of Satellite | 384,000 |
| Distance from centre to centre | 3,230,000 |
| Masse of Algol | 0.7 solar mass. |
| Masse of Satellite | 0.3 solar mass. |
| Mean density | about 1.4 solar. |

The plane of the joint orbit, in which no deviation from circularity has yet been detected, nearly coincides with the line of sight. The period of Algol, as measured by its eclipses, is subject to complex irregularities. It shortened fitfully by one-eighth of a second between 1700 and 1870; soon afterwards, restoration set in, and its exact length in 1903 was 26° 26' 56" 36', being only two seconds short of its original value. By an exhaustive discussion, Dr S. Chandler ascertained in 1888 the compensatory nature of these disturbances; and he afterwards found the most important among several which probably conspire to produce the observed effects, to be comprised in a period of 15,000 light-cycles, equivalent to 118 years. An explanatory hypothesis, propounded by him in 1892, is still on its trial. The system of Algol, according to this view, is triple; and the third large and faint body, whose eclipsing long period revolves in an orbit somewhat smaller than that of Uranus, very slightly elliptical, and inclined 20° to the line of sight, the periodic time being 118 years. The alternate delay and acceleration of the eclipses are then merely apparent; they represent the changes in the length of the light-journey as the stars perform their wide circuit. If these suppositions have a basis of reality, the proper motion of Algol should be disturbed by a small, but measurable undulation, corresponding to the projection of its orbit upon the sky; and although certain on the point cannot be attained for some years to come, Lewis Boss regarded the evidence available in 1893 as tending to confirm Dr Chandler's theory. 1

A rival interpretation of the phenomena it dealt with was put forward by P. Tisserand in 1853. It involved the action of no third mass, but depended solely upon the progression of the line of apsides in a moderately elliptical orbit due to the spheroidal shape of the globes traversing it. Inequalities of the required sort in the returns of the eclipses would ensue; moreover, their duration should concomitantly vary with the varying distance from periastron at the times of their occurrence. It is a moot question whether changes of the latter kind actually occur. When they are proved to do so, Tisserand's hypothesis will hold the field.

Algol gives a helium-spectrum which undergoes no alteration at minima. Hence the light from the marginal and central portions of the disc is identical in quality, and the limb can be little, if at all, darkened by the "smoke-vel" absorption conspicuous in the sun. The rays of this star spend close upon a century in travelling hither.

Dr Chase's measures with the Yale heliometer indicated for it, in 1894, a parallax of about 0°.035 ½; and it must, accordingly, be of nearly four times the total brightness of Sirius, while its aerial lustre exceeds seventy-fold that of the solar photosphere. Variables of the Algol class are rendered difficult to discover by the incidental character of their minima. The Algol system is also one of those of Algolian, which have been certainly recognized, besides some outlying cases of indeterminate type, in which continuous occultations by two bright stars, revolving in virtual contact, are doubtfully supposed to be in progress.

A. M. C.)

ALGONQUIN, or Algonkin (a word formerly regarded as a French contraction of Algomequin, "those on the other side" of the river, viz. the St Lawrence, but now believed to be from the Micmac algoomaking—"at the place of spearing fish"), a collective term for a number of tribes of North American Indians dwelling in the valley of the Ottawa river and around the northern tributaries of the St Lawrence. The Algonquins allied themselves with the French against the Iroquois.

Many were driven west by the later and latter became known as Ottawa. The French missionaries at work among the Algonquins early in the 17th century found their language to be the key to the many Indian dialects now included by philologists under the general term "Algonquin stock." The chief tribes included in this stock were the Algonquin, Malecite, Micmac, Naskapi, Penncook, Fox, Kickapoo, Delaware, Cheyenne, Conoy, Cree, Mohican, Massachuset, Menominee, Miami, Mississa, Mohegan, Nanticoke, Narragansett, Nipmuc, Ojibway, Ottawa, Pequot, Potawatami, Sac, Shawnee and Wampasogas. The Indians of Algonquian stock number between 80,000 and 100,000, of whom rather more than half are in the United States, the rest being in Canada. Of the Algonquins proper there remain about 1500 settled in the provinces of Quebec and Ontario.

For details see Handbook of American Indians, ed. F. W. Hodge, Washington, 1907.

ALGUAZIL, a Spanish title often to be met in stories and plays, derived from the Arabic "al-ğužil" and the article "al." The alguazil among the early Spaniards was a judge, and sometimes the governor of a town or fortress. In later times he has gradually sunk down to the rank of an officer of the court, who is trusted with the service of writs and certain police duties, but he is still of higher rank than the mere cortecele or catch-poll. The title has also been given to inspectors of weights and measures in market-places, and similar officials.

ALGUM, or Almug Tree. The Hebrew words Algummim or Almuggim are translated Alqum or Almug trees in the authorized version of the Bible (see 1 Kings x. 11, 12; 2 Chron. ii. 8, and ix. 10, 11; almug is an erroneous form (see Max Müller, Science of Language, vol. i.). The wood of the tree was very precious, and was brought from Ophir (probably some part of India), along with gold and precious stones, by Hiram, and was used in the foundations of pillars for the temple at Jerusalem, and for the king's house; also for the inlaying of stables, as well as for harps and psalteries. It is probably the red sanders or red sandal-wood of India (Pierocarpus santalinae). This tree belongs to the natural order Leguminosae, sub-order Papilionaceae. The wood is hard, heavy, close-grained and of a fine red color. It is different from the white fragrant sandal-wood, which is the produce of Santalum album, a tree belonging to a distinct natural order Santalacese...

ALHAMA DE GRANADA, a town of southern Spain, in the province of Granada, 24 m. S.W. of Granada. Pop. (1900) 7679. Alhama is finely situated on a ledge of rock which overlooks a deep gorge traversed by the river Marchan or Alhama; while the rugged peaks of the Sierra de Alhama rise behind it to a height of 6800 ft. The town is largely modern; for over one thousand of its houses have been resuced of the Moorish houses, which formerly rose in terraces up the mountain side, were destroyed, together with five churches, the hospital, the theatre, the prison, and 800 of the inhabitants, in an earthquake which took place in 1884. Subscriptions were received from all parts of Spain, and the present town was built at a little distance from its predecessor. Few vestiges of antiquity survived, except the baths from which Alhama (in Arabic "the Bath") derives its name. These are situated near the river, and appear to have been used continuously since Roman times (c. 19 B.C.—A.D. 400). The temperature is great enough for bathing: F; and, as the waters are considered beneficial in cases of gonorrhoea and dyspepsia, many visitors come to Alhama in spring and autumn, attracted also by the fine scenery of the district. In the 15th century Alhama, and the neighbouring fortress of Loja (g.v.), were generally regarded as the keys of the Kingdom of Granada, and their capture went far to insure the overthrow of the Moorish power.

Alhama was taken by the Spanish marquis of Cadiz in 1482; and its fall is celebrated in an ancient ballad, Ay de mi, Alhama, which Byron translated into English.

ALHAMBRA, THE, an ancient palace and fortress of the Moorish monarchs in Granada. In southern Spain, occupying a hilly terrace on the south-eastern border of the city of Granada. This terrace or plateau, which measures about 2430 ft. in length by 674 ft. at its greatest width, extends from W.N.W. to E.E., and covers an area of about 35 acres. It is enclosed by a strongly fortified wall, which is flanked by thirteen towers. The river Darro, which flows through a deep ravine on the north, divides the plateau from the Albaicin district of Granada; the Assabica valley, containing the Alhambra Park, on the west and south, and beyond this valley the almost parallel ridge of Monte Mauro, and east of the Alhambra, a long range of high mountains. These divide the city of Granada into two parts. The name Alhambra, signifying in Arabic "the red," is probably derived from the colour of the sun-dried tapia, or bricks made of fine gravel and clay, of which the outer walls are built. Some authorities, however, hold that it commemorates the red torches by whose light the work of construction was carried on nightly for many years; others associate it with the name of the founder, Mahomet Ibn Al Ahmar; and others derive it from the Arabic Dar al Amra, "House of the Master." (For an account of the period to which the Alhambra belongs, see Granada (city).) The palace was built chiefly between 1348 and 1354, in the reigns of Al Ahmar and his successors; but even the names of the principal artists employed are either unknown or doubtful. The splendid decorations of the interior are ascribed to Yusel I., who died in 1354. Immediately after the expulsion of the Moors in 1492, their conquerors began, by successive acts of vandalism, to spoil the marvellous beauty of the Alhambra. The open work was filled up with whitewash, the painting and gilding effaced, the furniture sold, torn or removed. Charles V. (1516-1550) rebuilt portions in the modern style of the period, and destroyed the greater part of the winter palace. After the Moorish structures were completed. Philip V. (1700-1746) Italianised the rooms, and completed the dégradations by running up partitions which blocked up whole apartments, gems of taste and patient ingenuity. In subsequent centuries the carelessness of the Spanish authorities permitted this masterpiece of Moorish art to be still further defaced; and in 1812 some of the towers were blown up by the French under Count Sebastiani, while the whole buildings narrowly escaped the same fate. In
1821 an earthquake caused further damage. The work of restoration undertaken in 1828 by the architect José Contreras was endowed in 1830 by Ferdinand VII; and after the death of Contreras in 1847, it was continued with fair success by his son Rafael (d. 1890), and his grandson Mariano.

The situation of the Alhambra is one of rare natural beauty; the plateau commands a wide view of the city and plain of Granada, towards the west and north, and of the heights of the Sierra Nevada, towards the east and south. Moorish poets describe it as "a pearl set in emeralds," in allusion to the brilliant colour of its buildings, and the luxuriant woods round them. The park (Alameda de la Alhambra), which in spring is overgrown with wild-flowers and grass, was planted by the Moors with roses, oranges and myrtles; its most characteristic feature, however, is the dense wood of English elms brought hither in 1812 by the duke of Wellington. The park is celebrated for the multitude of its nightingales, and is usually filled with the sound of running water from several fountains and cascades. These are supplied through a conduit 5 m. long, which is connected with the Darro at the monastery of Jesus del Valle, above Granada.

The Moorish portion of the Alhambra resembles many medieval Christian strongholds in its threefold arrangement as a castle, a palace and a residential annexe for subordinates. The Alcazaba or citadel, its oldest part, is built on the isolated and precipitous foreland which terminates the plateau on the north-west. Only its massive outer walls, towers and ramparts are left. On its watch-tower, the Torre de la Vela, 85 ft. high, the flag of Ferdinand and Isabella was first raised, in token of the Spanish conquest of Granada, on the 2nd of January 1492. A turret containing a huge bell was added in the 18th century, and restored after being injured by lightning in 1881. Beyond the Alcazaba is the palace of the Moorish kings, or Alhambra properly so-called; and beyond this, again, is the Alhambra Alta (Upper Alhambra), originally tenanted by officials and courtiers.

In spite of the long neglect, wilful vandalism and ill-judged restoration which the Alhambra has endured, it remains the most perfect example of Moorish art in its final European development, —freed from the direct Byzantine influences which can be traced in the cathedral of Cordova, more elaborate and fantastic than the Giralda at Seville. The majority of the palace buildings are, in ground-plan, quadrangular, with all the rooms opening on to a central court; and the whole reached its present size simply by the gradual addition of new quadrangles, designed on the same principle, though varying in dimensions, and connected with each other by smaller rooms and passages. In every case the exterior is left plain and austere, as if the architect intended thus to heighten by contrast the splendour of the interior. Within, the palace is unsurpassed for the exquisite detail of its marble pillars and arches, its fretted ceilings and the veil-like transparency of its filigree work in stucco. Sun and wind are freely admitted, and the whole effect is one of the most airy lightness and grace. Blue, red, and a golden yellow, all somewhat faded through lapse of time and exposure, are the colours chiefly employed. The decoration consists, as a rule, of stucco, conventional foliage, Arabic inscriptions, and geometrical patterns wrought into arabesques of almost incredible intricacy and ingenuity. Painted tiles are largely used as panelling for the walls.

Access from the city to the Alhambra Park is afforded by the Puerta de las Granadas (Gate of Pomegranates), a massive triumphal arch dating from the 13th century. A steep ascent leads past the Pillar of Charles V., a fountain erected in 1554, to the main entrance of the Alhambra. This is the Puerta Judiciaria
(Gate of Judgment), a massive horseshoe archway, surmounted by a square tower, and used by the Moors as an informal court of justice. A hand, with fingers outstretched as a talisman against the evil eye, is carved above this gate on the exterior; a key, the symbol of authority, occupies the corresponding place on the interior. A narrow passage leads inward to the Plaza de los Aljibes (Place of the Cisterns), a broad open space which divides the Alcazaba from the Moorish palace. To the left of the passage rises the Torre del Vino (Wine Tower), built in 1345, and used in the 16th century as a cellar. On the right is the palace of Charles V, a cold-looking but majestic Renaissance building, out of harmony with its surroundings, which it tends somewhat to dwarf by its superior size. Its construction, begun in 1526, was abandoned about 1540.

The present entrance to the Palacio Arabe, or Casa Real (Moorish palace), is by a small door from which a corridor conducts to the Patio de los Arrayanes (Court of the Myrtles), also called the Patio de la Alberca (Court of the Blessing or Court of the Pond), from the Moorish birka, "pond," or berka, "blessing." This court is 120 ft. long by 74 ft. broad; and in the centre there is a large pond set in the marble pavement, full of fish, and with myrtles growing along its sides. There are galleries on the north and south sides; that on the south 27 ft. high, and supported by a marble colonnade. Underneath it, to the right, was the principal entrance, and over it are three elegant windows with arches and miniature pillars. From this court the walls of the Torre de Comares are seen rising over the roof to the north, and reflected in the pond.

The Sala de los Ambassadors (Hall of the Ambassadors) is the largest in the Alhambra, and occupies all the Torre de Comares. It is a square room, the sides being 37 ft. in length, while the centre of the dome is 75 ft. high. This was the grand reception room, and the throne of the sultan was placed opposite the entrance. The tiles are nearly 3 ft. high all round, and the colours vary at intervals. Over them is a series of oval medallions with inscriptions, interwoven with flowers and leaves. There are nine windows, three on each façade, and the ceiling is admirably diversified with inlaid-work of white, blue and gold, in the shape of circles, crowns and stars—a kind of imitation of the vault of heaven. The walls are covered with various stucco-work of most delicate pattern, surrounding many ancient escutcheons.

The celebrated Patio de los Leones (Court of the Lions) is an oblong court, 116 ft. in length by 66 ft. in breadth, surrounded by a low gallery supported on 124 white marble columns. A pavilion projects into the court at each extremity, with filigree walls and light domed roof, elaborately ornamented. The square is paved with coloured tiles, and the colonnade with white marble; while the walls are covered 5 ft. up from the ground with blue and yellow tiles, with a border above and below enamelled blue and gold. The columns supporting the roof and gallery are irregularly placed, with a view to artistic effect; and the general form of the piers, arches and pillars is most graceful. They are adorned by varieties of foliage, &c.; about each arch there is a large square of arabesques; and over the pillars is another square of exquisite filigree work. In the centre of the court is the celebrated Fountain of Lions, a magnificent alabaster basin supported by the figures of twelve lions in white marble, not designed with sculptural accuracy, but as emblems of strength and courage.

The Sala de los Abencerrajes (Hall of the Abencerrages) derives its name from a legend according to which Boabdil, the last king of Granada, having invited the chiefs of that illustrious line to a banquet, massacred them there. This room is a perfect square, with a lofty dome and trellised windows at its base. The roof is exquisitely decorated in blue, brown, red and gold, and the columns supporting it spring out into the arch form in a remarkably beautiful manner. Opposite to this hall is the Sala de los Leones (the Court of the Two Sisters), so-called from two very beautiful white marble slabs laid as part of the pavement. These slabs measure 15 ft. by 73 ft., and are without flaw or stain. There is a fountain in the middle of this hall, and the roof—a dome honeycombed with tiny cells, all different, and said to number 3000—is a magnificent example of the so-called "stalactite vaulting" of the Moors.

Among the other wonders of the Alhambra are the Sala de la Justicia (Hall of Justice), the Patio del Mexuar (Court of the Council Chamber), the Patio de Daraxa (Court of the Vestibule), and the Peñador de la Reina (Queen's Robing Room), in which are to be seen the same delicate and beautiful architecture, the same costly and elegant decorations. The palace and the Upper Alhambra also contain baths, ranges of bedrooms and summer-rooms, a whispering gallery and labyrinth, and vaulted sepulchres. The original furniture of the palace is represented by the celebrated vase of the Alhambra, a splendid specimen of Moorish ceramic art, dating from 1320, and belonging to the first period of Moorish porcelain. It is 4 ft. 3 in. high; the ground is white, and the enamelling is blue, white and gold.

Of the outlying buildings in connexion with the Alhambra, the foremost in interest is the Palacio de Generalife or Giralafra (the Moorish Jennat el Arif, "Garden of Arif," or "Garden of the Architect"). This villa probably dates from the end of the 13th century, but has been several times restored. Its principal pavements, doors, windows, and details of construction, are of the 18th century. The Moorish architecture is at its best in the Arches of the Moorish Gateway, the famous "Patio de los Arrayanes," and the "Patio de los Reales Alcázares," which are entered through Moorish doors, and sited cypress trees, are said to retain their original Moorish character. The Villa de los Martires (Martyrs' Villa), at the summit of Monte Mauro, commemorates by its name the Christian slaves who were employed to build the Alhambra, and confined here in subterranean cells. The Torres Bermejas (Moorish Towers), also on Monte Mauro, are a well-preserved Moorish fortification, with underground cisterns, stables, and accommodation for a garrison of 200 men. Several Roman tombs were discovered in 1859 and 1857 at the base of Monte Mauro.

See Plans, Elevations, Sections and Details of the Alhambra; from drawings taken on the spot by J. Courby and Owen Jones; with a complete translation of the Arabic inscriptions and a historical notice of the Kings of Granada, by F. de Goyangos. These two magnificent volumes, published in London between 1838 and 1840, give the best pictorial representation of the Alhambra. See also Rafael Conterres, La Alhambra, El Alcázar, y la gran Mesquita de Occidente (Madrid, 1885); The Alhambra, by Washington Irving, was written in 1832, and rewritten in 1857, when it had already become widely celebrated for its picturesque and humorous descriptions. A well-illustrated edition was published in London in 1896.

ALHAZEN (Abo Ali Al-Hasan Ibn Alhaazen), Arabian mathematician of the 11th century, was born at Basra and died at Cairo in 1038. He is to be distinguished from another Alhazen, the 9th century poet, Abou de Alhazen. He not only boasted that he could construct a machine for regulating the inundations of the Nile, he was summoned to Egypt by the caliph Hakim; but, aware of the impracticability of his scheme, and fearing the caliph's anger, he feigned madness until Hakim's death in 1021. Alhazen was, nevertheless, a diligent and successful student, being the first great discoverer in optics after the time of Ptolemy. According to Giovanni Battista della Porta, he first explained the apparent increase of heavenly bodies near the horizon, although Bacon gives the credit of this discovery to Ptolemy. He taught, previously to the Polish physician Witelo, that vision does not result from the emission of rays from the eye, and wrote also on the refraction of light, especially on atmospheric refraction, showing, e.g. the cause of morning and evening twilight. He solved the problem of finding the point in a convex mirror at which a ray coming from one given point shall be reflected to another given point. His treatise on optics was translated into Latin by Witelo (1270), and afterwards published by F. Risner in 1572, with the title Opticae thesauri Alhazenii libri VII., cum ejusdem libri de crepusculis et nubium ascensibus. This work, besides a great number of middle ages works on geometrical subjects were found in the Bibliothèque nationale de Paris in 1834 by E. A. Sédillot; other manuscripts are preserved in the Bodleian library at Oxford and in the library of Leiden.

ALI, in full, 'Ali ben Abi Talib (c. 600-661), the fourth of the caliphs or successors of Mahomet, was born at Mecca about
THE COURT OF THE MYRTLES.
the year A.D. 600. His father, Abū Talib, was an uncle of the prophet, and Ali himself was educated by Mahomet and educated under his care. As a mere boy he distinguished himself by being one of the first to declare his adhesion to the cause of Mahomet, who some years afterwards gave him his daughter Fatimah in marriage. Ali proved himself a brave and faithful soldier, and when Mahomet died without male issue, a few emigrants thought him to have the best claim to succeed him. Abu Bekr, Omar and Othman, however, occupied this position before him, and it was not until 656, after the murder of Othman, that he assumed the title of caliph. The fact that he took no steps to prevent this murder is, perhaps, the only real blot upon his character. Almost the first act of his reign was the suppression of a rebellion under Talha and Zobair, who were instigated by Ayesha, Mahomet's widow, a bitter enemy of Ali, and one of the chief hindrances to his advancement to the caliphate. The rebel army was defeated by the “Battle of the Camel,” near Bassorah (Basra), the two generals being killed, and Ayesha taken prisoner.

Ali soon afterwards made Kufa his capital. His next care was to get rid of the opposition of Moawiya, who had established himself in Syria at the head of a numerous army. A prolonged battle took place in July 657 in the plain of Siffin (Susein), near the Euphrates; the fighting was at first, it is said, in favour of Ali, when suddenly a number of the enemy, fixing copies of the Koran to the points of their spears, exclaimed that ‘the faithful’ only ought to be killed by a Christian, which for some time the Muslims were led to believe just shed all others' blood.” The superstitious soldiers of Ali refused to fight any longer, and demanded that the issue be referred to arbitration (see further Caliphate, section B. 1). Abu Musa was appointed umpire on the part of Ali, and ‘Amr ibn-el-As, a veteran diplomatist, on the part of Moawiya. It is said that ‘Amr persuaded Abu Musa that it would be for the advantage of Islam that neither candidate should reign, and asked him to give his decision first. Abu Musa having proclaimed that he deposed both Ali and Moawiya, ‘Amr declared that he also deposed Moawiya, and that he had invested Moawiya with the caliphate. This treacherous decision (but see Caliphate, ib.) greatly injured the cause of Ali, which was still further weakened by the loss of Egypt. After much indecisive fighting, Ali found his position so unsatisfactory that according to some historians he made an agreement with Moawiya by which each retained his own dominions unmolested. It changed, however—according to a legend, the details of which are quite uncertain—that three of the fanatic sect of the Kharījites had made an agreement to assassinate Ali, Moawiya and ‘Amr, as the authors of disastrous feuds among the faithful. One of this victim of this plot was Ali, who died at Kufa in 661, of the wound inflicted by a poisoned weapon. A splendid mosque called Meshed Ali was afterwards erected near the city, but the place of his burial is unknown. He had eight wives after Fatimah's death, and in all, it is said, thirty-three children, one of whom, Hassan, a son of Fatimah, succeeded him in the caliphate. His descendants by Fatimah are known as the Fatimides (q.v.; see also Egypt: History, Mahommedan period). The question of Ali's right to succeed to the caliphate is an article of faith which divided the Mahommedan world into two sects, the Sunnites and the Shiites, the former denying, and the latter affirming, his right. The Turks, consequently, hold his memory in abhorrence; whereas the Persians, who are generally Shi'as, venerate him as second only to the prophet, call him the “Lion of God” (Sher-i-Khuda), and celebrate the anniversary of his martyrdom. Ali is described as a bold, noble and generous man, “the last and worthiest of the primitive Moslems, who imbued his religious enthusiasm from companionship with the prophet himself, and who followed to the last the simplicity of his example.” It is maintained, on the other hand, that his motives were throughout those of ambition rather than piety, and that, apart from the tragedy of his death, he would have been an insignificant figure in history. (See further Caliphate.)

In the eyes of the later Moslems he was remarkable for learning and wisdom, and there are extant collections (almost all certainly spurious) of proverbs and verses which bear his name: the Sentences (Naskheh) and the Sayings (Mawālid) of Ali.

He first tried to advance his candidate Musa ibn Numan to the title of caliph, but he was defeated at the battle of Idharnag, and driven to Constantinople; Fleischer, Alis handert Sprüche (Leipz. 1837); the Duan, by G. Kuypert (Leiden, 1745, and at Bulak, 1835); C. Brockelmann, Gesch. d. arabischen Lit. (vol. i., Weimar, 1899).

ALLI, as Ali Bey (1766-1818), the assumed name of Domingo Badía y Lederich, a Spanish traveller, born in 1766. After some years of wandering and famine, he began to pay attention to the Arabic language, and made a special study of the manners and customs of the East. Pretending to be a descendant of the Abbassids, Badía in 1803 set out on his travels. Under the name of Ali Bey el Abbassi, and in Musulman costume, he visited Morocco, Tripoli, Egypt, Arabia and Syria, and was received as a person of high rank wherever he appeared. He made the pilgrimage to Mecca, at that time in the possession of the Wahabites. On his return to Spain in 1807 he declared himself a Bonapartist, and was made intendant first of Segovia and afterwards of Cordova. When the French were driven from Spain, Badía was compelled to take refuge in France, and there in 1814, published an account of his travels under the title of Voyage d'Ali Bey en Asie et en Afrique, &c. A few years later he set out again for Syria, under the assumed name of Ali Othman, and, it is said, accredited as a political agent by the French government. He reached Aleppo, and there died on the 30th of August 1818, not without suspicion of having been poisoned.

An account of his Eastern adventures was published in London in 1816, in two volumes entitled Travels in Morocco, Tripoli, Cyprus, Egypt, Arabia, Syria and Turkey, between the years 1803 and 1807.

ALLI, as Ali Pascha (1741-1822), Turkish pasha of Iannina, surnamed Arslan, “the Lion,” was born at Tepeleni, a village in Albania at the foot of the Kiliussa mountains. He was one of the Toske tribe, and his ancestors had for some time held the hereditary office of bey of Tepeleni. His father, a man of mild and peaceful disposition, was killed when Ali was fourteen years old by neighbouring chiefs who seized his territories. His mother Khamko, a woman of extraordinary character, thereupon herself formed and led a brigand band to avenge her son and to recover his possessions. She was driven by numbers, and adopted an inoffensive, indomitable temper, with a view to revenge and the recovery of the lost property. In this wild school Ali proved an apt pupil. A hundred tales, for the most part probably mythical, are told of his powers and cunning during the years he spent among the mountains as a brigand leader. At last, by a picturesque stratagem, he gained possession of Tepeleni and took vengeance on his enemies. To secure himself from rivals in his own family, he is said to have murdered his brother and imprisoned his mother on a charge of attempting to poison him. With a view to establishing his own authority he made overtures to the Porte and was commissioned to chastise the rebellious pasha of Scutari, whom he defeated and killed. He also, on pretext of his disloyalty, put to death Selim, pasha of Delvino. Ali was now confirmed in the possession of all his father's territory and was also appointed lieutenant to the derwend-pasha of Rumelia, whose duty it was to suppress brigandage and highway robbery. This gave him an opportunity for amassing wealth by sharing the booty of the robbers in return for leaving them alone. The disgrace that fell on the son of Ali and the neglect of his heir to receive the title of pasha of Scutari, the only one still in existence, was at once felt. In 1787 he took part in the war with Russia, and was rewarded by being made pasha of Trikala in Thessaly and derwend-pasha of Rumelia. It soon suited his policy to suppress the brigands, which he did by enlisting most of them under his own banner. His power was now already considerable; and in 1788 he added to it by securing his nomination to the pashalik of Iannina by a characteristic trick.

The illiterate brigand, whose boyish ambition had not looked beyond the recovery of his father's byzilat, was now established as one of the most powerful vassals of the Ottoman government. Success only stimulated his insatiable ambition. He earned the confidence of the Porte by the cruel discipline he maintained in his own sanjak, and the regular flow of tribute and bribes which he directed to Constantinople; while he bent all his energies to extending his territories at the expense of his neighbours. The methods he adopted would have done credit to
Cesare Borgia; they may be studied in detail in the lurid pages of Pouqueville. Soon, by one means or another, his power was supreme in all central Albania. Two main barriers still obstructed the realization of his ambition, which now embraced Greece and Turkey, as well as Albania, and the establishment in the Mediterranean of a sea-power which should rival that of the day of Algiers. This was the first of these: resistance of the little Christian hill community of Suli; the second the Venetian occupation of the coast, within a mile of which—by convention with the Porte—no Ottoman soldier might penetrate. It needed three severe attacks before, in 1803, Ali conquered the Suliot stronghold. Events in western Europe gave him an earlier opportunity of becoming master of most of the coast towns. Ali had watched with interest the career of Bonaparte in Italy, and the treaty of Campo Formio (1797), which blotted the Venetian republic from the map of Europe, gave him the opportunity he desired. In response to his advances commissaries of the French republic visited him at Iannina and, affecting a sudden zeal for republican principles, he easily obtained permission to suppress the “aristocratic” tribes on the coast. His plans in Albania were interrupted by the war against Pasvan Oglu, the rebellious pasha of Widdin, in which Ali once more did good service. Meanwhile international politics had developed in a way that necessitated a change in All’s attitude. Napoleon’s occupation of the Ionian Islands and his relations with Ali had alarmed Russia, which feared that French influence would be substituted for her own in the Balkan peninsula; and on the 6th of September 1798 a formal alliance, to which Great Britain soon after acceded, was signed on behalf of the emperor Paul and the sultan. Once more Ali turned Turk and fought against his recent friends with such success that in the end he remained in possession of Butrinto, Prevesa and Vonitzza on the coast, was created pasha “of three tails” by the sultan, and received the congratulations of Nelson. But the campaign of Austerlitz followed, then the passage of Presburg which guaranteed to Napoleon his fortress of Vienna, and finally the treaty of Tilsit, which involved, among other things, the withdrawal of the Russians from the Ionian Islands and the Albanian coast.

Amid all the momentous changes the part of Ali was a difficult one. He had, moreover, to contend with domestic enemies, and with difficulty defeated a league formed against him by some Musulman tribes, under Ibrahim of Berat and Mustapha of Delvino, and the Suliots. He knew, however, how to retain the confidence of the sultan, who not only confirmed him in the possession of the whole of Albania from Epirus to Montenegro, but even in 1799 appointed him valli of Rumelia, an office which he held just long enough to enable him to return to Iannina laden with the spoils of Thessaly. He was now at the height of his power. In 1803 the Suliot stronghold fell; and he was undisputed master of Epirus, Albania and Thessaly, while the pashalik of the Morea was held by his son Veli, and that of Lepanto by his son Mukhtar. Only the little town of Parga held out against him on the coast; and in order to obtain this he once more in 1807 entered into an alliance with Napoleon. The French emperor, however, preferred to keep Parga, as a convenient gateway into the Balkan peninsula, and it remained in French occupation until March 1814, when the Pargiots rose against the garrison and handed the fortress over to the British to save it from falling into the hands of Ali, who had bought the town from the French commander, Cozi Nikolo, and was closely investing it. The cordial relations between Napoleon and the pasha of Iannina had not long continued. Ali was angered by the refusal to surrender Parga and justly suspicious of the ambitions which this refusal implied; he could not feel himself secure with the Ionian Islands and the Dalmatian coast in the hands of a power whose plans in the East were notorious, and he was glad enough to avail himself of Napoleon’s reverses in 1812 to help to rid himself of so dangerous a neighbor. His services to the allies received their reward. Still bent on obtaining Parga, he sent a special mission to London, backed by a letter from Sir Robert Liston, the British ambassador at Constantinople, calling the attention of the government to the pasha’s supereminent qualities” and his services against the French. After some hesitation it was decided to evacuate Parga and hand it over to the Ottoman government, i.e. Ali Pasha. The convention by which this was effected was ultimately signed on the 17th of May 1817, being ratified by the sultan on the 24th of April 1819. By its terms the Pargiots were to receive an asylum in the islands, the Ottoman government undertaking to pay compensation for their property. Ali had no difficulty in finding the money; the garrison, as soon as it was received, marched out with the bulk of the inhabitants; and the last citadel of freedom in the Balkans fell to the tyrant of Iannina.1

Ali’s authority in the great part of the peninsula subject to him now overshadowed that of the sultan; and Mahmud II., whose whole policy had been directed to destroying the overgrown power of the provincial pashas, began to seek a pretext for overthrowing the Lion of Iannina, whose bold bearing and daring seemed to threaten his own throne. The occasion came in 1820 when Ali, emboldened by impunity, violated the sanctity of Stamboul itself by attempting to procure the murder of his enemy Pacho Bey in the very precincts of the palace. A decree of disposition was now issued against the sacrilegious vali, who had dared “to fire shots in Constantinople, the residence of the caliph, and the centre of security.” Its execution was entrusted to Khurshid Pasha, with the bulk of the Ottoman forces.

For two years Ali, now over eighty years of age, held his own, in spite of his advanced years. He had no Ertugrul to second him in the east, or Leake to second him in the west; he had no Borgia; and the threat of the French power was not to be disregarded. But last, in the spring of 1822, after a prolonged siege in his island fortress at Iannina, which even the outbreak of the Greek revolt had not served to raise, the intrepid old man was forced to sue for terms. He asked and received an interview with Khurshid, was received courteously and dismissed with the most friendly assurances. As he turned to leave the grand vizier’s tent he was stabbed in the back; his head was cut off and sent to Constantinople. Notwithstanding their treason to their father, his sons met with fates no less disastrous. All the ferocious characteristics which have been suggested in the above sketch, Ali Pasha is undoubtedly one of the most remarkable, as he is one of the most picturesque, figures in modern history; and as such he was recognized in his own day. His court at Iannina was the centre of a sort of barbarous culture, in which astrologers, alchemists and Greek poets played their part, and was often visited by travellers. Amongst others, Byron came, and has left a record of his impressions in “Childe Harold’s Pilgrimage,” less interesting and vivid than the prose accounts of Pouqueville, T. S. Hughes and William M. Leake. Leake (Vol. ii. 250) reports a report addressed by Ali to the French renegade Ibrahim Efendi, who had ventured to remonstrate against some particular act of ferocity: “At present you are too young at my court to know how to comport yourself. . . . You are not yet acquainted with the Greeks and Albanians: when I hang up one of these wrinkles on the plane-tree, brother robs brother under the very branches: if I burn one of them alive, the son is ready to steal his father’s ashes to sell them for money. They are destined to be ruled by me; and no one but Ali is able to restrain their evil propensities.” This is perhaps as good an apology as could be made for his character and
ALIAGA—ALICE, PRINCESS 661

methods. To the wild people over whom he ruled none was needed. He had their respect, if not their love; he is the hero of a picture and his portrait still hangs among the ikons in the cottages of the Greek mountaineers. All accounts agree in describing him in later life as a man of handsome presence, with a venerable white beard, piercing black eyes and a benevolent cast of countenance, the effect of which was heightened in conversation by a voice of singular sweetness.

Authorities.—Apart from the scattered references in the published and unpublished diplomatic correspondence of the period, comparative political and legal books of the period contain no authentic material for the life of Ali. Of these may especially be mentioned François C. H. L. Pouqueville, Voyage en Maroc, à Constantinople, en Please, a l’Egypte, en Perse, et en Chine (Paris, 1805), and an Annonce, by A. Plumptre was published in 1815; ib. Voyage dans la France (5 vols., Paris, 1820, 1821). Pouqueville, who spent some time as French resident at Jannina, had special facilities for obtaining first-hand information, though his efforts to make his observations and deductions at times somewhat suspect. Very interesting also are Thomas Smart Hughes, Travels in Greece and Albania (2 vols., 1830); John Cam. Hobhouse (Lord Broughton), A Journey through Albania, &c. . . . during the years 1809 and 1810 (Lond., 4to, 1813, a new ed., 2 vols., 1825); William Martin Leake, Travels in Northern Greece (4 vols. Lond., 1843). See also Pouqueville, Histoire de la républication de la Grèce, 1794-1824, (4 vols. Paris, 1824, 3rd ed., Brussels, 1825); R. A. Davenport, Life of Ali Pasha, visiter de Épirus (1861). (W. A. P.)

ALIAGA, a town of the province of Nueva Ecija, Luzon, Philippine Islands, about 70 m. N. by W. of Manila. Pop. (1903) 11,950. It has a comparatively cool and healthful climate, and is pleasantly situated about midway between the Pampanga Grande and the Pampanga Chico rivers, and in a large and fertile valley of which the principal products are Indian corn, rice, sugar and tobacco. Tagalog is the most important language; Location, Pampanga and Pangasinan are also used.

ALIAS (Lat. for "at another time"), a term used to connect the different names of a person who has passed under more than one, in order to conceal his identity, or for other reasons; or, comprehensively, to describe the adopted name. The expression alias dictus was formerly used in legal indictments, and pleadings where absolute precision was necessary in identifying the person to be charged, as "John Jones, alias dictus James Smith." The adoption of a name other than a man's baptismal or surname need not necessarily be for the purpose of deception or fraud; pseudonyms or nicknames fall thus under the description of an alias. Where a person is married under an alias, the marriage is void when both parties have knowingly and wilfully connived at the adoption of the alias, with a fraudulent intent. But if one of the parties to a marriage has acquired a new name by use and reputation, or if the true name of any one of the parties is not known to the other, the use of an alias in these cases will not affect the validity of the marriage.

ALIBI (Lat. for "elsewhere"), in law, the defence resorted to in criminal prosecutions, where the person charged alleges that he was so far distant at the time from the place where the crime was committed that he could not have been guilty. An alibi, if substantiated, is the most conclusive proof of innocence.

ALICANTE, a province of south-eastern Spain; bounded on the N. by Valencia, W. by Albacete and Murcia, S. by Murcia, and S.E. and E. by the Mediterranean Sea. Pop. (1900) 470,149; area, 20,060 sq. m. Alicante was formed in 1835 of districts taken from the ancient provinces of Valencia and Murcia, Valencia contributing by far the larger portion. The surface of the province is extremely diversified. A portion of the north and north-eastern mountain ranges of calcareous formation, intersected by deep ravines; while farther south the land is more level, and there are many fertile valleys. On the Mediterranean coast, unhealthy salt marshes alternate with rich plains of pleasant and productive huertas or gardens, such as those of Alicante and Dénia. Apart from Segura, which flows from the highlands of Albacete and Murcia and Orihuela to the sea, there is no considerable river, but a few rivulets flow east into the Mediterranean. The climate is temperate, and the rainfall very slight. Despite the want of rivers and of rain, agriculture is in a flourishing condition. Many tracts, originally rocky and sterile, have been irrigated and converted into vineyards and plantations. Cereals are grown, but the inhabitants prefer to raise such articles of produce as are in demand for export, and consequently part of the grain supply has to be imported. Esparto grass, rice, olives, the sugar-cane, and tropical fruits and vegetables are largely produced. Great attention is given to the rearing of bees and silk-worms; and the wine of the province is held in high repute throughout Spain, while some inferior kinds are sent to France to be mixed with claret. There are iron and lignite mines, but the output is small. Mineral springs are found at various places. The manufactories consist of making cloths, silk, cotton, woollen and linen fabrics, girdles and lace, paper, hats, leather, earthenware and soap. There are numerous oil mills and brandy distilleries. Many of the inhabitants are engaged in the carrying trade, while the fisheries on the coast are also actively prosecuted, tunny and anchovies being caught in great numbers. Barilla is obtained from the sea-weed on the shores, and some of the saline marshes, notably those near Torrevieja, yield large supplies of salt. The principal towns, which are respectively described, include Alicante, the capital (pop. 1900, 50,142), San Juan de los Terreros (1,242), Elche (27,368), Novelda (11,388), Orihuela (28,530), and Villena (14,098). Other towns, of less importance, are Aspe (7927), Cocentaina (7907), Monóvar (16,601), Pinoso (7946), and Villajoyosa (8092).

ALICANTE, the capital of the Spanish province described above, and one of the principal seaports of the country. Pop. (1900) 50,142. It is situated in 38° 21' N. and 0° 26' W., on the Bay of Alicante, an inlet of the Mediterranean Sea. It is the terminus of railways from Madrid and Murcia. From its harbour, the town presents a striking picture. Along the shore extends the Paseo de los Martires, a double avenue of palms; behind this, the white flat-roofed houses rise in the form of a crescent towards the low hills which surround the city, and terminate, on the right, in a bare rock, 400 ft. high, surmounted by an ancient citadel. Its dry and equable climate renders Alicante a popular health-resort. The city is an episcopal see, and contains a modern cathedral.

The bay affords good anchorage, but only small vessels can come up to the two moles. The harbour is fortified, and there is a small lighthouse on the eastern mole; important engineering works, subsidized by the state, were undertaken in 1902 to provide better accommodation. In the same year 1737 vessels of 939,289 tons entered the port. The trade of Alicante consists chiefly in the manufacture of cotton, linen and woolen goods, cigars and confectionery; the importation of coal, iron, machinery, manures, timber, oak staves and fish; and the exportation of lead, fruit, farm produce and red wines, which are sent to France for blending with better vintages. Fine marble is quarried in the island of Plana near the coast.

Alicante was the Roman Lucentum; but, despite its antiquity, it has few Roman or Moorish remains. In 718, it was occupied by the Moors, who were only expelled in 1304, and made an unsuccessful attempt to recapture the city in 1331. Alicante was besieged by the French in 1799, and by the Federalists of Cartagena in 1873. For an account of the events which led up to these two sieges, see SPAIN.

For further details of the local history, see J. Pastor de la Roca, Historia general de la ciudad y castillo de Alicante, &c. (Alicante, 1854); and the Ensayo biográfico bibliográfico de escritores de Alicante y de su provincia, by M. R. García and A. Montero y Perez (Alicante, 1890).

ALICE MAUD MARY, GRAND-DUCHESS OF HESSE-DARMSTADT (1843-1878), second daughter and third child of Queen Victoria, was born at Buckingham Palace, on the 25th of April 1843. A pretty, delicate-featured child—"cheerful, merry, full of fun and mischief," as her elder sister described her—fond of gymnastics, a good skater and an excellent horsewoman, she was a general favourite from her earliest days. Her first years were passed without particular incident in the home circle, where the training of their children was a matter of the greatest concern to the queen and the prince consort. Among other things, the royal children were encouraged to visit the poor, and the effect of this training
was very noticeable in the later life of Princess Alice. After
the marriage of the Princess Royal in 1858, the new responsi-

bilities devolving upon Princess Alice, as the eldest daughter at
home, called forth the higher traits of her character, and brought
her into still closer relationship with her parents, and especially
with her father. In the summer of 1860, at Windsor Castle,
Princess Alice first met her future husband, Prince Louis of
Hesse. An attachment quickly sprang up, and on the prince's
second visit in November they were formally engaged. In
the following year, on the announcement of the contemplated
marriage, the House of Commons unanimously voted a dowry
of £50,000 and an annuity of £6000 to the princess. In December
1861, while preparations were being made for the marriage, the
prince consort was struck down with typhoid fever, and died
on the 14th. Princess Alice nursed her father during his short
illness with the utmost care, and after his death devoted herself
to comforting her mother under this terrible blow. Her marriage
took place at Osborne, on the 1st of July 1862. The princess
unconsciously wrote her own biography from this period in her
constant letters to Queen Victoria, a selection of which, edited by
Dr. Carl Sell, were allowed to be printed in 1883. These letters
give a complete picture of the daily life of the duke and duchess,
and they also show the intense love of the latter for her husband,
his mother and her native land. She managed to visit England
every year, and it was at her special request that when she died
her husband laid an English flag upon her coffin.

In the Austrian and Prussian wars in 1866, Hesse-Darmstadt
was upon the side of the Austrians; Prince Louis accompanied
his troops to the front, and was duly appointed by the
grand-duke to the command of the Hessian division. This
was a time of intense trial to the princess, whose husband
and brother-in-law, the crown prince of Prussia, were necessarily
fighting upon opposite sides. The duke of Hesse also took part
in the principal battles of the Franco-Prussian war, while the
duchess was actively engaged in organizing hospitals for the
relief of the sick and wounded. The death of the duke's father,
Prince Charles of Hesse, on the 20th of March 1877, was followed
by that of the grand-duke on the 13th of June, and Prince Louis
succeeded to the throne as Grand Duke Louis IV. In the summer
of 1878 the grand-duke and duchess, with their family, came
again to England, and went to Eastbourne, where the duchess
remained for some time. She returned to Darmstadt in the
autumn, and on the 8th of November 1878 her daughter, Princess
Victoria, was attacked by diphtheria. Three more of her
children, as well as her husband, quickly caught the disease, and
the youngest, "May," succumbed on the 16th. On the 7th of
December the prince's six-year-old daughter and Prince Louis,
by nursing and anxiety, had not strength to resist the disease,
which proved fatal on the 14th of December, the seventeenth
anniversary of her father's death. She left one son and four
dughters.

See Carl Sell, *Alice: Mittheilungen aus ihrem Leben und Briefen,
&c.* (Darmstadt, 1883), with English translation by the Princess

**ALIADÉ (from the Arab.),** the movable index of a graduated arc,
used in the measurement of angles. The word is used also to
designate the division of a circle into various parts, and the
names of the parts or the corresponding terms carrying the
microscopes or verniers of a graduated circle.

**ALIÉN (Lat. alius),** the technical term applied by British
constitutional law to anyone who does not enjoy the character of
a British subject; in general, a foreigner who for the purposes
of any state comes into certain domestic relations with it, other
than those applying to native-born or naturalized citizens, but
owns allegiance to a foreign sovereign.

English law, save with the special exceptions mentioned,
admits to the character of subjects all who are born within
the king's allegiance, that is, speaking generally, within the British
domains. In the celebrated question of the *post-natal* in the
realm of James I. of England, it was found, after solemn trial,
that natives of Scotland born before the union of the crowns were
aliens in England but that, since allegiance is to the person of the
king, those born subsequently were English subjects. A child
born abroad, whose father or whose grandfather on the father's
side was a British subject, may claim the same character unless
at the time of his birth his father was an attainted traitor, or in
the service of a state engaged in war against the British empire
(4th Geo. II. c. 21). Owing to this exceptional provision some
sons of Jacobite refugees born abroad, who joined in the
rebellion of 1745, were adjudged to the privilege of prisoners of war,
and alien status was engrafted in the United Kingdom with regard to
the national status of women and children that a married woman is
to be deemed a subject of the state of which her husband is for
the time being a subject; that a natural-born British woman, having
become an alien by marriage, and thereafter being a widow, may
be rehabilitated under conditions slightly more favourable than
are required for naturalization; that where a father or a widow
becomes an alien, the children in infancy becoming resident in the
country where the parent is naturalized, and being naturalized by
the local law, are held to be subjects of that country; that those
of a father or of a widow readmitted to British nationality or who
obtains a certificate of naturalization, becoming during infancy
resident with such parent in the British dominions in the former
case or in the United Kingdom in the latter, become readmitted
or naturalized (Naturalization Act 1870, s. 10). The nationality
of children not covered by these enactments is not affected by the
change of their parents' nationality. The same statute provides
that a declaration of alienage before a justice of peace or other
competent judge, having the effect of divesting the declarant
of the character of a British subject, may be made by a naturalized
British subject declaring the nationality of the country
to which he originally belonged, if there be a convention to that
effect with that country; by natural-born subjects who were also
born subjects of another state according to its law; or by persons
born abroad having British fathers.

Naturalization, which means conferring the character of a
subject, may now, under the act of 1870, be obtained by applying
to the home secretary and producing evidence of having resided
for not less than five years in the United Kingdom, or of having
been in the service of the crown for not less than five years, and
of intention to reside in the United Kingdom or serve under the
crown. Such a certificate may be granted by the secretary of
state to one naturalized previously to the passing of the act, or
to a British subject as to whose nationality a doubt exists, or to a
statutory alien, i.e. one who has become an alien by declaration
in pursuance of the act of 1870.

In the United States the separate state laws largely determine
the status of an alien, but subject to Federal treaties. (For
further particulars see ALLEGION and NATURALIZATION.)

Any of the disabilities to which aliens were subject in the
United Kingdom, either by the common law or by various acts
of parliament, have been repealed by the Naturalization Act
1870. It enables aliens to take, acquire, hold and dispose of real
and personal property of every description, and to transmit a
title to it, in all respects as natural-born British subjects. But
the act expressly declares that this relaxation of the law does not
qualify aliens for any office or any municipal, parliamentary or
other franchise, or confer any right of a British subject other than
those above expressed in regard to property, nor does it affect
intestacy and succession, or the liability of citizens of foreign
nations to the penalties provided by law in Great Britain, made
before the act, or by devolution of law on the death of any
one dying before the act. A ship, any share in which is owned by
an alien, shall not be deemed a British ship (Merchant Shipping
Act 1894, s. 1). By the Juries Act 1870, s. 8, aliens who have
been domiciled for ten years in England or Wales, if in other
respects duly qualified, are liable to serve on juries or inquests
in England or Wales; and by the Naturalization Act 1870, s. 5,
the aliens' old privilege of being tried by a jury de moditate linguae
(that is, of which half were foreigners), was abolished.

It seems to be a rule of general public law that an alien can be
sent out of the realm by exercise of the crown's prerogative; but
in modern English practice, whenever it seems necessary to expel
foreigners (see EXPULSION), a special act of parliament has to
be obtained for the purpose, unless the case falls within the
extradition acts or the Aliens Act 1905. The latter prohibits the
ALIENATION—ALIMENTARY CANAL

landing in the United Kingdom of undesirable alien steerage passengers, called in the act “immigrants,” from ships carrying more than twenty alien steerage passengers, called in the act “immigrant ships”; nor can alien immigrants be landed except at certain ports at which there is an “immigrant officer,” to whom power of prohibiting the landing is given, subject to a right of appeal to the immigration board of the port. The act contains a number of qualifications, and among these empowers the secretary of state to exempt any immigrant ship from its provisions if he is satisfied that a proper system is maintained to prevent the immigration of undesirable persons. The principal test of undesirable is not having or being in a position to obtain the means of supporting one’s self and one’s dependents, or appearing likely from disease or infirmity to become a charge on the rates, provided that the immigrant is not seeking to avoid prosecution or punishment on religious or political grounds, or persecution, involving danger of imprisonment or danger to life or limb, on account of religious belief. Lunatics, idiots, persons who from disease or infirmity appear likely to become a detriment to the public otherwise than through the rates, and persons sentenced in a foreign country for crimes for which they could be surrendered to that country, are also enumerated as undesirable. Power is also given to the secretary of state to expel persons sentenced as just mentioned, or, if recommended by the court in which they have been convicted, persons convicted of felony or some offence for which the court has power to impose imprisonment under the option of a fine. The bill imposes an act against the police laws: and persons in receipt of any such parochial relief as disqualifies for the parliamentary franchise, or wandering without ostensible means of subsistence, or living under insanitary conditions due to overcrowding. (Jno. W.)

ALIENATION (from Lat. alienus, belonging to another), the act or fact of being estranged, set apart or separated. In law the word is used for the act of transfer of property by voluntary deed and not by inheritance. In regard to church property the word has come to mean, since the Reformation, a transfer from religious to secular ownership. “Alienation” is also used to denote a state of insanity (q.v.).

ALIEN-HOUSES, religious houses in England belonging to foreign ecclesiastics, or under their control. They generally were built where property had been left by the donors to foreign orders to pray for their souls. They were frequently regular “priories,” but sometimes only “cells,” and even “granges,” with small chapels attached. Some, particularly in cities, seem to have been a sort of mission-houses. There were more than 100 in England. Many alien-houses were suppressed by Henry V. and the rest by Henry VIII.

ALIENIST (Lat. alienus, that which belongs to another, i.e. is external to one’s self), one who specializes in the study of mental diseases, which are often included in the generic name “Alienation.” (See Insanity.)

ALIGARH, a city and district of British India in the Meerut division of the United Provinces. The city, also known as Koli, was a station on the East Indian railway, 876 m. from Calcutta. Sir Sayyad Khan, K.C.S.I., who died in 1858, founded in 1864 the Aligarh Institute and Scientific Society for the translation of Western books into use in the country; and afterwards the Mahommedan Anglo-Oriental college, under English professors, with an English school attached. The college meets with strong support from the enlightened portion of the Mussulman community, whose aim is to raise it to the status of a university, with the power of conferring degrees. The population (1901) 70,434, showed an increase of 14% in the decade.

There are several flour-mills, cotton-presses and a dairy farm. Aligarh Fort, situated on the Grand Trunk road, consists of a regular polygon, surrounded by a very broad and deep ditch. It became a fortress of great importance under Sindhia in 1759, and was the depot where he drilled and organized his battalions in the European fashion with the aid of De Boigne. It was captured from the Mahrattas under the leadership of Perron, another French officer, by Lord Lake’s army, in September 1803, since which time it has been much strengthened and improved. In the rebellion of 1857 the troops stationed at Aligarh mutinied, but abstained from murdering their officers, who, with the other residents and ladies and children, succeeded in reaching Hathras.

The district of Aligarh has an area of 1957 sq. m. It is nearly a level plain, but with a slight elevation in the centre, between the two great rivers the Ganges and Jumna. The only other important river is the Kali Nadi, which traverses the entire length of the district from north-east to south-west. The district is traversed by several railways and also by the Ganges canal, which is navigable. The chief trading centre is Hathras. In 1901 the population was 1,200,822, showing an increase of 15% in the decade, due to the extension of irrigation. There are several factories for ginning and pressing cotton.

ALIGNMENT (from Fr. à and ligne, the Lat. linea, a line), a setting in line, generally straight, or the way in which the line runs; an expression used in surveying, drawing, and in military arrangements, the alignment of a regiment or a camp meaning the situation when drawn up in line or the relative position of the tents. The alignment of a rifle has reference to the way of getting the sights into line with the object, so as to aim correctly.

ALIMENT (from Lat. alimentum, from alere to nourish), a synonym for “food,” literally or metaphorically. The word has also been used in the same legal sense as ALIMONY (q.v.). Aliment, in Scots law, is the sum paid or allowance given in respect of the maintenance of children, of parents, of wife and husband, wife, grandparents and grandchildren, to contribute to each other’s maintenance. The term is also used in regard to a similar obligation of other parties, as of creditors to imprisoned debtors, the payments by parishes to paupers, &c. Alimentary funds, whether of the kind above mentioned, or set apart as such by the deed of a testator, are intended for the mere support of the recipient, and are not attachable by creditors.

ALIMENTARY CANAL, in anatomy. The alimentary canal, strictly speaking, is the whole digestive tract from the mouth to the anus. From the one orifice to the other the tube is some 25 to 30 ft. long, and the food, in its passage, passes through the following parts one after the other:—mouth, pharynx, oesophagus, stomach, small intestines, cæcum, large intestines, rectum and anus. Into this tube at various points the salivary glands, liver and pancreas pour their secretions by special ducts. As the mouth (q.v.) and pharynx (q.v.) are separately described, the detailed description will here begin with the oesophagus or gullet.

The oesophagus (q.v.), the tube, I will carry, and φαγεῖν, to eat), a muscular tube lined with mucous membrane, stretches from the lower limit of the pharynx, at the level of the cricoid cartilage, to the cardiac orifice of the stomach. It is about 10 in. long (25 cm.) and half to one inch in diameter. At first it lies in the lower part of the neck, then in the thorax, and lastly, for about an inch, in the abdomen. As far as the level of the fourth or fifth thoracic vertebra it lies behind the trachea, but when that tube ends, it is in close contact with the pericardium, and, at the level of the tenth thoracic vertebra, passes through the oesophageal opening of the diaphragm (q.v.), accompanied by the two vagi nerves, the left being in front of it and the right behind. In the abdomen it lies just behind the left lobe of the liver. Both in the upper and lower parts of its course it lies a little to the left of the mid line. Its mucous membrane is thrown into a number of longitudinal pleats to allow stretching.

The stomach (Gr. στόμαχος) is an irregularly pear-shaped bag, situated in the upper and left part of the abdomen. It is somewhat flattened from before backward and so has an anterior and posterior surface and an upper and lower border. When moderately distended the thick end of the pear or fundus bulges upward and to the left, while the narrow end is constricted to form the pylorus, by means of which the stomach communicates with the small intestine. The cardiac orifice, where the oesophagus enters, is placed about a third of the way along the upper border from the left end of the fundus, and, between it and the
pylorus, the upper border is concave and is known as the lesser curvature. From the cardiac to the pyloric orifice, round the lower border, is the greater curvature. The stomach has in front of it the liver (see fig. 1), the diaphragm and the anterior abdominal wall, while behind it are the pancreas, left kidney, left adrenal, spleen, colon and mesocolon. These structures form what is known as the stomach chamber. When the stomach is empty it contracts into a tubular organ which is frequently sharply bent, and the transverse colon ascends to occupy the vacant part of the stomach chamber.

The last inch of the stomach before reaching the pylorus is outer longitudinal. The peritoneal coat is described in the article on the coelom and serous membranes.

The small intestine is a tube, from 22 to 25 ft. long, beginning at the pylorus and ending at the ileo-caecal valve; it is divided into duodenum, jejunum and ileum.

The duodenum is from 9 to 11 in. long and forms a horseshoe or C-shaped curve, encircling the head of the pancreas. It differs from the rest of the gut in being retroperitoneal. Its first part is horizontal and lies behind the fundus of the gall-bladder, passing backward and to the right from the pylorus, the second part runs vertically downward in front of the hilum of the right kidney, and into this part the pancreatic and bile ducts open. The third part runs horizontally to the left in front of the aorta and vena cava, while the fourth part ascends to the left side of the second lumbar vertebra, after which it bends sharply downward and forward to form the duodeono-jejunal flexure.

The jejunum forms the upper two-fifths of the rest of the small intestine; it, like the ileum, is thrown into numerous convolutions and is attached by the mesentry to the posterior abdominal wall. (See COELOM AND SEROUS MEMBRANES.)

The ileum is the remaining three-fifths of the small intestine, though there is no absolute point at which the one ends and the other begins. Speaking broadly, the jejunum occupies the upper and left part of the abdomen below the subcostal plane (see ANATOMY: Superficial and Artistic), the ileum the lower and right part. About 3 ft. from its termination a small pouch, known as Meckel's diverticulum, is very occasionally found. At its termination the ileum opens into the large intestine at the ileo-caecal valve.

The caecum is a blind sac occupying the right iliac fossa and extending down some two or three inches below the ileo-caecal junction. From its posterior and left surface the vermiform appendix protrudes, and usually is directed upward and to the left, though it not infrequently hangs down into the true pelvis. This worm-like tube is blind at its end and is usually 3 or 4 in. long, though it has been seen as long as 10 in. Its internal opening into the caecum is about 1 in. below that of the ileum. On transverse section it is seen to be composed of (1) an external muscular coat, (2) a submucous coat, (3) a mass of lymphoid tissue, which appears after birth, and (4) mucous membrane. In many cases its lumen is wholly or partly obliterated, though this is probably due to disease (see R. Berry and L. Lack, Journ. Anat. & Phys., vol. xl. p. 247).

Guarding the opening of the ileum into the caecum is the ileo-caecal valve, which consists of two cusps projecting into the caecum; of these the upper forms a horizontal shelf, while the lower slopes up to it obliquely. Complete absence of the valve has been noticed, and in one such case the writer found that no abdominal inconvenience had been recorded during life. The caecum is usually completely covered by peritoneum, three special pouches of which are often found in its neighbourhood; of these the ileo-colic is just above the point of junction of the ileum and caecum, the ileo-caecal just below that point, while the retrocaecal is behind the caecum. At birth the caecum is a cone, the apex of which is the appendix; it is bent upon itself to form a U, and sometimes

---

**ALIMENTARY CANAL**

![Diagram of the abdomen](image-url)

**Fig. 1.**—The Abdominal Viscera in situ, as seen when the abdomen is laid open and the great omentum removed (drawn to scale from a photograph of a male body aged 56, hardened by formalin injections).

The ribs on the right side are indicated by Roman numerals; it will be observed that the eighth costal cartilage articulated with the sternum on both sides. The subcostal, Intertubercular, and right and left Poupart lines are drawn in black, and the mesial plane is indicated by a dotted line. The intercostal muscles and part of the diaphragm have been removed, to show the liver and stomach extending up beneath the ribs. usually tubular and is known as the pyloric canal. Before reaching this there is a bulging known as the pyloric vestibule (see D. J. Cunningham, *Tr. R. Soc. of Edinb.* vol. xlv. pt. 1, No. 2). The pylorus is an oval opening, averaging half an inch in its long axis but capable of considerable distension; it is formed by a special development of the circular muscle layer of the stomach, and during life is probably tightly closed. The mucous membrane of the stomach is thrown into pleats or rugae when the organ is not fully distended, while between these it has a mammillated appearance.

Superficial to the mucous coat is a sub-mucous, consisting of loose connective tissue, while superficial to this are three coats of unstriped muscle, the inner oblique, the middle circular and the...
ALIMENTARY CANAL

The ascending colon runs up from the caecum at the level of the ileo-caecal valve to the hepatic flexure beneath and behind the right lobe of the liver; it is about 8 in. long and posteriorly is in contact with the abdominal wall and right kidney. It is covered by peritoneum except on its posterior surface (see fig. 1).

The transverse colon is variable in position, depending largely on the distension of the stomach, but usually corresponding to the subcostal plane (see ANATOMY: Superficial and Artistic). On the left side of the abdomen it ascends to the splenic flexure, which may almost reach the spleen (see DUCTLESS GLANDS), and is bound to the diaphragm opposite the eleventh rib by a fold of peritoneum called the phrenico-colic ligament. The peritoneal relations of this part are discussed in the article on the coelom and serous membranes.

The descending colon passes down in front of the left kidney and left side of the posterior abdominal wall to the crest of the ilium; it is about 6 in. long and is usually empty and contracted while the rest of the colon is distended with gas; its peritoneal relations are the same as those of the ascending colon, but it is more likely to be completely surrounded.

The iliac colon stretches from the crest of the ilium to the inner border of the psoas muscle, lying in the left iliac fossa, just above and parallel to Poupart's ligament. Like the descending, it is usually uncovered by peritoneum on its posterior surface. It is about 6 in. in length.

The pelvic colon lies in the true pelvis and forms a loop, the two limbs of which are superior and inferior while the convexity reaches across to the right side of the pelvis. In the foetus this loop occupies the right iliac fossa, but, as the caecum descends and enlarges and the pelvis widens, it is usually driven out of this region. The distal end of the loop turns sharply downward to reach the third piece of the sacrum, where it becomes the rectum. This pelvic colon Sir F. Treves (Anatomy of the Intestinal Canal, London, 1885) has given the name of the omega loop. Formerly the iliac and pelvic colon were spoken of as the sigmoid flexure, but Treves and T. Jonnesco (Le Colon pelvien pendant la vie intra-utérine, Paris, 1892) have pointed out the non-commonality of the term, and to the latter author the modern description is due.

The rectum, according to modern ideas, begins in front of the third piece of the sacrum; formerly the last part of the Ō (or omega) loop was described as its first part. It ends in a dilatation or rectal ampulla, which is in contact with the back of the prostate in the male and of the vagina in the female and is in front of the tip of the coccyx. The rectum is not straight, as its name would imply, but has a concavity forward corresponding to that of the sacrum and coccyx.

When viewed from in front three bends are usually seen, the upper and lower of which are sharply concave to the left, the middle one to the right. At the end of the pelvic colon the mesocolon ceases, and the rectum is then only covered by peritoneum at its sides and in front; lower down the lateral covering is gradually reflected off and then only the front is covered. About the junction of the middle and lower thirds of the tube the anterior peritoneal covering is also reflected off on to the bladder or vagina, forming the recto-sigmoid pouch in the male and the pouch of Douglas in the female. This reflection is usually about 3 in. above the anal aperture, but may be a good deal lower.

The rectal canal is the termination of the alimentary tract, and runs downward and backward from the lower surface of the rectal ampulla between the levatores ani muscles. It is about an inch long and its lateral walls are in contact, so that in section it appears as an antero-posterior slit (see J. Symington, Journ. Anat. and Phys. vol. 23, 1888).

Structure of the Intestine.—The intestine has four coats: serous, muscular, submucous and mucous. The serous or peritoneal coat has already been described wherever it is present. The muscular coat consists of unstriped fibres arranged in two layers, the outer longitudinal and the inner circular (see fig. 2). In the large intestine the longitudinal fibres, instead of being arranged evenly round the tube as they are in the small, are gathered into three longitudinal bands called taeniae (see fig. 1); by the contraction of these the large intestine is thrown into a series of sacculi or slight pouches. The taeniae in the caecum all lead to the vermiform appendix, and form a useful guide to this structure. In the rectum the three taeniae once more become evenly arranged over the whole surface of the bowel, but more thickly on the anterior and posterior parts. The circular layer is always thicker than the longitudinal; in the small intestine it decreases in thickness from the duodenum to the ileum, but in the large it gradually increases again, so that it is thickest in the duodenum and rectum.

The submucous coat is very strong and consists of loose areolar tissue in which the vessels break up.

The mucous coat is thick and vascular (see fig.2); it consists of an epithelial layer most internally which forms the intestinal glands (see EPITHELIAL, ENDODERMAL AND GLANDULAR TISSUES). External to this is the basement membrane, outside which is a layer of retiform tissue, and this is separated from the submucous coat by a very thin layer of unstriped muscle called the muscularis mucosae. In the duodenum and jejenum the mucous membrane is thrown into a series of transverse pleats called valvulae conniventes (see fig. 3); these begin about an inch from the pylorus and gradually fade away as the ileum is reached. About 4 in. from the pylorus the common bile and pancreatic ducts form a papilla, above which one of the valvulae conniventes makes a hood and below which a vertical fold, the frenalum, runs downward. The surface of the mucous membrane of the whole of the small intestine has a velvety appearance, due to the presence of closely-set, minute, thread-like elevations called villi (see fig. 2). Throughout the whole length of the intestinal tract are minute masses of lymphoid tissue called solitary glands (see fig. 2); these are especially numerous in the caecum and appendix, while in the ileum they are collected into large oval patches, known as agminated glands or Peyser's patches, the long axes of which, from half an inch to 4 in. long, lie in the long axis of the bowel. They are always found in that part of the intestine which is farthest from the mesenteric attachment. In the interior of the rectum three shell-like folds,
one above the other, project into the cavity and correspond to the lateral concavities or kinks of the tube. They are not in the same line and the largest is usually on the right side. They are known as the *plicae recti* or *valves of Houston*. In the anal canal are four or five longitudinal folds called the *columns of Morgagni*. (For further details, see Quain's Anatomy, London, 1866; Gray's Anatomy, London, 1905; Cunningham's Anatomy, Edinburgh, 1906.)

**Embryology.**—The greater part of the alimentary canal is formed by the closing-in of the entoderm to make a longitudinal tube, ventral and parallel to the notochord. This tube is blind in front and behind (cephalad and caudal), but the middle part of its ventral wall is for some distance continuous with the wall of the yolk-sac, and this part of the canal, which at first opens into the yolk-sac by a very wide aperture, is called the *mid gut*. The part in front of it, which lies dorsal to the heart, is the *fore gut*, while the part behind the aperture of the yolk-sac is the *hind gut*.

The pharynx, oesophagus, stomach and part of the duodenum are developed from the *fore gut*, a good deal of the colon and the *serous membranes*. The intestine now grows very rapidly and is thrown into a series of coils; the caecum ascends and passes to the right ventral to the duodenum, and presses against the dorsal wall of the abdomen; then it descends toward its permanent position in the right iliac fossa.

Between the first and the hinder (caudal) closed end of the intestinal tube the *allantois* grows to form the placenta and bladder (see *Urinary System, Reproductive System and Placenta*), and this region is the *cloaca* into which the alimentary, urinary and generative canals or ducts all open, but later two lateral folds appear which, by their union, divide the cloaca into a ventral and a dorsal part, the former being genito-urinary and the latter alimentary or intestinal. In this way the rectum or dorsal compartment is shut off from the genito-urinary. Later an ectodermal invagination at the hind end of the embryo develops and forms the anal canal; this is the *proctodaeum* and for some time it is separated from the hind (caudal) end of the rectal part of the *mesodaeum* (or part of the intestinal canal formed from the mesoderm) by a membrane called the *anal membrane*. This is eventually absorbed and the digestive tract now communicates with the surface by the anus.

F. Wood Jones (British Medical Journal, 17th of December 1904) has given a somewhat different description of the development of the cloaca and anus, which better explains the various abnormalities met with in this region but requires further confirmation before it is generally accepted. For the development of the mouth, pharynx, muscles of the alimentary canal, the reader is referred to the special articles on those structures. (For further details, see W. His, *Anatomie menschlicher Embryonen* (Leipzig, 1880–1888); C. S. Minot’s *Embryology* (New York, 1897); and J. P. McMurrough, *Development of the Human Body* (London, 1906). (F. G. P.)

### Comparative Anatomy

The primitive condition of the vertebrate alimentary canal may be described as a straight, simple tube, consisting of an anterior portion, the *stomodeum*, formed by an ectodermal invagination, the *mesenteron*, a long median portion lined by endoderm, and a short posterior portion, the *proctodaeum*, formed by ectodermal invagination. In the lower vertebrates the primitive tube survived also the purpose of respiration, and traces of the double function remain in the adult structure of all vertebrates (see *Mouth, Pharynx*). In fish, the pharynx, or branchial region, suddenly becomes narrower, posterior to the gill-slits, to form the oesophagus; in higher animals the oesophagus, in the adult, is separated from the primitive pharyngeal region and lies dorsal to it. Probably, in the primitive vertebrates, the digestive tract was lined with ciliated cells. Traces of this ciliation persist in many living forms. In the *Ammonocoea*, the larval form of *Petromyzon* (see *Cyclostomata*), the whole canal is ciliated except the pharynx and the rectum; in *Dipnotus* the epithelium of the stomach and the intestines is ciliated; in *Selachia* that of the posterior part of the gut, and the spiral valve, is ciliated; extensive ciliation may occur in almost any region of the gut of the lower teleostomes, but in the higher forms (*Teleostei*) it is generally absent. In the latter, however, and in higher groups of vertebrates, a peculiar striated border on the columnar cells lining the intestinal tract has been held to be a final trace of ancestral ciliation.

The alimentary canal may be conveniently described in three divisions, the *oesophagus* or gutlet, the passage by which food reaches the stomach, the *stomach*, typically an expanded region in which the food remains for a considerable time and is mechanically pulped, mixed with mucus and certain digestive juices (see *Nutrition* and partly macerated, the *intestinal tract* or gut, extending from the distal end of the stomach to the cloaca or anus, in which the food is subjected to further digestive action, but which is above all the region in which absorption of the products of digestion takes place, the refuse material together with quantities of waste matter entering the gut from the blood and liver being gradually passed toward the anus for discharge from the body.

The *oesophagus* is essentially merely a passage, as straight as
may be, from the pharynx to the stomach, varying in length with the length of the neck and thoracic regions in different animals, and in cacti, with the mass of the food. It is almost invariably lined with a many-layered epithelium, forming a tough coating, readily repaired and not easily damaged by hard food masses. It is occasionally separated from the stomach by a slight constriction which may be capable of contraction so as to prevent regurgitation. There are few exceptions to this structural and functional simplicity. In fishes (see Ichthyology, Anatomy) the swim-bladder is developed as a dorsal outgrowth of the oesophagus and may remain in open connexion with it. In certain Teleosts (e.g. Latodeira) it is longer than the length it has to traverse and is thrown into convolutions. In some fish (Teleosts, Osteichthyes) there is a set of the lining wall project into the cavity near the stomach and have been supposed to aid in preventing food particles, or living creatures swallowed without injury, escaping backwards into the mouth. In some egg-eating snakes the sharp tips of the ventral spines (hypophyses) of the posterior cerebral vertebræ penetrate the wall of the oesophagus and are used for breaking the shells of the eggs taken as food. In some aquatic Chelonians, the food of which consists chiefly of seaweeds, the lining membrane is produced into pointed processes backwardly directed. In Opisthocomus it forms an enormously wide double loop, hanging down over the breast-bone, which is peculiarly flattened and devoid of a keel in the anterior portion. In many birds part of the oesophagus may be temporarily dilated, forming a "crop," as for instance in birds of prey and humming birds. In the flamingo, many ducks, storks, and the cormorant the crop is a permanent although not a highly specialized enlargement. Finally, in the vast majority of seed-eating birds, in gallinaceous birds, pigeons, sandgrouse, parrots and many Passeres, particularly the finches, the crop is a permanent globular dilatation, in which the food is retained for a considerable time, mixed with a slight mucous secretion, and softened and partly macerated by the heat of the body. Many birds feed their young from the soft contents of the crop, and in pigeons, at the breeding season, the cells lining the crop proliferate rapidly and are discharged as a soft cheesy mass into the cavity, forming the substance known as pigeon's milk. Amongst Mammalia, in Rodentia, Carnivora, elephants and ruminants, the wall of the oesophagus contains a layer of voluntary muscle, by the contraction of which these animals induce antiperistaltic movements and can so regurgitate food into the mouth.

**Stomach.—** Where the oesophagus passes into the stomach, the lining wall of the alimentary tract changes from a many-layered epithelium to a mucous epithelium, consisting of a single layer of endodermal cells, frequently thrown into pits or projecting as processes; from being chiefly protective, it has become secretory and absorbing, and maintains this character to the distal extremity where it passes into the epiblast of the procloacum. In most cases the course of the alimentary canal from the distal end of the oesophagus to the cloaca or anus is longer than the corresponding region of the body, and the canal is therefore thrown into folds. The fundamental form of the stomach is a sac-like enlargement of the canal, the proximal portion of which is continuous with the line of the oesophagus, but the distal portion of which is bent in the proximal portion, the whole forming an enlarged bent tube. At the distal end of the tube the intestinal tract proper begins, and the two regions are separated by a muscular constriction. In fishes the stomach is generally in one of two forms; it may be a simple bent tube, the proximal limb of which is almost invariably much wider than the distal, although directly posterior; or the oesophagus may pass directly into an expanded, globular or elongated sac, from the anterior lateral wall of which, not far from the oesophageal opening, the duodenum arises. In Batrachia and Reptilia the stomach is in most cases a simple sac, marked off from the oesophagus only by increased calibre. In the Crocodilia, however, the anterior portion of the stomach is much enlarged and very highly muscular, the muscles radiating from a central tendinous area on each of the flattened sides. The cavity is lined by a hardened secretion and contains a quantity of pebbles and gravel which are used in the mechanical triturating of the food, so that the resemblance to the gizzard of birds is well marked. This muscular chamber leads by a small aperture into a distal, smaller and more glandular chamber. In birds the stomach exhibits two regions, an anterior glandular region, the proventriculus, the walls of which are relatively soft and contain enlarged digestive glands aggregated in patches (e.g. some Steganopodes), in rows (e.g. most birds of prey) or in a more or less regular band. The distal region is larger and is lined in most cases by a more or less permanent lining which is thick and tough in birds with a muscular gizzard, very slight in the others. If the stomach's function is that of feeding on fish, the two regions of the stomach are of equal width, and are indistinguishable until, on opening the cavity, the difference in the character of the lining membrane becomes visible. In other birds the proventriculus is separated by a well-marked constriction from the posterior and larger region. In graminiferous forms the latter becomes a thick-walled muscular gizzard, the muscles radiating from tendinous areas and the cavity containing pebbles or gravel.

In mammals, the primitive form of the stomach consists of a greatly expanded expansion of the oesophageal region, forming the cardiac portion, and a forwardly curved, narrower pyloric portion, from which the duodenum arises. The whole wall is muscular, and the lining membrane's richly glandular. In the Insectivora, Carnivora, Perissodactyla, and in most Edentata, Chiroptera, Rodentia and Primates, this primitive disposition is retained, the difference consisting chiefly in the degrees of elongation of the stomach and the sharpness of the distal curvature. In other cases the cardiac portion may be prolonged into a cecal sac, a condition most highly differentiated in the blood-sucking bat, Desmodus, where it is longer than the entire length of the body. There are two cardiac extensions in the hippopotamus and in the peccary. In many other mammals one, two or three protrusions of the cardiac region occur, whilst in the manatee and in some rodents the cardiac region is constricted off from the pyloric portion. In the Artiodactyla the stomach is always complex, the complexity reaching a maximum in ruminating forms. In the Suidae a cardiac diverticulum is partly constricted from the general cavity, forming an incipient condition of the rumen of true ruminants; the general cavity of the stomach is the non-ruminant artiodactyls and true ruminants, the oesophagus opens into a wide cardiac portion, incompletely divided into four chambers. Three of these, towards the cardiac extremity, are lined with villi and correspond to the rumen or paunch; the fourth, which lies between the opening of the oesophagus and the pyloric portion of the stomach, is the ruminant reticulum and its wall is lined with very shallow "cells." A groove runs along its dorsal wall from the oesophageal aperture to a very small cavity lined with low, longitudinally disposed folds, and forming a narrow passage between the cardiac and pyloric divisions; this is an early stage in the development of the omasum, psaltery or manyplexes of the ruminant stomach. The fourth or true pyloric chamber is an elongated sac with smooth glandular walls and is the abomasum, or retent Narrow. In the camel the rumen forms an enormous globular paunch with villous walls and internally showing a trace of division into two regions. It is well marked off from the reticulum, the "cells" in which are extremely large, forming the well-known reticular chambers. The peuslery is sharply constricted off from the reticulum and is an elongated chamber showing little trace of the longitudinal ridges characteristic of this region; it opens directly into the relatively small abomasum. In the true ruminants, the rumen forms a capacious, villous reservoir, nearly always partly sacculated, into which the food is passed rapidly as the animal grazes. The food is subjected to a rotary movement in the paunch, and is thus repeatedly subjected to
moistening with the fluids secreted by the reticulum, as it is passed over the aperture of that cavity, and is formed into a rounded bolus. Most ruminants swallow masses of hairs, and these, by the rotary action of the paunch, are aggregated into peculiar dense, rounded balls which are occasionally discharged from the mouth and are known as ‘hair-balls’ or ‘bezoars.’ The food bolus, when the animal is lying down after grazing, is passed into the oesophagus and reaches the mouth by anterostaltic contractions of the oesophagus. After prolonged mastication and mixing with saliva, it is again swallowed, but is now passed into the pslaterium, which, in true ruminants, is a small chamber with conspicuous longitudinal folds. Finally it reaches the large abomasum where the last stages of gastric digestion occur.

In the Cetacea the stomach is different from that found in any other group of mammals. The oesophagus opens directly into a very large cardiac sac the distal extremity of which forms a long caecal pouch. At nearly the first third of its length this communicates by a narrow aperture into the elongated, relatively narrow pyloric portion. The latter is convoluted and constricted into a series of chambers that differ in different groups of Cetacea. In the Sirenia the stomach is divided by a constriction into a cardiac and a pyloric portion, and the latter has a pair of caeca. In most of the Marsupialia the stomach is relatively simple, forming a globular sac with the oesophageal and pyloric apertures closely approximated; in the kangaroos, on the other hand, the stomach is divided into a relatively small caecal cardiac portion and an enormously long sacculated and convoluted pyloric region, the general arrangement of which closely recalls the large caecum of many mammals.

**Intestinal Tract.**—It is not yet possible to discuss the general morphology of this region in vertebrates as a group, as, whilst the modifications displayed in birds and mammals have been compared and studied in detail, those in the lower groups have not yet been systematically co-ordinated.

In the Cyclostomata, Holocephali and a few Teleostei the course of the gut is practically straight from the pyloric end of the stomach to the exterior, and there is no marked differentiation into regions. In the Dipnoi, a contracted sigmoid curve between the stomach and the dilated intestine is a simple beginning of the complexity found in other groups. In very many of the more specialized osteo steans, the gut is much convoluted, exhibiting a series of watchspring-like coils. In a number of different groups, increased surface for absorption is given, not by increase in length of the whole gut, but by the development of an internal fold known as the spiral valve. This was probably originally a longitudinal fold similar to the typhlosole of chaetopterids. It forms a simple fold in the larval Ammocoete, and in its anterior region remains straight in some adult fish, e.g., Polypterus, but in the majority of cases it forms a complex spiral, wound round the inner wall of the expanded large intestine, the internal edge of the fold sometimes meeting to form a central column. It occurs in Cyclostomata, Selachii, Holocephali, Chondrostei, Crossopterygii, Amiidae, Lepidosteidae and Dipnoi. A set of organs peculiar to fish and known as the pyloric caeca are absent in Cyclostomata and Dipnoi, in most Selachii and in Amia, but present, in numbers ranging from one to nearly two hundred, in the vast majority of fish. These are outgrowths of the intestinal tract near the pyloric extremity of the stomach, and their function is partly glandular, partly absorbing. In a few Teleostei there is a single caecal diverticulum at the beginning of the ‘rectum,’ and in some regions a solid rectal gland occurs in most elasmobranchs, whilst, again, in the Dipnoi a similar structure opens into the cloaca. These caeca have been compared with the colic caeca of higher vertebrates, but there is yet no exact evidence for the homology.

In the Batrachia the course of the intestinal tract is nearly straight from the pyloric end of the stomach to the cloaca, in the case of the perennibranchiates there being no more than a few simple loops between the expanded ‘rectum’ and the straight portion that leaves the stomach. In the Caudicibranchia the anterior end of the enlarged rectum lies very close to the distal extremity of the stomach, and the gut, between these two regions, is greatly lengthened, forming a loop with many minor loops borne at the periphery of an expanse of mesentery, recalling the Meckelian tract of birds and mammals. In the tadpole this region is spirally coiled and is still longer relatively to the length of the whole tract. In Hyla and Pipa there is a small caecum comparable with the colic caecum of birds and mammals.

In Reptilia the configuration of the intestinal tract does not differ much from that in Batrachia, the length and complexity of the minor coils apparently varying with the general configuration of the body, that is to say, in reptiles with a long, narrow, and snake-like body the minor loops of the gut are relatively short and unimportant, whilst in those with a more spacious cavity, such as chelomians, many lizards and crocodiles, the gut may be relatively long and disposed in many minor coils. There is comparatively little differentiation between the mid-gut and the gut in cases where the whole gut is long; in the others the hind-gut is generally marked by an increase of calibre. A short caecal diverticulum, comparable with the colic caecum of birds and mammals, is present in many snakes and lizards and in some chelomians.

In fishes, batrachians and reptiles the intestinal tract is swung from the dorsal wall of the abdominal cavity by a mesentery which is incomplete on account of secondary absorption in places, and which grows out with the minor loops of the gut. There are also traces, more abundant in the lower forms, of the still more primitive ventral mesentery.

**Intestinal Tract in Birds and Mammals.**—There is no doubt that the similarity of the modes of disposition of the alimentary tract in birds and mammals points to the probability of the chief morphological features of this region in these animals having been laid down in some common ancestor, although we
mesentery grew out with these folds, but the presence of adjacent organs, the disturbance due to the outgrowth of the liver, and the secondary relations brought about between different portions of the gut, as the out-growing loops invaded each other's localities, disturbed the primitive simplicity. Three definite regions of outgrowth, however, became conspicuous and are to be recognized in the actual disposition of the gut in existing birds and mammals. The first of these is the duodenum. In the vast majority of birds, and in some of the simpler mammals, the portion of the gut immediately distal of the stomach grows out into a long and narrow loop (fig. 4, d), the proximal and distal ends of which are close together, whilst the loop itself may remain long and narrow, or may develop minor loops on its course. In mammals generally, however, the duodenum is complex and is not so sharply marked off from the distal portion of the gut as in birds. The second portion is Meckel's tract. It consists of the part generally known as the small intestines, the jejunum and ileum of human anatomy, and stretches from the distal end of the duodenum to the caecum or caeca. It is the chief absorbing portion of the gut, and in nearly all birds and mammals is the longest portion. It represents, however, only a very small part of the primitive straight gut, corresponding to not more than two or three somites of the embryo. This narrow portion grows out to form the greater part of what is called the pendent loop in mammalian embryology. Its anterior or proximal end lies close to the approximated

FIG. 5.—Intestinal Tract of Canis vulpes. S, cut end of duodenum; C, caecum; R, cut end of rectum.

end of the duodenum to the caecum or caeca. It is the chief absorbing portion of the gut, and in nearly all birds and mammals is the longest portion. It represents, however, only a very small part of the primitive straight gut, corresponding to not more than two or three somites of the embryo. This narrow portion grows out to form the greater part of what is called the pendent loop in mammalian embryology. Its anterior or proximal end lies close to the approximated

proximal and distal ends of the duodenal loop, whilst its distal end passes into the hind-gut at the colic caecum or caeca. In the embryos of all birds and mammals, the median point of Meckel's tract, the part of the loop which has grown out farthest from the dorsal edge of the mesentery, is marked by the diverticulum caecum vitellii, the primitive connexion of the cavity of the gut with the narrowing stalk of the yolk-sac (fig. 4, 9). Naturally, in birds where the yolk-sac is of great functional importance this diverticulum is large, and in a majority of the families of birds persists throughout life, forming a convenient point of orientation. In mammals, no doubt in association with the functional reduction of the yolk-sac, this diverticulum, which is known as Meckel's diverticulum, has less importance, and whilst it has been observed in a small percentage of adult human subjects has not been recognized in the adult condition of any lower Mammalia.

In birds, Meckel's tract falls into minor folds or loops, the disposition of which forms a series of patterns remarkably different in appearance and characteristic of different groups. In fig. 4 an extremely primitive type is represented. In mammals Meckel's tract remains much more uniform; it may be short, or increase enormously in length, but in either case it falls into a fairly symmetrical shape, suspended at the circumference of a nearly circular expansion of mesentery. Where it is short it is thrown into very simple minor loops (figs. 5, 6 and 7); where it is long, these minor loops form a convoluted mass (figs. 8 and 9).

The third portion of the gut should be termed the hind-gut and lies between the caecum or caeca and the anus, corresponding to the large intestines, colon and rectum of human anatomy. It is formed from a much larger portion of the primitive straight gut than the duodenum and Meckel's tract together, and its proximal portion, in consequence, lies very close to the origin of the duodenum. In the vast majority of birds, the hind-gut in the adult is relatively extremely short, often being only from

one-eighth to one-thirtieth of the whole length of the gut. A certain number of primitive birds, however, have retained a relatively long condition of the hind-gut (fig. 4), the greatest relative length occurring in struthious birds, and particularly in the ostrich, where the hind-gut exceeds in length the duodenum and Meckel's tract together. Mammals may be contrasted with birds as a group in which the hind-gut is always relatively long, sometimes extremely long, and in which, moreover, there is a strong tendency to differentiation of the hind-gut into regions
the characters of which are of systematic importance. The first region is the colon, which forms a very simple expansion in mammals such as Carnivora (fig. 3), where the whole hind-gut is relatively short, or a series of simple loops in mammals in which the whole gut has a primitive disposition (e.g. Marsupialia, fig. 6). In the odd-toed Ungulata, the colon (fig. 7) forms a bird-like only long loop, the two limbs of which are closely approximated and the calibre of which is very large. In Ruminantia (fig. 8) the colon is still more highly differentiated, displaying first a simple wide loop, then a complicated watchspring-like coil, and finally a very long, irregular portion. In the higher Primates (fig. 9) it forms one enormous very wide loop, corresponding to the ascending, transverse and descending colons of human anatomy, and a shorter distal loop, the omega loop of human anatomy. Other striking patterns are displayed in other mammalian groups.

The second region of the hind-gut is usually known as the rectum, and although it is sometimes lengthened it is typically little longer than the portion of the primitive straight gut that it represents.

Adaptations of the Intestinal Tract to Function.—The chief business of the gut is to provide a vascular surface to which the prepared food is applied so that the nutritive material may be absorbed into the system. Overlying and sometimes obscuring the morphological patterns of the gut, are many modifications correlated with the nature of the food and producing homoplastic resemblances independent of genetic affinity. Thus in birds and mammals alike there is a direct association of herbivorous habit with great relative length of gut. The explanation of this, no doubt, is simply that the vegetable matter which such creatures devour is in a form which requires not only prolonged digestive action, but, from the intimate admixture of indigestible material, a very large absorbing surface. In herbivorous mammals, the gut is very long, with a thick wall and a relatively small calibre, whilst there is a general tendency for the regions of the gut to be slightly or not at all defined. Fish, as it is eaten by wild animals, contains a large bulk of indigestible matter, and so requires an extended absorbing surface; the thick wall and relatively small calibre are protections against overpowering the fish bones. In frugivorous birds the gut is strikingly short, wide and simple, whilst a similar change has not taken place in frugivorous mammals. Carnivorous birds and mammals have a relatively short gut. In birds, generally, the relation of the length and calibre of the gut to the size of the whole creature is strongly in the direction of two birds of similar habit and of the same group be compared, it will be found that the gut of the larger bird is relatively longer rather than relatively wider. The same general rule applies to Meckel's tract in mammals, whereas in the case of the hind-gut increase of capacity is given by increase of calibre rather than by increased length.

The Celic Caeca.—These organs lie at the junction of the hind-gut with Meckel's tract and are homologous in birds and mammals although it happens that their apparent position differs in the majority of cases in the two groups. In birds, the hind-gut is relatively very short, and the caecal position, accordingly, is at a very short distance from the posterior end of the body, whereas in most mammals the hind-gut is very long and the position of the caecum or ceca is relatively very much farther

**Fig. 9.—Intestinal Tract of Gorilla. S, cut end of duodenum; R, cut end of rectum; C, vermiform appendix of caecum; X, X₁, X₂, cut ends of factors of the portal vein.**

**ALIMONY**

*Alimony* is the *very* her husband's estate for her support on a decree for judicial separation or for the dissolution of the marriage. Though, as a rule, payable to a wife, it may, if the circumstances of the case warrant it, be payable by the wife to the husband. Alimony is of two kinds, (a) temporary (pendente lite), and (b) permanent. *Temporary* alimony, or alimony pending suit, is the provision made by the husband for the wife in cases between whom a marriage was validly entered before the marriage was dissolved by divorce or annulment. *Permanent* alimony is alimony whether the suit is by or against the husband and whatever the nature of the suit may be. The usual English practice is to allot as temporary
alimony about one-fifth of the husband’s net income; where it appears that the husband has no means or is in insolvent circumstances, the court will refuse to allot temporary alimony. So where the wife is supporting herself by her own earnings, this fact will be taken into consideration. And where the wife and husband have lived apart for many years before the institution of the suit, and she has supported herself during the separation, no alimony will be allotted. Nor will the wife be entitled to alimony where she has sufficient means of support independent of her husband. Permanent alimony is that which is allotted to the wife after final decree. By the Matrimonial Causes Act 1907, the court may, if it think fit, on any decree for dissolution or nullity of marriage, order that the husband shall, to the satisfaction of the court, secure to the wife such a gross sum of money or such annual sum of money for any term not exceeding her life, as having regard to her fortune (if any), to the ability of her husband, and to the conduct of the parties, it may deem reasonable. The court may suspend the pronouncing of its decree until a proper deed or instrument has been executed by all necessary parties. The court may also make an order on the husband for payment to the wife during their joint lives of a reasonable monthly or weekly sum for her maintenance; the court may also at any time discharge, modify, suspend or increase the order according to the altered means of the husband; the court has also power to make provision for children. Alimony is paid direct to the wife or to a trustee or trustees on her behalf, but the court may impose any restrictions which seem expedient. We may also describe as a kind of alimony the allowance of a reasonable weekly sum not exceeding £2 which is paid, under the Summary Jurisdiction (Married Women) Act 1895, may be given to a married woman on applying to a court of summary jurisdiction if she has been forced by cruelty to leave her husband or has been deserted by him.

**United States.**—Alimony is granted by the courts of the several states on much the same principle as in England, though in many states the courts of equity as such may grant alimony without divorce or separation proceedings independently of any statute, on the ground that it is just that the husband should support his wife when she lives apart from him for his fault, and since the courts of common law provide no remedy the courts of equity will. This is so in Alabama (Brady v. Brady, 1905, 30 So. Rep. 237), Kentucky, North Carolina, Iowa, California, Ohio, Virginia, South Dakota and the District of Columbia. In other states alimony without such proceedings is allowed by statute, and such alimony is now very general throughout the United States. The usual grounds for the allowance of it are desertion and such conduct as would amount to legal cruelty. After divorce a vinculo, alimony or separate maintenance is sometimes granted on the ground of desertion. The marriage must be proven to have existed before the woman can validly claim a “common law” marriage, i.e. one established by cohabitation and repute, is sufficient. In several states alimony or maintenance is by statute allowed to the husband in certain cases out of the wife’s property. This is so in Massachusetts, Virginia, Rhode Island and Iowa. In Oregon he is entitled to one-third of his wife’s real estate in addition to maintenance on divorce for her fault. The amount of alimony depends upon the circumstances of each case as in England. Permanent alimony is generally meant when pendente lite, and usually one-third the husband’s income. It may generally be changed from time to time as the circumstances of the parties change. Judgment for alimony is considered a judgment in personam and not in rem, and can only be enforced outside the state where rendered in case the husband has been personally served with process within that state. The remarriage of the man is not sufficient ground for reducing the alimony (Smith v. Smith, 1905, 102 N.W. Rep. 631), but on remarriage of a woman to one able to support her, her former husband being in poor circumstances, it will be reduced (Kiralfy v. Kiralfy, 1901, 1 Wis. N.S. 467).

**ALIN, OSCAR JOSEF** (1846-1900), Swedish historian and politician, was born at Falun on the 22nd of December 1846. In 1872 he became docent, and in 1882 professor of political economy at Upsala, of which university he was afterwards rector. In September 1888 he was elected a member of the first chamber of the Riksdag, where he attached himself to the conservative protectionist party, over which, from the first, he exercised great authority. But it is as a historian that Alin is most remarkable. Among his numerous works the following are especially worthy of note: *Bidrag till svenska rådets historia under medeltiden* (Upsala, 1872); *Sveriges Historia, 1517-1601* (Stockholm, 1878; *Bidrag till svenska statsregistrets historia* (Stockholm, 1884-1887); *Den norr-norske Unionen* (Stockholm, 1889-1891), the best book on the Norwegian-Swedish Union question from the Swedish point of view; *Fjärde Artikeln af Fredstraktaten i Kiel* (Stockholm, 1890); *Carl Johan och Sveriges yttre politik, 1810-1832* (Stockholm, 1890); *Carl XIV. och Rikets Ständer, 1840-1847* (Stockholm, 1893). He also edited *Svenska Riksdagsakter, 1521-1554* (Stockholm, 1887), in conjunction with E. Hildebrand, and *Sveriges Grundlagar* (Stockholm, 1892). He died at Upsala on the 31st of December 1900.

(R. N. B.)

**ALIPUR,** a suburb of Calcutta, containing Belvedere House, the official residence of the lieutenant-governor of Bengal, and a number of handsome mansions. It lies within the limits of the south suburban municipality, and is a cantonment of native troops. On the Calcutta maidan, opposite Alipur Bridge, stood two trees under which duels were fought. It was here that the meeting in 1786 between Warren Hastings and Sir Philip Francis took place.

**ALIQUOT (a Lat. word meaning “some,” “so many”),** a term generally occurring in the phrase “aliquot part,” and meaning that one quantity is exactly divisible into another; thus 3 is an aliquot part of 6.

**ALIRAJPUR,** a native state of India, under the Bhopawar agency in Central India. It lies in Malwa, near the frontier of Bombay. It has an area of 836 sq. m.; and a population (1901) of 50,183. The country is hilly, and many of the inhabitants are aboriginal Bhils. It has from time to time been under British administration. The chief, whose title is Rana, is a Rahtor Rajput. He has an estimated revenue of £770, and pays a tribute of £700. The Victoria bridge at Alirajpur was built to commemorate the Diamond Jubilee of 1897.

**ALISMACEAE** (from the Gr. ἀλίμωσις, a water-plant mentioned by Dioscorides), in botany, a natural order of monocotyledons belonging to the series Helobiae, and represented in Britain by the water plantain, *Alisma Plantago*, the arrow-head, *Sagittaria*, the star-fruit, *Damasium*, and flowering rush, *Butomus* (from the Gr. βοης, ox, τιμωρ, to cut, in allusion to leaves cutting the tongues of oxen feeding on them). They are marsh- or water-plants with generally a stout stem (rhizome) creeping in the mud, radical leaves and a large, much branched inflorescence. The leaves show a great variety in shape, often

![Fig. 1.—Flowering Rush (*Butomus umbellatus*). 1. Flower in vertical section; 2, horizontal plan of arrangement of flower.](image-url)
arrangement thus recalls that of a buttercup, a resemblance which extends to the fruit, which is a head of achenes or follicles. The flowers contain honey, and attract flies, short-lipped bees or other small insects by the agency of which pollination is effected. The fruit of *Butomus* is of interest in having the seeds borne over the inner face of the wall of the leathery pod (follicle). *Damasionium* derives its popular name, star-fruit, from the fruits spreading when ripe in the form of a star. It is a western

Mediterranean plant which spreads to the south of England, where it is sometimes found in gravelly ditches and pools. The order contains about fifty species in fourteen genera, and is widely distributed in temperate and warm zones. *Alisma Plantago* (fig. 2), a common plant in Britain (except in the north) in ditches and edges of streams, is widely distributed in the north temperate zone, and is found in the Himalayas, on the mountains of tropical Africa and in Australia.

**ALISON, ARCHIBALD** (1737–1839), Scottish author, son of Patrick Alison, provost of Edinburgh, was born on the 13th of November 1737 at Edinburgh. After studying at the university of Glasgow and at Balliol College, Oxford, he took orders in the Church of England, and was appointed in 1778 to the curacy of Brancepeth, near Durham. In 1784 he married Dorothea, youngest daughter of Professor Gregory of Edinburgh. The next twenty years of his life were spent in Shropshire, where he held in succession the livings of High Ercaill, Roddington and Kenley. In 1800 he removed to Edinburgh, having been appointed senior incumbent of St Paul’s Chapel in the Cowgate. For thirty-four years he filled this position with much ability, his preaching attracting so many hearers that a new and larger church was built for him. His last years were spent at Colinton, near Edinburgh, where he died on the 17th of May 1839. Alison published, besides a *Life of Lord Woodhouselee*, a volume of sermons, which passed through several editions, and a work entitled *Essays on the Nature and Principles of Taste* (1790), based on the principle of association (see under AESTHETICS, p. 288). His elder son, Dr William Puilteny Alison (1790–1850), was a distinguished Edinburgh medical professor.

**Sir ARCHIBALD ALISON, Bart.** (1792–1867), the historian, was the younger son, and was born at Kenley, Shropshire, on the 29th of December 1792. He studied at the university of Edinburgh, distinguishing himself especially in Greek and mathematics. In 1814 he passed at the Scottish bar, but he did not at once practise. The close of the war had opened up the continent, and Alison set out in the autumn of 1814 for a lengthened tour in France. It was during this period that the idea of writing his history first occurred to him. A more immediate result of the tour was his first literary work of any importance, *Travels in France during the Years 1814–1815*, written in collaboration with his brother and A. F. Tytler, which appeared in the latter year. On his return to Edinburgh he practised at the bar for some years with very fair success. In 1824 he became one of the four Scottish advocates-depute. As a result of the experience gained in this office, which he held until 1836, he wrote his *Principles of the Criminal Law of Scotland* (1832) and *Practice of the Criminal Law of Scotland* (1833), which in 1834 led to his appointment by Sir Robert Peel to the office of sheriff of Lanarkshire, which ranks next to a judgeship in the supreme court. The office, though by no means a sinecure, gave him time not only to make frequent contributions to periodical literature, but also to write the long-projected *History of Europe*, for which he had been collecting materials for more than fifteen years. The history of the period from the beginning of the French Revolution till the restoration of the Bourbons in 1815 was completed in ten volumes in 1842, and met with a success almost unexampled in works of its class. Within a few years it ran through ten editions, and was translated into many of the languages of Europe, as well as into Arabic and Hindustani. At the time of the author’s death it was stated that 108,000 volumes of the library edition and 439,000 volumes of the popular edition had been sold. A popularity so widespread must have had some basis of merit, and the good qualities of Alison’s work are obvious at the surface. It brought together, though not always in a well-arranged form, an immense amount of information that had before been practically inaccessible to the general public. It at least made an attempt to show the organic connexion in the policy and progress of the different nations of Europe; and its descriptions of what may be called external history—of battles, sieges and state pages—were spirited and interesting. On the other hand the faults of the work are numerous and glaring. The general style is prolix, involved and vicious; mistakes of fact and false deductions are to be found in almost every page, and the constant repetition of trite moral reflections and egotistical references seriously detracts from its dignity. A more grave defect resulted from the author’s strong political partisanship, which entirely unfitted him for dealing with the problems of history in a philosophical spirit. His unbending Toryism made it impossible for him to give any satisfactory explanation of so complex a fact as the French Revolution, or accurately to estimate the forces that were to shape the Europe of the 19th century. A continuation of the History, embracing the period from 1815 to 1852, which was completed in four volumes in 1836, did not meet with the same success as the earlier work. The period being so near as to be almost contemporary, there was a stronger temptation, which he seems to have found it impossible to resist, to yield to political prejudice, while the materials necessary for a clear knowledge of the influences shaping European affairs were not as yet accessible. The book is now almost wholly out of date. In 1845 Alison was chosen rector of Marischal College, Aberdeen, and in 1851 of Glasgow University. In 1852 a baronetcy was conferred upon him, and in the following year he was made a D.C.L. of Oxford. His literary activity continued till within a short time of his
Alizarin took the west side of Mossel Bay. Both places were named in honour of Sir Harry Smith, governor of Cape Colony 1847-1842, Alwal (see above) being the village in the Punjab where in 1846 he gained a great victory over the Sikhs. Crossing the Orange River at this spot in September 1848, Sir Harry noted that it was "a beautiful site for a town," and in the May following the town was founded. In the early months of the Boer War of 1899-1902 Alwal North was held by the Boers. It was reoccupied by the British in March 1900.

Alizarin, or 1,2-dioxyantiarhquinoine,

\[ \text{C}_6\text{H}_4\text{(O)}\text{(CO)C}_6\text{H}_4(\text{OH})\text{H}_2 ]^2 \]

a vegetable dyestuff formerly prepared from madder root (Rubia tinctorum) which contains a glucoside ruberythric acid (C\text{H}_2\text{O}_4). This glucoside is readily hydrolysed by acids or ferments, breaking up into alizarin and glucose:

\[ \text{C}_6\text{H}_2\text{O}_4 + 2\text{H}_2\text{O} = 2\text{C}_2\text{H}_4\text{O}_4 + \text{C}_6\text{H}_4\text{O}_4 \]

Ruberythric acid = Glucose + Alizarin.

Alizarin was known to the ancients, and until 1868 was obtained entirely from madder root. The first step in the synthetic production of alizarin was the discovery in 1868 of C. Graebe and C. Liebermann that on heating with zinc dust, alizarin was converted into anthracene. In order to synthesize alizarin, they converted anthracene into anthraquinone and then brominated the quinone. The dibrominated product so obtained was then fused with caustic potash, the melt dissolved in water, and on the addition of hydrochloric acid to the solution, alizarin was precipitated. This process, owing to its expensive nature, was not in use very long, being superseded by another, discovered simultaneously by the above-named chemists and by Sir W. H. Perkin; the method being to sulphonate anthraquinone, and then to convert the sulphonic acid into its sodium salt and fuse this with caustic soda.

In practice, the crude anthracene is purified by solution in the higher pyridine bases, after which treatment it is frequently sublimed. It is then oxidized to anthraquinone by means of sodium dichromate and sulphuric acid in leat vats, steam then being so that the mixture can be brought to the boil. When oxidation is complete the crude anthraquinone is separated in filter presses and heated with an excess of commercial oil of vitriol to 130° C., the various impurities present in the crude material being sulphonated and rendered soluble in water, whilst the anthraquinone is unaffected: it is then washed, to remove impurities, and dried. The anthraquinone so obtained is then heated for some hours at about 150-160° C. with fuming sulphuric acid (containing about 40-50 % SO₃) and by this treatment is converted into anthraquinone-β-monosulphonic acid. The monosulphonic acid is added to neutralize the excess of acid, when the sodium salt of the monosulphonic acid (known as silver salt) separates out. This is filtered, washed, and then fused with caustic soda, when the sulpho-group is replaced by a hydroyxl group, and a second hydroxyl group is simultaneously formed; in order to render the formation of this second group easier, a little potassium chlorate or sodium nitrate is added to the reaction mixture. The melt is dissolved in water and the dyestuff is liberated from the sodium salt by hydrochloric or sulphuric acid, or is converted into the calcium salt by digestion with hot milk of lime, then filtered, and the calcium salt decomposed by acid. The precipitated alizarin is then well washed and made into a paste with water, in which form it is put on to the market.

K. Lagodzinskii (Berichte, 1895, 25, p. 1427) has synthesized alizarin by condensing hemipinic acid [(CH\text{O})\text{C}_6\text{H}_4] with benzene in the presence of aluminium chloride. The product on acidification gives a compound C\text{H}_7\text{O}_2\text{H}_2 which is probably an oxy-methoxy-benzoyl benzoic acid. This is dissolved in cold concentrated sulphuric acid, in which it forms a yellowish red solution, but on heating to 100° C. the colour changes to red and violet, and on pouring out upon ice, the monomethyl ether of alizarin is precipitated. This compound is hydrolysed by hydrochloric acid and alizarin is obtained. It
can also be synthesized by heating catechol with phthalic anhydride and sulphuric acid at 150°C.

\[
\text{C}_6\text{H}_4\text{(CO)}_2\text{O} + \text{C}_6\text{H}_4(\text{OH})_2 \rightarrow \text{H}_2\text{O} + \text{C}_6\text{H}_4\text{(CO)}_2\text{C}_6\text{H}_4(\text{OH})_2
\]

Pure alizarin crystallizes in red prisms melting at 290°C. It is insoluble in water, and not very soluble in alcohol. It dissolves readily in caustic alkalis on account of its phenolic character, and it forms a yellow-coloured di-acetate. Its value as a dyestuff depends on its power of forming insoluble compounds (lakes) with metallic oxides. It has no affinity for vegetable fibres, and consequently cotton goods must be mordanted before dyeing with it (see Dyestuff).

Numerous derivatives of alizarin are known. On solution in glacial acetic acid and addition of nitric acid, B-nitroalizarin
(alizarin orange) is produced, and this on heating with sulphuric acid and glycerin is converted into alizarin blue.

The threeoxyanthraquinones—purpurin, anthrapurpurin, anthragallo and flavopurpurin—are also very valuable dyestuffs. These compounds may be represented by the following formulae:

\[
\text{COOH} + \text{OH} \leftrightarrow \text{OH} + \text{COOH}
\]

Purpurin, Anthrapurpurin, Flavopurpurin, Anthragallo.

Purpurin (1-2-4 trioxanthraquinone) is found with alizarin in madder root; it is now prepared synthetically by oxidizing alizarin with manganese dioxide and sulphuric acid. After the separation of the silver salt (see above) obtained on sulphonating anthraquinone, the remaining acid liquid gives on treatment with calcium carbonate the calcium salt of anthraquinone 2,6-di sulphonic acid (anthraquinone-a-di sulphonic acid). This is converted into the sodium salt by means of sodium carbonate, and on alizarin it yields flavopurpurin. In a similar manner antara purpurin is prepared by alkali fusion of anthraquinone 2,8 di sulphonic acid. Anthragallo is synthetically prepared by the condensation of benzoic and gallic acids with sulphuric acid or from pyrogalloid and phthalic anhydride in the presence of sulphuric acid or zinc chloride.

A. Baeyer in 1890, by heating alizarin with fuming sulphuric acid for 24-48 hours at 35-40°C, obtained a product, which after treatment with caustic soda gave a sulphuric acid ester of quinalizarin, and this after acidification and boiling was converted into quinalizarin (Alizarin Bordeaux) or 1-2-6-9 tetra-oxanthraquinone. Penta-oxanthraquinones have been obtained from purpurin and anthrapurpurin, while a hexa-oxanthraquinone has been obtained from 1,5 dinitro-anthraquinone.

ALKAHEST (a pseudo-Arabic word believed to have been invented by Paracelsus), a liquid, much sought after by the alchemists, having the power of dissolving gold and every other substance, which it was supposed would possess invaluable medicinal qualities.

ALKALI, an Arabic term originally applied to the ashes of plants, from which by lixiviation carbonate of soda was obtained in the case of sea-plants and carbonate of potash in that of land-plants. The method of making these "mild" alkalis into "caustic" alkalis by treatment with lime was practised in the time of Pliny in connexion with the manufacture of soap, and it was also known that the ashes of shore-plants yielded a hard soap and those of land-plants a soft one. But the two substances were generally confounded as "fixed alkali" (carbonate of ammonia being "volatile alkali"), till Duhamel du Monceau in 1736 established the fact that common salt and the ashes of sea-plants contain the same base as is found in natural deposits of soda salts ("mineral alkali"), and that this body is different from the "vegetable alkali" obtained by incinerating land-plants or wood (pot-ashes). Later, Martin Heinrich Klaproth, finding vegetable alkali in certain minerals, such as leucite, proposed to distinguish it as potash, and at the same time assigned to the mineral alkali the name natron, which survives in the symbol, Na, now used for sodium. The word alkali supplied the symbol for potassium, K (kalium). In modern chemistry alkali is a general term used for compounds which have the property of neutralizing acids, and is applied more particularly to the highly soluble hydrates of sodium and potassium and of the "alkali" or "terrestrial" "alkali," pumichlor and liquid alkali, also to aqueous ammonia. An in smaller degree these alkaline properties are shared by the less soluble hydrates of the "metals of the alkaline earths," calcium, barium and strontium, and by thallium hydrate. An alkali is distinguished from an acid or neutral substance by its action on litmus, turmeric and other indicators.

ALKALI MANUFACTURE. The word "alkali" denotes both soda and potash, but by "alkali manufacture" we understand merely the manufacture of sodium sulphate, carbonate and hydrate. The corresponding potash compounds are not manufactured in the United Kingdom, but exclusively in Germany (from potassium chloride and from the mother-liquor of the strontia process in the manufacture of beetroot sugar) and in France (from sinasse). The term alkali is employed in a technical sense for the carbonate and hydrate (of sodium), but in the Leblanc process the manufacture of sodium sulphate necessarily precedes that of the carbonate, we include this as well as the manufacture of hydrochloric acid which is inseparable from it. We also treat of the utilization of hydrochloric acid for the manufacture of chlorine and its derivatives, which are usually comprised within the meaning of the term "alkali manufacture."

A great many processes have been proposed for the manufacture of alkali from various materials, but none of these has become of any practical importance except those which start from sodium chloride (common salt); and among the latter again only three classes of processes are actually employed for manufacturing purposes, viz. the Leblanc, the ammonia-soda, and the electrolytic processes.

I. THE LEBLANC PROCESS

The Leblanc process, which was invented by Nicolas Leblanc (q.v.) about 1790, begins with the decomposition of sodium chloride by sulphuric acid, by which sodium sulphate and hydrochloric acid are produced. The sodium sulphate is afterwards fluxed with calcium carbonate and coal, and a mixture is thus obtained from which sodium carbonate can be extracted by exhausting it with water.

Leblanc himself for a time carried out his process on a manufacturing scale, but he was ruined in the political troubles of the time and died by his own hand in 1806. His invention was, however, at one time utilized by others in France; and in Great Britain, after a few previous attempts on a small scale, it was definitely introduced by James Munstrap (q.v.) in 1823. From that time onward the Leblanc process spread more and more, and for a considerable period nearly all the alkali of commerce was made by it. The rise of the ammonia-soda process (since 1870) gradually took upon the Leblanc process, which in consequence has been greatly restricted in Great Britain and Germany, and has become practically extinct in all other countries, except as far as its first part, the manufacture of sodium sulphate and hydrochloric acid, is concerned.

The production of alkali in Great Britain, soon after the introduction of the Leblanc process, became the most extensive in the world, and outstripped that of all other countries put together. With the rise of the ammonia-soda process, for which the economic conditions are nearly as favourable in other countries, the predominance of Great Britain in that domain has become less, but even now that country produces more alkali than any other single country. Most of the British alkali works are situated in South Lancashire and the adjoining part of Cheshire, near the mouth of the Tyne and in the West of Scotland.
Various industries are carried on in Leblanc alkali works, as follows:—
1. Manufacture of sulphate.
2. Manufacture of hydrochloric acid.
3. Preparation of chlorine.
4. Employment of chlorine for the manufacture of bleaching-powder and of chlorates.
5. Manufacture of ordinary alkali from sulphate of soda.
6. Manufacture of caustic soda.
7. Manufacture of soda crystals.

1. Manufacture of Sodium Sulphate.—This is commercially known as salt-cake, and is made by decomposing common salt with sulphuric acid of about 80%, the reaction being $2\text{NaCl} + \text{H}_2\text{SO}_4 = \text{Na}_2\text{SO}_4 + 2\text{HCl}$. This reaction proceeds in two stages. At first principally acid sodium sulphate, $\text{NaHSO}_4$, is formed together with some normal sulphate; later, when the temperature has risen, the $\text{NaHSO}_4$ acts with more $\text{NaCl}$ so that nearly all of it is converted into $\text{Na}_2\text{SO}_4$. The gaseous hydrochloric acid evolved during all this time must be absorbed in water, unless it is directly converted into chlorine (see below, 2 and 3).

The process is carried out either in hand-wrought furnaces, or mechanical furnaces, both called “decomposing” or “salt-cake furnaces.” In the former case, the first reaction is produced in cast-iron pans or “pots,” very heavy castings of circular section, fired from below, either directly or by the waste heat from the muffle-furnace. The reaction is completed in a “roasting-furnace.” The latter was formerly often constructed as a reverberatory furnace, which is easy to build and to work, but the hydrochloric acid given off here, being mixed with the products of the combustion of the fuel, cannot be condensed to strong acid and is partly, if not entirely, wasted. It is, therefore, decidedly preferable to employ “muffle-furnaces,” in which the heating is performed from without, the fire-gases passing first over the arch and then under the bottom of the muffle. This requires more time and fuel than the work in “open” furnaces, but in the muffles the gaseous hydrochloric acid is separated from the fire-gases, just like that evolved in the pot, and can therefore be condensed into strong hydrochloric acid, like the pot-acid. This roaster-acid is, however, of less value than the pot-acid, as it contains more impurities.

It is not easy to keep the muffles permanently tight, and as soon as any leakages occur, either hydrochloric acid must escape into the fire-flue, or some fire-gases must enter into the muffle. The former is decidedly more objectionable than the latter, as it means that uncondensed hydrochloric acid is sent into the air. This drawback has been overcome by the construction of “plus-pressure” furnaces (figs. 1 and 2), where the fire-grate is placed 11 ft. below the top of the muffle. In consequence the fire-gases, when arriving there by the chimney shaft (a), have already a good upward draught, and when circulating round the muffle are at a lower pressure than the gases within the muffle, so that in case of any cracks being formed, no hydrochloric acid escapes into the fire-flues, but vice versa.

Since the work with ordinary hand-wrought salt-cake furnaces is disagreeable and costly, many attempts have been made to construct mechanical salt-cake furnaces. Of these J. Maclear’s furnaces (fig. 3) have met with the greatest success. They consist of a horizontal pan, 17 ft. wide, which is made up of a central pan (c), and a series of concentric compartments (c'), (c''), and which is supported on a frame (d d), revolving round a perpendicular axis on the wheels (n n). It is covered with an arch and heated on the top from one side (l), either by an ordinary coal-grate or by a gas-producer. A set of stirring blades carried in the frame (b b), and driven by gearing,

Figs. 1 and 2.—Salt-cake Furnace. (Sectional Elevation and Plan.) Scale 1/40.

ALKALI MANUFACTURE

subjected in a series of large cast-iron cylinders to the action of pyrites-burner gases and steam at a low red heat. The reaction going on here is: 2NaCl + SO₂ + O₂ + H₂O = Na₂SO₄ + 2HCl.

This means that the previous manufacture of sulphuric acid in the vitriol-chambers is done away with, but this apparently great simplification is balanced by the great cost of the Hargreaves plant, and by the fact that the whole of the hydrochloric acid is mixed with nine or ten times its volume of inert gases. Owing to this, it is practically impossible to condense the gaseous hydrochloric acid into the commercial acid, although this acid may be obtained sufficiently strong to be worked up in the Weldon chlorine process (see below). Therefore the Hargreaves process has been introduced only in a few places.

Although the consumption of salt-cake for the manufacture of alkali is now much less than formerly, since the Leblanc alkali process has been greatly restricted, yet it is largely made and will continue to be made for the use of glassmakers, who use it for the ordinary description of glass in the place of soda-ash. Nor must it be overlooked that salt-cake must be made as long

as there is a sale for hydrochloric acid, or a consumption of the latter for the manufacture of chlorine.

2. Manufacture of Hydrochloric Acid (commercially also known as "muriatic acid"). This unavoidable gaseous bye-product of the manufacture of salt-cake was, during the first part of the 19th century, simply sent into the air. When its deleterious effects upon vegetation, building materials, &c., became better known, and when at the same time an outlet had been found for moderate quantities of hydrochloric acid, most factories made more or less successful attempts to "condense" the gas by absorption in water. But this was hardly anywhere done to the fullest possible extent, and in those districts where a number of alkali works were located at no great distance from one another, their aggregate escapes of hydrochloric and other acids created an intolerable nuisance. This was most notably the case in South Lancashire, and it led to the passing of Lord Derby’s "Alkali Act," in 1863, supplemented by further legislation in 1874, 1881 and later. There is hardly another example in the annals of legislative efforts equal to this, in respect of the real benefit conferred by it both on the general public and on the manufacturers themselves. This is principally the consequence of the exemplary way in which the duties of inspector under these acts were carried out by Dr. R. Angus Smith (1817-1884) and his successors, who directed their efforts not merely to their

primary duty of preventing nuisance, but quite as much to showing manufacturers how to make the most of the acid formerly wasted in one shape or another. Not merely Great Britain but all mankind has been immensely benefited by the labours of the British alkali inspectors, which were, of course, supplemented by the work of technical men in all the countries concerned. The scientific and technical principles of the condensation of hydrochloric acid are now thoroughly well understood, and it is possible to recover nearly the whole of it in the state of strong commercial acid, containing from 32 to 35% of pure hydrochloric acid, although probably the majority of the manufacturers are still content to obtain part of the acid in a weaker state, merely to satisfy the requirements of the law prescribing the prevention of nuisance. The principles of the condensation, that is of converting the gaseous hydrochloric acid given off during the decomposition of common salt into a strong solution of this gas in water, can be summarized in a few words. The hydrochloric acid gas, which is always diluted with air, sometimes to a very great extent, must be brought into the most intimate contact possible with water, which greedily absorbs it, forming ordinary hydrochloric acid, and this process must be carried so far that scarcely any hydrochloric acid remains in the escaping gases. The maximum escape allowed by the Alkali Acts, viz. 5% of the total hydrochloric acid, is far above that which is now practically attained. For a proper utilization of the condensed acid it is nearly always imperative that it should be as strong as possible, and this forms a second important consideration in the construction of the condensing apparatus. Since the solubility of hydrochloric acid in water decreases with the increase of the temperature, it is necessary to keep the latter down—a task which is rendered somewhat difficult both by the original heat retained by the gases on their escape from the decomposing apparatus, and by the heat given off through the reaction of hydrochloric acid upon water.

Very different methods have been employed to effect all the above purposes. In Great Britain Gay-Lussac's coke-towers, adapted by W. Gossage to the condensation of hydrochloric acid, are still nearly everywhere in use, frequently combined with a number of stone tanks through which the gas from the furnaces travels before entering the towers, meeting on its way the acid condensed in the tower. This process is excellent for effecting a complete condensation of the hydrochloric acid as prescribed by the Alkali Acts, and for recovering the bulk of the acid in a tolerably strong state, but less so for recovering nearly the whole of it in the most concentrated state, although even this is occasionally attained. On the continent of Europe, where the last-named requirement has been for a long time more urgent than in Great Britain, another system has been generally preferred, namely, passing the gas through a long series of stoneware receivers, and ultimately through a small tower packed with stoneware or coke, making the acid flow in the opposite direction to the gas. Great success has also been obtained by "plate-towers" made of stoneware, which allow both the coke-towers and most of the stoneware receivers to be dispensed with.

3. Preparation of Chlorine.—In this place we speak only of
the preparation of chlorine from hydrochloric acid by chemical processes; the electrolytic processes will be treated hereafter. It is clear that free chlorine must be prepared from hydrochloric acid by oxidizing the hydrogen. This can be done most easily by "active" oxygen, such as is present in the peroxides, in chromic or permanganic acid. Practically the only agent employed in this way, and that already by C. W. Scheele, the discoverer of chlorine, in 1774, is the peroxide of manganese (manganese dioxide), found in considerable quantities in nature as "manganese ore" (the purest of which is called pyrolusite), and also artificially regenerated from the waste liquors of a former operation. Even now, where chlorine is required for immediate use in the manufacture of chlorine operations, a comparison of the two processes, the electrolytic and the permanganic acid, shows that the permanganic process is cheaper.

This action must be promoted by heating the mixture, but even then nothing like all of the hydrochloric acid employed is made to act as before, because the attack on the manganese ore requires a certain minimum concentration of the acid. Formerly, instead of free hydrochloric acid a mixture of common salt and sulphuric acid was sometimes employed, but this is never done on a manufacturing scale now. Owing to the impossibility of employing any metal in contact with the acid, the "chlorine stills," where the above reaction is carried out, must be made of acid-proof stone or "chemical" stoneware. This process is very costly, as much of the acid and all of the manganese is wasted. Moreover it is of a most disagreeable kind, as the waste "still-liquor," containing very much free hydrochloric acid and even some free chlorine, forms a most deleterious impurity when finding its way into drains or water-courses, apart from the intolerable nuisance caused by the escapes of chlorine from the stills and otherwise, which cannot be at all times avoided.

Many endeavours were made to avoid the loss of the manganese in this operation, but with only partial or no success. The difficulty was only overcome by the Weldon process, being the inventions of Walter Weldon from 1866 onwards, and his process up to this day furnishes the greater proportion of chlorine manufactured in the world. It begins with "still-liquor," obtained in the old way from native manganese ore and hydrochloric acid. This liquor is first treated with carbonate of lime (ground chalk or limestone) in a "neutralizing-well," made of acid-proof material and provided with wooden stirring-gear. Here the free hydrochloric acid is converted into calcium chloride, and at the same time any ferric chloride present is converted into insoluble ferric hydroxide: 2FeCl₃+3CaCO₃+3H₂O = 2Fe(OH)₃+3CaCl₂+3CO₂. The sulphuric acid present is mostly precipitated as calcium sulphate. The mud thus formed is settled out, and the clear liquor, which is now quite neutral and contains both manganese and calcium chlorides, is mixed with cream of lime and treated by a strong current of air, produced by a blowing-engine. This is done in a tall iron cylinder, say 9 ft. wide and 30 ft. high, called the "oxidizer." The air-pipe goes right to the bottom of the cylinder and there branches out into perforated side-pipes, so that the mass is thoroughly stirred up all the time. The first action of the line is to convert the manganese chloride into manganous hydrate (Mn(OH)₂) and calcium chloride; then more lime is added which greatly promotes and hastens the oxidizing process. The object of the latter is to convert the manganous hydroxide by the atmospheric oxygen into manganese dioxide, but this would take place much too slowly if there was not an excess of lime present ready to react with the manganese dioxide to form its calcium manganite. Only so much lime is used that an acid manganite is formed corresponding to one molecule of calcium oxide to two of manganese oxide. This additional lime, which is called the "basis," certainly takes up hydrochloric acid in the next stage of the process, but that causes no more waste of acid than the incomplete action on native manganese ore, mentioned before. The product obtained, called "Weldon mud," is of such fine texture that it acts immediately with hydrochloric acid when mixed with it in the "Weldon stills" (fig. 4), and that this acid can be almost entirely neutralized thereby. The new still-liquor formed in this manner is treated as above, so that the manganese does its work over and over again. There is only a slight mechanical loss, which is reduced in the best managed works to about 2 parts of manganese dioxide to 100 of bleaching-powder. There are also other advantages of this process which explain its wide extension, in spite of the fact that only from 30 to 35 parts of the hydrochloric acid employed is converted into chlorine, the remainder ultimately leaving the factory in the shape of a harmless but useless solution of calcium chloride. Weldon's later attempts at superseding his classical process by other inventions which utilise a larger proportion of the chlorine, introduced as hydrochloric acid, have not been successful in the long run, although some of them were aided by the great technical skill of A. R. Péchiney. But the Deacon process, the invention of Henry Deacon (who was greatly aided by his chemist Dr Ferdinand Hurter), carried out since 1868, has attained to better, although nothing like complete, success in that direction.

The Deacon process, like the Weldon process, effects its object by the oxidizing action of atmospheric air, but in a very different manner. Weldon retained the principle of the Scheele process, by employing the active oxygen of manganese dioxide to convert hydrochloric acid into free chlorine, and he employed the atmospheric oxygen only indirectly, for the recovery of manganese dioxide from the manganese chloride formed. But Deacon worked on the direct reaction: 2HCl+O=H₂O+Cl₂. This reaction in ordinary circumstances is so slow as to be practically useless. If, however, a "contact-substance" is employed and that at the proper temperature, the process goes on at an immensely quickened rate and can even be carried out as a continuous operation. The only substance which possesses sufficiently strong catalytic properties for the reaction is cupric chloride. If pieces of porous clay are soaked in a solution of this salt and dried and kept at a temperature of 450° C. (in practice it is necessary to go to a rather higher temperature), they are capable continuously to convert a united stream of hydrochloric acid and atmospheric air, passed through the contact-substance in a "decomposer" (fig. 5), to a larger extent into chlorine and water, of course mixed with the excess of oxygen and all the nitrogen of the air. On a small scale it is possible to push the decomposition as far as 90% of the hydrochloric acid, but on the large scale only at most 60% is reached. The mixture of hydrochloric acid and air is taken directly from the "decomposing-pan" of an ordinary salt-pan furnace, is first cooled down in pipes sufficiently to condense most of the moisture present.
(together with about 8% of the hydrochloric acid), and then passed through a cast-iron superheater and from this into the "decomposer." The gaseous mixture, issuing from the latter, is washed with water in the usual condensing apparatus, to remove the 40 or 50 parts of hydrochloric acid left unchanged, and can then be immediately employed for the manufacture of chlorate of potash.

Where (as is the more usual case) the chlorine has to serve for the manufacture of bleaching-powder, it must first be deprived of the great amount of moisture which it contains, by means of coke-towers fed with moderately strong sulphuric acid. As the gas issuing from these contains only about 5 volumes % of hydrochloric acid, it cannot be made to act upon lime in the ordinary bleaching-powder chambers, but specially constructed chambers must be provided (see fig. 4). The movement of the gases through all this complicated set of apparatus is produced by a Root's blower placed at the end of it all.

The Deacon process makes cheaper chlorine than the Weldon process, but the plant is complicated and costly and the working requires a great deal of attention. In skilled hands it has been proved to yield excellent results.

The hydrochloric acid from the calcining-furnaces or "roasters" cannot be employed immediately for the Deacon process, as the sulphuric acid always contained in the roaster gases soon "poisons" the contact-substance and renders it inoperative. This acid must, therefore, be condensed in the ordinary way into liquid hydrochloric acid and formerly could be worked up only by the Weldon process. R. Hasenclever has overcome this drawback by running this impure acid into moderately strong sulphuric acid (140° Twaddell), blowing in air at the same time. This produces a mixed current of pure hydrochloric acid gas and air, which is carried into a Deacon decomposer where it acts in the usual manner. The sulphuric acid, of which 6 or 7 parts are used to one of impure liquid hydrochloric acid, is always reserved for use in the same process, by driving off the excess of water in a lead pan, fired from the top, so that the principal expense of the process is that of the fuel required for the last operation.

4. Applications of Chlorine.—Some of the chlorine manufactured (practically only such as is obtained by the electrolysis of chlorides) is condensed by cold and pressure into liquid chlorine. If this is anhydrous, as it must be in any case for this purpose, it does not act upon the metal of the compressors, nor upon the iron bottles in which it is sent out. It may even be sent out in tank wagons, similar to those which are employed for carrying sulphuric acid, holding 10 tons each.

Sometimes the chlorine is employed directly for bleaching purposes, especially for some kinds of paper. A number of organic chlorinated products are also produced on a large scale. But most of the chlorine is utilized for the production of bleaching-powder, of bleach-lieuqor, and of chlorate of potash.

Bleaching-powder is a compound obtained by the action of free chlorine on hydrated lime, containing a slight excess of water at ordinary temperatures or slightly above these. Its composition approaches the formula CaOCl₂, and it is regarded as a double salt of calcium chloride and hypochlorite, which by the action of water splits up into a mixture of these salts. It always contains a certain quantity of chemically combined water and also an excess of lime. Usually this lime is regarded only as mechanically mixed with the bleaching-compound, CaOCl₂, but some chemists adopt formulae in which this lime is equally represented.

For the manufacture of bleaching-powder, limestone of high degree of purity (especially free from magnesia and iron) is carefully burned so as to drive out nearly all the carbon dioxide without overheating the lime. The quick-lime is then slaked with the requisite quantity of water; the product is passed through a fine-meshed wire sieve and is spread in layers of 2 or 3 in. at the bottom of large boxes, the "bleaching-powder chambers," made of lead, or sometimes of cast-iron protected by paint, of slate or even of tarred wood. Chlorine, generated in an ordinary or a Weldon still, is passed in and is rapidly absorbed.

When the absorption becomes slow, the gas is cut off and the chamber is left to itself for twelve hours or more, when it will be found that all the chlorine has been taken up. Now the door of the chamber is opened, the powder lying at the bottom is turned over and the treatment with gas is repeated. Sometimes a third treatment is necessary in order to get the product up to the strength required in commerce, viz. 35% of "available" chlorine. The finished product is packed into wooden casks lined with brown paper. The work of packing is a most disagreeable and unhealthy operation which is best relieved by erecting the chambers at a higher level and placing the casks underneath, communication being made by means of traps in the chamber-bottom, so that the packers can do their work.
outside the chambers. The bleaching-powder casks must be kept in a dry place, as cool as possible, and never exposed to the direct rays of the sun, in order to prevent a decomposition which now and then has even led to explosions.

The weak chlorine from the Deacon process cannot be treated in this manner, as chambers of impossibly large dimensions would be required. Originally the absorption of the Deacon chlorine took place in a set of chambers, constructed of large slabs of stone, containing a great many horizontal shelves superposed one over another. About sixteen such chambers were combined in such manner that the fresh gas passed into that chamber which had been the longest time at work and in which the bleaching-powder was nearly finished, and so forth until the gas, now all but entirely exhausted, reached the last-filled chamber in which it met with fresh lime and there gave up the last of the chlorine. These "Deacon chambers" occupied a large space, besides being expensive to build and difficult to keep in repair. They are now mostly replaced by an apparatus, the invention of R. Hasenclever, consisting of four horizontal cast-iron cylinders with internal stirring-gear. The fresh lime is continually charged into the top cylinder, is gradually moved towards the other end, falls down into the next lower cylinder and thus gradually makes its way to the lowest cylinder. The weak chlorine gas from the Deacon apparatus travels precisely the opposite way, from the bottom upwards, the result being that finished bleaching-powder is continually discharged at the bottom and air free from chlorine leaves the apparatus at the top.

Bleaching-powder is manufactured to the extent of several hundred thousands of tons annually, almost entirely for the use of papermakers and cotton bleachers. Smaller quantities are used for disinfection and other purposes. It is usually sold in "tiers," that is, casks containing about 10 cwt.

Bleach-liquors.—If the chlorine is made to act on cream of lime, care being taken that the temperature does not rise above 35° and that the chlorine is not in excess, a solution is obtained containing a mixture of calcium chloride and hypochlorite which is a very convenient agent for bleachers, but which does not bear the expense of carriage over long distances. Similar liquids are obtained with a basis of sodium ("eau de javel"), by passing chlorine into solutions of sodium carbonate. The former kind of bleach-liquor is mostly used in the industry of cotton, the latter in that of linen.

Chlorate of Potash.—Formerly all chlorate of potash, as some is still, was obtained by passing chlorine into milk of lime, allowing the temperature to rise almost to the boiling-point, and continuing until the bleaching-solution, originally formed, is converted into a mixture of calcium chlorate and chloride, the final reaction being 6Ca(OH)2 + 3Cl2 = 5CaCl2 + Ca(ClO)3 + 6H2O. On cooling this solution, after settling out the mud, a quantity of potassium chlorate equivalent to the calcium chlorate, the reaction Ca(ClO)3 + 2KCl = CaCl2 + 2KClO3 is produced, the ultimate proportions thus being theoretically 2KClO3 to 6CaCl2, though in reality there is rather more calcium chloride present. When this solution is concentrated by evaporation and cooled down, about five-sixths of the chlorate of potash crystallizes out. It is purified by redissolving and crystallization, and is sold either in the state of crystals or finely ground. During these operations care must be taken lest a spark should produce the inflammation of the chlorate on contact with any organic substance. Large quantities of potassium chlorate exposed to strong heat in contact with the wood of casks or the timber of a roof have produced violent explosions.

Most of the chlorate of potash is now prepared by electrolysis of potassium chloride (see below). It is employed for fire-works, for some descriptions of explosives, for safety matches and as an oxidizer in some operations, especially in dyeing and tissue printing. For the last-named purpose it is sometimes replaced by sodium chlorate. The chlorates are usually sold in wooden kegs containing 1 cwt. each.

5. The Manufacture of Soda-ash from Salt-cake by the Leblanc process.—This process consists in heating a mixture of commercial

FIG. 6.—Black-ash Furnace and Boiling-down Pan. Scale 1/8.
sulphate of soda (silt-cake) with about the same weight of crushed limestone and half its weight of coal, until the materials are fluxed and a reaction has taken place, the principal phase of which is expressed by the equation Na₂SO₃+CaCO₃→CaS+2CO₂+Na₂CO₃. A number of secondary reactions, however, occur, owing partly to the excess of calcium carbonate and coal and partly to the impurities present, so that the solid product of the process, which is called "black-ash," has a somewhat complicated composition. Its principal constituents are always sodium carbonate and calcium sulphide, which are separated by the action of water, the former being soluble and the latter insoluble.

The furnace in which the reaction takes place is shown in fig. 6 in a sectional plan. It is called a "black-ash" furnace, and belongs to the class of reverberatory furnaces. A large fire-grate (ab), having a cave (c) to facilitate stoking and stepped back at (d), is bounded on one side by a fire-bridge(e); on the other side of this, separated by an air-channel (g), there is first the proper fluxing bed (h), and behind this the "back-bed" (i) for pre-heating the charge. The flame issuing from the furnace by (o) is always further utilized for boiling down the liquors obtained in a later stage, either in a pan (p) fired from the top and supported on pillars (qq) as shown in the drawing, or in pans heated from below. The charge of salt-cake (generally 3 cwt.), limestone and coal is roughly mixed and put upon the back-bed; when the frontbed has become empty it is drawn forward and exposed to the full heat of the fire, with frequent stirring. After about three-quarters of an hour the substances are so far fluxed or softened that the reaction now sets in fully, as shown by the copious escape of gas. This is at first colourless carbon dioxide, but later on inflammable gases come out of the mass, which at this stage has turned into a thicker, pasty condition, showing that the end of the reaction is near. The inflammable gas is carbon monoxide, which, however, does not burn with its proper purple flame, but with a flame tinged bright yellow by the sodium present. This carbon monoxide is formed by the action of coal on the lime, formed at this stage from the original limestone. When the "candles" of carbon monoxide appear, the pasty mass is quickly drawn out of the furnace into iron "bogies," where it solidifies into a grey, porous mass, the "black-ash." Care must be taken to heat it no longer than necessary, as it otherwise turns red and yields bad soda.

The hand-wrought black-ash furnace has been mostly superseded in the large factories by the revolving black-ash furnace, shown in fig. 7. These furnaces possess a large cylindrical shell (e), lined with fire-bricks, and made to revolve round its horizontal axis by means of a toothed wheel fixed on its exterior; (f) are tire-seats holding tires (gg), which work in friction rollers (h). The flame of a fixed fireplace (a) enters through an "eye" (b) in the centre of the front end of the cylinder and issues in the centre of the back end, first into a large dust-chamber (m), and then over or under boiling-down pans (p). These mechanical furnaces do the work of from four to ten ordinary furnaces according to their size, with comparatively very little expense for labour, but they must be very carefully managed and the black-ash from them is more difficult to lixiviate than that from hand-wrought furnaces, because it is less porous. The lixiviation of the blackash requires great care, as the calcium sulphide is liable to be changed into soluble calcium compounds, which immediately react with sodium carbonate and destroy a corresponding quantity of the latter, rendering the soda weaker and impure. This change of the calcium sulphide may be brought about either by the oxidizing action of the air or by "hydrolysis," produced by prolonged contact with hot water, the use of which, on the other hand, cannot be avoided in order to extract the sodium carbonate itself. The apparatus which has been found most suitable for the purpose was devised by Professor H. Buff of Giessen, and first practically carried out by Charles Dunlop at St Rollox. It consists of a number of tanks or "vats," placed at the same level and connected by pipes which reach nearly to the bottom of one tank and open out at the top into the next tank. The vats are also provided with false bottoms, outlet cocks, steam pipes and so forth. Tepid water is run in at one end of the series, where nearly exhausted black-ash is present; the weak liquor takes up more soda from the intermediate tanks and at last gets up to full strength in the last tank, charged with fresh black-ash and kept at a higher temperature, viz. 60° C. When the first tank has been quite exhausted, the water is turned on to the next, the first tank is emptied by discharging the "alkali-waste," and is filled with fresh black-ash, whereupon it becomes the last of the series. In spite of all precautions a certain quantity of impurities is always formed, but this should be kept down as much as possible by strictly watching the temperature in the vats and by taking care that the black-ash in the wet state is never exposed to the air. The unavoidable contamination with muddy particles of vat-waste is removed by allowing the vat-liquor to rest for some hours in a separate tank and settling out the mud.

The clear vat-liquor, if allowed to cool down to ordinary temperature, would separate out part of the sodium carbonate in the shape of decahydrated crystals. As these do not come out sufficiently pure, they would not be marketable and therefore they are not allowed to be formed, but the liquid, while still hot, is either run into the boiling-down pans, or submitted to one of the purifying operations to be described below. If it is boiled down without further purification, the resulting soda-ash is not of the first quality, but it is sufficiently pure for many purposes. The boiling down is most economically performed by means of large iron pans covered with a brick arch and heated from the top by the waste flame issuing from the black-ash furnaces (see figs. 6 and 7). It is continued until the contents of the pan have been converted into a thick paste of small crystals of monohydrated sodium carbonate, permeated by a mother-liquor which is removed by draining on perforated plates or by a centrifugal machine, and is always returned to the pans. The drained crystals are dried and heated to redness in a reverberatory furnace; when "finished," the mass is of an impure white or light yellow colour and is sold as ordinary "soda-ash." It is not easy to make it stronger than 92% of sodium carbonate, which is technically expressed as "52 degrees of available soda" (see next page). If purer and stronger soda-ash is wanted, the boiling down must be carried out in pans fired from below, and the
crystals of monohydrated sodium carbonate “fished” out as they are formed, but this is mostly done after submitting the liquor to the purifying operations which we shall now describe.

The dried or “finished” soda-ash is ground to a pretty fine powder and is packed into wooden casks or “tierces,” holding from 10 to about 20 cwt. each, according to the way of filling them.

The principal impurities of crude vat-liquor are sodium hydrate and sulphide, the latter of which always leads to the formation of soluble double sulphur salts of sodium and iron. The other impurities are of minor importance. The sulphides can be removed by “oxidizing” them into thiosulphates by means of atmospheric air, with or without the assistance of other agents, such as manganese peroxide; or by “carbonating” them with lime-kiln or other gases containing carbon dioxide; or by precipitating them with lead or zinc oxide. The last mentioned is the best but costliest method, and is employed only in the manufacture of the highest strengths of caustic soda. The most usual process, where soda-ash is to be made, is the “carbonating.” This is usually effected either by forcing lime-kiln gas through the liquor, contained in a closed iron vessel, or by passing the gases through an iron tower filled with coke or other materials, such as lime-kiln, which sublime the stream of the gases and that vat-liquor which trickles down in the tower. The same apparatus is used for “oxidizing” by means of atmospheric air passed through by means of an injector; sometimes both air and carbon dioxide are passed in at the same time. The operation is finished when all the sodium sulphide has been converted into normal sodium carbonate, partly also into acid sodium carbonate (bicarbonate) NaHCO₃; at the same time a precipitate is formed, consisting of ferrous sulphide, alumina and silica, which is removed by another settling tank, and the clear liquor is now ready either for boiling down in a fish-pan for the manufacture of white soda-ash, or for the process of causticizing. Soda-ash (as well as caustic soda) is sold by degrees of “available soda.” This means that portion which neutralizes the acid employed for testing, and the degrees mean the percentage of Na₂O thus found, whether it be present as Na₂CO₃, NaOH, or sodium aluminate or silicate. The purest soda-ash, equal to 100% Na₂CO₃, would be 58% degrees of available soda. The ordinary commercial strength of Leblanc soda-ash is from 52 to 54 degrees (in former times much was sold in the state of 49 degrees).  

6. Manufacture of Caustic Soda.—Most of the Leblanc liquor is nowadays converted into caustic soda, as white soda-ash is more easily and cheaply made by the ammonia-soda process. We shall therefore in this place describe the manufacture of caustic soda. This is always made from the carbonate by the action of slaked lime: Na₂CO₃ + Ca(OH)₂ = CaCO₃ + 2NaOH. The calcium carbonate, being insoluble, is easily separated from the caustic liquor by filtration. But as this reaction is reversible, we must observe the conditions necessary for directing it in the right sense. These are: diluting with water so as not to exceed 10% of sodium carbonate to 90% of water; boiling this mixture; and keeping it well agitated. At the best about 92% of the sodium carbonate can be converted into caustic soda, 8% remaining unchanged.

The operation is performed in iron cylinders, provided with an agitating arrangement. This may consist of a steam injector by means of which air is made to bubble through the liquid, which produces both the required agitation and the heating, and at the same time oxidizes at least part of the sulphides; but this method of agitation causes a great waste of steam and at the same time shortens the duration of the liquor. Many, therefore, prefer mechanical stirring by means of paddles, fixed either to a vertical or to a horizontal shaft, and inject only sufficient steam to keep the mass at the proper temperature. Some heat is also gained by the slaking of the caustic lime within the liquor. After from half an hour to a whole hour the conversion of sodium carbonate into sodium hydrate is brought about as far as is practicable. The whole mass is now run into the filters, which are always constructed on the vacuum principle. They are iron boxes, in which a bed is made of bricks, above them gravel, and over this sand, covered on the top by iron grids. The space below the sieve thus formed is connected by means of an outlet tap with a closed tank, and this again communicates with a vacuum pump. By this means the filtration is quickened by the atmospheric pressure, and goes on very rapidly, as also does the subsequent washing. The filtered caustic liquor passes to the concentration plants; the washings are employed for diluting fresh vat-liquor for the next operation, or for dissolving solid soda-ash for the same purpose. The washed-out calcium carbonate, which always contains much calcium hydrate and 2 or 3% of soda in various forms, usually goes back to the black-ash furnaces, but it cannot be always used up in this way, and what remains is thrown upon a heap outside the works. Attempts have been made to use it in the manufacture of Portland cement, but without much success.

The clear caustic soda liquor must be concentrated in such a way that the caustic soda cannot to any great extent be converted into sodium carbonate, and that the “sals,” which it contains, sodium carbonate, sulphate, chloride, &c., can be separated during the process. Formerly the most usual concentrating apparatus was the “boat-pan” (Fig. 8). This is an oblong iron pan, the bottom of which slopes from both sides to a narrow channel. The latter rests on a brick pillar; the remaining part of the sloping bottom is heated, either by the waste fire from a black-ash furnace or by a special fireplace. This arrangement has the effect that the salts, as they separate out, slide down the sloping part and arrive in the central channel, which is not exposed to the fire-gases, so that they quietly settle there, without caking to the pan, until they are fished out by means of perforated lades. These boat-pans were for many years almost everywhere employed, and did their work quite well, but rather expensively. At many works they have been replaced by either Thélén pans or vacuum pans.

The “Thélén pan” (thus named from its inventor, a foreman at the Rhenania works near Aachen) is a mechanically worked fishing-pan, which requires considerably less labour and coal than ordinary boat-pans. It is a long trough, of nearly semi-circular section, the whole bottom being exposed to the fire-gases. A horizontal shaft runs length-ways through the trough, and is provided with stirring blades, arranged in such a manner that they constantly scrape the bottom, so that the salts cannot burn fast upon it, and are at the same time moved forward towards one of the ends of the trough where they are automatically removed by means of a chain of buckets.

The most efficient evaporating apparatus, as far as economy of fuel is concerned, is the vacuum-pan, of which from two to five are combined to form a set, but it has the drawback that the removal of the salts is much more difficult than with the
older pans, described above. In this apparatus only the first of the pans is heated directly, usually by means of ordinary boiler-steam circulating round a number of pipes, containing the liquid to be concentrated. The steam rising from the latter is passed into a similar pan, in which it circulates round another set of pipes, but as it could not bring the liquid in the latter to boil under ordinary conditions, the second pan is connected with a vacuum-pump so that the boiling-point of the liquid in this pan is lowered. This pan may be followed by a third pan, in which a stronger vacuum is maintained, and so forth. By this means the latent heat of the steam, issuing from all pans but the last, is utilized for evaporating purposes, and from half to three-fourths of the fuel is saved.

After being concentrated up to a certain point, and after the separation of nearly all the salts, the caustic liquor is transferred to cast-iron "finishing-pots" (fig. 9), holding from ten to twenty tons. Here it is further boiled down until the greater part or nearly all of the water has been removed, and until the salts on cooling would set to a solid mass. This requires ultimately a good red heat. Before the mass has reached that point the sulphides still present have been destroyed, either by the addition of solid nitrate of soda or by blowing air through the red-hot melt. Before finishing, the molten mass must be kept at a quiet heat for some hours in order to settle out the ferric oxide which it always contains, and which becomes insoluble (through the destruction of the sodium ferrite) only at high temperatures. When it has completely cleared, the liquid caustic is laddled or pumped out into sheet-iron drums, holding about 6 cwt. each, where it solidifies and forms the caustic soda known to commerce.

The best caustic soda tests from 75 to 76 degrees of "available soda"; this is only a few per cent removed from the composition of pure NaOH, which would be = 77.5 degrees NaO. Most of the caustic soda is sold at a strength of 70 degrees, sometimes as low as 60 degrees.

Caustic soda is used in very large quantities in the manufacture of soap, paper, textile fabrics, alizarin and other colouring matters, and for many other purposes.

7. Soda-Crystals.—Another product made in alkali works is soda-crystals. Their formula in Na₂CO₃, 10H₂O, corresponding to 37% of dry sodium carbonate. They are made by dissolving ordinary soda-ash in hot water, adding a small quantity of chloride of lime for the destruction of colouring matter and the oxidation of any ferrous salts present, carefully settling the solution, without allowing its temperature to fall below the point of maximum solubility (34° C.), and running the clarified liquid into cast-iron crystallizers or "cones," where, on cooling down, most of the sodium carbonate is separated in large crystals of the decahydrated form. This process lasts about a week in winter, and up to a fortnight in summer. In France the crystallization of soda is performed not in large tanks but in sheet-iron dishes holding only about ½ cwt., and requires only from 27 to 48 hours in the cool season; it is not carried on at all in warmer climates during the summer months. The mother-liquor, drained from the soda-crystals, on boiling down to dryness yields a very white, but low-strength soda-ash, as the soluble impurities of the original soda-ash are nearly all collected here; it is called "mother-alkali."

Although the soda-crystals contain the alkali combined with such a large quantity of water, they are made in large quantities, because their form, together with their complete freedom from caustic soda, makes them very suitable for domestic purposes. Hence they are best known as "washing-soda." Sometimes they are made, not from soda-ash, but from Leblanc soda-liquor before finishing the ash, or from the crude bicarbonate of the ammonia-soda process by prolonged boiling, until nearly half of the carbonic acid has been expelled.

Formerly bicarbonate of soda was made from Leblanc soda-crystals by the action of carbonic acid, but this article is now almost exclusively made in the ammonia-soda process.

8. The Recovery of Sulphur from Alkali-waste.—For many years all the sulphur used in the Leblanc process in the shape of sodium sulphate, and originally imported into the manufacture in the shape of brimstone or pyrites, was wasted in the crude calcium sulphide remaining from the lixiviation of black-ash. This "alkali-waste," also called tank-waste or vat-waste, was thrown into heaps where the calcium sulphide was gradually acted upon by the moisture and the oxygen of the air. The sulphur was by these converted partly into gaseous sulphur-hydrogen, partly into soluble polysulphides, thiosulphates and other soluble compounds, and in all shapes caused a nuisance which became more and more intolerable as the number and size of alkali works increased. Both the air and the water in their neighbourhood were contaminated thereby.

Both this nuisance and the loss of the sulphur (whose cost sometimes amounted to more than half of the total cost of the soda-ash) led to many attempts at extracting the sulphur from the alkali-waste. This was first done with a certain amount of success by the processes of M. Schaffiner (1861) and L. Mond (1862), but as these required the use of hydrochloric acid, and as they only recovered about half of the sulphur, they were superseded by another—a process which had been originally proposed by W. Gossage in 1837, but has been made practicable only by the inventions of C. F. Claus, in 1883, and from 1887 onward by the technical skill of Messrs Chance Brothers, of Oldbury. The Claus-Chance process, as it is called, comprises the following operations. The wet alkali-waste as it comes from the lixiviating vats, is transferred into upright iron cylinders in which it is systematically treated with lime-kiln gases until the whole of the calcium sulphide has been converted into calcium carbonate, the carbon dioxide of the lime-kiln gases being entirely exhausted. The sulphur issues as sulphured hydrogen, mixed with the nitrogen of the air. It is mixed with fresh air containing sufficient oxygen for the combustion of the hydrogen, and the mixture is passed through red-hot iron oxide (burnt pyrites) which by its catalytic action causes the reaction H₂S+O=H₂O+S to take place. By cooling the vapours the sulphur is condensed in a very pure form, and about 85% of the whole of it is recovered, the remaining 15% escaping in the shape of sulphur dioxide (SO₂) and H₂S. Unfortunately it has been hitherto found impossible to deal with these gases in any profitable way.

It should be noted that this "recovered sulphur," which is equal in purity to the "refined brimstone" of commerce, has a far higher value than the sulphur contained in the originally employed pyrites, so that the recovery is a paying process, in spite of the somewhat considerable cost of the plant and of the working operations. It has been introduced at most large Leblanc alkali works, and has, so to say, given them a new lease of life.
In spite of the great improvements effected during recent times the Leblanc process cannot economically compete with the ammonia-soda process, principally for two reasons. The sodium in the latter costs next to nothing, being obtained from natural or artificial brine in which the sodium chloride possesses an extremely slight value. The fuel required is less than half the amount used in the Leblanc process. Moreover, the ammonia process has been gradually elaborated into a very complicated but perfectly regularly working scheme, in which the cost of labour and the loss of ammonia are reduced to a minimum. The only way in which the Leblanc process could still hold its own was by being turned in the direction of making caustic soda, to which it lends itself more easily than the ammonia-soda process; but the latter has invaded even this field. One advantage, however, still remained to the Leblanc process. All endeavours to obtain either hydrochloric acid or free chlorine in the ammonia-soda process have proved commercial failures, all the chlorine of the sodium chloride being utterly lost in the shape of worthless calcium chloride. The Leblanc process thus remained the sole purveyor of caustic soda, and in this way the fact is accounted for that, at least in Great Britain, the Leblanc process still furnishes nearly half of all the alkali made, though in other countries its proportional share is very much less. The profit made upon the chloride produced has to make up for the loss on the alkali.

The ammonia-soda process was first patented in 1838 by H. G. Dyar and J. Hemmings, who carried it out on an experimental scale in Whitechapel. Many attempts were soon after made in the same direction, both in England and on the continent of Europe, the most remarkable of which was the ingenious combination of apparatus devised by J. J. T. Schoelzing and E. Rolland. But a really economical solution of the problem was first definitely found in 1872 by Ernest Solvay, as the result of investigations begun about ten years previously. The greater portion of all the soda-ash of commerce is now made by Solvay's apparatus, which alone we shall describe in this place, although it should be borne in mind that the principles laid down by Dyar and Hemming have been and are still successfully carried out in a number of factories by an entirely different kind of apparatus.

The leading reaction of this process is the mutual decomposition of ammonium bicarbonate and sodium chloride:

$$NaCl + NH_4HCO_3 = NaHCO_3 + NH_3 + Cl^−.$$  

It begins, however, not with ready-made ammonium bicarbonate, but with the substances from which it is formed—ammonia, water and carbon dioxide—which are made to act on sodium chloride. In practice the process is carried out as follows. A nearly saturated solution of sodium chloride is obtained by purifying natural or artificial brine, i.e. an impure solution of common salt, especially removing the alkaline earths and so forth by addition of sodium or ammonium carbonate and settling out the precipitate formed. This solution is saturated with ammonia, produced in the recovery plant (see below), in vessels provided with mechanical agitators and strongly cooled by coils of pipes through which cold water is made to flow. These vessels, as well as all others which are used in the process, are not open to the air, but communicate with it through washers in which fresh salt solution is employed for retaining any escaping vapours of ammonia. The ammonical salt solution is now saturated with carbon dioxide. This is employed in the shape of lime-kiln gases, obtained in a comparatively pure and strong form (up to 33 % CO₂), in very large kilns, charged with lime-stone and coke. The kilns are closed at the top, and the gases are drawn out by powerful air-pumps, washers being interposed between the kilns and the pumps for the purpose of purifying and cooling the gas. The heat evolved by the compression in the air-pumps (which rises to four atmospheres or upwards) is again removed by cooling, and the gas is now passed upwards in the "Solvay tower" (fig. 10). This is a tall iron erection, built up fromsuperposed cylinders, which are separated from one another by perforated horizontal diaphragms, constructed in such a way that the gases are over and over again subdivided into many smaller streams and are thus thoroughly brought into contact with the ammoniacal salt solution with which the tower is about two-thirds filled. There the reaction mentioned above takes place, and owing to the concentration of the liquid the sodium bicarbonate formed is to a great extent precipitated in the shape of small crystals, forming with the mother-liquor a thin magma. This takes place with considerable evolution of heat which is removed by internal and external cooling with water. The temperature must not be allowed to rise beyond a certain point, for the reaction $NaCl + NH_4HCO_3 = NaHCO_3 + NH_3 + Cl^−$ is reversible, and at a temperature of about 60° or 70° C. it is in fact practically going the wrong way, viz. from right to left. On the other hand the cooling must not be carried too far, for in this case the crystals of sodium bicarbonate form and become so fine that the muddy mass is very difficult to filter. The best temperature seems to be about 35° C.

Either at certain intervals, or continuously, a portion of the contents of the tower is withdrawn and fresh ammoniacal salt solution is introduced higher up. The muddy liquid running out is passed on to the vacuum filters (Z, fig. 19). Here a separation takes place between the crystals of sodium bicarbonate and the mother-liquor. The former are washed with water until the chlorides are nearly removed, and are then carried into the drying apparatus. This must be constructed in such a manner that the bicarbonate, which always contains some ammonium salts, is first freed from these by moderate heating (of course taking care that the ammonia is completely recovered), and later on, by raising the temperature, it is decomposed into solid sodium carbonate and gaseous carbon dioxide. The former needs only grinding to constitute the final product, ammonia-soda ash; the latter is again employed in the process of treating the ammoniacal salt solution with carbon dioxide. Various forms of apparatus are employed for this treatment of the crude bicarbonate—sometimes semi-circular troughs with mechanical agitators on the principle of the Thélen pan (see above)—all acting on the principle that the escaping ammonia and carbon dioxide must be fully utilized over again. The soda-ash obtained in the end is of a high degree of purity, testing from 98 to 99 % $Na_2CO_3$, the remaining 1 or 2 % consisting principally of NaCl.

A very important part of the process has still to be described, viz. the recovery of the ammonia from the mother-liquor coming from the vacuum filters and various washing liquors. Unless
this recovery is carried out in the most efficient manner, the process cannot possibly pay; but so much progress has been made in this direction that the loss of ammonia is very slight indeed, merely a fraction per cent.

The ammonia is for the most part the solute of the mother-liquor in our process.

A smaller but still considerable portion exists here and in the washings in the shape of ammonium carbonates. These compounds differ in their behaviour to heat. The ammonium carbonates are driven out from their solutions by mere prolonged boiling, being thereby decomposed into ammonia, carbon dioxide and water, but the ammonium chloride is not volatile under these conditions, and must be decomposed by milk of lime: \( 2\text{NH}_2\text{Cl} + \text{Ca(OH)}_2 \rightarrow \text{CaCl}_2 + 2\text{NH}_3 + \text{H}_2\text{O} \). The solution of calcium chloride is run to waste, the ammonia is re-introduced into the process from the ammonium stulls.

Both these reactions are carried out in tall cylindrical columns or "stills," consisting of a number of superposed cylinders, having perforated horizontal partitions, and provided with a steam-heating arrangement in the enlarged bottom portion. The milk of lime is introduced at a certain distance from the bottom. The steam causes the action of the lime on the ammonium chloride to take place in this lower portion of the still, from which the steam, mixed with all the liberated ammonia, rises into the upper portion of the column where its heat serves to drive out the volatile ammonium carbonate. Just below the top there is a cooling arrangement, so that nearly all the water is condensed and runs back into the column, while the ammonia, with the carbon dioxide formerly combined with part of it, passes on first through an outside cooler where the remaining water is condensed, and afterwards into the vessels, already described, where the ammonia is absorbed by a solution of salt and thus again introduced into the process.

The reversible character of the principal reaction has the consequence that a considerable portion of the sodium chloride (up to 35%) is lost, being contained in the waste calcium chloride solution with which issues from the ammonium stulls. This is, however, not of much importance, as it had been introduced in the shape of a brine where its value is very slight (6d. per ton of NaCl). It is true that all the chlorine combined with the sodium is lost partly as NaCl and partly as CaCl₂; none of the innumerable attempts at recovering the chlorine from the waste liquor has been made to pay, and success is less likely than ever since the perfection of the electrolytic processes. (See CHLORINE.) For all that, especially in consequence of the small amount of fuel required, and the total absence of the necessity of employing suitably designed and constructed apparatus to accomplish the process, the process has supplanted the Leblanc process almost entirely on the continent of Europe and to a great extent in Great Britain.

III. ELECTROLYTIC ALKALI MANUFACTURE

In theory by far the simplest process for making alkalis together with free chlorine is the electrolysis of sodium (or potassium) chloride. When this takes place in an aqueous solution, the alkaline metal at once reacts with the water, so that a solution of an alkaline hydride is formed while hydrogen escapes. The reactions are therefore (we shall in this case speak only of the sodium compounds): (1) \( \text{NaCl} = \text{Na} + \text{Cl} \), (2) \( \text{Na} + \text{H}_2\text{O} = \text{NaOH} + \text{H} \).

The chlorine escapes at the anode, the hydrogen at the cathode. If the chlorine and the sodium hydride can act upon each other within the liquid, bleaching-liquors are formed: \( 2\text{NaOH} + \text{Cl}_2 = \text{NaOCl} + \text{NaCl} + \text{H}_2\text{O} \). The production of these for the use of paper-makers and bleachers of textile fabrics has become an important industry, but does not enter into our present purview.

If, however, the action of the chlorine on the sodium hydride is prevented, which can be done in various ways, they can both be collected in the isolated state and utilized as has been previously described, viz. the chlorine can be used for the manufacture of liquid chlorine, bleaching-powder or other bleaching compounds, or chlorates, and the solution of sodium hydride can be sold as such, or converted into solid caustic soda.

Precisely the same can be done in the electrolysis of potassium chloride.

There is a third way of conducting the action, viz. so that the chlorine can act upon the caustic soda or potash at a higher concentration and temperature, in which case chlorates are directly formed in the liquid: \( \text{KCl} + 3\text{H}_2\text{O} = \text{KCIO}_3 + 3\text{H}_2 \). This has indeed become the principal, because it is the cheapest, process for the manufacture of potassium and sodium chlorate. Perchlorates can also be made in this way.

In all these cases the chlorine, or the products made from it, really play a greater part than the alkali. From 38.5 parts by weight of NaCl we obtain theoretically 23Na = 40NaOH = 53Na₂CO₃, together with 34.5 Cl, or 100 bleaching-powder. As the weight of bleaching-powder consumed in the world is at most one-fifth of that of alkali, calculated as Na₂O, it can be calculated that only about one-tenth of all the alkali required could be made by electrolysis, even supposing the Leblanc process to be entirely abolished. The remaining nine-tenths of alkali must be supplied from other sources, chiefly the ammonia-soda process. As long as the operation of the Leblanc process is continued, it will supply a certain share of both kinds of products. Trustworthy statistics on this point cannot be obtained, because most firms withhold any information as to the extent of their production from the public.

The first patents for the electrolysis of alkaline chlorides were taken out in 1857 and several others later on; but commercial success was utterly impossible until the invention of the dynamo machine allowed the production of the electric current at a sufficiently cheap rate. The first application of this machine for the present purpose seems to have been made in 1857 and the number of patents soon rapidly increased; but although a large amount of capital was invested and many very ingenious inventions made their appearance, it took nearly another twenty years before the manufacture of alkali in this way was carried out in a continuous way on a large scale and with profitable results. A little earlier the manufacture of potassium chlorate (on the large scale since 1890) had been brought to a definite success by H. Gall and the Vicomte A. de Montlaur; a few years later the processes worked out at the Griesheim alkali works (near Frankfort) for the manufacture of caustic potash and chlorine established definitely the success of electrolysis in the field of potash, but even then none of the various processes working with sodium chloride had emerged from the experimental stage. Only more recently the manufacture of caustic soda by electrolysis has also been developed and successfully carried on, but as the greatest secrecy is maintained in everything belonging to this domain, and as neither patent specifications nor the sanguine assertions and anticipations of interested persons throw much real light on the actual facts of the case, nothing certain can be said either in regard to the date at which the profitable manufacture of caustic soda was first carried out by electrolysis, or as to what extent this is the case at the present moment.

We shall here give merely an outline of those more important processes which are known to be at present working profitably on a large scale.

(1) The DIAPHRAGM process is probably the only one employed at present for the decomposition of potassium chloride, and it is also used for sodium chloride. A hot, concentrated solution of the alkaline chloride is treated by the electric current in large iron tanks which at the same time serve as cathodes. The anodes are made of retort-carbon or other chlorine-resisting material, and they are mounted in cells which serve as diaphragms. The material of these cells is usually cement, mixed with certain soluble salts which impart sufficient porosity to the material. The electrolysis is carried on until about a quarter of the chloride has been transformed; it must be stopped at this stage lest the formation of hypochlorite and chlorate should set in. The alkaline liquid is now transferred to vacuum pans, constructed in such a manner that the unchanged chloride, which "salts out" during the concentration, can be removed without disturbing the vacuum, and here at last a concentrated pure
solution of KOH or NaOH is obtained which is sold in this state, or "finished" as solid caustic in the manner described in the section treating of the Leblanc soda. (2) The Caustic-Kaliner process employs no diaphragm, but a membranous cathode. The electrolysis takes place in the central compartment of a tripartite trough which can be made to rock slightly either to one side or the other. The bottom of the trough is covered with mercury. The sodium as it is formed at the cathode at once dissolves in the mercury which protects it against the action of the water as long as the percentage of sodium in the mercury does not exceed, say, 0-05%. When this percentage has been reached, the cell is rocked to the other side, so that the amalgam flows into one of the outer compartments where the sodium is converted by water into sodium hydrate. At the same time fresh mercury, from which the sodium had been previously extracted, flows from the other outside compartment into the central one. After a certain time the whole is rocked towards the other side, and the process is continued until the outer compartments contain a strong solution of caustic soda, free from chloride and hypochlorite.

(3) Ausss process.—Here the anode is fixed in a bell, mounted in a larger iron tank where the cathodes are placed. The whole is filled with a solution of common salt. As the electrolysis goes on, NaOH is formed at the cathodes and remains at the bottom. The intermediate layer of the salt solution, floating over the caustic soda solution, plays the part of a diaphragm, by preventing the chlorine evolved in the bell from acting on the sodium hydrate formed outside, and this solution offers much less resistance to the electric current than the ordinary diaphragms. This process therefore consumes less power than most others.

(4) The Acker-Douglas process electrolyses sodium chloride in the molten state, employing a cathode consisting of molten lead. The latter dissolves the sodium as it is formed and carries it to an outer compartment where by the action of water the sodium is converted into caustic soda, while the lead returns to the inner compartment. This process is carried on at Niagara Falls, but it is uncertain to what extent.

(5) The Hargreaves-Bird process avoids certain drawbacks attached to other processes, by employing a wire diaphragm and converting the caustic soda as it issues on the other side of this, by means of carbon dioxide, into a mixture of sodium carbonate and bicarbonate, which separates out in the solid state. This process is but little used.

It stands to reason that the electrolytic processes have been principally developed in localities where the electric current can be produced in the cheapest possible manner by means of water power, but this is not the only condition to be considered, as the question of freight to a centre of consumption and other circumstances may also play an important part. Where coal is very cheap indeed and the other conditions are favourable, it is possible to establish such an industry with a prospect of commercial success, even when the electric current is produced by means of steam-engines.

Natural Soda.—This is the term applied to certain deposits of alkaline salts, or their solutions, which occur, sometimes in very large quantities, in various parts of the world. The oldest and best known of these are the Natron lakes in Lower Egypt. The largest occurrence of natural soda hitherto known is that in Owen's Lake and other salt lakes situated in eastern California. The soda in all of these is present as "sesquicarbonate" in reality 4/3 carbonate: NaHCO₃·Na₂CO₃·2H₂O, and is always mixed with large quantities of chloride and sulphate, which makes its extraction more difficult than would appear from the outset. Hence, although for many centuries (up to Leblanc's invention) hardly any soda was available except from this source, and although we now know that millions of tons of it exist, especially in the west of the United States, there is as yet very little of it practically employed, and that only locally.

References.—The principal work on the manufacture of alkali is G. Lunge's Sulphuric Acid and Alkali (2nd ed., vols. ii. and iii., 1895-1896). This work has also appeared in a German and a French edition. The same author wrote the articles on the manufacture of sodium and potassium compounds and on chlorine in Thorpe's Dictionary of Applied Chemistry (3 vols., 1890-1893). The subject is also treated, very much more briefly, in Soret's Industrie chimique minérale (1902), and of course in every other general treatise on chemical technology. A special treatise on the manufacture of ammonia soda ash has been published in German by W. Schreib. Consult also the official Annual Reports on Alkali, &c., and, from 1862 onwards, Journal of the Society of Chemical Industry, Fischer's Jahresberichte der chemischen Technologie, and Zeitschrift für angewandte Chemie.

G. L.

ALKALINE EARTHS. The so-called alkaline earth-metals are the elements beryllium, magnesium, calcium, strontium and barium. By the early chemists, the term earth was used to denote those non-metallic substances which were insoluble in water and were unaffected by strong heating; and as some of these substances (e.g. lime) were found to be very similar in properties to those of the alkalis, they were called alkaline earths. The alkaline earths were assumed to be elements until 1807, when Sir H. Davy showed that they were oxides of various metals. The metals comprising this group are never found in the uncombined condition, but occur most often in the form of carbonates and sulphates; they form oxides of the type RO, and in the case of calcium, strontium and barium, of the type RO₂. The oxides of type RO are soluble in water, the solution possessing a strongly alkaline reaction and rapidly absorbing carbon dioxide from the atmosphere; they are basic in character and dissolve readily in acids with the formation of the corresponding salts. As the atomic weight of the element increases, it is found that the solubility of the sulphates in water decreases.

Beryllium to a certain extent stands alone in many of its chemical properties, resembling to some extent the metal aluminium. Beryllium and magnesium are permanent in dry air; calcium, strontium and barium, however, oxidize rapidly on exposure. The salts of all the metals of this group usually crystallize well, the chlorides and nitrates dissolve readily in water, whilst the carbonates, phosphates and sulphates are either very sparingly soluble or are insoluble in water.

ALKALOID, in chemistry, a term originally applied to any organic base, i.e. a nitrogenous substance which forms salts with acids; now, however, it is usual to restrict the term to bases of vegetable origin and characterized by remarkable toxicological effects. Such bases occur almost exclusively in the dicotyledons, generally in combination with malic, citric, tartaric or similar plant-acids. They may be extracted by exhausting the plant-tissues with hot water, and precipitating the bases with potash, soda, lime or marl; or the pure bases of the mixed bases so obtained is effected by repeated fractional crystallization, or by taking advantage of certain properties of the constituents.

A chemical classification of alkaloids is difficult on account of their complex constitution. I. A. Wyschnegradsky, and afterwards W. Köhling, expressed the opinion that the alkaloids were derivatives of pyridine or quinoline. This view has been fairly well supported by later discoveries; but, in addition to pyridine and quinoline nuclei, alkaloids derived from isoquinoline are known. The purely chemical literature on the alkaloids is especially voluminous; and from the assiduity with which the constitutions of these substances have been and are still being attacked, we may conclude that their synthesis is but a question of time. Piperine, conine, atropine, belladone, cocaine, hyoscymamine and nicotine have already been synthesized; the constitution of several others requires confirmation, while there remain many important alkaloids—quinine, morphine, strychnine, &c., whose constitution remains unknown.

The following classification is simple and convenient; the list of alkaloids makes no pretence at being exhaustive.

1. Pyridine group. Piperine; conine; trigonelline; arecaidine; guvacine; pilocarpine; cytisine; nicotine; spartine.

2. Tropine group. Alkaloids characterized by containing the tropine (q.v.) nucleus. Atropine; cocaine; hygrine; ecgonine; pellateline.

3. Quinoline group. The alkaloids of the quina-barks:
ALKAN—ALLAH

quine, &c.; the strychn bases: strychné, brucine, and the seratrum alkaloids: veratrine, cedavine, &c.

ALKAN (dim. from Span. alcacor, Arab. al-hecka = henna, Egyptian privet, or Lawsonia inermis), a plant, Alkanna or Anchusa laciniosa, of the order Boraginaceae, also known as orphanet, dyes's bugloss, Spanish bugloss or bugloss of Languedoc, which is grown in the south of France and on the shores of the Levant. Its root yields a fine red colouring matter which has been used to tint tinctures, oils, vinegars, &c.

AL KASR AL KEBIR ("the great castle," in Span. Alcázar Kebrá, in Port. Alcácer Queirós), a town of Morocco, on the river Lekkus, 80 m. N.W. of Fez. Pop. about 10,000. Its mud and palm 4th century buildings and towers, and by a mosque, but the aspect of the town is far from inviting. It is frequently flooded in winter and in consequence fever is prevalent. The weekly market, held on Sundays in the centre of the town, gives to the place an appearance of bustle. A vice-governor is appointed for the town by the basha of Larache, one for the country round by the sultan of Morocco, a condition which causes much confusion on market-days. Al Kasr al Kebir was built, according to Leo Africanus, by Yakub el Mansur (1584-1599). Not far from the town, by the banks of the river Makhzan, is the site of the battle fought in 1578 between Dom Sebastian, king of Portugal, and the Moors under Abd el Malek, in which the Moors were victorious, though both kings perished, as well as the deposed Mahomed XI, who had called in the Portuguese to his aid against Abd el Malek.

ALKMAAR, a town in the province of North Holland, kingdom of Holland, 24 m. by rail N.N.W. of Amsterdam, connected by steam-tramway with Haarlem and Amsterdan, and on the North Holland canal. Pop. (1900) 18,373. Alkmaar is a typical North Holland town, with tree-lined canals and brightly coloured houses, and by the canal. The old city walls have been replaced by pleasant gardens and walks, and there is a park in which stands a fine monument (1876) by J. T. Stracké (1817-1891), symbolising Alcmenia victrix, to commemorate the siege by the Spaniards in 1573. The Groote Kerk (1470-1498), dedicated to St Lawrence, is a handsome building and contains the tomb of Floris V., count of Holland (d. 1396), a brass of 1546, and some paintings (1507). In the town hall (1507) are the library and a small museum with two pictures by the 17th-century artist Caesar van Everdingen, who with his more celebrated brother Allart van Everdingen (q.v.) was a native of the town. The weigh-house (1582) is a picturesque building with quaint gable and towers. Just outside the town lies the Alkmaar wood, at the entrance to which stands a monument which serves as a preparatory school for the royal military academy at Breda. Alkmaar derives its chief importance from being the centre of the flourishing butter and cheese trade of this region of Holland. It is also a considerable market for horses, cattle and grain, and there is a little boat-building and salt and sailcloth manufacture. Tramways connect Alkmaar with Egmond and with the pretty summer resort of Bergen, which lies sheltered by woods and dunes.

The name of Alkmaar, which means "all sea," first occurs in the 10th century, and recalls its former situation in the midst of marshlands and lakes. It was probably originally a fishing-village, but with the reclamation of the surrounding moorases, e.g. that of the Schermer in 1685, and their conversion into rich meadow land, Alkmaar gradually acquired an important trade. In 1524 it received a charter from William II., count of Holland, similar to that of Haarlem, but in the 15th century duke Philip the Good of Burgundy made the impoverishment of the town, due to ill-government, the excuse for establishing an oligarchy, the same ducal princes of 1436 and 1437. As the capital of the ancient district of Kennemerland between den Heider and Haarlem, Alkmaar frequently suffered from raids of the English. In 1574 Alkmaar was captured by the United Provinces, and in 1575 it successfully sustained a seven-weeks' siege by 16,000 Spaniards under the duke of Alva. In 1579 Alkmaar gave its name to a confraternity of women founded by that date but suppressed in 1587, in accordance with which the Dutch-British army of 23,000 men, which was defeated at Bergen, evacuated Holland. A monument was erected in 1691 to commemorate the Russians who fell.

ALLACCI, LEONE [Leo Allatiis] (1586-1669), Greek scholar and theologian, was born in the island of Chios. His early years were passed in Carthage and at Rome, where he finally settled as teacher of Greek at the Greek college, at the same time devoting himself to the study of classics and theology. In 1622, after the capture of Heidelberg by Tilly, the elector Maximilian of Bavaria presented its splendid library composed of 106 cases of MSS. (bibliotheca Palatina) to Pope Gregory XV. Allacci was sent to superintend its removal to Rome, where it was incorporated with the Vatican library. On the death of Gregory, Allacci became librarian to Cardinal Berberini, and subsequently (1661) librarian of the Vatican, which post he held till his death on the 16th (or 19th) of January 1669. It is noteworthy that, although a Greek by birth, he was a Roman by adoption, and had the bitter enemy of all heretics, including his own countrymen. Allacci was a very industrious and voluminous writer, but his works, although they bear ample testimony to his immense learning, show an absence of the true critical faculty, and are full of intolerance, especially on religious subjects. For a list of these, J. A. Fabricius's Bibliotheca Graeca (xi. 437) should be consulted, where they are divided into four classes: editions, translations and commentaries on ancient authors; works relating to the dogmas and institutions of the Greek and Roman Churches; historical works; miscellaneous works. The number of his unpublished writings is also very large; the majority of them are included in the MSS. of the Vaticanian library.

The main source of our knowledge of Allati is the incomplete life by Stephanus Gradi, Leonis Allatiis vita, published by Cardinal Mai, in Nova Bibliotheca Patrum. A complete enumeration of his works is contained in E. Legrand, Bibliographie hellénique du XVIIIe siécle (Paris, 1895, iii. 455-471). The accounts of C. N. Sathas in Nea hellénika filologias (Athens, 1868), and of the pseudo-prince Demetrius Rodokinakis, Leonis Allatiis Helvetica, Athens (Athens, 1896) are inaccurate and unreliable. For a special account of his share in the foundation of the Vatican Library, see Curro Mazzu, Leone Allacci e la Biblioteca di Heidelberg (Bologna, 1893). The critical apparatus of his works is best treated by the Assumptionist Father L. Petit in A. Vacant's Dictionnaire de théologie (Paris, 1900, cols. 830-833).

ALLAH, the Arabic name used by Moslems of all nationalities for the one true God. It is compounded of all, the definite article, and lâh, meaning a god. The same word is found in Hebrew and Aramaic as well as in ancient Arabic (Sabaean). The meaning of the root from which it is derived is very doubtful; cf. Lane's
ALLAHABAD—ALLAN

Arabic-English Lexicon, p. 82, and the Oxford Hebrew and English Lexicon, pp. 61 ff.

ALLAHABAD, a city of British India, the capital of the United Provinces of Agra and Oudh, giving its name to a district and a division. The city is situated at the confluence of the Ganges and the Jumna in 25°56' N. lat. and 82°56' E. long., 564 m. from Calcutta by rail. Its most conspicuous feature is the fort, which rises directly from the banks of the confluent rivers and completely commands the navigation of both streams. Within the fort are the remains of a splendid palace, erected by the Emperor Akbar, and once a favourite residence of his. A great portion of it has been destroyed, and its hall is converted into an arsenal. Outside the fort the places of most importance are the sarai and gardens of Khasru, the son of the Emperor Jehangir, and the Jama Masjid or Great Mosque. When the town first came into the hands of the English this mosque was used as a residence by the military officer commanding the station, and afterwards as an assembly room. Ultimately it was returned to its former owners, but the Mahomedans considered it desecrated, and it has never since been used as a place of worship. Allahabad (Illahabad) was the name given to the city when Akbar built the great fort. To the Hindus it is still known by its ancient name of Prag or Prayag ("place of sacrifice"), and it remains one of the most noted resorts of Hindu pilgrimage. It owes its sanctity to its being the reputed confluence of three sacred streams—the Ganges, the Jumna and the Saraswati. This last stream, however, actually loses itself in the sands of Sirhind, 400 m. north-west of Allahabad, and the North-Western army asserts that the streams of the two rivers underground, and in a subterranean temple below the fort a little moisture trickling from the rocky walls is pointed out as the waters of the Saraswati. An annual fair is held at Allahabad at the confluence of the streams on the occasion of the great bathing festival at the full moon of the Hindu month of Magh. It is known as the Magh-mela, lasts for a whole month, and is attended by as many as 250,000 persons in ordinary years, either for religious or commercial purposes. Every twelfth year there is a special occasion called the Kumbh-mela, which is attended by a million of devotees at one time. Allahabad was taken by the British in 1765 from the wazir of Oudh, and assigned as a residence to Shah Alam, the titular emperor of Delhi. Upon that prince throwing himself into the hands of the Maharratts, the place was resumed by the British in 1771 and again transferred to the nawab of Oudh, by whom it was finally ceded together with the district to the British in 1803, in commutation of the subsidy which the wazir had agreed to pay for British protection. During the Mutiny of 1857, Allahabad became the scene of one of the most serious outbreaks and massacres which occurred in the Northern Province. The mutineers were suppressed by a small garrison of Europeans and loyal Sikhs, until it was relieved by General Nell on June 11th of that year.

The modern buildings of Allahabad include Government House, the High Court, the Mayo memorial and town hall, the Muir central college, the Thornhill and Mayne memorial library and museum, the Naini central jail, and the Anglican and Roman Catholic cathedrals. The Jumna is crossed by a railway bridge and there are two bridges of boats over the Ganges. The military cantonments contain accommodation for all three arms and are the headquarters of a brigade in the 8th division of the eastern army corps. At Allahabad is published the Pioneer, perhaps the best known English paper in India. There is an American mission college. Here is the junction of the great railway system which unites Bengal with Central India and Bombay, and is developing into a great centre of inland and export trade. The population in 1901 was 172,052.

The DISTRICT of ALLAHABAD has an area of 2612 sq. m. In shape it is an irregular oblong, and it is very difficult to define its boundaries, as at one extremity it wanders into Oudh, while on the south the villages of the state of Rewa and those of this district are hopelessly intermingled. The Jumna and the Ganges enclose within their angle a fertile tract well irrigated with tanks and wells. The East Indian railway and the Grand Trunk road afford the principal means of land communication. In 1901 the population was 1,489,358, showing a decrease of 4% in the decade due to famine.

The division of Allahabad has an area of 17,700 sq. m. The population in 1901 was 5,540,702, showing a decrease of 4% in the decade due to the famine of 1896-1897, which was severely felt throughout the division. It comprises the seven districts of Cawnpore, Fatehpur, Banda, Hamirpur, Allahabad, Jhansi and Jalaun.

ALLAMANDA, named after J. N. S. Allamand (1713-1787), of Leiden, a genus of shrubby, evergreen climbers, belonging to the natural order Apocynaceae, and a native of tropical America. Several species are grown in hot-houses for the beauty of their foliage and flowers; the latter, borne in many-flowered panicles, have a funnel-shaped corolla with a narrow tube, and often yellow in colour. The plants are of comparatively easy culture, and very effective when trained to wires beneath the roof of the house.

ALLAN, DAVID (1744-1790), Scottish historical painter, was born at Allan. On leaving Foulis's academy of painting at Glasgow (1762), after seven years' successful study, he obtained the patronage of Lord Cathcart and of Er skine of Mar, on whose estate he had been born. The latter furnished him with the means of proceeding to Rome (1764), where he remained for a number of years engaged principally in copying the old masters. Among the original works which he then painted was the "Origin of Portraiture"—representing a Corinthian maid drawing her lover's shadow—well known through Domenico Cunego's excellent engraving. This gained him the gold medal, and he was elected an Associate of the Accademia di San Luca in the year 1778, and was given the best specimen of historical composition. Returning from Rome in 1777, he resided for a time in London, and occupied himself in portrait-painting. In 1780 he removed to Edinburgh, where, on the death of Alexander Runciman in 1786, he was appointed director and master of the Academy of Arts. There he painted and etched in aquatint a variety of works, those by which he is best known—as the "Scotch Wedding," the "Highland Dance," the "Repentance Stool," and his "Illustrations of the Gentle Shepherd"—being remarkable for their comic humour. He was called the "Scottish Hogarth," but his drolleries hardly entitle him to this comparison. Allan died at Edinburgh on the 6th of August 1796.

ALLAN, SIR HUGH (1810-1882), Canadian financier, was born on the 29th of September 1810, at Saltcoats; Ayrshire, Scotland, the son of Captain Alexander Allan, a shipmaster. He emigrated to Canada in 1826, and in 1832 entered the employ of the chief shipbuilding and grain-shipping firm of Montreal, of which he became a junior partner in 1853. In 1853 he organized the Allan Line of steamships, plying between Montreal, Liverpool, and Glasgow; till his death in 1882. The firm then became associated with the commercial growth and prosperity of Canada, and in 1871 was knighted in recognition of his services. In 1872-1873 he obtained from the Canadian government a charter for building the Canadian Pacific railway, but the disclosures made with reference to his contributions to the funds of the Conservative party led to the Pacific scandal (see CANADA, History), and that company was soon afterwards dissolved. He died in Edinburgh on the 9th of December 1882.

See J. C. Dent, Canadian Portrait Gallery (1881).

ALLAN, SIR WILLIAM (1782-1850), Scottish painter, was born at Edinburgh, and at an early age entered as a pupil in the School of Design established in Edinburgh by the Board of Trustees for Arts and Manufactures, where he had as companions, John Wilkie, John Burnet the engraver, and others who afterward distinguished themselves as artists. Here Allan and Wilkie were placed at the same table, studied the same designs, and contracted a lifelong friendship. Allan continued his studies for some time in London; but his attempt to establish himself there was unsuccessful, and after exhibiting at the Royal Academy (1803) his first picture, "A Gipsy Boy and Ass," in imitation in style of Opie, he determined, in spite of his scanty resources, to seek his fortune abroad. He accordingly set out the same year for Russia, but was carried by stress of weather to Memel,
where he remained for some time, supporting himself by his pencil. At last, however, he reached St Petersburg, where the kindness of Sir Alexander Crichton, the court physician, and other friends procured him abundant employment. By excursions into southern Russia, Turkey, the Crimea and Circassia, he filled his portfolio with vivid sketches, of which he made admirable use in his subsequent pictures. In 1814 he returned to Edinburgh, and in the following two years exhibited at the Royal Academy "The Circassian Captives" and "Hashiaks conducting Convicts to Siberia." The former picture remained so long unsold, that, thoroughly disheartened, he threw up his retirement and went abroad. Through the kindness of Sir Walter Scott, a subscription of 1000 guineas was obtained for the picture, which fell by lot into the possession of the earl of Wemyss. About the same time the Grand Duke Nicholas, afterwards tsar of Russia, visited Edinburgh, and purchased his "Siberian Exiles" and "Haslan Gheray crossing the River Kuban," giving a very favourable turn to the fortunes of the painter, whose pictures were now sought for by collectors. From this time to 1834 he achieved his greatest success and firmly established his fame by the illustration of Scottish history. His most important works of this class were: "The Minstrelsy of the Scottish Border," etched by John Magus Moor; "John Knox admonishing Mary Queen of Scots" (1823), engraved by Burnet; "Mary Queen of Scots signing her Abjuration" (1824); and "Regent Murray shot by Hamilton of Bothwellhaugh." The last procured his election as an associate of the Royal Academy (1825). Later Scottish subjects were "Lord Byron" (1831), portraits of Scott and "The Orphan" (1834), which represented Anne Scott seated near the chair of her deceased father. In 1830 he was compelled, on account of an attack of ophthalmia, to seek a milder climate and visited Rome, Naples and Constantiopolis. He returned with a rich store of materials, of which he made excellent use in his "Constantiopol Slave Market" and other productions. In 1834 he visited Spain and Morocco, and in 1841 went again to St Petersburg, where he undertook, at the request of the tsar, his "Peter the Great teaching his Subjects the Art of Shipbuilding," exhibited in London in 1845, and now in the Winter Palace of St Petersburg. His "Polish Exiles" and "Moorish Love-letter," &c., had secured his election as a Royal Academician in 1835; he was appointed president of the Royal Scottish Academy (1838), and royal limner for Scotland, after Wilkie's death (1841); and in 1842 received the honour of knighthood. His later years were occupied with battle-pieces, the last he finished being the second of his two companion pictures of the "Battle of Waterloo." He died on the 22nd of February 1850, leaving a large unfinished picture—"Bruce at Bannockburn."

ALLAN-Despréaux, Louise Rosalie (1810-1836), French actress, was "discovered" by Talma at Brussels in 1820, when she played Joise with him in Athalie. At his suggestion she changed her surname, Ross, for her mother's maiden name, and, as Mlle. Despréaux, was engaged for children's parts at the Comédie Française. At the same time she studied at the Conservatoire. By 1825 she had taken the second prize for comedy, and was engaged to play ingénue parts at the Comédie Française, where her first appearance in this capacity was as Jenny in L'Argent on the 8th of December 1826. In 1831 the director of the Gymnase succeeded in persuading her to join his company. Her six years at this theatre, during which she married Allan, an actor in the company, were a succession of triumphs. She was then engaged at the French theatre at St Petersburg. Returning to Paris, she brought with her, as Legouvé says, a thing she had never seen, a talent that threatened to bloom, a talent which never acted till she took it up, a production half-forgotten, and esteemed by those who knew it as a pleasing piece of work in the Marivaux style—Un Caprice by Alfred de Musset, which she had played with success in St Petersburg. Her selection of this piece for her reappearance at the Théâtre Française (1847) laid the corner-stone of Musset's lasting fame as a dramatist. In the following year his comedy Il ne faut jurer de rien was acted at the same theatre, and thus led to the production of his finer plays. Among plays by other authors in which Mme. Allan won special laurels at the Théâtre Française, were Pour droit de conquête, Pèril en la demeure, La joie fait peur, and Lady Tartuffe. In the last, with a part of only fifty lines, and playing by the very side of the great Rachel, she yet held her own as an actress of the first rank. Mme. Allan died in Paris, in the height of her popularity, in March 1856.

Allantoin, $\text{C}_4\text{H}_6\text{N}_2\text{O}_3$ or $\text{CO}_2\text{NH} - \text{CH} - \text{NH} - \text{CO}$, the diureide of glyoxylic acid. It is found in the allantoic liquid of the cow, and in the urine of sucking calves. It can be obtained by the oxidation of uric acid by means of lead dioxide, manganese dioxide, ozone or potassium permanganate:

$$\text{C}_6\text{H}_5\text{N}_2\text{O}_3 + \text{H}_2\text{O} + \text{O} = 3\text{H}_2\text{O} + \text{C}_2\text{H}_4\text{N}_2\text{O}_4.$$  

It has been synthesized by E. Grimaux by heating one part of glyoxylic acid with two parts of urea for ten hours at 100°C.

$$2\text{CO(NH}_2\text{)} + \text{CH(OH)}_2\text{COOH} = 3\text{H}_2\text{O} + \text{C}_2\text{H}_4\text{N}_2\text{O}_4.$$  

This forms glyoxylic acid with ammonia and carbon monoxide and dioxide. By dry distillation it gives ammonium cyanide.

**Allleghany, or The Alleghanies** (a spelling now more common than Alllegeney), a name formerly used of all the Appalachian Mountains (q.e.), U.S.A., and now sometimes of all that system lying W. and S. of the Hudson river, being steep and narrow-crested in Pennsylvania (1500-1800 ft.), and in Maryland, Virginia and West Virginia higher (3000 ft.-4475 ft.) and with broader crests. The name applies to the ridges ("the Alleghany Ridges") parallel to the Blue Ridge; the north-western part of this region is sometimes called the Alleghany Front or the Front of the Alleghany Plateau. The Alleghany Plateau is the north-westernmost division of the Appalachian system; it is an eroded mass of sedimentary rock sloping north-westward to the Prairies and Lake Plains and reaching south-west from the north-western part of New York state through Tennessee and into Alabama.

**Alllegheny, formerly a city of Allegheny county, Pennsylvania, U.S.A., on the N. bank of the Allegheny and Ohio rivers, a town of 6 miles from the mouth of the Allegheny, but the city of Pittsburg, Pop. (1890) 105,287; (1900) 129,896, of whom 30,216 were foreign-born and 3315 were negroes; of the foreign-born 12,022 were from Germany, 5070 from Ireland, 3029 from Austria, and 2177 from England; (1906, estimate) 145,240. Allegheny is served by the Baltimore & Ohio and the Pittsburg & Western railways, by the Pittsburg, Ft. Wayne & Chicago, the Western Pennsylvania, the Buffalo & Allegheny Valley, the Cleveland & Pittsburgh, the Erie & Pittsburg, the Pittsburg, Youngstown & Ashtabula, and the Chautauqua divisions of the Pennsylvania railway system, and by Ohio river freight and passenger boats. Extending along the river fronts for about 61 m. are numerous large manufactories and the headquarters of the shipping interests; farther back are the mercantile quarters and public buildings; and on the hills beyond are the residence districts, commanding extensive views of the valley. Two of the principal thorough-fares, Federal and Ohio streets, intersect at a central square, in which are the city hall, public library, post office and the market-place; and surrounding the main business section on the E., N. and W. is City Park of 100 acres, with lakes and fountains, and monuments to the memory of Alexander Von Humboldt, George Washington and T. A. Armstrong. Further out is Riverview Park (210 acres), in which is the Allegheny Astronomical Observatory, and elsewhere are a soldiers' monument and a monument (erected by Andrew Carnegie) in memory of Colonel Johnes Anderson. In Allegheny are the following institutions of higher learning—the Allegheny Theological Seminary (United Presbyterian), opened in 1825; the Western Theological Seminary of the Presbyterian Church, opened in 1827; and the Theological Seminary of the Reformed Presbyterians, opened in 1856. There is a fine Carnegie library with a music-hall. Among penal
and charitable institutions are the Riverside State Penitentiary, three hospitals, three homes for orphans, a home for the friendless and an industrial school. Six bridges spanning the river and electric lines crossing them have brought Allegheny into close industrial and social relations with the main part of Pittsburgh, and on the hills of Allegheny are beautiful homes of wealthy men. As a manufacturing centre Allegheny was outranked in 1905 by only two cities in the state—Philadelphia and Pittsburgh; among the more important of its large variety of manufactures are the products of slaughtering and meat-packing establishments, iron and steel works, foundries, steel mills, the products of foundries and machine shops, pickles, preserves and sauces, the products of railway-construction and repair shops, locomotives, structural iron and plumbers' supplies. In 1905 the total value of Allegheny's factory products was $45,830,272; this showed an apparent decrease (exceeded by one city only) of $7,356,106, from the product-value of 1900, but the decrease was partly due to the more careful census of 1905, in which there were not the duplications of certain items which occurred in the 1900 census. But in the five years there was a decrease of 3865 in the average number of wage-earners, and the iron and steel output was much less. In 1900 it was second in the United States in the value of its products, in the manufacture of pickles, preserves and sauces, the product ($6,216,778) being 20% of that for the whole country. An important industry is the shipment of coal, especially on barges down the Ohio.

Allegheny was laid out in 1788 on a tract which the state had previously reserved opposite Pittsburg, with a view to bringing some valuable land into the market for the payment of its soldiers' claims. When ordered by the state to be laid out, it was also named as the site of the county-seat of the newly erected county of Allegheny, but the opposition of Pittsburg was so strong that by a supplementary act in the following year that town was made the county-seat. In 1828 Allegheny was incorporated as a borough and in 1840 it was chartered as a city. The city suffered severely in 1874 from a fire started by a fire-cracker on the 4th of July and from a flood caused by a great rain-storm on the 26th of the same month, but these calamities were followed by years of great prosperity and rapid growth. In 1906 the question of uniting Allegheny with Pittsburg under one municipal government was submitted to a joint vote of the electorate of the two cities, in accordance with an act of the state legislature, which had been passed in February of that year, and a large majority voted for the union; but there was determined opposition in Allegheny, every ward of the city voting in the negative; the constitutionality of the act was challenged; the supreme court of the state on the 11th of March 1907 declared the act valid, and on the 18th of November 1907 this decision was affirmed by the Supreme Court of the United States.

See J. E. Parke, Recollections of Seventy Years and Historical Gleanings of Allegheny, Pennsylvania (Boston, 1886).

ALLEGIANC'E (Mid. Eng. iigeanice; med. Lat. iigandia, &c.; the al- was probably added through confusion with another legal term, allegiance, an allegation; the Fr. allegiance comes from the Latin term which is derived under that heading; the connection with Lat. ligare, to bind, is erroneous), the duty which a subject or a citizen owes to the state or to the sovereign of the state to which he belongs. It is often used by English legal commentators in a larger sense, divided by them into natural and local, the latter applying to the deference which even a foreigner must pay to the institutions of the country in which he happens to live; but it is in its proper sense, in which it indicates national character and the submission due to that character, that the word is important. In that sense it represents the feudal liege homage, which could be due only to one lord, while simple homage might be due to every lord under whom the person in question held land. The English doctrine, which was at one time adopted in the United States, asserted that allegiance was indissoluble: Nemo potest exuere patrim. Accordingly, as the law stood before 1879, every person who by birth or naturalization satisfied the conditions described in the article Alien, though he should be removed in infancy to another country where his family resided, owed an allegiance to the British crown which he could never resign or lose, except by act of parliament or by the recognition of the independence or the cession of the portion of British territory in which he resided. By the Naturalization Act 1870, it was made possible for British subjects to renounce their nationality and allegiance, and the ways in which that nationality is lost are defined. So British subjects voluntarily naturalized in a foreign state are deemed aliens from the time of such naturalization, unless, in the case of persons naturalized before the passing of the act, they have declared their desire to remain British subjects within two years from the passing of the act.

Persons who from having been born within British territory are British subjects, but who at birth became under the law of any foreign state subjects of such state, and also persons who though born abroad are British subjects by reason of parentage, may by declarations of alienage get rid of British nationality. Emigration to an uncivilized country leaves British nationality unaffected: indeed the right claimed by all states to follow with their authority their subjects so emigrating is one of the usual and recognized means of colonial expansion. The condition of the holder of his native allegiance without the consent of his sovereign was early abandoned in the United States, and in 1868 Congress declared that "the right of expatriation is a natural and inherent right of all people, indispensable to the enjoyment of the rights of life, liberty and the pursuit of happiness," and one of "the fundamental principles of the republic" (United States Revised Statutes, sec. 1990). Every citizen of a foreign state in America owes a double allegiance, one to it and one to the United States. He may be guilty of treason against one or both. If the demands of these two sovereigns upon his duty of allegiance come into conflict, those of the United States have the paramount authority in American law.

The oath of allegiance is an oath of fidelity to the sovereign taken by all persons holding important public office and as a condition of naturalization. By ancient common law it might be required of all persons above the age of twelve, and it was repeatedly used as a test for the disaffected. In England it was first imposed by statute in the reign of Elizabeth (1558) and its form has more than once been altered since. Up to the time of the revolution the promise was, 'to be true and faithful to the king and his heirs, and truth and faith to bear of life and limb and terrene honour, and not to know or hear of any ill or damage intended him without defending him therefrom.' This was thought to favour the doctrine of absolute non-resistance, and accordingly the convention parliament enacted the form that has been in use since that time—'I do sincerely promise and swear that I will be faithful and bear true allegiance to His Majesty ...' (see OATH).

ALLEGORY (Ἀλλογραφία, other, and ἄλογος, to speak, a figurative representation conveying a meaning other than and in addition to the literal. It is generally treated as a figure of rhetoric, but the medium of representation is not necessarily language. An allegory may be addressed to the eye, and is often embodied in painting, sculpture or some form of mimetic art. The etymological meaning of the word is wider than that which it bears in actual use. An allegory is distinguished from a metaphor by being longer sustained and more fully carried out in its details, and from an analogy by the fact that the one appeals to the fable or parable is a short allegory with one definite moral. The allegory has been a favourite form in the literature of nearly every nation. The Hebrew scriptures present frequent instances of it, one of the most beautiful being the comparison of the history of Israel to the growth of a vine in the 80th psalm. In classical literature one of the best known allegories is the story of the stomach and its members in the speech of Menenius Agrippa (Livy ii. 32); and several occur in Ovid's Metamorphoses. Perhaps the most elaborate and the most successful specimens of allegory are to
be found in the works of English authors. Spenser’s Faerie Queene, Swift’s Tale of a Tub, Addison’s Vision of Mirza, and above all, Bunyan’s Pilgrim’s Progress, are examples that it would be impossible to match in elaboration, beauty and fitness, from the literature of another nation, which had other needs; but in the former, with Lady Farewell, grand-daughter of the protector Somerset—bear witness to the attraction of Alleine’s private life. His public life was a model of pastoral devotion. This is all the more remarkable as he found time to continue his studies, one memorandum of which was his Theologia Philosophica (1623). I learned at Oxford the science of revelation and nature, which drew forth the wonder of Baxter. Alleine was no mere scholar or divine, but a man who associated on equal terms with the founders of the Royal Society. These scientific studies were, however, kept in subordination to his proper work. The extent of his influence was, in so young a man, unique, resting on the earnestness and force of his nature. The year 1663 found senior and junior pastors like-minded, and both were among the two thousand ejected ministers. Alleine, with John Wesley (grandfather of the celebrated John Wesley), also ejected, then travelled about, preaching wherever opportunity was found. For this he was cast into prison, indicted at sessions, bullied and fined. His Letters from Prison were an earlier Carthiophina than John Newton’s. He was released on the 26th of May 1664; and in spite of the Conventicle, or Five Mile Act, he resumed his preaching. He found himself again in prison, and again and again a sufferer. His remaining years were full of troubles and persecutions nobly borne, till at last, worn out by them, he died on the 17th of November 1668; and the mourners, remembering their beloved minister’s words and example, were allowed to accompany the body to Taunton, where he was buried. It was an Alarm to the Unconverted (1672), otherwise known as The Sure Guide to Heaven, which had an enormous circulation. His Remains appeared in 1674.

See Life, edited by Baxter; Joseph Alleine: his Companions and Times, by Charles Stanford (1861); Wood’s Athenea, i. 819; Palmer’s Nonc. Mem., iii. 206.

ALLEINE, RICHARD (1611–1687), English Puritan divine, was born a Ditcheat, Somerset, where his father was rector. He was a younger brother of William Alleine, the saintly vicar of Blandford. Richard was educated at St Alban’s Hall, Oxford, where he was entered commoner in 1627, and whence, having taken the degree of B.A., he transferred himself to New Inn, remaining there until he proceeded M.A. On being ordained he became assistant to his father, and immediately stirred the entire county by his burning eloquence. In March 1641 he succeeded the many-sided Richard Bernard as rector of Batcombe (Somerset). He declared himself on the side of the Puritans by subscribing to the Act of Uniformity, and became one of the commissioners of the parliament in their work of ejecting unsatisfactory ministers. Alleine continued for twenty years rector of Batcombe and was one of the two thousand ministers ejected in 1662. The Five Mile Act drove him to Frome Selwood, and in that neighbourhood he preached until his death on the 22nd of December 1681. His works are all of a deeply spiritual character. His Vindiciae Piatatis (which first appeared in 1666) was refused licence by Archbishop Sheldon, and was published, in common with other nonconformist books, without it. It was rapidly read and highly esteemed in the Christian world.”

Roger North, the king’s printer, caused a large part of the first impression to be seized on the ground of its not being licensed and to be sent to the royal kitchen. Glancing over its pages, however, it seemed to him a sin that a book so holy—and so saleable—should be destroyed. He therefore bought back the sheets, says Calamy, for an old song, bound them and sold them in his own shop. This in turn was complained of, and he had to beg pardon on his knees before the council-table; and the remaining copies were sentenced to be “hisked,” or rubbed over with yet bigger brush, and sent back to the kitchen for lighting fires. Such “hisked” copies occasionally occur still. The book was not killed. It was often reissued with additions, The Godly Man’s Portion in 1663, Heaven Opened in 1666, The World Conquered in 1668. He also published a book of sermons,
See Calamy, s.v.; Palmer’s Nonconf. Mem. iii. 167-168; C. Stanford’s Joseph Allin; Researches at Belchom and Fronse Seelwood; Wood’s Athenae (Bliss), iv. 13.

**ALLEMANDE** (Fr. for dans allemande, or German dance), a name for two kinds of dance, one a German national dance, in 2-4 time, the other somewhat resembling a waltz. The movement in a suite following the prelude, and preceding the courante (g.s.), with which it is contrasted in rhythm, is also called an allemande, but has no connexion with the dance. The name, however, is given to pieces of music based on the dance movements, examples of which are found in Beethoven’s German dances for the orchestra.

**ALLEN, ETHAN** (1739-1789), American soldier, was born at Litchfield, Connecticut, on the 10th of January 1739. He removed, probably in 1760, to the “New Hampshire Grants,” where he took up lands, and eventually became a leader of those who refused to recognize the jurisdiction of New York, and contended for the organization of the “Grants” into a separate province. About 1771 he was placed at the head of the “Green Mountain Boys,” an irregular force organized for resistance to the “Yorkers.” On the 10th of May 1775, soon after the outbreak of the War of American Independence, in command of a force, which he had assisted some members of the Connecticut assembly to raise for the purpose, he captured Ticonderoga from its British garrison, calling upon its commanding officer accordingly to name the place within ten minutes “in the name of the great Jehovah and the Continental Congress.” Seth Warner being elected colonel of the “Green Mountain Boys” in July 1775, Allen, piqued, joined General Philip Schuyler, and later with a small command, but without rank, accompanied General Richard Montgomery’s expedition against Canada. On the 25th of September 1775 near Montreal he was captured by the British, and until exchanged on the 6th of May 1776 remained a prisoner at Falmouth, England, at Halifax, Nova Scotia, and in New York. Upon his release he was brevetted colonel by the Continental Congress; in 1777 he was appointed brigadier-general of the militia of Vermont, resumed his opposition to New York, and from 1777 to 1783, acting with his brother, Ira Allen, and several others, carried on negotiations, indirectly, with Governor Frederick Haldimand of Canada, who hoped to win the Vermonters over to the British cause. He seems to have assured Haldimand’s agent that “I shall do everything in my power to make this state a British province.” In March 1781 he wrote to Congress, with characteristic bluster, “I am as resolutely determined to defend the independence of Vermont as congress that of the United States, and rather than fall into the hands of the hardy Green Mountain Boys into the desolate caverns of the mountains and wage war with human nature at large.” He removed to Burlington, Vermont, in 1787, and died there on the 11th of February 1789. He was, says Tyler, “a blustering frontier hero—an able-minded ignoramus of rough and ready humour, of boundless self-confidence, and of a shrewdness in thought and action equal to almost any emergency.” Allen wrote a Narrative of Colonel Ethan Allen’s Captivity (1779), the most celebrated book in the “prison literature” of the American revolution; A Vindication of the Inhabitants of Vermont to the Government of New York and their Right to form an Independent State (1779); and Reason, the Only Oracle of Men; or A Compendious System of Natural Religion, Alternately adorned with Confusions of a Variety of Doctrines incompatible with it (1784).

Ethan’s youngest brother, Ira Allen (1751-1814), born on the 21st of April 1751 at Cornwall, Connecticut, also removed to the New Hampshire Grants, where he became one of the most influential political leaders. In 1775 he took part in the capture of Ticonderoga and the invasion of Canada. He was a member of the convention which met at Winchester, Vermont, and in January 1777 declared the independence of the New Hampshire Grants; served (1776-1786) as a member of the Vermont council of safety; conducted negotiations, on behalf of Vermont, for a truce with the British and for an exchange of prisoners, in 1781; served for eight terms in the general assembly, and was state treasurer from 1778 to 1786 and surveyor-general from 1778 to 1757. In 1789, by a gift of $4,000, he made possible the establishment of the university of Vermont, of which institution, chartered in 1791 and built at Burlington in deference to his wishes, he was thus virtually the founder. In 1795, on behalf of the state, he purchased from the French government for the Vermont militia, of which he was then the ranking major-general, but he was captured by a British cruiser west of Ireland on his return journey, was charged with attempting to furnish insurrectionary Irish with arms, and after prolonged litigation in the British courts, the case not being finally decided until 1804, returned to Vermont in 1804. During his absence he had been dispossessed of his large holdings of land through the operation of tax laws, and to escape imprisonment for debt, he removed to Canada, where he died on the 4th of January 1814. He published a dull and biassed, but useful, *Natural and Political History of Vermont* (1758), reissued (1870) in vol. i. of the Collections of the Vermont Historical Society.

There is no adequate biography of Ethan Allen, but Henry Hall’s Ethan Allen (New York, 1892) may be consulted. The best literary estimate may be found in M. C. Tyler’s *Literary History of the American Revolution* (2 vols., New York, 1897).

**ALLEN, GRANT** [Charles Grant Blakefinde], (1848-1899), English author, son of a clergyman of Irish descent, was born at Kingston, Ontario, Canada, on the 24th of February 1848. He was educated partly in America and France, and in England at King Edward’s School, Birmingham, and afterwards at Merton, Oxford. He went to the West Indies as a young man in 1867, but then made his home in England, where he became prominent as a writer. He died at his house on Hindhead, Haslemere, on the 24th of October 1899. Grant Allen was a voluminous author. He was full of interesting scientific knowledge and had a gift for expression both in biological exposition and in fiction. His more purely scientific books (such as *Physiological Aesthetics*, 1877; *The Evolutionist at Large*, 1881; *The Evolution of the Idea of God*, 1897) contain much original matter, popularly expressed, and he was a cultured exponent of the evolutionary idea in various aspects of biology and anthropology. He first attracted attention as a novelist with a sensational story, *The Devil’s Die* (1888), though this was by no means his first attempt at fiction; and *The Woman who Did* (1895), which had a succès de scandale on account of its treatment of the sexual problem, had for the moment a number of cheap imitators. Other volumes flowed from his pen, and his name became well known in contemporary literature. But his reputation was essentially contemporary and characteristic of the vogue peculiar to the journalistic type.

**ALLEN, JAMES LANE** (1850-1925), American novelist, was born at Reading, Kentucky, on January 16, 1850. He graduated at Kentucky University, Lexington, in 1872, taught at Fort Spring, Kentucky, at Richmond and at Lexington, Missouri, and from 1877 to 1879 at the academy of Kentucky University, where he was principal and taught modern languages; in 1880 he was professor of Latin and English at Bethany College, Bethany, West Virginia; and then became head of a private school at Lexington, Kentucky. Subsequently he gave up teaching, went to New York City, where he secured commissions for sketches of the “Blue Grass” region, and thereafter devoted himself to literature. His *Invisible Boy* (1892), *The Inhabitants* (1893), and *The New England Survey* (1895) were books by which he gained his reputation; *The Munificent Five* (1897), *A Devil’s Jest* (1898), *The Woman who Did* (1900), *The Mistletoe of the Pasture* (1903), and *The Bride of the Mistleton* (1909) were books of sketches which made his name well known in England as well as America. His published works include: With flute and violin (1891), The Blue Grass Region (1892). John Gray (1893), A Kentucky Cardinal (1894), Aftermath (1895), A Summer in Arcady (1896), The Choir Invisible (1897), The Reign of Lady (1900), The Mistletoe of the Pasture (1903) and The Bride of the Mistleton (1909).

**ALLEN, JOHN** (1476-1534), English divine, after studying at both Oxford and Cambridge, was sent by Archbishop Warham on an ecclesiastical mission to Rome. On his return he held a number of livings in succession, and in 1516 he was rector of South Ockenden, Essex, and prebendary of Lincoln Cathedral. In the suppression of the minor monasteries in 1534-1535 he gave Wolsey much assistance, and became prebendary of Nottingham in 1536 and of St Paul’s, London, in 1527. These prebends he resigned in 1528 on his election as archbishop of Dublin. For
four years he was chancellor of Ireland but his career was full of trouble. In 1531 he was fined under the Statutes of Provisors and Pramunire, and in 1534 met a violent death at the hands of Lord Thomas Fitzgerald's followers.

**ALLEN, or ALVEY, THOMAS** (1522–1632), English mathematician, was born at Upton, in Staffordshire on the 21st of December 1522. He was admitted scholar of Trinity College, Oxford, in 1541; and graduated as M.A. in 1567. In 1580 he quitted his college and fellowship, retired to Gloucester Hall, and became famous for his knowledge of antiquity, philosophy and mathematics. Having received an invitation from Henry Percy, Earl of Northumberland, a great friend and patron of men of science, he spent some time at the earl’s house, where he became acquainted with Thomas Harriot, John Dee and other famous mathematicians. He was also intimate with Sir Robert Cotton, William Camden, and their antiquarian associates. Robert Dudley, Earl of Leicester, had a particular esteem for Allen, and would have conferred a bishopric upon him, but his love of solitude made him decline the offer. His great skill in mathematics and astrology earned him the credit of being a magician; and the author of *Leicester’s Commonwealth* accuses him of employing the art of “figuring” to further the earl of Leicester’s unlawful designs, and of endangering the black art to bring about a match between his patron and Queen Elizabeth. Allen was indentured in collecting manuscripts relating to history, antiquity, astronomy, philosophy and mathematics. A considerable part of his collection was presented to the Bodleian library by Sir Kenelm Digby. He died on the 30th of September 1632 at Gloucester Hall. He published in Latin the second and third books of *Claudius Ptolomy of Pelusium, Concerning the Judgment of the Stars, or, as it is commonly called, of the Quadruplicate Construction*, with an Exposition. He also wrote notes on John Bale’s *De Scriptoribus M. Britanniae*. 

**ALLEN, WILLIAM** (1532–1594), English cardinal, was born at Roswell, Lancashire, in 1547. He entered the college, Oxford, and in 1566 was made Master of ball at Magdalen Hall and kept a school there. According to Anthonie Wood, he was appointed to a canonry at York in or about 1582; he therefore had already entered the clerical state by receiving the tonsure. On the accession of Elizabeth, he was deprived upon refusing the oath of supremacy, but remained in the university until 1561. His known opposition to the new learning in religion giving much offence, he escaped from England and went to Louvain, where he gathered many students who had left the English universities for conscience’ sake. Here he continued his theological studies and began to write controversy treatises. In 1583, on account of health, he returned secretly to Lancashire and did much, by exhortation and private meetings, to restrain those Catholics who attended the new services in order to save their property from confiscation. His presence being known to the government, he fled Lancashire and retired to the neighbourhood of Oxford, which he frequently visited, and where he influenced many of the students. After writing a treatise in defence of the priestly power to remit sins, he was obliged to leave and retired to Norfolk, leaving England soon after in 1585. He returned to Flanders, was ordained at Malines, and began to lecture in theology at the Benedictine college in that city. In 1567 he went to Rome for the first time, and there began his plan for establishing a college where English students could live together and finish their theological course. The idea subsequently developed into the establishing of a missionary college, or seminary, to keep up a supply of priests for England as long as the country remained separated from the Holy See. With the help of friends, and notably of the Benedictine abbeys of the neighbouring monasteries, a college was established at Douai (September 29, 1568); and here Allen was joined by many of the English exiles. This college, the first of the seminaries ordered by the council of Trent, received the papal approval shortly after its establishment; the king of Spain took it under his protection and assigned it an annual grant. Allen continued his own theological studies and, after taking his doctorate, became regius professor at the university. Gregory XIII, in 1575 granted him a monthly pension of 100 golden crowns, and, as the number of students had now risen to one hundred and twenty, summoned him to Rome to undertake the establishing of a similar college in the papal city. By Allen’s advice, the old English hospice was turned into a seminary and the death of Mary, queen of Scots, he wrote to Philip II. (March 1575) Allen moved his establishment to Reims under the protection of the house of Guise; and it was here that the English translation of the Scriptures, known as the Douay Version, was begun under his direction (see BISHOP, ENGLISH). In 1577 he began a correspondence with Robert Parsons (q.v.), the Jesuit, an intimacy that was fraught with disaster. He was summoned again to Rome in 1579 to quell the first of the many disturbances that befell the English college under the Jesuit influence. Brought now into personal contact with Parsons, Allen fell completely under the dominating personality of the redoubtable Jesuit, and gave himself up entirely to his influence. He arranged that the Society should take over the English college at Rome and should begin the Jesuit mission to England (1580). This short-sighted policy was the cause of much grave trouble in the near future. Returning to Rome he began to take a part in all the political intrigues which Parsons’s fertile brain had hatched for the promotion of the Spanish interest in England. Allen’s political career dates from this period. Parsons had already intended to remove Allen from the seminary at Reims, and for this purpose, as far back as the 6th of April 1581, had recommended him to Philip II. to be promoted to the cardinalate. In furtherance of the intrigues, Allen and Parsons went to Rome again in 1585 and there Allen was kept for the rest of his life. In 1587, during the time that he was being skillfully played with by Philip's agents, he wrote a letter to his friend Sir William Dugdale. In this letter he declared that he was about to return to England, and that he had been made a cardinal by Philip's influence. In 1594 he was created cardinal of the name of Sixtus V. on the 7th of August 1587, nominally to supply the loss of the queen of Scotland, but in reality to ensure the success of the Armada. On his promotion Allen wrote to Reims that he owed the hat, under God, to Parsons. One of his first acts was to issue, under his own name, two violent works for the purpose of inclining the Catholics of England to rise against Elizabeth: "The Declaration of the Sentence of Sixtus V." a broadside, and a book, *An Admonition to the Nobility and People of England* (1588). On the failure of the Armada, Philip, to get rid of the burthen of supporting Allen as a cardinal, nominated him to the archbishopric of Malines, but the canonical appointment was never made. Gregory XIV. made him librarian at the Vatican; and he served on the commission for the revision of the Vulgate. He took part in four conclaves, but never had any real influence after the failure of the Armada. Before his death, which took place in Rome on the 16th of October 1594, he found reasons to change his mind concerning the wisdom of the Jesuit politics in Rome and England, and would have tried to curb their activities, had he been spared. The rift became so great that ten years after his death, Agazzari could write to Parsons: "So long as Allen walked in this matter (the scheme for England) in union with and fidelity to the Company, as he used to do, God preserved
him, prospered and exalted him; but when he began to leave this path, in a manner, the threads of his plans and life were cut short together.” As a cardinal Allen had lived in poverty and he died in debt.

Though I cannot withhold a tribute of respect from Allen for his zeal and earnestness, and recognize that his foundation at Douai survives to-day in the two Catholic colleges at Ushaw and Ware, it is impossible to deny that he injured the work with which his name will ever be associated, by his disastrous intercourse with Father Parsons. Known as a sharer in that plotter’s schemes, he gave a reasonable pretext to Elizabeth’s government for regarding the seminaries as hotbeds of sedition. That they were not so is abundantly proved. The superior kept their political actions secret from the students, and would not allow such matters even to be talked about in treated the theological abstractions in the schools. Dr Barrett, writing (April 14, 1853) to Parsons, makes open complaint of Allen’s secrecy and refusal to communicate. How far Allen was really admitted to the full confidence of Parsons is a question; and his later attitude to the Society goes to prove that he at last realized that he had been tricked. Like James II. with Fr. Petre, Allen had been “be-witched” for a time and only recovered himself when too late. They were notably the judges of Memorial Letters concerning Cardinal Allen (London, 1882); A. Bellesheim, Wilhelm Cardinal Allen und die englischen Seminare auf dem Festlande (Mainz, 1888); First and Second Diaries of the English College, Douai (London, 1878); Nicholas Fitzherbert, De Antiquitate et continuacione reliquiae in Anglia et de Alani Cardinalis vita libellos (Rome, 1608); E. Taunton, History of the Jesuits in England (London, 1901); Teulet, vol. v.; the Spanish State Papers (Gimmena), vols. iii. and iv.; a list of Allen’s works in J. G. Petre, Biographical Dictionary of English Catholics, vol. i., under his name. (E. T.K.)

**ALLEN, WILLIAM FRANCIS (1830-1889),** American classical scholar, was born at Northborough, Massachusetts, on the 5th of September 1830. He graduated at Harvard College in 1851 and subsequently devoted himself almost entirely to literary work and teaching. In 1857 he became professor of ancient languages and in 1858 a fellow of the Romanic language, at the University of Wisconsin. He died in December 1880. His contributions to classical literature chiefly consist of schoolbooks published in the Allen (his brother) and Greenough series. The Collection of Slave Songs (1867), of which he was joint-editor, was the first work of the kind ever published.

**ALLEN, BOG OF,** the name given to a congeries of morasses in Kildare, King’s County, Queen’s County and Westmeath, Ireland. Clan Bog, the eastern extremity, is within 17 m. of Dublin, and the morasses extend westward almost to the Shannon. Though there is about 138,000 acres. They do not form one continuous bog, the tract of the country to which the name is given being intersected by strips of cultivated land. The rivers Brosna, Barrow and Boyne take their rise in these morasses, and the Grand and Royal canals cross them. The Bog of Allen has a general elevation of 250 ft. above sea level, and the average thickness of the peat of which it consists is 25 ft. It rests on a subsoil of clay and marl.

**ALLENSTEIN,** a garrison town of Germany, in the province of East Prussia, on the river Alle, 100 m. by rail N.E. from Thorn, and 30 m. from the Russian frontier. Pop. (1890) 24,295. It has a medieval castle, several churches, a synagogue and various industries—iron-foundries, saw-mills, brick-works, and breweries; also an extensive trade in cereals and timber.

**ALLENTOWN,** a city and the county-seat of Lehigh county, Pennsylvania, U.S.A., on the Lehigh river, about 62 m. N.W. of Philadelphia. Pop. (1890) 25,228; (1900) 35,416, of whom 2994 were foreign-born, 1065 being of German birth; (1910) 51,613. It is served by the Central of New Jersey, the Lehigh Valley, the Perkiomen (of the reading system) and the Philadelphia & Reading railways. The city is situated on high ground sloping gently towards the river and commanding diversified views of the surrounding country. Hamilton Street, the principal business thoroughfare, extends over 2 m. from E. to W., and in what was once the centre of the city is Centre Square, in which there is a monument to the memory of the soldiers and sailors who fell in the Civil War. Allentown is the seat of a state homoeopathic hospital for the insane, of the Allentown College for Women (Reformed Church, 1867), and of Muhlenberg College (1867), an Evangelical Lutheran institution which grew out of the Allentown Seminary (established in 1848 and incorporated as the Allentown Collegiate Institute and Military Academy in 1864); in 1907 the college had 191 students, taught in the Allentown Preparatory School (1904), formerly the academic department of the college and still closely affiliated with it. The surrounding country is well adapted to agriculture, and slate, iron ore, cement rock and limestone are found in the vicinity. Allentown is an important manufacturing centre, and the value of its manufactured products increased 90-9% from 1870 to 1900, and of its factory product 13-2% between 1900 and 1905. In 1905 the city ranked sixth among the cities of the country in the manufacture of silk and silk goods, its most important industry. Other important manufactures are iron and steel, slaughtering and meat-packling products, boots and shoes, cigars, furniture, men’s clothing, hosiery and knit goods, jute and jute goods, linen-thread, malt liquors, brick, cement, barbed wire, wire nails and planing-mill products. Allentown’s total factory product in 1905 was valued at $16,666,550, of which $3,901,249, or 23%, was the value of silk and silk goods. The municipality owns and operates its water-works. Allentown was first settled in 1751; in 1792 it was laid out as a town by the “Allentown, the son of a chief-justice of the province, in honour of whose family the city is named; in 1811 it was incorporated as a borough and its name was changed to Northampton; in 1812 it was made the county-seat; in 1838 the present name was again adopted; and in 1867 the first city charter was secured. The silk industry was introduced in 1881.

**ALLEPPI,** or AULAPALAY, a seaport of southern India, in the state of Travancore, 33 m. south of Cochin, situated on a strip of coast between the sea and one of those backwaters that here form the chief means of inland communication. Pop. (1901) 38,750. It is on the Malabar railway 11 m. from the light visible 18 m. out at sea. Though the third town in the state in point of population, Alleppi is the first in commercial importance. It commands a fine harbour, affording safe anchorage for the greater part of the year. It was opened to foreign trade towards the latter end of the 18th century. The exports consist of coffee, pepper, cardamoms and coco-nuts. There are factories for coir-mattting. The raja has a palace, and Protestant missionaries have a church.

**ALLESTREE, or ALLESTREE, RICHARD (1610-1681),** royalist divine, was provost of Eton College, son of Robert Allestree, and a descendant of an ancient Derbyshire family, was born at Uppington in Shropshire. He was educated at Coventry and later at Christ Church, Oxford, under Richard Busby. He entered as a commoner in 1636, was made student shortly afterwards, and took the degree of B.A. in 1640 and of M.A. in 1643. In 1642 he took up arms for the king under Sir John Biron. On the arrival of the parliamentary forces soon afterwards in Oxford he secreted the Christ Church valuables, and the soldiers found nothing in the treasury “except a single groat and a halter in the bottom of a large iron chest.” He escaped severe punishment only by the hasty retirement of the army from the town. He was present at the battle of Edgehill in October 1642, after which, while hastening to Oxford to prepare for the king’s visit to Christ Church, he was captured by a troop of Lord Say’s soldiers from Broughton House, being soon afterwards set free on the surrender of the place to the king’s forces. In 1643 he was again under arms, performing “all duties of a common soldier” and “frequently holding his musket in one hand and his book in the other.” At the close of the Civil War, he returned to his studies, took holy orders, was made curate and became a “noted tutor.” But he still remained an ardent royalist. He voted for the university degree against the Covenant, and, refusing submission to the parliamentary visitors in 1648, he was expelled. He found a retreat as chaplain in the house of the Hon. Francis Newport, Afterwards Viscount Newport, in whose interests he undertook a journey to France. On his return he joined two of his friends, Dolen and Fell, afterwards respectively archbishop of York
and bishop of Oxford, then resident at Oxford, and later joined the household of Sir Antony Cope of Hanwell, near Banbury. He was now frequently employed in carrying despatches between the king and the royalists in England. In May 1650 he brought a command from Charles in Brussels, directing the bishop of Salisbury to preach at Oxford, where in Henslowe's diary the capable clergyman to various sees "to secure a continuation of the order in the Church of England," then in danger of becoming extinct. While returning from one of these missions, in the winter before the Restoration, he was arrested at Dover and committed a prisoner to Lambeth Palace, then used as a gaol for apprehended royals, but was liberated after confinement of a few weeks at the instance, among others, of Lord Shaftesbury. At the Restoration he became canon of Christ Church, D.D, and city lecturer at Oxford. In 1663 he was made chaplain to the king and regis preacher of divinity. In 1665 he was appointed provost of Eton College, and proved himself a capable administrator. He introduced order into the disorganized finances of the college and procured the confirmation of Laud's decree, which reserved five of the Eton fellowships for members of King's College. His additions to the college buildings were less successful; for the "Upper School," constructed by him at his own expense, was falling into ruin almost in his lifetime, and was replaced by the present structure in 1689. Allestree died on the 28th of January 1681, and was buried in the chapel at Eton College, where in 1859 his gravestone was unveiled. His"sopere omne, The Privileges of the University of Oxford in point of Visitation (1647)—a tract answered by Prynne in the University of Oxford's Plea Rejected; 18 sermons whereof 15 preached before the king . . . (1669); 40 sermons whereof 21 are now first published . . . (2 vols., 1684); sermons published separately including A Sermon on Acts xii. 2, (1660); A Paraphrase and Annotations upon all the Epistles of St. Paul (joint author with Abraham Woodhead and Obadiah Walker, 1675, see edition of 1833 and preface by W. Jacobson). In the Cases of Conscience by J. Barlow, Bishop of Lincoln (1693), Allestree's name is included. A share in the composition, if not the sole authorship, of the books published under the name of the author of the Whole Duty of Man has been attributed to Allestree (Nichols's Anecdotes, ii. 603), and the tendency of modern criticism is to regard him as the author. His lectures, with which he was dissatisfied, were not published. Allestree was a man of extensive learning, of moderate views and a fine preacher. He was generous and charitable, of "a solid and masculine kindness," and of a temper hot, but completely under control.

ALLEY (from the Fr. alleé, a walk), a narrow passageway between two buildings available only for foot passengers or hand-carts, sometimes entered only at one end and known as an alley, or cul-de-sac. The name is also given to the long narrow passages where bowls or skittles were played.

ALLEY, EDWARD (1566–1626), English actor and founder of Dulwich College, was born in London on the 1st of September 1566, the son of an innkeeper. It is not known at what date he began to act, but he certainly gained distinction in his calling while a young man, for in 1586 his name was on the list of the earl of Worcester's players, and he was eventually rated by common consent as the foremost actor of his time. Ben Jonson, a critic little prone to extol the merits of men of mark among his contemporaries,督办 wonderful unstinted praise on Alley's acting (Epigrams, No. 89). Nash expresses in prose, in Pierce Penniless, his admiration of him, while Heywood calls him "inimitable," "the best of actors," "Proteus for shapes and Roscius for a tongue." Alley inherited house property in Bishopsgate from his father. His marriage on the 22nd of October 1592 with Joan Woodward, stepsister of Philip Henslowe, brought him eventually more wealth. He became bailiff of Moorfields, and was the proprietor of several play-houses and other profitable pleasure resorts. Among these were the Rose Theatre at Bankside, the Paris Garden and the Fortune Theatre in St. Luke's—the latter occupied by the earl of Nottingham's company, of which Alleyn was the head. He filled, too, in conjunction with Henslowe, the post of "master of the king's games of bears, bulls and dogs." On some occasions he directed the sport in person, and Stow in his Chronicles gives an account of how Alleyn baited a lion before James I. at the Tower. Alleyn's connexion with Dulwich began in 1600, when he bought the manor of Dulwich from Sir Francis Calton. The landed property, of which the entire estate had not passed into Alleyne's hands earlier than 1614, stretched from the crest of that range of Surrey hills on whose summit now stands the Crystal Palace, to the crest of the parallel ridge, three miles nearer London, known in its several portions as Herne Hill, Denmark Hill and Champion Hill. Alleyn acquired this large property for little more than £10,000. He had barely got full possession, however, before the question how to dispose of it arose. He arranged for his family's future, and, in the twelfth year of his wedded life. Then it was that the prosperous player—the man "so acting to the life that he made any part to become him" (Fuller, Worthies)—began the task of building and endowing in his own lifetime the College of God's Gift at Dulwich. All was completed in 1617 except the charter or deed of incorporation for setting his lands in mortmain. Tedioc delays occurred in the Star Chamber, where Lord Chancellor Bacon was scheming to bring the pressure of kngly authority to bear on Alleyne with the aim of securing a large portion of the proposed endowment for the maintenance of lectureships at Oxford and Cambridge. Alleyne finally carried his point and the College of God's Gift at Dulwich was founded, and endowed under letters patent of James I., dated the 21st of June 1619. The building had been already begun in 1613 (see DULWICH). Alleyne was never a member of his own foundation, but he continued to the close of his life to guide and control its affairs under powers reserved to himself in the letters patent. His diary shows that he mixed much and intimately in the life of the college. Many of the buttoings in that curious record of daily doings and incidents favour the inference that he was a genial, kind, amiable and hospitable man. One is surprised by the fact that he engaged the boys in occasional theatrical performances. At a festive gathering on the 6th of January 1622 "the boys play'd a play." Alleyne's first wife died in 1623. The same year he married Constance, daughter of John Donne, the poet and dean of St. Paul's. Alleyne died in November 1626 and was buried in the chapel of the college which he had founded. His gravestone fixes the day of his death as the 21st, but there are grounds for the belief that it was the 23rd. A portrait of the actor is preserved in his own collection. Alleyn is remembered as the founder of the corporation of wardens of St. Saviour's, Southwark, in 1619, and there is a memorial window to him in the cathedral.

ALL FOURS, a card game (known also in America as Seven Up, Old Sedge or High-Low-Jack) usually played by two players, though four may play. A full pack is used and each player receives seven counters. Four points can be scored, one each for high, the highest trump out, for low, the lowest trump dealt, for Jack, the knave of trumps, and for game, the majority of piles in the cards of the tricks that a player has won. The player who wins the majority of the tricks is the winner. The winner of the majority of the tricks is the winner. Jack is scored by the player who finally has it among his tricks. If Jack is turned up the dealer scores the point. A player who plays a high or low trump is entitled to ask if they are high or low. The game is 10 or 11 points. Six
cards are dealt to each, the thirteenth being turned up for trumps. The non-dealer may propose or beg if he does not like his hand. If the dealer refuses the elder hand scores a point; if he consents he gives and takes three more cards, the seventh being turned up for trumps, which must be of a different suit from the original trump card; otherwise six more cards are dealt out, and so on till a fresh trump suit appears. The non-dealer then leaves the trump suit if he can trump it with a face suit or, if not, with a different suit. Jack may be played to any trick. Each pair of cards is a trick, and is collected by the winner. A fresh deal may be claimed if the dealer exposes one of his adversary's cards, or if he gives himself or his adversary too few or too many. In that case the error must be discovered before a card is played (see also Auction Pitch).

**ALLIA—ALLIER**

695
cards are dealt to each, the thirteenth being turned up for trumps. The non-dealer may propose or beg if he does not like his hand. If the dealer refuses the elder hand scores a point; if he consents he gives and takes three more cards, the seventh being turned up for trumps, which must be of a different suit from the original trump card; otherwise six more cards are dealt out, and so on till a fresh trump suit appears. The non-dealer then leaves the trump suit if he can trump it with a face suit or, if not, with a different suit. Jack may be played to any trick. Each pair of cards is a trick, and is collected by the winner. A fresh deal may be claimed if the dealer exposes one of his adversary's cards, or if he gives himself or his adversary too few or too many. In that case the error must be discovered before a card is played (see also Auction Pitch).

**ALLIA (mod. Fosso Betina),** a small tributary of the river Tiber, joining it on the left (east) bank, about 11 m. N. of Rome. It gave its name to the terrible defeat which the Romans suffered at the hands of the Gauls on the 18th of July 300 B.C. Livy (v. 37) and Diodorus (v. 114) differ with regard to the site of the battle, the former putting it on the left, the latter on the right bank of the Tiber. Mommsen and others support Diodorus, but the question still remains open.

**ALLIANCE,** a city of Stark county, Ohio, U. S. A., on the Mahoning river, about 57 m. S.E. of Cleveland, about 108 ft. above the sea, and about 705 ft. above the level of Lake Erie. Pop. (1800) 760, (1810) 8074, of whom 1020 were foreign-born: (1910, census) 15,083. It is served by the Pennsylvania and the Lake Erie, Alliance & Wheeling railways, and by an electric line connecting with Canton and Salem. The city is the seat of Mount Union College (Methodist Episcopal), opened in 1826 as a preparatory school and having in 1907 a library of about 10,000 volumes, a collegiate department (opened in 1859), a normal department (1838), a school of music (1855), a commercial school (1868), a faculty of 29 teachers, and an enrolment of 524 students, of whom 274 were non-residents. Among the manufactures of Alliance are structural iron, steel castings, pressed sheet steel, gun carriages, boilers, travelling cranes, pipe organs, street-car indicators, sashes and doors, and account registers and other material for file and cabinet-bookkeeping. The municipality owns and operates its water-works. Alliance was first settled in 1838, when it was laid out as a town and was named Freedom; it was named Alliance in 1851, was incorporated as a village in 1854, and became a city of the second class in 1888.

**ALLIANCE,** in international law, a league between independent states, defined by treaty, for the purpose of common action, defensive or offensive, or both. Alliances have usually been directed to specific objects carefully defined in the treaties. Thus the Triple Alliance of 1688 between Great Britain, Sweden and the Netherlands, and the Grand Alliance of 1689 between the emperor, Holland, England, Spain and Saxony, were both directed against the power of Louis XIV. The Quadruple or Grand Alliance of 1814, defined in the treaty of Chaumont, between Great Britain, Austria, Russia and Prussia, had for its object the overthrow of Napoleon and his dynasty, and the confining of France within her traditional boundaries. The Triple Alliance of 1858 between Germany, Austria and Italy was ostensibly directed to the preservation of European peace against any possible aggressive action of France or Russia; and this led in turn, some ten years later, to the Dual Alliance between Russia and France, for mutual support in case of any hostile action of the other powers. Occasionally, however, attempts have been made to give alliances a more general character. Thus the “Holy Alliance” (q.v.) of the 26th of September 1815 was an attempt, inspired by the religious idealism of the emperor Alexander I. of Russia, to find in the “sacred precepts of the Christian religion” a common basis for the relations of the European governments, its object being, primarily, the preservation of peace. So, too, by Article VI. of the Quadruple Treaty signed at Paris on the 20th of November 1815—which renewed that of Chaumont and was again renewed, in 1818, at Aix-la-Chapelle—the scope of the Grand Alliance was extended to objects of common interest not specifically defined in the treaties. The article runs:—“In order to consolidate the intimate tie which unites the four sovereigns for the happiness of the world, the High Contracting Powers have agreed to renew at fixed intervals, either under their own auspices or by their respective ministers, meetings consecrated to great common objects and to the examination of such measures as at each one of these epochs shall be judged most salutary for the peace and prosperity of the nations and the maintenance of the tranquillity of Europe.”

It was this article of the treaty of the 20th of November 1815, rather than the “Holy Alliance,” that formed the basis of the serious effort made by the great powers, between 1815 and 1822, to govern Europe in concert, which will be found outlined in the article on the history of Europe. In general it proved that an alliance, to be effective, must be clearly defined as to its objects, and that in the long run the treaty in which these objects are defined must—to quote Bismarck’s somewhat cynical dictum—“be reinforced by the interests” of the parties concerned. Yet the “moral alliance” of Europe, as Count Nesselrode called it, though it failed to secure the permanent harmony of the powers, was an effective instrument for peace during the years immediately following the downfall of Napoleon; and it set the precedent for those periodic meetings of the representatives of the powers, for the discussion and settlement of questions of international importance, which, though numerous and inefficient for constructive work, have contributed much to the preservation of the general peace (see European History). And again in 1879, the Triple Alliance was renewed, and is continued down to the present.

**ALLIARIA OFFICINALIS,** also known botanically as *Sisymbrium Alliaria,* and popularly as garlic-mustard, Jack-by-the-hedge, or sauce-alone, a common hedge-bank plant belonging to the natural order Cruciferae. It is a rankly scented herb, 2 to 3 ft. high, with long-stalked, coarsely-toothed leaves, and small white flowers which are succeeded by stout long four-sided pods. It is widely spread through the north temperate region of the Old World.

**ALLIBONE, SAMUEL AUSTIN** (1816–1889), American author and his brother, was born in Philadelphia, Pennsylvania, on the 17th of April 1816, of French Huguenot and Quaker ancestry. He was privately educated and for many years was engaged in mercantile business in his native city. He, however, devoted himself chiefly to reading and to bibliographical research; acquired a very unusual knowledge of English and American literature, and is remembered as the compiler of the well-known *Critical Dictionary of English Literature and British and American Authors* (3 vols.: vol. 1, 1834, vols. ii. and iii. 1871). To this, two supplementary volumes, edited by John Foster Kirk, were added in 1871. (See *Epistles to an Historian,* and again in 1879.) Allibone was book editor and corresponding secretary of the American Sunday School Union; and from 1879 to 1888 he was librarian of the Lenox Library, New York City. He died at Lucerne, Switzerland, on the 2nd of September 1889. In addition to his *Critical Dictionary* he published three large anthologies and several religious tracts.

See the “Memoir” by S. D. M’Connell, an address delivered before the Historical Society of Philadelphia (Philadelphia, 1890).

**ALLIER (anc. Elaver),** a river of central France flowing into the Loire. It rises in the department of Lozère, among the Margeride mountains, a few miles east of the town of Mende. The upper course of the Allier separates the mountains of the Margeride from those of the Velay and lies for the most part through deep gorges. The river then traverses the plains of Langec and Brioude, and receives the waters of the Alagon some miles above the town of Issore. Swifted by torrents from the mountains of Dore and Dôme, it unites with the river Dore at its entrance to the department to which it gives its name. It then flows through a wide but shallow channel, joining the Sioule some distance above Moulins, the chief town on its banks. It soon after becomes the boundary line between the departments of Cher and Nivière, and reaches the Loire 4 m. west of Nevers, after a course of 269 m. Its basin has an area of 67,55 sq. m. The Allier is classed as navigable for the last 154 m. of its course, but there is little traffic on it.
ALLIER—ALLISON

ALLIER, a department of central France, formed in 1790 from the old province of Bourbonnais. Pop. (1906) 417,061. Area, 2840 sq. m. It is bounded N. by the department of Nièvre, E. by Saône-et-Loire, from which it is divided by the river Loire, S.E. by Loire, S. by Puyl-de-Dôme, S.W. by Creuse and N.W. by Cher. Situated on the northern border of the Central Plateau, the department slopes from south to north. Its highest altitudes are found in the south-east, in the Bois-Noirs, where one point reaches 4233 ft., and in the Monts de la Madeleine. Plains alternating with forests occupy the northern zone of the department, while the central and western regions form an undulating and well-watered plateau. Entering the department in the south, and, like the other chief rivers, flowing almost due north, the Allier drain the central district, receiving on its left the Sioule. East of the Allier is the Bèbre, which joins the Loire within the limits of the department; and on the west the Cher, with its tributary the Aumance. Rigorous and sandy in the south-east, the climate elsewhere is milder though subject to sudden variations. Agriculturally the department is flourishing, the valleys of the Allier and the Sioule known as the Limagne Bourbonnaise comprising its most fertile portion. Wheat, oats, barley and other cereals are grown and exported, and owing to the abundance of pasture and forage, sheep and cattle-rearing are actively carried on. Potatoes and mangels yield good crops. Wines of fair quality are grown in the valley of the Sioule; walnuts, chestnuts, plums, apples and pears are principal fruits. Goats, from the milk of which choice cheese is made, and pigs are plentiful. A large area is under forests, the oak, beech, fir, birch and hornbeam being the principal trees. The mineral waters at Vichy (q.v.), Nériss, Theneuil, Lusset and Bourbon l'Archambault are in much repute. The mineral wealth of the department is considerable, including coal as well as manganese and bituminous schist; plaster, building stone and hydraulic lime are also produced. Manufactories of porcelain, glass and earthenware are numerous. Montluçon and Commentry are iron-working centres. There are flour mills, breweries and saw-mills; and paper, chemicals, wooden shoes, wool and woollen goods are produced. Besides the products of the soil Allier exports coal, mineral waters and cattle for the Paris market. Building materials, brandy and coal are among the imports. The railways belong chiefly to the Orléans and Paris-Paris-Lyons-Mediterranean companies. The lateral canal of the Loire, the Berry Canal and the canal from Roanne to Digoin together traverse about 57 m. in the department. Allier is divided into the arrondissements of Moulins, Gannat, Lapalisse and Montluçon (29 cantons, 321 communes). It forms the diocese of Moulins and part of the ecclesiastical province of Bourges, and falls within the department (educational division) of Clermont-Ferrand and the region of the Auvergne. Its capital is Moulins. Rioms, the capital, Montluçon and Vichy, are the principal towns. Souvigny possesses the church of a famous Cluniac priory dating from the 11th and 12th centuries, and containing the splendid tombs (15th century) of Louis II. and Charles I. of Bourbon. At St Menoux, Ebreuil and Gannat there are fine Romanesque churches. Huriel has a church of the 11th century and a well-preserved keep, the chief survival of a mediaeval castle. St Pouçain-sur-Sioule has a large château, containing from the castle of Bourbon l'Archambault, which belonged to the dukes of Bourbon and Portes, dates from the 13th and 15th centuries. The Romanesque churches of Veauce and Ygrandre, and the châteaux of Veauce and Lapalisse, are also of interest, the latter belonging to the family of Chabanais.

ALLIES, THOMAS WILLIAM (1833-1903), English historical writer, was born at Midsomer Norton, near Bristol, on the 12th of February 1833. He was educated at Eton and at Wadham College, Oxford, of which he became a fellow in 1853. In 1840 Bishop Blomfield of London appointed him his examining chaplain and presented him to the rectory of Landen, Oxfordshire, which he resigned in 1850 on becoming a Roman Catholic. Allies was appointed secretary to the Catholic Poor school committee in 1853, a position which he occupied till 1890. He died in London on the 17th of June 1903. Allies was one of the ablest of the English churchmen who joined the Church of Rome in the early period of the Oxford movement, his chief work, The Formation of Christendom (London, 8 vols., 1865-1875) showing much originality of thought and historical knowledge. His other writings are: St Peter, St Paul and Office (1852); The See of St Peter in the Rock of the Church (1850); Per Crucem ad Lucem (2 vols., 1879), have gone through many editions and been translated into several languages.

See his autobiography, A Life's Decision (1880); and the study by his daughter, Mary H. Allies, Thomas Allies, The Story of a Mind (London 1896), which contains a full biography of his work.\n
ALLIFAE (mod. Alife), a town of the Samnites, 15 m. N.W. of Telesia, and 17 m. E.N.E. of Teanum. The site of the Samnite city, which in the 4th century a.c. had a coinage of its own, is not known; the Roman town lay in the valley of the Vulturines, and its walls (4th century) enclose a circuit of 1/2 m., in which are preserved remains of large baths (Thermae Herculis) and a theatre.

ALLIGATOR (Spanish el lagarto, "the lizard"), an animal so closely allied to the crocodile that some naturalists have classed them together as forming one genus. It differs from the true crocodile principally in having the head broader and shorter, and the snout more obtuse; in having the fourth, enlarged tooth of the under jaw received, not into an external notch, but into a pit formed for it within the upper one; in wanting a jagged fringe which appears on the hind legs and feet of the crocodile; and in having the toes of the hind feet webbed not more than half way to the tips. Alligators proper occur in the fluvial deposits of the age of the Upper Chalk in Europe, where they did not die out until the Pliocene age; they are now restricted to two species, A. mississippiensis and A. laticeps, in the southern states of North America up to 12 ft. in length, and the small A. sinensis in the Yang-tse-kiang. In Central and South America alligators are represented by five species of the genus Caiman, which differs from Alligator by the absence of a bony septum between the nostrils, and the ventral armour is composed of overlapping bony scutes, each of which is formed of two parts united by a suture. C. scutopus, the spectacled alligator, has the widest distribution, from southern Mexico to the northern half of Argentina, and grows to a bulky size. The largest, attaining an enormous bulk and a length of 20 ft., is the C. niger, and the C. lacertoides of the Amazonas. The names "alligator" and "crocodile" are often confounded in popular speech; and the structure and habits of the two animals are so similar that both are most conveniently considered under the heading CROCODILE.

ALLINGHAM, WILLIAM (1824-1889), Irish man of letters and poet, was born at Ballyshannon, Donegal, on the 19th of March 1824 (or 1828, according to some authorities), and was the son of the manager of a local bank. He obtained a post in the custom-house of his native town and filled several similar situations in Ireland and England until 1870, when he retired from the service, and became sub-editor of Fraser's Magazine, which he edited from 1874 to 1879. He had published a volume of Poems in 1850, followed by Day and Night Songs, a volume containing many charming lyrics, in 1855. Allingham was on terms of close friendship with D. G. Rossetti, who contributed to the illustration of the Songs. His Letters to Allingham (1824-1879) were edited by Dr Birbeck Hill in 1871. Lawrence Bloomfield, a narrative poem illustrative of Irish social conditions, appeared in 1864. Allingham married in 1874 Helen Paterson, known under her married name as a water-colour painter. He died at Hampstead on the 18th of November 1889. Though working on an unostentatious scale, Allingham produced much excellent lyrical and descriptive poetry, and the best of his pieces are thoroughly national in spirit and local colouring.

William Allingham: a Diary (1907), edited by Mrs Allingham and her son, contains editorials reminiscences of Tennant and Carlyle and other famous contemporaries.

ALLISON, WILLIAM BOYD (1829-1908), American legislator, was born at Perry, Ohio, on the 2nd of March 1829. Educated at Allegheny and Western Reserve Colleges, he studied law, and practised in Ohio until 1857. In that year he settled in Dubuque, Iowa, where he took a prominent part in Republican politics;
and in 1860 he was a delegate to the national convention at Chicago which nominated Abraham Lincoln for the presidency. In 1861 he was appointed a member of the staff of Governor Samuel J. Kirkwood (1813-1894), and was of great service in the work of equipping and organizing the Iowa volunteers. From 1863 until 1871 he served with distinction in the House of Representatives; in 1873 he was elected to the United States Senate, and re-elected in 1878, 1884, 1890, 1896 and 1902. Here he became one of the highest authorities on questions connected with finance, and from 1877 he was a member of the Senate committee on finance. In 1881-1893, and again from 1895, he was chairman of the committee on appropriations, in which position he had great influence. He declined offers of the secretarieship of the treasury made to him by Presidents Garfield and Harrison, but in 1885 and 1894 he was a candidate for the presidential nomination in the Republican national conventions of 1888 and 1896. In 1892 he was chairman of the American delegation to the International Monetary Conference at Brussels. He died at Dubuque, Iowa, on the 4th of August 1908.

**ALLITERATION** (from Lat. **ad,** 'to,' and **ittera,** letter), the commencing of two or more words, in close juxtaposition, with the same sound. As Milton defined rhyme to be "the jingling sound of like endings," so alliteration is the jingle of like beginnings. All language has a tendency to jingle in both ways, even in prose. Thus in prose we speak of "near and dear," "high and dry," "health and wealth." But the initial form of jingle is much more common—"safe and sound," "thick and thin," "weal or woe," "fair or foul," "spick and span," "fish, flesh, or fowl," "kith and kin." The poets of nearly all times and tongues have not been slow to seize upon the emphasis which could thus be produced.

Although mainly Germanic in its character, alliteration was known to the Latins, especially in early times, and Cicero blames Ennius for writing "O Tite tute, Tati, tibi tanta, tyrannae, tutili." Lucretius did not disdain to employ it as an ornament.

We read in Shakespeare:—

"Full fathom five thy father lies:
Of his bones are coral made."

In Pope:—

"Here flies of pins extend their shining rows,
Puffs, powders, patches, bibles, billet-doux."

In Gray:—

"Weave the warp and weave the woof,
The winding-sheet of Edward's race!"

In Coleridge:—

"The fair breeze blew, the white foam flew,
The furrow followed free;\
We were the first that ever burst
Into that silent sea."

Churchill describes himself, in his Prophecy of Famine, as one "Who often, but without success, had prayed"

For apt alliteration's artful aid:—

an example which is itself a proof of his failure; for alliteration is never effective unless it runs upon consonants.

As thus far considered, alliteration is a device wholly dependent on the poet's fancy. He may use it or not, or use it much or little, at his pleasure. But there is an extensive range of Teutonic poetry whose metrical laws are entirely based on alliteration. This, for example, is the principle on which Icelandic verse is founded; and we have a yet nearer interest in it, because it furnishes the key to Anglo-Saxon and a large portion of early English verse. For a specimen take the following lines, the spelling modernized, from the beginning of *Piers the Plowman*:

"But in a May morning I on Malvern hills,
Me be/fel a ferly j of fairy methought;
I was weary of wandering I and went me to rest
Under a broad bank I by a burn-side;
And I lay and leaned I and looked on the waters,
I slumbered in a sleeping I it sounded so merry."

The rule of this verse is indifferent as to the number of syllables it may contain, but imperative as to the number of accented ones. The line is divided in the middle by a pause, and each half ought to contain two accented syllables. Of the four accented syllables, the first three should begin with the same letter; the fourth is free and may start with any letter. Those who wish for a more minute analysis of the laws of alliterative verse, as practised by the Anglo-Saxon and early English poets, may consult an exhaustive essay on the subject by Professor W. W. Skeat, prefixed to vol. ii. of *Bishop Percy's Folio Manuscript*; only the reader must bear in mind that many and many others object with some reason to the classical terms, and therefore brushing them aside, let us put the question in the simplest form—Has the movement of alliterative verse got the initial or the final beat? In the middle of the 18th century Bishop Percy decided this question with sufficient accuracy, though he mixed up his statement with a blunder which it is not easy to account for. He points out how the poets began to introduce rhyme into alliterative verse, until at length rhyme came to predominate over alliteration, and "thus was this kind of metre at length swallowed up and lost in the common poetry of the English people: "A cobbler there was, and he lived in a stall." Percy made a serious mistake when he gave the name of Alexandrine to anaepatic verse; but he is quite right in his general statement that alliterative verse became lost in a measure the movement of which had the final beat. Conybeare has stated the fact still more accurately. "In the Saxon poetry a trochaic character is predominant. In *Piers the Plowman* there is a prevailing tendency to an anaepatic cadence." It is the result of a change in the language—the loss of inflexion. Take the word the. The modernized *be* or *beet* in English, of *man,* an ambuscade. The tendency of the language was thus to pass from a metrical movement, in which the beat was initial, to one in which it was final. It may therefore be quite right to speak of Anglo-Saxon alliterative poetry as trochaic or dactylic, and quite wrong to apply the same terms to the cadence of our later alliterative verse. And this is precisely the error into which Skeat has fallen. He says—"Lines do not always begin with a loud syllable, but often one or two and sometimes (in early English especially) even three soft syllables precede it. These syllables are an aid to the sense, but not to the scansion of the line." That is just the point at issue. By leaving out of account the light syllable or syllables at the beginning of a line, and taking his start from the first syllable that has the alliterative beat, Skeat may certainly prove that all the later alliterative poetry has a movement of initial beat. But English ears will not submit to this rule. It is those light syllables of no account which have altered the rhythm of English dactyls from one of initial to one of final beat.

**ALLIUM** (Lat, for "garlic"), a genus of plants, natural order Liliaceae, with about 250 species (seven of which occur in Britain), found in Central and South Europe, North Africa, the dry country of West and Central Asia, and North and Central America. The plants are bulbous herbs, with flat or rounded radical leaves, and a central naked or leafy stem, bearing a head or umbel of small flowers, with a spreading or bell-shaped white, pink, red, yellow or blue perianth. Several species afford useful foods, such as onion (*Allium cepa*), leek (*A. Porrum*), shallot or shallot (*A. ascalonicum*), garlic (*A. sativum*), and chives (*A. schoenoprasum*). A few species are cultivated as border plants; such as *A. Monarde,* an old garden plant with but not yellow flowers, and *A. neapolitanum* the well-known white-flowered species, both natives of southern Europe.

**ALLIX, PIERRE** (1641-1717), French Protestant divine, was born at Alençon. He was pastor first at St Agobil in Champagne, and then at Charenton, near Paris. The revocation of the edict of Nantes in 1685 compelled him to take refuge in London, where, under the sanction of James II., he opened a
church for the French exiles. His reputation for learning was such as to obtain for him, soon after his arrival, the degree of doctor of divinity from both universities, and in 1690 he received from Bishop Burnet the more substantial honour of the treasurership and a canonry in Salisbury Cathedral. He died at London in March 1717. The works of Allon, which are numerous, are chiefly of a critical and apologetic character, and must be used with caution. In opposition to Bosseuet he published Some Remarks upon the Ecclesiastical History of the Ancient Churches of Piedmont (1690), and Remarks upon the Ecclesiastical History of the Ancient Churches of the Albigenese (1692), with the idea of showing that the Albigenese were not Manichaeans, but historically identical with the Waldenses.

**ALLMAN, GEORGE JAMES** (1827-1898), British biologist, was born in Cork, Ireland, in 1827, and received his early education at the Royal Academy Institution, Belfast. For some time he studied for the Irish bar, but ultimately gave up law in favour of natural science. In 1843 he graduated in medicine at Dublin, and in the following year was appointed professor of botany in that university, succeeding his namesake, William Allman (1776-1846). This position he held for about twelve years until he removed to Edinburgh as regius professor of natural history. There he remained till 1870, when considerations of health induced him to resign his professorship and retire to Dorsetshire, where he devoted himself to his favourite pastime of horticulture. The scientific papers which came from his pen are very numerous. His most important work was upon the gymnoblastic hydrea, on which he published in 1871-1872, through the Ray Society, an exhaustive monograph, based largely on his own researches and illustrated with drawings of remarkable excellence from his own hand. Biological science is also indebted to him for several convenient terms which have come into daily use, e.g. endoderm and ectoderm for the two cellular layers of the body-wall in Coelenterata. He became a fellow of the Royal Society in 1854, and received a Royal medal in 1873. For seven years he occupied the presidential chair of the Linnean Society, and in 1870 he presided over the Sheffield meeting of the British Association. He died on the 24th of November 1898 at Parkstone, Dorsetshire.

**ALLOA**, a municipal and police burgh and seaport of Clackmannanshire, Scotland. It is situated on the north bank of the Forth, 32 m. from Edinburgh by the North British railway via the Forth Bridge, and 28 m. from Leith by steamer. Pop. (1891) 12,643; (1901) 14,458. The Caledonian railway enters the town from the south-west by a bridge across the river, and also owns a ferry to South Alloa, on the opposite shore, in Stirling shire. Between Alloa and Stirling the stream forms the famous "links," the course being so sinuous that whereas by road the two towns are but 63 m. apart, the distance between them by river is nearly 12 m.

For its size and population the town enjoys unusual prosperity, in consequence of its several flourishing industries. Its manufactures of yarn are on the largest scale, the spinning mills often working night and day for many months together. There are also numerous breweries, and Alloa ale has always been famous. The great distillery at Carsebridge yields an immense supply of yeast as well as whisky. Other thriving trades include the glass-works on the shore, pottery-works in the "auld toon," dye-works and a factory for the making of electrical appliances. There is a good deal of shipbuilding, some ironfounding and a brass foundry. The chief article of export is coal from the neighbouring collieries, the other leading exports being ale, whisky, glass and manufactured goods. The imports comprise timber, grain, iron, linseed and flax. The docks, accessible only at high water, include a wet basin and a dry dock. Amongst the principal buildings are the fine Gothic parish church, with a spire 200 ft. high; the town hall, including the free public library from designs by Alfred Waterhouse, R.A., the gift of Mr J. Thomson Paton; the county and municipal buildings; handsome public baths and gymnasium, presented to the town by Mr David Thomson; the accident hospital; the fever hospital; the museum of the Natural Science and Archaeological Society; the academy, the burgh school and a secondary school with the finest technical equipment in Scotland, given by Mr A. Forrester Paton. There is a public park, besides bowling greens and football fields. The old burying-ground was the kirkyard of the former parish church, the tower of which still remains, but a modern cemetery has been formed in Sunnyside. The town is the water-carriage, gas and electric-lighting.

Alloa Park, the seat of the earl of Mar and Kellie, is in the immediate vicinity, and in its grounds stand the ruins of Alloa Tower, an ancient structure 80 ft. high, with walls 11 ft. thick, which was built about 1315, and was once the residence of the powerful family of Erskine, descendants of the earl of Mar. The earl who promoted the Jacobite rising in 1715 was born here. Many of the Scots princes received their education as wards of the Lords Erskine and the earls of Mar, the last to be thus educated being Henry, the eldest son of James VI.

**ALLOBROGES** (in Gr. usually 'Ἀλόμπρωγες'), a Celtic tribe in the north of Gallia Narbonensis, inhabiting the low ground called the "island" between the Rhodanus, the Isara and the Graian Alps, corresponding to the modern Dauphiné and Savoy. If the name is rightly interpreted as meaning "aliens," they would seem to have driven out the original inhabitants. Their chief towns were Vienna (Vienne), Genava (Geneva) and Curalo (afterwards Gratianopolis, whence Grenoble). The Allobroges first occur in history as taking part with Hannibal in the invasion of Italy. After the subjugation of the Salluvii (Salyes) by the Romans in 183 B.C., they sided with Catognatus and refused to surrender him, the Allobroges were attacked and finally defeated (August 8, 121) at the junction of the Rhodanus and Isara by Q. Fabius Maximus (afterwards Allobroicus). But they still remained hostile to Rome, as is shown by the conduct of their ambassadors in the Catilinarian conspiracy (63; see Catiline); two years later a revolt under Catognatus was put down by Gaius Pompotius at Solonium. Under Augustus they were included in Gallia Narbonensis; later, in Gallicia Narbonensis.

See A. Desjardins, Geographie historique de la Gaule romaine, ii (1876-1893); E. Herzog, Galliae Narbonensis Historia (Leipzig, 1864); Mommsen, Hist. of Rome (Eng. trans.), bk. iii. ch. 4, iv. ch. 51. T. R. Holmes, Caesar's Conquest of Gaul (1890); G. Long in Smith's Dict. of Greek and Roman Geography: M. Ihm in Fauly-Wissowa's Realencyclopédie, i. 2 (1894); A. Holder, All-celtischer Sprachschatz; and bibliography in La grande encyclopédie (s.v.).

**ALLOCATUR** (from med. Lat. allocatur, it is allowed), in law, a certificate given by a taxing master, at the termination of an action, for the allowance of costs.

**ALLOCUTION** (Lat. allocutio, address), a name given to the formal address made by the pope to the College of Cardinals and through them to the church generally. They are usually called forth by ecclesiastical or political circumstances, and aim at safeguarding papal principles and claims. They are published by being affixed to the door of St Peter's Church.

**ALLODIUM**, or ALODUM, a legal term for lands which are the absolute property of their owner, and not subject to any service or acknowledgment to a superior. It is thus the opposite of fo-edum or fief. The proper derivation of the word has been much discussed and is still doubtful, though it is probably compounded of all, which or entire, and edum, pertaining to illodial tenure seems to have been common throughout northern Europe. It exists in Orkney and Shetland, but is unknown in England, the feudal system having been made universal by William the Conqueror.

**ALLOMEROUS** (Gr. ἀλόρος, other μέκος, part), the quality of bodies (e.g. mineral) by virtue of which they can change their elements and proportions while preserving their form.

**ALLON, HENRY** (1818-1892), English Nonconformist divine, was born on the 9th of October 1818 at Welton near Hull in Yorkshire. Under Methodist influence he decided to enter the ministry, but, developing Congregational ideas, was trained at Cheshunt College. In 1844 he became co-pastor with the Rev. Thomas Lewis of Union Chapel, Islington. In 1852, on the death of Lewis, Allon became sole pastor, and this position he held with increasing influence till his death in 1892. Union Chapel,
originally founded by evangelical members of the Church of England and Nonconformists acting in harmony, became during Allon's co-pastorate definitely Congregational in principle and fellowship, and exercised an ever-expanding influence. His chief service to Nonconformity was in connexion with the improvement of congregational worship, and especially the service of prayer. In 1843 T. J. Gauntlett became organist at Union Chapel and conductor of a lay prebendary class. To meet the wants of this class, Allon published the original edition of his well-known Congregational Psalmist. For many years his collection of hymns, chants and anthems was used in hundreds of churches throughout England. In 1860 Allon began to write, at first chiefly for the Patriot, then under the editorship of T. C. Turberville. In 1884, at the age of forty-five, he was elected chairman of the Congregational Union, and in 1886 he undertook the editorship of the British Quarterly Review with H. R. Reynolds, the principal of Cheshunt. In 1877 he became sole editor, and in that capacity came into touch with such men as W. E. Gladstone, Matthew Arnold, F. D. Maurice and Dean Stanley. The magazine was discontinued in 1886. In 1871 he received the degree of D.D. from the university of Yale, U.S.A. In 1874 the congregation at Islington decided to erect new buildings. The church, which was built at a cost of £50,000, was specially adapted for congregational worship and was mentioned by an architectural journal as one of the hundred remarkable buildings of the century. The church had in its various departments about 300 teachers in charge of more than twenty-five hundred in attendance, and its membership was one of the earliest instances of the type known as the institutional church. In 1881, on the occasion of the jubilee of the Congregational Union of England and Wales, Allon was again elected chairman. In March 1892 he died suddenly from heart failure. His books were A Memoir of James Sherman (1863); the Sermons of Thomas Binney, with a biographical and critical sketch (1869); The Vision of God and other sermons (1879); The Indwelling Christ (1892). Allon was a man of sound judgment, strong will, great moral courage and personal kindness. His acquaintance with literature was wide, his own style lucid and decisive. In social and political affairs he was a convinced individualist. Both as leader of Union Chapel and in denominational affairs his courage and discretion, his simple faith, combined with a broad-minded sympathy with the intellectual movements of the time, made his ministry a widespread influence for good. (D. M.N.)

**ALLONGE—ALLOTMENTS**

from Fr. allonger, to draw out, a slip of paper affixed to a negotiable instrument, as a bill of exchange, for the purpose of receiving additional indorsements for which there may not be sufficient space on the bill itself. An indorsement written on the Allonge is deemed to be written on the bill itself. An Allonge is more usually met with in those countries where the Code Napoléon is in force, as the code requires every indorsement to express the consideration. Under English law, as the simple signature of the indorser on the bill, without additional words, is sufficient to operate as a negotiation, an Allonge is seldom necessary.

**ALLOPHANE**, one of the few minerals known only in the amorphous state. It is a glassy substance, usually occurring as thin encrustations with a manner of opalescent appearance, sometimes as powdery and pulverulent. The colour varies considerably, from colourless to yellow, brown, blue or green. Specimens of a brilliant sky-blue colour, such as those found formerly in Wheat Hamblin, near Bridestowe in Devonshire, and in Sardinia, are specially attractive in appearance; the colour is here due to the presence of the copper mineral chrysocolla. The hardness is 3, and the specific gravity 1-9. Chemically, it is a hydrous aluminium silicate, \( \text{Al}_2\text{SiO}_5 \cdot 5\text{H}_2\text{O} \). Allophane is always of secondary origin, resulting from the decomposition of various amorphous silicates, such as felspar. It is frequently found as a matrix cement and as a replacement of copper ore veins. It was first observed in 1809 in marl at Gräfenthal, near Saalfeld in Thuringia; and has been found in some quantity in the chalk pits at Charlton in Kent, where it lines fissures and funnel-shaped cavities. The name allophane was given by F. Stromeyer in 1816, from the Gr. ἀλλός, another, and φαῖνω, to appear, in allusion to the fact that the mineral crumbles and changes in appearance when heated before the blowpipe. Other names for the species are rieumontite and cluyharyste, whilst closely allied minerals are carolathine, samoite and schröttite (opal-allophane).

**ALLORI, ALESSANDRO** (1535-1607), Italian painter of the Florentine school who was the son of Angelo Bronzino (q.v.) whose name he sometimes assumed in his pictures. Visiting Rome in his nineteenth year, he carefully studied the works of Michelangelo; but the influence of that great master can only be traced in the anatomical correctness of his drawing of nude figures. He was successful as a portrait painter. His son CRISTOFANO ALLORI (1577-1621), born at Florence, received his first lessons in painting from his father, but becoming dissatisfied with the hard anatomical drawing and cold colouring of the latter, he entered the studio of Gregorio Pagani (1558-1609) who was one of the leaders of that later Florentine school which endeavoured to unite the rich colouring of the Venetians with the correct drawing of Michelangelo's disciples. Allori became one of the foremost of this school. His pictures are distinguished by their close adherence to nature and the delicacy and technical perfection of their execution. His technical skill is proved by the fact that several copies he made after Correggio have been taken to be duplicates by Correggio himself. His extreme fastidiousness limited his power of production, though the number of his works is not so small as is sometimes asserted. Several of his portraits are to be seen in Florence and elsewhere. The finest of all his works is his "Judith and Holofernes," in the Pitti Palace. The model for the Judith was his mistress, the beautiful Mazzafirra, who is also represented in his Magdalene; and the head of Holofernes is generally supposed to represent himself.

**ALLOTMENT** (from O. Fr. a and later, to divide by lot), the act of allotting; a share or portion assigned. In England, the term denotes a portion of land assigned on partition or under an inclosure award (see Cotswolds); also a division of land into small portions for cultivation by a labourer or artisan at a small rent (see Allotments and Small Holdings). In company law, "allotment" is the appropriation to an applicant by a resolution of the directors of a certain number of shares in response to an application. The document sent to such an applicant, which announces the number of shares assigned and concludes the contract, is called a letter of allotment or allotment certificate. A letter of allotment in England requires a sixpenny stamp if the value of the shares amounts to £5 or over, and a penny stamp if less than £5. (See Company.)

**Allotment note** is writing by a seaman authorizing his employers to make an allotment of part of his wages, while he is on a voyage, in favour either of a "near" relative (wife, father, mother, grandfather, grandmother, child, grandchild, brother or sister of the seaman), or of a savings bank. Every allotment note must be in a form sanctioned by the Board of Trade.

**Allotments and Small Holdings.** As the meaning of these terms in agricultural tenure varies in different localities, it may be as well to say at once that for the present purpose they are defined as land detached from cottages, and hired or owned by labouring men to supplement their main income. We do not include any farm, however small, from which the occupier derives his entire support by dairying, market-gardening, or other form of la petite culture. So, also, no account is taken of the tiny garden plot, used for growing vegetables for the table and simple flowers, which is properly an appurtenance of the cottage. Clearing away what is extraneous, the essential point round which much controversy has raged is the land on which the tenant is liable to be assessed for rates. In the land on which the tenant is liable to be assessed for rates. In agriculture, the oldest of all industries, a cash payment is not even now regarded as discharging the obligations between master and servant. Mr Wilson Fox, in reporting to the Board of Trade on the earnings of agricultural labourers in Great Britain, gives, as a typical survival of an old custom, the case of a shepherd whose total income was calculated at £60 a year, but who got
only £16 in money, the rest being made up by rights of grazing live-stock, growing crops on his master's land, and kindred privileges. That is exactly in the spirit that used to pervade agriculture, and doubtless had its origin in the manorial system. If we turn back to the 13th century, from Walter of Henley's *Husbandry* it will be seen that practically there were only two classes engaged in agriculture, and corresponding with these were two kinds of land. There were, on the one hand, the employer, the lord, and his demesne land; on the other, the villeins and the land held in villegage. Putting aside for the moment any discussion of the exact degree of servitude, it will be seen that the essence of the bargain was that the villein should be permitted to cultivate a virgate of land for his own use in return for service rendered on the home farm. This is not altered by the fact that the conditions approached those of slavery, that the villeins were *adscripti glabae*, that in some cases their wives and sons were bequeathed by deed to the service of religious houses, and that in many other respects their freedom was limited. Out of this, in the course of centuries, was developed the system prevailing to-day. Llammas lands are indeed a survival from it. There are in the valley of the Lea, and close to London, to take one example, lands allotted annually in little strips till the crops are carried, when, the day being fixed by a reeve, the land becomes a common pasture till the spring closing takes place once more. Perhaps the feature of this old system that bears most directly on the question of allotments was the tradition of the waste. Of that, the most amusing feature was that it was limited by custom as regards the number of beasts he could graze on. After the havoc of the Black Death in 1349, many changes were necessitated by the scarcity and dearness of labour. It became less unusual for land to be let and for money payment to be accepted instead of services. There was a great demand for wool, and to conduct sheep-farming on a large scale necessitated a re-arrangement of the manor and the enclosure of many common fields under the statute of Merton and the statute of Westminster the Second. Nevertheless, up to the 18th century, a vast proportion of agricultural land was technically waste, on which rights of common were exercised by yeomen, some of whom had acquired holdings by the ordinary methods of purchase or inheritance, while others had merely squatted and built a house on the waste. It is to this period that belongs a certain injustice to which the peasantry were subject. No reasonable doubt can be entertained of the necessity of enclosure. Husbandry, after long stagnation, was making great advance; and among others, Arthur Young raised his voice against the clumsy inconvenient common fields that were the first to be enclosed. Between 1799 and 17177 of the waste that remained before the Reformation was calculated, about 3,000,000 acres, were put into operation. They seem mostly to have been directed to the common fields. In the first half of the 19th century the movement went on apace. In a single year, 1801, no fewer than 119 acts were passed; and between 1801 and 1842 close on 2000 acts were passed—many of them expressly directed to the enclosure of wastes and commons. The same thing continued till 1869. It touched the peasant directly and indirectly. The enclosure of the common fields proved most hurtful to the small farmer; the enclosure of the waste injured, by driving men from employment, compensation, of such useful privileges as the right to graze a cow, a pig, goose or other small animals. It also discouraged him by tending to the extinction of small tenancies and freeholds that were no longer workable at a profit when common rights ceased to go with them. The industrious labourer could previously nourish a hope of bettering his condition by obtaining a small holding. Yet though the labourer suffered, impartial study does not show any intentional injustice. He held a very weak position when those interested in a common affixed to the church door a notice that they intended to petition. As Mr Cowper (afterwards Lord Mount Temple) said in the House of Commons on the 13th of March 1844, "the course adopted had been to compensate the owner of the cottage to whom the common right belonged, forgetting the claims of the occupier by whom they were enjoyed"; and in the same debate Sir Robert Peel pointed out that not only the rights of the tenant, but those of his successors ought to have been studied. The course adopted divorced the labourer from the soil.

Parliament, as a matter of fact, had from a very early period recognized the wisdom of containing the peasant. In the 14th century the labourer lived in rude abundance. Next century a rural exodus began, owing to the practice of enclosing the holdings and turning them into sheep walks. In 1487 an act was passed enjoining landlords to "keep up houses of husbandry," and attach convenient land to them. Within the next hundred years a number of similar attempts were made to control what we may call the sheep fever of the time. Then we arrive at the reign of Elizabeth and the famous Small Holdings Act passed in 1597—an anticipation of the three-acres-and-a-cow policy advocated towards the end of the 19th century. It required that no person shall build, convert or ordain any cottage for habitation or dwelling for persons engaged in husbandry unless the owner "do assign or lay to the same cottage or building four acres of ground at the least." It also provided against any "inmate or under-sitter" being admitted to what was sacred to one family. This measure was not conceived in the spirit of modern political economy, but it had the effect of staying the rural exodus. It was repealed in 1775 on the ground that it restricted the building of cottages. By that time the modern feeling in favour of allotments had begun to ripen, and it was contended that any compensation should be made to the labourers for depriving them of the advantages of the waste. Up to then the English labouring rustic had been very well off. Food was abundant and cheap, so were clothes and boots; he could graze his cow or pig on the common, and also obtain fuel from it. Now he fell on evil days. Prices rose, wages fell, privileges were lost, and in many cases he had to sell the patch of land whose possession made all the difference between hardship and comfort. All this was seen plainly enough both by statesmen and private philanthropists. One of the first experiments was described by Sir John Sinclair in a note to the report of a select committee of the House of Commons on waste lands in 1795. About 1772 the lord of the manor of some comonable lands near Tewkesbury had with great success set out 25 acres in allotments for the use of some of the poor. Sir John was very much struck with the result, and so heartily applauded the idea that the committee recommended that any general enclosure bill should have a clause in it providing for "the accommodation of land." Sir Thomas Bernard and W. Wilberforce took an active part in advocating the principle of allotments, on the ground, to summarize their argument in language employed later by Sir John Peel, "where a man is but one of the cottagers, that it keeps the cottagers buoyant and makes them industrious." In 1806, at the suggestion of the rector, a clause assigning an allotment of half an acre to every cottage was inserted in an enclosure bill then under consideration for the parish of Broad Somerford in Wiltshire. This was done, "and the example was followed by nearly every adjoining parish in that part of Wiltshire." Passing over several praiseworthy establishments of allotments by private persons, we come to 1819, when parliament passed an act akin to several that came into existence during the later portion of the Victorian era, by which the overseers of any parish, with the consent of the vestry, to purchase or hire land not exceeding 25 acres, and to let it in portions to "any poor and industrious inhabitant of the parish." This was amended in 1831 by an act extending the quantity of land to 50 acres, and also conveying an important new power to enable the same authorities to enclose from any waste or common, land not exceeding 50 acres to be devoted to the same purpose. This was followed next year by an act relating to fuel, and in 1834 the Poor Law Commissioners reported favourably on the principle of granting allotments. In 1843 an important inquiry into the subject was made by a committee of the House of Commons, which produced a number of valuable suggestions. One consequence was the bill of 1845, brought into parliament by Mr Cowper. It passed the House of Commons; and there Mr Bright made a remark that probably summarized a general
opinion, since it never came to a third reading in the House of Lords. He said that "the voluntary system of arrangement would do all the good that was expected to accrue from the allotment system."

At this point in the history of the movement it may be as well to pause and ask what was the net result of so much legislation and benevolent action. Messrs Tremellen and Tufnall, who prefixed an admirable epistle of what had been done to the report of the commission "appointed to inquire into the employment of women, young persons and children in agriculture" (1867), expressed considerable disappointment. Between 1870 and 1887, 7,666,413 statute acres were added to the cultivated area of England and Wales, or about one-third of the area in cultivation at the latter date; and of this total, 484,893 acres were enclosed between 1875 and 1879. Of the latter, only 2119 acres were assigned as public allotments for gardens to the labouring poor. It was found to be the case, as it is now, that land was taken up more readily when offered privately and voluntarily than when it came through official sources. Meanwhile competent and thoughtful men saw well that the sullen discontent of the peasantry continued, in Lord Bacon's phrase, to threaten "the might and manhood of the kingdom." It had existed since the beginning of the Napoleonic wars, and had become more articulate with the spread of education. We shall see, a consciousness of its presence reflected in the minds of statesmen and politicians as we briefly examine the later phase of the movement. This found expression in the clauses against enclosure introduced by Lord Beaconsfield in 1876, and gave force to the three-acres-and-a-cow agitation, of which the more prominent leaders were Joseph Arch and Jesse Collings. In 1882 the Allotments Extension Act was passed, the object of which was to let the parishioners have charity land in allotments, provided it or the revenue from it was not used for apprenticeship, ecclesiastical or educational purposes. A committee of the Lords was appointed to inquire into the housing of the working classes, reported strongly in favour of allotments, and this was followed in 1887 by the Allotments Act—the first measure in which the principle of compulsory acquisition was admitted in regard to other than charity lands. Its administration was first given to the sanitary authority, but passed to the district councils when these bodies were established in 1894. The local body is empowered to hire or purchase suitable land, and if they do not find any in the market they are to petition the county council, which after due inquiry may find a suitable order compelling owners to sell land, and the Local Government Board may introduce a bill into parliament to confirm the order. It was found that the sanitary authority did not carry out the scheme, and in 1890 another act was passed for the purpose of allowing applicants for allotments, when the sanitary authority failed to provide land, to appeal to the county council. Judging from the evidence laid before the commission on agricultural depression (1894), the act of 1887 was not a conspicuous success. Most of the witnesses reported in such terms as these—"the Allotments Act has been quite inoperative in Cornwall," "the act has been a dead letter in the district (Wigtownshire)," "the Allotments Act has not been in operation in Flintshire," "nothing has been done in the district of Pembrokeshire under the act." No evidence whatever was adduced to show that in a single district a different state of things had to be recorded. From a return presented by the Local Government Board to parliament in 1896 we learn that eighty-three rural sanitary authorities had acquired land for allotment prior to the 30th of December 1894, the date at which these authorities ceased to exist under the provisions of the Local Government Act 1894. Land was acquired by compulsory purchase in only one parish; by purchase or agreement in eighteen parishes; by hire by agreement in 132 parishes. The total acreage dealt with was 1836 acres, 1 rood 34 poles, and the total number of tenants 4711. The number of county councils that up to the same date had acquired land was twelve, and they had done so by compulsory purchase in one parish, by purchase or agreement in five parishes, by hire by agreement in twenty-four parishes. The total area dealt with was only 413 acres, 1 rood 5 poles, and the total number of tenants 815. The complete totals affected at the date of the return (August 21, 1895) by the acts, therefore, were 2240 acres, 2 roods 29 poles, and 5536 tenants. A considerable extension has taken place since.

The Small Holdings Act introduced by Mr Henry Chaplin, and passed by parliament in 1892 was an attempt to appease the rural discontent that had been seething for some time past and was silently but most eloquently expressed in a steady migration from the villages. The object of this measure was to help the deserving labouring man to acquire a small holding, that is to say, a portion of land not less than one acre or more than fifty acres in extent and of an annual value not exceeding £50. It is not necessary here to describe the legal steps by which this was to be accomplished. The essence of the bargain was that if a fifth of the purchase money should be paid down, and the remainder in half-yearly instalments spread over a period not exceeding fifty years. But if the local authority thought fit a portion of the purchase money, not exceeding one-fourth, might remain unpaid, and be secured by a perpetual rent charge upon the holding. It cannot be said that this act has attained the object for which it was drawn up. From a return made to the House of Commons in 1895 it was shown that eight county councils had acquired land under the Small Holdings Act, which amounted in the aggregate to 483 acres. A further return was made in 1903, which showed that the total quantity of land acquired from the commencement of the act up to the end of 1902 was only 652 acres.

It is, however, an English characteristic to prefer private to public arrangements, and probably a very great majority of the allotments and small holdings cultivated in 1897 were due to individual initiative. There are no means of arriving at the exact figures, but data exist whereby it is at least possible to form some rough idea of them. It is not the custom to give in the annual agricultural returns any statement of the manner in which land is held, and the information is to be found in the returns presented to parliament from time to time. From the following table, which includes both the holdings owned and tenanted, it will be seen that between 1865 and 1904 the tendency was for the holdings to decrease in number; while the holdings of less than 300 acres slightly increased, those from 5 to 50 acres were almost stationary, and there was a decrease in those between 1 and 5 acres.

These figures become doubly instructive when considered in connexion with the decline of the strictly rural population. It will, therefore, be useful to place beside them a summary published in a report on the decline of rural population in Great Britain issued by the Board of Agriculture and Fisheries in 1906.

The table above shows the decrease in the number of agricultural workers from 1881 to 1901.
ALLOTMENTS AND SMALL HOLDINGS

These figures must of course be approximate. The effect of recent development in methods of travelling and the growing custom for townsmen either to live wholly in the country or to take week-end cottages, has made it impossible to draw a strict line of demarcation between rural and urban populations. Still they are near enough for practical purposes, and they amply justify the efforts of those who are trying to stay the rural exodus. While legislation had not, up to 1908, achieved any noteworthy result in the creation of small holdings, and still left doubts as to the practicability of re-creating the English yeoman by act of parliament, many successful efforts have been made by individuals. One of the most interesting is that of the earl of Cowdroy at Catshill in Worcestershire. In this case the most noteworthy feature is that between the landlord and the tenants there is a body called the South Lincolnshire Small Holdings Association, which took 650 acres from Lord Carrington on a twenty years' lease. These acres used to be let to four or five tenants. They were in 1905 divided among one hundred and seventy tenants. The Small Holders' Association guaranteed the rent, which works out at about 3s. per acre, to Lord Carrington. They let the men on yearly tenancy have it at about 4s. an acre, the difference being used to meet the expenses of the Association. The tenants are held responsible for maintaining their fences, and other improvements. In this way the landlord is assured of his rent, and the association has lost nothing, as the men were very punctual in their payments. But very great care was bestowed in choosing the men for the holdings. They were in a sense picked men, but men must be picked to work the business satisfactorily. Lincolnshire is pre-eminenti a county of small holdings, and the labouring residents in it have been accustomed to the management of them from their infancy onwards. Here as elsewhere the provision of suitable houses formed a difficulty, some of the tenants having to walk several miles to their holdings. Lord Carrington availed himself as much as possible of the buildings that existed, dividing the old farm houses so as to make them suitable for the small tenants. At Cowbit farm, many of the ordinary labourers' cottages, which were put up at a cost of about £300 a pair, have by the addition of little dairies and other alterations been made suitable for the tenants. From facts collected on the spot we have come to the conclusion that on the small holdings a good tenant makes an average profit of about £4 an acre, but on an allotted acre the cultivator of a spade would probably lose at the rate of about £6 an acre. Lord Carrington was successful in establishing small holdings on the Humberston estate in North Lincolnshire and on his Buckinghamshire estate, near Aylesbury. At Newport Pagnell the attempt failed because the demand was artificial, the ground arable, and the men not capable of dealing with it.

Other examples of the establishment of small holdings can only receive brief reference. The Norfolk Small Holdings Association acquired three farms at Whissonsett, Watton and Swaffham, which are broken up into small lots and let mostly to the village tradespeople. Sir Pearce Edgcumbe established small holdings at Rew, some of which have been purchased by the occupiers, and Mr A. B. Markham created similar holdings at Twyford (Leicestershire). At Cudworth in Surrey a group was formed, but the owners were actuated more by the desire to lead a simple life than to prove the remunerative value of small holdings. Mr W. J. Harris created small holdings in Devon, of which is let on a life tenancy. There the rural exodus has been more than arrested. Mr James Tomkinson established in Cheshire a number of graduated holdings, so contrived as to offer the successful holders a chance of stepping upwards.

The earl of Harrowby made an interesting experiment on his Sandon estate in Staffordshire in the midst of a pretty, broken and undulating country. The estate consists of about 6000 acres, one-third of which is laid out in small holdings. These fall naturally into three divisions. First, there are those which belong to men who have regular employment, and would therefore find it impossible to cultivate any great quantity of land. Many of that class are anxious to have a holding of some sort, as it lends a certain elasticity to their incomes and provides them with a never-failing interest. One who may be taken as typical hired six acres with a good cottage and a large garden, paying a rent of £20 a year. When this holding was created it had already a suitable cottage, but £100 was needed to provide outbuildings, and Lord Harrowby's custom is to charge 5% on outlay of this kind. This £5, however, is included in the total rent of £20 paid for cottage, land and garden. The man was not only content, but wished to get some more land. The next class consists of those who have not enough land to live on but eke out their livelihood by casual labour. Usually a man of this sort requires from 35 to 50 acres of land mostly pasture. He can afford to it, of course, and is certain of 2s. an acre. His holding is of course that of the small farmer who gains his entire livelihood from the land. The obstacle to breaking up large farms into small lots of course in the expense of providing the necessary equipment. It has been found here that a cottage suitable for a small farmer costs about £400 to build in a substantial manner, and the outbuildings about £200. This makes an addition therefore of about £30 to the rent of the land. The arbour with which these tenancies were sought when vacant formed the best testimony to the soundness of the principle applied by Lord Harrowby.

A nest of small holdings was created at Winterslow, near Salisbury, by Major R. M. Poore. The holders completed the purchase by 1906, and the work may be pronounced a complete success. Major Poore originally conceived the idea when land was cheap in 1892, owing to the depression in agriculture. He purchased an estate that came into the market at the time. The price came to an average of £10 an acre, and the men themselves made the average for selling it out again £15 on a principle of instalments. His object was not to make any profit from the transaction, and he formed what is termed a Landholders' Court, in order that every man might be assured of his own rights, and none of the tenants chosen at random. This court was found to act well. It collected the instalments, which are paid in advance; and of course the members of it, down to the minutest detail, knew not only the circumstances but the character of every applicant for land. The result speaks for itself. The owners are, in the true sense of the word, peasants. They do not depend on the land for a living, but work in various callings—many being woodmen—for wages that average about 13s. a week. The holdings vary in size from less than an acre to ten acres, and are technically held on a lease for 990 years, with option to purchase the freehold at a nominal price. A saving was effected in the cost of transfer. On the holdings most of the men have erected houses, using for the purpose chalk dug up from their gardens, it lying only a few inches below the surface. It is not rock, but soft chalk, so that they are practically mud walls; but being as a rule at least 8 inches thick, the houses are very cool in summer and warm in winter. Major Poore calculated that in seven years these poor people—there are not thirty of them altogether—managed to produce for their houses and land a gross sum of not less than £5000. This he attributed to the loyal manner in which even distant members of the family have helped. The class of holding which owes its existence to the act of 1892 may be illustrated by the history of the Worcestershire small holdings. The inception of the scheme was due to the decline of the nail-making business, which caused a number of the inhabitants to be without occupation. Two candidates for election to the county council looking out for a popular cry found it in the demand for land. They promised to do their best in this direction, and thanks to the energetic action of Mr Willis Bund, of Bromsgrove, the idea was to come into force. Woodrow Farm, adjoining the village of Catshill in the neighbourhood of Birmingham, was purchased on terms that enabled the land to be sold to the peasant cultivator at £40 an acre. They were paying this back at the rate of 4% on the purchase money, a rate that included both interest and sinking fund, so that at the end of forty years they would own the small estates free from encumbrance. The huge population of Birmingham is close to the properties. The men turned their attention mostly to
strawberries, to which many acres were devoted. Costermongers would come out from Birmingham and buy the fruit on the spot, selling part of it to the villages on the way back, and part in the Birmingham market. The experience gained in working the act enabled the committee on small holdings to make a number of practical suggestions for future legislation.

It remains to note the passing in 1907 of a new English Small Holdings and Allotments Act, experience of which is too recent for its provisions to be more than indicated here. The act transferred to the Board of Agriculture the duties generally of the Local Government Board, and transferred to parish councils or parish meetings the powers and duties of rural district councils; it required county councils to ascertain the demand for land without previous representation to them, and gave power for its compulsory acquisition; and the maximum holding of an allotment was raised from one acre to five. Both compulsory purchase and compulsory hiring (for not less than 14 nor more than 35 years) were authorized, value and compensation being decided by a single arbitrator. A coercive authority was applied to the county councils in the form of commissioners appointed by the Board of Agriculture, who were to hold inquiries independently and to take action themselves in case of a defaulting county council. They were to ascertain the local demand for small holdings, and to report to the Board, who might then require a county council to prepare a scheme, which, when approved, it was to carry out, the commissioners being empowered to do so in the alternative.

**Foreign Countries.**—It remains to give a brief outline of what small holdings are like outside Great Britain. From the results of the Belgian Agricultural Inquiry of 1895 the following table has been compiled, assuming that one hectare = 2.4 acres—

It will be seen from this table that Belgium is pre-eminently a country of small holdings, more than half of the total number being under 50 acres in extent. Of course it is largely a country of market gardens; but as the holdings are most numerous in Brabant, East and West Flanders and Hainault, the provinces showing the largest number of milk cows, it would seem that dairying and *la petite culture* go together.

There is a slight tendency for the holdings to decrease in number. In Germany the number of small holdings is proportionately much larger than in Great Britain. The returns collected in 1895 showed that there were 3,235,169, or 59.2% of the total number of holdings under 5 acres in area; and of these no fewer than 11.7% are held by servants as part of their wages. The table below compiled for the *Journal of the Board of Agriculture* enables us to compare the other holdings with those of Great Britain. Great Britain, it will be seen, has over 40% of large farms of between 50 and 500 acres as compared with Germany's 12.6, while the latter has 86.8 of small holdings, compared with England's 58.6.

France also has a far larger proportion of small holdings than Great Britain; its cultivated area of 85,759,000 acres being divided into 5,618,000 separate holdings, of which the size averages a little over 15 acres as against 63 in Great Britain. Of the whole number, 4,101,795 are farmed by the owners, 934,338 are in métayage, and 1,078,184 by tenants. The leading feature is the peasant proprietor. Half of the arable, more than half of the pasture, six-sevenths of the vineyards and two-thirds of the garden lands are farmed by their owners. Comparison with Great Britain is difficult; but it would appear that, whereas only 11.7% of British 350,000 agricultural holdings are farmed by the owners, the proportion in France is 75%. A further point to be noted is that the average agricultural tenancy in France is just one-fourth of what it is in Great Britain, and the average owner-farmed estate only one-sixth.

In France the tendency is for the very small holdings to increase in number owing to subdivision, with a consequent decrease of the size of the average holding. Between the years 1882 and 1892 there was a decrease of 138,237 in the total number of proprietors, the larger properties moving towards consolidation and those of the peasant proprietors towards subdivision.

Those interested in the formation of small holdings in Great Britain will find much to interest them in the history of Danish legislation. British policy for many generations was to preserve demesne land, and there are many devices for insuring that a spendthrift life-owner shall not be able to scatter the family inheritance; but as long as 1760 the Danish legislators set an exactly opposite example. They enacted that peasant land should not be incorporated or worked with estate land; it must always remain in the owner's and occupation of peasants. In this spirit all subsequent legislation was conceived, and the allotment law that came into force in October 1890 bears some resemblance to the English Small Holdings Act of 1892. It provides that labourers able to satisfy certain conditions as to character may obtain from the state a loan equal to nine-tenths of the purchase money of the land they wish to acquire. This land should be from 5 to 7 acres in extent and of medium quality, but the limits are from 2½ to 5½ acres in the case of better or poorer land. The total value should not exceed 4000 kr. (£222). The interest payable on the loan received from the state is 3%. The loan itself is repayable after the first five years by annual instalments of 4½% until half is paid off; the remainder by instalments of 3½%, including interest. Provision is, however, made for cases where the borrower desired to pay off the loan in larger sums. Regulations are laid down regarding the transfer of such properties and also their testamentary disposition. The Treasury was empowered to devote a sum of 2,000,000 kr.

Even before this law was passed Denmark was a country of small holdings, the peasant farms amounting to 66% of the
whole, and the number is bound to increase, since the incorporation of farms is illegal, while there is no obstacle to their division. Between 1835 and 1885, the number of small holdings of less than one tönökarthorn increased from 24,800 to 92,850. What gives point to these remarks is, that Denmark's means in the way to arrest its rural exodus, and was one of the first countries to escape from the agricultural depression due to the extraordinary fall in grain prices. The distribution of land in Denmark may be gathered from a glance at the preceding table for the compilation of which we are indebted to Major Craigie.

ALLOTROPY (Gr. ἀλλοτρόπος, other, and τρόπος, manner), a name applied by J. J. Berzelius to the property possessed by certain substances of existing in different modifications. Custom has to some extent restricted its use to inorganic chemistry; the corresponding property of organic compounds being generally termed isomerism (q.v.). Conspicuous examples are afforded by oxygen, carbon, boron, silicon, phosphorus, mercuric oxide and iodide.

ALLOWANCE (from "allow," derived through O. Fr. alouer from the two Lat. origins adludare, to praise, and allocare, to assign a place; so that the English word combined the general idea of "assigning with approval," the action of allowing, or the thing allowed; particularly, a certain limited apportionment of money or food and diet (see DIETARY). Allowing, use in commerce, usage "allowance" signifies the deduction made from the gross weight of goods to make up for the weight of the box or package, waste, breakages, &c. Allowing, which is customary in most industries, varies according to the trade, district or country; e.g. in the coal trade it is customary for the merchant to receive from the pit 21 cwts. of coal for every ton purchased by him, the difference of 1 cwt. being the allowance for the purpose of making good the waste caused through transshipment, screening and cartage (see TAKE AND TREAT).

ALLOXAN, or MESOXYLYL UREA, C₃H₅NO₂ or CO(NH₂)₂CO., an oxidation product of uric acid, being obtained from it by the action of cold nitric acid, C₄H₄N₂O₁₄ + H₂O + O = C₂H₂N₂O₃ + CO(NH₂)₂. It crystallizes from water in colourless rhombic prisms, containing four molecules of water of crystallization, and possesses a very acid reaction. It serves as the starting-point for the preparation of many related substances. Zinc and hydrochloric acid, the cold convert it into alloxanthic (q.v.), hydroxylamine gives nitrosobarbituric acid, C₂H₅NO₃NHNH₂, baryta water gives alloxonic acid, C₂H₅NO₂, hot dilute nitric acid oxidizes it to parabanic acid (q.v.), hot potassium hydroxide solution hydrolys it to urea and mesoxalic acid (q.v.) and zinc and hot hydrochloric acid convert it into diuric acid, C₂H₅NO₄. M. Nencki has shown that alloxan combines with thiourea in alcoholic solution, in the presence of sulphur dioxide to form pseudothyounic acid, C₂H₅N₄SO. Methyl and dimethylalloxans are also known, the former being obtained on oxidation of methyl uric acid, and the latter on oxidation of caffeine (q.v.).

ALLOXANTIN, C₃H₅N₂O₃·3H₂O, a product obtained by the combination of alloxan and diacetic acid, probably possessing the constitution

\[
\begin{align*}
\text{NH} & \equiv \text{C} - \text{OH} - \text{OH} - \text{CH} - \text{CO} \\
\text{CO} & \equiv \text{CH} - \text{NH} - \text{CO} \\
\text{NH} & \equiv \text{CO} - \text{NH} \\
\text{CO} & \equiv \text{NH} - \text{CO}
\end{align*}
\]

one of the three molecules of water being possibly constitutional. It forms small hard prisms which become red on exposure to air containing ammonia, owing to the formation of murexide (ammonium purpureate), C₃H₄(NH₂)N₃O₢. It may also be obtained by the action of sulphuretted hydrogen on alloxan. The tetra- (or methyl) ammonium nitrate acid, C(NH₂)₄N₃O₢, has been prepared by oxidizing caffeine (q.v.) with chlorine water, and forms colourless crystals which are only slightly soluble in hot water. The formation of murexide is used as a test for the presence of uric acid, which on evaporation with dilute nitric acid gives alloxantin, and by the addition of ammonia to the residue the purple red colour of murexide becomes apparent.

ALLOYS (through the Fr. aloyer, from Lat. alligare, to combine), a term generally applied to the intimate mixtures obtained by melting together two or more metals, and allowing the mass to solidify. It may conveniently be exemplified by similar mixtures of sulphur and selenium or tellurium, of bismuth and sulphur, of copper and cuprous oxide, and of iron and carbon, in fact to all cases in which substances can be made to mix in varying proportions without very marked indication of chemical action. The term "alloy" does not necessarily imply obedience to the laws of definite and multiple proportion or even uniformity throughout the material; but some alloys are homogeneous and some are chemical compounds. In what follows we shall confine our attention principally to metallic alloys.

If we melt together an alloy containing 60% of iron, 20% of zinc, and 20% of tin, we obtain uniform liquids which when solidified are the well-known substances brass and bell-metal. These substances are for all practical purposes new metals. The difference in the appearance of brass and copper is familiar to everyone; brass is also much harder than copper and much more suitable for being turned in a lathe. Similarly, bell-metal is harder, more sonorous and more brittle than either of its components. It is almost impossible by mechanical means to detect the separate ingredients in such an alloy; we may cut or file or polish it without disturbing it, and any lack of homogeneity be only to be ascertained, for example, by becoming redder with increase in the percentage of zinc, and a paler yellow when there is more zinc. The possibility of continuously varying the percentage composition without the substance losing the properties characteristic of brass; the properties change more or less continuously, the colour, for example, becoming redder with increase in the percentage of zinc, and a paler yellow when there is more zinc. The possibility of continuously varying the percentage composition suggests analogy between an alloy and a solution, and A. Matthiessen (Phil. Trans., 1860) applied the term "solidified solutions" to alloys. Regard as descriptive of the genesis of an alloy from a uniform liquid containing two or more metals, the term is not incorrect, and it may have acted as a signpost towards profitable methods of research. But modern work has shown that, although alloys sometimes contain solid solutions, the solid alloy as a whole is often far more like a conglomerate rock than a uniform solution. In fact the uniformity of brass and bell-metal is only superficial; if we adopt the methods described in the article METALLOGRAPHY, and if, after polishing a plane face on a bit of gun-metal, we etch away the surface layer and examine the new surface with a lens or a microscope, we find a complex pattern of at least two materials. Fig. 1 (Plate) is from a photograph of a bronze containing 23·3% by weight of tin. The acid used to etch the surface has darkened the parts richest in copper, while those richest in tin remained white. The two ingredients involved by this process are not pure copper and pure tin, but each material contains both metals. In this case the white tin-rich portions are themselves a complex that can be resolved into two substances by a higher magnification. The majority of alloys, when examined thus, prove to be complexes of two or more metals, and the patterns showing the distribution of these materials throughout the alloy are of a most varied character. It is certain that the structure existing in the alloy is closely connected with the mechanical properties, such as hardness, toughness, rigidity, and so on, that make particular alloys valuable in the arts, and many efforts have been made to trace this connection. These efforts have, in some cases, been very

(This Article contains Metallography, Alloys, Gun-making, Iron and Steel.)
ALLOYS

successful; for example, in the case of steel, which is an alloy of iron and carbon, a microscopical examination gives valuable information concerning the suitability of a sample of steel for special purposes.

Mixture by fusion is the general method of producing an alloy, but it is not the only method possible. It would seem, indeed, that any process by which the particles of two metals are intimately mingled and brought into close contact, so that diffusion of one metal into the other can take place, is likely to result in the formation of an alloy. For example, if vapours of the volatile metals cadmium, zinc and magnesium are allowed to act on platinum or palladium, alloys are produced. The methods of manufacture of steel by cementation, case-hardening and the Harvey process are important operations which appear to depend on the diffusion of the carburetting material into the solid metal. When a solution of silver nitrate is poured on to metallic mercury, the mercury replaces the silver in the solution, forming nitrate of mercury, and the silver is precipitated; it does not, however, appear as pure metallic silver, but in the form of crystalline needles of an alloy of silver and mercury. F. B. Mylius and O. Fromm have shown that alloys may be precipitated from dilute solutions by zinc, cadmium, tin, lead and copper. Thus a strip of zinc plunged into a solution of silver sulphate, containing not more than 0.03 grammie of silver in the litre, becomes covered with a flocculent precipitate which is a true alloy of silver and zinc, and in the same way, when copper is precipitated from its sulphate by zinc, the alloy formed is brass. They have also formed in this way certain alloys of definite composition, such as AuCd, CuCd, and, more interesting still, CuSn. A very similar fact, that brass may be formed by electrodeposition from a solution containing zinc and copper, has long been known. W. V. Spring has shown that by compressing a finely divided mixture of 15 parts of bismuth, 8 parts of lead, 4 parts of tin and 3 parts of cadmium, an alloy is produced which melts at 100°C, that is, much below the melting-point of any of the four metals. But these methods of forming alloys, although they suggest questions of great interest, cannot receive further discussion here.

Our knowledge of the nature of solid alloys has been much enlarged by a careful study of the process of solidification. Let us suppose that a molten mixture of two substances A and B, which at a sufficiently high temperature form a uniform liquid, and which do not combine to form definite compounds, is slowly cooled until it becomes wholly solid. The phenomena which succeed each other are then very similar, whether A and B are two metals, such as lead and tin or silver and copper, or are a pair of fused salts, or are water and common salt. All these mixtures when solidified may fairly be termed alloys.

If a mixture of A and B be melted and then allowed to cool, a thermometer immersed in the mixture will indicate a gradually falling temperature. But when solidification commences, the thermometer will cease to fall, it may even rise slightly, and the temperature will remain almost constant for a short time. This halt in the cooling, due to the heat evolved in the solidification of the first crystals that form in the liquid, is called the freezing-point of the mixture; the freezing-point can generally be observed with considerable accuracy. In the case of a pure substance, and of a certain small class of mixtures, there is no further fall in temperature until the substance has become completely solid, but, in the case of most mixtures, after the freezing-point has been reached the temperature soon begins to fall again, and as the amount of solid increases the temperature becomes lower and lower. There may be other halts in the cooling, both before and after complete solidification, due to evolution of heat in the mixture. These halts in temperature that occur during the cooling of a mixture should be carefully noted, as they give valuable information concerning the physical and chemical changes that are taking place. If we determine the freezing-point of a number of mixtures varying in composition from pure A to pure B, we can plot the freezing-point curves.

In such a curve the percentage composition can be plotted horizontally and the temperature of the freezing-point vertically, as in fig. 5. In such a diagram, a point P defines a particular mixture, both as to percentage, composition and temperature; a vertical line through P corresponds to the mixture at all possible temperatures, the point Q being its freezing-point. In the case of two substances which neither form compounds nor dissolve each other in the solid state, the complete freezing-point curve takes the form shown in fig. 5. It consists of two branches AC and BC, which meet in a lowest point C. It will be seen that as we increase the percentage of B from nothing up to that of the mixture C, the freezing-point becomes lower and lower, but that if we further increase the percentage of B in the mixture, the freezing-point rises. This agrees with the well-known fact that the presence of an impurity in a substance depresses its melting-point. The mixture C has a lower freezing or melting point than that of any other mixture; it is called the eutectic mixture. All the mixtures whose composition lies between that of A and C deposit crystals of pure A when they begin to solidify, while mixtures between C and B in composition deposit crystals of pure B. Let us consider a little more closely the solidification of the mixture represented by the vertical line PQR. As it cools from P to Q the mixture remains wholly liquid, but when the temperature Q is reached there is a halt in the cooling, due to the formation of crystals of A. The cooling soon recommences and these crystals continue to form, but at lower and lower temperatures because the still liquid part is becoming richer in B. This process goes on until the state of the remaining liquid is represented by the point C. Now crystals of B begin to form, simultaneously with the A crystals, and the composition of the remaining liquid does not alter as the solidification progresses. Consequently the temperature does not change and there is another well-marked halt in the cooling, and this halt lasts until the mixture has become wholly solid. The corresponding changes in the case of the mixture TUVW are easily understood—the first halt at U, due to the crystallization of pure B, will probably occur at a different temperature, but the second halt, due to the simultaneous crystallization of A and B, will always occur at the same temperature whatever the composition of the mixture. It is evident that every mixture except the eutectic mixture C will have two halts in its cooling, and that its solidification will take place in two stages. Moreover, the three solids S,D and W will differ in minute structure and therefore, probably, in mechanical properties. All mixtures whose temperature lies above the line ABC are wholly liquid, hence this line is often called the "liquidus"; all mixtures at temperatures below that of the horizontal line through C are wholly solid, hence this line is sometimes called the "solidus," but in more complex cases the solidus is often curved. At temperatures between the solidus and the liquidus a mixture is partly solid and partly liquid. This general case has been discussed at length because a careful study of it will much facilitate the comprehension of the similar but more complicated cases that occur in the examination of alloys. A great many mixtures of metals have been examined in the above-mentioned way.

Fig. 6 gives the freezing-point diagram for alloys of lead and tin. We see in it exactly the features described above. The two sloping lines cutting the eutectic point are the freezing-point curves of alloys that, when they begin to solidify, deposit crystals of lead and tin respectively. The horizontal line through the
eutectic point gives the second halt in cooling, due to the simultaneous formation of lead crystals and tin crystals. In the case of this pair of metals, or indeed of any metallic alloy, we cannot see the crystals forming, nor can we easily filter them off and examine them apart from the liquid, although this has been done in a few cases. But if we polish the silver alloys, etch them if necessary, and examine them microscopically, we shall find that alloys on the lead side of the diagram consist of comparatively large crystals of lead embedded in a minute complex, which is due to the simultaneous crystallization of the two metals during the solidification at the eutectic temperature. If we examine alloys on the tin side we shall find large crystals of tin embedded in the same complex. The eutectic alloy itself, fig. 2 (Plate), shows the minute complex of the tin-lead eutectic, photographed by J. A. Ewing and W. Rosenhain, and fig. 3 (Plate), photographed by F. Osmond, shows the structure of a silver-copper alloy containing considerably more silver than the eutectic. Here, the large dark masses are the silver or silver-rich substance that crystallized above the eutectic temperature, and the more minute black and white complex represents the eutectic. It is not safe to assume that the two ingredients we see are pure silver and pure copper; on the contrary, there is reason to think that the crystals of silver contain some copper uniformly diffused through them, and vice versa. It is, however, not possible to detect the copper in the silver by means of the microscope. This uniform distribution of a solid substance throughout the mass of another, so as to form a homogeneous material, is called "solid solution," and we may say that solid silver can dissolve copper. Solid solutions are probably very common in alloys, so that when an alloy of two metals shows two constituents under the microscope it is never safe to infer, without further evidence, that these are the two pure metals. Sometimes the whole alloy is a uniform solid solution. This is the case with the copper-tin alloys containing less than 9% by weight of tin; a microscopic examination reveals only one material, a copper-like substance, the tin having disappeared, being in solution in the copper.

Much information as to the nature of an alloy can be obtained by placing several small ingots of the same alloy in a furnace which is above the melting-point of the alloy, and allowing the temperature to fall slowly and uniformly. We then extract one ingot after another at successively lower temperatures and chill each ingot by dropping it into water or by some other method of very rapid cooling. The chilling stereotypes the structure existing in the ingot at the moment it was withdrawn from the furnace, and we can afterwards study this structure by means of the microscope. We thus learn that the bronzes referred to above, although chemically uniform when solid, are not so when they begin to solidify, but that the liquid deposits crystals richer in copper than itself, and therefore that the residual liquid becomes richer in tin. Consequently, as the final solid is uniform, the crystals formed at first must change in composition at a later stage. We learn also that solid solutions which exist at high temperatures often break up into two materials as they cool; for example, the bronze of fig. 1, which in that figure shows two materials so plainly, if chilled at a somewhat higher temperature but when it was already solid, is found to consist of only one material; it is then a uniform solid solution. The difference between softness and hardness in ordinary steel is due to the permanence of a solid solution of carbon in iron if the steel has been chilled or very rapidly cooled, while if the steel is slowly cooled this solid solution breaks up into a minute complex of two substances which is called pearlite. The pearlite when highly magnified, somewhat resembles the lead-tin eutectic of fig. 2 (Plate). In the case of steel (see also these compounds), the solid solution is very hard, while the pearlite complex is much softer. In the case of some bronzes, for example that with about 25% of tin, the solid solution is soft, and the complex into which it breaks up by slow cooling is much harder, so that the same process of heating and chilling which hardens steel will soften this bronze.

If we melt an alloy and chill it before it has wholly solidified, we often get evidence of the crystalline character of the solid matter which first forms. Fig. 4 (Plate) is the pattern found in a bronze containing 27.7% of tin when so treated. The dark, regularly oriented crystal skeletons were already solid at the moment of chilling; they are rich in copper. The lighter part surrounding them was liquid before the chill; it is rich in tin. This alloy, if allowed to solidify completely before chilling, turns into a uniform solid solution, and at still lower temperatures the solid solution breaks up into a pearlite complex. The analogy between the breaking up of a solid solution on cooling and the formation of a eutectic is obvious. Iron and phosphorus unite to form a solid solution which breaks up on cooling into a pearlite. Other cases could be quoted, but enough has been said to show the importance of solid solutions and their influence on the mechanical properties of alloys. These uniform solid solutions must not be mistaken for chemical compounds; they can, within limits, vary in composition like an ordinary liquid solution. But the occasional or indeed frequent existence of chemical compounds in alloys has now been placed beyond doubt.

We can sometimes obtain definite compounds in a pure state by the action of appropriate solvents which dissolve the rest of the alloy and do not attack the crystals of the compound. Thus, a number of copper-tin alloys when digested with hydrochloric acid leave the same crystalline residue, which on analysis proves to be the compound CuSn. The bodies SnNa, BiN, SnNa2, compounds of iron and molybdenum and many other substances, have also been isolated in this way. The freezing-point curve sometimes indicates the existence of chemical compounds. The simple type of curve, such as that of lead and tin, fig. 6, consisting of two downward sloping branches meeting in the eutectic point, and that of thallium and tin, the upper curve of fig. 7, certainly give no indication of chemical combination. But the curves are not always so simple as the above. The lower curve of fig. 7 gives the freezing-point curve of mercury and thallium; here A and E are the melting-points of pure mercury and pure thallium, and the branches AB and ED do not cut each other, but cut an intermediate rounded branch BCD. There are thus two eutectic alloys B and D, and the alloys with compositions between B and D have higher melting-points. The summit C of the branch BCD occurs at a percentage exactly corresponding to the formula Hg3Tl. It is probable that all the alloys of compositions between B and D, when they begin to solidify, deposit crystals of the compound; the lower eutectic B probably corresponds to a solid complex of mercury and the compound. The point B is at -60 C, the lowest temperature at which any metallic substance is known to exist in the liquid state. The higher eutectic D may correspond to a complex of solid-thallium and the compound; but the possible existence of solid solutions makes further investigation necessary here. The curves of fig. 7 were determined by N. S. Kurnakow and N. A. Puschin. Sometimes a freezing-point curve contains more than one intermediate summit, so that more than one compound is indicated. For example, in the curve for gold-aluminium, ignoring minor singularities, we find two intermediate summits, one at the percentage Au3Al, and another at the percentage AuAl. Microscopic examination fully confirms the existence of these compounds. The compound Au3Al is the most remarkable compound of two metals that has so far been discovered; although it contains so much aluminium its melting-point is as high as that of gold. It also possesses a splendid purple
colour, more remarkable than that of any other metal or alloy. Many other inter-metallic compounds have been indicated by
summits in freezing-point curves. For example, the system
sodium-mercury has a remarkable summit at the composition
NaHg. This compound melts at 350° C, a temperature far
above the melting-point of either sodium or mercury. In the
system potassium-mercury, the compound KHg is similarly
indicated. In the curve for sodium-cadmium, the compound
NaCd is plainly shown. These three examples are taken from
the work of N. S. Kurnakov. Various compounds of the alkali-
metals with bismuth, antimony, tin and lead have been prepared
in a pure state. Such are the compounds SnNa₂, BiNa₂, PbNa₂,
SnNa₄. These of the, the first three are well indicated on the
freezing-point curves. The intermediate summits occurring in
the freezing-point curves of alloys are usually rounded; this feature
is believed to be due to the partial decomposition of the
compound which takes place when it melts. The formulation
of the group of substances last mentioned are in harmony with
the ordinary views of chemists as to valency, but the formations
NaHg, NaCd, NaTl, AuAl₃ are more surprising. They indicate
the great gaps in our present knowledge of the subject of valency.
We must not take it for granted, when the freezing-point curve
gives no indication of the compound, that the compound does
not exist in the solid alloy. For example, the compound Cu₃Sn
is not indicated in the freezing-point curve, and indeed a liquid
alloy of this percentage does not begin to solidify by the formation
of crystals of Cu₃Sn; the liquid solidifies completely to a uniform
solid solution, and only at a lower temperature does this change
into crystals of the compound, the transformation being accom-
panied by a considerable evolution of heat. Until recently the
vast subject of inter-metallic compounds has been an unopened
book to chemists. But the subject is now being vigorously studied,
and, apart from its importance as a branch of descriptive
chemistry, it is throwing light, and promises to throw more,
on obscure parts of chemical theory.

The graphical representation of the properties of alloys can be
extended so as to record all the changes thermal and chemical,
which the alloy undergoes after, as well as before, solidification,
including the formation and breaking up of solid solutions and
compounds. For an example of such a diagram, see the Bakerian
Lecture, 1903, Phil. Trans., A, 196-10. The Phases of Willard
Gibbs, especially as developed by Bakshis Roozbeboom, is a most
useful guide in such investigations.

So far we have been considering alloys containing two metals;
the phenomena they present are by no means simple. But when
three or more metals are present, as is often the case in useful
alloys, the phenomena are much more complicated. With three
component metals the complete diagram giving the variations in
any property must be in three dimensions, although by the use of
contour lines the essential facts can be represented in a plane
diagram. The following method, depend-

Fig. 8.

The electrical conductivity of a metal is often very much
depressed by alloying with it even small quantities of another
metal. This is so when gold and silver are alloyed with each
other, and is true in the case of alloys of copper. When a pure
metal is cooled to a very low temperature its electrical con-
ductivity is greatly increased, but this is not the case with an
alloy. Lord Rayleigh has pointed out that the difference may
arise from the heterogeneity of alloys. When a current is passed
through a solid alloy, a series of Peltier effects, proportional to
the current, are set up between the particles of the different
metals, and these create an opposing electromotive force which
is indistinguishable experimentally from a resistance. If the
alloy were a true chemical compound the counteracting elec-
romotive force should not occur; experiments in this direction are
much needed.
Sir William Chandler Roberts-Austen has shown that in the case of molten alloys the conduction of electricity is apparently metallic, no transfer of matter attending the passage of the current. A group of bodies may, however, be yet discovered between alloys and electrolytes in which evidence may be found of some gradual change from wholly metallic to electrolytic conduction. A. P. Laurie has determined the electromotive force of a series of copper-zinc, copper-tin and gold-tin alloys, and as the result of his experiments he proposes for some definite compounds. Explosive alloys have been formed by H. St Claire Deville and H. J. Debray in the case of rhodium, iridium and ruthenium, which evolve heat when they are dissolved in zinc. When the solution of the rhodium-zinc alloy is treated with hydrochloric acid, a residue is left which undergoes a change with explosive violence if it be heated in vacuo to 400°. The alloy is then insoluble in "aqua regia." The metals have therefore passed into an insoluble form by a comparatively slight elevation of temperature.

Metals do not appear to have been studied from the point of view of surfusion until 1860, when A. D. van Riemsdijk showed that gold and silver would both pass below their actual freezing-points without becoming solid. Roberts-Austen pointed out that surfusion might be easily measured in metals and in alloys by the sensitive method of recording pyrometry perfected by him. He also showed that the crossing of curves of solubility, which had already been observed by H. Le Chatelier and by A. C. A. Dahms in the case of salts, could be measured in the lead-tin alloys. The investigation of the mutual relations of partially miscible liquids, due to F. Alexejew, D. P. Koneff, and to P. E. Duclaux, was extended to alloys by Alder Wright.

The addition of a third metal will sometimes render the mixture of two other metals homogeneous. C. T. Heycock and F. H. Neville proved that when one metal is alloyed with a small quantity of some other metal, the solidification obeys the law of F. M. Raoult. Their experiments, although not conclusive, appear to indicate that the metal of a metal when in dilute solution often consists of one atom. There are, however, numerous exceptions to this rule. In the cases of aluminium dissolved in tin and of mercury or bismuth in lead, it is at least probable that the molecules in solution are Al, Hg, and Bi respectively, while tin in lead appears to form a molecule of the type Sn.

Since 1875 increased attention has been devoted to the applications of the rarer metals. Thus nickel, which was formerly used in the manufacture of "German silver" as a substitute for silver, is now widely employed in naval construction and in the manufacture of steel armour-plates and projectiles. Alloyed with copper, it is used for the envelopes of bullets. A nickel steel containing 56% of nickel has the property of retaining an almost constant volume when heated or cooled through a considerable range of temperature; it is therefore useful for the construction of pendulums and for measures of length. Another steel containing 45% of nickel has, like platinum, the same coefficient of expansion as glass. It can therefore be employed, instead of that costly metal, in the construction of incandescent lamps where a wire has to be fused into the glass to establish electrical connection between the inside and the outside of the bulb. Manganese not only forms with iron several alloys of great interest, but alloyed with copper it is used for electrical purposes, as an alloy can thus be obtained with an electrical resistance that does not alter with change of temperature; this alloy, called manganin, is used in the construction of resistance-boxes. Chromium also, in comparatively small quantities, is taking its place as a constituent of steel axles and tires, and in the manufacture of tool-steel.

Steel containing as much as 12% of tungsten are now used as a material for tools intended for turning and planing iron and steel. The peculiarity of these steels is that no quenching or tempering is required. They are normally hard and remain so, even at a faint red heat. The cutting tools can therefore be taken at a high speed without blunting the tool. Vanadium, molybdenum and titanium may be expected soon to play an important part in the constitution of steel. Titanium is alloyed in small quantities with aluminium for use in naval architecture. Aluminium, when alloyed with a few per cent of magnesium, gains greatly in rigidity while remaining very light; this alloy, under the name of maganilium, is coming into use for small articles in which lightness and rigidity have to be combined. One of the most interesting amongst recent alloys is Conrad Heusler's alloy of copper, aluminium and manganese, which possesses magnetic properties, and as a result of its high resistance, it is employed for carrying alternating currents.

The importance is now widely recognized of considering the mechanical properties of alloys in connexion with the freezing-point curves to which reference has already been made, but the subject is a very complicated one, and all that need be said here, is that when considered in relation to their melting-points the pure metals are consistently weaker than alloys. The presence in an alloy of a eutectic which solidifies at a much lower temperature than the main mass, implies a great reduction in tenacity, especially if it is to be used above the ordinary temperature as in the case of pipes conveying super-heated steam. It has also been stated that alloys of metals with similar melting-points have higher tenacity when the atomic volumes of the constituent metals differ than when they are nearly the same.

REFERENCES.—Alloys have formed a subject of reports to several scientific societies. Sir W. C. Roberts-Austen's six Reports (1891 to 1904) to the Alloys Research Committee of the Institution of Electrical Engineers, are especially valuable. Among other works, mention may be made of the report by William Gowland; the Cantor Lectures on Alloys delivered at the Society of Arts and the Contribution à l'étude des alliages (1901), published by the Société d'encouragement pour l'industrie nationale under the direction of A. L. Couturier and J. B. Amelot. It should be consulted. The theoretical aspect is discussed in Léon Guillet's Étude thórique des alliages métalliques (1904), W. T. Brann' s The Metallic Alloys (1896); Roberts-Austen's Introduction to the Study of Metallurgy (1902); and R. G. Thurston's Materials of Engineering, should be consulted for the more practical details.

Recent progress is reported in the scientific periodicals, especially in A. J. T. and Foster's Journal (Boston, Mass.), and Journal für anorganische Chemie, and by E. S. Shepherd in the Journal of Physical Chemistry, may also be consulted. (W. C. R. A.; F. H. N. E.)

ALLPORT, SIR JAMES JOSEPH (1817–1899), English railway manager, born on the 27th of February 1811, was a son of William Allport, of Birmingham, and was associated with railways from an early period of his life. In 1843 he became general manager of the Birmingham and Derby railway, and in the following year succeeded to the same position on the Newcastle and Darlington line. Six years later he assumed the charge of the Manchester, Sheffield and Lincolnshire (now the Great Central) railway, and finally, in 1853, was appointed to the general managership of the Midland railway—an office which he held continuously, with the exception of a few years between 1857 and 1860, when he was managing director to Palmer's Shipbuilding Company at Jarrow, until his retirement in 1880, when he became a director. During these twenty-seven years the Midland grew to be one of the most important railway systems in England, partly by the absorption of smaller lines and partly by the construction of two main extensions—on the south to London and on the north to Carlisle—whereby it obtained an independent through-route between the metropolis and the north. In the railway world Sir James Allport was known as a keen tactician and a vigorous fighter, and he should be remembered as the pioneer of cheap and comfortable railway travelling. He was the first to appreciate the importance of the third-class passenger as a source of revenue, and accordingly, in 1872, he inaugurated the policy—subsequently adopted more or less completely by all the railways of Great Britain—of carrying third-class passengers in well-fitted carriages at the uniform rate of one penny a mile on all trains. The diminution in the receipts from second-class passengers, which was one of the results, was regarded by some authorities as a sign of the unwisdom of his action, but to him it appeared a legitimate and necessary step, which therefore disappeared from the Midland system in 1875, the first-class fares being at the same time substantially reduced.
He was also the first to introduce the Pullman car on British railways. Allport received the honour of knighthood in 1884. He died in London on the 25th of April 1892.

**ALLPORT, SAMUEL** (1816-1897), English petrologist, brother of the above, was born in Birmingham on the 23rd of January 1816, and educated in that city. Although occupied in business during the greater portion of his life, his leisure was given to geological studies, and when residing for a short period in Bahia, S. America, he made observations on the geology, published by the Geological Society in 1860. His chief work was in microscopic petrology, to the study of which he was attracted by the investigations of Dr H. C. Sorby; and he became one of the pioneers of this branch of geology, preparing his own rock-sections with remarkable skill. The basaltics of S. Staffordshire, the diorites of Warwickshire, the phonolite of the Wolf Rock (to which he first directed attention), the pitchstones of Arran and the altered igneous rocks near the Land's End were investigated and described by him during the years 1869-1879 in the Quarterly Journal of the Geological Society and in the Geological Magazine. In 1886 he was appointed librarian in Mason College, a post which he relinquished on account of ill-health in 1887. In that year the Lyell medal was awarded to him by the Geological Society. A few years later he retired to Cheltenham, where he died on the 7th of July 1897.

**ALL-ROUND ATHLETICS.** Specialization in athletic sports, although always existing, is to a great extent a modern product. In ancient times athletes were encouraged to excel in several branches of sport, often quite opposite in character. Thus the athlete held in highest honour at the Olympic Games (see Greece, Classical) was the victor of the pentathlon, which consisted of running, jumping, throwing the javelin and the discus, and wrestling. All-round championships have existed for many years both in Scotland and Ireland, and in America there are both national and sectional championships. The American national championship was instituted in 1884, the winner being the athlete who succeeds in obtaining the highest marks in the following eleven events; 100 yards run; putting 16 lb shot; running high jump; half-mile walk; throwing 16 lb hammer; 120 yards hurdle race; pole vault; throwing 56 lb weight; one mile run; running broad jump; quarter-mile run. In each event 1000 points are allowed for equalling the "record," and an increasing number of points is taken off for performances below "record," down to a certain "standard," below which the competitor scores nothing. For example, in the 100 yards run the time of 9.8 seconds represents 1000 points; that of 10 seconds scores 998, or 42 points less; 10.2 seconds scores 916, &c.; and below 14.1 seconds the competitor scores nothing. Should the record be broken 42 points are added for each 1/2 second. (See also Athletic Sports.)

**ALL SAINTS, FESTIVAL OF** (Feast omnium sanctorum), also formerly known as All Hallowes, or Hallowmas, a feast of the Catholic Church celebrated on the 1st of November in honour of all the saints, known or unknown. In the Roman Catholic Church it is a festival of the first rank, with a vigil and an octave. Common commemorations, by several churches, of the deaths of martyrs began to be celebrated in the 4th century. The first trace of a general celebration is in Antichon on the Sunday after Pentecost, and this custom is also referred to in the 74th homily of St Chrysostom (407). The origin of the festival of All Saints as celebrated in the West is, however, somewhat obscure. In 609 or 611, G. d'Autun decorated the Pantheon at Rome to the Blessed Virgin and all the martyrs, and the feast of the dedicatio Sanctae Mariae ad Martyres has been celebrated at Rome ever since on the 13th of May. The idea, based on the medieval liturgiologists, that this festival was the origin of that of All Saints has now been abandoned. The latter is possibly traceable to the foundation by Gregory III. (731-741) of an oratory in St Peter's for the relics "of the holy apostles and of all saints, martyrs and confessors, of all the just members with their bodies Whatever was written concerning the Western Church generally is concerned, though the festival was already widely celebrated in the days of Charlemagne, it was only made of obligation throughout the Frankish empire in 835 by a decree of Louis the Pious issued "at the instance of Pope Gregory IV, and with the assent of all the bishops," which fixed its celebration on the 1st of November. The festival was retained at the Reformation in the calendar of the Church of England, and also in that of many of the Lutheran churches. In the latter, in spite of attempts at revival, it has fallen into complete disuse.

**ALL SOULS' DAY** (Commemoratio omnium fidelium defunctorum), the day set apart in the Roman Catholic Church for the commemoration of the faithful departed. The celebration is based on the doctrine that the souls of the faithful which at death have not been cleansed from venial sins, or have not atoned for past transgressions, cannot attain the Beatific Vision, and that they may be helped to do so by prayer and by the sacrifice of the mass. The feast falls on the 2nd of November; or on the 3rd if the 2nd is a Sunday or a festival of the first class. The practice of setting apart a special day for intercession for certain of the faithful departed is of great antiquity; but the establishment of a feast of general intercession was in the first instance due to Odilo, abbot of Cluny (d. 1048). The legend connected with its foundation is given by Peter Damiani in his Life of St Odilo. According to this, a pilgrim returning from the Holy Land was cast by a storm on a desolate island where dwelt a hermit. From him he learned that amid the rocks was a chasm communicating with purgatory, from which rose perpetually the groans of tortured souls, the hermit asserting that he had also heard the demons complaining of the efficacy of the prayers of the faithful, and especially of the monks of Cluny, in rescuing their victims. On returning home the pilgrim hastened to inform the abbot of Cluny, who forthwith set apart the 2nd of November as a day of intercession on the part of his community for all the souls in purgatory. The decree ordaining the celebration is printed in the Bollandist Acta Sanctorum (Sac. VI, pt. i. p. 583).

From Cluny the custom spread to the other houses of the Cluniac order, was soon adopted in several dioceses in France, and spread thence throughout the Western Church. At the Reformation the celebration of All Souls' Day was abolished in the Church of England, though it has been renewed in certain churches in connexion with the "Catholic revival." Among continental Protestants its tradition has been more tenaciously maintained. Even Luther's influence was not sufficient to abolish its celebration in Saxony during his lifetime; and, though its ecclesiastical sanction lapsed before long even in the Lutheran Church, its memory survives strongly in popular custom. Just as it is the custom of French people, of all ranks and creeds, to decorate the graves of their dead on the jour des morts, so in Germany the people stream to the grave-yards once a year with offerings of flowers.

Certain popular beliefs connected with All Souls' Day are of pagan origin and immortal antiquity. They are believed by the peasantry of many Catholic countries to return to their former homes on All Souls' night and partake of the food of the living. In Tirol cakes are left for them on the table and the room kept warm for their comfort. In Brittany the people flock into the cemeteries at nightfall to kneel bare-headed at the graves of their loved ones, and to fill the hollow of the tombstone with holy water or to pour libations of milk upon it, and at bedtime the supper is left on the table for the soul's refreshment.

**ALLSTON, WASHINGTON** (1779-1843), American historical painter and poet, was born on the 5th of November 1779 at Waccamaw South Carolina, where his father was a planter. He graduated at Harvard in 1800, and for a short time pursued his artistic studies at Charleston with Edward Greene Malbone (1777-1807) the miniature painter, and Charles Fraser (1782-1860). With the former, in 1801, he went to London, and entered the Royal Academy as a student of Benjamin West, with whom he formed a lifelong friendship. In 1804 he went to Paris, and, after a few months' residence there, to Rome, where he spent the greater part of the next four years. During this period he made a visit to Colderie and Thorwalden. From 1809 to 1811 he resided in his native country, and from 1811 to 1817 he painted in England. After visiting Paris a
second time, he returned to the United States, and practised his profession at Boston (1818-1830), and afterwards at Cambridge, Massachusetts, where he died on the 6th of July 1843. He was elected an associate of the Royal Academy in 1819. In colour and the management of light and shade Allston closely imitated the Venetian school, and he has hence been styled the "American Titian." Many of his pictures have Biblical subjects, and Allston himself had a profoundly religious nature. His first considerable painting, "The Dead Man Revived," executed shortly after his second visit to England, and now at the Pennsylvania Academy of Fine Arts in Philadelphia, gained a prize of 200 guineas. In England he also painted his "St Peter Liberated by the Angel," "Uriel in the Sun" (at Stafford House), "Jacob's Dream" (at Petworth) and "Elijah in the Wilderness." To the period of his residence in America belong "The Prophet Jeremiah" (at Yale), "Saul and the Witch of Endor," "Miri'am," "Beatrice," "Rosalia," "Spalten's Vision of the Bloody Hand," and the vast but unfinished "Belshazzar's Feast." (in the Boston Athenaeum), at which he was working at the time of his death. As a writer, Allston shows great facility of expression and imaginative power. His friend George Ticknor (a portrait of which by Allston is in the National Gallery) said of him that he was surpassed by no man of his age in artistic and poetic genius. His literary works are—The Sphyns of the Seasons and other Poems (1813), where he displays true sympathy with nature and deep knowledge of the human heart; Monadli (1841), a tragical romance, the scene of which is laid in Italy; and Lectures on Art, edited by his brother-in-law, R. H. Dana the novelist (1850).

**ALLUVION** (Lat. *alluvio*, washing against), a word taken from Roman law, in which it was one of the examples of *accessio*, that is, acquisition of property without any act being done by the acquirer. It signifies the gradual accretion of land or formation of an island by imperceptible degrees. If the accretion or formation be by a torrent or flood, the property in the severed portion or new island continues with the original owner until the trees, if any, swept away with it take root in the ground. Alluvion never attached at all in the case of *agri limitati*, that is, lands belonging to the state and leased or sold in plots. Dig. xii. 1, 7, is the main authority. English law is in general agreement (except as to *agri limitati*) with Roman, as appears from the judgment in *Foster v. Wright*, 1878, 4 C.P.D. 438. The Scottish law, as laid down by the House of Lords in *Earl of Zetland v. Glover Incorporation*, 1872, L.R. 2 H.L., Sc., 70, is in accordance with the English. (See Water Rights.)

**ALLUVIUM**, soil or land deposited by running water. All streams, from the tiniest rill to the greatest river, are continually engaged in transporting downstream solid particles of rock, the product of weathering agencies in the area which they drain. Since the capacity of a stream to carry matter in suspension is proportional to its velocity, it follows that any circumstance tending to retard the rate of flow will induce deposition. Thus a fall in the gradient at any point in the course of a stream; any snag, projection or dam, impeding the current; the reduced velocity caused by the overflowing of streams in flood and the dissipation of their energy where they enter a lake or the sea, are all contributing causes to alluviation, or the deposition of streambed borne sediment. It is evident from the foregoing remarks, that while even the smallest stream may make deposits of alluvial character it is in the flood-plains and deltas of large rivers that the great alluvial deposits are to be found. The finer material constituting alluvium, often described as "silt," is sand and mud. Although it may be exceedingly fine-grained, there is usually very little clay in alluvium. The larger materials include gravel of all degrees of coarseness; carbonaceous matter is often an important element. The amount of solid matter borne by large streams is enormous; many rivers derive their names from the character thereby imparted to the water, e.g. Hwang Ho = Yellow river, Mississippi = Big Muddy, the Red river, &c. It has been estimated that the Mississippi annually carries 400,000 million tons of sediment to the sea; the Hwang Ho 706 million tons; the Po 67 million tons. Many shallow lakes have been completely filled with alluvium and their sites are now occupied by fertile plains; this process may be seen in operation almost anywhere; a good illustration is the delta of the Rhone in Lake Geneva. Alluvial deposits may be of great size. The flood-plain of the Mississippi has an area of 50,000 sq. m.; the great delta of the Ganges and Brahmaputra has an area of about 60,000 sq. m.; that of the Hwang Ho reaches out 300 m. into the sea and has a coastal border of about 400 m. Old alluvial deposits are left high above the existing level of many rivers, in the form of "terraces" of gravel and loam, the streams to which these owe their existence having modified their courses and cut deeper channels; such are the alluvial gravels and brick-earths upon which much of "greater London" is built. In some regions alluvial deposits are the resting places of gemstones and gold, platinum, &c.; it is from these deposits that the largest nuggets of gold have been obtained. Alluvial soils are almost invariably of great fertility; it is due to the alluvial mud annually deposited by the Nile that the dwellers in Egypt have been able to grow their crops for over 4000 years. Artificial fertilization is not necessary to the maintenance of fertility of these deposits.

**ALLYL ALCOHOL** (CH₃=CH-CH₂-OH) is a compound which occurs in very small quantities in wood spirit. It may be prepared from allyl iodide by the action of moist silver oxide; by the reduction of acrolein; or by heating glycerin with oxalic acid and a little ammonium chloride to 260° C. In this last reaction glycerol monoformin is produced as an intermediate product, but is decomposed as the temperature rises:

\[
C₄H₃(CHOH)₂+6H₂CO₂ = C₄H₃(CHOH)₂-O-CHO + CO₂ + H₂O
\]

It is a colourless mobile liquid of pungent smell, boiling at 97° C. Being an unsaturated compound it combines readily with the halogens. Oxidation by strong oxidizing agents converts it successively into its aldehyde, acrolein, and into acrylic acid. By gentle oxidation with potassium permanganate it may be converted into glyceric acid.

**ALMA**, a river of Russia, in the S.W. of the Crimea, entering the Black Sea 17 m. N. of Sevastopol. It gives its name to a famous victory gained over the Russians, on the 20th of September 1854, by the allied armies in the Crimean War (q.v.). The south bank of the river is bordered by a long ridge, which becomes steeper as it approaches the sea, and upon this the Russians, under Prince Menshikov, were drawn up, to bar the Sevastopol road to the allies, who under General Lord Raglan and Marshal St Arnaud approached from the north over an open plain. The Russian commander massed his troops in heavy columns after the fashion of 1813, and drew in his left wing so that it should as far as possible be out of range of the allied men-of-war, which were sailing down the coast in line with their land forces. The allied generals decided that the French (right wing) and the Turks should attack Menshikov's left, while the British, further inland, were to assault the front of the Russian position. The forces engaged are stated by Hamley (War in the Crimea) as, French and Turks, 35,000 infantry, with 68 guns; British, 23,000 infantry, 1000 cavalry and 60 guns; Russians, 33,000 infantry, 3800 cavalry and 120 guns; by the Austrian writer Herndl (Zahl im Kriege) the allied forces are reckoned at 57,000 men with 108 guns, and the Russians at 33,600 men with 96 guns. The French advance met at first with little opposition, and several divisions scaled the cliffs of the lower Alma without difficulty. Menshikov relied apparently on being able to detach his reserves to cope with them, but the assailants moved with a rapidity which he had not counted upon, and the Russians only came into action piecemeal in this quarter. Opposite the British, who as usual deployed at a distance and then advanced in long continuous lines, the Russians were posted on the crest of a long glais-like slope, which offered but little dead ground to an assailant. The village of Burluk, and the vineyards which bordered the river, were quickly cleared by the British skirmishers, and the line of battle behind them crossed, though with some difficulty. On emerging from the cover afforded by the river-bed the British divisions, now crowded together, but still
preserving their general line, came under a terrible fire from heavy guns and musketry. The enemy's artillery was three hundred yards away, yet the British pressed on in spite of their losses, and as some of the Light Division troops reached the "Great Battery" the Russians hurried their guns away to safety. In the meantime, on both sides of this battery, the assailants had come to close quarters with the Russian columns, which were aided by their field guns. A brave counter-attack was made by the Russian Vladimir regiment, 3000 strong, against the troops which had stormed the great battery, and for want of support the British were driven out again. But they soon rallied, and now the second line had crossed and formed for attack. The Guards brigade attacked the Vladimir regiment, and on the left the Highland brigade and the cavalry moved forward also. Some of the field artillery, which had now crossed the Alma, fired steadily into the closed masses of the Russian reserve, and the Vladimir regiment lost half of its numbers under the volleys of the Guards. The French were now severely pressing the Russian left, and one-third of Menshikov's forces were drawn into the fight in that quarter. The success of the frontal assault had dissipated the remainder of the defenders, and Menshikov drew off his forces southwards. He had lost 7500 men (Berndt and Hamley). The British had about 2000 killed and wounded; the French stated their losses at 1340 men.

ALMACANTAR (from the Arabic for a sun-dial), an astronomical term for a small circle of the sphere parallel to the horizon; when two stars are in the same almacantar they have the same altitude. The term was also given (1886) to an instrument invented by S. C. Chandler to determine the latitude or correct the time-piece, of great value because of its freedom from instrumental errors.

ALMAC'S, formerly the name of a famous London club and assembly rooms. The founder, known as William Almac, is usually said to have been one Macall, or McCaul, of which name Almac is an anagram. In 1764 he founded a gentlemen's club in Pall Mall, where the present Marlborough Club stands. It was famous for its high play. In 1787 it was taken over by one Brooks, and established as Brooks's Club in St James's Street, where it still exists. In 1765 Almac built a suite of assembly rooms in King's Street, St James's. Here for a ten-guinea subscription a series of weekly balls was given for twelve weeks. They were managed by a committee of ladies of rank, and admission was exceedingly difficult. At Almac's death in 1781 they were left to his niece Mrs Willis. As "Willie's Rooms" they lasted till 1809, when they became a restaurant, but as "Almac's" they ceased in 1836. Several clubs, including a mixed club for ladies and gentlemen, held meetings at Almac's during the 18th and beginning of the 19th centuries. A new London social club (1904) has also adopted the name of Almac's.

ALMADÍN, or ALMADÍN del AZOQUE, a town of Spain, in the province of Ciudad Real; situated in mountainous country at 55 m. W.S.W. of the city of Ciudad Real. Pop. (1900) 7375. Almadín, the Stoppaon of the Romans, is celebrated for its mercury mines, which were extensively wrought by the Romans and Moors, and are still productive, the ore increasing in richness with the depth of the descent. The mines ranked with those of Adria, in South Austria, as the most valuable in the world, until the great development of the mercury deposits at New Almadén, in California, U.S.A., between 1853 and 1857. They were long worked by convict labour, owing to their unrulyness and atmosphere, and exemption from military service is granted to miners who have worked at Almadén for two years. The annual yield is about 1,400,000 lb. Lead and sulphur are obtained in the neighbourhood. The nearest railway station is that of Chillón, 3 m. S. on the Madrid-Badajoz-Lisbon line.

ALMACRO, DIEGO DE (1475-1538), Spanish commander, the companion and rival of Pizarro (q.v.), was born at Aldea del Rey in 1475. According to another account he was a foundling in the village from which he derived his name. In 1525 he joined Pizarro and Hernando de Luque in the expedition of conquest of Peru (see History). He was executed by order of Pizarro in 1538 in consequence of a dispute as to their respective territories.

ALMANAC, a book or table containing a calendar of the days, weeks and months of the year, a register of ecclesiastical festivals and saints' days, and a record of various astronomical phenomena &c. The derivation of the word is doubtful. The word almanac was used by Roger Bacon (Opus Majus, 1267) for tables of the apparent motions of the heavenly bodies. The Italian form is almancoc, French almanach, and the Spanish almaceo; all of which, according to the New English Dictionary, are probably connected with the Arabic al-manākh, a combination of the definite article al- and mànakh, a word of uncertain origin. An Arabic-Castilian vocabulary (1305) gives manos, a calendar, and manahk, a sun-dial; manos has also been connected with the Latin manacus, a sun-dial.

The attention given to astronomy by Eastern nations probably led to the early construction of such tables as are comprised in our almanacs; of these we know little or nothing. The fasti (q.v.) of the Romans are far better known and were similar to modern almanacs. Almanacs of a rude kind, known as dagg almanacs, consisting of square blocks of hard wood, about 8 in. in length, with notches along the four angles corresponding to the days of the year, were in use in some parts of England as late as the end of the 17th century. Dr Robert Plot (1640-1696), keeper of the Ashmolean Museum and professor of chemistry at Oxford, describes one of these in his Natural History of Staffordshire (Oxford, 1680); and another is represented in Gough's edition of Camden's Britannia (1806, vol. ii. p. 499).

The earliest almanac regarding which J. J. L. de Laleande (Bibliographie astronomique, Paris, 1803) could obtain any definite information belongs to the 12th century. Manuscript almanacs of considerable antiquity are preserved in the British Museum and in the libraries of Oxford and Cambridge. Of these the most remarkable are a calendar ascribed to Roger Bacon (1202), and those of Peter de Dacia (about 1300), Walter de Elvendene (1327) and John Somers (1380). It is to be remembered that early calendars (such as the Kalendarium Lincolniense of Bishop Robert Grosseteste) frequently bear the names, not of their compilers, but of the writers of the treaties on ecclesiastical computation on which the calendars are based. The earliest English calendar in the British-Museum is one for the year 1431. The first printed almanac known was compiled by Püribuch, and appeared between the years 1450 and 1467; the first of importance is that of Regiomontanus, which appears to have been printed at Nuremberg in 1472. In this work the almanacs for the different months embrace three Metonic cycles, or 57 years from 1475 to 1531 inclusive. The earliest almanac printed in England was The Kalendar of Shapards, a translation from the French, printed by Richard Pynson about 1497.

Early almanacs had commonly the name of "prognostications" in addition, and what they professed to show may be gathered from titles like the following, which is quoted by J. O. Halliwell: "Pronostoycacyon of Mayster John Thibault, medycynyer and astronomer of the Emperyall Majeste, of the year of our Lorde God MCCCCXXXII, comprizing the iiij, partes of this yere, and of the influence of the mone, of peas and warre, and of the syknesses of this yere, with the constellacions of them that be under the viij. piaenette, and the revolucions of kynges and princes, and of the eclipses and comets." Among almanacs of this class published in England, and principally by the Stationers' Company, are Leonard Digges's Prognostication Everlasting of Right Good Effect, for 1553, 1555, &c.; William Lilly's Merliuins Anglicus Junior for 1644, &c., and other almanacs and "prognostications"; John Booker's Bloody Almanac and Bloody Irish Almanac for 1643, 1647, &c.—the last attributed erroneously to Richard Napier; John Partridge's Mercurius Coelestis for 1681, Merliuins Redivivus, &c. The name of Partridge has been immortalized in Pope's The Rape of the Lock; and his almanacs were very cleverly burlesqued by Swift, who predicted Partridge's own death, in genuine prophetic verse's within thirty years. The Stationers' Company's predicting almanacs was the Vox Stellarum of Francis Moore (1657-1745?), the first number of which was completed in July 1700, and contained predictions for 1701.
Its publication has been continued under the title of Old Moore's Almanac. Of a different but not a better sort was Poor Robin, dating from 1663, and published by the company down to 1828, which abounded in coarse, sometimes extremely coarse, humour.

The exclusive right to sell "almanacs and prognostications" in England, enjoyed in the time of Elizabeth by two members of the Company of Stationers, was extended by James I. to the two universities and the Stationers' Company jointly; but the universities commuted their privilege for an annuity from the company. This monopoly was challenged by Thomas Carnan, a bookseller, who published an almanac for three successive years, 1675-1677. The company in that account by the company. The case came, in 1775, before the court of common pleas, and was decided in Carnan's favour, the question argued being, "Whether almanacs were such public ordinances, such matters of state, as belonged to the king by his prerogative, so as to enable him to communicate an exclusive right of printing them to a grante of the crown?" In 1779 Lord North attempted to reverse this decision by a parliamentary enactment, but the bill was thrown out. In consequence of this the universities lost their title to their annuity, and in lieu of it they received a proportion of the receipts. The company, however, virtually retained its monopoly for many years, by buying up as much as possible all the almanacs issued by other publishers, but in more recent times this power has altogether ceased, although a considerable proportion of the almanacs published in England still issue from the hall of the Stationers' Company. A description of "Almanac Day" at Stationers' Hall will be found in Knight's Cyclopaedia of London (1851), p. 388.

On the 1st of January 1828 the Society for the Diffusion of Useful Knowledge issued the British Almanac for that year—a publication greatly superior in every way to the almanacs of the time. The success of the British Almanac, with its valuable supplement, the Companion to the Almanac, led to a great improvement in this class of publications. The Stationers' Company issued the Englishman's Almanac, a work of a similar kind. The entire reappearance in 1834, by the 3rd and 4th Will.IV. c.57, of the heavy stamp duty, first imposed in 1710, on all almanacs of fifteenpence per copy, gave an additional stimulus to the publication of almanacs of a better class, and from that time the number has greatly increased. Since 1870, the British Almanac and Companion have been the principal publication of the Stationers' Company. Whittaker's Almanac, commenced in 1868 by Joseph Whittaker (1820-1895), is perhaps the best known of modern almanacs.

In Scotland, almanacs containing much astrological matter appeared to have been published at about the beginning of the 16th century; and about a century later those published at Aberdeen enjoyed considerable reputation. In 1683, the Edinburgh's True Almanac, or a New Prognostication, appeared; a publication which improved with years and was issued after 1837 as Oliver and Boyd's New Edinburgh Almanac, a standard book of reference for Scottish affairs. Thom's Irish Almanac (since 1843) deals mainly with Ireland.

The earliest almanac published in the United States is probably to be ascribed to Bradford's press in Philadelphia, for the year 1687. Poor Richard's Almanac, commenced in 1732 by Benjamin Franklin under the pseudonym of "Richard Saunders," and continued by him for twenty-five years, gained a high reputation for its wise and witty sayings; it may have been suggested by a somewhat similar publication by Thomas, of Dedham, Massachusetts. The American Almanac and Repository of Useful Knowledge was published at Boston from 1828 to 1861; a continuation, The National Almanac, was published only twice, for 1863 and 1864. The Old Farmer's Almanac enjoys considerable popularity and has been published for many years. At the present time nearly every religious denomination, trade and newspaper have almanacs or year-books.

In France prophetic almanacs circulated very freely among the poorer and rural classes, although an ordinance of Charles IX. required the seal of a diocesan bishop on all almanacs. In 1579 Henry III. prohibited the publication of predictions relating to political events, a prohibition renewed by Louis XIII. Of such almanacs, the most famous was the Almanach Liégeois first published in 1625 at Liège by Matthieu Laensbergh, a person of very problematic existence. Publications of this class subsequently increased in number to such an extent that, in 1852, their circulation was forcibly checked by the government. The most important French almanac is the Almanach Royal, afterwards Impérial, and now National, first published in 1679.

A number of publications, issued in Germany, from the middle of the 18th to the middle of the 19th century, under such titles as Musenalmanach, modelled on the Almanach des Muses, a competition of almanacs at Paris—contain some of the best works of some of the most celebrated German poets. The Almanach de Gotha, which has existed since 1763, published since 1871 both in French and German, gives a particular account of all the royal and princely families of Europe, and ample details concerning the administration and the statistics of the different states of the world.

For the Nautical Almanac and similar publications, see Ephemeris.

ALMANDE, or ALMADITE, a name applied to certain kinds of precious garnet, being apparently a corruption of almandine-garnet, which is also called by the name of almandine. Garnets were probably cultivated or worked at Almadena, a town in Caria in Asia Minor. Almandine is an iron alumina garnet, of deep red colour inclining to purple. It is frequently cut with a convex face, or en cabochon, and is then known as carbuncle. Viewed through the spectroscope in a strong light, it generally shows three characteristic absorption bands, as first pointed out by Prof. A. H. Church.

Almandine occurs rather abundantly in the gem-gravels of Ceylon, whence it has sometimes been called Ceylon-ruby. When the colour inclines to a violet tint, the stone is often called Syrian garnet, a name said to be taken from Syria, an ancient town of Pegu. Large deposits of fine almandine-garnets were found, some years ago, in the Northern Territory of South Australia, and were at first taken for rubies, whence they were known in trade for some time afterwards as Australian rubies.

Almandine is widely distributed. Fine rhombic dodecahedra occur in the schistose rocks of the Zillerthal, in Tyrol, and are sometimes cut and polished. An almandine in which the ferrous oxide is replaced partly by magnesia is found at Luissenfeld in German East Africa. In the United States there are many localities at which yield fine garnets. Dr. G. G. Kunze has figured a large crystal of coarse almandine weighing 3 lb. from New York city. Fine crystals of almandine embedded in mica-schist occur near Fort Wrangell in Alaska. The coarse varieties of almandine are often crushed for use as an abrasive agent. (See Garnet.)

ALMANSA, or ALMANZA, a town of eastern Spain, in the province of Albacete; 35 m. S.E.S. of Albacete, on the Madrid-Alcalaicante railway. Pop. (1890) 11,780. Almanza is built at the foot of a white limestone crag, which is surmounted by a Moorish castle, and rises abruptly in the midst of a fertile and irrigated plain. About 1 m. S. stands an obelisk commemorating the battle fought here on the 25th of April 1707, in which the French under the duke of Berwick, a natural son of James II. of Great Britain, routed the allied British, Portuguese and Spanish troops. (See Spanish Succession, War of the.)

ALMADA, SIR LAURENCE (Laprens) (1836- ), British artist, was born on the 8th of January 1836, at Dronrijp, a Frisian village near Leeuwarden, the son of Pieter Tadema, a notary, who died when he was four years old. Alma was the name of his godfather. His mother (d. 1856) was his father's second wife, and was left with a large family. It was designed that the boy should follow his father's profession; but he had so great a leaning towards art that he was eventually sent to Antwerp, where in 1852 he entered the academy under Gustav Wappers. Thence he proceeded to the atelier of Henri (afterwards Baron) Leys. In 1859 he assisted Leys in the latter's frescoes in the hall of the hôtel de ville at Antwerp. In the exhibition of Alma-Tadema's collected works at the Grosvenor Gallery in London in the winter of 1882-1883 there were two pictures which may be said to mark the beginning and end of his first period. These were a portrait of himself, dated 1852, and "A Bargain," painted...
in 1860. His first great success was a picture of "The Education of the Children of Clovis" (1861), which was exhibited at Antwerp. In the following year he received his first gold medal at Amsterdam. The "Education of the Children of Clovis" (three young children of Clovis and Clotilde practising the art of hurling the axe in the presence of their widowed mother, who is training them to avenge the murder of their own parent) was the first of a series of Merovingian legends in which family feeling was the "Freedegonda" of 1878 (exhibited in 1880), where the depicted wife or mistress is watching from behind her curtain window the marriage of Chilperic I, with Galeswinita. It is perhaps in this series that we find the painter moved by the deepest feeling and the strongest spirit of romance. One of the most passionate of all is "Freedegonda at the Death-bed of Praetextatus," in which the bishop, stabbed by order of the queen, is cursing her from his dying bed. Another distinct series is designed to reproduce the life of ancient Egypt. One of the first of this series, "Egyptians 2000 Years Ago," was painted in 1863. A profound depth of pathos is sounded in "The Death of the Firstborn," painted in 1873. Among Alma-Tadema's other notable Egyptian pictures are "An Egyptian at his Doorway" (1862), "The Mummy" (1867), "The Chamberlawn of Sesostris" (1869), "A Widow" (1873), and "Joseph, Overseer of Pharaoh's Granaries" (1874). On these scenes from Frankish and Egyptian life Alma-Tadema spent great energy and research; but his strongest art-impulse was towards the presentation of the life of ancient Greece and Rome, especially the latter. Amongst the best of his pictures of historical times are "Tarquinius Superbus" (1867), "Phidias and the Elgin Marbles" (1868), and "The Pyrrhic Dance" and "The Wine Shop" (1869). "The Pyrrhic Dance," though one of the simplest of his compositions, stands out distinctly from them all by reason of its striking movement. "Phidias and the Elgin Marbles" is the first of those glimpses of the art-life of classical times, of which "Hadrian in England," "The Sculpture Gallery," and "The Picture Gallery" are later examples. The "Wine Shop" is one of his many pictures of historical genre, but marked with a more robust humour than usual. In 1883 Alma-
Tadema married a Kentish lady, and lived at Brussels till 1889, when she died, leaving him a widower with two daughters, Laurence and Anna, both of whom afterwards made reputations —the former in literature, the latter in art. In 1889 he sent from Brussels to the Royal Academy two pictures, "An Amateur romain" and "Une Danse pyrrhique," which were followed by three pictures, including "Un Jongleur," in 1870, when he came to London. By this time, besides his Dutch and Belgian distinctions, he had been awarded medals at the Paris Salon of 1864 and the Exposition Universal of 1867. In 1871 he married Mme. Anne St. Léon, an English lady, whom he had met in Paris. After her marriage, he moved to Brussels and opened a studio there, and lived with his wife until 1889, when she died. He then returned to London, where he continued to paint. In 1877, he was knighted on the occasion of Queen Victoria's eighty-first birthday, 1890. He was made an associate of the Royal Academy in 1876, and a Royal Academician in 1879. In 1907 he was included in the Order of Merit. He became a knight of the order Pour le Mérite of Germany (Arts and Science Division); of Léopold, Belgium; of the Dutch Lion; of St. Michael of Bavaria; of the Golden Lion of Nassau; and of the Crown of Prussia; an officer of the Legion of Honour, France; a member of the Royal Academies of Munich, Berlin, Madrid and Vienna. He received a good medal at Berlin in 1872 and a grand medal at Berlin in 1874; a first class medal at the Paris International Exhibitions of 1889 and 1900. He also became a member of the Royal Society of Water-colours.

ALME or ALMA (from dim, wise, learned), the name of a class of singing girls in Egypt who are present at festivals and entertainments, and act as hired mourners at funerals. They are to be distinguished from the ghawwazee, or dancing girls, who perform in the public streets and are of a lower order.

ALMEIDA, DOM FRANCISCO DE (c. 1450-1510), the first viceroy of Portuguese India, was born in Lisbon about the middle of the 15th century. He was the seventh son of the second count of Abrantes, and thus belonged to one of the most distinguished families in Portugal. In his youth he took part under Ferdinand of Aragon in the wars against the Moors (1485-1492). In March 1505, having received from Emmanuel I, the appointment of viceroy of the newly conquered territory in India, he set sail from Lisbon in command of a large and powerful fleet, and arrived in July at Quilao (Kilwa), which yielded to him almost without a struggle. A much more vigorous resistance was offered by the Moors of Mombasa, but the town was taken and destroyed, and its large treasures went to strengthen the resources of Almeida. At other places on his way, such as the island of Anegada, near Goa, and Cannanore, he built forts, and adopted measures to secure the Portuguese supremacy. On his arrival in India he took up his residence at Cochín, where a Portuguese fort had been built by Alphonso d'Albuquerque in 1503. The most important events of Almeida's brief but vigorous administration were the conclusion of a commercial treaty with Malacca, and the discoveries made by his son Lorenzo, who acted as his lieutenant. Lorenzo was probably the first Portuguese who visited Ceylon, where he established a settlement, and Fernando Soares, a captain commanding a squadron of his fleet, appears to have been the first European to sight Madagascar. In 1508 he was killed at Dabul in a naval engagement with the Egyptians, who at this time endeavoured to dispute Portuguese supremacy in the Indian Ocean. His son, Almeida (q.v.), arrived in Cochín, and presented a commission empowering him to supersede Almeida in the government. It was probably Almeida's unwillingness to be thwarted in his scheme of vengeance that chiefly induced him to refuse to recognize Albuquerque's commission, and to cast him into prison. The punishment he inflicted on the Arabs and their Egyptian allies was speedy and terrible. Sailing along the coast he pillaged and burned various ports, including Goa and Dabul, and finally, encountering the enemy's combined fleet off Diu in February 1509, he completely destroyed it. Returning immediately to Cochín, he held out for a few months against the claims of Albuquerque, but in November 1509 he was compelled to yield. On the 1st of December he set sail for Europe with an escort of three vessels. On the voyage the fleet called at Table Bay, then known as Saldanha Bay, to procure water, and here Almeida was killed (on the 1st of March 1510) in an attack upon the Hottentot natives, during which he showed great personal courage. In this fight, which took place on the site of Cape Town, 65 Portuguese perished, including 12 captains. Almeida's body was recovered on the following day and buried on the spot where he fell. ALMEIDA, a town of northeastern Portugal, in the district of Guarda and formerly included in the province of Beira; situated in hilly country between the river Cá, a tributary of
the Douro, and the river Turones, a branch of the Agueda. Pop. (1900) 2330. Almeida was long one of the principal frontier fortresses of Portugal. It was captured by the Spaniards in 1762. During the Peninsular War (q.v.), the country between the Cba and the Spanish fortress of Ciudad Rodrigo, 25 m. E.S.E., was the scene of hard fighting. Almeida was taken by the French in 1810, and, for recapture, by the allied British and Portuguese forces under Lord Wellington, was only effected after a relieving force under Marshal Masséna had been defeated at Fuentes d'Onor (or Fuentes de Oñoro), 14 m. S.S.E. The battle was fought on the 4th of May 1811 and the fortress fell five days later.

ALMELO, a town in the province of Overysel, Holland, 12 m. by rail N.W. of Hengelo, at the junction of the Overysel and Almelo canals. Pop. (1900) 9957. It is a place of considerable antiquity, having been the seat of an independent lordship before the 14th century. But it first rose into importance in the second half of the 14th century owing to its share in the extraordinary industrial development of the Twente district, and now possesses numerous cotton and damask factories. Among the public buildings are a town hall, court house, corn exchange, and churches of various denominations, as well as a synagogu.

The lordship of Almelo belonged to the lords of Heeckeren, who acquired the barony of Rechteren by marriage in 1350 and the countyship of Limpourgh in 1711. The elder branch of the mediatised house of Rechteren-Limpouh is still established at Almelo; the younger, German branch, at Markt Eiersheim in Baden-Württemberg.

ALMENDRALEJO, a town in western Spain, in the province of Badajoz; situated 27 m. E.S.E. of Badajoz, on the Merida-Seville railway. Pop. (1900) 15,687. Almendralejo is a thriving town, with broad streets and good modern houses; including the palace of the marquesses of Monsalud, which contains a museum of Roman antiquities discovered in the neighbourhood. Local prosperity was greatly enhanced during the period 1875-1905 by the improvement of communications, which enabled the grain, fruit and wine of the Guadiana valley, on the north, and of the upland known as the Sierra de Barros, on the south, to be readily exported by the Merida-Seville railway. Brandy is produced in large quantities.

ALMERIA, a maritime province of southern Spain, formed in 1833, and comprehending the eastern territories of the ancient kingdom of Granada. Pop. (1900) 359,023; area, 3360 sq. m. Almería is bounded on the N. by Granada and Murcia, E. and S. by Murcia and the Mediterranean Sea, and W. by Granada. It is traversed by mountain ridges, with peaks of 6000 to 8000 ft. in altitude; and it is grouped into valleys of great fertility. The chief rivers are those of Marta, in the north; Estancias and Oria, north of the Almogávares, La Alcarria; the middle of the province; Cabrera and Gata, along the southeast coast; Alhamilla, east of the city of Almería; Gádor in the southwest; and, in the west, some outlying valleys of the Sierra Nevada.

Three small rivers, the Adra, or Rio Grande de Adra, in the west, the Almeria in the centre, and the Almanzora in the north and east, flow down from the mountains to the sea. On the south coast is the Gulf of Almeria, 25 m. wide at its entrance, and terminating, on the east, in the Cabo de Gata, the southernmost point of Spain. The climate is mild, except among the higher mountains. The valleys near the sea are well adapted for agriculture; oranges, lemons, almonds and other fruit trees thrive; silk is produced in the west; and the vine is extensively cultivated, less for the production of wine than to meet the foreign demand for white Almería grapes. Although the cost of transport is very heavy, the exportation of grapes is a flourishing industry, and more than 2,000,000 barrels are annually sent abroad. The cattle of the central districts are celebrated for size and quality. Almería is rich in minerals, especially iron and lead; silver, copper, mercury, zinc and sulphur are also obtained. At the beginning of the 20th century the mines at work numbered more than two hundred, and proved very attractive to foreign as well as native capitalists. Garnets are found in the Sierra de Gata and in the Sierra Nevada and marbles quarried. The development of mining was facilitated by the extension of the railway system between 1805 and 1905. The main line from Madrid to Almería conveys much ore from Granada and Jaén to the sea; while the railway from Baza to Lorca skirts the Almanzora valley and transports the mineral products of eastern Almería by a branch line from Huércal-Oivera to the Murcian port of Águilas. Light railways and aerial cables among the mountains supplement these lines. The chief imports comprise coal, timber, especially oak staves, and various manufactured goods. The exports are minerals, esparto, oil, grain, grapes and farm produce generally. The principal seaports are Almería, the capital, pop. (1900) 74,326, Almeria, pop. (1900) 11,188, and Garrucha (4661), which, with Berja (13,224), Cuevas de Vera (20,562), Huércal-Oivera (15,763) and Nifar (12,497), are described in separate articles. Other towns, important as mining or agricultural centres, are Albox (10,040), Dália (7136), Lubrín (6593), Sorbas (7360), Tabernas (7620), Veléz Blanco (6825), Veléz Rubio (10,105) and Vera (5426). Education is backward and the standard of comfort low. A constant annual loss of 2000 or 3000 emigrants to Algeria and elsewhere prevents any rapid increase of population, despite the high birth-rate and low mortality.

ALMERÍA, the capital of the province of Almería, and one of the principal seaports on the Mediterranean coast of southern Spain; in 30° 5' N. and 3° 32' W., on the river Almería, at its outflow into the Gulf of Almería, and at the terminus of a railway from Madrid. Pop. (1900) 47,326. The city occupies part of a rich alluvial valley enclosed by hills. It is an episcopal see, and the site of the ancient Almohad fortress, now dismantled, the Castillo de San Cristóbal, overlooking the city, which contains four Moorish towers rising conspicuously above its modern streets. Two long piers shelter the harbour, and vessels drawing 25 ft. can lie against the quays. About 1400 ships, of nearly 1,000,000 tons, enter the port every year, bringing fuel and timber, and taking cargoes of iron, lead, esparto and fruit. White grapes are exported in very large quantities.

Under its ancient name of Urci, Almería was one of the chief Spanish harbours after the final conquest of Spain by the Romans in 15 B.C. It reached the summit of its prosperity in the middle ages, as the foremost seaport of the Moorish kingdom of Granada. At this time its population numbered 150,000; its cruisers preyed upon the fleets of the neighbouring Christian states; and its merchant ships traded with countries as distant as Egypt and Syria. Almería was captured in 1147 by King Alphonso VII. of Castile and his Genoese troops, but speedily retaken and held by the Moors until 1489, when it was finally secured by the Spaniards.

See D. F. Margalida, Almería, (Barcelona, 1886).

ALMERY, ALMERY, ALMBRIF, or AMBRY (from the medieval form almairium, cf. Lat. armarium, a place for keeping tools; cf. O. Fr. armoirie and mod. armoire), in architecture, a recess in the wall of a church, sometimes square-headed, and sometimes arched over, and closed with a door like a cupboard—used to contain the chalices, basins, cruets, &c., for the use of the priest; many of them have stone shelves. They are sometimes near the piscina, but more often on the opposite side. The word also seems in medieval times to be used commonly for any closed cupboard and even bookcase.

ALMODÖVAR DEL CAMPO, or ALMODÖVAR, a town of Spain, in the province of Ciudad Real, 18 m. S.S.W. of Ciudad Real, on the northern side of the Sierra de Alcudia. Pop. (1900) 12,525. Almodóvar was a Moorish fortress in the middle ages, but contains little of antiquarian interest. It owes its modern prosperity to the nearness of the valuable Puertollano coal-field, 3 m. S. by a branch of the Madrid-Badajoz-Lisbon railway. Its manufactures are lace and linen and it has a brisk trade in live-stock, oil and wine. South of the Sierra lies the Alcudía valley, owned by the crown, and used as pasture for immense flocks of sheep.

ALMOGÁVARES (from the Arab. Al-Mugannari, a scout), the name of a class of Spanish soldiers, well known during the
ALMOHADES—ALMON

Christian reconquest of Spain, and much employed as mercenaries in Italy and the Levant, during the 13th and 14th centuries. The Almogávares (the plural of Almogávar) came originally from the Pyrenees, and were in later times recruited mainly in Navarre, Aragon, and Catalonia. They were frontiersmen and foot-soldiers who wore no armour, dressed in skins, were shod with brogues (abarcas), and carried the same arms as the Roman legionaries—two heavy javelins (Spanish asagaya, the Roman pilum), a short stabbing sword and a shield. They served the king, the nobles, the church or the towns for pay, and were professional soldiers. When Peter III. of Aragon made war on Charles of Anjou after the Sicilian Vespers—30th of March 1282—for the possession of Naples and Sicily, the Almogávares formed the most effective element of his army. Their discipline and ferocity, the force with which they hurled their javelins, and their activity, made them very formidable to the heavy cavalry of the Angevin armies. When the peace of Calatella-bellota in 1302 ended the war in southern Italy, the Almogávares followed Roger di Flor (Roger Blum) the unfrocked Templar, who entered the service of the emperor of the East, Andronicus, as condottieri to fight against the Turks. Their campaign in Asia Minor, 1303 and 1304, was a series of romantic victories, but their greed and violence made them intolerable to the Christian population. When Roger di Flor was assassinated by his Greek employer in 1304, the Almogávares reunited them in the neighbourhood of Constantinople. In 1310 they marched against the duke of Athens, of the French house of Brienne. Walter of Brienne was defeated and slain by all his knights at the battle of Cephasius, or Orchemenus, in Boeotia in March. They then divided the wives and possessions of the Frenchmen by lot and summoned a prince of the house of Aragon to rule over them. The foundation of the Aragonese duky of Athens was the culmination of the achievements of the Almogávares. In the 16th century the name died out. It was, however, revived and given to a party nickname in the civil wars of the reign of Ferdinand VII.

AUTHORITIES.—The Almogávares are admirably described by one who fought with them, Ramon de Muntaner, whose Chronicle has been translated into French by J. A. Buchon, Chroniques des Espagnoles (Paris, 1860). The original text was reprinted and edited by K. Lanz at Stuttgart, 1844. See also the Expédition des "Almogávares" ou routiers catalans en orient, de l'an 1302 à l'an 1311, by G. Schumburger (Paris, 1902).

ALMOHADES (properly Muwahhādis, i.e. "Unitarians," the name being corrupted through the Spanish), a Mahomedan religion, was the power which founded the fifth Moslem dynasty in the 11th century, and conquered all northern Africa as far as Egypt, together with Meslem Spain. It originated with Mahomed ibn Tūmār, a member of the Maṣūda, a Berber tribe of the Atlas. Ibn Tūmār was the son of a lamplighter in a mosque and had been noted for his piety from his youth; he was small, ugly, and misshapen and lived the life of a devotee-beggar. As a youth he performed the pilgrimage to Mecca, whence he was expelled on account of his severe stricures on the laxity of others, and thence wandered to Bagdad, where he attached himself to the school of the orthodox doctor al Ashārī. But he made a system of his own by combining the teaching of his master with parts of the doctrines of others, and with mysticism imbibed from the great teacher Ghazālī. His main principle was a rigid unitarianism which denied the independent existence of the attributes of God, as being incompatible with his unity, and therefore a polytheistic idea. Mahomed in fact represented a revolt against the anthropomorphism of commonplace Mahomedan orthodoxy, but he was a rigid predestinarian and a strict observer of the law. After his return to Spain, at the age of twenty-eight, he founded a schism, and agitating, headlong roused on wine-shops and on other manifestations of laxity. He even went so far as to assault the sister of the Murābiṭ (Almoravide) amir’Ali III., in the streets of Fez, because she was going unveiled after the manner of Berber women. ‘Ali, who was very deferential to any exhibition of piety, allowed him to escape unpunished.

Ibn Tūmār, who had been driven from several other towns for exhibitions of reforming zeal, now took refuge among his own people, the Maṣūda, in the Atlas. It is highly probable that his influence would not have outlived him, if he had not found a lieutenant in ‘Abd-el-Mūmin el Kūmī, another Berber, from Algeria, who was undoubted a soldier and statesman of a high order. When Ibn Tūmār died in 1128 he divided his dominions among his son or ribāḥ which he had founded in the Atlas at Tūmāl, after suffering a severe defeat by the Murābiṭ, ‘Abd-el-Mūmin kept his secret for two years, till his own influence was established. He then came forward as the lieutenant of the Māḥdi Ibn Tūmār. Between 1130 and his death in 1163, ‘Abd-el-Mūmin not only rooted out the Murābiṭ, but also extended his power over all northern Africa as far as Egypt, becoming amir of Morocco in 1149. Mahomedan Spain followed the fate of Africa, and in 1170 the Mūwāḥḥādīs transferred their capital to Seville, a step followed by the founding of the great mosque, now suppressed by the cathedral, the tower of which they erected in 1184 to mark the accession of Ya’kūb el Mānsūr. From the time of Yūsuf II., however, they governed their co-religionists in Spain and Central North Africa through lieutenants, their dominions outside Morocco being treated as provinces. When their amirs crossed the Straits it was to lead a jehad against the Christians and to return to their capital, Marrakesh.

The Mūwāḥḥādī princes had a longer and a more distinguished career than the Murābiṭ or “Almoravides” (p. 518). Yūsuf II. or “Abu Ya’kūb” (1163-1184), and Ya’kūb I. or “El Mānsūr” (1184-1190), the successors of ‘Abd-el-Mūmin, were both able men. They were fanatical, and their tyranny drove numbers of their Jewish and Christian subjects to take refuge in the growing Christian states of Portugal, Castile and Aragon. But in the end they became less fanatical than the Murābiṭ, and Ya’kūb el Mānsūr was a highly accomplished man, who wrote a good Arabic style and who protected the philosopher Averroes. His title of El Mānsūr, “The Victorious” was earned by the defeat he gave the Almoravide, Alphonso VIII. of Castile at Alarcos, and the Christian states in Spain were becoming too well organized to be over-run by the Mahomedans, and the Mūwāḥḥādī made no permanent advance against them. In 1212 Mahomed III., “En-Nāṣir” (1190-1214), the successor of El Mānsūr, was utterly defeated by the allied five Christian princes of Spain, Navarre and Portugal, at Las Navas de Tolosa in the Sierra Morena. All the Moorish dominions in Spain were lost in the next few years, partly by the Christian conquest of Andalusia, and partly by the revolt of the Mahomedans of Granada, who out themselves under the protection of the Christian kings and became their vassals.

The fanaticism of the Mūwāḥḥādī did not prevent them from encouraging the establishment of Christians even in Fez, and after the battle of Las Navas de Tolosa they occasionally entered into alliances with the kings of Castile. In Africa they were successful in expelling the garrisons placed in some of the coast towns by the Norman kings of Sicily. The history of their decline differs from that of the Murābiṭ, whom they had displaced. They were not assailed by a great religious movement, but destroyed piecemeal by the revolt of tribes and districts. Their most effective enemies were the Beni Marīn (“Merinides”) who founded the next Moroccan dynasty, the sixth. The last representative of the line, Idrīs IV., “El Wāṭīk,” was reduced to the possession of Marrakesh, where he was murdered by a slave in 1260.

The amirs of the Mūwāḥḥādī Dynasty were as follows:—

Abd-el-Mūmin (1145); Yūsuf II. “Abu Ya’kūb” (1163); Ya’kūb I., “Abu Ya’ṣīf el Mānsūr” (1184); Mahomed III., “El Mānsūr” (1184-1190); “Abu Ya’kūb” (1214); “Abd-el-Wāḥīd, El Makhlūwī” (1223); “Abd-Allāh II., “Abu Mahomed” (1224); Yaḥyā V., “El Muṭāṣīm” (1226); Idrīs III., “El Māṭūm” (1229); Rashīd I., “Abd-el-Wāḥīd II.” (1232); “Ali IV., “Es-Sa’īd el Muṭadī” (1242); Omar I., “El Mortadā” (1248); Idrīs IV., “El Wāṭīk” (1260-1265).

( B. M. *; D. H.)

ALMON, JOHN (1737-1805), English political pamphleteer and publisher, was born at Liverpool on the 17th of December
1737. In early life he was apprenticed to a printer in his native town, and he also spent two years at sea. He came to London in 1758 and at once began a career which, if not important in itself, had a very important influence on the political history of the country. The Whig opposition, harried and harassed by the Government to an extent that threatened the total suppression of independence, continued a career of undiminished vigour in a number of able and brave correspondents, and found what they wanted in Almon. He had become personally known to the leaders through various publications of his own which had a great though transient popularity; the more important of these being The Conduct of a late Noble Commander [Lord George Sackville] Examined (1759); a Review of his late Majesty's Reign (1760); A Review of Mr Pitt's Administration (1761); and a number of letters on political subjects. The review of Pitt's administration passed through four editions, and secured for its author the friendship of Earl Temple, to whom it was dedicated. Brought thus into the counsels of the Whig party, he was persuaded in 1763 to open a bookseller's shop in Piccadilly, chiefly for the publication and sale of political pamphlets. This involved considerable personal risk, and though he generally received with every pamphlet a sum sufficient to secure him against all contingencies, he deserves the credit of having done much to secure the freedom of the press. The government strengthened his influence by their repressive measures. In 1765 the attorney-general moved to have him tried for the publication of an 'alleged libel,' but the prosecution failed; and in 1770, for merely selling a copy of the London Magazine containing Junius's celebrated "Letter to the King," he was sentenced by Lord Mansfield to pay a fine of ten marks and give security for his good behaviour. It was this trial that called forth the letter to Lord Mansfield, one of the bitterest of the Junius series. Almon himself published an account of the trial, and of course did not let slip the opportunity of reprinting the matter that had been the ground of indictment; but no further proceedings were taken against him. In 1774 Almon commenced the publication of his Parliamentary Register, a monthly report of the debates in parliament, and he also issued an abstract of the debates from 1742, when Richard Chandler's Reports ceased, to 1774. About the same time, having earned a competency, he retired to Boxmoor in Hertfordshire, though he still continued to write on political subjects. He became proprietor in 1784 of the General Advertiser, in the management of which he lost his fortune and was declared insolvent. To these calamities was added an imprisonment for libel. The claims of his creditors compelled him to leave the country, but after some years in France he was enabled to return to Boxmoor, where he lived for more than twenty years, publishing among other works an edition of Junius. His last work was an edition of Wilkes's correspondence, with a memoir (1805). He died on the 12th of December 1805. Almon's works, most of which appeared anonymously, have no great literary merit, but they are of very considerable value to the student of the political history of the period.

**ALMOND** (from the O. Fr. almande or alemande, late Lat. *amandula*, derived through a form *amingdola* from the Gr. *amygdalos*, an almond; the *al-* for *a-* is probably due to a confusion with the common English word having first dropped the *a-* as in the Italian form *mandola*; the English pronunciation *a-*mond and the modern French *amande* show the true form of the word). The almond is the fruit of *Amygdalus communis*, a plant belonging to the tribe Prunae of the natural order Rosaceae. The genus *Amygdalus* is very closely allied to *Prunus* (Plum, Cherry), in which it is sometimes merged; the distinction lies in the fruit, the soft pulp attached to the stone in the plum being replaced by a leathery separable coat in the almond. The tree appears to be a native of western Asia, Barbary and Montenegro; but it has been extensively distributed over the warm temperate region of the Old World. It ripens its fruit in the south of England. It is a tree of moderate size; the leaves are lanceolate, and serrated at the edges; and it flowers early in spring. The fruit is a drupe, having a downy outer coat, called the epicarp, which encloses the reticulated hard stony shell or endocarp. The seed is the kernel which is contained within these coverings. The shell-almonds of trade consist of the endocarps enclosing the seeds. The tree grows in Syria and Palestine; and is referred to in the Bible under the name of *Shaked*, meaning "hasten." The word Luz, which occurs in Genesis xxx. 37, and which has been translated hazel, is supposed to be another name for the almond. In Palestine the tree flowers in January, and this hardening of the period of flowering seems to be alluded to in Jeremiah i. 11, 12, where the Lord asks the prophet, "What seest thou?" and he replies, "The rod of an almond-tree;" and the Lord says, "Thou hast well seen, for I will hasten my word to perform it." In Ecclesiastes xii. 5 it is said the "almond-tree shall flourish." This has often been supposed to refer to the resemblance of the hoary locks of age to the flowers of the almond; but this exposition is not borne out by the facts of the case, inasmuch as the flowers of the almond are not white but pink. The passage is more probably intended to allude to the hastening or rapid approach of old age. The application of Shaked or hasten to the almond is similar to the use of the name "May" for the hawthorn, which usually flowers in that month in Britain. The rod of Aaron, mentioned in Numbers xvii., was taken from an almond-tree; and the Jews still carry rods of almond-blossom to the synagogues on great festival days. The fruit of the almond supplied a model for certain kinds of ornamental carved wood (Exodus xxv. 33, 34; xxxiii. 19, 20).

There are two forms of the plant, the one (with pink flowers) producing sweet, the other (with white flowers) bitter almonds. The kernel of the former contains a fixed oil and emulsion. It is used internally in medicine, and must not be adulterated with the bitter almond. The *Pulvis Amygdalae Compositus* of the British Pharmacopoeia consists of sweet almonds, sugar and gum acacia. It may be given in any dose. The *Mistura Amygdalae* contains one part of the above to eight of water; the dose is 1/2 to 1 oz.

The bitter almond is rather broader and shorter than the sweet almond and has a bitter taste. It contains about 50% of the fixed oil which also occurs in sweet almonds. It also contains a ferment *emulsin* which, in the presence of water, acts on a soluble glucoside, amygdalin, yielding glucose, prussic acid and the essential oil of bitter almonds or benzaldehyde (q.v.), which is not used in medicine. Bitter almonds may yield from 6 to 8% of prussic acid.

*Oleum Amygdalae*, the fixed oil, is prepared from either variety of almond. If intended for internal use, it must, however, be prepared only from sweet almonds. It is a glycerol ester, with slight odour and a nutty taste. It is almost insoluble in alcohol but readily soluble in chloroform. It is used for medicinal purposes and can be used as a pleasant substitute for olive oil. The pharmacopoeial preparations of the sweet almond are used only as vehicles for other drugs. The sweet almond itself, however, has a special dietetic value. It contains practically no starch and may therefore be made into flour for cakes and biscuits for patients suffering from *diabetes mellitus* or any other form of glycosuria. It is a nutritious and very pleasant food.

There are numerous commercial varieties of sweet almond, of which the most important is the *Prunus amygdalus* of Malaga. Valencia almonds are also valued. Fresh sweet almonds are nutritious and demulcent, but as the outer brown skin sometimes causes irritation of the alimentary canal, they are blanched by removal of this skin when used at dessert.

**ALMONER** (from Lat. *eleeosynarius*, through med. Lat. *almosynarius, almonarius*, and Fr. *almonier, aumônier*, &c., mod. Fr. *aumônie*), in the primitive sense, an officer in religious houses to whom belonged the management and distribution of the alms of the house. By the ancient canons all monasteries were to spend at least a tenth part of their income in alms to the poor, and all bishops were required to keep almoners. Almoners, as distinct from chaplains, appear early as attached to the court of the kings of France; but the title of grand almoner of France first appears in the reign of Charles VIII.
He was an important court official whose duties comprised the superintendence of the Chapel Royal and all the religious ceremonies of the court. He was a director of the great hospital for the blind (Quaife-Vings), and nominated the regius professors and readers in the Collège de France. The office was revived by Napoleon I., was abolished in 1836, and again created by Napoleon III.; it existed till 1876. In England, the royal almonry still forms a part of the sovereign's household, the officers being the hereditary grand almoner (the marquess of Exeter), the lord high almoner, the sub-almoner, and the secretary to the lord high almoner. The office of hereditary grand almoner is now merely titular. The lord high almoner is an ecclesiastical officer, usually a bishop, who had the rights to the forfeiture of all devouts (q.v.) and the goods of a felo de se, for distribution among the poor. He had, also, by virtue of an ancient custom, the power of giving the first dish from the king's table to whatever person he pleased, or, instead of it, alms in money, which custom is kept up by the lord high almoner distributing as many silver pennies as the sovereign has years of age to poor men and women on Maundy Thursday (q.v.).

ALMONRY (Lat. eleemosynarium, Fr. aumônerie, Ger. Almosenhaus), the name for the place or chamber where alms were distributed to the poor in churches or other ecclesiastical buildings. At Bishopstone church, Wiltshire, it is a sort of covered porch attached to the south transept, but not communicating with the interior of the church. The right side of the Cathedral the alms are said to have been distributed on stone tables, on each side, within the great porch. In large monastic establishments, as at Westminster, it seems to have been a separate building of some importance, either joining the gatehouse or near it, that the establishment might be disturbed as little as possible.

ALMORA, a town and district of British India, the chief town and administrative headquarters of the Kumaon division of the United Provinces, situated on a mountain-ridge of the Himalayas, 90 miles N.W. of Naini Tal. The town has a college called after Sir Henry Ramsay; a government high school; a Christian girls' school; and a large cantonment. The town was captured by the Gurkhas in 1790, who constructed a fort on the eastern extremity of the ridge. Another citadel, Fort Moira, is situated on the other extremity of the ridge. Almora is also celebrated as the scene of the British victory which terminated the war with Nepal in April 1814, and which resulted in the evacuation of Kumaon by the Gurkhas and the annexation of the province by the British.

The district of Almora was constituted in 1891, together with Naini Tal, by a redistribution of the two former districts of Kumaon and the Tarai. It lies among the mountains of Kumaon, between the upper waters of the Ganges and the Gogra, here called the Kali. Area, 5410 sq. m.; pop. (1901) 465,853, showing an increase of 13% during the decade. Tea is grown in the district, which includes the military sanatorium of Ranikhet. The nearest railway via Naini Tal is the extension of the Oudh and Rohilkhand line from near Bareilly to Kathgodam.

ALMORAVIDES (properly Murābīţīs, the name being corrupted through the Spanish), a Berber horde from the Sahara which, in the 11th century, founded the fourth dynasty in Morocco. By this dynasty the Moorish empire was extended over Tlemcen and a great part of Spain and Portugal. The name is derived from the Arab. Murābīt, a religious ascetic (see MARABOUT). The most powerful of the invading tribes was the Lamtūna ("veiled men") from the upper Niger, whose best-known representatives now are the Tuareg. They had been converted to Mahommedanism in the early times of the Arab conquest, but their knowledge of Islam did not go much beyond the formula of the creed—"there is no god but God, and Mahomet is the apostle of God,"—and they were ignorant of the law. About the year 1040 or a little earlier, one of their chiefs, Yahya ibn Thrāhīm, made the pilgrimage to Mecca. On his way home he attended the teachers of the mosque at Kairawān, in Tunisia, who soon learnt from him that his people knew little of the religion they were supposed to profess, and that though his will was good, his own ignorance was great. By the good offices of the theologians of Kairawān, one of whom was from Fez, Yahya was provided with a missionary, 'Abd-Allah ibn Yāzīn, a zealous partisan of the Mālekis, one of the four orthodox sects of Islam. His preaching was for long rejected by the Lamtūnas, so on the advice of the Almoravides he went to the desert. He there came in contact with the Almoravides and it was decided that he should go to the island of Tenerife, where he founded a riḥāfī or Moslem monastery, from which as a centre his influence spread. There was no element of heresy in his creed, which was mainly distinguished by a rigid formalism and strict obedience to the letter of the Koran and the orthodox tradition or Sunna. 'Abd-Allah imposed a penitential scourging on all converts as a purification, and enforced a regular system of discipline for every breach of the law, even on the chiefs. Under such directions the Murābīţīs were brought to excellent order. Their first military leader, Yahya ibn Omar, gave them a good military organization. Their main force was infantry, armed with javelins in the front ranks and pikes behind, formed into a phalanx and supported by camelmen and horsemen on the flanks. From the year 1053 the Murābīţīs began to impose their orthodox and puritanical religion on the Berber tribes of the desert, and on the pagan negroes. Yahya was killed in battle in 1056, but 'Abd-Allah, whose influence as a religious teacher was paramount, named his brother Abu Bakr as chief. Under him the Murābīţīs soon began to spread their power beyond the desert, and subjected the country of the Almoravides, the "Morocco City." He is distinguished as Yusuf I. In 1086 he conquered the kingdom of Tlemcen and founded the present city of that name, his rule extending as far east as Oran. In 1086 he was invited by the Mahommedan princes in Spain to defend them against Alphonso VI., king of Castile and Leon. In that year Yusuf passed the straits to Algeciras, and on the 23rd of October inflicted a severe defeat on the Christians at Zacaynas, or in Arabic, Zallākā, near Badajoz. He was debarred from following up his victory by trouble in Africa which he had to settle in person. When he returned to Spain in 1090 it was avowedly for the purpose of deposing the Mahommedan princes and annexing their states. He had in his favour the mass of the inhabitants, who were won out by the oppressive taxation imposed by their spendthrift rulers. Their religious teachers detested the native Mahommedan princes for their religious indifference, and gave Yusuf a fetva—or legal opinion—to the effect that he had good moral and religious right to dethrone the heterodox rulers who did not scruple to seek help from the Christians whose bad habits they had adopted. By 1094 he had removed them all, and though he regained little from the Christians except Valencia, he restored the Mahommedan power and gave a check to the reconquest of the country by the Christians. After friendly correspondence with the caliph at Bagdad, whom he acknowledged as Amir el Mūmīnin, "Prince of the Faithful," Yusuf in 1097 assumed the title of "Prince of the Resigned"—Amir el Muslimin. He died in 1106, when he was reputed to have reached the age of 100.
The Murābi dynasty was at its height at Yusuf's death, and the Moorish empire then included all North-West Africa as far as Algiers, and all Spain south of the Tagus, with the east coast as far as the mouth of the Ebro, and the Balearic Islands. Three years afterwards, under Yusuf's son and successor, 'Ali III., of Morocco, Madrid, Lisbon and Oporto were added, and Spain was again invaded in 1110 and 1111, but the tide had turned, the Moorish mission was the Argonese to recover Saragossa. In 1138 'Ali III. was defeated by Alphonso VII. of Castile and Leon, and in 1139 by Alphonso I. of Portugal, who thereby won his crown, and Lisbon was recovered by the Portuguese in 1147.

'Ali III. was a pious fanatic, who fasted and prayed while his empire fell to pieces under the combined action of his Christian foes in Spain and the agitation of the Muwahhids or "Almohades" (q.v.) in Morocco. After 'Ali's death in 1142, his son Tashfin lost ground rapidly before the Muwahhids, and in 1145 he was killed by a fall from a precipice while endeavouring to escape after a defeat near Oran. His two successors Ibrahim and Isâkh are mere names. The conquest of the city of Marrakesh by the Muwahhids in 1147 marked the fall of the dynasty, though fragments of the Murâbi dynasty continued to struggle in the Balearic Islands, and finally in Tunisia.

The allies of the Murâbi dynasty were as follows:—Yusuf I., bin Tashfin (1061); 'Ali III. (1106); Tashfin I. (1143); Ibrahim II. (1145); Isâkh (1146).

ALMQVIST, KARL JONAS LUDWIG (1703–1836), Swedish writer, was born at Stockholm in 1703. He became a student at Upsala, where his father was professor of theology, in 1708, and took his degree in 1715. He began life under highly favourable auspices, but losing the use of one of his eyes, in 1715, he threw up the position he held in the capital to lead a colony of friends to the wilds of Wermeland. This ideal Scandinavian life soon proved a failure; Almqvist found the pen easier to wield than the plough, and in 1728 he returned to Stockholm as a teacher in the new Elementary School there, of which he became rector in 1729. Now began his literary life; and after bringing out several educational works, he made himself suddenly famous by the publication of his great series of novels, called The Book of the Thorn-Rose (1832–1833). The career so begun developed with extraordinary rapidity, and he was soon in possession of a world-wide celebrity. His production, but the love and interest for his work was never lessened, and he was always ready to meet his admirers and to write for them. He died at Stockholm in 1836, leaving a mass of material which was afterwards published in a posthumous edition. His works are still read and admired, and his name is one of the best known in Swedish literature. His works are still read and admired, and his name is one of the best known in Swedish literature.

ALMUCE, or AMICE (O. Fr. amuce, O. Eng. amuce, amys, amze, &c., from late Lat. almuce, almucium, armuce, &c.), a hooded cape of fur, or fur-lined, worn as a choir vestment by canons. The first reference to it occurs in 1121, when the term is applied to a garment worn by a canon of St. Pons (1121) in the Diocese of Sens. The original word almucium is a philological mystery. The al is probably the Arabic article, since the word originated in the south (Sicilian almusia, Prov. almussa, Span. almucio, &c.), but the derivation of the second part of the word from a supposed old Teutonic term for cap—Ger. Mütze, Dutch Mutsche, Scot. mutch (New Eng. Dict. s.v. "Amice"); Diez, Wörterbuch der rom. Sprachen —is the exact reverse of the truth. The almuce was originally a head-covering only, worn by the clergy, but adopted also by the laity, and the German word Mütze, "cap," is later than the introduction of the almuce in church, and is derived from it (M. H. G., 13th century, almutz; 14th century, armes, aemus, &c.; 15th century, mutze, mütze, &c.). The word mutzen, to dock, cut off, which first appears in the 14th century, does not help much, though the name of another vestment akin to the almuce—the mozetta—has been by some traced to it through the Ital. mozze and muzo (but see below).

In numerous documents from the 12th to the 15th century the almucium is mentioned, occasionally as identical with the hood, but more often as a sort of cap distinct from it, e.g. in the decree of the council of Sens (1455)—non capitula et almucium vel bireta tenentes in capite. By the 14th century two types of almucium were distinguished: (1) a cap coming down just over the ears; (2) a hood-like cap falling over the back and shoulders. This latter was reserved for the more important canons, and was worn over surplice or rochet in choir. The introduction of the biretta (q.v.) in the 15th century tended to replace the use of the almuce as a head-covering, and the hood now became smaller, while the cape was enlarged still in some cases it fell below the elbows. Another form of almuce at this period covered the back, but left the shoulders and back of the head free, while in front it was elaborated into two stole-like ends. Almuces were occasionally made of silk or wool, but from the 15th century onward usually of fur, the hem being sometimes fringed with tails. Hence they were known in England as "grey amices" (from the ordinary colour of the fur), to distinguish them from the liturgical amice (q.v.). By the 16th century the almuce had become definitely established as the distinctive choir vestment of canons; but it had ceased to have any practical use, and was often only carried over the left arm as a symbol of office. The almuce has now been almost entirely superseded by the mozetta, but it is still worn at some cathedrals in France, e.g. Amiens and Chartres, at three churches in Rome, and in certain cathedrals elsewhere in Italy. The "grey amice" of the canons of St. Paul's at London was put down in 1540, the academic hood being substituted. It was again put down in 1559, and was
finally forbidden to the clergy of the English Church by the unratified canons of 1571 (Report of the sub-committee of Convocation, 1907). See du Cange, Glossarium, s. "Almucia"; Joseph Braun, Die liturgische Gewandung, p. 359, &c. (Freiburg im Breisgau, 1907); also the bibliography to the article VESTMENTS.

ALNAGE, or AULNAGE (from Fr. oenre, ell), the official supervision of the shape and quality of manufactured woollen cloth. It was first ordered in the reign of Richard I. that "woollen cloths, wherever they are made, shall be of the same width, to wit, of two ells within the lists, and of the same goodness in the middle and sides." This ordinance is usually known as the Assize of Arches or the Assize of Cloth. Article 35 of Magna Carta re-enacted the Assize of Cloth, in the reign of Edward I. an official called an "alnager" was appointed to enforce it. His duty was to measure each piece of cloth, and to affix a stamp to show that it was of the necessary quality and size. As, however, the diversity of the wool and the importation of cloths of various sizes from abroad made it impossible to maintain any specific standard of width, the rules as to size were repealed in 1353. The increased growth of the woollen trade, and the introduction of new and lighter drapery in the reign of Queen Elizabeth, combined with a revision of the standards, made a change inevitable. A statute was passed in 1669 creating the office of alnager of the new drapery, and defining the sizes to which cloth should be woven. The object of the statute was to prevent people being deceived by buying spurious woollen cloth, and to provide against fraud and imposition. Owing to the introduction of the alternative standard, a distinction arose between "broadcloth" (cloth of two yards) and "street" or "strait" (narrow cloth of one yard). The meaning now attached to broadcloth, however, is merely that of material of superior quality. Alnage duties and the office of alnager were abolished in 1699.

See W. J. Ashley, Economic History; and W. Cunningham, Growth of English Industry and Commerce.

ALNWICK, a market-town and the county-town of Northumberland, England, in the Berwick-upon-Tweed parliamentary division, 309 m. N. by W. from London, on a branch of the North Eastern railway. Pop. of urban district (1901) 6716. It is beautifully situated on the small river Aln, in a hilly district. Its history has left many marks. Dominating the town from an eminence above the south bank of the river stands the castle, held by the Percys since 1309, and long before this an important border stronghold. A gateway of c. 1350, a fine Norman arch of the 11th century, and the ancient well in the keep, are among noteworthy ancient portions; but the castle was extensively renovated and altered in the second half of the 18th century, while in 1854, when the lofty Prudhoe tower was built, a scheme of decoration in Italian style was adopted in the interior; so that the castle, though magnificent, has largely lost its historic character. It contains numerous fine examples of the works of Italian and other artists, and collections of British and Roman and Egyptian antiquities. In the beautiful park are a monument commemorating the capture of William the Lion of Scotland when besieging the town in 1174, two memorial towers, and a British stone chamber. Remains of the wall which formerly surrounded Alnwick are visible, and one of the four gates, the Bondgate, stands, dating from the early part of the 15th century. The church of St Michael has Norman remains, but is principally Perpendicular; it contains several ancient monuments and incised slabs. The modern church of St Paul has a fine east window of German stained glass. Within the confines of the park are ruins of two abbots. Alnwick Abbey was founded in the monastician foundation of 1147; only a gateway tower stands, but the ground-plan was excavated in 1884 and is outlined on the surface. At 3 m. from the town are more extensive remains of Hulme Abbey (1240), an early Carmelitte monastery. The long narrow church remains unroofed; there are also a gateway tower, and portions of the chapter-house and cloisters. The Norman chapel of the hospital of St Leonard, which, as well as Alnwick Abbey, was founded by Eustace Fitz John, completes the series of antiquities in Alnwick. In this interesting locality, however, there must be mentioned the mansion of Howick, built in the 18th century, in a fine situation near the coast to the N.E. Not far from this, overlooking the sea from a rocky cliff pierced by deep gullies, are the ruins of Dunstanburgh Castle; it dates from the 14th century, though the site was probably occupied as a stronghold from earlier times.

The chief industries are brewing, tobacco, snuff and fishing-tackle making, and corn milling. Alnwick is under an urban district council, but is a borough by prescription, and its freemen form a body corporate without authority over the affairs of the town. It is, however, required to pay, under an act of 1882, a sum not less than £300 out of the corporate property towards the upkeep of corporation schools. An ancient peculiar ceremony was attached until modern times to the making of freemen which elected were required to ride in procession to a large pool called Freeman's Well and there rush through the water. According to tradition the observance of this custom was enjoined by King John to punish the inhabitants, the king having lost his way and fallen into a bog owing to the neglected condition of the roads in the neighbourhood.

According to the Chronicle of Alnwick Abbey, the barony of Alnwick belonged before the Conquest to Gilbert Tyson, whose son Walter was killed at Hastings, and whose estates with his daughter were granted by the king to Ivo de Vescy, although this theory does not seem probable since Gilbert Tyson was certainly not a Saxon. In 1297 William de Vescy, a descendant of Ivo, dying without issue, left the barony to the bishop of Durham, who in 1309 sold it to Sir Henry Percy, in whose family it still continues. The town evidently grew up round the castle, which is said to have been built by Eustace FitzJohn about 1140. Tradition states that it received its borough charter from King John. However, Alnwick is first definitely mentioned as a borough in a charter given by William de Vescy in the reign of Henry II., by which the burgesses were to have common of pasture on Haydon Moor and to hold of him "as freely and quietly as the burgesses of Newcastle hold the king." This charter was confirmed by his grandson, William de Vescy, in an undated charter, and again by William, son of the latter William, in 1290. According to an inquiry of 1321 a market and fair were held in Alnwick from time immemorial. In 1297 Edward L, in addition, granted the bishop of Durham a market on Saturday, and a fair on the 17th of March and six following days. By charters of Henry VI. the burgesses received licence to enclose a part of the earthworks around Alnemouth, a market on Wednesday as well as Saturday, and two new fairs on the feast of SS Philip and James and St Lucy, and eight days following each. Naming and wearing were formerly the principal industries carried on in Alnwick, and in 1646 there were twenty-two tanneries there. Alnwick has never been represented in parliament.

See George Tate, The History of the Borough, Castle, and Barony of Alnwick, 2 vols. (Alnwick, 1866-1869); Victoria County History, Northumberland.

ALOE, a genus of plants belonging to the natural order Liliaceae, with about 90 species growing in the dry parts of Africa, especially Cape Colony, and in the mountains of tropical Africa. Members of the closely allied genera Gasteria and Haworthia, with a similar mode of growth, are also cultivated and popularly known as aloes. The plants are apparently stemless, bearing a rosette of large, thick, fleshy leaves, or have a shorter or longer (sometimes branched) stem, along which, or towards the end of which and its branches, the generally fleshy leaves are borne. They are much cultivated as ornamental plants, especially in public buildings and gardens, for a wall, or to have a base porte. The leaves are generally lance-shaped with a sharp apex and a spiny margin; but vary in colour from grey to bright green, and are sometimes striped or mottled. The rather small tubular yellow or red flowers are borne on simple or branchless leafless stems, and are generally densely clustered. The juice of the leaves of certain species yields aloes (see below). In some cases, as in Aloe venenasa, the juice is poisonous. The plant called American
Aloe, *Aloe americana* (g.v.), belongs to a different order, viz. Amaryllidaceae.

*Aloes* is a medicinal substance used as a purgative and produced from various species of aloe, such as *A. vera*, *vulgari*, *socotrina*, *chinenis*, and *Perryi*. Several kinds of aloe are distinguished in commerce—Barbadoes, Socotrine, hepatic, Indian, and Cape aoles. The first two are those commonly used for medicinal purposes. Aloe is the expressed juice of the leaves of the plant. When the leaves are cut the juice flows out, and is collected and evaporated. After the juice has been obtained, the leaves are sometimes boiled, so as to yield an inferior kind of aloe.

From these plants active principles termed *aleins* are extracted by water. According to W. A. Shenton, two classes are to be recognized: (1) Natalonais, which yield piccic and oxalic acids with nitric acid, and do not give a red coloration with nitric acid; and (2) Barbaloins, which yield alectic acid, $\text{CH}_3\text{H}_2\text{NO}_3$, chrysammic acid, $\text{CH}_3\text{H}_2\text{NO}_2$, piccic and oxalic acids with nitric acid, being reddened by this reagent. This second group may be divided into α-Barbaloins, obtained from Barbadoes aloe, and Barbaloins and Zanzibar aloe, reddened by ordinary nitric acid only when warmed in the cold, the former being as bright yellow scales, melting at 212°-222°; barbaloins, $\text{CH}_3\text{H}_2\text{O}$, forms yellow prismatic crystals. Aloe also contains a trace of volatile oil, to which its odor is due.

The dose is 3 to 5 grains, that of aloin being 5 to 2 grains. Aloe can be absorbed from a broken surface and will then cause purging. When given internally it increases the actual amount as well as the rate of flow of the bile. It hardly affects the small intestine, but markedly stimulates the muscular coat of the large intestine, causing purging in about fifteen hours. There is hardly any increase in the intestinal secretion, the drug being emphatically not a hydragogue cathartic. There is no doubt that its habitual use may be a factor in the formation of haemorrhoids; as in the case of all drugs that act powerfully on the lower part of the intestine, without simultaneously lowering the venous pressure by causing increase of secretion from the bowel. Aloe also tends to increase the menstrual flow and therefore belongs to the group of emmenagogues. Aloin is preferable to aloe for therapeutic purposes, as it causes less, if any, pain. It is a valuable drug in many forms of constipation, as its continual use does not, as a rule, lead to the necessity of enlarging the dose. Its combined action on the capital. The placenta uterine is of especial value in chlorosis, of which amenorrhoea is an almost constant symptom. The drug is obviously contra-indicated in pregnancy and when haemorrhoids are already present. Many well-known patent medicines consist essentially of aloe.

The lign-aloeus is quite different from the medicinal aloe. The word is used in the Bible (Numb. xxiv. 6), but as the trees usually supposed to be meant by this word are not native in Syria, it has been suggested that the LXX. reading in which the word does not occur is to be preferred. Lign-aloeus is the woody portion of the plant. It is a woody substance, not a resin. Dioscorides refers to it as *agallochon*, a wood brought from Arabia or India, which was odoriferous but with an astringent and bitter taste. This may be *Aquilaria agallochon*, a native of East India and China, which supplies the so-called eagle-wood or aloes-wood, which contains much resin and oil.

**ALÓIDAE** or **ALOIDEAE**, i.e. Otus and Ephialtes, in ancient Greek legend, the twin-sons of Poseidon by Ihphimeades, wife of Aloeus. They were celebrated for their extraordinary stature and strength. According to Homer (Od. xii. 316), they made war upon the Olympian gods and endeavoured to pile Pelion upon Ossa in order to storm heaven itself; had they reached the age of manhood, their attempt would have been successful, but Apollo destroyed them before their beards began to grow. In the *Iliad* (v. 365) Ares is imprisoned by them, but delivered by Hermes. Apollodoros says that they succeeded in piling Pelion upon Ossa. Another story is that they were presumptuous enough to seek Artemis and Hera in marriage, and that Artemis caused them to slay each other unintentionally on the island of Naxos, where they were afterwards worshipped as heroes. In punishment for their offences they were bound back to back with snakes to a pillar in the lower world (Hyginus, Fab. 28). The **Aloidae** (here connected with *Aloph*—threshing-floor) represent the spirits of the fertile earth and agriculture, conceived of by the Greeks as engaged in combat with the Olympian gods. In contrast to these legends, Pausanias tells us that they were regarded as the first to worship the Muse on Mount Helicon, while Diodorus represents them as historical personages, princes of Thessaly, who defeated the Thracians in Strongyle, i.e. Naxos, where they made themselves rulers, and subsequently slew one another in a quarrel.

**ALOMPRA, ALONG P’HOURA** (1711-1766), founder of the last Burmese dynasty, was born in 1711 at Mōtsahobo, a small village 50 m. north-west of Ava. Of humble origin, he had risen to be chief of his native village when the invasion of Burma by the king of Pegu in 1752 gave him the opportunity of attaining to the highest distinction. The whole country had tamely submitted to the invader, and the leading chiefs had taken the oaths of allegiance. Alompra, however, with a more independent spirit, not only contrived to regain possession of his village, but was so strong that he was invited by the king to punish him. Upon this the Burmese, to the number of a thousand, rallied to his standard and marched with him upon Ava, which was recovered from the invaders before the close of 1753. For several years he prosecuted the war with uniform success. In 1754 the Peguans, to avenge themselves for a severe defeat at Keoum-nuoum, slew the king of Burma, who was their prisoner. The son of the latter claimed the throne, and was supported by the tribe of Quois; but Alompra resisted, being determined to maintain his own supremacy. In 1755 Alompra founded the city of Rangoon. In 1757 he had established his position as one of the most powerful monarchs of the East by the invasion and conquest of Pegu. Before a year elapsed the Peguans revolted; but Alompra, with his usual promptitude, at once quelled the insurrection. The Europeans were suspected of having instigated the rising, and the massacre of the English at Negrais in October 1759 is supposed to have been approved by Alompra after the event, though there is no evidence that he ordered it. Against the Siamese, who were also suspected of having abetted the Peguan rebels, he proceeded more openly and severely. Entering their territory, he was just about to invest the capital, when he was surprised and engaged in battle with an illness which proved fatal on the 15th of May 1760. Alompra is one of the most remarkable figures in modern Oriental history. To undoubted military genius he added considerable political sagacity, and he deserves particular credit for his efforts to improve the administration of justice. His cruelty and deceitfulness were faults common to all Eastern despots.

**ALONE**. This adjective or adverb requires no definition for its meaning of "by oneself" or "solitary"; but its etymological history, as simply a combination of the words "all" and "one" is rather curious (compare the Ger. *allein*). "Lone" is merely a clipped form of the word, and so "lonely." The *New English Dictionary* traces the English word back to the year 1300.

**ÁLORA**, a town of southern Spain in the province of Málaga; 17 m. W.N.W. of Málaga, on the right bank of the river Guadalhorce, and on the Cordova-Málaga railway. Pop. (1900) 10,255. Álora, which is an ancient and picturesque town, with several Moorish ruins, occupies an outlying hill of the Sierra de Tolox, and overlooks a fertile valley where maize, sugar-cane and date-palms are cultivated. There are hot sulphurous springs in the town, which has also a number of mineral baths, and among the wealthy families from Málaga reside here in summer.

**ALOST** (Flem. Aalst), a town of Belgium, in the province of East Flanders, situated on the left bank of the Dender; the ancient capital of what was called Imperial Flanders. Pop. (1897) 28,717; (1904) 31,655. Flanders in the feudal period was a fief of the king of France—the count of Flanders being the first of the twelve peers of France; but there was a small strip
extending from Alost to the isles of Zeeland, designated Imperial Flanders, of which the count was the vassal of the Holy Roman emperor. Attached to the hôtel de ville is a fine belfry of the 13th century; but unfortunately it was seriously damaged by fire in 1879. In the church of St. Martin, dating from 1498 but unfinished, is a fine Rubens. The subject is St. Roch, the patron saint of lepers, and the colouring of the scaly skin of the leper in the foreground of the picture is generally regarded as one of the master's most striking effects. The work was painted to the order of the Brewers' Guild in 1612. (It is said) it was eight days. It was outside Alost that William Clinton, grandson of William the Conqueror, who was then endeavouring to establish his claims as count of Flanders, was mortally wounded in 1128. Of all the claims Alost possesses to fame perhaps the most remarkable is that Thierry Maartens (c. 1474) set up there one of the first printing presses in Europe. Alost is famous to-day for its hop gardens and linen-bleaching establishments. The meadows south of Alost are often covered with the linen undergoing the process of bleaching, which makes them assume the aspect of a whitish-blue carpet.

**ALP.** To the Swiss dwellers in the plains the term "the Alp" (q.v.) signifies the high snowy mountains which they see on the horizon, but to the dwellers in the valleys which nature has carved in the sides of those high mountains, the word alp means exclusively the summer pastures situated on the slopes above the valley, though below the snow-line. In fact such pastures are essential to the inhabitants of pastoral alpine districts, for the fodder to be obtained in the valley itself would not suffice to support the number of cattle which are required to afford sustenance to the inhabitants. Such mountain pastures, made use of only during the summer months, are of almost immemorial antiquity, cases occurring in 739, 868 and 909, while they are found in all parts of the Alpine chain. In France and Italy the system is badly managed, as also in Tirol (where the local name is Almen), where, too, these pastures have in the course of years been largely alienated by the valley inhabitants, and belong to large villages or small towns almost in the plains. But in Switzerland, and especially in the German-speaking mountain districts, the alps are the centre round which the entire pastoral life of the inhabitants turns. It is reckoned that in that country there are now about 4778 alps in all, the capital value of which is put at rather over £3,000,000. Of these alps about 45% are owned by the communities (exclusively or jointly) and 54% by individuals, the remaining 1% being the property of the state or a few great monasteries. In the case of the alps belonging to the Swiss communes, it must be borne in mind that "commune," here does not signify either Einwohnergemeinden or Bürgergemeinden, but a special class called Alpgemeinden (for instance in the well-known valley of Göschenen near Zürich, the Einwohnergemeinden, but see Alpgemeinden). These Alpgemeinden are composed of the persons who have a right to send cattle up to any particular alp in summer, this right being attached (in different places) either to certain plots of ground in the valley or certain houses in the village, or to certain persons. In any case the owners of an alp fix the greatest number of cattle which it can support during the summer without being permanently damaged. The plot of ground which can support a single cow (or 2 heifers, 3 calves or sheep, 4 pigs or 8 goats) is called a Küsstos (of which there are in, 389 in Switzerland), and it is in these terms that the productiveness of the alp is reckoned. Sometimes a particular alp, or a portion of it, is reserved exclusively to heifers and calves, or to goats (in this case it is the left portion). On each alp there are several sets of huts wherein live the cow-herds and cheese-makers (the latter are called Sennen or Frütters), the cattle being generally kept in the open. The cattle, with their attendants, shift from one to the other of these sets of huts, between the end of June and the end of September, making but one sojourn at the highest huts, but two at the lower. The proper name for these eights is Semmhütten or chalets, but the latter term is incorrectly applied also to houses in the village below. The milk given each day by each cow is entered in a book, and then made into butter and cheese, the cow-herds and cheese-makers having the right to a certain proportion of milk, butter and cheese (guenac from the commune), and receiving a small sum per head of cattle for looking after them. At the end of the season the net amount of cheese produced by milk from each cow is handed over to the owner of that particular cow, and is carried down by him to his home in the valley from the hut (a small building on four stone legs to secure the contents from mice) wherein the cheeses have been stored since they were made—this hut is called a Speicher. As the owners of Kühsässen (among them provisionally for others on another alp, or may hire them out (they can only sell them with the plot or house to which they are attached), the persons who in any given summer actually send cows up to an alp (these form the Betwieserschaft) need not necessarily be absolutely identical with the true owners of these rights or Betwieserschaft. Hay is never mown on the true alps save in spots which are not easily accessible to cattle (in very high spots it belongs to the mower, and is then called Wldhen), but hay-crops are made on the Mayens or Voralpen, the lowest pastures, situated between the homesteads and the true alps; these Voralpen are individual (not communal) property, though probably in olden days cut out of the true Alpen. In the winter the cattle consume the hay mown on these Voralpen (which, to a certain extent, are grazed in late spring and early autumn, that is, before and after the summer sojourn on the alps), either living in the huts on the Voralpen while they consume it, or in the stable attached to the dwelling-houses in the village; in the barn is stored the hay mown on the homestead and on the meadows near the village, which may belong to the owner of the cattle. The whole system is well organized and is well understood by the natives, though not always by strangers who visit the Alps in summer.

**ALPACA,** one of two domesticated breeds of South American camel-like ungulates, derived from the wild huancaco or guanaco. Alpacas are kept in large flocks which graze on the level heights of the Andes of southern Peru and northern Bolivia, at an elevation of from 14,000 to 16,000 ft. above the sea-level, throughout the year. They are not used as beasts of burden like llamas, but are valued only for their wool, of which the Indian blankets and ponchos are made. The colour is usually dark brown or black and the coat of great length, reaching nearly to the ground. In stature the alpaca (Lama huacanacos pacos) is considerably inferior to the llama, but has the same unpleasant habit of spitting. In the textile industries "alpaca" is a name given to two distinct things. It is primarily a term applied to the wool, or rather hair, obtained from the Peruvian alpaca. It is, however, more broadly applied to a style of fabric originally made from the alpaca wool but now frequently made from an allied type of wool, viz. mohair, Iceland, or even from lustrous English wool. In the trade, distinctions are made between alpacas and the several styles of mohairs and lustres, but so far as the general purchaser is concerned little or no distinction is (W. A. B. C.)
by skilled native women. The colour of the greater proportion of alpaca imported into the United Kingdom is black and brown, but there is also a fair proportion of white, grey and fawn. It is customary to mix these colours together, thus producing a curious ginger-coloured yarn, which upon being dyed black in the piece takes a fuller and deeper shade than can be obtained by piece-dyeing a solid-coloured wool. In physical structure alpaca is somewhat akin to hair, being very glossy, but its softness and fineness enable the spinner to produce satisfactory yarns with comparative ease.

The history of the manufacture of this wool into cloth is one of the romances of commerce. Undoubtedly the Indians of Peru employed this fibre in the manufacture of many styles of fabrics for centuries before its introduction into Europe as a commercial product. The first European importations would naturally be into Spain. Spain, however, transferred the fibre to Germany and France. Apparently alpaca yarn was spun in England for the first time about the year 1808. It does not appear to have made any headway, however, and alpaca wool was condemned as an unworkable material. In 1830 Benjamin Outram, of Greetsil, near Halifax, appears to have again attempted the spinning of this fibre, and for the second time alpaca was condemned. These two attempts to use alpaca were failures owing to the style of fabric into which the yarn was woven—a species of camlet. It was not until the introduction of cotton wovens into the Bradford trade about 1836 that the true qualities of alpaca could be developed in the fabric. Where the cotton warp and mohair weft plain-cloth came from is not known, but it was this simple yet ingenious structure which enabled Titus Salt (q.v.), then a young Bradford manufacturer, to utilize alpaca successfully. Bradford is still the great spinning and manufacturing centre for alpacas, large quantities of yarns and cloths being exported annually to the continent and to the United States, although the quantities naturally vary in accordance with the fashions in vogue, the typical "alpaca-fabric" being a very characteristic "dress-fabric."

The following statistics, taken from Hooper's *Statistin of the Woollen and Worsted Trades of the United Kingdom*, give an idea of the extent of the trade in yarns and fabrics of the alpaca type; unfortunately statistics for alpaca alone are not published.

**Alpaca, Vicuña, and Llama Wool imported into the United Kingdom.**

Owing to the success in the manufacture of the various styles of alpaca cloths attained by Sir Titus Salt and other Bradford manufacturers, a great demand for alpaca wool arose, and this demand could not be met by the native product, for there never seems to have been any appreciable increase in the number of alpacas available. Unsuccessful attempts were made to acclimate the alpaca goat in England, on the European continent and in Australia, and even to cross certain English breeds of sheep with the alpaca. There is, however, a cross between the alpaca and the llama—a true hybrid in every sense—producing a material placed upon the Liverpool market under the name "Huarizo." Crosses between the alpaca and vicuña have not proved satisfactory.

The preparing, combing, spinning, weaving and finishing of alpacas and mohairs are dealt with under Wool. (A. P. 1.)

**Alp Arslan,** or **AXAN, MAHMOMED BEN DA'UD** (1029–1072), the second sultan of the dynasty of Seljuk, in Persia, and great-grandson of Seljuk, the founder of the dynasty, was born in the year A.D. 1029 (421 of the Hegira). He assumed the name of Mahmomed when he embraced the Mussulman faith; and on account of his military prowess he obtained the surname Alp Arslan, which signifies "a valiant lion." He succeeded his father Da'ud as ruler of Khorasan in 1039, and his uncle Togrul Bey as sultan of Oran in 1063, and thus became sole monarch of Persia from the river Oxus to the Tigris. In consolidating his empire and subduing contending factions he was ably assisted by Niżām ul-Mulk, his vizier, one of the most eminent statesmen in early Mahomedan history. Peace and security being established in his dominions, he convoked an assembly of the states and declared his son Malik Shah his heir and successor. With the hope of acquiring immense booty in the rich church of St Basil in Caesarea, the capital of Cappadocia, he placed himself at the head of the Turkish cavalry, crossed the Ephratus and entered and plundered that city. He then marched into Armenia and seize Persia, which he in 1064, was finally subdued. In 1068 Alp Arslan invaded the Roman empire. The Emperor Romanus Diogenes, assuming the command in person, met the invaders in Cilicia. In three arduous campaigns, the two first of which were conducted by the emperor himself while the third was directed by Manuel Comnenus, the Turks were defeated in detail and finally (1070) driven across the Ephratus. In 1071 Romanus again took the field and advanced with 100,000 men, including a contingent of the Turkish tribe of the Uzes and of the French and Normans, under Ursul of Balliol, into Armenia. At Manzikert, on the Murad Tcheli, north of Lake Van, he was met by Alp Arslan; and the sultan having proposed terms of peace, which were scornfully rejected by the emperor, a battle took place in which the Greeks, after a terrible slaughter, were totally routed, a result due mainly to the rapid tactics of the Turkish cavalry. Romanus was taken prisoner and conducted into the presence of Alp Arslan, who treated him with generosity, and terms of peace having been agreed to, dismissed him, loaded with presents and respectfully attended by a military guard. The dominion of Alp Arslan now extended over the fairest part of Asia Minor; 1,500 princes or sons of princes surrounded his throne and 200,000 warriors were on his pay. He next prepared to march to the conquest of Turkestan, the original seat of his ancestors. With a powerful army he advanced to the banks of the Oxus. Before he could pass the river with safety it was necessary to subdue certain fortresses, one of which was for several days vigorously defended by the governor, Yusuf Kothual, a Kharizmian. He was, however, obliged to surrender and was carried a prisoner before the sultan, who condemned him to a cruel death. Yusuf, in desperation, drew his dagger and rushed upon the Alp. A piece of the orderer's hair fell upon the dagger. When the Alp raised his head, motioned to his guards not to interfere and drew his bow, but his foot slipped, the arrow glanced aside and he received the assassin's dagger in his breast. The wound proved mortal, and Alp Arslan expired a few hours after he received it, on the 15th of December 1072.

See Gibbon, *Decline and Fall of the Roman Empire*, edited by J. B. Bury (1893), vi. pp. 323 et seq., and authorities there cited.

**ALPENA,** a city and the county seat of Alpena county, Michigan, U.S.A., on Thunder Bay, a small arm of Lake Huron, at the mouth of Thunder Bay river, in the N.E. part of the lower peninsula. Pop. (1890) 11,283; (1900) 11,802, of whom 4193 were foreign-born; (1910 census) 12,706. It is served by the Detroit & Mackinac railway and by steamboat lines to Detroit and other ports. The city is built on sandy ground on both sides of the river and has a good harbour, which has been considerably
improved by the Federal government; in 1907 the maximum draft that could be carried over the shallowest part of the channel was 14 ft. There is good farming land in the vicinity and Alpena has lumber and shingle mills, pulp works, Portland cement manufactories and tanneries; in 1905 the city's factory products were valued at $2,905,385. In 1906 the commerce of the port, chiefly in lumber, cement, coal, cedar posts and ties, fodder and general merchandise, was valued at $3,015,894. Alpena occupies the site of an Indian burying-ground. A trading-post was established here in 1835, but the permanent settlement dates from 1838; in 1871 Alpena was chartered as a city.

**ALPENHORN, ALPHORN**, a musical instrument, consisting of a natural wooden horn of conical bore, having a cup-shaped mouthpiece, used by mountaineers in Switzerland and elsewhere. The tube is made of thin strips of birchwood soaked in water until they have become quite pliable; they are then wound into a tube of conical form from 4 to 8 ft. long, and neatly covered with bark. A cup-shaped mouthpiece carved out of a block of hard wood is added and the instrument is complete. The alpenhorn has no lateral openings and therefore gives the pure natural harmonic series of the open pipe. The harmonics are the more readily obtained by reason of the small diameter of the bore in relation to the length. An alpenhorn made at Rigi-Kulm, Schwyz, and now in the South Kensington Museum, measures 8 ft. in length and has a straight tube. The well-known *Rosen des Vaches* is the traditional melody of the alpenhorn, which has been immortalized by Beethoven in the finale of the Pastoral Symphony, where the music is generally rendered by a *cor anglais* (q.v.). Rossini has introduced the melody into his opera *William Tell*. Wagner, in the third act of Tristan and Isolde, was not entirely satisfied with the tone quality of the *cor anglais* for representing the natural pipe of the peasant. Having in his mind the timbre of the alpenhorn, he had a wooden horn made for him with one valve only and a small pear-shaped bell, which is used at Bayreuth (see Holz trompete). The Swiss alpenhorn varies in shape according to the locality, being curved near the bell in the Bernese Oberland. Michael Praetorius mentions the alpenhorn under the name of *holzeren trompet* in *Syntagma Musicum* (Wittenberg, 1615-1619).

**ALPES MARITIMES**, a department in the S.E. of France, formed in 1860 out of the county of Nice, to which were added the districts of Grasse (formerly in the department of the Var) and of Mentone (purchased from the prince of Monaco). Pop. (1906) 334,007. It is bounded N.E. and E. by Italy, S. by the Mediterranean Sea, and W. by the departments of the Var and the Basses Alpes, while its northern extremity forms a sharp angle between France and Italy. Its area is 1,444 sq. m., its greatest length is 59 m. and its greatest breadth 481 m. It is composed of the valley of the Var river (which is not lost completely within this department), together with those of its chief affluents, the Tinée and the Vésou.* The region of Grasse is hilly, but the rest of the department is mountainous, its loftiest point being the Mont Tinibus (994 ft.) at the head of the Tinée valley. Two singular features of the frontier of the department towards the east are only to be explained by historical reasons. One is that the central bit of the Roja valley is French, while the upper and lower parts of this valley are Italian; the reason is that those bits which are now Italian formed part of the county of Ventimiglia, and the central bit part of the county of Nice, which always belonged to France in 1860. The result is that the Italians are now unable to build a railway from Cuneo by the Col de Tenda and down the Roja valley direct to Ventimiglia. The other strange feature is that from near Isola in the upper Tinée valley southwards the political frontier does not coincide with the physical frontier, or the main watershed of the Alpine chain; the reason (it is said) is that in 1860 all the higher valleys of the Maritime Alps (on both sides of the watershed) were expressly excepted from the treaty of cession, in order that Victor Emmanuel II. might retain his right of chamois hunting in these parts. The department is divided into (1) the county of Nice, (2) the county of Grasse, and (3) the county of Puget Théniers, 72 cantons and 155 communes. It forms the bishopric of Nice (the first bishop certainly known is mentioned at the end of the 4th century), which till 1792 was in the ecclesiastical province of Embrun, then (1802) in that of Aix en Provence, next in that of Genoa (1814), and finally (1860) in that of Aix again. Its chief town is Nice. The broad-gauge railways in the department cover 56 m., including the line along the coast, while there are also 82 m. of narrow-gauge railways. The chief industries are distilleries for perfumes and manufacture of olive oil, of pottery and of tiles, besides a great commerce in cut flowers. To foreigners the department is best known for its health resorts, Nice, Cannes, Mentone, Antibes and Beaulieu, while other important towns are Grasse and Puget Théniers.

(W. A. B. C.)

**ALPHA and OMEGA** (A and Ω), the first and last letters of the Greek alphabet, corresponding to the *Aleph* and *Taw* of the Hebrew. They are used as a designation of Himself by the speaker in Rev.1.8; xxii.6; xxi.13. The first and last letters of the Hebrew alphabet are used in Rabbinic writings in a similar way. We find also "the seal of God is Emeth," Emeth (truth) being composed of the first, middle and last letters of the Hebrew alphabet. God is thus represented as the beginning, middle and end of all things (see the Jewish Encyclopaedia, s.v.).

**ALPHABET** (see also Writing). By the word *alphabet*, derived from the Greek names for the first two letters—alpha and beta—of the Greek alphabet, is meant a series of conventional symbols each indicating a single sound or combination of sounds. The ideal alphabet would indicate one sound by one symbol, and not more than one sound by the same symbol. Symbols for a combination of sounds are not necessary, though they may be convenient as abbreviations. In the writing of some languages, e.g. Sanskrit, such abbreviations are carried to an extreme; in most Greek MSS. also they are of very frequent occurrence. These contractions, however, may prove too great a strain upon the eyesight or the memory, and thus become a hindrance instead of a help. This was apparently the case in Greek, for though the early printers cast types for all the contractions of the Greek MSS. these have now with one consent been given up. A consonant like ξ can only be regarded as an abbreviation; it expresses nothing that cannot as well be expressed by χ or ξ, both of which combinations in different situations it may represent (see Ξ). No alphabet corresponds exactly to the ideal which we have postulated, nor if it did, would it continue long so to do, as the sounds of most languages are continually changing. Hence in the case of dead languages or past forms of living languages, it is often very difficult to define with precision what the sounds of the past epoch were. The study of the history of English pronunciation occupied the late Dr A. J. Ellis for a large part of his life, and the results fill five large volumes. The sounds which are most difficult to define exactly are the vowels; a great many may be indicated by the same symbol. In the English Dictionary no fewer than thirteen different nuances of vowel sound are distinguished under the symbol A alone. In English, moreover, the vowel sounds tend to become diphthongs, so that the symbol for the simple sound tends to become the symbol for that combination which we call a diphthong. Thus the long i in ride, wine, &c., has become the diphthong ai, and the name of the symbol I is itself so pronounced. In familiar, if vulgar, dialects, A tends in the same direction. In the "cockney" dialect, really the dialect of Essex but now no less familiar in Cambridge and Middlesex, the i sound of ii is represented by ai. In American "Tennessee time," while a has become ai in Kate, pane, &c. In all southern English a becomes more rounded while it is being pronounced, so that it ends with a slight w sound. In the vulgar dialect already mentioned, the sound begins as a more open sound than in the cultivated pronunciation, so that no is really pronounced as *now*. It is clear, therefore, that the best alphabet would not long indicate very precisely the sounds which it was intended to represent. See Phonetics.

But the history of the alphabet shows that at no time has it represented any European language with much precision because it was an importation adapted in a somewhat rough and ready fashion to represent sounds different from those which it represented outside Europe. Wherever the alphabet may have
ALPHABET

originated, there seems no doubt that its first importation in a form closely resembling that with which we are familiar in modern times was from the Phoenicians to the Greeks. The Phoenicians were certainly using it with freedom in the 9th century B.C.; with so much freedom, indeed, that they must have been in possession of it for a considerable time before we can trace it. With the materials available up to August 1910 it would be idle here to attempt to trace its earlier history. Meanwhile, Capitoline inscriptions in Cappadocia, Assyria and Egypt were then only at their beginnings and any statement was liable to be quickly disproved by the appearance of new evidence. The prevalent theory, universally accepted till a few years ago, was that of Vicomte Emmanuel de Rouge, first propounded to the Académie des Inscriptions in 1859, but unnoticed by the world at large till republished, after de Rouge’s death, by his son in 1874. According to this view the alphabet was borrowed by the Phoenicians from the cursive (hieratic) form of Egyptian hieroglyphics. The resemblances between some Egyptian symbols and some symbols of the Phoenician alphabet are striking; in other cases the differences are no less remarkable. As a matter of fact the Egyptians might have passed about thirty-five centuries B.C. from the picture writing of hieroglyphs to genuine alphabetic signs.1 They did not, however, profit by their discovery, because, amongst the Egyptians, writing was clearly a mystery in both senses—only possible at that period for masters in the craft, and also something, like the writing of medical prescriptions at the present day in Latin, which was not to be made too easily intelligible to the common people. At all periods, moreover, hieroglyphic writing was a branch of divination to which only a privileged few had access. The Egyptians, like the modern Turk, resented too much lucidity, and liked its literary compositions to be veiled in a certain obscurity. The alphabet devised by the Egyptians consisted of twenty-four letters. Egyptologists are at variance on the question whether this alphabet was the original, or had any influence upon the development of the Phoenician alphabet. “With the papyrus paper,” says Professor Breasted,2 “the hand customarily written upon it in Egypt now made its way into Phoenicia, where before the 10th century B.C. it developed into an alphabet of consonants, which was quickly transmitted to the Ionian Greeks and thence to Europe.” On the other hand, Professor Spiegelberg,3 writing soon after Professor Breasted, says that investigation has not as yet furnished proof that the Phoenician alphabet is of Egyptian origin, though he admits that in some respects the development of the two alphabets, both without vowel signs, is curiously parallel.

The most recent view is that of Dr A. J. Evans, who argues ingeniously that the alphabet was taken over from Crete by the "Cretethites and Pelethites," or Phylaeans, who established themselves on the coast of Palestine.4 From there it passed to the Phoenicians, who were their near neighbours, if not their kinsfolk. Symbols like the letters of the alphabet have been found in European soil painted upon pebbles belonging to a stratum between the Palaeolithic and Neolithic age.5 This was in France at Mas d’Azil on the left bank of the Arize. Elsewhere several series of such symbols resembling inscriptions have been found scratched on bones of the same period. For the history of writing these may be important, but for the history of the alphabet itself, they are not in question. The alphabet may have originated as Dr Evans thinks, but at present the proof is not conclusive. The Greek names of the letters, their forms, and the order of the symbols show that the Greek alphabet as we know it must have been imported by or from a Semitic people, and there is no evidence to contradict ancient tradition that this people was the Phoenicians. The view proposed by Deecke6 in 1877, that the Phoenician alphabet had developed out of the late Assyrian cuneiform, never met with much acceptance and has really no evidence in its favour.

The earliest alphabetic document which can be dated with comparative certainty is the famous Moabite stone, which was discovered in 1868, and after a controversy between rival claimants which led to its being broken in pieces by the Arabs, ultimately reached O. G. S. Crawford in the Louvre where in a restored form it remained.7

The long inscription upon these fragments of Mesha, king of Moab, who had been a tributary of Ahab, king of Israel, and rebelled after his death (I Kings iii. 4, 5). Though the chronology of the period is somewhat uncertain, the date must be in the first half of the 9th century B.C. It is to be remembered, however, that important as this monument is for the development of the alphabet, and because it can be dated with tolerable accuracy, the dialect and alphabet of Moab are not in themselves proof for the Phoenician forms which influenced the peoples of the Aegean, and through them Western Europe. The fragment of a bronze bowl discovered in Cyprus in 1876, which bears round its edge an inscription dedicating it to Baal-Lebanon as a gift from a servant of Hiram, king of the Sidonians, is probably the oldest Phoenician document which we possess. This bowl, though perhaps a little earlier than the Moabite stone, in all probability is not more than a century older, while some authorities think it is even later. The earliest alphabet consisted of twenty-two letters, and bears a very close resemblance to the earliest Greek alphabet from A to T. The symbols in the Greek alphabet #, $, ¥, @, and from ¥ to @, are not found in the Phoenician alphabet.

As already mentioned, the twenty-two symbols of the Phoenician alphabet indicate consonantal sounds only. Greek did not possess so many consonants. The Phoenician alphabet possessed many more aspirates than were required in Greek, which tended more and more to drop all its aspirates. Before history begins it had also lost, except sporadically in out-of-the-way dialects, the semi-vowel i (approximately English y). It therefore made the aspirates A, E, O and the semi-vowel i into vowels, and apparently converted the semi-vowel ¥ into the vowel ¥ = u, which it placed at the end of the alphabet and substituted for it as the sixth symbol of the alphabet the letter F with the old value of u. The superfluous sibilants were also adapted in various ways (see below).

The discovery of a large number of very archaic inscriptions in the island of Thera, which was made by Freiherr Hiller von Gärtringen in 1869, has shown that the earliest Greek alphabet was even more like the Phoenician than had been heretofore believed. The symbol for θ in Thera (δ) is nearer than any previously known to the Semitic letter (ς) though, as not infrequently happens in the transference of a symbol from one people to another, its position is inverted—a fate which in this alphabet has befallen also L (Semitic l, Thera 1), and possibly e (Semitic v, Thera M). The era of excavation initiated by Dr Schliemann on the grand scale has increased our knowledge of Greek inscriptions beyond anything that was earlier dreamt of. Besides the excavations of Athens, Delos, Epidaurus and Delphi, the results of which are most important for the 5th century B.C. and later, the exploration of the sites of Olympia, of the Heraeum near Argos, of Naucratis in Egypt, and of various Cretan towns (above all the ancient Gortyn), has revolutionized our knowledge of the archaic alphabets of Greece. We can moreover how long and laborious was the process by which the Greeks attained to uniformity in writing and in numeration. In no field, perhaps, was the centrifugal tendency of the Greeks more persistent than in such matters. In numeration, indeed, uniformity was not attained till at least the 2nd century of the Christian era. The differentiation of the local alphabets is found

3 Scripüa Minos, l. (1899), § 16, p. 108 ff.
4 E. Pette, L'Anthropologie, xvi. (1905) pp. 8-9. The apparent inscriptions of this period are conveniently collected and figured together in Dechelette's Manuel d'archéologie préhistorique celtique et gallo-romaine, i. (1908) p. 235.
ALPHABET

from the very beginning of our records. Unfortunately, as yet no record is preserved which can with any probability be dated earlier than the 7th century B.C., and the Phoenician influence had already then many times been borrowed. How long this influence lasted we cannot tell. If in Crete a system resembling that of an entirely different nature had been developed seven or eight centuries before, there must have been some very important reason for the entire abandonment of the old method and the adoption of a new. In Crete, at least, the excavations show that the old civilization must have ended in a social and political cataclysm. The magnificent palace of Minos—there seems no reason to withhold from it the name of the great prince whom Thucydides recognized as the first to hold the empire of the seas—perished by the flames, and that part of its treasures plundered beforehand of everything that a conqueror would regard as of value. The Greeks of the Greek history which we know that could have produced this change was that of the Dorian conquest. As everywhere in the Peloponnesse, except at Argos, there seems to have been a sudden break with the earlier civilization, which can have been occasioned only by the semi-barbarous Dorian tribes, so the same result seems to have followed from the same cause in Thera. The Dorians apparently were without an alphabet, and consequently when Phoenician traders and pirates occupied the place left vacant by the Dorian invaders, they had to use the alphabet of the inhabitants, people of the island, and of the sea coasts generally, adopted from them the Phoenician alphabet. The Greeks who migrated to Cyprus, possibly as the result of the Dorian invasion, adopted a syllabary, not an alphabet (see Plate; also WRITING). That the alphabet was borrowed and adapted independently by different places not widely separated, and that the earliest Greek alphabets did not spread from one or a few centres in Greek lands, seem clear (a) from the different Greek sounds for which the Phoenician symbols were utilized; (b) from the different names of the letter, and (c) from the lengthening of the vowel sound as the result of the loss of a consonant, as in εὐαγγέλιος for εὐαγγέλα:. The short ơ sound is represented by B; ơ is found at Corinth in its oldest form (έι), and also as Σ, while in Thera it is ơ. In Thera the ơ sound of digamma (Ϝ) was entirely lost, and therefore is not represented. Both Thera and Corinth employ in the earliest inscriptions Η for ή, not ơ, though in both alphabets the ordinary use as ơ is adopted, no doubt through the influence of trade with other states. On the other hand, at Cleonae, which is distant not more than 8 or 9 m. from Corinth, an ancient inscription written βερούσηδον has recently been discovered, which shows that though Cleonae for B wrote δ, like the Corinthian Ι, and, at Corinth, wrote Β for a vowel sound, the vowel thus represented was no longer ơ, but long ơ (ε and η) as at Corinth, but η only, as in ΤΡΩΜΑ. ΙΜΑ (γυναικείον). Here αριστεύομαι represents ε, and the spurious diphthong ων is represented by ι. See also below.

Regarding three other questions controversy still rages. These are: (1) how Greek utilized the four sibilants (Sh, Samech, Zain and Zade), which it took over from the Phoenician; (2) what was the method of development in the symbols for ơ, η, ω (the history of η belongs to both heads); (3) the history of the symbol for the digamma F. In the Phoenician alphabet Α was the seventh letter, occupying the same position and having the same form approximately (ι) as the early Greek Ζ, while in pronunciation it was a voiced s-sound; Samech (ש) followed the symbol for η and was the ordinary s-sound, though, as we have seen, it is in different Greek states at the earliest period ι as well. While the letter that we called Zade (צ), which was a strong palatal ơ, though in pronunciation very close to the Greek ζ, while lastly Χ followed the symbol for ơ, and was an sh-sound. The Greek name for the sibilant (συμμάχον) may simply mean the letter and the syllable, and according to some authorities, however, it is held that it is a corruption of a Canaanite name. Unfortunately, it is not clear how many sibilants were distinguished in Greek pronunciation, nor over what areas a particular pronunciation prevailed. There is, however, considerable evidence in support of the view that Greek σσ represented the sound arising from ςς, ις, ις, ις, ις, ις pronounced as sh (ι), while representing γδ, δγ, ơγ, ơγ, γδ om spelled in some districts ις ις.

An inscription of Philistia, a city of the ancient Philistines on the coast of the Mediterranean Sea, the coast of the old Palestine, while the coins of Mesembria in Thrace show regularly META and МЕТΑΜΠΙΑΝΩΝ, where T represents the sound which resulted from the fusion of ςς, and which appears in Homer as in μιος, while in later Greek it becomes μιος. This symbol Ơ is in all probability the early form of the letter which was known to the Greeks as Σ (ς) and in modern times as Sampi, and which is utilized as the numeral for 900 in the shape ፹. According to Herodotus (v. 139), San was only the Dorian name for the letter which the Ionians called Sigma. This would bring it into connexion with the Greek σ, which, through a right angle, is possibly the Greek Σ, though some forms of Zade on old Hebrew coins and gems (כ כ) equally resemble the Greek letter. From other forms of Sade, however, the other early form of σ, viz. M, is derived. As it was derived, the sound of the letter assimilated in Greek to the names θ and θα becomes θ, though the form is that of Zain; the name of Samech is possibly the origin of Sigma, while the form of Sampi is that of T which has not taken over a Phoenician name. It is probable that the form Ῥ is an abbreviation in writing from right to left of the earlier Μ, and Μ of the four strokes. That the confusion of the sibilants was not confined to the Greeks only, but that pronunciation varied within a small area even among the Semitic stock, is shown by the difficulty which the Ephraimites found in pronouncing "shibboleth." (Judges xii. 6).

For the history of the additional symbols which are not Phoenician, we must begin with the alphabet used by the Babylonians, who he suggests a possible Babylonian origin. Different views with regard to some of these symbols are expressed by Liddzsbarizi, Ephemerides für semitische Epigraphik, ii (1906). The earliest tradition of the names is discussed by Noldeke in his Beiträge zur semitischen Sprachwissenschaft (1904), pp. 124 ff.

1 In an excellent summary of the different views held as to the origin of the alphabet (Journal of the American Oriental Society, vol. ivii., p. 99.) Mr. Streeter expresses (pp. 191 ff.) that the best test is the etymology of the names of the letters. He shows that "twelve of the letter-names are words with meanings [in the northern dialects of Semitic], all of them indicating simple objects, six of the twelve being parts of the body. The objects denoted by the other six names—ơx, house, valve of a door, water, fish and mark or cross—clearly do not belong to any people in a nomadic state, but to a settled, town-abiding population. Six of the letter-names are not words in any known tongue, and appear to be syllables only. Four letter-names are triliterals, and resemble in form their Semitic words." As 11 of the 12 which have been analyzed are written in the Assyrian syllabary, he suggests a possible Babylonian origin. Different views with regard to some of these symbols are expressed by Liddzsbarizi, Ephemerides für semitische Epigraphik, ii (1906). The earliest tradition of the names is discussed by Noldeke in his Beiträge zur semitischen Sprachwissenschaft (1904), pp. 124 ff.

2 See, for example, the tables at the end of Roberts’s Introductory to Greek Epigraphy (1887; or Kirchhoff’s Untersuchungen über das Griechische Alphabet, 4th ed. 1887; or Larfeld’s Handbuch der griechischen Epigraphik, vol. i. (1907).

4 See Witton, in American Journal of Philology, xix. pp. 420 ff., and Lagercrantz, Zur griechischen Lautgeschichte (Upsala, 1898). See also Poat, "The sade and Sampi" (Journal of Hellenic Studies, xxi., pp. 69 ff., and xxv. pp. 69 ff.; or see also, xxvi. pp. 69 ff., and xxv. pp. 69 ff.). The latter are uncertainly raised by A. Gercke, "Zur Geschichte des ältesten griechischen Alphabets" (Hermes, xii., 1906, pp. 540 ff.).
The alphabet is a system of writing using a set of distinct symbols, letters, or characters to represent words or concepts. It is the foundation of many modern alphabets, which are used to write a wide variety of languages. The development of the alphabet is often attributed to the ancient Greeks, who borrowed the Phoenician alphabet and adapted it to their own needs. However, the origins of the alphabet are thought to date back to the ancient Near East, where several scripts were developed that incorporated the notation of vowels. 

The Greeks developed a system of notating vowels, which is known as the koiné Greek alphabet. This system used certain letters to represent vowels, which were often not written in everyday writing. The system was later adapted by the Romans, who developed their own version of the alphabet, which is still used today.

The development of the alphabet was a significant step in the development of literacy, as it provided a way for people to record and communicate ideas. It also played a crucial role in the development of science and technology, as it allowed for the systematic recording of knowledge and the sharing of ideas.

The alphabet has been adapted and modified over time, and today there are many different versions of the alphabet used in different parts of the world. Some alphabets include additional characters to represent sounds that do not exist in the English language, while others have fewer characters than the standard 26-letter English alphabet.

In conclusion, the alphabet is a fundamental tool for communication and has played a key role in the advancement of human civilization. The development of the alphabet, and the various forms that have evolved over time, continue to be a subject of study and fascination for scholars and language enthusiasts alike.
is remarkable. In the Dervós inscription the perfect of jacto is feecd; here it is a reduplicated form with the same vowel as the present. The spelling also is interesting. The symbol K is still in ordinary use, and not merely used for abbreviations as in the classical age. But most remarkable is the representation of Latin F by FH. The reason for this is clear. The value of F in the Greek alphabet is ω and not f as in Latin. Greek had no sound corresponding to Latin F, consequently an attempt is made by combining F and H to indicate the difference of sound. Etruscan uses FH in the same way. As Latin, however, made the symbol V indicate not only the vowel sound ω, but also the consonant sound z (i.e. English v), the sign for the digamma F was a marked variant of a symbol representing a sound which did not exist in Greek, the second element came to be left out in writing. Thus F came to be the representative of the unvoiced labiodental spirant instead of that for the bilabial voiced spirant. Whether the form jefaked was ever good Latin in Rome may be doubted, for the Romans, in spite of the few miles that separate Praenestra from Rome, were inclined to sneer at the pronunciation and idiom of the Praenestines (cf. Plautus, Trin. 609, True. 691; Quintilian i. 5, 56). (a) The last, and in some respects the most important, of these factors of backwriting is closely connected with the ancient sound FH is obviously still employed in the Comitium at the north-west corner of the Roman Forum. It is engraved upon the four sides and one bevelled edge of a pillar, the top of which has been broken off. As the writing is σωρωροφόθι, beginning at the bottom of the pillar and running upwards and down again, no single line of the inscription is complete. Probably more than half the pillar is lost, so that it is not possible to make out the sense with certainty. The inscription is probably not older than that on the fibula from Praeneste, but has the additional interest of being undoubtedly couched in the Latin of Rome. The surviving portion of the inscription contains examples of all the letters of the early alphabet, though the forms of F and B are fragmentary and doubtful. As in the Praeneste inscription, the alphabet is still the western (Chalcidian) alphabet. K is still in use as an ordinary consonant, and not limited to a symbol for abbreviations as in the classical period. The rounded form of γ is found with the value of G in RECEI, which is probably the dative of rex. H has still the closed form, M has the five-stroke form, S is the three-stroke, tending to become rounded. R appears in the Greek form without a tail, and V and Y are both found for the same sound. The manner of writing up and down instead of from right to left is a feature of the stone itself appropriate to a surface which is of considerable length, but comparatively narrow, a connected sense being thus much easier to observe than in writing across a narrow surface where, as in the gravestones of Melos, three lines are required for a single word. The form of the monument corresponds to that which we are told was given to the revolving wooden pillars on which the laws of Solon were painted. That the writing of Solon's laws, which was βωρωροφόθι, was also vertical is rendered probable by the phrase κάραθες νύμοι in Demostenes' speech Against Aristocrates, § 28, for which Harpocrates is unable to supply a satisfactory explanation.

The differentiation of the Roman alphabet from the Greek is brought about (a) by utilizing the digamma for the unvoiced labiodental spirant F; (b) by dropping out the aspirates θ, ϑ, χ (in the Chalcidian alphabet, whence the Roman is derived) from the alphabet proper and employing them only as numerals; (c) by being gradually transformed into symbols for a which was not only a vowel (as in Latin) but unvoiced (as in Etruscan) alphabet. K in time passed out of use except as an abbreviation, its place being taken by C, which, as we have seen, is in the earliest inscription still g. Three points here require explanation: (1) Why K fell into disuse; (2) why C took the place of K? (3) why the new symbol G was put in the place of the lost Z. It is clear that C must have become an equivalent of K before the latter fell out of use. There is some evidence which seems to point to a pronunciation of the voiced mutes which, like the South German mutes, were before the Latin mutes, and consequently from the unvoiced mutes, so that confusion might easily arise. The Etruscans, who were separated from the Romans only by the Tiber, gradually lost the voiced mutes, but another factor, perhaps more potent, C and G, as k was frequently written, would enable them to fused in writing, and Professor Hempel (Transactions of the American Philological Association for 1895, pp. 24 f.) shows that the Chalcidian form of FH was a development of the same sound. Owing to this confusion, the new symbol G, differentiated from C, took the place of the useless X. In abbreviations, however, C remained as before in the value of G, as in the names Lahmann, Osenus, Abellanus, where they are used as a republic for in transliterating Greek words containing v and ｧ.

The dialect which was most closely akin to Latin was Faliscan. The men of Falerii, however, occasionally took the side of the Etruscans in wars with Rome, and it is clear that the civilization of the old Falerii, destroyed for its rebellion in 241 B.C., was Etruscan and not Roman in character. Peculiar to this alphabet is the form and F. Much more important than the scanty remains of Faliscan is the Oscan alphabet. The history of this alphabet is different from that of Rome. It is certain from the symbols which they develop or drop that the people of Campania and Samnium borrowed their alphabet and language from the Etruscans from the 8th to the 5th century B.C. Probably the Punics came to Campania had reached a higher stage of civilization than Rome. Latin thereby, the difficulty of reading the ancient letters, and our knowledge of the official alphabet outside Capua, and at a later period Pompeii, is practically confined to two important inscriptions, the tabula Agonemis, now in the British Museum, and the Aedive of Abellanus, which is preserved in the Seminary at Nola. Of Etruscan origin also is the Umbrian alphabet, represented first and foremost in the bronze tablets from Gubbio (the Igurium). The Umbrian alphabet is very closely alike the Latin, and of Chalcidian origin. That it was borrowed at an early date is shown by the fact that most of its numerous inscriptions run from right to left, though some are written βωρωροφόθι. That it too over the whole Chalcidian alphabet is rendered probable by the survival in Umbrian and Oscan, its daughter alphabets, of forms which are not found in Etruscan itself. This mysterious language, despite the existence of more than 6000 inscriptions, and the discussion in writing in Sabinus and his works, remains as obscure as ever, but apparently it underwent very great phonetic changes at an early period, so that the voiced mutes B, D, G disappeared. Of the existence of the vowel O there is no evidence. If it ever existed in Etruscan, it had been lost before the Oscans and Umbrians borrowed their alphabets. On the other hand, both of their alphabets preserve B and Umbrian G in the form ƙ. Etruscan also retained this symbol in the form ã, and utilized it exactly as Latin did to replace Χ. Oscan, in order to represent D, introduced later a form ȃ, thus creating confusion between the symbols for d and r. This form was adopted for G by the Osans and Umbrians. Þ had also disappeared as a symbol for r, although it is also found on Etruscan inscriptions. For the Greek digamma Etruscan used both ã and ã, but the former only was borrowed by the other languages. Etruscan, like Latin, used ð (from right to left) to represent the sound of Latin F, but, unlike Latin, adopted ñ as the single symbol. This form it then wrote as two lozenge γ, whence developed a later sign, B, which is used also in Umbrian and Oscan. As the old digamma was kept, this new sign was placed after those borrowed from the Chalcidian alphabet. Similarly ð was placed after D and Z, for the first time in Etruscan inscriptions. For B was still closed Ë, which Etruscan passed on to Oscan, while Umbrian modified it to Ø. The form m has five strokes; from a later form the Oscan form was borrowed. Of the two sibilants, M and Ø, or S, Oscan adopted only Ø, Umbrian both M and the rounded form, Ø, is found on Etruscan inscriptions, but not in the alphabet series preserved; neither Umbrian nor Oscan has this form. T appears in Etruscan as ƙ, γ, and χ; of these Umbrian borrowed the first two. The two last were borrowed, the people of Campania, and took over the Greek aspirates, θ, ϑ, χ, in their Chalcidian forms; θ survives in Umbrian as O, the others naturally disappear. Both Umbrian and Oscan devised two new symbols. Umbrian and
took over from Etruscan perhaps the sign Q, but gave it the new value of a spirant which developed out of an earlier d-sound, which is written in the Latin alphabet with Z. The second Umbrian symbol was Q, which was the representative of an ɛ-sound developed by palatalization of an earlier k. In Osca, which had an o-sound, but not ɛ-sound, and in which the letter K was used to represent a voiceless plosive, the symbol Q was used for the logs of the symbol for u - V. This, however, is found only in the best-written documents, and on some materials the dot cannot be distinguished. The symbol θ was invented for the open ɛ-sound and close ɛ-sound.1 In a much later epoch it was introduced into the Latin alphabet by the emperor Claudius to represent ι and η, which the sound was written as i or u in maxima, maximus, &c.

The Italic alphabets already mentioned, which are all derived from the Greek alphabet, were used in the Latin alphabet in Italy, where there were at least four other alphabets in use in different parts of Italy: (1) the Messapian of the south-east part of the peninsula, in which the signs of the Greek alphabet were used; (2) the Gallo-Celtic alphabet, which is supposed to have been invented in the 2nd century B.C., in the region of southern France and of the Rhine. The alphabet which was written, an alphabet which, according to Pauli (All-italische Forschungen, iii. chap. ii.) was borrowed from the Lorician alphabet; (2) the Sabellic alphabet, derived from that of Corinth and Corcyra, and found in a few inscriptions of eastern Greece; (3) the alphabet of the Veneti of north-east Italy derived from the Elean; (4) the alphabet of Sondrio (between Lakes Como and Garda), which Pauli, on the assumption that it possessed no symbols corresponding to ϕ and χ, derives from a source at the same stage of development as the oldest alphabets of Thessaly, Melos and Crete.

From the fact that upon the Galassi vase (unearthed at Cervetri, but probably of Etruscan make) a Corybantic song is inscribed in the Museum of the Vatican, a syllabary is found along with one of the most archaic Greek alphabets, and that a similar combination was found upon the Vinius Colle, near Siena, it has been argued that syllabic preceded alphabetic writing in Italy. But even this syllabary where each syllable is made by the combinations of a symbol for a consonant with that for a vowel can furnish no proof of the existence of a syllabary in the Indo-European race, whereas the symbol represents a syllable; it is rather evidence against the existence of such writing. The syllabary upon the Galassi vase indicates in all probability that the vase, which resembles an ink-bottle, belonged to a child, for whose education the syllabaries pa, pe, pe, etc., and the rest were intended. The evidence adduced from the Latin grammarians, and from abbreviations on Latin inscriptions like lods for ludens, is not sufficient to establish the theory.

It has been argued that the runes of the Teutonic peoples have been derived from a form of the Etruscan alphabet, in which are spread over a great part of northern Italy, but of which the most characteristic and best-known are found in the neighbourhood of Lugano, and in Tiro near Innsbruck, Botzen and Trent. The Danish scholar L. F. A. Wimmer, in his great work Die Runenschrift (Berlin, 1887), contends that the resemblance, though striking, is superficial. Wimmer’s own view is that the runes were developed from the Latin alphabet in use at the end of the 2nd century A.D. Wimmer supports his thesis with great learning and ingenuity, and when allowance is made for the fact that a script to be written upon wood or stone must be very different from the one of necessity avoids horizontal lines which run along the fibres of wood, it is not to be wondered at that the indistinct, most of the runic signs thus receive a plausible explanation. The strongest argument for the derivation from the Latin alphabet is undoubtedly the value of f attaching to P; for, as we have seen, the Greek value of this symbol is ϕ, and its value as f arises only by abbreviation from FH. On the other hand, several of Wimmer’s equations are undoubtedly forced. Even if we grant that the Latin signs were invented or set at an angle (a proceeding which is paralleled by the treatment of the ę-sound in the Greek alphabet), so that D represents Latin V, M Latin ι, N Latin ι, L Latin ι, while the symbol for the voiced spirant θ is doubled, [x], it is difficult to believe that the symbol for the spirant g, viz. x, represents a Latin K (which was of rare occurrence), or again, a, χ, a Latin N, or that the symbol for ng, ω, represents a c doubled. Moreover, the date of the borrowing seems too late. The runes are found in all Teutonic countries, and the Romans were in close contact with the Germans on the Rhine before the beginning

1 For further details of these alphabets, see Conway, The Italic Dialect, ii. pp. 458 ff. The recent discovery by Keil and Premerstein (Deutschland und die Litteratur der litoralis (Die literaturwissenschaftliche Abhandlungen, iii. lll. p. 306) of Lydian inscriptions containing the symbol Q suggests that the old derivation of the Etruscans from Lydia may be true and that they brought this symbol with them (see article on F). But the inscriptions are not yet deciphered, so that conclusive proof is still wanting.

2 Of the Christian era. We hear of correspondence between the Romans and German chieftains in the early days of the empire. It is strange, therefore, if the Roman alphabet, which formed the model for the runes, was that of two whole centuries later, and even then the formal alphabet of inscriptions. By that time the Teutons were likely to have more convenient means than wood whereon to write, so that the adaptation of the forms would not have been necessary. That the Germans were familiar with some sort of marks on wood at a much earlier period is shown by Tacitus’s Germania, chap. x. There we are told that for purposes of divination certain signs were scratched on slips of wood from a fruit-bearing tree (including, no doubt, the bee; cp. book, German Bach, and Buchskabe, a letter of the alphabet); the slips were then thrown down promiscuously on a white cloth, whence the expert picked them up at random and by them interpreted fate. In these slips we have the origin of the Norse kof, which were and are still used as lots. The fishermen of north-east Scotland, when they return after a successful haul, divide the spoils into as many shares as there are men in the boat, with one share more for the boat. Each man then procures a piece of wood or stone, on which he puts a private mark. These lots are put in a heap, and an outsider is called in who throws one lot or kaivel upon each heap of fish. Each fisherman then finds his kaivel, and the heap on which it lies is his. This system of "casting kaivels" as it is called, is certainly of great antiquity. But its existence will not help to prove an early knowledge of reading or writing, for in order that everything may be fair, it is clear that the umpire should not be able to identify the lot as belonging to a particular individual. It has, however, been contended that a system of primitive runes existed whence some at least of the later runes were borrowed, and the ownership marks of the Lapps, who have no knowledge of reading and writing, have been regarded as borrowed from these early Teutonic runes. To be as this it may, the resemblances between the runes and the Greek alphabet are not of such a sort as to admit of denial that it is from a Greek alphabet, whether directly, or indirectly, that the runes are derived. That Wimmer postulates the introduction of the runic alphabet seems clear from the archaic forms and method of writing. It is very unlikely that a people borrowing an alphabet which was uniformly written from left to right should have used it in order to write from right to left, or γοροφοοδον. Hence Hempl contends2 that Wimmer’s view must be discarded, and that the runes were derived about 600 n.c. from a western Greek alphabet which closely resembled the Formello alphabet (of the ancient Campania) and the Sabellic and North Etruscan alphabets. He thus places the date at the same period as Isaac Taylor had done in his Greeks and Goths and The Alphabet. Taylor, however, derived the runes from the alphabet of a Greek colony on the Black Sea. Hempl’s initiative was followed by Professor Guntermann of Gesslen, who announced in November 1894 that he had discovered the source of the runic alphabet, the introduction of which he declares preceded the first of the phonetic changes known as the “Teutonic sound-shifting,” since ≈ gis is used for k, x x for f, a, O u and B b, because at this time b was a bilabial spirant and not a stop), ultimately obtains an order—a b d e f k kw h j p r s t u l m n o. As neither Guntermann nor Hempl has published the full evidence for his view, no definite conclusion at the moment is possible.

about A.D. 600.

Prehistoric Linear Script from Crete.

Cyprian Inscription (4th century B.C.) from Curium (British Museum Excavations, p. 64). Below are (1) the transliteration of the symbols; (2) the Greek words, both like the Cyprian reading from right to left.

Oldest Attic Inscription. From a Dipylon Vase probably of 8th century B.C. Right to left.

Inscription on Buddha Vase, perhaps 4th century B.C.

I. 728.
The form of the ogam alphabet made it easy to carve hastily; hence in the old sagas, when a hero is killed we find the common formula, "he was written in ogam." According to Sophus Müller (Nordische Altertumskunde, ii. p. 264), it was from Britain that the use of runes upon gravestones was derived, a usage, which, to judge by the number of bilingual inscriptions in Britain, the Celts derived from the Romans.

The special forms of the alphabet—the Cyrrillic and the Glagolitic—have indeed been adopted by certain of the Slavonic peoples, are both sprung directly from the Greek alphabet of the ninth century A.D., with the considerable additions rendered necessary by the number of bilingual inscriptions in Britain, the Celts derived from the Romans.

Apart from other evidence, the use of B with the value of β, of H as well as I with the value of i, of Φ with the value of θ, and X with that of the Scotch ch, would be proof that the alphabet was not borrowed till long after the Greek classical period, for not till later did β, Φ, X become spirants and θ become identified with τ. The confusion of β with η necessitated the invention of a new symbol γ in the Cyrillic, ἵ in the Glagolitic, for h, while combinations of symbols s (ει), τs (θf), η (ch in church), τ (h, ι, ў (u without protrusion of the lips), ɛ (a close long e sound), (for the combination of o, a with consonantal ι (English y) and for the pronunciation of e (in e), o (in pronunciation) and the combinations jε and jσ (English y, ȥ). In all these matters Glagolitic differs very little from Cyrillic; it has only one symbol for jε (ζ) and it became both in Cyrillic and Glagolitic a sound in no way comparable to the English y.

In all these matters Glagolitic and Cyrillic differ very little from each other; Cyrillic, which is the alphabet for Slavic languages, has only one symbol for jε (ζ) and it became both in Cyrillic and Glagolitic a sound in no way comparable to the English y. In all these matters Glagolitic and Cyrillic differ very little from each other; Cyrillic, which is the alphabet for Slavic languages, has only one symbol for jε (ζ) and it became both in Cyrillic and Glagolitic a sound in no way comparable to the English y. In all these matters Glagolitic and Cyrillic differ very little from each other; Cyrillic, which is the alphabet for Slavic languages, has only one symbol for jε (ζ) and it became both in Cyrillic and Glagolitic a sound in no way comparable to the English y.
Like the Phoenician, these Hebrew signs are distinctly cursive in character, but, as the legend on the coins of the Macchabees shows, became an ordinary document script, though not a cursive in character; and C. K. G. Thomsen early adopted the Semitic writing, whence the square Hebrew script is descended. The Samaritans alone stuck fast to the old Hebrew as part of their contention that they, and not the Jews, were the true Israel.

The oldest records in Arabic were found at Sindjirli, in the north of Syria, in 1890, and date to about 800 B.C. At this epoch the Aramaic alphabet, or at any rate the alphabet of these inscriptions, is in its literal form. From this epoch onwards, the Monbrite stone was inscribed. Either two stones are confused under one name, or these records represent a dialect which, like Hebrew and Aramaic, is derived from the Semitic speech. Any writer who is familiar with the Semitic sounds would have no difficulty in concluding that it was the monbrite stone. The Semitic soundings are $f$, $p$, $u$, $t$, and $a$, the Arabic $b$, $d$, and $h$. The Aramaic alphabet became more or less the most important of the northern Semitic alphabets. While even long and important documents in Assyrian are still written in cuneiform, the Semitic cursive was adopted by the Persians, and this became the regular mode of writing. The development of the Semitic cursive writing—a fact which explains its later development. Changes, the distinction of which is early, and the completion of which belongs to the Persian period, gave the impulse which Aramaic obeyed in all its later developments. These are (a) the opening of the heads of letters, so that both $ג$ and $ד$ became $ג$ and $ד$, and (b) the opening of the heads of letters, so that $ו$ and $ז$ became $ו$ and $ז$. In this way the Semitic cursive writing is reduced in size, and finally disappears. (b) As was natural in cursive writing, angles tend to become rounded, and the tails of the letters, which in Phoenician are very long, are curled round in the Semitic alphabet. A number of characteristic peculiarities were thus preserved, but at the same time a gradual development of this script into the square Hebrew, and the more ornamental writing of Palmyra, may be traced in the works of Berger and Lidzbarski.

In the language of the Sabaeans, a people of Arabian origin, the Semitic alphabet was employed in a form which ultimately developed into the modern Arabic alphabet. Probably the earliest form of the Semitic script in Arabia is the stele of 750 B.C., which was discovered in the south of Arabia, and established the form of an alphabet. This monument, now in the Louvre, is not later than the 5th century B.C. In it, as in Semitic cursive writing, the closed letters being very occasionally opened. The Nabataean inscriptions belong to a different epoch and a different style. They were first discovered by Charles Doughty in 1876-1877, who was followed between 1838 and 1884 by Huber and Zeitz, to whom a complete collection of these records is due. The records are fortunately dated, and belong to the period from 9 B.C. to A.D. 75. A further development can be traced in the epigraphics, which in both forms the heads tend to be reduced in size, and finally disappear. The Semitic alphabet is not a continuous development from the Semitic cursive writing, the original causes of confusion being the continuous development of cursive writing and the adoption of ligatures. Arabic writing, as known to us from documents of the early centuries of the Christian era, is an entirely different type, known respectively as the Cufic and the naskhi. The former soon fell into disuse for ordinary purposes and was retained only for inscriptions, coins, &c.; the latter, which is more cursive in character, is the parent of the Arabic writing of the present day. Another form of the Semitic alphabet, namely, the so-called Estrangela writing, which was in use amongst the Christians of northern Syria, was carried by Nestorian missionaries into Central Asia and formed the ancestor of a multitude of alphabets spreading through the Turkomans as far east as Manchuria.

The date of the first development of a cursive form of the Semitic languages which, except for one or two of the languages belonging to it, was practically unknown till recent years. This is the South Semitic.

Till the 19th century the earliest form known of this alphabet is that adopted by the Ethiopians. The alphabets of Biblical documents have been preserved from the early centuries of our era, and which is still used by the Abyssinians for liturgical purposes. The inscriptions of two English naval officers, Welling and Cruftt, through Yemen in southern Arabia in 1835, first called attention to the earlier manuscripts of Arabia. Fulgence Fresnel first established the importance of the inscriptions discovered by these Englishmen, and also the Semitic cursive alphabet in which the first travel to Abyssinia was made by the French traveller, Francois Arnaud, information about other monuments of the same kind. In 1869 Joseph Halévy brought back nearly seven hundred inscriptions from Yemen, and this number has been increased from other quarters by several thousands, through Chiefly by Eduard Glaser's repeated journeys. The South Semitic alphabet is divided into Monbrite stone and the terms Himyaritic and Sabaeana are applied in many cases, the Sabaeans proper and the Minaeans. These are distinguished by their use of a kinder writing. The relative age of the Minaean and Sabaeana manuscripts is a matter of dispute amongst Semitic scholars. Inscriptions in a kindred dialect were brought from El-Ola, in the north of the Arabian Peninsula, to Dusseldorf, at this time. To D. H. Müller 1 that the Sabaeans had colonized Abyssinia as early as 1000 B.C. Other inscriptions were brought to Aalke in the 2nd to the 4th century A.D. and later. Two of the oldest inscriptions are written in Sabaean characters, but in the language which is known as Geez or Ethiopic. From about A.D. 500 Ethiopic was written in an alphabet which according to Müller was no gradual growth but an ingenious device of a Greek scholar of this period at the court of Abyssinia. The Sabaeans, like other Semitic, inscriptions are generally written from right to left, but a few are bwermopussions, the Ethiopic is written from left to right, and the Semitic Ethiopic system is a Semitic manner of writing by indicating the vowels. This is done by varying the form of the consonant according to the vowel which it is supposed to carry. These are written in the same alphabet. It is noticeable that the changes thus established were made upon the basis of the old Sabaean script, which in its present form is evidently closely related to the old Phoenician, though it would appear that the nature of the Sabaean alphabet is derived from the Phoenician. It is as likely, considering the date of both, that they are equally descended from an original source. The modern form of the Semitic alphabet is therefore of great size, and bears some resemblance to the outlines of the Greek letter which it is the most to differ in its shape from the Semitic, the sound being that in which a symbol is to differ from another symbol, whereby it is enabled to express the Semitic sounds which are not distinguished from one another in the writing of the northern Semites. As we have seen, a tendency to a regular form of writing in Semitic opened the heads of letters, and therefore it is possible that the Sabean form for $ז$ may be older than the Phoenician $צ$. Similarly if $פ$ means mouth, Hommel is right in contending that the Sabean $פ$ is more like the object than the Phoenician $צ$, if we suppose the form, like $י$ and $ץ$ or the Phoenician $יו$ and $יו$ for the Phoenician $יו$, turned through an angle of 90°. So also if $กา$ refers to the Babylonian $כ$, sheet of paper, among the Semites they open the heads of letters, and the thumb raised is a better pictograph than the various meaningless forms of $כ$ and $יך$. The rock inscriptions in the wild district of Safa near Damascus which have been collected within the last hundred years are also cursive in form, but, owing chiefly to their careless execution, they are to a large extent unintelligible. The character appears to be akin to the Sabaeans. It has been suggested that they were the work of Arabians under the Sassanid emperors.

There are still remains for discussion the alphabets of the Indo-European peoples of Persia and India from which the other alphabets of the Farther East are descended. When Darius in 520 B.C. caused the great Behistun inscription to be engraved, it was in the cuneiform writing, already long in use for the languages of Mesopotamia, that was adopted for this purpose. We have seen that at Babylon itself the Semitic language and character were well known. It is probable therefore, a priori, that from the Semitic alphabet the later writing of Persia should be developed. The conclusion is confirmed by the coins, the only records with Iranian script which are so far found. The rock inscriptions from which the Iranian alphabet is derived must at present be left undecided. The later developments of the Iranian alphabet are the Pahlavi and the Zend, in which the MSS. of the Zend, which are called the Avesta, are written. These manuscripts none is older than the 13th century A.D. The Pahlavi is properly the alphabet of the Sassanid kings who ruled in Persia from A.D. 226 till the Arab conquest in the 7th century A.D. The Zend was that of the Saivas of Persia or fallen with the Achaemenid dynasty in Alexander's time, and

1. Müller, Epigraphische Denkmäler aus Arabien (Vienna, 1886).
2. Epigraphische Denkmäler aus Abessinien (Vienna, 1894). Praetorius (Z.D.M.G. 28th, pp. 724.) holds that the oldest Sabaeana inscriptions may have come from Phoenicia and that these are at earliest of the Hellenistic period and the Saifa inscriptions still later.
3. Praetorius (Z.D.M.G. 28th, p. 361) attempts to trace the development of the Sabean forms from the Phoenician.

1 See Berger's Histoire de l'écriture dans l'antiquité, p. 252 ff.; Lidzbarski, Nordsemitische Epigraphik, p. 186 ff., from whom this summary is taken. Lidzbarski's second volume and G. A. Cooke's Travels in Northern Inscriptions (Oxford, 1903) contain the most convenient collections of Northern Semitic inscriptions for the student's purposes.
had been neglected by the subsequent Arsacid line, was revived and the remains of its liturgical literature collected. The name is, however, also applied to the alphabet on the coins of the Parthian or Arsacid dynasty, which in its beginnings was clearly under Greek influence; while later, when a knowledge of Greek had disappeared, the attempts to imitate the old legends are as grotesque as those in western Europe to copy the inscriptions on Roman coins. The relationship between the Pahlavi and the Aramaic is clearest in the records written in the "Chaldaeo-Pahlavi" characters; the

The most important of these documents is the liturgical inscription of Hadji-alab, where the Arsacid and Sassanian alphabets are found side by side. Taylor (The Alphabet, ii, p. 248 f.) regards the former as probably derived from the "ancient alphabet of Eastern Iran, a sister alphabet of the Aramaean of the satrapies," while the Sassanian belongs to a later stage of Aramaic.

The alphabets of India all sprang from two sources: (a) the Kharoṣṭhī, (b) the Brahmi alphabet. The history of the former is fairly clear. It was always a local alphabet, and never attained the importance of its rival. According to Bühler,¹ its range lay between 69° and 73° 30' E. and 33° to 35° N.,

¹ Bühler, Indian Studies, iii. (2nd ed., 1898), p. 93. The account of the Achaemenid kings of Persia. As Bühler shows in detail, the Kharoṣṭhī alphabet is derived from the alphabet of the Aryan inscriptions which date from the earlier part of the Achaemenid period. The Aramaic alphabet passed into India with the staff of subordinate officials by whom Darius organized his conquests there. The people of India already possessed their Brahmi alphabet, of these alphabets is drawn from this work and from the same author's Indische Paläographie in the Grundriss der indoirischen Philologie, to which is attached an atlas of plates (Strasbourg, 1896), and in which a full bibliography is given.
but had this other alphabet forced upon them in their dealings with their rulers. The Kharosti is then the gradual development under local influence of the Aramaic Tetrachords (see Bibliotheca Archimedes). As Stein's explorations show, both alphabets may be found on opposite sides of the same piece of wood; in some cases that of the Kharosti is more difficult. In its later forms it is so unlike other alphabets that many scholars have regarded it as an invention within India itself. The discovery of earlier inscriptions than those hitherto known has, however, caused the position of the Kharosti to change, and the modern and developed form of the Semitic alphabet is identified. Taylor (The Alphabet, ii. p. 314 ff.), following Weber, argues that it comes from the Sabaeans who were carrying on trade with India as early as 1000 B.C. The first inscriptions do not belong to the Semitic and the second to the Pehlevi. Proceeding to a more detailed discussion Taylor contends that the alphabet was derived from the Phoenician. He shows that the forms in the Phoenician and Moabite alphabets agree with those in the alphabet, while the Sabean alphabet does not. He further argues that the scribes of the Semitic alphabet had to some extent been influenced by the Egyptian, which was then known to them. He shows that the Semitic alphabet, like the Phoenician, was written from right to left, while the Sabean alphabet was written from left to right. He also shows that the Semitic alphabet was used for writing Semitic languages, while the Sabean alphabet was used for writing Indian languages.

\[\text{ALPHABET, SIBERIA.} \]

The earlier alphabets were not attached to the same systems, but were used for writing different systems. The older alphabets were constructed on the basis of the cuneiform script, which was used for writing Semitic languages. The later alphabets were constructed on the basis of the Greek alphabet, which was used for writing Greek languages. The Semitic alphabets were constructed in the 3rd century B.C., while the Greek alphabets were constructed in the 8th century B.C.

was recognized in cult and myth as the chief or typical river-god in the Peloponnesus, as was Achelous in northern Greece. His waters were said to pass beneath the sea and rise again in the fountain Arethusa at Syracuse; such is the earlier version from which later mythologists and poets evolved the familiar myth of the loves of Alpheus and Arethusa.

ALPHONSE I, Count of Toulouse (1103-1148), son of Count Raymond IV. by his third wife, Elvira of Castile, was born in 1103, in the castle of Mont-Pélerin, Tripoli. He was surnamed Jourdain on account of his being baptized in the river Jordan. His father died when he was two years old and he remained under the guardianship of his cousin, Guillaume Jourdain, count of Cerdagne (d. 1109), until he was five. He was then taken to Europe and his brother Bertrand gave him the countship of Rouergue; in his tenth year, upon Bertrand's death (1112), he succeeded to the countship of Toulouse and marquisate of Provence, but Toulouse was taken from him by William IX., count of Poitiers, in 1114. He recovered a part in 1110, but continued to fight for his possessions until about 1123. When at last successful, he was excommunicated by Pope Calixtus II. for having expelled the monks of Saint-Gilles, who had aided his enemies. He next fought for the sovereignty of Provence against Raymond Berenger I., and not till September 1123 did the war end in an amicable agreement. Under it Jourdain became absolute master of the regions lying between the Pyrenees and the Alps, Auvergne and the sea. His ascendency was unmixed, giving him for during a period of fourteen years a free hand to labour and industry flourished. About 1135 he seized the countship of Narbonne, only restoring it to the Viscountess Ermengarde (d. 1197) in 1143. Louis VII., for some reason which has not appeared, besieged Toulouse in 1145, but without result. Next year Jourdain again incurred the displeasure of the church by siding with the rebels of Montpellier against their lord. A second time he was excommunicated; but in 1146 he took the cross at the meeting of Vézelay called by Louis VII., and in August 1147 embarked for the East. He lingered in the Holy Land on account of the personal character and as the founder of their kingdom.

ALPHONSE II., “the Fat,” was born in 1185, and succeeded his father, Sancho I., in 1211. He was engaged in war with the Moors and gained a victory over them at Alcácer do Sal in 1217. He also endeavoured to weaken the power of the clergy and to apply a portion of their enormous revenues to purposes of national utility. Having been excommunicated for this by the pope (Honorious III.), he promised to make amends to the church; he died 1223 before doing anything to fulfil his engagement. He framed a code which introduced several beneficial changes into the laws of his kingdom.

ALPHONSE III., son of Alphonso II., was born in 1210, and succeeded his brother, Sancho II., in 1248. Besides making war upon the Moors, he was, like his father, frequently embroiled with the church. In his reign Algarve became part of Portugal. He died in 1270. Alphonso IV. was born in 1320, and in 1325 succeeded his father, Dions, whose death he had hastened by his intrigues and rebellions. Hostilities with the Castilians and with the Moors occupied many years of his reign, during which he gained some successes; but by consenting to the barbarous murder of Jémez de Castro, who was secretly espoused to his son Peter, he has fixed an indelible stain on his character. Enraged at this barbarous act, Peter put himself at the head of an army and devastated the whole of the country between the Douro and the Minho before he was reconciled to his father. Alphonso died almost immediately after, on the 29th of May 1355. Alphonso V., “the Cruel,” was born in 1342, and succeeded his father Edward in 1438. During his minority he was placed under the regency, first of his mother and latterly of his uncle, Dom Pedro. In 1448 he assumed the reins of government and at the same time married Isabelia, Dom Pedro's daughter. In the following year, being led by what he afterwards discovered to be false representations, he declared Dom Pedro a rebel and deposed his army in a battle at Alfarrobeira, in which his uncle was slain. In 1458, and with more numerous forces in 1472,
he invaded the territories of the Moors in Africa and by his successes there acquired his surname of “the African.” On his return to Portugal in 1475 his ambition led him into Castile, where two princesses were disputing his succession to the throne. Having been affianced to the Princess Juana, Alphonso caused himself to be proclaimed king of Castile and Leon; but in the following year he was defeated at Toro by Ferdinand, the husband of Isabel of Castile. He went to France to obtain the assistance of Louis XI., but finding himself deceived by the French monarch, he abdicated in favour of his son John. When he returned to Portugal, however, he was compelled by his son to resume the sceptre, which he continued to wield for two years longer. After that he fell into a deep melancholy and retired into a monastery at Cintra, where he died in 1481.

Alphonso VI., the second king of the house of Braganza, was born in 1543 and succeeded his father in 1566. In 1567 he was compelled by his wife and brother to abdicate the throne and was banished to the island of Terceira. These acts, which the vices of Alphonso had rendered necessary, were sanctioned by the Cortes in 1568. He died at Cintra in 1575.

Spanish Kings.—From Alphonso I. (750-757) to Alphonso V. (999-1028) the personal history of the Spanish kings of this name is unknown and their very dates are disputed. Alphonso I. is said to have married Ormesinda, daughter of Pelayo, who was raised on the shield in Asturias as king of the Goths after the Arab conquest. He is also said to have been the son of Peter, duke of Cantabria. It is not improbable that he was in fact a hereditary chief of the Basques, but no contemporary records exist. His title of “the Catholic” itself may very well have been the invention of later chroniclers. Alphonso II. (789-842), his reputed grandson, bears the name of “the Chaste.” The Arab writers who speak of the Spanish kings of the north-west as the Beni-Alfons, appear to recognize them as a royal stock derived from Alphonso I. The events of his reign are in reality unknown. Poets of a later generation invented the story of the secret marriage of his sister Ximena with Sancho, count of Saldaña, and the feats of their son Bernardo del Carpio. Bernardo is the hero of a cantar de gesta (chanson de geste) written to please the unarched spirit of the nobles.

The first faint glimmerings of medieval Spanish history begin with Alphonso III. (866-914) surnamed “the Great.” Of him also nothing is really known except the bare facts of his reign and of his comparative success in consolidating the kingdom known as “of Galicia” or “of Oviedo” during the weakness of the Omeyyad princes of Cordova. Alphonso IV. (924-931) has a faint personality. He resigned the crown to his brother Ramiro and went into a religious house. A certain instability of character is revealed by the fact that he took up arms against Ramiro, having repented of his renunciation of the world. He was defeated, blinded, and sent back to die in the cloister of Sahagun. It fell to Alphonso V. (999-1028) to begin the work of reorganizing the Christian kingdom of the north-west after a most disastrous period of civil war and Arab inroads. Enough is known of him to justify the belief that he had some of the qualities of a soldier and a statesman. His name, and that of his wife Geloria (Elvira), are associated with the grant of the first franchises of Leon. He was killed by an arrow while besieging the town of Viseu in northern Portugal, then held by the Mahomedans. (For all these kings see the article Spain: History.)

With Alphonso VI. (1065-1109) we come to a sovereign of strong personal character. Much romance has gathered round his name. In the cantar de gesta of the Cid he plays the part attributed by medieval poets to the greatest kings, to Charlemagne himself. He is alternately the oppressor and the victim of heroic and self-willed nobles—the idealized types of the patrons for whom the jongleurs and troubadours sang. (For the events of his reign see article Spain: History.) He is the hero of a cantar de gesta which, like all ballads in the Iberian Spanish, songs, like the cantar of Bernardo del Carpio and the Infantes of Lara, exists now only in the fragments incorporated in the chronicle of Alphonso the Wise or in ballad form. His flight from the monastery of Sahagun, where his brother Sancho endeavoured to imprison him, his chivalrous friendship for his host Almamun of Toledo, caballero aunque mon, a gentlema although a Moor, the passionate loyalty of his vassal Peranuelas and his brotherly love for his sister Urraca of Zamora, may owe something to the poet who took him for hero. They are the answer to the poet of the nobles who represented the king as having submitted with the degrading oath at the hands of Roland Bivar (the Cid), in the church of Santa Gadea at Burgos, and as having then persecuted the brave man who defied him. When every allowance is made, Alphonso VI. stands out as a strong man fighting for his own hand, which in his case was the hand of the king whose interest was law and order and who was the leader of the nation in the reconquest. On the Arabs he impressed himself as an enemy very fierce and astute, but as a keeper of his word. A story of Mahomedan origin, which is probably no more historical than the oath of Santa Gadea, tells of how he allowed himself to be tricked by Ibn Ammar, the favourite of Al Motamid, the king of Seville. They played chess for an extremely beautiful table and set of men, belonging to Ibn Ammar. Table and men were to go to the king if he won. If Ibn Ammar gained he was to name the stake. The latter did win and demanded that the Christian king should spare Seville. Alphonso kept his word. Whatever truth may lie behind the romantic tales of Christian and Mahomedan, we know that Alphonso represented in a remarkable way the two great influences then shaping the character and civilization of Spain. At the instigation, it is said, of his second wife, Constans of Burgundy, he brought the Cistercians into Spain, established them in Sahagun, chose a French Cistercian, Bernard, as the first archbishop of Toledo after the reconquest in 1085, married his daughters, legitimate and illegitimate to French princes, and in every way forwarded the spread of French influence—then the greatest civilizing force in Europe. He also drew Spain nearer to the papacy, and it was his decision which established the Roman ritual in place of the old missal of St Isidore—the so-called Mozarabic. On the other hand he was very open to Arabic influence. He protected the Mahomedans among his subjects and struck coins with inscriptions in Arabic letters. After the death of Constans he perhaps married and he certainly lived with Zaida, said to have been a daughter of “Benabet” (Al Motamid), Mahomedan king of Seville. Zaida, who became a Christian under the name of Maria or Isabel, bore him the only son among his many children, Sancho, whom Alphonso designed to be his successor, but who was slain at the battle of Ucle in 1108. Women play a great part in Alphonso’s life.

Alphonso I., king of Aragon, “the Battler,” who married Urraca, daughter of Alphonso VI. (1104-1134), is sometimes counted the VIIIth in the line of the kings of Leon and Castile. A passionate fighting-man (he fought twenty-nine battles against Christian or Moor), he was married to Urraca, widow of Raymond of Burgundy, a very dissolute and passionate woman. The marriage had been arranged by Alphonso VI. in 1106 to unite the two chief Christian states against the Almoravides, and to supply them with a capable military leader. But Urraca was taciturn of her right as proprietary queen and had not learnt chastity in the polygamous household of her father. Husband and wife quarrelled with the brutality of the age and came to open war. Alphonso had the support of one section of the nobles who found their account in the confusion. Being a much better soldier than any of his opponents he gained victories at Sepúlveda and Fuente de la Culebra, but his only trustworthy supporters were his Aragonese, who were not numerous enough to keep down Castile and Leon. The marriage of Alphonso and Urraca was declared null by the pope, as they were third cousins. The king quarrelled with and particularly the Cistercians, almost as violently as with his wife. As he beat her, so he would bludgeon the priory of the castle of San Juan into silence and expel the monks of Sahagun. He was finally compelled to give way in Castile and Leon to his stepson Alphonso, son of Urraca and her
first husband. The intervention of Pope Calixtus II. brought about an arrangement between the old man and the young. Alphonso the Battler won his great successes in the middle Ebro, where he expelled the Moors from Saragossa; in the great raid of 1125, when he carried away a large part of the subject-Christians from Granada, and in the south-west of France, where he had rights as king of Navarre. Three years before his death he made a will leaving his kingdom to the Templars, the Hospitalers, and the Knights of the Sepulchre, which his subjects refused to carry out. He was a fierce, violent man, a soldier and nothing else, whose piety was wholly militant. Though he died in 1134 after an unsuccessful battle with the Moors at Braga, he has a great place in the reconquest.

Alphonso VII., "the Emperor" (1126-1157), is a dignified and somewhat enigmatical figure. A vague tradition had always assigned the title of emperor to the sovereign who held Leon as the most direct representative of the Visigoth kings, who were themselves the representatives of the Roman empire. But though given in charters, and claimed by Alphonso VI. and the Battler, the title had been little more than a flourish of rhetoric. Alphonso VII. was crowned emperor in 1135 after the death of the Battler. The weakness of Aragon enabled him to make his superiority effective. He appears to have striven for the formation of a national unity, which Spain had never possessed since the fall of the Visigoth kingdom. The elements he had to deal with could not be welded together. Alphonso was at once a patron of the church, and a protector if not a favourer of the Mahommedans, who formed a large part of his subjects. His reign ended in an unsuccessful campaign against the rising power of the Almohades. Though he was not actually defeated, his death in the pass of Muradél in the Sierra Morena, while on his way back to Toledo, occurred in circumstances which showed that no man could be what he claimed to be—"king of the men of the two religions." His personal character does not stand out with the emphasis of those of Alphonso VI. or the Battler. Yet he was a great king, the type and to some extent the victim of the confusions of his age—Christian in creed and ambition, but more than half oriental in his household.

Alphonso VIII. (1158-1214), king of Castile only, and grandson of Alphonso VII., is a great name in Spanish history, for he led the coalition of Christian princes and foreign crusaders who broke the power of the Almohades at the battle of the Navas de Tolosa in 1212. The events of his reign are dealt with under SPAIN. His personal history is that of many medieval kings. He succeeded to the throne on the death of his father, Sancho, at the age of a year and a half. Though proclaimed king, he was regarded as a mere name by the unruly nobles to whom a minority was convenient. The devotion of a squire of his household, who carried him on the pommel of his saddle to the stronghold of San Esteban de Gormaz, saved him from falling into the hands of the contending factions of Castro and Lara, or of his uncle Fernando of Leon, who claimed the regency. The loyalty of the town of Avila protected his youth. He was barely fifteen when he came forth to do a man's work by restoring his kingdom to order. It was only by a surprise that he recovered his capital Toledo from the hands of the Laras. His marriage with Leonora of Aquitaine, daughter of Henry II. of England, brought him under the influence of the greatest governing intellect of his time. Alphonso VIII. was the founder of the first Spanish university, the studium generale of Palencia, which, however, did not survive him.

Alphonso IX. (1188-1230) of Leon, first cousin of Alphonso VIII. of Castile, and numbered next to him as being a junior member of the family (see the article SPAIN for the division of the kingdom and the relationship), is said by Ibn Khaldun to have been called the "Baboso" or Slobberer, because he was subject to fits of rage during which he foamed at the mouth. Though he took a part in the work of the reconquest, this king is chiefly remembered by the difficulties in which he led his life. He was first married to his cousin Teresa of Portugal, who bore him two daughters, and a son who died young. The marriage was declared null by the pope, to whom Alphonso paid no attention till he was presumably tired of his wife. It cannot have been his conscience which constrained him to leave Teresa, for his next step was to marry Berengaria of Castile, who was his second cousin. For this act of contumacy the king and kingdom were placed under interdict. The pope was, however, compelled to modify his measures by the threat that if the people could not obtain the services of religion they would not support the clergy, and that heresy would spread. The king was left under interdict personally, but to that he showed himself indifferent, and he had the support of his clergy.

Berengaria left him after the birth of five children, and the king then returned to Teresa, to whose daughters he left his kingdom by will.

Alphonso X., El Sabio, or the learned (1252-1284), is perhaps the most interesting, though he was far from being the most capable, of the Spanish kings of the middle ages. (His merits as a writer are dealt with in the article SPAIN: Literature.) His scientific fame is based mainly on his encouragement of astronomy. It may be pointed out, however, that the story which represents him as boosting of his ability to make a better world than this is of later antiquity. If he said so, he was speaking of the Ptolemaic cosmogony as known to him through the Arabs, and his vaunt was a humorous proof of his scientific instinct. As a ruler he showed legislative capacity, and a very commendable wish to provide his kingdoms with a code of laws and a consistent judicial system. The Fuero Real was undoubtedly his work, and he began the code called the Siete Partidas, which, however, was only promulgated by his great-grandson. Unhappily for himself and for Spain, he wanted the singleness of purpose required by a ruler who would devote himself to organization, and also the combination of firmness with temper needed for dealing with his nobles. His descent from the Hohenstaufen through his mother, a daughter of the emperor Philip, gave him claims to represent the Swabian line. The choice of the German electors, after the death of Conrad IV. in 1254, misled him into wild schemes which never took effect but caused immense expense. To obtain money he debased the coinage, and then endeavoured to prevent a rise in prices by an arbitrary tariff. The little trade of his dominions was ruined, and the burgheers and peasants were deeply offended. His nobles, whom he tried to cow by sporadic acts of violence, rebelled against him. His second son, Sancho, enforced his claim to be heir, in preference to the children of Ferdinand de la Cerda, the elder brother who died in Alphonso's life. Son and nobles alike supported the Moors, when he tried to unite the nation in a crusade; and when he allied himself with the rulers of Morocco they denounced him as an enemy of the faith. A reaction in his favour was beginning in his later days, but he died defeated and deserted at Seville, leaving a boy about whom he endeavoured to exclude Sancho and a heritage of civil war.

Alphonso XI. (1312-1350) is variously known among Spanish kings as the Avenger or the Impalacable, and as "he of the Rio Salado." The first two names he earned by the ferocity with which he repressed the disorder of the nobles after a long minority; the third by his victory over the last formidable African invasion of Spain in 1340. The chronicler who records his death prays that "God may be merciful to him, for he was a very great king." The mercy was needed. Alphonso XI. never learned to the insane lengths of his predecessors, but he could be abundantly sultanesque in his methods. He killed for reasons of state without form of trial, while his open neglect of his wife, Maria of Portugal, and his ostentatious passion for Leonora de Guzman, who bore him a large family of sons, set Peter an example which he did not fail to better. It may be that his early death, during the great plague of 1350, at the siege of Gibraltar, only averted a desperate struggle with his legitimate son, though it was a misfortune in that it removed a ruler of eminent capacity, who understood his subjects well enough not to be abashed.

Four other kings of Aragon, besides the Battler, bore the name of Alphonso. All these princes held territory in the south-east of France, and had a close connexion with Italy. Alphonso II. of Aragon (1162-1196) was the son of Raymond Berenger,
ALPHONSO A SANCTA MARIA

count of Barcelona, and of Petronilla, niece of Alphonso the
Battler, and daughter of Ramiro surnamed the Monk. He
succeeded to the county of Barcelona in 1152 on the death of his
father, at the age of eleven, and in 1164 his mother renounced
her rights in Aragon in his favour. Though christened Ramon
(Raymond), the favourite name of his line, he reigned as Alphonso
out of a wish to please his Aragonese subjects, twomwhom the
memory of the Battler was dear. As king of Aragon he took a share in
the work of the reconquest; by helping his cousin Alphonso VIII.
of Castile to conquer Cuenca, and to suppress one Pero Ruiz de
Azagra, who was endeavouring to carve out a kingdom for himself
in the debatable land between Christian and Mahommedan.
But his double position as ruler both north and south of the
eastern Pyrenees distracted his policy. In character and interests
he was rather Provençal than Spanish, a favourer of the troubadours,
no enemy of the Albigenian heretics, and himself a poet
in the southern French dialect. ALPHONSO III. of Aragon (1285-
1291), the insignificant son of the notable Peter III., succeeded
to the Spanish and Provençal possessions of his father, but his
short reign did not give him time even to marry. His inability to
resist the demands of his nobles left the Provençal world in
Aragon. By recognising their right to rebel in the articles called
the Union he helped to make anarchy permanent. ALPHONSO IV.
of Aragon (1327-1356) was a weak man whose reign was in-
significant. ALPHONSO V. of Aragon (1416-1458), surnamed the
Magnanimous, who represented the old line of the counts of
Barcelona only through women, and was on his father’s side
descended from the Castillian house of Trastamara, is one of
the most conspicuous figures of the early Renaissance. No man of
his time had a larger share of the quality called by the Italians of
the day “virtue.” By hereditary right king of Sicily, by the
will of Joanna II. and his own sword king of Naples, he fought
and triumphed amid the exuberant development of individuality
which accompanied the revival of learning and the birth of the
modern world. When a prisoner in the hands of Filipo Maria.
Visconti, duke of Milan, in 1435, Alphonso persuaded his ferocious
and crafty captor to let him go by making plain that it was the
interest of Milan not to prevent the victory of the Aragonese
party in Naples. Like a true prince of the Renaissance he
favoured men of letters whom he trusted to preserve his reputa-
tion after postercity. His devotion to the classics was exceptional
even in that time. He halted his army in pious respect before
the birthplace of a Latin writer, carried Livy or Caesar on his
campaigns with him, and his panegyrist Panormita did not think
it an incredible lie to say that the king was cured of an illness
by having a few pages of Quintus Curtius read to him. The
classics had not refined his taste, for he was amused by设置
the wandering scholars, who swarmed to his court, to abuse one
another in the indecively filthy Latin scolding matches which
were then the fashion. Alphonso founded nothing, and after his
conquest of Naples in 1442 ruled by his mercenary soldiers,
and no less mercenary men of letters. His Spanish possessions
were ruled for him by his brother John. He left his conquest of
Naples to his bastard son Ferdinand; his inherited lands, Sicily and
Sardinia, going to his brother John who survived him.] ALPHONSO XII. (1857-1885), king of modern Spain, son of
Isabella II. and Maria Fernando Francisco de Assisi, eldest son
of the duke of Cadiz, was born on the 28th of November 1857.
When Queen Isabella and her hushband were forced to leave
Spain by the revolution of 1868 he accompanied them to Paris,
and from thence he was sent to the Theresianum at Vienna to
continue his studies. On the 25th of June 1870 he was recalled
to Paris, where his mother abdicted in his favour, in the presence
of a number of Spanish nobles who had followed the fortunes of
the exiled queen. He assumed the title of Alphonso XIII.; for
although no king of united Spain had previously borne the name,
the Spanish monarchy was regarded as continuous with the
more ancient monarchy, represented by the eleven kings of
Visigothic Spain. His studies were interrupted when he
was compelled to proceed to Sandhurst to continue his military
studies, and while there he issued, on the 1st of December 1874, in reply to a
birthday greeting from his followers, a manifesto proclaiming
himself the sole representative of the Spanish monarchy. At
the end of the year, when Marshal Serrano left Madrid to take
command of the northern army, General Martinez Campos, who
had long been working more or less openly for the king, carried
off some battalions of the central army to Sagunto, rallied to his
own flag the troops sent against him, and entered Valencia in
the king’s name. Thereupon the president of the council
resigned, and the power was transferred to the king’s pleni-
potency and adviser, Canovas del Castillo. In the course of a
few days the king arrived at Madrid, passing through Barcelona
and Valencia, and received everywhere with acclamation
(1875). In 1876 a vigorous campaign against the Carlists, in
which the young king took part, resulted in the defeat of Don
Carlos and his abandonment of the struggle. Early in 1878
Alphonso married his cousin, Princess Maria de las Mercedes,
daughter of the duc de Montpensier, but she died within six
months of her marriage. Towards the end of the same year
a young workman of Tarragona, Oliva Marcou, fixed at the king in
Madrid. On the 26th of November 1879 he married a princess
of Austria, Maria Christina, daughter of the Archduke Charles
of Austria, and was crowned in December. Don Carlos, after
having been fired at the young sovereigns as they were driving in Madrid.
The children of this marriage were Maria de las Mercedes, titular
queen from the death of her father until the birth of her brother,
born on the 11th of September 1880, married on the 14th of
February 1901 to Prince Charles of Bourbon, died on the 17th of
October 1904; Maria Teresa, born on the 12th of November 1882,
moved to Prince Ferdinand of Bavaria on the 12th of
January 1906; and Alphonso (see below). In 1881 the king
refused to sanction the law by which the ministers were to remain
in office for a fixed term of eighteen months, and upon the con-
sequent resignation of Canovas del Castillo, he summoned
Sagasta, the Liberal leader, to form a cabinet. Alphonso died
of phthisis on the 24th of November 1885. Coming to the throne
at such an early age, he had served no apprenticeship in the art
of ruling, but he possessed great natural tact and a sound
judgment ripened by the trials of exile. Benevolent and sym-
pathetic in disposition, he won the affection of his people by
fearlessly visiting the districts ravaged by cholera or devastated
by earthquake in 1885. His capacity for dealing with men was
considerable, and he never allowed himself to become the instru-
ment of any particular party. In his short reign peace was
established both at home and abroad, the finances were well
regulated, and the various administrative services were placed
on a basis that afterwards enabled Spain to pass through
the disastrous war with the United States without even the threat
of a revolution.

ALPHONSO XIII. (1886— ), king of Spain, son of Alphonso
XII., was born, after his father’s death, on the 17th of May 1886.
His mother, Queen Maria Christina, was appointed regent during
his minority (see SPAIN: History). In 1902, on attaining his
16th year, the king assumed control of the government. On the
31st of May 1906 he married Princess Victoria Eugénie Julia Ena
Maria Christina of Battenberg, niece of Edward VII. of England.
As the king and queen were returning from the wedding they
narrowly escaped assassination in a bomb explosion, which
killed and injured many bystanders and members of the royal
procession. An heir to the throne was born on the 10th of May
1907, and received the name of Alphonso.

AUTHORITIES.—The lives of all the early kings of Spain will be
found in the general histories (see the article SPAIN: Authorities),
of which the most trustworthy is the Anales de la Corona de Aragon.
1626. During the reign of Ferdinand VI. are also the Chronicles
of the Kings of Castile in the Biblioteca de Autores Españoles de Río
deneyer (Madrid, 1846-1880, vols. 66, 68, 70).

(D. H.)

ALPHONSUS A SANCTA MARIA, or ALPHONSO DE CARTAGENA
(1396-1456), Spanish historian, was born at Cartagena, and
succeeded his father, Paulus, as bishop of Burgos. In 1451 he
was deputed by John II., king of Castile, to attend the council
which made him conspicuous by his learning.

He was the author of several works, the principal of which is
entitled Rerum Hispanorum Romanorum imperatorum, sum-
orum pontificum, nec non regum Francorum anacophelaxis.
This is a history of Spain from the earliest days down to 1456, and was published at Granada in 1545, and also in the *Rerum Hispanicarum Scriptores aliquot*, by R. Bel (Frankfort, 1579). Alphonsus died on the 12th of July 1456.

**ALPINI—ALPS**

Alpini, Prospero (Prosper Alpinus), 1553-1617, Italian physician and botanist, was born at Marostica, in the republic of Venice, on the 23rd of November 1553. In his youth he served for a time in the Milanese army, but in 1574 he went to study medicine at Padua. After taking his doctor’s degree in 1578, he settled as a physician in Campo San Pietro, a small town in the Paduan territory. But his tastes were botanical, and to extend his knowledge of exotic plants he travelled to Egypt in 1582. An eyewitness to George Emo or Hemi, the Venetian consul in Cairo. In Egypt he spent three years, and from a practice in the management of date-trees, which he observed in that country, he seems to have deduced the doctrine of the sexual difference of plants, which was adopted as the foundation of the Linnaean system. He says that the female date-trees or palms do not bear fruit unless the branches of the male and female plants are mixed together; or as is generally done, unless the dust found in the male sheath or male flowers is sprinkled over the female flowers. On his return, he resided for some time at Genoa as physician to the Duke of Doria, and in 1593 he was appointed professor of botany at Padua, where he died on the 6th of February 1617. He was succeeded in the botanical chair by his son Alpino Alpini (d. 1637). His best-known work is *De Plantis Aegypti liber* (Venice, 1592). His *De Medicina Egyptianum* (Venice, 1591) is said to contain the first account of the coffee plant published in Europe. The genus *Alpinia*, belonging to the order Zingiberaceae, was named after him by Linnaeus.

**ALPS**, the collective name for one of the great mountain systems of Europe.

1. *Position and Name.*—The continent of Europe is no more than a great peninsula extending westwards from the much vaster continent of Asia, while it is itself broken up by two inland seas into several smaller peninsulas—the Mediterranean forming the Iberian, the Italian and the Greek peninsulas, while the Baltic forms that of Scandinavia and the much smaller one of Denmark. Save the last-named, all these peninsulas of Europe are essentially mountainous. But in height and importance the ranges that rise therein are much surpassed by a great mountain-chain stretching from south-eastern France to the borders of Hungary, as well as between the plains of northern Italy and of southern Germany. This chain is collectively known as the Alps, and is the most important physical feature of the European continent. The Alps, however, do not present so continuous a barrier as the Himalayas, the Andes or even the Pyrenees. They are formed of numerous ranges, divided by comparatively deep valleys, which, with many local exceptions, tend towards parallelism with the general direction of the whole mass. This, between the Dauphiné and the borders of Hungary, forms a broad band convex towards the north, while most of the valleys lie between the directions west to east and south-west to north-east. But in many parts deep transverse valleys intersect the prevailing direction of the ridges, and facilitate the passage of man, plants and animals, as well as of currents of air which mitigate the contrast that would otherwise be found between the climates of the opposite slopes.

The derivation of the name Alps is still very uncertain, some writers connecting it with a Celtic root *alb*, said to mean height, while others suggest the Latin adjective *albus* (white), referring to the colour of the snowy peaks. But in all parts of the great chain itself, the term *Alp* (or *Alm* in the Eastern Alps) is exclusively applied to the high mountain pastures (see ALP), and not to the peaks and ridges of the chain.

2. *Limits.*—These will depend on the meaning we attach to the word Alps as referring to the great mountain-chain of central Europe. If we merely desire to distinguish it from certain minor ranges (e.g. the Cévennes, the Jura, the hills of central Germany, the Carpathians, the Apennines), which are really independent ranges rather than offshoots of the main chain, the best limits are on the west (strictly speaking south), the Col d’Aldrige or di Cadibona (1624 ft.), leading from Turin to Savona and Genoa, and on the east the line of the railway over the Predil Pass (3151 ft.) from Vienna to Marburg in the Mur valley, and thence to Ljubljana. But if we confine the meaning of the term Alps to those parts of the chain which are what is commonly called “Alpine,” where the height is sufficient to support a considerable mass of perpetual snow, our boundaries to the west and to the east must be placed at spots other than those mentioned above. To the west the limit will then be the Col de Tenda (6145 ft.), leading from Cuneo (Coni) to Ventimiglia, while on the east our line will be the route over the Radstätter Tauern (3702 ft.) and the Katschberg (5394 ft.) from Salzburg to Villach in Carinthia, and thence by Klagenfurt to Marburg and so past Lainach in Carniola on to Trieste; from Villach the direct route to Trieste would be over the Predil Pass (3813 ft.) or the Pontebbana or Saifnitz Pass (2615 ft.), more to the west, but in either case this would exclude the Terglou (4900 ft.), the highest summit of the entire South-Eastern Alps, as well as its lower neighbours.

On the northern side the Alps (in whichever sense we take this term) are definitely bounded by the course of the Rhine from Basel to the Lake of Constance, the plain of Bavaria, and the low region of foot-hills that extend from Salzburg to the neighbourhood of Vienna. One result of this limit, marked out by Nature herself, is that the waters which flow down the northern slope of the Alps find their way either into the North Sea through the Rhine, or into the black Sea by means of the Danube, not a drop reaching the Baltic Sea. On the southern side the mountains extending from near Turin to near Trieste subside into the great plain of Piedmont, Lombardy and Venetia. But what properly forms the western bit of the Alps running from near Turin to the Col de Tenda, in a southerly direction, then bending eastwards to the Col d’Aldrige that divides it from the Apennines.

It should be borne in mind that the limits adopted above refer purely to the topographical aspect of the Alps as they exist at the present day. Naturalists will of course prefer other limits according as they are geologists, botanists or zoologists.

3. Climate.—It is well known that as we rise from the sea-level into the upper regions of the atmosphere the temperature decreases. The effect of mountain-chains on prevailing winds is to carry warm air belonging to the lower region into an upper valley, where it expands in volume at the cost of a proportionate loss of heat, often accompanied by the precipitation of moisture in the form of snow or rain. The position of the Alps about the centre of the European continent has profoundly modified the climate of all the surrounding regions. The accumulation of vast masses of snow, which have gradually been converted into permanent glaciers, maintains a gradation of very different climates within the narrow space that intervenes between the foot of the mountains and their upper ridges; it cools the breezes that are wafted to the plains on either side, but its most important function is to regulate the water-supply of that large region which is traversed by the streams of the Alps. Nearly all the moisture that is precipitated during six or seven months is stored up in the form of snow, and is gradually diffused in the course of the succeeding summer; even in the hottest and driest seasons the reserves accumulated during a long preceding period of years in the form of glaciers are available to maintain the regular flow of the greater streams. Nor is this all; the lakes that fill several of the main valleys on the southern side of the Alps are somewhat above the level of the plains of Lombardy and Venetia, and afford an inexhaustible supply of water, which, from a remote period, has been used for that system of irrigation to which they owe their proverbial fertility. Six regions or zones, which are best distinguished by their characteristic vegetation, are found in the Alps. It is an error to suppose that these are indicated by absolute height above the sea-level. Local conditions of exposure to the sun, protection from cold winds, or the reverse, are of primary importance in determining the climate and the corresponding vegetation.
The great plain of Upper Italy has a winter climate colder than that of the British Islands. The olive and the characteristic shrubs of the northern coasts of the Mediterranean do not thrive in the open air, but the former valuable tree ripens its fruit in sheltered places at the foot of the mountains, and penetrates along the deeper valleys and the shores of the Italian lakes. The evergreen oak is wild on the rocks about the Lake of Garda, and lemons are cultivated on a large scale, with partial protection in winter. The olive has been known to survive severe cold when of short duration, but it cannot be cultivated with success where frosts are prolonged, or where the mean winter temperatures fall below 40° F.; and to produce fruit it requires a heat of at least 75° F. during the day, continued through four or five months of the summer and autumn.

The vine is far more tolerant of cold than the olive, but to produce tolerable wine it demands, at the season of ripening, a degree of heat not much less than that needed by the more delicate tree. These conditions are satisfied in the deeper valleys of the Alps, even in the interior of the chain, and up to a considerable height on slopes exposed to the sun. The protection afforded by winter snow enables the plant to resist severe and prolonged frosts, such as would be fatal in more exposed situations. Many wild plants characteristic of the warmer parts of middle Europe are seen to flourish along with the vine. A mean summer temperature of at least 60° F. is not infrequently necessary to produce tolerable wine, but in ordinary seasons this is much exceeded in many of the great valleys of the Alps.

Many writers take the growth of grain as the characteristic of the mountain region; but so many varieties of all the common species are in cultivation, and these have such different climatic requirements, that they do not afford a satisfactory criterion. A more natural limit is afforded by the presence of the chief deciduous trees—oak, beech, ash and sycamore. These do not reach exactly to the same elevation, nor are they often found growing together; but their upper limit corresponds accurately enough to the change from a temperate to a colder climate that is further proved by a change in the wild herbaceous vegetation. This limit usually lies about 4000 ft. above the sea on the north side of the Alps, but on the southern slopes it often rises to 5000 ft., sometimes even to 5500 ft. It must not be supposed that this region is always marked by the presence of the characteristic trees. The interference of man has in many districts almost extinguished them, and, excepting the beech forests of the Austrian Alps, a considerable wood of deciduous trees is scarcely anywhere to be found. In many districts where such woods once existed, their place has been occupied by the Scottish pine and spruce, which suffer less from the ravages of goats, the worst enemies of tree vegetation. The mean annual temperature of this region differs little from that of the British Islands; but the climatic conditions are widely different. Here snow usually lies for several months, till it gives place to a spring and summer considerably warmer than the average of British seasons.

The Subalpine is the region which mainly determines the manner of life of the population of the Alps. On a rough estimate we may reckon that, of the space lying between the summits of the Alps and the low country on either side, one-quarter is available for cultivation, of which about one-half may be vineyards and corn-fields, while the remainder produces forage and grass. About another quarter is utterly barren, consisting of snow-fields, glaciers, bare rock, lakes and the beds of streams. There remains about one-half, which is divided between forest and pasture, and it is the produce of this half which mainly supports the relatively large population. For a quarter of the year the flocks and herds are fed on the upper pastures; but the true limit of the wealth of a district is the number of animals that can be supported during the long winter, and while one part of the population is engaged in tending the beasts and in making cheese and butter, the remainder is busy cutting hay and storing up winter food for the cattle. The larger villages are mostly in the mountain region, but in many parts of the Alps the villages stand in the subalpine region at heights varying from 4000 ft. to 5500 ft. above the sea, more rarely extending to about 6000 ft. The most characteristic feature of this region is the prevalence of coniferous trees, which, where they have not been artificially kept down, form vast forests that cover a large part of the surface. These play a most important part in the natural economy of the country. They protect the valleys from destructive avalanches, and, retaining the superficial soil by their roots, they mitigate the destructive effects of heavy rains. In valleys where they have been rashly cut away, and the waters pour down the slopes unchecked, every tiny rivulet becomes a raging torrent, that carries off the grassy slopes and devastates the floor of the valley, covering the soil with gravel and débris. In the pine forests of the Alps the prevailing species are the common spruce and the silver fir; on siliceous soil the larch flourishes, and surmounts every other European species in height. The Scottish pine is chiefly found at a lower level and rarely forms forests. The Siberian fir is found scattered at intervals throughout the Alps but is not common. The mugho, creeping pine, or Krummholz of the Germans, is common in the Eastern Alps, and sometimes forms on the higher mountains a distinct zone above the level of its congeners. In the Northern Alps the pine forests rarely surpass the limit of 6000 ft. above the sea, but on the south side they commonly attain 9000 ft., while the larch, Siberian fir and mugho often extend to nearly the ultimate limit of vegetation. Throughout the Teutonic region of the Alps the word Alp is used specifically for the upper pastures where cattle are fed in summer, but this region is held to include the whole space between the uppermost limit of trees and the first appearance of permanent masses of snow. It is here that the characteristic vegetation of the Alps is developed in its full beauty and variety. Shrubs are not wanting. Three species of rhododendron vie with each other in the brilliancy of their masses of red or pink flowers; the common juniper rises higher still, along with three species of bilberry; and several dwarf willows attain nearly to the utmost limit of vegetation. The upper limit of this region coincides with the so-called limit of perpetual snow.

On the higher parts of lofty mountains more snow falls in each year than is melted on the spot. A portion of this is carried away by the wind before it is consolidated; a larger portion accumulates in hollows and depressions of the surface, and is gradually converted into glacier-ice, which descends by a slow secular motion into the deeper valleys, where it goes to swell perennial streams. As on a mountain the snow does not lie in beds of uniform thickness, and some parts are more exposed to the sun and warm winds than others, we commonly find beds of snow alternating with exposed slopes covered with brilliant vegetation; and to the observer near at hand there is no appearance in the least corresponding to the term limit of perpetual snow, though the case is otherwise when a high mountain-chain is viewed from a distance. Similar conditions are repeated at many different points, so that the level at which large snow-beds show themselves along its flanks is approximately horizontal. But this holds good only so far as the sides of the same chain the exposure to the sun or to warm winds may cause a wide difference in the level of permanent snow; but in some cases the increased fall of snow on the side exposed to moist winds may more than compensate the increased influence of the sun's rays. Still, even with these reservations, the so-called line of perpetual snow is not fixed. The occurrence of favourable meteorological conditions during several successive seasons may and does increase the extent of the snow-fields, and lower the limit of seemingly permanent snow; while the opposite state of things may cause the limit to rise higher on the flanks of the mountains. Hence all attempts to fix accurately the level of perpetual snow in the Alps are fallacious, and can at the best approach only to local accuracy for a particular district. In some parts of the Alps the limit may be set at about 8000 ft. above the sea, while in others it cannot be placed much below 8500 ft.
As very little snow can rest on rocks that lie at an angle exceeding 60°, and this is soon removed by the wind, some steep masses of rock remain bare even near the summits of the highest peaks, but as almost every spot offering the least hold for vegetation is covered with snow, few flowering plants are seen above 11,000 ft. There is reason to think, however, that it is the want of soil rather than climatal conditions that checks the upward extension of the alpine flora. Increased direct effect of solar radiation compensates for the cold of the nights, and in the few spots where plants have been found in flower up to a height of 12,000 ft., nothing has indicated that the processes of vegetation were arrested by the severe cold which they must sometimes endure. The climate of the glacial region has often been compared to that of the polar regions, but they are widely different. Here, intense solar radiation by day, which raises the surface when dry to a temperature approaching 80° F., alternates with severe frost by night. There, a sun which never sets sends feeble rays that maintain a low equable temperature, rarely rising more than a few degrees above the freezing-point. Hence the upper region of the Alps sustains a far more varied and brilliant vegetation.

4. Main Chain.—In the case of every mountain system geographers are disposed to regard, as a general rule, the watershed (or boundary dividing the waters flowing towards opposite slopes of the range) as marking the main chain, and this usage is justified in that the highest peaks often rise on or very near the watershed. Yet, as a matter of fact, several important mountain groups are situated on one or other side of the watershed of the Alps, and form almost independent ranges, being only connected with the main chain by a kind of peninsula; such are the Dauphiné Alps, the Eastern and Western Graians, the entire Bernese Oberland, the Töidi, Albula and Silvretta groups, the Ortler and Adamello ranges, and the Dolomites of south Tirol, not to speak of the lower Alps of the Vorarlberg, Bavaria and Salzburg. Of course each of these semi-detached ranges has a watershed of its own, like the lateral ridges that branch off from the main watershed. Thus there are lofty ranges parallel to that which forms the main watershed. The Alps, therefore, are not composed of a single range (as shown on the old maps) but of a great "divide," flanked on either side by other important ranges, which, however, do not comprise such lofty peaks as the main watershed. In the following remarks we propose to follow the main watershed from one end of the Alps to the other.

Starting from the Col d’Altare or di Cadibona (west of Savona), the main chain extends first south-west, then north-west to the Col de Tenda, though nowhere rising much beyond the zone of coniferous trees. Beyond the Col de Tenda the direction is first roughly west, then north-west to the Rocher des Trois Évêques (9,300 ft.), just south of the Mont Enchastraye (9,065 ft.), several peaks of about 10,000 ft. rising on the watershed, though the highest of all, the Punta dell’ Argentera (10,794 ft.) stands a little way to its north. From the Rocher des Trois Évêques the watershed runs due north for a long distance, though of the two loftiest peaks of this region one, the Aiguille de Chambeýron (11,155 ft.), is just to the west, and the other, the Monte Viso (12,600 ft.), is just to the east of the watershed. From the head of the Val Pellice the main chain runs north-west, and diminishes much in average height till it reaches the Mont Thabor (10,440 ft.), which forms the apex of a salient angle which the main chain here presents towards the west. Hence the main watershed extends eastwards, culminating in the Aiguille de Scolette (11,500 ft.), but makes a great curve to the north-west and back to the south-east before rising in the Rochemelonn (11,605 ft.), which may be considered as a re-entering angle in the great rampart by which Italy is guarded from its neighbours. Thence the direction taken is north as far as the eastern summit (11,693 ft.) of the Levanna, the watershed rising in a series of snowy peaks, though the loftiest point of the region, the Pointe de Charbonel (12,336 ft.), stands a little to the west. Once more the chain bends to the north-west, rising in several lofty peaks (the highest is the Aiguille de la Grande Sassière, 12,572 ft.), before attaining the considerable depression of the Little St Bernard Pass. Thence for a short way the direction is north to the Col de la Seigne, and then north-east along the crest of the Mont Blanc chain, which culminates in the peak of Mont Blanc (15,782 ft.), the loftiest in the Alps. A number of high peaks crown our
watershed before it attains the Mont Dolent (12,543 ft.). Thence after a short dip to the south-east, our chain takes nearer the Great St Bernard Pass the generally eastern direction that it maintains till it reaches Monte Rosa, whence it bends northwards, making one small dip to the east as far as the Simplon Pass. It is in the portion of the watershed between the Great St Bernard and the Simplon runs in the main chain maintains a greater average height than in any other part. But, though it rises in a number of lofty peaks, such as the Mont Vélan (12,535 ft.), the Matterhorn (14,782 ft.), the Lyskamm (14,889 ft.), the Nord End of Monte Rosa (15,132 ft.), and the Weissemies (13,226 ft.), yet many of the highest points of the region, such as the Grand Combin (14,164 ft.), the Dent Blanche (14,318 ft.), the Weisshorn (14,804 ft.), the true summit or Dufourspitze (15,177 ft.) of Monte Rosa Itself, and the Dom (14,942 ft.), all rise on its northern slope and not on the main watershed. On the other hand the chain between the Great St Bernard and the Simplon sinks at barely half a dozen points below a level of 10,000 ft. The Simplon Pass corresponds to what may be called a dislocation of the main chain. Thence to the St Gotthard the divide runs north-east, all the higher summits (including the Monte Leone, 11,684 ft., and the Pizzo Rotondo, 10,489 ft.) rising on it, a curious contrast to the long stretch just described. From the St Gotthard to the Maloja the watershed between the basins of the Rhine and Po runs in an easterly direction as a whole, though making two great dips towards the south, first to near the Vogelberg (15,065 ft.) and again to near the Pizzo Gallerone (10,307 ft.), so that the 51st parallel presents a broken and irregular appearance. But all the loftiest peaks rise on it: Scopi (10,490 ft.), Piz Medel (10,509 ft.), the Rheinwaldhorn (11,140 ft.), the Tambohorn (10,740 ft.) and Piz Timun (10,502 ft.).

From the Maloja Pass the main watershed dips to the south-east for a short distance, and then runs eastwards and nearly over the highest summit of the Bernina group, the Piz Bernina (13,504 ft.), to the Bernina Pass. Thence to the Reschen Scheideck Pass the main chain is ill-defined, though on it rises the Corn de Campo (10,844 ft.), beyond which it runs slightly north-east past the sources of the Adda and the Fréiale Pass, sinks to form the depression of the Ofen Pass, soon bends north and rises once more in the Piz Sesvenna (10,568 ft.).

The break in the continuity of the Alpine chain marked by the deep valley, the Vintschgau, of the upper Adige (Etsch) is one of the most remarkable features in the orography of the Alps. The little Reschen lake which forms the chief source of the Adige is only 13 ft. below the Reschen Scheideck Pass (4,002 ft.), and by it is but 7 m. from the Inn valley. Eastward of this pass, the main chain runs north-east to the Brenner Pass along the snowy crest of the Oetztal and Stubai Alps, the loftiest point on it being the Weisskugel (12,209 ft., Oetztal), for the highest summits both of the Oetztal and of the Stubai districts, the Wildspitze (12,382 ft.) and the Zuckerrhitl (11,520 ft.) stand a little to the north.

The Brenner (4,045 ft.) is almost the lowest of all the great carriage-roads passes across the main chain, and has always been the chief means of communication between Germany and Italy. For some way beyond it the watershed runs eastwards over the highest crest of the Zillerthal Alps, which attains 11,550 ft. in the Hochfeiler. But, a little farther, at the Dreiherrnspitze (11,500 ft.) we have to choose between following the watershed southwards, or keeping due east along the highest crest of the Greater Tauern Alps. (a) The latter course is adopted by many geographers and has much in its favour. The eastward direction is maintained and the watershed (though not the chief Alpine watershed) continues through the Greater Tauern Alps, culminating in the Gross Venediger (12,068 ft.), for the Gross Grieser (12,461 ft.) rises to the south. Our chain bends north-east near the Rastakfer Tarn Pass, and preserves that direction through the Lesser Taurer Alps to the Semmering Pass. (b) On the other hand, if from the Dreiherrnspitze we cleave to the true main watershed of the Alpine chain, we find that it dips south, passes over the Hochgall (11,287 ft.), the culminating point of the Rieserferner group, and then sinks to the Toblach Pass, but at a point a little east of the great Dolomite peak of the Drei Zinnen it bends east again, and rises in the Monte Coglans (9,287 ft.), the monarch of the Carnic Alps. Soon after our watershed makes a last bend to the south-east and culminates in the Terglou (9,400 ft.), the highest point of the Julic Alps, though the Grizövo (8,249 ft.), the culminating point of the Karvankas Alps stands more to the east. Finally our watershed turns south and ends near the great limestone plateau of the Birnbaumwald, between Laibach and Görz.

As might be expected, the main chain boasts of more glaciers and eternal snow than the independent or external ranges. Yet it is a curious fact that the three longest glaciers in the Alps (the Great Altsch, 169 m., and the Unterara and the Fiescher, each 10 m.) are all in the Bernese Oberland. In the main chain the two longest are both 92 m., the Mer de Glace at Chamonix and the Gorner at Zermatt. In the Eastern Alps the longest glacier is the Pasterze (rather over 64 m.), which is not the true main watershed, though it clings to the slope of the Greater Tauern range, east of the Drescherenspitze. But the next two longest glaciers in the Eastern Alps (the Hintereris, 61 m., and the Gepatsch, 6 m.) are both in the Oetztal Alps, and so close to the true main watershed.

The so-called alpine lakes are the sheets of water found at the foot of the Alps, on either slope, just where the rivers that form them issue into the plains. There are, however, alpine lakes higher up (e.g. the lake of Thun, and those in the Upper Engadine, in the heart of the mountains, though they are naturally smaller and more irregular, but while the true lakes of the highest Alps are represented by the glacier lakes of the Mürzjensee (near the Great Altsch glacier) and those on the northern slope of the Col de Fenêtre, between Aosta and the Val de Bagnes. The most singular, and probably the loftiest, lake in the Alps is the ever-frozen tarn that forms the summit of the Roccia Viva (11,976 ft.) in the Eastern Grains.

Among the great Alpe rivers we may distinguish two classes: those which spring directly from glaciers and which rise in lakes, these being fed by eternal snows or glaciers. In the former class belong the Isère, the Rhone, the Aar, the Ticino, the Tosa, the Hinter (or main) Rhine and the Linth; while in the latter class we have the Durance, the Po, the Rh晚餐, the Vorder and middle branches of the Rhine, the Inn, the Adda, the Oglio and the Adige. The Piave and the Drave seem to be outside either class.

5. Principal Passes.—Though the Alps form a barrier they have never formed an impassable barrier, since, from the earliest days onwards, they have been traversed first, perhaps, for purposes of war or commerce, and later by pilgrims, students and tourists. The spots at which they were crossed are called passes (this word is sometimes though rarely applied to gorges only), and are the points at which the great chain sinks to form depressions, up to which deep-cut valleys lead from the plains. Hence the oldest name for such passes is Mont (still retained in cases of the Mont Cenis and the Monte Moro), for it was many ages before this term was especially applied to the peaks of the Alps, which with a few very rare exceptions (e.g. the Monte Viso was known to the Romans as Vesulus) were long simply disregarded. The native inhabitants of the Alps were naturally the first to use the alpine passes. But to the outer world these passes first became known when the Romans traversed them in order to conquer the world beyond. In the one case we have no direct knowledge (though the Romans probably selected the passes pointed out to them by the natives as the easiest), while in the other we hear almost exclusively of the passes across the main chain or the principal passes of the Alps. For obvious reasons the Romans, having once found an easy direct pass across the main chain, did not trouble to seek for harder and more devious routes. Hence the passes that can be referred to are comparatively few in number: they are, in topographical order from west to east, the Col de l’Argentière, the Mont Genèvre, the two St Bernards, the Splügen, the Septimer, the Brenner, the Radstädter Tauern, the Sölkcharte, the Pöcken and the Pontebba (or Sàfinz) of these the Mont Genèvre and the Brenner were the most frequented, while it will be noticed that in the Central Alps only
twelve passes (the Splügen and the Septimer) were certainly known to the Romans. In fact the central portion of the Alps was by far the least Romanised and least known till the early middle ages. Thus the Simplon is first certainly mentioned in 1233, the St Gotthard (without name) in 1236, the Lukmanier in 906, the San Bernardino in 941; of course they may have been known before, but authentic history is silent as regards them till the dates specified. Even the Mont Cenis (from the 15th to the 19th century the favourite pass for travellers going from France to Italy) is first heard of in 756 only. In the 13th century many hitherto unknown passes came into prominence, even some of the easier glacier passes. It should always be borne in mind that in the Western and Central Alps there is but one ridge to cross, to which access is gained by a deep-cut valley, though often it would be shorter to cross a second pass in order to gain the plains, e.g. the Mont Genèvre, that is most directly reached by the Col du Lautaret; and the Simplon, which is best gained by one of the lower passes over the western portion of the Bernese Oberland chain. On the other hand, in the Eastern Alps, it is generally necessary to cross three distinct ridges between the northern and southern plains, the central ridge being the highest and most difficult. Thus the passes which crossed a single ridge, and did not involve too great a detour through a long valley of approach, became the most frequented, and the most popular, e.g. the Mont Cenis, the Great St Bernard, the St Gotthard, the Septimer and the Brenner. As time went on the travellers (with whatever object) who used the great alpine passes could not put up any longer with the bad old mule paths. A few passes (e.g. the Semmering, the Brenner, the Tenda and the Arlberg) can boast of carriage roads constructed before 1800, while those over the Umbrian and the Great St Bernard were not completed till the early years of the 20th century. Most of the carriage roads across the great alpine passes were thus constructed in the 19th century (particularly its first half), largely owing to the impetus given by Napoleon. As late as 1905, the highest pass over the main chain that had a carriage road was the Great St Bernard (8111 ft.), but three still higher passes over side ridges have roads—the Stelvio (9955 ft.), the Col du Galibier (8721 ft.), in the Dauphiné Alps, and the Umbrail Pass (8242 ft.). Still more recently the main alpine chain has been subjected to the further indignity of having railway lines carried over it or through it—the Brenner and the Pontebba lines being cases of the former, and the Col de Tenda, the Mont Cenis (though the tunnels here are only 37 m. to the west), the Simplon and the St Gotthard, not to speak of the side passes of the Alpstein, Albula and Prättigau of the Bernese Oberland chain. There are also schemes (more or less advanced) for piercing the Splügen and the Hohe Tauern, both on the main ridge, and the Lötschental, on one of the external ranges. The numerous mountain railways, chiefly in Switzerland, up various peaks (e.g. the Rigi and Pilatus) and over various side passes (e.g. the Brunig and the Lütschine) do not concern us here.

6. Divisions.—The Alps, within the limits indicated under (2) above, form a great range, consisting of a main chain, with ramifications, and of several parallel minor chains. They thus form a single connected whole as contrasted with the plains at their base, and nature has made no breaks therein, save at the spots where they sink to comparatively low depressions or passes. But for the sake of practical convenience it has long been usual to select certain of the best marked of these passes to serve as limits within the range, whether to distinguish several great divisions from each other, or to further break up each of these great divisions into smaller groups. As these divisions, great or small, are so to speak the social and economic yokes to which the Alps may be divided. We give below that which seems to us to be the most satisfactory (based very largely on personal acquaintance with most parts of the range), considering, as in the case of the limits of the chain, only its topographical aspect, as it exists at the present day, while leaving it to geologists, botanists and zoologists to elaborate special divisions as required by these various sciences. Our selected divisions relate only to the High Alps between the Col de Tenda and the

route over the Radstätter Tauerne, while in each of the 18 subdivisions the less elevated outlying peaks are regarded as appendages of the higher group within the topographical limits of which they rise. No attempt, of course, has been made to give a complete catalogue of the peaks and passes of the Alps, while in the case of the peaks the culminating point of a lower half-detached group has been included rather than the loftier spurs of the higher and main group; in the case of the passes, the villages or valleys they connect have been indicated, and also the general character of the route over each pass.

As regards the main divisions, three are generally distinguished; the Western Alps (chiefly French and Italian, with a small bit of the East V'alais) being held to extend from the Col de Tenda to the Simplon Pass; the Central Alps (all but wholly Swiss and Italian) thence to the Reschen Scheideck Pass, and the Eastern Alps (wholly Austrian and Italian, save the small Bavarian bit at the north-west angle) thence to the Radstätter Tauerne route, with a bend outwards towards the south-east, as explained under (2) in order to include the higher summits of the Southeastern Alps. Strictly speaking, we should follow the Reschen Scheideck route down the Adige valley, but as this would include in the Central Alps the Ortler and some other of the highest Tibetan systems, it is best (remembering the artificial character of these systems) to take the greater part of the Eastern Alps upwards either over the Umbrail Pass (the old historical pass) or the Stelvio (well-known only since the carriage road was built over it in the 1st quarter of the 19th century) to the head of the Valtellina, and then over the Aprica Pass (as the Bergamasque Alps properly belong to the Central Alps) to the Oglio valley or the Val Camonica, and down that valley to the Lake of Iseo and Brescia.

Assuming these three main divisions, we must now consider in detail the 18 sub-divisions which we distinguish; the first 5 forming the Western Alps, the next 7 the Central Alps, and the rest the Eastern Alps, the divisions throughout being, of course, given in English feet and representing the latest measurements.

1. Western Alps

2. Cottian Alps (from the Col de l'Argentière to the Mont de Cenis and westwards to the Col du Galibier).

2. Cottian Alps

I. Western Alps

Chief Peaks of the Western Alps.

Brec de Chambeiron 11,116 Rochebrune 10,908
Rognasa d'Etache 11,106 Punta Sonnemiller 10,868

2. Cottian Alps (from the Col de l'Argentière to the Mont de Cenis and westwards to the Col du Galibier).
Chief Passes in the Cottian Alps.

Col of the Colleone (La Grave to Valloire), footpath 9,449
Pas de la Cavale (Valloise to Champolion), carriage road 8,990
Col d’Oricières (Dormillouse to Orcières), bridle path 8,859
Col d’Internat (La Grave to St Jean d’Arves), footpath 8,826
Col du Galibier (Hot enterprise to St Michel de Maurienne), carriage road 8,721
Brèche de Vansenestre (Bourg d’Oisans to Vansenestre), footpath 8,642
Col du Galibier (Bourg-d’Oisans to St Jean d’Arves), footpath 8,542
Col du Valfriére (Bourg d’Oisans to Champolion), footpath 8,596
Col du Valtérivière (La Grave to St Jean d’Arves), footpath 8,531
Col of Martignare (La Grave to St Jean d’Arves), footpath 8,531
Col de Martigues (Orcières to St Christophe, Vansenestre), bridle path 8,465
Col de l’Eychauda (Valloise to Monestier), footpath 8,202
Col d’Ansere (La Grave to Monestier), bridle path 7,874
Col d’Ars (Valloise to Le Freney to St Jean d’Arves), footpath 7,532
Col des Sept Laux (Alleval to Bourg d’Oisans), bridle path 7,166
Col du Lautaret (Briançon to Bourg d’Oisans), carriage road 6,808
Col de la Croix de Fer (Bourg d’Oisans to St Jean d’Arves), carriage road 6,765
Col du Glandon (Bourg-d’Oisans to La Chamble), carriage road 6,401
Col de l’Alpe de Vénosé (Vénosé to Le Freney), bridle path 5,446
Col d’Ornon (Bourg d’Oisans to La Mure), carriage road 4,086
Col du Frejus (La Mure to Gap), carriage road 4,082
3. Col de la Croix Frejus (Greble to Veynes and Gap), rail line over 3,829
4. Grana Alps (from the Mont Cenis to the Little St Bernard Pass). These areas are usually divided into three groups, the Central (the watershed between the two passes named), the Western or French, and the Eastern or Italian; in the following lists the initials "C", "W" and "E" show to which group each peak and pass belongs.

Chief Peaks of the Grana Alp.

Grand Paradis (E) 13,342
Grivola (E) 13,022
Grand Casse (W) 12,558
Mont Pourri (W) 12,487
Mont Herbetet (E) 12,396
Pointe de Charbonel (C) 12,336
Aiguille de Glaisher (C) 12,006
Sassière (C) 12,323
Dent Parrachée (W) 12,179
Tour du Grand St Pierre (W) 12,113
Uja di Camularea (W) 12,061
Cima di Charforon (C) 12,025
Gentilli (C) 11,508
Albaron (C) 12,015
Roccia Viva (W) 11,974
Revanna (C) 11,771
Punta di Gai (W) 11,874
Pointe de Ronc (E) 11,871
Dôme de l’Arpont (C) 11,839
Tantale (C) 11,831
Dôme de Chasseforêt (W) 11,802
Croce Rossa (C) 11,703
Aiguille de Pélét (C) 11,700
Dôme de Val d’Isère (C) 11,802
Punta d’Armas (C) 11,615
Uja di Moncrite (C) 11,674
Aiguille de Pellet (C) 11,608
Bollagard (C) 11,643
Rochemelon (C) 11,605
Mont Chalansson (C) 11,582
Grande Traversière (C) 11,467
Tête du Rutor (C) 11,438
Mont Civrad (C) 7,553

Chief Passes of the Gran Sasso.

Col de la Grande Rousse (Rhemès Valley to the Val Grenische), snow (C) 11,483
Col de Géroulais (Arc Valley to Moûtiers Tarentaise), snow (W) 11,385
Col Sanguin (Cogne to Locana), snow (C) 11,487
Col du Grand Paradis (Ceresole to the Val Grenische), snow (E) 10,982
Col du Charforon (same to same), snow 10,992
Col de Telsiaco (Cogne to Locana), snow 10,913
Col de Luzzon (Cogne to the Val Grenische), bridle path (E) 10,831
Col du Bouquetin (Bonval to Val d’Isère), snow (C) 10,827
Col de la Grande Traversière (Ceresole to the Val Grenische), snow (E) 10,608
Col de l’Herbetet (Cogne to the Val Grenische), snow (E) 10,686
Col du Collier (Bessans to Balme), snow (C) 10,598
Col du Grand Estré (Ceresole to the Val Grenische), snow 10,361

The text continues with additional details about various peaks and passes in the Pennine Alps. The table format is used to list the mountain names and their respective elevations.
6. Bernese Oberland (from the Lake of Geneva to the Furka, the Reuss Valley and the Lake of Lucerne). This general name seems best to describe the range, though, of course, portions of it are in Cantons other than that of Berne, viz. Vaud, Fribourg, the Valais, Lucerne and Uri and Unterwalden.

**Chief Peaks of the Bernese Oberland.**

18. South-Eastern Alps (east of the Monte Croce Pass). This division includes three small groups, the Juliic, Carnic and Karawanks Alps—each peak and pass being distinguished by one of the initials "J," "C" or "K."
back the house of Savoy across the Alps, thus forcing it to become a purely Italian power. One turning-point in the rivalry was the treaty of Utrecht (1713), by which France gave up to Savoy the districts (all forming part of the Dauphiné, and lying on the Italian slope of the Alps) of Exilles, Bardonnèche, Oulx, Fénestrelle, and Château Noir. The Prince of Carignan was sent to France to negotiate the Peace of Barcelonnette, situated on the western slope of the Alps and forming part of the county of Nice. The final act in the long-continued struggle took place in 1860, when France obtained by cession the rest of the county of Nice and Savoy, thus removing sole mistress on the western slope of the Alps.

In the Central Alps the chief event, on the northern side of the chain, is the gradual formation from 1291 to 1815 of the Swiss Confederation, at least so far as regards the mountain Cantons, and with especial reference to the independent confederations of the Grisons and the Valais, which only became full members of the Confederation in 1803 and 1815 respectively. The attraction of the south was too strong for both the Forest Cantons and the Grisons, so that both tried to secure, and actually did secure, various bits of the Milanese. The former, in the 15th century, won the Val Leventina (down which the St Gotthard train now thunders) as well as Bellinzona and the Val Blenio (though the Ossola Valley was held for a time only), while the latter added to the Val Bregaglia (which had been given to France by the treaty of Châtelard in 1466) by the cession handed on by the valleys of Mesocco and of Poschiavo. Further, in 1412, the Swiss Confederation as a whole won the valleys of Locarno and Lugano, which, combined with the 15th century conquests by the Forest Cantons, were formed in 1803 into the new Canton of Ticino or Tessin. On the other hand, the Grisons won in 1512 the Valtellina, with Bormio and Chiavenna, but in 1707 these regions were finally lost to it as well as to the Swiss Confederation, though the Grisons retained the valleys of Mesocco, Bregaglia and Poschiavo, while in 1762 it had bought the upper bit of the valley of Münster which lies on the southern slope of the Alps.

In the Eastern Alps the political history is almost monotonous, for it relates simply to the advance or retreat of the house of Habsburg, which still holds all but the whole of the northern portion (the exception is the small bit in the north-west that belongs to Bavaria) of that region. The Habsburgers, whose original home was in the lower valley of the Aar, where still stand the ruins of their ancestral castle, lost that district to the Swiss in 1415, as they had previously lost various other bits of what is now Switzerland. But they received a rich compensation in the Eastern Alps of Coire Dauphin, which General Cornaro had won there gathered in the harvest that numerous minor dynasties had prepared for them, albeit unconsciously. Thus they won the duchy of Austria with Styria in 1282, Carinthia and Carniola in 1335, Tirol in 1363, and the Vorarlberg in bits from 1375 to 1523, not to speak of minor "rectifications" of frontiers on the northern slope of the Alps. But on the other slope their progress was slower, and finally less successful. It is true that they early won Primiero (1373), as well as (1517) the Ampezzo Valley and several towns to the south of Trent. In 1707 they obtained威尼斯, as well as other Venetian towns, in 1805 they gave up Trent and Brixen (as well as that of Salzburg, more to the north), besides the Valtellina region, and in 1875 the Bergamasque valleys, while the Milanese had belonged to them since 1555. But, as is well known, in 1859 they lost to the house of Savoy both the Milanese and the Bergamasca, and in 1866 Venetia proper also, so that the Trentino is now their chief possession on the southern slope of the Alps. The gain of the Milanese in 1859 by the future king of Italy (1861) meant that Italy then won the valley of Livigno (between the Upper Engadine and Bormio) which is the only important bit it holds on the non-Italian slope of the Alps, besides the county of Tenda (obtained in 1575, and not lost in 1860), with the heads of certain glens in the Maritime Alps, reserved in 1860 for reasons connected with hunting. Thus the Alpine states (Italy, Switzerland and Austria), other than France and Bavaria, hold bits of territory on the slope of the Alps where one would not expect to find them. Roughly speaking, in each of these five lands the Alpine population speaks the tongue of the country, though in Italy there are a few French-speaking districts (the Waldensian valleys as well as the Aosta and Oulx valleys) as well as some German-speaking districts such as the Valsesia and the Val d'Aosta, and in Austria the languages spoken are Italian-speaking regions, as well as some spots (in the Grisons) where the old Romance dialect of Romansch or Latini survives; while in Austria, besides German, Italian and Latini, we have a Slavonic-speaking population in the South-Eastern Alps. The highest permanently inhabited village in the Alps is Juif, 6998 ft. (Grisons); while in the French Alps, L'Écot, 6713 ft. (Savoie), and St Véran, 6726 ft. (Dauphiné), are rivals; the Italian Alps boast of Trepalle, 6788 ft. (between Livigno and Bormio), and the Tirolean Alps of Ober Gurgl, 6322 ft., and Fend, 6211 ft. (both in the Oetztal).

8. Exploration of the High Alps.—The higher region of the Alps was long left to the exclusive attention of the men of the adjoining valleys, even when Alpine travellers (as distinguished from Alpine climbers) began to visit these valleys. It is reckoned that about 20 glacier passes were certainly known before 1600, about 25 more before 1700, and yet another score before 1800; but though the attempt of P. A. Arnod (an official of the duchy of Aosta) in 1686 to "re-open" the Col du Géant may be counted as made by a non-native, we do not come upon another case of the kind till the last quarter of the 18th century, when there did fare much better with the high peaks, though the two earliest recorded ascents were due to non-natives, that of the Rochemelon in 1538 having been undertaken in fulfilment of a vow, and that of the Mont Aiguille in 1492 by order of Charles VIII. of France, in order to destroy its immense reputation for inaccessibility—in 1555 Conrad Gesner did not climb Pilatus proper, but only the grassy mound of the Gneipstein, the lowest and the most westerly of the seven summits. The two first men who really systematically explored the regions of ice and snow were H. B. de Saussure (1740–1790), as regards the Pennine Alps, and the Benedictine monk of Disentis, Placidus à Specha (1757–1883), most of whose ascents were made before 1806, in the valleys at the sources of the Rhine. In the early 19th century the Meyer family of Aarau conquered in person the Jungfrau (1811) and by the deputy the Finsteraarhorn (1812), besides opening several glacier passes, their energy being entirely confined to the Bernese Oberland. Their pioneer work was continued in that district, as well as others, by a number of Swiss, pre-eminent among whom were Gottlieb Studer (1804–1890) of Bern, and Eduard Desor (1811–1882) of Neuchâtel. The first-known English climber in the Alps was Colonel Mark Beauvoir (1764–1827), who made an ascent of the fourth of Mont Blanc, a mountain to which his fellow-countrymen long exclusively devoted themselves, with a few noteworthy exceptions, such as Principal J. D. Forbes (1809–1868), A. T. Malkin (1803–1888), John Ball (1818–1880), and Sir Alfred Wills (b. 1828). Around Monte Rosa the Vincent family, Josef Zumstein (1783–1861), and Giovanni Gnifetti (1801–1867) did good work during the half century between 1778 and 1842, while in the Eastern Alps the Archduke John (1782–1859), Prince F. J. C. von Schwarzenberg, archbishop of Salzburg, and the Duke of Modena (1790–1830) made an ascent (1829) of Wolf; Schaubach (1830–1850), all above, P. J. Thurwieser (1780–1865), deserve to be recalled as pioneers in the first half of the 19th century. In the early fifties of the 19th century the taste for mountaineering rapidly developed for several very different reasons. A great stimulus was given to it by the foundation of the various Alpine clubs, each of which drew together the climbers who dwelt in the same country. The first was the English Alpine Club (founded in the winter of 1857–1858), followed in 1862 by the Austrian Alpine Club (which in 1873 was fused, under the name of the German and Austrian Alpine Club, with the German Alpine Club, founded in 1869), in 1863 by the Italian and Swiss Alpine Clubs, and in 1874 by the French Alpine Club, not to mention numerous minor societies of more local character. It was by the members of these clubs (and a few others) that the minute exploration (now all but complete)
crust of the earth has been ridged up into a complex system of creases or folds, out of which the greater mountain chains of southern Europe and Asia have been carved by atmospheric agencies. Superficially, the continuity of the zone is broken at intervals by gaps of greater or less extent; but these are due, in part at least, to the subsidence of portions of the folded belt and their subsequent burial by more recent accumulations. Such a gap is that between the Alps and the Carpathians, but a glance at a geological map of the region will show that the folding was probably at one time continuous. Leaving, however, the larger question of the connexion between the great mountain ranges of Europe and Asia, we find that the Alps are formed of a series of wrinkles or folds, one behind another, frequently arranged en échelon. The folds run, in general, in the direction of the chain, and together they form an arc around the plain of Lombardy and Piedmont. Outside this arc lies a depression along which the waters of the upper Danube and the lower Rhone find their way towards the sea; and beyond rise the ancient crystalline masses of Bohemia, the Black Forest and the central plateau of France, together with the intervening Mesozoic beds of southern Germany and the Jura. The depression is filled by Miocene and later beds, which for the most part are flat and inclined undisturbedly down. Beyond the depression also, excepting in the Jura Mountains, there is no sign of the folding which has raised the Alpine chain. Some of the older beds indeed are crumpled, but the folding is altogether different in age and direction from that of the Alps.

To assist in forming a clear idea of the relations of the Alps to the surrounding regions, a simple illustration will suffice. Upon a table covered by a cloth lay two books in the relative positions shown in figure. The book A represents the central plateau of France and the book B represents the rocks of Bohemia and southern Germany.

If the two hands be placed flat upon the table, in the angle between the two books, and the cloth pushed towards the corner, it will at once be rocked up into a fold which will follow a curve not unlike that of the Alps. The precise character and form of the folds produced will depend upon the nature of the cloth and other accidental circumstances; but with a cloth of similar texture, not only a representation of the chain of the Alps, but even a subsidiary fold in front in the position of the Jura Mountains may be obtained. Imperfect though this illustration may be, it will serve to explain the modern conception of the forces concerned in the formation of the Alps. Within the crust of the earth, whether by the contraction of the interior or in any other way, tangential pressures were set up. Since the crust is not of uniform strength throughout, only the weaker portions yielded to the pressure; and these were crumpled up against the more resisting portions and sometimes were pushed over them. In the case of the Alps it seems natural enough that the crystalline masses of Bohemia, the Black Forest and the central plateau of France should be firmer than the more modern sedimentary deposits; but it is not so easy to understand why the Mesozoic rocks of southern Germany resisted the folding, while those of the Jura yielded. It should, however, be borne in mind that the resisting mass is not necessarily at the surface. Such is in outline the process by which the Alps were elevated; but when the chain is examined in detail, it is found that its history has not been uniform throughout; and it will be convenient, for purposes of description, to divide it into three portions, which may be called the Eastern Alps, the Swiss Alps, and the Western Alps.

The Eastern Alps consist of a central mass of crystalline and schistose rocks flanked on each side by a zone of Mesozoic beds and on the north by an outer band of Tertiary deposits. The Italian side there is usually no zone of folded Tertiary and the Mesozoic band forms the southern border of the chain. Each of these zones is folded within itself,
and the folding is more intense on the Bavarian side than on the Italian, the folds often leaning over towards the north. The Tertiary zone of the northern border is of especial significance and is remarkable for its extent and uniformity. It is divided longitudinally into an outer zone of Molasse and an inner zone of Flysch. The line of separation is very clearly defined; nowhere does the Molasse pass beyond it to the south and nowhere does the Flysch extend beyond it to the north. The Molasse, in the neighbourhood of the mountains, consists chiefly of conglomerates and sandstones, and the Flysch consists of sandstone and shales; but the Molasse is of Miocene and Oligocene age, while the Flysch is mainly Eocene. The relations of the two series are never normal. Along the line of contact, which is often a fault, the oldest beds of the Molasse crop out, and they are invariably overturned and plunge beneath the Flysch. A few miles farther north these same beds rise again to the surface at the summit of an anticlinal which runs parallel to the chain. Beyond this point all signs of folding gradually cease and the beds lie flat and undisturbed.

The Flysch is an extraordinarily thick and uniform mass of sandstones and shales with scarcely any fossils excepting fuscoïds. It is intensely folded and is constantly separated from the Mesozoic zone by a fault. Throughout the whole extent of the Eastern Alps it is strictly limited to the belt between this fault and the marginal zone of Molasse. Eocene beds, indeed, penetrate farther within the chain, but these are limestones with nummulites or limestone-bearing shales and have nothing in common with the Flysch. But although the Flysch is so uniform in character, and although it forms so well-defined a zone, it is not everywhere of the same age. In the west it seems to be entirely Eocene, but towards the east intercalated beds of Inoceramus, &c., indicate that it is partly of Cretaceous age. It is, in fact, a facies and nothing more. The most probable explanation is that the Flysch consists of the detritus washed down from the hills upon the flanks of which it was formed. It bears, indeed, very much the same relation to the Alps that the Siwalik beds of India bear to the Himalayas.

The Mesozoic belt of the Bavarian and Austrian Alps consists mainly of the Trias, Jurassic and Cretaceous beds playing a comparatively subordinate part. But between the Trias of the Eastern Alps and the Trias of the region beyond the Alpine folds there is a striking contrast. North of the Danube, in Germany as in England, red sandstones, shales and conglomerates predominate, together with beds of gypsum and salt. It was a continental formation, such as is now being formed within the desert belt of the globe. Only the Muschelkalk, which does not reach so far as England, and the uppermost beds, the Rhaetic, contain fossils in any abundance. The Trias of the Eastern Alps, on the other hand, consists chiefly of great masses of limestone with an abundant fauna, and is clearly of marine origin. The Jurassic and Cretaceous beds also differ, though in a less degree, from those of northern Europe. They consist largely of limestone; but marls and sandstones are by no means rare, and there are considerable gaps in the succession indicating that the region was not continuously beneath the sea. Tithonian fossils, characteristic of southern Europe, occur in the upper Jurassic, while the Gobian beds, belonging to the upper Cretaceous, contain many of the forms of the Hippuritic sea. Nevertheless, the difference between the deposits on the two sides of the chain shows that the central ridge was dry land during at least a part of the period.

The central zone of crystalline rock consists chiefly of gneisses and schists, but folded within it is a band of Palaeozoic rocks which divides it longitudinally into two parts. Palaeozoic beds also occur along the northern and southern margins of the crystalline zone. The age of a great part of the Palaeozoic belt is somewhat uncertain, but Permian, Carboniferous, Devonian and Silurian fossils have been found in various parts of the chain, and it is not unlikely that even the Cambrian may be represented.

The Mesozoic belt of the southern border of the chain extends from Lago Maggiore eastwards. Jurassic and Cretaceous beds play a larger part than on the northern border, but the Trias still predominates. On the west the belt is narrow, but towards the east it gradually widens, and north of Lago di Garda its northern boundary is suddenly deflected to the north and the zone spreads out so as to include the whole of the Dolomite mountains of Tirol. The sudden widening is due to the great Judicaria fault, which runs from Lago d’Idro to the neighbourhood of Meran, where it bends round to the east. The throw of this fault may be as much as 2000 metres, and the drop is on its south-east side, i.e., towards the Adriatic. It is probable, indeed, that the fault took a large share in the formation of the Adriatic depression. On the whole, the Mesozoic beds of the southern border of the Alps point to a deeper and less troubled sea than those of the north. Clastic sediments are less abundant and there are fewer breaks in the succession. The folding, moreover, is less intense; but in the Dolomites of Tirol there are great outbursts of igneous rock, and faulting has occurred on an extensive scale.

West of a line which runs from Lake Constance to Lago Maggiore the zones already described do not continue with the same simplicity. The zone of the Molasse is little changed, but the Flysch is partially folded in the Mesozoic belt and no longer forms an absolutely independent band. The Trias has almost disappeared, and what remains is not of the marine type characteristic of the Eastern Alps but belongs rather to the continental facies which occurs in Germany and France. Jurassic and Cretaceous beds form the greater part of the Mesozoic band. On the southern side of the chain the Mesozoic zone disappears entirely a little west of Lago Maggiore and the crystalline rocks rise directly from the plain.

Perhaps the strangest problem in the whole of Switzerland is that presented by the so-called Klippen. Within the Alps, when normally developed, we may trace the individual folds for long distances and observe how they arise, increase and die out, to be replaced by others of similar direction. But at times, within or on the border of the northern Eocene trough, the continuity of the folds is suddenly broken by mountain masses of quite different constitution. These are the Klippen, and they are especially important in the Chablais and between the Lakes of Geneva and Thun. Not only is the folding of the Klippen wholly independent of that of the zone in which they lie, but the rocks which form them are of foreign facies. They consist chiefly of Jurassic and Triassic beds, but it is the Trias and the Jura of the Eastern Alps and not of Switzerland. Moreover, although they interrupt the folding of the zone in which they occur, they do not disturb it: they do not, in fact, rise through the zone, but lie upon it like unconformable masses—in other words, they rest upon a thrust-plane. Whence they have come into their present position is by no means clear; but the character of the beds which form them indicates a distant origin. It is interesting to note, in this...
connexion, that the pebbles of the Swiss Molasse are not generally such as would be derived from the neighbouring mountains, but resemble the rocks of the Eastern Alps. The Klippen are, no doubt, the remains of a much larger mass brought into the region upon a thrust-plane, and much of the Molasse has been derived from its destruction. Although the explanation here given of the origin of the Swiss Klippen is that which now is usually accepted, it should be mentioned that other theories have been proposed to account for their peculiarities.

In the Western Alps the outer border of Molasse persists; but it no longer forms so well-defined a zone, and strips are infolded amongst the older rocks. The Eocene has altogether lost its independence as a band and occurs only in patches within the Mesozoic zone. The latter, on the other hand, assumes a greater importance and forms nearly the whole of the subalpine ranges. It consists almost entirely of Jurassic and Cretaceous beds, the Trias in these outer ranges being of very limited extent. The main chain is formed chiefly of crystalline and schistose rocks, which on the Italian side rise directly from the plain without any intervening zone of Mesozoic beds. But it is divided longitudinally by a well-marked belt of stratified deposits, known as the zone of the Briançonnais, composed chiefly of Carboniferous, Triassic and Jurassic beds. The origin of the schistose rocks has long been under discussion, and controversy has centred more particularly around the schistès lustrès, which are held by some to be of Triassic age and by others to be pre-Carboniferous and even, perhaps, Archæan. Partly in consequence of the uncertainty as to the age of these and other rocks, there is considerable difference of opinion as to the structure of the Western Alps. According to the view most widely accepted in France the main chain as a whole forms a fan, the folds on the eastern side leaning towards Italy and those on the western side towards France. The zone of the Briançonnais lies in the middle of the fan.

From the above account it will at once appear that between the convex and the concave margins of the Alpine chain there is a striking difference. Upon the outer side of the arc the central zone of crystalline rocks is flanked by Mesozoic and Tertiary belts; towards the west, indeed, the individuality of these belts is lost, to a large extent, but the rocks remain. Upon the inner side the Tertiary band is found only in the eastern part of the chain, while towards the west, first the Tertiary and then the Mesozoic band disappears against the modern deposits of the low land. The appearance is strongly suggestive of faulting; and probably the southern margin of the chain lies buried beneath the plain of northern Italy.

The chain of the Alps was not raised by a single movement nor in a single geological period. Its growth was gradual and has not been uniform throughout. In the Eastern Alps the central ridge seems to have been in existence at least as early as Triassic times, but it has since been subject to several oscillations. The most conspicuous folding, that of the Mesozoic and Tertiary belts, must have occurred in Tertiary times, and it was not completed till the Miocene period. The structure of the zones in the Bavarian Alps seems to suggest that the chain grew outwards in successive stages, each stage being marked by the formation of a boundary fault. A precisely similar structure is seen in the Himalayas.

11. Flora.—The Alps owe the richness and beauty of their plant life partly to their position as the natural boundary between the
“Baltic” flora on the north and the “Mediterranean” flora on the south, but chiefly to the presence on their heights of a third flora which has but little in common with either of the others. The stronghold of this last, the distinctively “Alpine” flora, is the region above the tree-limit. Its closest relationship is with the flora of the Pyrenees; but an alpine flora is characteristic of all the lofty mountains of central Europe. According to J. Ball, 2010 well-marked species of flowering plants occur within the limits of the Alps. If now we confine our attention to the alpine and higher regions of the Alps and exclude from our list all those plants which, however abundant in these regions, are not less so in the adjacent lowlands, we have left some 700 species, of which about 300 are restricted to the Alps. Even more striking are the plants of the lower Alpine region, that it is the actual presence of a forest vegetation, rather than the theoretical tree-limit, which affects their vertical distribution; so that, e.g. they overflow into the extensive clearings made by man in the primeval mountain forests. Indeed, an analysis of the composition of the alpine flora as a whole leads to the conclusion that the chief bond of union between its members consists in the treeless character of their habitat.

We may broadly distinguish two main geographical elements in the flora of the Alps, the northern and the endemic element. This division (which is not, however, strictly exhaustive) directs special attention to what is undoubtedly the most striking feature of the flora—namely, that of its 693 species no less than 271 reappear in the extreme north. This relation of the alpine to the flora of the Alps is all the more remarkable in view of the very important differences between the alpine and arctic climates. The following circumpolar species are common, and widely distributed throughout the whole of the Alps: Silene acaulis, Dryas octopetala, Saxifraga oppositifolia, Salix alba, S. stellata, Erigeron alpinus, Asalea procumbens, Myosotis alpestris, Polygonum viviparum, Salix retusa, S. herbacea, Phleum alpinum, Juniperus nana. The proportion of northern forms, as regards both species and individuals, increases as we ascend to the higher regions. In the highest vegetation-zone, the snow-region—i.e. on islands of rock above the snow-line—they attain to an equality with the endemic forms. As examples of northern flowers which are characteristic of the snow-region, we may mention Silene acaulis, Eririchium nanum and Arenaria ciliata. On the other hand, typical arctic endemic species of this highest zone (i.e. above Parnassia, Salix herbacea, Salix arctica, Myosotis alpestris, Polygonum viviparum, Salix retusa, S. herbacea, Phleum alpinum, Juniperus nana) are found as low as 1500 m above the level of the sea. The most frequent of these are the following: Salix herbacea, Salix retusa, S. alba, Silene acaulis, Myosotis alpestris, Myosotis alpina, Polygonum viviparum, Oxytropis nivalis, Erigeron alpinus, Alchemilla alpina, Oxytropis nivalis, Parnassia, Salix herbacea, Phleum alpinum, Juniperus nana. All the plants just named, and we observe, are “cushion-plants.” Their compact, moss-like growth and general structural peculiarities are not an expression of mutual affinity, but are in adaptation to the combined cold and dryness of their habitat. It is noteworthy that among the northern plants of the alpine zone, in the narrower sense of the term (i.e. of the region between the tree-limit and the snow-line), there is a marked predominance of species that affect moist localities; and conversely, the majority of alpine flowers of wet habitat are found also in the north. For example, in the genus Primula, a highly characteristic genus of the alpine flora, whose members are among the most striking ornaments of the rocks, the single northern species, P. farinosa, grows only in marshy meadows. On the whole, then, adaptation to cold and wet is the note of the northern element.

As for the explanation of the community between the alpine and arctic floras, all authorities are agreed that the key to the problem is furnished by the occurrence of the glacial period. In the ice-free belt, between the northern ice-sheet and the vastly extended glaciers of the Alps, the two floras have found a common refuge and conjugial conditions of existence; and this view is confirmed by direct palaeontological evidence. With the return of a milder climatic, the so-called northern forms of the present alpine flora were split in two, one portion following close on the northern ice in its gradual retreat to the Arctic, the other following the shrinking glaciers till the plants were able to establish (or re-establish) themselves on the slopes of the Alps. The same explanation covers the case of the similarity of the flora (not merely as regards the northern element) on all the high mountains of central Europe. So much seems to be beyond reasonable doubt. But at this point disagreement begins between the most eminent writers on the subject. While some (e.g. Sir J. D. Hooker, Heer) regard the Arctic, and some (e.g. Wettstein) the Alps, as the original home of at least the bulk of the “northern” element, others (e.g. Ball, Christ) locate this in the highlands of temperate Asia. For it is a remarkable fact that, of the 230 northern species which are most typical of the far north, 182 are found also in the Alps (taking this as a collective name for the mountains that form the southern boundary of Siberia). In any case, however, the migration of these plants to the Alps must for the most part have taken place via the Arctic. But the question of how far the alpine flora of the Alps has been matured by a migration having taken place direct from the Alps to the Alps appears to be excluded by the fact that 50% of the arctico-alpine plants are absent from the Caucasus. A score of species, it is true—not such a number, be it observed, as was formerly supposed—are common to the Alps and the Altai, but absent from the Arctic. But the species composing this Altai element are not so numerous as the arctico-alpine species that are absent from the Altai. On the whole, a common origin in the north for at least the arctico-alpine group of alpine plants seems to be the most reasonable hypothesis.

Side by side with the northern element (which in some respects, we may observe to point the contrast, would be better named the tundra-element) we find a group of species usually spoken of as the xerothermic or meridional element. These do not, however, form an “element,” in the strict geographical sense in which this term is otherwise used here. They are those species which, on general phyto-geographical grounds, must be regarded as having originated under steppe-like conditions. Their affinities are chiefly, though not exclusively, with the present Mediterranean flora—about fifty are of presumably Mediterranean origin—and a large proportion of them are restricted to the southern slopes of the Alps. The following, however, among others, are distributed throughout the whole, or a great part, of the range: Colchicum alpinum, Crocus verus, Orchis globosa, Petroralis pyrenaica, Astragalus depressus, A. aristatus, Oxytropis Halleri, Eryngium alpinum, Erica carnea, Linaria alpina, Globularia nudicaulis, G. cordifolia, Leontopodium alpinum. The last named (the well-known “edelweiss”) is at the present day characteristic of the Siberian steppes. The presence of these plants among the alpine flora is traceable to the steppe-like conditions which prevailed in central Europe both during the warmer inter-glacial periods and (probably) for a time after the close of the ice-age. Subsequently, as the climate of the plains assumed a colder and more humid character, they retired before the invading forests to the high mountains. Here, in the intenser insolation which they enjoy on the alpine slopes, they seem to find a compensation for the drawbacks incidental to the altitude of their present station.

As regards now the endemic element as a whole, the question as to the time and place of its origin is of a highly complicated and controversial nature. The question, too, in the case of this element, is necessarily of genetic rather than purely geographical scope. It must suffice to say that the weight of scientific opinion inclines to the view that at least the majority of endemic species are of pre-glacial origin, and are either strictly indigenous or products of the neighbouring lowlands. About 40% of the endemic element in the alpine flora are endemic also in the narrower sense, i.e. they are confined to the Alps. Many of them are restricted to some one small portion of the chain; these occur chiefly in the southern and eastern Alps. It is an interesting fact that the steeply situated Bernese Alps produce hardly a single peculiar species. The greater richness of certain districts in the matter of species is partly due to the variety of soils encountered therein; but in part may be explained by the fact that these districts were the first to be freed from the ice-sheet at the end of the glacial period.

The following is a list of the most thoroughly characteristic alpine plants—all of them ipso facto members of the endemic element—which are at once peculiar to the Alps (or practically
so) and widely distributed within the limits of the chain. These are: Festuca pulchella, Carex microstyla, Salix caesia, Rumex nivalis, Alnus viridis, Aquilegia alpina, Thlaspi rotundifolium, Saxifraga sp., A. pygmaea, Alyssum leontopodium, Daucus striatus, Eryngium alpinum, Bupleurum stellatum, Androsace helvetica, A. glacialis, Gentiana bavarica, Phyteuma humile, Campanula thyrsoides, C. cenisia, Achillea atrata, Cirsiurn spinosissimum, Crepis Troglovensis.

12. Fauna.—The fauna of the lower zones in the Alps is, on the northern side of the chain, practically identical with that of central Europe, and on the southern side with that of the Mediterranean basin. But in the higher regions it presents many features of special interest alike to the zoologist and the traveller. It seems therefore best to treat here principally of the animal inhabitants of the high Alps.

Though among mammals—as also in the case of the birds—there are less forms peculiar to the Alps, many interesting animals have found in the high mountains at least a temporary refuge from man. The European bison, the urus, the elk and the wild swine have disappeared since Roman times. But the lynx (Lynx vulgaris) perhaps lingers in remote parts, and the brown bear (Ursus arctos) still survives in the dense forests of the Lower Engadine. The fox (Canis vulpes), the stonemarten (Martes foina) and the stoat or ermine (Mustelum ermine) range in summer above the tree-limit. The Ungulata are represented by the chamois (Rupicapra rupicapra) and the bouquetin or steinbock (Capra ibex). The former is the characteristic representative, in western Europe, of the antelopes—is found elsewhere only in the Pyrenees, Carpathians, Caucasus and the mountains of eastern Turkey; the latter survives only in the eastern Graian Alps. Of the Rodentia the most interesting and conspicuous is the marmot (Arctomys marmota), which lives in colonies close to the snow-line. The snow-mouse (Arvicola nivalis) is confined to the alpine and snow regions, and is abundant at these levels throughout the whole chain of the Alps. The mountain hare (Lepus variabilis or timidus) replaces the common hare (Lepus europaeus) in the higher regions; though absent from the intervening plains it again appears in the north of Europe and in Scotland. Among the Insectivora, the alpine shrew (Sorex alpinus) is restricted to the Alps. Of the Cheiroptera (bats) only Vesperugo moravus is characteristic alpine. The birds of the Alps are proportionately very numerous. The lammersgейr (Gypaetus barbatus), once common, is now extremely rare, even if it has not already become extinct in the Alps; but the golden eagle (Aquila chrysaetos) still holds its own. Some of the smaller species of prey are not uncommon, but there is none that can be regarded as specially characteristic of the Alps, as a whole or of the alpine region. As characteristic birds of the snow-region may be mentioned the alpine chough (Pyrrhocorax alpinus), which is frequently seen at the summits even of the loftiest mountains, the alpine swift (Cypselus melba), the wall-creeper (Tichodroma muraria), snow-finch (Montifringilla nivalis) and ptarmigan (Lagopus mutus); the geographical distribution of this last being similar to that of the mountain hare. The black redstart (Ruticilla ilia), though common in the lower regions, is also met with in fair numbers almost up to the snow-line. The raven (Corvus corax) is fairly common in the alpine and sub-alpine regions. On the highest pastures we find, further, the alpine accentor (Acrocephalus collaris) and the alpine pipit (Anthus spinuloseus). The crag-martin (Cotylo rupescriti) haunts lofty cliffs in the alpine region. On the upper verge of the pine forests, or in the study vegetation just beyond, the following are not uncommon—black woodpecker (Picus martius), ring-oisel (Turdus torquatus), Bonelli's warbler (Phylloscopus bonelli), crested tit (Parus cristatus), citril finch (Cistinella alpina), siskin (Chrysocephalus spinus), crossbill (Loxia curvirostra), nutcracker (Nucifraga caryocactae), blackcock (Teira tetra), and the alpine varieties of the chamois (Rupicapra alpestris, borealis) and tree-creeper (Certhia familiaris, coturnix). The remaining classes of Vertebrata are very sparsely represented in the high Alps; and what few species occur are mostly common to the plains as well. In fact, among the remaining land vertebrates, only the black salamander (Salamandra atra) is exclusively alpine. This interesting animal, though a member of the Amphibia, is terrestrial and viviparous.

The former connexion between the Arctic and the Alps, which has left such unmistakable traces in the present alpine flora, affords, as regards the fauna also, the only possible explanation of the characteristic geographical distribution of many alpine forms; but it is chiefly among the Invertebrata that we find this collateral testimony to the influence of the glacial period. In this respect we may note that two small crustaceans, Diaemus bacillifer and D. denticornis, swarm in the ice-cold waters of the highest alpine tarns throughout the entire chain; and the former of these is also a characteristic inhabitant of pools formed from melting snow in the extreme north. Among the remaining divisions of Invertebrata special mention may be made of the air-breathing Arthropoda—on the whole the most important and interesting group. About one-third of the animals belonging thereto that occur in the higher regions are exclusively alpine (or alpine and northern); these characteristic alpine forms being furnished chiefly by the spiders, beetles and butterflies. Most numerous are the beetles. Those of the highest zone are remarkable for the great predominance of predacious species and of wingless forms. In this last respect they present a striking analogy with the endemic coleopterous fauna of oceanic islands. As for the butterflies, not more than one-third of the species found in the alpine region occur in the neighbouring lowlands. The relations between the alpine and lowland fauna are therefore extremely interesting, as regards not only their hitherto interdependence but also the analogies of their geographical distribution. It should be noted that butterflies are the chief agents in securing the continued existence of such alpine flowers as depend on insect fertilization, the other insect fertilizers being mostly wanting at great heights.

The classic of alpine zoology is F. von Tschudi's Das Tierleben der Alpen (11th ed., 1896). See also zoological section, by K. W. v. Dalla Torre, of Anleitung zu wissenschaftlichen Beobachtungen auf Alpenreisen. For the Vertebrata, see V. Fatio's Faune des vertébrés de la Suisse (5 vols., 1869-1904). Die Tierwelt der Hochgebirgsseen, by F. Zachokke (1900) is an important treatise on an interesting department of alpine natural history. C. Zeller's Alpenbiere im Wechsel der Zeit (1892) gives a reliable account of the gradual disappearance of some of the larger forms of life from the Alps. For the butterflies and other insects, the recent discussions of A. Boissier's Alpenblumen, ihre Befruchtung durch Insekten, und ihre Anpassung an dieselben (1881). (H. V. K.)

ALPUJARRAS, or Alpuxarras, the Moorish Al Busherat, or "the grass-land"), a mountainous district of southern Spain, in the province of Granada, consisting principally of valleys which descend at right angles from the crest of the Sierra Nevada mountains. On the north and north-west, to the south of the Guadalfeo, which sever it from the Mediterranean Sea, on the south. These valleys are among the most Beautiful and fertile in Spain. They contain a rich abundance of fruit trees, especially oranges, vines, olives, lemons and figs, and in some parts present scenes of almost Alpine grandeur. The inhabitants are the descendants of the Moors, who, after the Spanish conquest of Granada in 1492, vainly sought to preserve the last relics of their independence in their mountain fastnesses. Many of the names of places in the
Alpujarras are of Moorish origin. The district contains many villages of 1000 to 4000 inhabitants, the four largest being Lanjarón, with its ruined castle and chalybeate baths, Orgía, Trevelez and Ugijar; all situated at a considerable elevation. Trevelez, the highest, stands 13 m. above the sea, and was the seat of the famed 4th century poet Aluredus, generally known as Alurredus, an Arabian poet of the tribe Tamim, who flourished in the second half of the 6th century. Of his life we know practically nothing except that his chief poem concerns an incident in the wars between the Lakhmids and the Ghassânids (see Arabia, History). Even the date of this is doubtful, but it is generally referred to the period after the middle of the 6th century. His poetic description of ostriches is said to have been famous among the Arabs. His diwân consists of three qasidas (elegies) and eleven fragments. Asma' I considered three of the poems genuine.

The poems were edited by A. Socin with Latin translation as Die Gedichte des Alurredus (Leipzig, 1867), and are contained in W. Alwardt's The Dying of the six ancient Arabic Poets (Lond., 1870); cf. W. Ahlwardt's Bemerkungen über die Äethenheit der alten arabischen Gedichte (Greifswald, 1872), pp. 66-71 and 146-168.

Alquifou (etymologically the same word as alcohol), a lead ore found in Cornwall, used for its green glaze.

Alredues, Alured or Alurredus, of Beverley, was said to be a disciple of St. Bevin and held in high esteem among the monks of the 11th century. He wrote, apparently about the year 1148, a chronicle entitled Annales sive Historia de gestis regum Britanniae, which begins with Brutus and carries the history of England down to 1129. This work was edited by T. Hearne (Oxford, 1716), and at one time enjoyed some reputation as an authority. It is, however, a mere compilation and of no value.

Geoffrey of Monmouth and Simeon of Durham are Alured's chief sources. Among the Cottonian MSS. there is a collection of records relating to Beverley, Liberatic Ecclesiae S. Johannis de Beverle, which is attributed to Alured, but of no good authority.

Alsace (Ger. Elsass), a former province of France, divided after the Revolution into the departments of Haut-Rhin and Bas-Rhin, and incorporated since the war of 1870 with the German empire (see Alsace-Lorraine). It is bounded on the north by the Rhenish Palatinate, on the east by the Rhine, on the south by Switzerland and on the west by the Vosges Mountains, and it comprises an area of 3344 English sq. m. The district possesses many natural attractions, and is one of the most fertile in central Europe. There are several ranges of hills, the highest of which of the region is a provine with the elevation of the Ill. The river of importance is the Ill, which falls into the Rhine after a course of more than 100 m., and is navigable below Colmar. The hills are generally richly wooded, chiefly with fir, beech and oak. The agricultural products are corn, flax, tobacco, grapes and various other fruits. The country has a great wealth of minerals, silver having been found, and copper, lead, iron, coal and rock-salt being wrought with profit. There are considerable manufactures, chiefly of cotton and linen. The chief towns are Müllhausen and Colmar in the upper district and Strassburg in the lower. The province is traversed from east to west by the railway from Strassburg to Nancy, and the main line north and south runs between Basel and Strassburg.

History.—From a very early period Alsace has been a disputed territory, and has suffered in the contentions of rival races. Inhabited by the Rauraci and the Sequani, it formed part of ancient Gaul, and was therefore included in the Roman empire in the provinces of Germania Superior and Maxima Sequanorum. The Romans held it nearly five hundred years, and on the dissolution of their power it passed under the sway of the Franks. In the Merovingian period it formed a duchy attached to the kingdom of Austrasia, and was governed by the descendants of duke Eticho, one of whom was St. Odilia. After the death of Charlemagne, Alsace, like the rest of the empire, was divided into countships. But the duchy was re-established after the death of the German king Henry I., and became hereditary in the Hohenstaufen family, and then in Austria, which succeeded in 1273 to the imperial dignity. In the beginning of the 12th century the country was divided between the two landgraves of Upper and Lower Alsace, but to counteract the power of the nobles the emperors established in Alsace a great number of free towns. This state of things continued until 1648, when a large part of Alsace, comprising the two landgraves of Upper and Lower Alsace and the prefecture of the ten free imperial towns, was ceded to France by the treaty of Westphalia. In the war which preceded this peace (generally known as the Thirty Years' War) Alsace had been so terribly devastated by the Swedes and the French that the German emperor found himself unable to hold it. The population was greatly reduced in numbers, and much of the land was left uncultivated. In the war between France and the Empire, arising out of the attempt of Louis XIV. to seize Holland, the part of Alsace which remained to Germany was again overrun by the French. Although this war was terminated in 1678 by the treaty of Nijmegen, the French monarch was desirous of incorporating a still larger amount of Rhine territory; and accordingly in 1680 he laid claim to a number of territories, belonging to princes of the Empire, which he alleged had been dismembered from Alsace. It was ordered that these territories should be at once restored to that province under the crown of France, and several independent sovereignties were cited to appear before a German magistracy at Aix-la-Chapelle. To these Louis had established at Brisach and Metz. The princes appealed to the emperor and to the diet; but the previous wars had so exhausted the power of the former that nothing could be done to resist the aggression. In 1681 the French troops under Louvois seized Strassburg, aided by the treachery of the bishop and other great men of the city. A further war broke out, but by the treaty of Ratisbon (Regensburg) in 1683, Strassburg was secured to France. The war was renewed in 1688 and continued until 1697, when the peace of Ryswick confirmed definitively the possession of Strassburg to France. Some remaining territories of small importance were acquired by the French after the revolution of 1789, including Mullhausen, which had been a republic allied to Switzerland.

Originally Celtic, the population was modified during the Roman period by the arrival of a Germanic people, the Triboci. In the 5th century came other German tribes, the Alaman, and then the Franks, who drove the Alamanni into the south. Since that period the population has in the main been Teutonic; and the French conquests of the 17th century, while modifying this element, still left it predominant. The people continued to speak their own language, and the aristocratic classes of the 13th century, which were educated, spoke French. The educated classes also spoke French. Protestantism was professed by a large number of the inhabitants; and in many respects their characteristics identified them rather with the race to the east than that to the west of the Rhine. In process of time, however, they considered themselves French, and lost all desire for reannexation to any of the German states.

Alsace suffered a good deal in the war of 1870-71. The earlier battles of the campaign were fought there; Strassburg and other of its fortified towns were besieged and taken; and its people were compelled to submit to very severe exactions. The civil and military government of the province, as well as that of Lorraine, was assumed by the Germans as soon as they obtained possession of those parts of France, which was very shortly after the commencement of the war. The Alsatian railways were reorganized and provided with a staff of German officials. German stamps were introduced from Berlin; the occupied towns were garrisoned by the Landwehr; and requisitions on a large scale were demanded, and paid for in cheques which, at the close of the war, were to be honoured by whichever side should stand in the unpleasant position of the conqueror. The people, notwithstanding their German origin, showed a very strong feeling against the invaders, and in no part of France was the enemy resisted with greater stubbornness. It was evident from an early period of the war, however, that Prussia was resolved to reannex Alsace to German territory. When the preliminaries of peace came to be discussed at Versailles in
February 1871, the cession of Alsace, together with what is called German Lorraine, was one of the earliest conditions laid down by Bismarck and accepted by Thiers. The sacrifice of territory was afterwards ratified by the Naval Convention at Bordeaux, though with a protest from the representatives of the departments about to be given up; and thus Alsace once more became German. By the bill for the incorporation of Alsace and German Lorraine, introduced into the German parliament in May 1871, it was provided that the sole and supreme control of the two provinces should be vested in the German emperor and the federal council until the 1st of January 1874, when the constitution of the German empire was established. Bismarck admitted the aversion of the population to Prussian rule, but said that everything would be done to conciliate the people. His policy appears really to have been carried out, and it was not long in bearing fruit. Many of the inhabitants of the conquered districts, however, still clung to the old connexion, and on the 30th of September 1872—the day by which the people were required to determine whether they would consider themselves German subjects and remain, or French subjects and transfer their domicile to France—45,000 elected to be still French, and sorrowfully took their departure. The German system of compulsory education of every child above the age of six was introduced directly after the annexation.

Alsace-Lorraine is a Ger. (Elsass-Lothringen), a German imperial territory (since 1871), consisting of the former French province Alsace (then divided into the departments of Haut-Rhin and Bas-Rhin), together with its capital Strasbourg, and German Lorraine (which included the department of the Moselle and portions of the departments of Meurthe and Vosges), together with the capital and fortress of Metz. The imperial territory (Reichsland) is bounded S. by Switzerland; E. by Baden, from which it is separated by the Rhine; N.E. and N. by the Bavarian Palatinate, the Prussian Rhine Province; Luxemburg, and W. by France, which is its neighbour. The maximum length from N. to S. is 145 m.; the maximum breadth E. to W. 195 m., and the minimum breadth, on a line drawn through Schletstadt, 24 m. In respect of its physical features, Alsace-Lorraine falls into three parts—mountain land, plain and plateau. The first, practically co-extensive with the western half of Alsace, consists of the Vosges range, which running in a northerly direction from the deep gap or pass of Belfort (route de Belfort) forms in its highest ridges the natural frontier line between Germany and France. Between the Rhine and the Vosges there is a fertile plain forming the eastern half of Alsace. In the N.W. a high and undulating plateau, which gently descends in the W. to the valley of the Moselle, occupies nearly the whole area of Lorraine. The drainage of the Vosges valleys and of the Rhine valley is collected and carried into the Rhine about 10 m. below Strasbourg by the Ill, which has a course of more than 100 m. and is navigable below Colmar. With the exception of a few streams which run to the Rhone, all the waters of Alsace flow into the Rhine. The climate is on the whole temperate—warmest in the lowest districts (400 ft. above sea-level) of N. Alsace, and coldest on the summits of the Vosges, where snow lies six months in the year. The mean annual temperature at Strasbourg is 49°8 F., at Metz 48°2; the rainfall at Strasbourg 264 in., and at Metz 271 in. The Rhine in great part fertile, yielding good crops of potatoes, cereals (including maize), sugar beet, hops, tobacco, flax, hemp and products of olericulture. But grapes and fruit are amongst the most valuable of the crops. The cereals chiefly grown are wheat, oats, barley and rye. Great quantities of hay are harvested. This description embraces also the production of Lorraine, where agriculture is less strenuously carried on, and the fertility of the soil is less. But Lorraine possesses, in compensation, greater riches in the earth, in coal and iron and salt mines. Cows are grazed on the S. Vosges in summer, and large quantities of cheese (Münster cheese) are made and exported.

Total population (1905) 1,814,626. The farms in Alsace are mostly small and are held partly as a private possession, partly on the communal system; in Lorraine there are some larger occupations. The manufacture of cottons, and on a smaller scale of woollens, is special to Alsace, the chief centres of the industry being Mulhausen, Colmar and the valleys of the Vosges. The territory has always been the centre of an active commerce, owing to its situation on the confines of Germany, France and Switzerland, and alongside the great highway of the Rhine. The communications embraced some 1,249 m. of railway (1903), of which 1,108 m. belonged to the state, a good system of roads, and several canals (notably the Rhine-Rhône, the Rhine-Marie and the Ill Canal), in addition to the rivers. Administratively the territory is divided into the following three districts, showing a density of population of about 316 to the sq. m.—

On the sea division, 935,395 were in 1905 males, and 879,321 females. The percentage of illegitimacy is about 7. The rural population occupies 51% of the whole, the urban population 48%. The largest towns are Strasbourg (the capital of the territory), Mulhausen, Metz, Colmar, all above 20,000 inhabitants each. Classed according to religion there were, in 1904, 373,978 Protestants, 3,316,391 Roman Catholics, and 32,379 Jews. Education is provided for at the university of Strasbourg, in 21 classical and pro-classical schools, in 18 modern schools, and in nearly 4000 elementary schools. Over 85% of the people speak German as their mother-tongue, the rest French, or a patois of French. The annual revenue and expenditure are each somewhat in excess of £3,000,000. Customs and indirect taxes yield more than three-fifths of the total revenue, and direct taxes less than one-twentieth. The state forests give about one-ninth of the whole. The higher administration of justice is devolved upon six provincial courts and a supreme court, sitting at Colmar. Moreover, there are purely industrial tribunals at Mulhausen, Thann, Markirch, Strassburg and Metz. The fish-breeding establishment at Hüttingen in Upper Alsace should be mentioned.

Constitution.—The sovereignty over the territory was by a law (Reichsgesetze) of the 9th of June 1871 vested in the German emperor, who, until the introduction of the imperial constitution on the 1st of January 1874, was the Elector (Landesfürst) of the federal state of Elsass-Lothringen, and in a few cases, that of the imperial diet (Reichstag), the sole right of initiating legislation. In October of this last year a committee (Landesausschuss) of the whole territory was appointed to deliberate on laws proposed to it before they received the final sanction of the emperor. On the 2nd of May 1877, the Landesausschuss was itself empowered to initiate legislation within the competence of the territory, and in 1879 the imperial viceroy (Statthalter), representing the imperial chancellor, who had until then been the responsible minister, took up his residence in Strasbourg. He is assisted in the government by 4 ministers of departments, under the presidency of a secretary of state, and, when occasion demands the extraordinary discussion of legislative proposals, by a council of state (Staatsrat), consisting of the secretary of state, under secretaries, the president of the supreme court of justice of the territory and, as a rule, of 12 nominees of the emperor. The Landesausschuss, a constitutional body with parliamentary privileges, consists of 35 members, 34 being appointed out of their number by the various district councils (Bezirksstage), 4 by the large towns, and 20 by the rural districts. Alsace-Lorraine is represented in the Bundesrat by two commissioners, who have, however, one vote; and the territory returns 15 members to the Reichstag.

See A. Schmidt, Elsass und Lothringen (Leip., 1899); Spach, Histoire de la basse Alsace et de la ville de Strasbourg (Stras., 1860): von Mülheimen Rechberg, Die Annexion des Elsas durch
ALSATIA—ALSTROMER

Frankreich und Rückblick auf die Verwaltung des Landes, 1648—1697 (Strasbourg, 1787; Stras., 1877); L. Petersen, Das Deutschtum in Elsass-Lothringen (Munich, 1902.)

ALSATIA (the old French province of Alsace), long a "debatable ground" between France and Germany, and hence a name applied in the 17th century to the district of Wurttemberg between the Thurnes and Fleet Street, in London, which afforded sanctuary (q.v.) to debtors and criminals. The privileges were abolished in 1697. The term is also used generally of any refuge for criminals.

ALSEN (Danish Ald), an island in the Baltic, off the coast of Schleswig, in the Little Belt. It formerly belonged to Denmark, but, as a result of the Danish war of 1864, was incorporated with Germany. Its area is 105 sq. m.; the length nearly 20, and the breadth from 3 to 12 m. Pop. (1900) 25,000, most of whom speak Danarre. The island is fertile, richly wooded, and yields grain and fruit. Sonderburg, the capital, with a good harbour and a considerable trade, is connected with the mainland by a pontoon bridge. Other places of note are Norburg and Augustenburg.

On the peninsula Kekenis at the S.W. end of Alsen there is a lighthouse. Here, in 1848, the Danes directed their main attack against Field-marshall Wrangel's army. In 1864 the Prussians under Herwarth von Bittenfeld took Alsen, which was occupied by 9000 Danish troops under Steinmann, thus bringing the Danish war to a close. Since 1870 Alsen has been fortified.

'ALSheKH, MOSES, Jewish rabbi in Safed (Palestine) in the later part of the 16th century: He was the author of many homiletical commentaries on the Hebrew Bible. His works still justly enjoy much popularity, largely because of their powerful influence as practical exhortations to virtuous life.

ALSIETINUS LACUS (mod. Lago di Martignano), a small lake in southern Etruria, 15 m. due N.N.W. of Rome, in an extinct crater. Augustus drew from it the Aqua Alsietina; the water was hardly fit to drink, and was mainly intended to supply his nymphaeum (lake made for a sham naval battle) at Rome, near S. Francesca. That a Ripa, on the right bank of the Tiber, where some traces of the aqueduct were perhaps found in 1720, the course of the aqueduct, which was mainly subterranean, is practically unknown: Frontinus tells us that it received a branch from the lake of Bracchanio near Carcace (Galera): and an inscription relating to it was found in this district in 1887 (F. Barnabei, Notizie degli Scavi, 1887, 181.).

ALSIUM (mod. Polo), an ancient town of Etruria, 30 m. W. by N. of Rome by rail, on the Via Aurelia, by which it is about 22 m. from Rome. It was one of the oldest cities of Etruria, but does not appear in history till the Roman colonisation, 247 B.C., and was never of great importance, except as a resort of wealthy Romans, many of whom (Pompey, the Antonine emperors) had villas there. About 13 m. N.E. of Polo is a row of large mounds called I Monteroni, which belong to tombs of the Etruscan cemetery. Considerable remains of ancient villas still exist along the low sandy coast, one of which, about 1 m. E. of Polo, occupies an area of some 400 by 250 yds. The medieval castle belongs to the Odescalchi family. Near Polo is the modern sea-bathing resort, Ladispoli, founded by Prince Odescalchi.

See G. Dennis, Campi Etrusci, 1 1839.

ALSO, VINCENT (c. 1630—1703), English Nonconformist divine, was of Northamptonshire origin and was educated at St John's College, Cambridge. He received deacon's orders from a bishop, whereupon he settled as assistant-master in the free school of Oakham, Rutland. He was re-elected from different courses and associated itself with a very "painful" minister, the Rev. Benjamin King. Subsequently he married Mrs. King, and "becoming a convert to his principles, received ordination in the Presbyterian way, not being satisfied with that which he had from the bishop." He was presented to the living of Wilby in Northamptonshire; but was thence ejected under the act of Uniformity in 1662. After his ejection he preached privately at Oakham and Wellington, sharing the common pains and penalties of nonconformists,—e.g. he was imprisoned six months for praying with a sick person. A book against William Sherlock, dean of St Paul's, called Antisessio, (against Socinus), written in the vein of Andrew Marvell's 'Rehearsal Transcribed,' procured him much celebrity as a wit. Dr Robert South, no friend to nonconformists, publicly pronounced that Alse had the advantage of Sherlock in every way. Besides fame, Antisessio procured for its author an invitation to succeed the venerable Thomas Cawton (the younger) as independent minister in Westminster. He accepted the call and drew great multitudes to his chapel. He published other books, which showed a fecundity of wit, a playful strength of reasoning, and a provoking indomitableness of railery. Even with Dr. Goodman and Dr Stillington for antagonists, he more than held his own. His Mischief of Impositions (1680) in answer to Stillington's Mischief of Separation, and Melius Inquirendum (1679) in answer to Goodman's Compassionate Inquiry, remain historical landmarks in the history of nonconformity. Later on, from the entanglements of a son in alleged treasonable practices, he had to sue for and obtained pardon from King James II. This seems to have given a somewhat diplomatic character to his closing years, inasmuch as, while remaining a nonconformist, he had a good deal to do with proposed political-ecclesiastical compromises. He died on the 8th of May 1703, having preserved his "spirits and smartness" to the last.

See Wood's Athenae (Bliss) iv. 106; Calamy's Life of Baxter, ii. 487; Wilson's History and Ani. of Dissenting Churches, iv. 63-66. (A. J. G.)

ALSTED, JOHANN HEINRICH (1838—1939), German Protestant divine. He was some time professor of philosophy and theology at Herborn, in Nassau, and afterwards at Weissenburg in Transylvania, where he remained till his death in 1838. He was a marvellous prolific writer. His Encyclopaedia (1630), the most considerable of the earlier works of that class, was long held in high estimation.

ALSTON, CHARLES (1683—1760), Scottish botanist, was born at Eddlewood, near Hamilton, in 1683, and became lecturer in materia medica and botany at Edinburgh and also superintendent of the botanical gardens, of the plants in which he published a catalogue in 1740. He was a critic of Linnaeus's system of plant-classification (see Botany). He died on the 22nd of November 1760 at Edinburgh. His Lectures on Materia Medica were published posthumously in 1770.

ALSTON, a market-town in the Penrith parliamentary division of Cumberland, England, 29 m. by road E.S.E. of Carlisle, on a branch of the North-Eastern railway from Haltwhistle. Pop. (1821) 2125. It lies in the uppermost part of the valley of the South Tyne, among the high bleak moors of the Pennines. Copper and blende are found, and there are limestone quarries. The mines of argentierring lead, belonging to Greenwich Hospital, London, were formerly of great value, and it was in order that royalties on the Alston lead mines and on those elsewhere in the county might be jointly collected that the parish was first included within the borders of Cumberland, in the 18th century. As many as 119 lead mines were worked in the parish in 1768, but the supply of metal has been almost exhausted. Coal is worked chiefly for lime-burning, and timber is prepared for the manufacture of colours. Thread and flannel are also made. Whitley Castle, 2 m. N., was a Roman fort, the original name of which is not known, guarding the road which ran along the South Tyne valley and over the Pennines. It has no connexion with Alston itself.

ALSTRÖMER, JONAS (1685—1761), Swedish industrial reformer, was born at Alingsås in Vastergötland, on the 7th of January 1685. He left his native village at an early age, and, in 1707 became clerk to Alberg, a merchant of Stockholm, whom he accompanied to London in the spring of the same year. Three years later, Alberg failed, and Alström (as his name was before his ennoblement) engaged in the business of shipbroker on his own account, and eventually proved very successful. After traveling for several years on the continent, he was seized with the patriotic desire to transplant to his native country some of the industries he had seen flourishing in Britain. He accordingly returned to Alingsås, and in 1724 established a woolen factory in
ALTAI

reach 14,850 and 14,500 ft. respectively, and give origin to several glaciers (30 sq. m. in aggregate area). Here also are the Kuitun (12,000 ft.) and several other lofty peaks. Numerous spurs, striking in all directions from the Sibillium mountains, fill up the space between that range and the lowlands of Tomsk, in the Ural, the Urall and the Bukhtarma open south-westwards. Such are the Chuya Alps, having an average altitude of 10,000 ft., with summits from 11,500 to 12,000 ft., and at least ten glaciers on their northern slope; the Katun Alps, which have a mean elevation of about 10,000 ft. and are mostly snow-clad; the Kholzun range; the Korgon (6300 to 7000 ft.), Talitsk and Selitsk ranges; the Tigreretsk Alps, and so on. Several secondary plateaus of lower altitude are also distinguished by geographers. The Katun valley begins as a wild gorge on the south-west slope of Byelukha; then, after a big bend, the river (400 m. long) pierces the Katun Alps, enters a wider valley, lying at an altitude of from 2000 to 3000 ft., which it follows until it emerges from the Altai highlands to join the Biya in a most picturesque region. The Katun and the Biya together form the Ob. The next valley is that of the Charysh, which has the Korgon and Tigreretsk Alps on one side and the Talitsk and Bashalatst Alps on the other. This, too, is very fertile. The Altai, seen from this valley, presents the most romantic scenes, including the small but deep Kolyvan lake (altitude, 1180 ft.), which is surrounded by fantastic granite domes and towers. Farther west the valleys of the Alpa rise, the Ubra and the Bukhtarma open south-westwards towards the Irtysh. The lower part of the first, like the lower valley of the Charysh, is thickly populated; in the valley of the Ulba is the Riddersk mine, at the foot of the Ivanovsky peak (6770 ft.), clothed with beautiful alpine meadows. The valley of the Bukhtarma, which has a length of 200 m., also has its origin at the foot of the Byelukha and the Kuitun peaks, and as it falls some 5000 ft. in less than 200 m., from an alpine plateau at an elevation of 6200 ft. to the Bukhtarma fortress (1130 ft.), it offers the most striking contrasts of landscape and vegetation. Its lower parts are abound in glaciers, the greatest of which is the Beler, which comes down from the Byelukha. On the northern side of the range which separates the upper Bukhtarma from the upper Katun is the Katun glacier, which after two ice-falls widens out to 7000-9000 yards. From a grotto in this glacier bursts tumultuously the Katun river. The middle and lower parts of the Bukhtarma valley have been colonized since the 18th century by runaway Russian peasants—serfs and nonconformists (Raskolniks)—who created there a free republic on Chinese territory; and after this part of the valley was annexed to Russia in 1860, the river runs north to the same name. The valleys farther north, on the same western face of the Sibillium range, are but little known, their only visitors being Kirghiz shepherds. Those of Bashkaus, Chuyluksman, and Chuulka, all three leading to the beautiful alpine lake of Teletskoye (length, 48 m.; maximum width, 3 m.; altitude, 1700 ft.; area, 87 sq. m.; maximum depth, 1020 ft.; mean depth, 660 ft.), are only inhabited by nomad Telenghites or Telets. The shores of the lake—reminding a visitor somewhat of the Swiss lake of Lucerne—rise almost sheer to over 6000 ft. and are too wild to accommodate a numerous population. From this lake issues the Biya, which joins the Katun at Biysk, and then meanders through the beautiful prairies of the north-west of the Altai. Farther north the Altai highlands are continued in the Kuznetsk district, which has a slightly different geological aspect, but still belongs to the Altai system. But the Abakan river, which rises on the western shoulder of the Sayan mountains, belongs to the system of the Yenisei. The Kuznetsk Ala-tau range, on the left bank of the Abakan, runs north-east into the government of Yeniseist, while on the right bank of the river (480 m. long) rises the country northwards towards the Siberian railway and westwards towards the Ob. The Tom and its numerous tributaries rise on the northern slopes of the Kuznetsk Ala-tau, and their fertile valleys are occupied by a

1 Mr. S. Turner estimates the culminating peak of Mt. Byelukha at 14,800 ft., but to Willier’s Peak, a little to the N.W. of Byelukha, he assigns an altitude of 17,800 ft. (p. 205 of Siberia).
dense Russian population, the centre of which is Kuznetsk, on the Tom.

**Geology.**—Geologically the Altai mountains consist of two distinct elements which differ considerably from each other in composition and structure. The Russian Altai is composed mainly of mica and chlorite schists and slates, together with beds of limestone, and in the higher horizons Devonian and Carboniferous fossils occur in many places. There is no axial zone of gneiss, but intrusions of granite and other plutonic rocks occur, and the famous ore deposits are found chiefly near the contact of these intrusions with the schists. The strata are thrown into folds which run in the direction of the mountain ridges, forming a curve with the convexity facing the south-east. The Mongolian or Great Altai, on the other hand, consists mainly of gneiss and Archean rocks. The strike of the rocks is independent of the direction of the chain, and the chain is bounded by faults. It is, in fact, a horst and not a zone of folding.

**Flora.**—The flora of the Altai, explored chiefly by Karl F. von Ledebour (1785-1851), is rich and very beautiful. Up to a level of 1000 ft. on the northern and 2000 ft. on the southern slopes, plant life belongs to the European flora, which extends into Siberia as far as the Yenisei. The steppe flora penetrates into the mountains, ascending some 1100-1200 ft., and in sheltered valleys even up to 5500 ft., when it of course comes into contact with the purely Alpine flora. Up to an altitude of 6000 ft. and 8500 ft., the latter limit on the north and west, consists of magnificent forests of birch, poplar, aspen, and Coniferæ, such as Pinus sibirica, Abies sibirica, Larix sibirica, Picea obovata, and so on, though the fir is not found above 2500 ft., while the meadows are abundantly clothed with brightly-coloured, typical assortments of herbaceous plants. The Alpine meadows, which have many species in common with the European Alps, have also a number of their own peculiar Altai species.

**Mineral wealth.**—The Altai proper is rich in silver, copper, lead, and iron. Gold is also known in the Kuznetsk, iron, gold, and iron are the chief mineral resources. The Kuznetsk Altai mines are only now beginning to be explored, while the copper, and perhaps also the silver, ores of the Altai proper were worked by the mysterious prehistoric race of the Chudes at a time when the use of iron was not yet known. Russians began to mine in 1727 at Kolyvan, and in 1739 at Barnaul. Most of the Altai region, covering an area of some 170,000 sq. m. and including the Kuznetsk district, has since 1746 formed a domain of the imperial family under the name of the Altai Mining District. The ores of the Altai proper nearly always appear in irregular veins, containing silver, lead, copper, and gold—and they are, or were, worked chiefly by Zmeinogorsk (or Zmeiev), Zyr'yanyovsk, Ust-Kamenogorsk and Riddersk (abandoned in 1861). They offer, however, great difficulties, especially on account of their continually varying productivity and temperature of fusion. The beautiful varieties of porphyry—green, red, striped— which are obtained, often in big monoliths, near Kolyvan, are cut at the imperial stone-cutting factory into vases and other ornaments, familiar in the art galleries and palaces of Europe. Aquamarines of medicoe quality but enormous size (up to 3 in. in diameter) are found in the Kuznetsk mine. The northern, or Salair, mining region is rich in silver ores, and the mine of this name used formerly to yield up to 93,000 oz. of silver in the year. But the chief wealth of the northern Altai is in the Kuznetsk coal-basin, also containing iron-ores, which fills up a valley between the Kuznetsk Ala-tau and the Salair range for a length of about 270 m., with a width of about 65 m. The coal is considered equal to the best coal of England and south Russia. The country is also covered with thick clilluvial and alluvial deposits containing gold. However, all the mining is now on the decline.

**Population.**—The Russian population has rapidly increased since the fertile valleys belonging to the imperial family have been thrown open to settlement, and it has been estimated that in 1908 the population of the region (Biysk, Barnaul and Kuznetsk districts) reached about 500,000. Their chief occupations are agriculture (about 3,500,000 acres under culture), cattle-breeding, bee-keeping, mining, gathering of cedar-nuts and hunting. All this produce is exported partly to Tomsk and partly to Kobido in Mongolia. The natives may represent a population of about 45,000. They are Altaians in the west and Tlemschans in the north of the territory with a few Kalmucks and Tartars. Although all are called Kalmucks by the Russians, they speak a Turkish language. Both the Telyengites and the Altaians are Shamanists in religion, but many of the former are already quite Russified. The virgin forests of the Kuznetsk Ala-tau—the Chern, or Black Forest of the Russians—are peopled by Tartars, who live in very small settlements, sometimes of the Russian type, but mostly in wooden yards or huts of the Mongolian fashion. They can hardly keep any cattle, and lead the precarious life of forest-dwellers, living upon various wild roots when there is no grain in the spring. Hunting and fishing are resorted to, and the skins and furs (the rusks) are remarkable.

**Towns.**—The capital of the Altai region is Barnaul, the centre of the mining administration and an animated commercial town; Biysk is the commercial centre; Kuznetsk, Ust-Kamenogorsk, and the mining towns of Kolyvan, Zmeinogorsk, Riddersk and Salairsk are the next largest places.

**ALTAMURA—ALTAR.**

*Altamura, a town of Apulia, Italy, in the province of Bar, 28 m. S.S.W. of the latter city. The town is situated on the road from Altamura to Gioia del Colle. Pop. (1901) 22,725. It possesses a fine Romanesque cathedral begun in 1232 and restored in 1330 and 1531, the portal being especially remarkable. It is one of the four Palatine churches of Apulia. The surrounding territory is fertile. The medieval walls, erected by the emperor Frederick II., rest upon the walls of an ancient city of unknown name. These early walls are of rough blocks of stone without mortar. Ancient tombs with fragments of vases have also been found, and there are cases which have been used as primitive tombs or dwellings with a satellite and an altar or votive shrines. The Altamurans were sun-worshippers, and the chief altar and shrines were the chief materials. They are of varying form; an altar shown in a relief at Khorsabad is ornamented with stepped battlements, which are the equivalent of the familiar "altar-horns" in Hebrew ritual. An altar also from Khorsabad (now in the British Museum) has a circular table and a solid base triangular on plan, with pilasters ornamented with animals' paws at the angles. A third variety, of which an 8th century B.C. example from Nimrud exists in the British Museum, is a rectangular block ornamented at the ends by cylindrical rolls. These altars are in height from 2 to 3 ft. According to Strabo, a city in Attica (i. e. 185) the great altars of Babylonia were made of gold.

**Egypt.**—In Egypt altars took the form of a truncated cone or of a cubical block of polished granite or of basalt, with one or more basin-like depressions in the upper surface for receiving fluid libations. These had channels whereby fluids poured into the receptacles could be drained off. The surface was plain,
inscribed with dedicatory or other legends, or adorned with symbolic carving.

Palestine.—Recent excavations, especially at Gezer, have shown that the earliest altars, or rather sacrifice hearths, in Palestine were circular spaces marked out by small stones set on end. At Gezer a pre-Semitic place of worship was found in which three such hearths stood together, and drained into a cave which may reasonably be supposed to have been regarded as the reservoir of the divinity. These circular hearths persisted into the Canaanite period, but were ultimately superseded by the Semitic developments. To the primitive nomadic Semite the presence of the divinity was indicated by springs, shady trees, remarkable rocks and other landmarks; and from this earliest conception grew the theory that a *numen* might be induced to take up an abode in an artificial heap of stones, or a pillar set upright for the purpose. The blood of the victim was poured over the stone as an offering to the divinity dwelling within it; and from this conception of the stone arose the further and final view, that the stone was a table on which the victim was to be burned.

Very few specimens of early Palestinian altars remain. The megalithic structures common in the Hauran and Moab may be entirely sepulchral. At Gezer no definite altar was discovered in the great High Place; though it is possible that a bank of intensely hard compact earth, in which were embedded a large number of human skulls, took its place. A very remarkable altar, at present unique, was found at Tanach by the Austrian excavators. It is pyramidal in shape, and the surface is ornamented with human-headed and animal relief. This, like the earliest Babylonian altars, is of baked brick.

The Old Testament conception of the altar varies with the stage of religious development. In the pre-Deuteronomistic period altars are erected in any place where there had appeared to be a manifestation of deity, or under any circumstance in which the aid of deity was invoked; not by heretical individuals, but by the acknowledged religious leaders, such as Noah at Ararat, Abraham at Shechem, Bethel &c., Isaac at Beer-sheba, Jacob at Bethel, Moses at Rephidim, Joshua at Ebal, Gideon at Ophrah, Samuel at Ramah, Elijah at Carmel, and others. These primitive altars were of the simplest possible description—in fact they were required to be so by the regulation affecting them, preserved in Exodus xx. 24, which prescribes that in *every place where Yahweh records his name* an altar of earth or of unhewn stone, without steps or other extraneous ornamentation, shall be erected.

The priestly regulations affecting altars are of a very elaborate nature, and are framed with a single eye to the essential theory of later Hebrew worship—the centralization of all worship at one shrine. These recognize two altars, which by the healers of this portion of the Pentateuch are placed from the first in the tabernacle in the wilderness—a theory which is inconsistent with the other evidences of the nature of the earlier Hebrew worship, to which we have just alluded.

The first of these altars is that for burnt-offering. This altar was in the centre of the court of the tabernacle, of acacia wood, 3 cubits high and 5 square. It was covered with copper, was provided with "horns" at the corners (like those of Assyria), hollow in the middle, and with rings on the sides into which the staves for its transportation could be run (Ex. xxvii. 1-8). The altar of the Solomonic temple is on similar lines, but much larger. It is now generally recognized that the description of the tabernacle altar is intended to provide a precedent for this vast structure, which would otherwise be inconsistent with the traditional view of the simple Hebrew altars. In the second temple a new altar was built after the fashion of the former (1 Macc. iv. 47) of "whole stones from the mountain." In Herod's temple the altar was again built after the same model. It is described by Josephus (v. 5, 6) as 15 cubits high and 50 cubits square, with angle horns, and with "an insensible acutum, prope corollas" leading up to it (a device to evade the pre-Deuteronomic regulation about steps). It was made without any use of iron, and no iron tool was ever allowed to touch it. The blood and refuse were discharged through a drain into the brook Kedron; this drain probably still remains, in the "Bir el-Arwoh, under the "Dome of the Rock" in the mosque which covers the site of the temple.

The second altar was the altar of incense, which was in the holy place of the tabernacle. It was of similar construction to the altar of burnt-offering, but smaller, being 2 cubits high and 1 cubit square (Ex. xxx. 1-5). It was overlaid with gold, and had a golden ring on either side for the carrying of the incense (Ex. xxi. 26) is referred to in sacrifices. This altar was removed by Antiochus Epiphanes (1 Macc. i. 21) and restored by Judas Maccabaeus (1 Macc. iv. 49). That in the temple of Herod is referred to in Luke i. 11.

The ritual uses of these altars are sufficiently explained by sacred images. On the first was a fire continually burning, in which the burnt-offerings were consumed. On the second an offering of incense was made twice a day.

In the pre-Deuteronomistic passage, Exodus xxii. 14, the use of the altar as an asylum is postulated, though denied to the wilful murderer. This is a survival of the ancient belief that the deity resided in the pillar or stone-heap, and that the faithful place himself under the protection of the local *numen* by seeking sanctuary. From Kings i. 50 it would appear that the suppliant caught hold of the altar-horns (compare 1 Kings ii. 28), as though special protective virtue resided in this important though obscure part of the structure.

Greece and Rome.—According to the difference in the service for which they were employed, altars fell into two classes. Those of the first class were pedestals, so small and low that the suppliant could kneel upon them; these stood inside the temples, in front of the sacred image. The second class consisted of larger tables destined for burnt sacrifice; these were placed in the open air, and, if connected with a temple, in front of the entrance. Possibly altars of the former class were in historical times substitutes for, and rendered the same service as, the bases of the sacred images within the temples in earlier ages. In this case the altar of Apollo at Delphi, upon which the Greek vases Neoptolemus is frequently represented as taking refuge from Orestes, might be regarded as the pedestal of an invisible image of the god, and as fulfilling the same function as did the base of the actual image of Athena in Troy, towards which Cassandra fled from Ajax. The second class of altars, called *byzoi* by the Greeks and *altaria* by the Romans, appears to have originated in temporary constructions such as heaps of earth, turf or stone, made for kindling a sacrificial fire as occasion required. But sacrifices to earth deities were made on the earth itself, and those to the infernal deities in sunk hollows (Odys. x. 25; Festus s.v. *Altaria*). The note of Eustathius (Odyss. xlii. 252) perhaps indicates some customs reminiscent of a primitive antiquity in which the sacrifice was made without an altar at all. He says ἀποτάομα τινα λειφ ὕπνω οὐ̂ εἶναι μύσαν ὅν καθαρισμὸς ἀλλ’ εἶναι ἑδάφους—"some holy places away from altars, whose offering is made not on an altar but on the floor." Pausanias (vi. 20. 7) speaks of an altar at Olympia made of unbaked bricks. In some primitive holy shrines the bones and ashes of the victims sacrificed were allowed to accumulate, and upon this new fires were kindled. Altars so raised were, like most religious survivals, considered as endowed with particular sanctity; the most remarkable recorded instances of such are the altars of Hera at Samos, and of Pan at Olympia (Paus. v. 14. 6; v. 15. 5), of Heracles at Thebes (Paus. ix. 11. 7), and of Zeus at Olympia (Paus. v. 13. 5). The last-mentioned stood on a platform (πρόπος) measuring 125 ft. in circumference, and led up to by steps, the altar itself being 22 ft. high. Women were excluded from the platform. Where hecatombs were sacrificed, the *skarabeai* were erected, whether as an independent structure, as in the case of the altar at Parion, where it measured on each side 660 ft. The altar of Apollo at Delos (ὁ κερατῖνος βυζόμ) was made
FIG. 1.—SANT' AMBROGIO, MILAN.

FIG. 2.—SANTA CECILIA, ROME.
of the horns of goats believed to have been slain by Diana; while at Miletus was an altar composed of the blood of victims sacrificed (Paus. v. 13. 6). The altar at Phorse in Achaea was of unhewn stones (Paus. vii. 22. 3). The altar used at the festival in honour of Dactylus on Mt. Citharon was of wood, and was consumed along with the sacrifice (Paus. ix. 3. 4). Others of bronze are mentioned. But these were exceptional, the usual material of an altar was marble, and its form, both among the Greeks and Romans, was either square or round; polygonal altars, of which examples still exist, being exceptions. When sculptured decorations were added they frequently took the form of imitations of the actual festoons with which it was usual to ornament altars, or of symbols, such as crania and horns of oxen, referring to the victims sacrificed. As a rule, the altars which existed apart from temples bore the name of the deity by whom they were dedicated and the names of the deities in whose service they were, or, if not the name, some obvious representation of the deity. Such, for example, is the purpose of the figures of the Muses on an altar dedicated to them, now to be seen in the British Museum. An altar was retained for the service of one particular god, except where through local tradition two or more deities had become intimately associated, as in the case of the altar at Olympia to Artemis and Alpheus jointly, or that of Poseidon and Erechtheus in the Erechtheum at Athens. This type, which was, however, at Oropus, where the altar was divided into five parts, one dedicated to Heracles, Zeus, and Paeon Apollo, a second to heroes and their wives, a third to Hestia, Hermes, Amphiarautus and the children of Amphiochus, a fourth to Aphrodite Panacea, Jason, Health, and Healing Athene, and the fifth to the Nymphs, Pan, and the rivers Achelous and Cephissus (Paus. i. 34. 2). Such deities were styled ἄγαλμα, each having a separate part of the altar (Paus. i. 34. 2). Other terms are ἄγαλμα, or ἄγαλμα. Deities of an inferior order, who were conceived as working together—e.g. the winds, god of the air—were common. In the same way, the "unknown gods" were regarded as a unit, and had in Athens and at Olympia one altar for all (Paus. i. 1. 4; v. 14. 5; cf. Acts of Apostles, xvii. 18). An altar to all the gods is mentioned by Aeschylus (Soph. 222). Among the exceptional classes of altars are also to be mentioned those on which fire could not be kindled (βυόσ λαμάρυ), and those which were kept free from blood (βυόσ κατάλαμας), of which in both respects the altar of Zeus Hypatos at Athens was an example. The ἐκτισισ was a round altar; the ἑγκύρα, one employed apparently for sacrifice to inferior deities (but ἑγκύρα, Πάδηξ, Aesch., Pers. 205). In Rome an altar erected in front of a statue of a god was always required to be lower than the statue itself (Vitr. vi. 9). Altars were always places of refuge, and even criminals and slaves were there safe, violence offered to them being insults to the gods whose suppliants the refugees were for the time being. They were also taken hold of by the Greeks when making their most solemn oaths.

Ancient America.—As a single specimen of an altar, wholly unrelated to any of the foregoing, we may cite the ancient Mexican example described by W. Bullock (Six Months in Mexico, London, 1824, p. 335). This was cylindrical, 25 ft. in circumference, with sculpture representing the conquests of the national warriors in fifteen different groups round the side.1 Portable altars and tables of offerings were used in pre-Christian as well as in Christian ritual. One such was discovered in the Gezer excavations, dating about 200 B.C. It was a slab of polished limestone about 6 in. square with five cups in its upper surface. Another from the same place was a small cubical block of limestone bearing a dedication to the gods of Heracles. They have also been found in Assyria. Portable altars are still used in some forms of worship in India. See the Journal of the Royal Asiatic Society, 1852, p. 71.

1 Bullock also says (p. 354) that the altar in the church of the Indians would be wholly covered with a name of the same nature as those in use before the introduction of Christianity.
St. Cuthbert (A.D. 687), but the history of the origin and development of this practice is not fully worked out. According to the Caeremoniale (12. 13) a canopy (baldachinum) should be suspended over the altar; this should be square, and of sufficient size to cover the altar and the predella on which the officiating priest stands. This baldachin, called liturgically the ciborium, is sometimes hung from the roof by chains or supports, so that it can be lowered or raised; sometimes it is fixed to the wall or reredos; sometimes it is a solid structure of wood covered with metal or of marble supported on four columns. The latter form is, however, usually only in large churches, more especially of the basilica type, e.g. St. Peter's at Rome or the Roman Catholic cathedral at Westminster. The origin of the ciborium is not certain, but it is represented in a mosaic at Thessalonica of a date not later than A.D. 900. Even at the present day, in spite of a decree of the Congregation of Rites (27th of May 1697) ordering it to be placed over all altars, it is—even at Rome itself—usually only found over the high altar and the altar of the Blessed Sacrament.

Multiplication of altars is another medieval characteristic. This also is probably a result of the edict of Pope Felix already mentioned. In a vault where more than one martyr was buried an altar might be erected for each. It is in the 6th century that we begin to find traces of the multiplication of altars. In the church of St. Gall, Switzerland, in the 9th century there were seventeen. In the modern Latin Church almost every large church contains several altars—dedicated to certain saints, in private side chapels, established for masses for the repose of the founder's soul, &c. Archbishop Wulffred in 816 ordered that beside every altar there should be an inscription recording its dedication. This regulation fell into abeyance after the 12th century, and such inscriptions are very rare. One remains mutilated at Deerhurst (Archaeologia, vol. i. p. 60).

Where there is in a cathedral or church more than one altar, the principal one is called a "high altar." Where there is a second high altar, it is generally at the end of the choir or chancel. In monastic churches (e.g. formerly at St. Albans) it sometimes stands at the end of the nave close to the choir screen. Beside the altar was a drain (pisicina) for pouring away the water in which the communion vessels were rinsed. This seems originally to have been under the altar, as it is still in the Eastern Church.

That the primitive communion table was covered with a communion-cloth is highly probable, and is mentioned by Optatus (c. A.D. 370), bishop of Milevis. This had developed by the 14th or 15th century into a cerecloth, or waxed cloth, on the table itself; and three linen coverings one above the other, two of about the size of the table and one rather wider than the altar, and long enough to hang down at each end. Five crosses are worked upon it, four in the corners and one in the middle, and there is an embroidered edging. In front was often a hanging panel of embroidered cloth (the frontal; but frontals of woollen, ornamented with carving or embroidery, &c., are also to be found). These embroidered frontals are changeable, so that the principal colour in the pattern can accord with the liturgical colour of the day. Speaking broadly, red is the colour for feasts of Christ, green for the Church, violet for Lent, and blue or indigo for the medieval seasons, &c.; no less than sixty-three different uses differing in details have been enumerated. A similar panel of needlework (the dossal) is suspended behind the altar.

Portable altars have been used on occasion since the time of Bede. They are small slabs of hard stone, just large enough for the chalice and paten. They are consecrated and marked with the five incised crosses in the same way as the fixed altar, but they may be placed upon a support of any suitable material, with or without cover or stone. They are used on a journey in a heretical or heathen country, for instance. In the inventory of the field apparel of Henry, earl of Northumberland, A.D. 1513, is included "A coffer wyth ij liddes to serve for an Awter and ne" (Archaeologia, xxvi. 403).

On the altar are placed a cross and candlesticks—six in number, and seven when a bishop celebrates in his cathedral; and over it is suspended or fixed a tabernacle or receptacle for the reservation of the Sacrament.

III. Post-Reformation Altars.—At the Reformation the altars in churches were looked upon as symbols of the reformed doctrine, especially where the struggle lay between the Catholics and the Calvinists, who on this point were much more radical revolutionaries than the Lutherans. In England the name "altar" was retained in the Communion Office in English, printed in 1549, and in the complete English Prayer-book of the following year, known to students as the First Book of Edward VI. But orders were given soon after that the altars should be destroyed, and replaced by movable wooden tables; while from the revised Prayer-book of 1552 the word "altar" was carefully expunged, "God's board" or "the table" being substituted. The short reign of Mary produced a temporary reaction, but the work of reformation was resumed on the accession of Elizabeth.

The name "altar" has been all along retained in the Corona- tion Office of the kings of England, where it occurs frequently. It was also recognised in the canons of 1640, but with the reservation that "it was an altar in the sense in which the primitive church called it an altar and in no other." In the same canons the rule for the position of the communion tables, which has since regularly followed throughout the Church of England, was formulated. In the modern English church the altars seem to have been so placed that, like those of the Hebrews, they could be surrounded by the worshippers. The chair of the bishop or celebrant was on their east side, and the assistant clergy were ranged on each side of him. But in the middle ages the altars were placed against the east wall of the churches, or else against a reredos erected at the east side of the altar, so as to prevent all access to the table from that side; the celebrant was thus brought round to the west side and caused to stand between the people and the altar. On the north and south sides were often curtains. When tables were substituted for altars in the English churches, these were not merely movable, but at the administration of the Lord's Supper were actually moved into the body of the church, and placed table-wise—that is, with the long sides turned to the north and south, and the narrow ends to the east and west,—the officiating clergyman standing at the north side. In the time of Archbishop Laud, however, the present practice of the Church of England was introduced. The communion table, though still of wood and movable, is, as a matter of fact, never moved; it is placed altar-wise—that is, with its longer axis running north and south, and close against the east wall. Often there is a reredos behind it; it is also fenced in by rails to preserve it from profanation of various kinds.

In 1841 the ancient church of the Holy Sepulchre at Cambridge was robbed of most of its interest by a calamitous "restoration" carried out under the superintendence and partly at the charge of the Camden Society. On this occasion a stone altar, consisting of a flat slab resting upon three other upright slabs, was presented to the parish, and was set up in the church at the east wall of the chancel. This was at the instance of the notice of the Court of Arches in 1845, and Sir H. Jenner Fust (Pauker v. Lichfield and St burn) ordered it to be removed, on the ground that a stone structure so worthy that it could not be carried about, and seeming to be a mass of solid masonry, was not a communion-table in the sense recognized by the Church of England.

BIBLIOGRAPHY.—For altars in the ancient East see M. Jastrow, Religion of Assyria and Babylonia; Porot and Chipiez, Art in Chaldea (1. 143, 255); Sir J. Gardiner Wilkinson, A Second Series of the Monuments and Customs of the Ancient Egyptians. ii. 387; Benzing's and Nowack's works on Hebräische Archäologie. For classical altars, much information can be obtained from the notes in J. G. Frazer's Pausanias. See also Schönherr, Griechische Altäre, vol. ii.; the vol. viii. "Götterdienstliche Altäre" in Hermann's Lehrbuch der griechischen Antiquitäten. On domestic altars and worship see Petersen, Hausgottesdienst der Griechen (Cassel, 1851).

1 Except in one place where the term used is "God's board."

1 In the Eastern Church four small pieces of cloth marked with the signs of the Evangelists are placed on the four corners of the altar, and covered with three cloths, the uppermost (the corporal) being of smaller size.
On plural dedications consult Maurer, *De arboris graecorum fratribus*; 1839. For Christian references is best made to the articles on the subject in the dictionaries of Christian and liturgical antiquities of Migne, Martigny, Smith and Cheetham, and Fugig, where practically all the available information is gathered. For Martigny’s *De antiquis Ecclesiae ritibus, ill. vi. (Rouen, 1700); Voigt, *Thesaurus historico-theologico* (Berlin, 1768); and *Dictionnaire encyclopédique de l’Eglise* (1790); and the liturgical works of Bon. Many articles on various sections of the subject have appeared in the journals of archaeological societies; we may mention Neubich on the churches of Rome earlier than 1130 (Archaeologiae, xcl.v. 1824); and Christian, *Tradition etchrétien* (Annales archéologiques, iv. p. 238), and a paper by Teyxier on enamelled altars in the same volume. (R. A. S. M.)

**ALTDORF**—the capital of the Swiss canton of Uri. It is built at a height of 1516 ft. above sea-level, a little above the right bank of the Reuss, not far above the point where this river is joined by the Schächen torrent. In 1900 the population was 3137, all Romanists and German-speaking. Altdorf is 34 m. from Lucerne by the St Gotthard railway and 22 m. from Goesschenen. Its port on the Lake of Lucerne, Flitelen, is 2 m. distant. There is a stately parish church, while above the little town is the oldest Capuchin convent in Switzerland (1581). Altdorf is best known as the place where, according to the legend, William Tell shot the apple from his son’s head. This act by tradition happened on the market-place, where in 1805, at the foot of an old nurse (with rude frescoes commemorating the feat), there was set up a fine bronze statue (by Richard Kissling of Zürich) of Tell and his son. In 1894 a theatre was opened close to the town for the sole purpose of performing Schiller’s play of *Wilhelm Tell*. The same year a new carriage-road was opened from Altdorf through the Schächen valley and over the Klausen Pass (6404 ft.) to the village of Lintibhal (30 m.) and so to Glarus. One and a half mile from Altdorf by the Klausen road is the village of Bürgeln, where by tradition Tell was born; while he is also said to have lost his life, while saving that of a child, in the Schächen torrent that flows past the village. On the left bank of the Schächen opposite Altdorf is Tellstatt, where Tell’s birth house and carriage house where he was born. The ruins of Tell and his son. In 1804 a theatre was opened close to the town for the purpose of performing Schiller’s play of *Wilhelm Tell*. The alpine museum of antiquities. (W. A. B. C.)

**ALTDORFERT, ALBRECHT** (1480–1538), German painter and engraver, was born at Regensburg (Ratisbon), where in 1503 he was enrolled a burgher, and described as “twenty-five years old.” Soon afterwards he is known to have been prosperous, and as city architect he erected fortifications and a public slaughter-house. Altdorfer has been called the “Giotto of the North.” His style was a mixture of the Gothic and Italianate, and carried on to the old-fashioned, for close study of nature. The most important of them are to be found in the Pinakothek at Munich. A representation of the battle of Arbela (1529), included in that collection, is usually considered his chief work. His engravings on wood and copper are very numerous, and rank next to those of Albrecht Dürer. The most important collection is at the Berlin museum. Albrecht’s brother, Erhard Altdorfer, was also a painter and engraver, and a pupil of Lucas Cranach.

**ALENNE, SIR CHARLES** [Karl] (1764–1840), Hanoverian and British soldier, son of Baron Alten, a member of an old Hanoverian family, entered the service of the elector as a page at the age of twelve. In 1781 he received a commission in the Hanoverian guards, and as a captain took part in the campaigns of 1793–1795 in the Low Countries, distinguishing himself particularly on the Lys in command of light infantry. In 1803 the Hanoverian army was disbanded, and Alten took service with the King’s German Legion in British pay. In command of the light infantry of this famous corps he took part with Lord Cathcart in the Hanoverian expedition of 1805 and in the siege of Copenhagen in 1807, and was with Moore in Sweden and Spain, as well as in the disastrous Walcheren expedition. He was soon employed once more in the Peninsula, and at Albuera commanded a brigade. In April 1813 Wellington placed him at the head of the famous “Light Division” (43rd, 52nd, 93rd, and Caçadores), in which post he worthy continued the records of Moore and Robert Craufurd at Nivelle, Nive, Orthez and Toulouse. His officers presented him with a sword of honour as a token of their esteem. In 1815 Alten commanded Wellington’s 3rd division and was severely wounded at Waterloo. His conduct won for him the rank of Count von Alten. When the King’s German Legion ceased to exist, Alten was given the command of the British forces in France, and in 1818 returned to Hanover, where he became subsequently minister of war and foreign affairs, and rose to be field-marshall, being retained on the British army list at the same time as Major-General Sir Charles Alten, G. C. B. He died in 1840. A memorial to Alten has been erected at Hanover.

See Gentleman’s Magazine, 1840; N. L. Beamish, Hist. of the King’s German Legion, 2 vols. (1832–1837).

**ALTENA,** a town of Germany, in the Prussian province of Westphalia, on the river Lenne, 38 m. S.S.E. from Dortmund. pop. (1900) 12,760. It consists of a single street, winding up a deep valley for about 3 m. There are three churches, a museum, high grade and popular schools. Its hardware industries are important, and embrace iron rolling, the manufacture of fine wire, needles, springs and silver ornaments. On the neighbouring Schlossberg is the ancestral castle of the counts of La Marck, ancestors, on the female side, of the Prussian royal house.

**ALTBURG,** a town of Germany, capital of the duchy of Saxe-Altenburg, situated near the river Pleisse, 23 m. S. of Leipzig, and 12 m. W. of Altenburg, in the 3rd district of the local government. It belongs to the central department of the Saxon duchies, and possesses a cathedral and several churches, a library, a gallery of pictures and a school of art, an infirmary and various learned societies. There is also a museum, with natural history, archaeological, and art collections, and among other buildings may be mentioned St Bartholomew’s church (1086), the town hall (1562–1564), a lunatic asylum, teachers’ seminary and an agricultural academy. There is considerable traffic in grain and cattle brought from the surrounding districts; and twice a year there are large horse fairs. Commonly known goods, gloves, hats and porcelain are among the chief manufactures. There are lignite mines in the vicinity.

**ALTENEITEN,** a castle upon a rocky mountain in Saxe-Meiningen, on the south-western slope of the Thuringerwald, not far from Eisenach. It is the summer residence of the dukes of Meiningen, and is surrounded by a noble park, which contains, among other objects of interest, a remarkable underground cavern, 500 ft. long, through which flows a large and rapid stream. Boniface, the apostle of the Germans, lived and preached at Altenstein in 724; and near by is the place where, in 514, Luther was seized, by the order of the elector Frederick the Wise, to be carried off to the Wartburg. An old beech called “Luther’s tree,” which tradition connected with the reformer, was blown down in 1841, and a small monument now stands in its place.

**ALTERNATION** (from Lat. *alternare,* to do by turns), strictly, the process of “alternating,” i.e. of two things following one another regularly by turns, as night alternates with day. A somewhat different sense is attached to some usages of the derivatives. Thus, in American political representative bodies the case of compounding of revenue, or the case of a substitute, is sometimes called an “alternate.” An “alternative” is that which is offered as a choice of two things, the acceptance of the one implying the rejection of the other. It is incorrect to speak of more than two alternatives, though Mr Gladstone wrote in 1857 of a fourth (Oxf. Essays, 26). When there is only one course open there is said to be no alternative.
ALTHAEA, in classical legend, daughter of Thetis, king of Aetolia, wife of Oeneus, king of Calydon, and mother of Melanget (q.v.).

ALTING, JOHANN HEINRICH (1583-1644), German divine, was born at Emden, where his father, Menso Altting (1541-1612), was minister. Johann studied with the Jesuits at the universities of Gröningen and Herborn. In 1608 he was appointed tutor of Frederick, afterwards elector-palatine, at Heidelberg, and in 1612 accompanied him to England. Returning in 1613 to Heidelberg, after the marriage of the elector with Princess Elizabeth of England, he was appointed professor of dogmatics, and in 1616 director of the theological department in the Collegium Sapientiae. In 1618, along with Abraham Scultetus, he represented the university in the synod of Dort. When Count Tilly took the city of Heidelberg (1622) and handed it over to plunder, Altting found great difficulty in escaping the fury of the soldiers. He first retired to Schornдорf; but, offended by the "semi-Pelagianism" of the Lutherans with whom he was brought in contact, he removed to Holland, where the unfortunate elector and "Winter King" Frederick, in exile after his brief reign in Bohemia, made him tutor to his eldest son. In 1627 Altting was appointed to the chair of theology at Gröningen, where he continued to lecture, with increasing reputation, until his death in 1644. Though an orthodox Calvinist, Altting laid little stress on the sterner side of his creed and, when at Dort he opposed the conscripts, he did so mainly on the ground that they were "innovators." Among his works are:—Nota in Decodem Problematum Jacobi Behm (Heidelberg, 1618); Scripta Theologica Heidelbergensia (Amst., 1662); Exegetis Augustanae Confessionis (Amst., 1647).

ALTINUM (mod. Altono), an ancient town of Venetia, 12 m. S.E. of Tarvisium (Treviso), on the edge of the lagoons. It was probably only a small fishing village until it became the point of junction of the Via Postumia and the Via Popilia (see ACQUILEIA). At the end of the republic it was a municipium. Augustus and his successors took it into further importance as a point on the route between Italy and the north-eastern portions of the empire. After the foundation of the naval station at Ravena, it became the practice to take ship from there to Altinum, instead of following the Via Popilia round the coast, and thence to continue the journey by land. A new road, the Via Claudia Augusta, was constructed by the emperor Claudius from Altinum to the Danube, a distance of 350 m., apparently by way of the Lake of Constance. The place thus became of considerable strategic and commercial importance, and the comparatively mild climate (considering its northerly situation) led to the erection of villas which Martial (Epigr. iv. 25) compares with those of Baiae. It was destroyed by Attila in A.D. 452, and its inhabitants took refuge in the islands of the lagoons, forming settlements from which Venice eventually sprang.

ALTITUDE (Lat. altitude, from allus, high), height or eminence, and particularly the height above the ground or above sea-level. In geometry, the altitude of a triangle is the length of the perpendicular from the vertex to the base. In astronomy, the altitude of a heavenly body is the apparent angular elevation of the body above the plane of the horizon (see ASTRONOMY: Spherical). Apparent altitude is the value which is directly observed; true altitude is deduced by correcting for astronomical refraction and dip of the horizon; geocentric altitude by correcting for parallax.

ALTMÜHL, a river of Germany, in the kingdom of Bavaria. It is an important left bank tributary of the Danube, rising in the Franconian plateau (Fränkische Terrasse), and after a tortuous course of 116 m., at times flowing through meadows and again in weird romantic gorges, joins the Danube at Kelheim. From its mouth it is navigable up to Dietfurt (18 m.), whence the Ludwigschannel (100 m. long) proceeds to Bamberg on the Regnitz, thus establishing communication between the Danube and the Rhine.

ALTO (Ital. for "high"), a musical term applied to the highest adult male voice or counter-tenor, and to the lower boy's or woman's (contralto) voice.

ALTONA, a market-town in the Fareham parliamentary division of Hampshire, England, 46½ m. S.W. of London by the London & South-Western railway. Pop. of urban district (1901) 5479. It has a pleasant undulating site near the headwaters of the river Wey. Of the church of St Lawrence part, including the tower, (founded 1370) and the sequence of a severe conflict between the royalist and parliamentary troops in 1643. There is a museum of natural history; the collection is reminiscent of the famous naturalist Gilbert White, of Selborne in this vicinity. Large markets and fairs are held for corn, hops, cattle and sheep; and the town contains some highly reputed ale breweries, besides paper mills and iron foundries.

ALTON, a city of Madison county, Illinois, U.S.A., in the W. part of the state, on the Mississippi river, about 10 m. above the mouth of the Missouri, and about 25 m. N. of St Louis, Missouri. Pop. (1860) 70,294; (1900) 14,212, of whom 1638 were foreign-born; (1910) 17,528. Alton is served by the Chicago & Alton, the Chicago, Peoria & St Louis, the Cleveland, Cincinnati, Chicago & St Louis, and the Illinois Terminal railways. The river is here spanned by a bridge. The residential portion of the city lies on the river bluffs, some of which rise to a height of 250 ft. above the water level, and the business streets are on the bottom lands of the river. Alton has a public library and a public park. Upper Alton (pop. 2918 in 1910), about 1½ m. N.E. of Alton, is the seat of the Western Military Academy (founded in 1827 as Wyman Institute; chartered in 1834), and of Shurtleff College (Baptist, founded in 1827 at Rock Spring, removed to Upper Alton in 1831, and chartered in 1833), which has a college of liberal arts, a divinity school, an academy and a school of music; and the village of Godfrey, 5½ m. N. of Alton, is the seat of the Monticello Ladies' Seminary, founded by Benjamin Godfrey, opened in 1838, and chartered in 1841. Among the manufactures of Alton are iron and glass ware, miners' tools, shovels, coal-mine cars, flour, and agricultural implements; and there are a large oil refinery and a large lead smelting works. In 1848 the city's factory produced increased from $4,250,389 in 1900 to $8,366,814 in 1905, or 104½%.

The first settlement on the site of Alton was made in 1807, when a trading post was established by the French. The town was laid out in 1817, was first incorporated in 1821, and in 1827 was made the seat of a state penitentiary, which was later removed to Joliet, the last prisoners being transferred in 1860. Alton was first chartered as a city in 1837. In 1836 the Rev. Elijah P. Lovejoy (1802-1837), a native of Alton, Maine, removed the Observer, a religious (Presbyterian) periodical of which he was the editor, from St Louis to Alton. He had attracted considerable attention in St Louis by his criticisms of slavery, but though he believed in emancipation, he was not a radical abolitionist. After coming to Alton his anti-slavery views soon became more radical, and in a few months he was an avowed abolitionist. His views were shared by his brother, Owen Lovejoy (1811-1864), a Congregational minister, who also at that time lived in Alton, and who from 1837 until his death was an able anti-slavery member of Congress. Most of the people of southern Illinois were in sympathy with slavery, and consequently the Lovejoys became very unpopular. The press of the Observer was three times destroyed, and on the 7th of November 1837 E. P. Lovejoy was killed while attempting to defend against a mob a fourth press which he had recently obtained and which was stored in a warehouse in Alton. His death caused intense excitement throughout the country, and he was everywhere regarded by abolitionists as a martyr to their cause. In 1837 a monument, a granite column surmounted by a bronze statue of Victory, was erected in his honour by the citizens of Alton and by the state.

See Henry Tanner, The Martyrdom of Lovejoy (Chicago, 1881), and "The Alton Tragedy" in S. J. May's Some Recollections of Our Anti-Slavery Conflict (Boston, 1869).

ALTONA, a town of Germany, in the Prussian province of Schleswig-Holstein, on the right bank of the Elbe immediately west of Hamburg. Though administratively distinct, the two cities so closely adjoin as virtually to form one whole. Lying
ALTOONA—ALTRINCHAM

higher than Hamburg, Altona enjoys a purer and healthier atmosphere. It has spacious squares and streets, among the latter the Palmaile, a stately avenue ending on a terrace about 100 ft. above the Elbe, whence a fine view is obtained of the river and the lowlands beyond. Of the six Evangelical churches, the Hauptkirche (parish church), with a lofty spire, is particularly worthy. The main thoroughfares are embellished by several striking monuments, notably the memorials of the wars of 1864 and 1870, bronze statues of the emperor William I. and Bismarck and the column of Victory (Siegessäule). The museum (1901) is an imposing building in the German Renaissance style and contains, in addition to a valuable library, ethnographical and natural history collections. Its site is that formerly occupied by the terminus of the Schleswig-Holstein railways, but a handsome central station lying somewhat farther to the N., connected with Hamburg by an elevated railway, now accommodates all the traffic and provides through communication with the main Prussian railway systems. There are also fine municipal and judicial buildings, a theatre (under the same management as the Stadttheater in Hamburg), a gymnasium, technical schools, a school of navigation and a hospital. In respect of its local industries Altona has manufactures of tobacco and cigars, of machinery, woollens, cottons and chemicals. There are also extensive breweries, tanneries and soap and oil works. Altona carries on an extensive maritime trade with Great Britain, France and America, but it has, by no means, stepped in as a direct trading city, of its commercial superiority—indeed, so dependent is it upon its rival that most of its business is transacted on the Hamburg exchange, while the magnificent warehouses on the Altona river bank are to a large extent occupied by the goods of Hamburg merchants. Since 1888, when Altona joined the imperial Zollverein, approximately half a million sterling has been spent upon harbour improvement works. The exports and imports resemble those of Hamburg. In the ten years 1871-1880, the port was entered on an average annually by 737 vessels of 67,735 tons, in 1881-1890 by 659 vessels of 154,743 tons, and in 1891-1895 by 839 vessels of 253,843 tons. In 1890 the populous suburbs of Ottensen to the W., where the poet Gottlieb Klopfstock lies buried, Bahrenfeld, Othmarschen and Ovelgönne were incorporated. Without these suburbs the growth of the town may be seen from the following figures:—

(1864, when it ceased to be Danish) 53,030; (1880) 91,049; (1885) 104,717; (1890) together with the four suburbs, 143,249; (1895) 148,944; (1900) 161,508; (1905) 168,301. Altona is the headquarters of the IX. German army corps.

The name Altona is said to be derived from alternah ("all too near"), the Hanseatic term for a small town which in the middle of the 16th century lay too close to their territory. For a long time this was the only house in the locality. When in 1640 Altona passed to Denmark it was a small fishing village. Its rise to its present position is mainly due to the fostering care of the Danish kings who conferred certain customs privileges and exemptions upon it with a view to making it a formidable rival to Hamburg. In 1713 it was burnt by the Swedes, but rapidly recovered from this disaster, and despite the trials of the Napoleonic wars, gradually increased in prosperity. In 1851, owing to the stimulation of trade by the Treaty of Paris, its trade waned. In 1864 Altona was occupied in the name of the German Confederation, passed to Prussia after the war of 1866, and 1888 together with Hamburg joined the Zollverein, while retaining certain free trade rights over the Freihafengebiet which it shares with Hamburg and Wandsbek.

ALTOONA, a city of Blair county, Pennsylvania, U.S.A., about 177 m. E. by N. of Pittsburg. Pop. (1890) 30,337; (1900) 38,973, of whom 3301 were foreign-born, 1518 being German; (1910) 52,127. It lies in the upper end of Logan Valley at the base of the Alleghany mountains, about 1180 ft. above sea-level, and commands views of some of the most picturesque mountain scenery in the state. A short distance to the W. is the famous Horseshoe Bend of the Pennsylvania railway. Altoona is served by the Pennsylvania railway, and is one of the leading railway cities in the United States. Its freight yard is 7 m. long, and has 221 m. of tracks. Large numbers of eastbound coal trains from the mountains and westbound "empties" returning to the mines stop here; and also the cars of the express train classified here and new trains made up. Locomotives and cars are sent to Altoona to be repaired from all over the Pennsylvania railway system E. of Pittsburgh, and cars and locomotives are built here; and in the south Altoona foundries car wheels and general castings for locomotives and cars are made. The several departments of railway work are used to give training in a sort of railway university. Graduates of technical schools are received as special apprentices and are directed in a course of four years through the erecting shops, vice shop, blacksmith shop, boiler shop, roundhouse, test department, machine shop, air-brake shop, iron foundry, car shop, work of firing on the road, office work in the motive power accounting department, and drawing room; the most competent may be admitted through the grades of inspector, in the office of the master mechanic or of the road foreman of engines, assistant master mechanic, assistant engineer of motive power, master mechanic and superintendent of motive power. The Pennsylvania railway, co-operating with the public school authorities, established at Altoona, in 1907, a railway high school, the first institution of the kind in the country. It has a well-equipped shop and workshop, the latest machinery, drawing offices, laboratories and machinery department, in which expert instruction is given. In 1905 the city's factory products were valued at $14,349,963, and in this year the railway shops gave employment to 83.7 % of all wage-earners employed in manufacturing establishments. The manufacture of silk is the only other important industry in the city. The site of the city (formerly farming land) was purchased in 1849 by the Pennsylvania Railroad Company and was laid out as a town. It was incorporated as a borough in 1854 and was chartered as a city in 1896.

ALTO-RELIEVO (Ital. for "high relief"), the term applied to sculpture that projects from the plane to which it is attached to the extent of more than one-half the outline of the principal figures, which may be nearly or in parts entirely detached from the background. It is thus distinguished from basso-relievo (q.v.), in which there is a greater or less approximation in effect to the pictorial method, the figures being made to appear as projecting more than half their outline without actually doing so. At the same time it is not only the actual degree of relief which is implied by these two terms, but a resultant difference also in the materials used and their treatment, elaborated by the contingent differences of light and shadow. (See RELIEF and SCULPTURE.)

ALTÖTTING, a town of Germany, in the kingdom of Bavaria, on the Mörren, not far from its junction with the Inn, and on the Mühldorf-Burghausen railway. Pop. (1900) 4344. It has long been a place of pilgrimage to which Roman Catholics, especially from Austria, Bavaria and Swabia resort in large numbers, on account of a celebrated image of the Virgin Mary in the Holy Chapel, which also contains the heads of some Bavarian princes in silver caskets. In the church of St Peter and St Paul is one of the oldest of its custom which is still kept up.

ALTRÄNSTADT, a village of Germany, in Prussian Saxony near Memelburg (q.v.), with (1900) 513 inhabitants. Altranstädt is famous in history for two treaties concluded here: (1) the peace which Augustus II., king of Poland and elector of Saxony, was forced to ratify, on the 24th of September 1706, with Charles XII. of Sweden, whereby the former renounced the throne of Poland in favour of Stanislaus Leszczynski—a treaty which Augustus declared null and void after Charles XII.'s defeat at Poltava (5th of July 1709); (2) the treaty of the 31st of August 1709, by which the emperor Joseph I. guaranteed to Charles XII. religious toleration and liberty of conscience for the Silesian protestants.

ALTRINGHAM, or ALTRINCHAM (and so pronounced), a market-town in the Altrincham parliamentary division of Cheshire, England, 8 m. S.W. by S. of Manchester, on the London
& North-Western, Manchester, South Junction & Altrincham and Cheshire Lines railways. Pop. of urban district (1901) 16,831. Many residences in the locality are occupied by those whose business lies in Manchester, attracted by the healthy climate and the vicinity of Bowdon Downs and Dumhan Massey Woods. Market gardening is carried on, large quantities of fruit and flowers being grown for sale in Manchester. Cabinet-making is also practised; and there are sawmills, iron foundries, and manufactures of cotton, yarn and worsted.

Altrincham (Aldringham) was originally included in the barony of Dumhan Massey, one of the eight baronies founded by Hugh, earl of Chester, after the Conquest. An undated charter from Hamo de Massey, lord of the barony, in the reign of Edward I., confirmed the privilege of Altrincham a free borough, with a gild merchant, the customs of Macclesfield, the right to elect reeves and bailiffs for the common council and other privileges. In 1290 the same Hamo obtained a grant of a Tuesday market and a three days' fair at the feast of the Assumption of the Virgin; but in 1319, by a charter from Edward II., the date of the fair was changed to the feast of St James the Apostle. A mayor of Altrincham is mentioned by name in 1452, but the office probably existed long before this date; it has now for centuries been a purely nominal appointment, the chief duty consisting in the opening of the annual game fair.

The trade in worsted and woollen yarns, which, for several centuries, has formerly furnished employment to a large section of the population, has now completely declined, partly owing to the introduction of Irish worsted.

See *Victoria County History, Cheshire*; Alfred Ingham, *History of Altrincham and Bosodun* (Altrincham, 1879).

**ALTRUISM** (Fr. *austrui, from Lat. *alter, the other of two), a philosophical term used in ethics for that theory of conduct which regards the good of others as the end of moral action. It was invented by Auguste Comte and adopted by the English positivists as a convenient antithesis to egoism. According to Comte the only practical method of social regeneration is gradually to inculcate the true social feeling which subordinates itself to the welfare of others. The application to sociological problems of the physical theory of organic evolution further developed the altruistic theory. According to Herbert Spencer, the life of the individual in the perfect society is identical with that of the state: in other words, the first object of him who would live well must be to take his part in promoting the well-being of his fellows individually and collectively. Pure egoism and pure altruism are alike impracticable. For on the one hand unless the egoist's happiness is compatible to some extent with that of his fellows, their opposition will almost inevitably vitiate his perfect enjoyment; on the other hand, the altruist whose primary object is the good of others, must derive his own highest happiness—i.e. must realize himself most completely—in the fulfilment of this object. In fact, the altruistic idea, in itself and apart from a further definition of the good, is rather a method than an end.

The self-love theory of Hobbes, with its subtle perversions of the motives of ordinary humanity, led to a reaction, which culminated in the utilitarianism of Bentham and the two Mills; but their theory, though superior to the extravagant egoism of Hobbes, had this main defect, according to Herbert Spencer, that it conceived the world as an aggregate of units, and was so far individualistic. Sir Leslie Stephen in his *Science of Ethics* insisted that the unit is the social organism, and therefore that the aim of moralists is not the "greatest happiness of the greatest number," but rather the "health of the organism." The socialistic tendencies of subsequent thinkers have emphasized the ethical importance of altruistic action, but it must be remembered that the development of altruism is usually a form of action, that it may be commended in all types of ethical theory, and that it is a practical guide only when it is applied in accordance with a definite theory of "the good." Finally, he who devotes himself on principle to furthering the good of others as his highest moral obligation is from the highest point of view realizing, not sacrificing, himself.

See works of Comte, Spencer, Stephen, and text-books of ethics (cf. bibliography at end of article Ethics).

**ALTWasser**, a town of Germany, in the Prussian province of Silesia, 43 m. by rail S.W. from Breslau, and 3 m. N. from Waldenburg. It has factories for glass, porcelain, machinery, cotton-spinning, iron-foundries and coal-mines. Pop. (1900) 12,144.

**ALTYN-TAGH**, or Astyn-Tagh, one of the chief constituent ranges of the Kuen-lun (q.v.) in Central Asia, separating Tibet from east Turkestan and the Desert of Gobi.

**ALUM**, in chemistry, a term given to the crystallized double sulphates of the typical formula $\text{M}_2\text{SO}_4\cdot\text{M}^2\text{O}(\text{SO}_4)\cdot2\text{H}_2\text{O}$, where $\text{M}$ is the sign of an alkali metal (potassium, sodium, lithium, calcium, strontium, silver or ammonium, and $\text{M}^2$ denotes one of the trivalent metals, aluminium, chromium or ferric iron. These compounds are used mainly in dyeing and as mordants. They are crystallized from the juice of the organisms which produce alumina. They are soluble in water, have an astringent, acid, and sweetish taste, react acid to litmus, and crystallize in regular octahedra. When heated they liquefy; and if the heating be continued, the water of crystallization is driven off, the salt froths and swells, and at last an amorphous powder remains.

Potash alum is the common alum of commerce, although both soda alum and ammonium alum are manufactured. The presence of sulphuric acid in potash alum was known to the alchemists. J. H. Pott and A. S. Marggraf demonstrated that a similar substance was manufactured in ancient times. They observed that when the precipitate obtained when an alkali is poured into a solution of alum is quite different from lime and chalk, with which it had been confounded by G. E. Stahl. Marggraf showed that alumina is one of the constituents of alum, but that this earth possesses peculiar properties, and is one of the ingredients in common clay (*Expériences faites sur la terre de l'ouan, Marggraf's Opusc. ii. 111*). He also showed that crystals of alum cannot be obtained by dissolving alumina in sulphuric acid and evaporating the solutions, but when a solution of potash or ammonia is dropped into this liquid, it immediately deposits perfect crystals of alum (*Sur la régénération de l'ouan, Marggraf's Opusc. ii. 86*).

T. O. Bergman also observed that the addition of potash or ammonia made the solution of alumina in sulphuric acid crystallize, but that the same effect was not produced by the addition of soda or of lime (*De confectione aluminis, Bergman's Opusc. i. 225*), and that potassium sulphate is frequently found in alum.

After M. H. Klaproth had discovered the presence of potassium in leucite and lepidolite, it occurred to L. N. Vauquelin that it was probably the ingredient likewise present in other minerals. Knowing that alum cannot be obtained in crystals without the addition of potash, he began to suspect that this alkali constituted an essential ingredient in the salt, and in 1797 he published a dissertation demonstrating that alum is a double salt, composed of sulphuric acid, alumina and potash (*Annales de chimie, xxii. 258*). Soon after, J. A. Chaptal published the analysis of four different kinds of alum, namely, Roman alum, Levant alum, British alum and alum manufactured by himself. This analysis led to the same result as that of Vauquelin (*Ann. de chim. xxii. 280*).

The word *alumen*, which we translate *alum*, occurs in Pliny's *Natural History*. In the 15th chapter of his 35th book he gives a detailed description of it. By comparing this with the account of *στένυγα* given by Dioscorides in the 123rd chapter of his 5th book, it is obvious that the two are identical. Pliny informs us that alumum was found naturally in the earth. He calls it *salsugydroa*. Different substances were distinguished by the name of *alumen*; but they were all characterized by a certain degree of astringency, and were all employed in dyeing and manufacturing. The light-coloured alum being useful in brilliant dyes, the dark-coloured only in dyeing black or very dark colours. One species was a liquid, which was apt to be adulterated; but when pure it had the property of blackening when added to pomegranate juice. This property seems to characterize a solution of iron sulphate in water; a solution of ordinary (potash) alum would possess no such property. Pliny says that there is another kind of alum which the Greeks call *schitos*. It forms in white threads upon the surface of certain stones.
octahedra and is very soluble in water. The solution reddens litmus and is an astringent. When heated to nearly a red heat it gives a porous friable mass which is known as "burnt alum." It fuses at 92° C. in its own water of crystallization. "Neutral alum" is obtained by the addition of as much sodium carbonate to a solution of alum as will begin to cause the separation of alumina; it is much used in mordanting. Alum finds application as a mordant, in the preparation of lakes for sizing hand-made paper and in the clarifying of turbid liquids.

Sodium alum, Na₂SO₄·Al₂(SO₄)₃·24H₂O, occurs in nature as the mineral mendozite. It is very soluble in water, and is extremely difficult to purify. In the preparation of this salt, it is prudent to mix the component solutions in the cold, and to evaporate them at a temperature not exceeding 60° C. 100 parts of water dissolve 110 parts of sodium alum at 0° C. (W. A. Tilden, *Joum. Chem. Soc.*, 1884, 45, p. 409), and 51 parts at 16° C. (E. Augé, *Comptes rendus*, 1890, 110, p. 1139).

Chrome alum, K₂SO₄·Cr₂(SO₄)₃·24H₂O, appears chiefly as a by-product in the manufacture of alizarin, and as a product of the reaction in bichromate batteries.

The solubility of the various alums in water varies greatly, sodium alum being readily soluble in water, whilst caesium and rubidium alums are only sparingly soluble. The various solubilities are shown in the following table:

Poggiole C. Settgerter

ALUMINIUM (symbol Al; atomic weight 27.0), a metallic chemical element. Although never met with in the free state, aluminium is very widely distributed in combination, principally as silicates. The word is derived from the Lat. *alumen* (see Alum) and is probably akin to the Gr.  ἄλας (the root of salt, kalogen, &c.). In 1772 F. Hoffmann announced the base of alum to be an individual substance; L.B. Gayton de Morveau suggested that this base should be called *alumine*, after *Sul alumineux*, the French name for alum; and about 1820 the word was changed into *alumina*. In 1760 the French chemist, T. Baron de Henouville, unsuccessfully attempted to "reduce the base of alum" to a metal, and shortly afterwards various other investigators essayed the problem in vain. In 1868 Sir Humphry Davy, fresh from the electrolytic isolation of potassium and sodium, attempted to decompose alumina by heating it with potash in a platinum crucible and submitting the mixture to a current of electricity; in 1850, with a more powerful battery, he raised iron wire to a red heat in contact with alumina, and obtained distinct evidence of the production of an iron-aluminium alloy. Naming the new metal in anticipation of its actual birth, he called it *aluminium;* but for the sake of analogy he was soon persuaded to change the word to *aluminium*, in which form, alternately with aluminium, it occurs in chemical literature for some thirty years.

In the year 1834, endeavouring to prepare it by chemical means, H. C. Oersted heated its chloride with potassium amalgam, and failed in his object simply by reason of the mercury, so that when F. Wöhler repeated the experiment at Göttingen in 1827, employing potassium alone as the reducing agent, he obtained it in the metallic state for the first time. Contaminated as it was with potassium and with platinum from the crucible, the metal formed a grey powder and was far from pure; but in 1845 he improved his process and succeeded in producing metallic globules wherein he examined its chief
properties, and prepared several compounds hitherto unknown. Early in 1854, H. St. Claire Deville, accidentally and in ignorance of Wöhler’s later results, imitated the 1845 experiment. At once observing the reduction of the chloride, he realized the importance of his discovery and immediately began to study the commercial production of the metal. His attention was at first divided between two processes—the chemical method of reducing the chloride with potassium, and an electrolytic method of decomposing it with a carbon anode and a platinum cathode, which was simultaneously imagined by himself and R. Bunsen. Both schemes appeared practically impossible; potassium chloride at 

\[ \text{Al}Cl_3 + 3KCl \rightarrow 2K \text{Cl} + 6\text{Al} \]

furnished per lb, gave a very small yield and was dangerous to manipulate, while on the other hand, the only source of electric current then available was the primary battery, and zinc as a store of industrial energy was utterly out of the question. Deville accordingly returned to pure chemistry and invented a practicable method of preparing sodium which, having a lower atomic weight than potassium, reduced a larger proportion. He next devised a plan for manufacturing pure alumina from the natural ores, and finally elaborated a process and plant which held the field for almost thirty years. Only the discovery of dynamo-electric machines and their application to metallurgical processes rendered it possible for E. H. and A. H. Cowles to remove the industry from the hands of chemists, till the time when P. T. L. Héroutil and C. M. Hall, by devising the electrolytic method now in use, inaugurated the present era of industrial electrolysis.

The chief natural compounds of aluminium are four in number: oxide, hydroxide (hydrated oxide), silicate, and fluoride. Corundum, the only important native oxide (\(\text{Al}_2\text{O}_3\)), occurs in large deposits in southern India and the United States. Although it contains a higher percentage of metal (52-9%) than any other natural compound, it is not at present employed as an ore, not only because it is so hard as to be crushed with difficulty, but also because its very hardness makes it valuable as an abrasive. Cryolite (\(\text{Na}_3\text{AlF}_6\)) is a double fluoride of aluminium and sodium, which is scarcely known except on the west coast of Greenland. Formerly it was used for the preparation of the metal, but the inaccessibility of its source, and the fact that it is not sufficiently pure to be employed without some preliminary treatment, caused it to be abandoned in favour of other salts. When required in the Héroult-Hall process as a solvent, it is sometimes made artificially. Aluminium silicate is the chemical body of which all clays are nominally composed. Kaolin or China clay is essentially a pure dislicate (\(\text{Al}_2\text{O}_3\cdot 2\text{SiO}_2\cdot 2\text{H}_2\text{O}\)), occurring in large beds almost throughout the world, and containing in its anhydrous state 24-4% of the metal, which, however, in common clays is more or less replaced by calcium, magnesium, and the alkalis, the proportion of silica sometimes reaching 70%. Kaolin thus seems to be the best ore, and it undoubtedly was used were it not for the fatal objection that no satisfactory process has yet been discovered for preparing pure alumina from any mineral silicate. If, according to the present method of winning the metal, a bath containing silica as well as alumina is submitted to electrolysis, both oxides are dissociated, and as silicon is a very undesirable impurity, an alumina contaminated with silica is not suited for reduction. Bauxite is a hydrated oxide of aluminium of the ideal composition, \(\text{Al}_2\text{O}_3\cdot 2\text{H}_2\text{O}\). It is a somewhat widely distributed mineral, being met with in Styria, Austria, Hesse, French Guiana, India and Italy; but the most important beds are in the south of France, the north of Ireland, and in Alabama, Georgia and Arkansas in North America. The chief Irish deposits are in the neighbourhood of Glenravel, Co. Antrim, and have the advantage of being near the coast, so that the alumina can be transported by water-carriage. After being dried at 100°C, Antrim bauxite contains from 33 to 60% of alumina, from 2 to 30% of ferric oxide, and from 7 to 24% of silica, the balance being titanic acid and water of combination. The American bauxites contain from 38 to 67% of alumina, from 1 to 23% of ferric oxide, and from 31 to 52% of silica. The French bauxites are of fairly constant composition, containing usually from 58 to 70% of alumina, 3 to 15% of foreign matter, and 27% made up of silica, iron oxide and water in proportions that vary with the colour and the situation of the beds.

Before the application of electricity, only two compounds were found suitable for reduction to the metallic state. Alumina itself is so refractory that it cannot be melted save by the oxy-hydrogen blowpipe or the electric arc, and except in the molten state it is not susceptible of decomposition by any chemical reagent. Deville first selected the chloride as his raw material, but observing it to be volatile and extremely deliquescent, he soon substituted in its place a double chloride of aluminium and potassium. Early in 1855, John Percy suggested that cryolite should be more convenient, as it was a natural mineral and might not require purification, and at the end of March in that year, Faraday exhibited before the Royal Institution samples of the metal reduced from its fluoride by Dick and Smith. H. Rose also carried out experiments on the decomposition of cryolite, and expressed an opinion that it was the best of all compounds for reduction; but, finding the yield of metal to be low, receiving a report of the difficulties experienced in mining the ore, and fearing to cripple his new industry by basing it upon the employment of a mineral of such uncertain supply, Deville decided to keep to his chlorides. With the advent of the dynamo, the position of affairs was wholly changed. The first successful idea of using electricity depended on the enormous heating powers of the arc. The insufficiency of alumina was no longer prohibitive, for the molten oxide is easily reduced by carbon. Nevertheless, it was found impracticable to smelt alumina electrically except in presence of copper, so that the Cowles furnace yielded, not the pure metal, but an alloy. So long as the metal was principally regarded as a necessary ingredient of aluminium-bronze, the Cowles process was popular, but when the advantages of aluminium itself became more apparent, there arose a fresh demand for some chief method of obtaining it unalloyed. It was soon discovered that the faculty of inducing dissociation possessed by the current might now be utilized with some hope of pecuniary success, but as electrolytic currents are of lower voltage than those required in electric furnaces, molten alumina again became impossible. Many metals, of which copper, silver and nickel are types, can be readily won or purified by the electrolysis of aqueous solutions, and theoretically it may be feasible to treat aluminium in an identical manner. In practice, however, it cannot be thrown down electrolytically with a dissimilar anode so as to win the metal, and certain difficulties are still met with in the analogous operation of plating by means of a similar anode. Of the simple compounds, only the fluoride is amenable to electrolysis in the fused state, since the chloride begins to volatilize below its melting-point, and the latter is only 5° below its boiling-point. Cryolite is not a safe body to electrolyse, because the minimum voltage needed to break up the aluminium fluoride is 4-0, whereas the sodium fluoride requires only 4-7 volts; if, therefore, the current rises in tension, the alkali is reduced, and the final product consists of an alloy with sodium. The corresponding double chloride is a far better material; first, because it melts at about 180°C, and does not volatilize below a red heat, and second, because the voltage of aluminium chloride is 2-3 and that of sodium chloride 4-5, so that there is a much wider margin of safety to cover irregularities in the electric pressure. It has been found, however, that molten cryolite and the analogous double fluoride represented by the formula \(\text{AlF}_2\cdot 2\text{NaF}\) are very efficient solvents of aluminium, and that these solutions can be easily electrolysed at about 500°C by means of a current that completely decomposes the oxide but leaves the haloid salts unaffected. Molten cryolite dissolves roughly 30% of its weight of pure alumina, so that when ready for treatment the solution contains about the same proportion of what may be termed "available" aluminium as does the fused double chloride of aluminium and sodium. The advantages lie with the oxide because of its easier preparation. Alumina dissolves readily enough in aqueous hydrochloric acid to yield a solution containing the chloride, but molten cryolite containing sodium chloride can be evaporated to dryness without decomposition. To obtain the anhydrous single or
double chloride, alumina must be ignited with carbon in a current of chlorine, and to exclude iron from the finished metal, either the alumina must be pure or the chloride be submitted to purification. This preparation of a chloride compound suited for electrolysis becomes more costly and more troublesome than that of the oxide, and in addition four times as much raw material must be handled.

At different times propositions have been made to win the metal from its sulphide. This compound possesses a heat of formation so much lower that electrically it needs but a voltage of 0-9 to decompose it, and it is easily soluble in the fused sulphides of the alkali metals. It can also be reduced metallurgically by the action of molten iron. Various considerations, however, tend to show that there cannot be so much advantage in employing it as would appear at first sight. As it is easier to reduce than any other compound, so it is more difficult to produce. Therefore while less energy is absorbed in its final reduction, more is needed in its initial preparation, and it is questionable whether the economy possible in the second stage would not be neutralized by the greater cost of the first stage in the whole operation of winning the metal from bauxite with the sulphide as the intermediary.

The Deville process as gradually elaborated between 1835 and 1890 exhibited three distinct phases—Production of metallic sodium, formation of the pure double chloride of sodium and aluminium, and reduction of the latter by the action of the two former substances. To produce the alkali metal, a calcined mixture of sodium carbonate, coal and chalk was strongly ignited in flat retorts made of boiler-plate; the sodium distilled over into condensers and was preserved under heavy petroleum. In order to prepare pure alumina, bauxite and sodium carbonate were heated in a furnace until the reaction was complete; the product was then extracted with water to dissolve the sodium aluminate, the solution treated with carbon dioxide, and the precipitate removed and dried. The dried precipitate of pure sodium chloride and coal tar was carbonized at a red heat, and ignited in a current of dry chlorine as long as vapours of the double chloride were given off, these being condensed in suitable containers. For the production of the final aluminium, 100 parts of the chloride and 45 parts of cryolite to serve as a flux were powdered together and mixed with 35 parts of sodium cut into small pieces. The whole was thrown in several portions on to the hearth of a furnace previously heated to low redness and was stirred at intervals for three hours. At length when the furnace was tapped a white slag was drawn off from the top, and the liquid metal beneath was received in a ladle and poured into cast-iron moulds. The process was worked out by Deville in his laboratory at the Ecole Normale in Paris.

Early in 1855 he conducted large-scale experiments at Javel in a factory lent him for the purpose, where he produced sufficient to show at the French Exhibition of 1855. In the spring of 1856 a complete plant was erected at La Glacière, a suburb of Paris, but becoming a nuisance to the neighbours, it was removed to Nanterre in the following year. Later it was again transferred to Salindres, where the manufacture was continued by Messrs. Péchiney till the advent of the present electrolytic process, when it no longer paid.

When Deville quitted the Javel works, two brothers C. and A. Tissier, formerly his assistants, who had devised an improved soda furnace and had acquired a thorough knowledge of their leader’s experiments, also left, and erected a factory at Amfreville, near Rouen, to work the cryolite process. It consisted simply in reducing cryolite with metallic sodium exactly as in Deville’s chloride method, and it was claimed to possess various mythical advantages over its rival. Two grave disadvantages were soon obvious—the limited supply of ore, and, what was even more serious, the large proportion of silicon in the reduced metal. The Amfreville works existed some eight or ten years, but achieved no permanent prosperity. In 1858 or 1859 a small factory, the first in England, was built by F. W. Gerhard at Battersea, who also employed cryolite, made his own sodium, and was able to sell the product at 3s. 9d. per oz. This enterprise only lasted about four years. Between 1860 and 1874 Messrs. Bell Brothers manufactured the metal at Washington, near Newcastle, under Deville’s supervision, producing nearly 2 cwt. per year. They took part in the International Exhibition of 1862 and sold a price of 40s. per cwt.

In 1881 J. Webster patented an improved process for making alumina, and the following year he organized the Aluminium Crown Metal Co. of Hollywood to exploit it in conjunction with Deville’s method of reduction. Potash-alum and pitch were calcined together, and the mass was treated with hydrochloric acid; charcoal and water to form a paste were next added, and the whole was dried and ignited in a current of air and steam. The residue, consisting of alumina and potassium sulphate, was leached with water to separate the insoluble matter which was dried as usual. All the by-products—phosphates, sulphur and aluminium of iron, were capable of recovery, and were claimed to reduce the cost of the oxide materially. From this alumina the double chloride was prepared in essentially the same manner as practised at Salindres, but sundry economies accrued in the process, owing to the larger scale of working and to the adoption of W. Weldon’s method of regenerating the spent chloride liquors. In 1886 H. Y. Castner’s sodium patents appeared, and The Aluminium Co. of Oldbury was promoted to combine the advantages of Webster’s alumina and Castner’s sodium. Castner had long been interested in aluminium, and was the first to use the sunlight to photolyse some sodium chloride. Being a successful patent lawyer and being a small but very able chemist, he at once exhibited a number of claims to the discovery of the double chloride which had been made by the Société de Chimie Pure et Appliquée in 1882. He also showed that by this process it was possible to reduce aluminium by means of sodium in a vessel which could be made of iron, by the simple process of allowing the sodium to act on the aluminium, the sodium being continually replenished from the electrode.

In the same year L. Grabau patented a method of reducing the simple fluoride of aluminium with sodium, and his process was operated at Trotha in Germany. It was distinguished by the unusual purity of the metal obtained, some of his samples containing 99.35 to 99.8%. In 1888 the Alliance Aluminium Co., organized to work certain patents for winning the metal cryolite by means of sodium, erected plant in London, Hebburn and WallSEND, and by 1888 were selling the metal at 115s. to 125s. per lb. The Aluminium Company’s price in 1888 was 20s. per lb and in 1889 about 25s. per lb. In 1889 the price was 16s., but by 1891 the electricians commenced to offer metal at 4s. per lb, and aluminium reduced with sodium became a thing of the past.

About 1879 dynamos began to be introduced into metallurgical practice, and from that date onwards numerous schemes for utilizing this cheaper source of energy were brought before the public. The first electrical method worthy of notice is that patented by E. H. and A. H. Cowles in 1885, which was worked both at Lockport, New York, U.S.A., and at Milton, Staffordshire. The furnace consisted of a flat, rectangular, firebrick box, packed with a layer of finely-powdered charcoal 2 in. thick. Through stuffing-boxes at the ends passed the two electrodes, made after the fashion of arc-light carbons, and capable of being approached together according to the requirements of the operation. The central space of the furnace was filled with a mixture of corundum, coarsely-powdered charcoal and copper; and an iron lid lined with firebrick was luted in its place to exclude air. The charge was reduced by means of a 50-volt current from a 300-kilowatt dynamo, which was passed through the furnace for 24 hours till decomposition was complete. About 100 lb of briquetting containing from 15 to 20 lb of aluminium, were obtained from each run, the yield of the alloy being reported at about 1 lb per 18 e.h.p.-hours. The composition of the alloys thus produced could not be predetermined with exactitude; each batch was therefore analysed, a number of them were bulked together or mixed with copper in
the necessary proportion, and melted in crucibles to give mer-
chantable bronzes containing between 1/2 and 10 % of aluminium.
Although the copper took no part in the reaction, its employment
was found indispensable, as otherwise the aluminium partly
volatilized, and partly combined with the carbon to form a
 carbide. It was also necessary to give the fine charcoal a thin
 coating of calcium oxide by soaking it in lime-water, for the
temperature was so high that unless it was thus protected it was
gradually converted into graphite, losing its insulating power
and diffusing the current through the lining and walls of the
furnace. That this process did not depend upon electrolysis, but
was simply an instance of electrical smelting or the decomposition
of an oxide by means of carbon at the temperature of the electric
arc, is shown by the fact that the Cowles furnace would work
with an alternating current.

In 1883 R. Critzel patented a useless electrolytic process with
fused cryolite or the double chloride as the raw material, and in
1886 Dr E. Kleiner propounded a cryolite method which was
worked for a time by the Aluminium Syndicate at Tyldesley near
Manchester, but was abandoned in 1890. In 1887 A. Minet took
out patents for electrolyzing a mixture of sodium chloride with
aluminium fluoride, or with natural or artificial cryolite. The
operation was continuous, the metal being regularly run off from
the bottom of the bath, while fresh alumina and fluoride were
added as required. The process exhibited several disadvantages,
the electrolyte had to be kept constant in composition lest either
fluorine vapours should be evolved or sodium thrown down, and
the raw material had to be prepared in a pure state. After
prolonged experiments in a factory owned by Messrs
Bernard Frères at St Michel in Savoy, Minet's process was given
up, and at the close of the 19th century the Héroult-Hall method
was alone being employed in the manufacture of aluminium
throughout the world.

The original Deville process for obtaining pure alumina from
bauxite was greatly simplified in 1889 by K. T. Bayer, whose
improved process is exploited at Larne in Ireland and at Gardanne
in France. New works on the same process have recently been
erected near Marseilles. Crude bauxite is ground, lightly
calcined to destroy organic matter, and agitated under a pressure
of 70 or 80 lb per sq. in. with a solution of sodium hydroxide
having the specific gravity 1.45. After two or three hours the
liquid is diluted till its density falls to 1.25, when it is passed
through filter-presses to remove the insoluble ferric oxide and
silica. The solution of sodium aluminate, containing aluminium
oxide and sodium oxide in the molecular proportion of 6 to 1,
is next agitated for thirty-six hours with a small quantity of
hydrated alumina previously obtained, which causes the liquor
to settle and the alumina to come down in almost 70 % of the aluminium hydroxide to be
thrown down. The filtrate, now containing roughly two mole-
cules of alumina to one of soda, is concentrated to the original
gravity of 1.45, and employed instead of fresh caustic for the
attack of more bauxite; the precipitate is then collected, washed
till free from soda, dried and ignited at about 1000° C. to convert
it into a crystalline oxide which is less hygroscopic than the
former amorphous variety.

The process of manufacture which now remains to be described
was patented during 1886 and 1887 in the name of C. M. Hall
in America, that of P. T. L. Héroult in England and France,
and it would be idle to discuss to whom the credit of first imagining
the method rightfully belongs, for probably this is only one of the
many occasions when new ideas have been born in several
brains at the same time. By 1888 Hall was at work on a com-
mmercial scale at Pittsburg, reducing German alumina; in 1891
the plant was removed to New Kensington for economy in fuel,
and was gradually enlarged to 1500 h.p. in 1894 a factory
driven by water was erected at Niagara Falls, and subsequently
works were established at Shawenegan in Canada and at Massena
in the United States. In 1890 also the Hall process operated
by steam power was installed at Patricroft in Lancashire, where
the plant had a capacity of 500 lb per day, but by 1894 the turbines
of the Swiss and French works ruined the enterprise. About
1897 the Bernard factory at St Michel passed into the hands of
Mesrs Péchiney, the machinery soon being increased, and there,
under the control of a firm that has been concerned in the
industry almost from its inception, aluminium is being manu-
factured by the Hall process on a large scale. In July 1888 the
Société Métallurgique de France erected plant driven by a 300 h.p.
turbine to carry out Héroult's alloy process, and at the end of
that year the Algemeine Elektricitäts-Gesellschaft united with the
Swiss firm in organizing the Aluminium Industrie Aetien Gesell-
schaft of Neuenas, which has factories in Switzerland, Germany
and Austria. The Société Electrométallurgique Française, started
under the direction of Héroult in 1888 for the production of
aluminium in France, began operations on a small scale at
Froges in Isère; but soon after large works were erected in Savoy
at La Praz, near Modane, and in 1905 another large factory was
started in Savoy at St Michel. In 1895 the British Aluminium
Company was founded to mine bauxite and manufacture alumina
in Ireland, to prepare the necessary electrodes at Greenwich,
and to reduce the aluminium by the aid of water-power at the Falls
of Foyers, and to refine and work up the metal into marketable
shapes at the old Milton factory of the Cowles Syndicate,
remodeled to suit modern requirements. In 1907 this company
began works for the utilization of another water-power at Loch
Leven.

In 1907 a new company, The Aluminium Corporation, was
started in England to carry out the production of the metal by
the Héroult process, and new factories were constructed near
Conway in North Wales and at Wallsend-on-Tyne, quite close
to where, twenty years before, the Alliance Aluminium Co. had
their works.

The Héroult cell consists of a square iron or steel box lined
with carbon rammed and baked into a solid mass; at the bottom
is a cast-iron plate connected with the negative pole of the
dynamo, but the actual working cathode is undoubtedly the
layer of already reduced and molten metal that lies in the bath.
The anode is formed of a bundle of carbon rods suspended
from overhead so as to be capable of vertical adjustment. The cell
is filled up with cryolite, and the current is turned on till this
is 700 amperes per sq. ft. of cathode surface, and the number of
hours, as long as the operation proceeds. The current is supplied at
a tension of 3 to 5 volts per cell, passing through 10 or 12 in series;
and it performs two distinct functions:—(1) it overcomes
the chemical affinity of the aluminium oxide, (2) it overcomes
the resistance of the electrolyte, heating the liquid at the same
time. As a part of the voltage is consumed in the latter duty, only
the residue can be converted into chemical work, and as the theoretical
voltage of the aluminium fluoride in the cryolite is 4.9, provided
the bath is kept properly supplied with alumina, the "fluorides are
not necessary. It follows, therefore, except for small losses,
that one charge of cryolite lasts indefinitely, that the sodium and
other impurities in it are not liable to contaminate the product,
and that only the alumina itself need be carefully purified.

The operation is essentially a dissociation of alumina into aluminium,
which collects at the cathode, and into oxygen, which combines
with the anodes to form carbon monoxide, the latter escaping
and being burnt to carbon dioxide outside. Theoretically 36
parts by weight of carbon are oxidized in the production of 54
parts of aluminium; practically the anodes waste at the same
rate at which metal is deposited. The current density is about
1000 amperes per sq. ft. of cathode surface, and the number of
rods in the anode is such that each delivers 6 or 7 amperes per
sq. in. of cross-sectional area. The working temperature lies
between 750° and 850° C., and the actual yield is 1 lb of metal per
12 e.h.p. hours. The bath is heated internally with the current
rather than by means of external fuel, because this arrangement
permits the vessel itself to be kept comparatively cool; if it
were fired from without, it would be hotter than the electrolyte,
and no material suitable for the construction of the cell is competent
to withstand the attack of nascent aluminium at high temperature.

Aluminia, therefore, is a material requiring some ingenuity to
select a convenient solvent through which it shall sink quickly, for if it does not sink, it short-circuits the electrolyte.

The molten metal has a specific gravity of 2.54, that of molten
Aluminium is a white metal with a characteristic tint which most nearly resembles that of tin; when impure, or after prolonged exposure to air, it has a slight violet shade. Its atomic weight is 27 (26-77, H=1, according to J. Thomsen). It is trivalent. The specific gravity of cast metal is 2-383, and of rolled 2-688 at 6°C. It melts at 626°C. (freezing-point 654-5°, Heycock and Neville.) It is the third most malleable and sixth most ductile metal, yielding sheets 0-00025 in. in thickness, and wires 0-004 in. in diameter. When quite pure it is somewhat harder than tin, and its hardness is considerably increased by rolling. It is not magnetic. It stands near the positive end of the list of elements arranged in electromagnetic series, being exceeded only by the alkalis and metals of the alkaline earths; it therefore combines eagerly, under suitable conditions, with oxygen and chlorine. Its coefficient of linear expansion by heat is 0-0000222 (Richards) or 0-0000231 (Roberts-Austen) per °C. Its mean specific heat between 0° and 100° is 0-227, and its latent heat of fusion 100 calories (Richards). Only silver, copper and gold surpass it as conductors of heat, its value being 31-33 (Ag=100, Roberts-Austen). Its electrical conductivity, determined on 99-6% metal, is 60-5% that of copper. In equal volumes, or double that of copper for equal weights, and when chemically pure it exhibits a somewhat higher relative efficiency. The average strength of 98% metal is approximately shown by the following table:

Weight for weight, therefore, aluminium is only exceeded in tensile strength by the best cast steel, and its own alloy, aluminium bronze. An absolutely clean surface becomes tarnished in damp air, an almost invisible coating of oxide being produced, just as happens with zinc; but this film is very permanent and prevents further attack. Exposure to air and rain also causes slight corrosion, but to nothing like the same extent as occurs in iron. Copper or brass, on the other hand, is much more susceptible to atmospheric corrosion than aluminium, the latter being essentially aluminium itself. The metal in mass is not affected by hot or cold water, the foil is very slowly oxidized, while the amalgam decomposes rapidly. Sulphuretted hydrogen having no action upon it, articles made of it are not blackened in foggy weather or in rooms where crude coal gas is burnt. To inorganic acids, except hydrochloric, it is highly resistant, ranking well with tin in this respect; but alkalis dissolve it quickly. Organic acids such as vinegar, common salt, the natural ingredients of food, and the various excretory substances used as food preservatives, alone or mixed together, dissolve traces of it if boiled for any length of time in a chemically-clean vessel; but when aluminium utensils are submitted to the ordinary routine of the kitchen, being used to heat or cook milk, coffee, vegetables, meat and even fruit, and are also cleaned frequently in the usual fashion, no appreciable quantity of metal passes into the food. Moreover, did it do so, the action upon the human system would be infinitely less harmful than similar doses of copper or of lead.

The highly refractory character of aluminium is most important. At elevated temperatures the metal decomposes nearly all other metallic oxides, wherefore it is most serviceable as a metallurgical reagent. In the casting of iron, steel and brass, the addition of a trifling proportion (0-005%) removes oxide and renders the molten metal more fluid, causing the finished products to be more homogeneous, free from blow-holes and solid all through. On the other hand, its electro-positive nature necessitates some care in its utilization. If it be exposed to damp, to sea-water or to corrosive influences of any kind in contact with another metal, or if it be mixed with another metal so as to form an alloy which is not a true chemical compound, the other metal being highly negative to it, powerful galvanic action will be set up and the structure will quickly deteriorate. This explains the failure of boats built of commercially pure aluminium which have been put together with iron or copper rivets, and the decay of other boats built of a light alloy, in which the alloying metal (copper) has been injudiciously chosen. It also explains why aluminium is so difficult to join with low-temperature solders, for these mostly contain a large proportion of lead. This disadvantage, however, is often overestimated since in most cases other means of uniting two pieces are available.

The metal produces an enormous number of useful alloys, some of which, containing only 1 or 2% of other metals, combine the lightness of aluminium itself with far greater hardness and strength. Some with 90 to 95% of other metals exhibit the general properties of those metals conspicuously improved. Among the heavy alloys, the aluminium bronzes (Cu, 95-97-5%; Al, 10-2-5%) occupy the most important position, showing mean tensile strengths increasing from 20 to 40 tons per sq. in. on the proportion of aluminium, and all strongly resisting corrosion in air or sea-water. The light copper alloys, in which the proportions just given are practically reversed, are of considerably less utility, for although they are fairly strong, they lack power to resist galvanic action. This subject is far from being exhausted, and it is not improbable that the alloy-producing capacity of aluminium may eventually prove its most valuable characteristic. In the meantime, ternary light alloys appear the most satisfactory, and tungsten and copper, or tungsten and nickel, seem to be the best substances to use.

The uses of aluminium are too numerous to mention. Probably the widest field is still in the purification of iron and steel. To the general public it appeals most strongly as a material for constructing cooking utensils. It is not brittle like porcelain and cast iron, not poisonous like lead-glazed earthenware and untinned copper, needs no enamel to chip off, does not rust and wear out like cheap tin-plate, and weighs but a fraction of other substances. It is largely replacing brass and copper in all departments of industry—especially where dead weight has to be moved about, and lightness is synonymous with economy—for the production of aluminium trestles and all strongly resisting corrosion in air or sea-water. Light copper alloys, in which the proportions just given are practically reversed, are of considerably less utility, for although they are fairly strong, they lack power to resist galvanic action. This subject is far from being exhausted, and it is not improbable that the alloy-producing capacity of aluminium may eventually prove its most valuable characteristic. they are in frequent demand and give perfect satisfaction. Difficulties were at first encountered in making the necessary joints, but these have been overcome by practice and experience.

Two points connected with this metal are of sufficient moment to demand a few words by way of conclusion. Its extraordinary lightness forms its chief claim to general adoption, yet is apt to cause mistakes when its price is mentioned. It is the weight of a mass of metal which governs its financial value; its industrial value, in the vast majority of cases, depends on the volume of that mass. Provided it be rigid, the bed-plate of an engine is no better for weighing 30 cwt. than for weighing 10 cwt. A saucepan is required to have a certain diameter and a certain depth in order that it may hold a certain bulk of liquid: its weight is merely an encumbrance. Copper being 3½ times as heavy as aluminium, whenever the latter costs less than 3½ times as much as copper it is actually cheaper. It must be remembered, too, that electrolytic aluminium only became known during the last decade of the 19th century. Samples dating from the old sulphur days are still in existence, and when they exhibit unpleasant properties the defect is often ascribed to the metal instead of to the process by which it was won. Much has yet to be learnt about the practical qualities of the electrolytic product, and although every day's experience serves to place the metal in a firmer industrial position, a final verdict can only be passed after the lapse of time. The individual and collective influence of the several impurities which occur in the product of the Héroult cell is still to be seen, and the importance of this inquiry will be even when we consider that if cast iron, wrought iron and steel, the three totally different metals all contain, in the generic name of "iron"—which are only distinguished one from another chemically by minute differences in the proportion of certain non-metallic ingredients—had only been in use for a comparatively few years, attempts might occasionally be made to forge cast iron, or to employ wrought iron in the manufacture of edge-tools.

(E. J. R.)

**Compounds of Aluminium.**

Aluminium oxide or alumina, $\text{Al}_2\text{O}_3$, occurs in nature as the mineral corundum (q.v.), notable for its hardness and abrasive powers (see Emery), and in well-crystallized forms it constitutes, when coloured by various metallic oxides, the gem-stones, sapphire, oriental topaz, oriental amethyst and oriental emerald. Alumina is obtained as a white amorphous powder by heating aluminium hydroxide. This powder, provided that it has not been too strongly ignited, is soluble in strong acids; by ignition it becomes denser and nearly as hard as corundum; it fuses in the oxyhydrogen flame or electric arc, and on cooling it assumes a crystalline form closely resembling the mineral species. Crystallized alumina is also obtained by heating the fluoride with boron trioxide; by fusing aluminium phosphate with sodium sulphate; by heating alumina to a dull redness in hydrochloric acid gas under pressure; and by heating alumina with lead oxide to a bright red heat. These reactions are of special interest, for they culminate in the production of artificial ruby and sapphire (see Gems, Artificial).

**Aluminium Hydrates.**—Several hydrated forms of aluminium oxide are known. Of these hydrargillite or gibbsite, $\text{Al(OH)}_3$, diaspor, $\text{AlO(OH)}_2$, and bauxite, $\text{Al}_2\text{O}_3\text{H}_2\text{O}$, occur in the mineral kingdom. Aluminium hydrate, $\text{Al(OH)}_3$, is obtained as a gelatinous white precipitate, soluble in potassium or sodium hydroxide, but insoluble in ammonium chloride, by adding ammonia to a cold solution of an aluminium salt; from boiling solutions the precipitate is opaque. By drying at ordinary temperatures, the hydrate $\text{Al(OH)}_3\cdot\text{H}_2\text{O}$ is obtained; at 300° this yields $\text{AlO(OH)}$, which on ignition gives alumina, $\text{Al}_2\text{O}_3$. Precipitated aluminium hydrate finds considerable application in dyeing. Soluble modifications were obtained by Walter Crum (Journ. Chem. Soc., 1854, vi. 216), and Thomas Graham (Phil. Trans., 1861, p. 163); the first named decomposing aluminium acetate (from lead acetate and aluminium sulphate) with boiling water, the latter dialysing a solution of the basic chloride (obtained by dissolving the hydroxide in a solution of the normal chloride).

Both these soluble hydrates are readily coagulated by traces of a salt, acid or alkali; Crum's hydrate does not combine with dye-stuffs, neither is it soluble in excess of acid, while Graham's compound readily forms lakes, and readily dissolves when coagulated in acids.

In addition to behaving as a basic oxide, aluminium oxide (or hydrate) behaves as an acid oxide towards the strong bases with the formation of aluminates. Potassium aluminate, $\text{K}_2\text{AlO}_3$, is obtained by dissolving aluminium hydrate in caustic potash; it is also obtained, as crystals containing three molecules of water, by fusing alumina with potash, exhauusting with water, and crystallizing the solution in vacuo.

Sodium aluminate is obtained in the manufacture of alumina; it is used as a mordant in dyeing, and has other commercial applications. Other aluminates (in particular, of iron and magnesium), are of frequent occurrence in the mineral kingdom, e.g. spinel, garnite, &c.

**Salts of Aluminium.**—Aluminium forms one series of salts, derived from the trioxide, $\text{Al}_2\text{O}_3$. These exhibit, in certain cases, marked crystallographical and other analogies with the corresponding salts of chromium and ferric iron.

Aluminium fluoride, $\text{AlF}_3$, obtained by dissolving the metal in hydrofluoric acid, and subliming the residue in a current of hydrogen, forms transparent, very obtuse rhombohedra, which are insoluble in water. It forms a series of double fluorides, the most important of which is cryolite (q.v.); this mineral has been applied to the commercial preparation of the metal (see above). Aluminium chloride, $\text{AlCl}_3$, was first prepared by Oersted, who heated a mixture of carbon and alumina in a current of chlorine, a method subsequently improved by Wöhler, Bunsen, Deville and others. A purer product is obtained by heating aluminium turnings in a current of dry chlorine, when the chloride distils over. So obtained, it is a white crystalline solid, which slowly sublimes just below its melting point (104°). Its vapour density at temperatures above 750° corresponds to the formula $\text{AlCl}_3$; below this point the molecules are associated. It is very hygroscopic, absorbing water with the evolution of hydrochloric acid. It combines with ammonia to form $\text{AlCl}_3\cdot3\text{NH}_3$; and forms double compounds with phosphorus pentachloride, phosphorus oxychloride, selenium and tellurium chlorides, as well as with many metallic chlorides; sodium aluminium chloride, $\text{AlCl}_3\cdot\text{NaCl}$, is used in the production of the metal. As a synthetic agent in organic chemistry, aluminium chloride has rendered possible more reactions than any other substance; here we can only mention the classic syntheses of benzene homologues. Aluminium bromide, $\text{AlBr}_3$, is prepared in the same manner as the chloride. It forms colourless crystals, melting at 90°, and boiling at 265°-270°. Aluminium iodide, $\text{AlI}_3$, results from the interaction of iodine and aluminium. It forms colourless crystals, melting at 156°, and boiling at 356°. Aluminium sulphide, $\text{Al}_2\text{S}_3$, results from the direct union of the metal with sulphur, or when carbon disulphide vapour is passed over strongly heated alumina. It forms a yellow fusible mass, which is decomposed by water into alumina and sulphuretted hydrogen. Aluminium sulphate $\text{Al}_2(\text{SO}_4)_3\cdot9\text{H}_2\text{O}$ occurs in the mineral kingdom as keramohalite, $\text{Al}_2(\text{SO}_4)_3\cdot18\text{H}_2\text{O}$, found near volcanoes and in alum-shale; aluminate or websterite is a basic salt, $\text{Al}_2(\text{SO}_4)(\text{OH})_3\cdot7\text{H}_2\text{O}$. Aluminium sulphate, known commercially as "concentrated alum" or "sulphate of alumina," is manufactured from kaolin or china clay, which, after roasting (in order to oxidize any iron present), is heated with sulphuric acid, the clear solution run off, and evaporated. "Alum cake" is an impure product. Aluminium sulphate crystallizes as $\text{Al}_2(\text{SO}_4)_3\cdot18\text{H}_2\text{O}$ in tablets belonging to the monolitic system. It has a sweet astringent taste, very soluble in water, but scarcely soluble in alcohol. On heating, the crystals lose water, swell up, and give the anhydrous sulphate, which, on further heating, gives alumina. It forms double salts with the sulphates of the metals of the alkalis, known as the alums (see Alum).

Aluminium nitrate $\text{Al(NO}_3)_3$ is obtained by fusing yellow crystals when aluminium is strongly heated in nitrogen. The nitrate, $\text{Al(NO}_3)_3$, is obtained as deliquescent crystals (with $\text{8H}_2\text{O}$).
by evaporating a solution of the hydroxide in nitric acid.
Aluminium phosphates may be prepared by precipitating a soluble aluminium salt with sodium phosphate. Wavellite \( \text{Al}_2(\text{PO}_4)_3(\text{OH})_4 \cdot \text{H}_2\text{O} \) is a naturally occurring basic phosphate, while the gem-stone turquoise (q.v.) is \( \text{Al}_2(\text{PO}_4)_3(\text{OH})_2 \cdot 2\text{H}_2\text{O} \), coloured by traces of copper. Aluminium silicates are widely diffused in the mineral kingdom, being present in the commonest rock-forming minerals (feldspars, &c.), and in the gem-stones, topaz, heryl, garnet, &c. It also constitutes with sodalite the mineral lapis-lazuli and the pigment ultramarine (q.v.).

Forming the basis of all clays, aluminium silicates play a prominent part in the manufacture of pottery and porcelain.

**ALUNITE, or ALUMSTONE,** a mineral first observed in the 15th century at Tafal, near Rome, where it is mined for the manufacture of alum. Extensive deposits are also worked in Tuscany and Hungary, and at Bulladale in New South Wales. By repeatedly boiling and leaching the mineral, alum is obtained in solution, and this is crystallized out by evaporation. Alunite occurs as seams in trachytic and allied volcanic rocks, having been formed by the action of sulphuric vapours on these rocks. The white, finely granular masses somewhat resemble limestone in appearance, and the more compact kinds from Hungary are so hard and tough that they are used for millstones. Distinct crystals of alunite are rarely met with in cavities in the massive material; these are rhombohedra with interfacial angles of 90° to 90°, so that they resemble cubes in appearance. Minute glistening crystals have also been found loose in cavities in altered rhyolite. The hardness is 4 and the specific gravity 2-6. The mineral is a hydrated basic aluminium and potassium sulphate, \( \text{KAl}_3(\text{SO}_4)_2(\text{OH})_3 \). It is insoluble in water, but soluble in sulphuric acid. First called aluninite by J. C. Delamétherie in 1797, this name was contracted by F. S. Beudant in 1824 to alunite.

**ALUR** (Lur, Luri, Lurem), a Negro people of the Nile valley, living on the north-west coast of Albert Nyanza. They are akin to the Acholi (q.v.), speaking practically the same language.

**ALURE** (O. Fr., from aller, to walk), an architectural term for an alley, passage, the waterway that lies behind a palace, the galleries of a clerestory, sometimes even the aisle itself of a church. The term is sometimes written valure or valoring.

**ALVA, or ALVA, FERNANDO ALVAREZ DE TOLEDO, DUKE OF,** (1508-1583), Spanish soldier, descended from one of the most illustrious families in Spain, was born in 1508. His grandfather, Ferdinand of Toledo, educated him in military science and politics; and he was engaged with distinction at the battle of Pavia while still a youth. Selected for a military command by Charles V., he took part in the siege of Tunis (1535), and successfully defended the fort of Fortel against the French. He was present at the battle of Mühlberg (1547), and the victory gained there over John of Saxony was due mainly to his exertions. He took part in the subsequent siege of Wittenberg, and presided at the court-martial which tried the elector and condemned him to death. In 1552 Alva was intrusted with the command of the army intended to invade France, and was engaged for several months in an unsuccessful siege of Metz. In consequence of the success of the French arms in Piedmont, he was made commander-in-chief of all the emperor's forces in Italy, and at the same time invested with unlimited power. Success did not, however, attend his first attempts, and after several unfortunate attacks he was obliged to retire into winter quarters. After the abdication of Charles he was continued in the command by Philip II., who, however, restrained him from extreme measures. Alva had subdued the whole Campaigna and was at the gates of Rome, when he was compelled by Philip's orders to negotiate a peace. One of its terms was that the duke of Alva should in person ask forgiveness of the haughty pontiff whom he had conquered. Proud as the duke was by nature, and accustomed to treat with persons of the highest dignity, he confessed his mistake to him and at the same time revealed his horror of his fate. Not long after this (1559) he was sent at the head of a splendid embassy to Paris to espouse, in the name of his master, Elizabeth, daughter of Henry, king of France. In 1567, Philip, who was a bigoted Catholic, sent Alva into the Netherlands at the head of an army of 10,000 men, with unlimited powers for the extirpation of heretics. When he arrived he soon showed how much he merited the confidence which his master reposed in him, and instantly erected a tribunal which soon became known to its victims as the "Court of Blood," to try all persons who had been engaged in the late commotions which the civil and religious tyranny of Philip had excited. He imprisoned the counts Egmont and Horn, the two popular leaders of the Protestants, brought them to an unjust trial and condemned them to death. In a short time he totally annihilated every privilege of the people, and with unrelenting cruelty put multitudes of them to death. The executioner was employed in removing all those friends of freedom whom the sword had spared. In most of the considerable towns Alva built citadels. In the city of Antwerp he erected a statue of himself, which was a monument no less of his vanity than of his tyranny: he was figured trampling on the necks of two smaller statues, representing the two estates of the Low Countries. His attempt to raise money by imposing the Spanish alcabala, a tax of 5% on all sales, aroused the opposition of the Catholic Netherlands themselves. The exiles from the Low Countries, encouraged by the general resistance to his government, fitted out a fleet of privateers, and after strengthening themselves by successful depredations, ventured upon the bold exploit of seizing the town of Brüelle. Thus Alva by his cruelty became the unwitting instrument of the future independence of the seven Dutch provinces. The fleet of the exiles, having met the Spanish fleet, totally defeated it, and reduced North Holland and Mons. Many cities hastened to throw off the yoke; while the states-general, assembling at Dordrecht, openly declared against Alva's government, and marshalled under the banners of the prince of Orange. Alva's preparations to oppose the gathering storm were made with his usual vigour, and he succeeded in recovering Mons, Mechlin and Zutphen, under the conduct of his son Frederick. With the exception of Zeeland and Holland, he regained all the provinces; and at last his son stormed Naarden, and massacring its inhabitants, proceeded towards the capital, where he, who had been so fortunate, was taken and pillaged. Their next attack was upon Alkmaar; but the spirit of desperate resistance was raised to such a height in the breasts of the Hollandersthat the Spanish veterans were repulsed with great loss and Frederick constrained reluctantly to retire. Alva's feeble state of health and continued disasters induced him to solicit his recall from the government of the Low Countries; a measure which, in all probability, was not displeasing to Philip, who was now resolved to make trial of a milder administration. In December 1573 the much-oppressed country was relieved from the presence of this monarch, who, during his approach to the north, his son, made the infamous boast that during the course of six years, besides the multitudes destroyed in battle and massacred after victory, he had consigned 18,000 persons to the executioner. On his return he was treated for some time with great distinction by Philip. A tardy and imperfect justice, however, overtook him, when he was banished from court and confined in the castle of Uzeda for complicity in certain disgraceful conduct of his son. Here he had remained two years, when the success of Don Antonio in assuming the crown of Portugal determined Philip to turn his eyes towards Alva as the person in whose fidelity and abilities he could most confide. A secretary was instantly
despatched to Alva to ascertain whether his health was sufficiently vigorous to enable him to undertake the command of an army. The aged chief returned an answer full of loyal zeal, and was immediately appointed to the supreme command in Portugal. It is a striking fact, however, that the liberation and elevation of Alva were not followed by forgiveness. In 1581 Alva entered Portugal, defeated Antonio, drove him from the kingdom, and soon reduced the whole under the subjection of Philip. Enterprising, he seized an immense treasure, and saved the fortresses of the country, which he rewarded by the temporary surrender of all his forces to his power and authority, to sack the suburbs and vicinity. It is reported that Alva, being requested to give an account of the money expended on that occasion, sternly replied, "If the king asks me for an account, I will make him a statement of kingdoms preserved or conquered, of signal victories, of successful sieges and of sixty years' service." Philip deemed it proper to make no further inquiries. Alva, however, did not enjoy the honours and rewards of his last expedition, for he died in January 1583 at the age of 74.

ALVAREZ, Pedro de (1495-1541), one of the Spanish leaders in the discovery and conquest of America, was born at Badajoz about 1495. He held a command in the expedition sent from Cuba against Yucatan in the spring of 1518, and returned in a few months, bearing reports of the wealth and splendour of Montezuma's empire. In February 1519 he accompanied Hernando Cortes in the expedition for the conquest of Mexico, being appointed to the command of one of the eleven vessels of the fleet. He acted as Cortes's principal officer, and on the first occupation of the city of Mexico was left there in charge. When the Spaniards had temporarily retired before the Mexican uprising, Alvarado led the rear-guard (1st of July 1520), and the Salto de Alvarado—a long leap with the use of his spear—by which he saved the life of the famous Francisco Pizarro. He was engaged (1523-24) in the conquest of Guatemala, of which he was subsequently appointed governor by Charles V. In 1534 he attempted to bring the province of Quito under his power, but had to content himself with the exaction of a pecuniary indemnity for the expenses of the expedition. During a visit to Spain, three years later, he had the governorship of Honduras conferred upon him in addition to that of Guatemala. He died in Guatemala in 1541.

ALVAREZ, Francisco (c. 1465-1541?), Portuguese missionary and explorer, was born at Coimbra. He was a chaplain-priest and almoner to Dom Manuel, king of Portugal, and was sent in 1515 as secretary to Duarte Galvão and Rodrigo da Lima on an embassy to the negros of Abyssinia (Lebna Dengel Dawit (David II)). The expedition having been delayed by the way, it was not until 1520 that he reached Abyssinia, where he remained six years, returning to Lisbon in 1526-27. In 1533 he was sent to Rome on an embassy to Pope Clement VII. The precise date of his death, like that of his birth, is unknown, but it must have been later than 1540, in which year he published at Lisbon under the king's patrocinium an account of his travels in one volume folio, entitled Verdadera Informacion das terras do Presto Jostm. This curious work was translated into Italian (G. B. Ramusio, Navigationi, vol. i., Venice, 1550); into Spanish (Historia de las Cosas de Ethiopia, by Fray Thomas de Padilla, Antwerp, 1557); into French (Historielle Description de l'Ethiopie, Christ. Plantin, Antwerp, 1558); into German (Wahrhaftiger Bericht von . . . Ethiopein, Eidele, 1560); and into English (Sam. Purchas, Pilgrimes, part ii., London, 1625). The information it contains must, however, be received with caution, as the author is prone to exaggerate, and does not confine himself to what came within his own observation.

ALVAREZ, Don José (1768-1827), Spanish sculptor, was born at Friego, in the province of Cordova, in 1768. His full name was José Alvarez de Pereira y Cubero. Bred to his father's trade of a stone-mason, he devoted all his spare time to drawing and modelling. His education in art was due partly to the teaching of the French sculptor Verdiguier at Cordova, and partly to lessons at Madrid, where he attended the lectures of the academy of San Fernando. In 1799 he obtained from Charles IV. a pension of 12,000 reals to enable him to visit Paris and Rome. In the former city he executed in 1804 a statue of Ganymede, which placed him at once in the front rank of the sculptors of his time, and which is now in the sculpture gallery of the Prado. Shortly afterwards his pension was more than doubled, and he left Paris for Rome, where he remained till within a year of his death. He had married in Paris Elizabeth Bougel, by whom he had a son in 1805. This son, known as Don José Alvarez y Bougel, also distinguished himself as a sculptor and a painter, but he died at Burgos before he had reached the age of twenty-five, a little more than two years after his father's death in Madrid in 1827. One of the most successful works of the elder Alvarez was a group representing Antilochus and Menon, which was commissioned in marble (1818) by Ferdinand VII., and secured for the artist the appointment of court-sculptor. It is now in the museum of Madrid. He also modelled a few portrait busts (Ferdinand VII., Rossini, the duchess of Alba), which are remarkable for their vigour and fidelity.

ALVAREZ, Don Manuel (1777-1797), Spanish sculptor, was born at Salamanca. He followed classical models so closely that he was styled by his countrymen El Greco, 'The Greek.' His works, which are very numerous, are chiefly to be found at Madrid.

ALVARY, Max (1858-1889), German singer, was born at Düsseldorf. Gifted with a fine tenor voice and handsome presence he speedily made a reputation in Germany; in the leading rôles in Wagnerian opera, and from 1885 onwards appeared also in America and England. He was at his best in 1882, when his performances as Tristan and Siegfried at Covent Garden aroused great enthusiasm.

ALVEY (from the Lat. alvearius), a beekeeper; used, like alveus, for any dwelling of the bee, as for a collection of hard-working people, or a scholarly work (e.g. dictionary) involving bee-like industry. By analogy the term is used for the hollow of the ear, where the wax collects.

ALVENSLEBEN, Konstantin von (1809-1892), Prussian general, was born on the 26th of August 1809 at Eichenbarleben in Prussian Saxony, and entered the Prussian guards from the cadet corps in 1827. He became first lieutenant in 1842, captain in 1849, and major on the Great General Staff in 1853, whence after seven years he went to the Ministry of War. He was soon afterwards promoted colonel, and commanded a regiment of Guard infantry up to 1864, when he became a major-general. In this rank he commanded a brigade of guards in the war of 1866. At the action of Soor (Bürensorff) on the 28th of June he distinguished himself very greatly, and at Königgrätz, where he led the advanced guard of the Guard corps, his energy and initiative were still more conspicuous. Soon afterwards he succeeded to the command of his division, General Hiller v. Gärtringen having fallen in the battle; he was promoted lieutenant-general, and retained this command after the conclusion of peace, receiving in addition the order pour le mérite for his services. In 1870, on the outbreak of war with France, von Alvensleben succeeded Prince Frederick Charles in command of the III army corps which formed part of the II German
Army commanded by the prince. Under their new general, the Brandenburg regiments forming the III corps proved themselves collectively the best in the whole German army, with the possible exception of the Prussian guards, and, if Prince Frederick Charles is entitled to the chief credit in training the III corps, Alvensleben had contributed in almost equal degree to the efficiency of the Guard infantry, while his actual leadership of the III corps in the battles of 1870 and 1871 showed him afresh as a fighting general. Roland, the corps, with its comrades of Spichern, on the 6th of August, was initiated and practically directed throughout by him, and in the confusion which followed this victory, for which the superior commanders were not prepared, Alvensleben showed his energy and determination by resuming the advance on his own responsibility. This led to the great battles of the 14th, 16th and 18th of August around Metz, and again the III corps was destined, under its resolute leader, to win the chief credit. Crossing the Moselle the instant that he received permission from his army commander to do so, Alvensleben struck the flank of Bazaine’s whole army (August 16th) in movement westward from Metz. The III corps attacked at once, and for many hours bore the whole brunt of the battle at Vionville. By the most resolute leading, and at the cost of very heavy losses, Alvensleben held the whole French army at bay while other corps of the I and II German Armies gradually closed up. In the battle of Gravelotte, on the 18th, the corps took little part. Its work was done, and it remained with the II Army before Metz until the surrender of Bazaine’s army. Prince Frederick Charles then moved south-west to co-operate with the grand-duke of Mecklenburg on the Loire. At the battle of Le Mans, he was first to the scene of battle. At Vionville, the X corps under General v. Voltaire-Rhetz, won new laurels, and it participated in the advance on Le Mans and the battle at that place on the 12th of January 1871. At the close of the war Alvensleben received the oak-leaves of the order pour le mérite, the first class of the Iron Cross and a grant of 100,000 thalers. He became full general of infantry in 1873 and retired immediately afterwards. In 1888 the emperor William II. ordered that the 52nd infantry regiment (one of the distinguished regiments of Vionville) should thereafter bear Alvensleben’s name. Ried in 1892, on the anniversary of the battle of Le Mans, the old general received the order of the Black Eagle. He died on the 28th of March 1892 at Berlin.

His brother, Gustav von Alvensleben (1803–1881), Prussian general of infantry, was born at Eichenbarleben on the 30th of September 1803, entered the Guard infantry in 1821, and took part as a general staff officer in the suppression of the Baden insurrection of 1849. He became a major-general in 1858, aide-de-camp to the king in 1861, and lieutenant-general in 1863, and in the campaign of 1866 performed valuable military and political services. He was promoted general of infantry in 1868. In the war of 1870 he commanded the IV army corps, which took a conspicuous part in the action of Beaumont and afterwards served in the siege of Paris. He received the Iron Cross, the order pour le mérite, and a money grant, as a reward for his services, and retired in 1872. He died at Germrode in the Harz on the 30th of June 1881.

Another brother, Albrecht, Count von Alvensleben (1794–1858), was a distinguished Prussian statesman.

**ALVEOLATE** (from Lat. *alveolus*), honeycombed, a word used technically in biology, &c., to mean pitted like a honeycomb.

**ALVERSTONE,** Richard Everard Webster, 1st Baron (1842– ), lord chief justice of England, was born on the 22nd of December 1842, being the second son of Thomas Webster, Q.C. He was educated at King’s College and Charterhouse schools, and Trinity College, Cambridge; was called to the bar in 1868, and became Q.C. only ten years afterwards. His practice was chiefly in commercial, railway and patent cases until (June 1883) he was appointed attorney-general in the Conservative Government in the exceptional circumstances of never having been solicitor-general, and not at the time occupying a seat in parliament. He was elected for Lowestoft in the following month, and in November exchanged this seat for the Isle of Wight, which he continued to represent until his elevation to the House of Lords. Except under the brief Gladstone administration of 1886, and the Gladstone-Rosebery cabinet of 1892–1895, Sir Richard Webster was attorney-general from 1885 to 1900. In 1890 he was leading counsel for The Times in the Parnell inquiry; in 1893 he represented Great Britain in the Bering Sea arbitration; and in 1898 he discharged the same function in the matter of the boundary between British Guiana and Venezuela. His range was from 12 to 20 members of the Alaska Boundary Commission. He was well known as an athlete in his earlier years, having represented his university as a runner, and his interest in cricket and foot-racing was kept up in later life. In the House of Commons, and outside it, he was throughout his political career prominently associated with church work; and his speeches were distinguished for gravity and earnestness. In 1900 he succeeded Sir Nathaniel Lindley as Master of the Rolls, being raised to the peerage as Baron Alverstone, and in October of the same year he was elected to the office of lord chief justice upon the death of Lord Russell of Killowen.

**ALWAR,** or Ulwar, a native state of India in the Rajputana agency. It is bounded on the E. by the state of Bharatpur and the British district of Gurgaon, on the N. by Gurgaon district and the state of Patiala, on the W. by the states of Nabha and Jaipur, and on the S. by the state of Jaipur. Its configuration is irregular, the greatest length from north to south being about 80 m., and breadth from east to west about 60 m., with a total area of 3,143 sq. m. The eastern portion of the state is open and highly cultivated; the western is diversified by hills and peaks, which form a continuation of the Aravalli range, from 2 to 20 m. in breadth. These hills run in rocky and precipitous parallel ridges, in some places upwards of 2,000 ft. in height. The Sabhi river flows through the north-western part of the state, the only other stream of importance being the Ruparel, which rises in the Alwar hills, and flows through the state into the Bharatpur territory. The population in 1901 was 82,487, showing an increase of 8% during the decade. When compared with a heavy decrease elsewhere throughout Rajputana, this increase may be attributed to the successful administration of famine relief, under British officials. The revenue is £15,000. The maharaja Jai Singh, who succeeded in 1892 at the age of ten, was educated at the Mayo college, where he excelled both in sports and in knowledge of English. He came of age in 1903, when he was invested by the viceroy with full ruling powers.

Alwar was the first native state to accept a currency struck at the Calcutta mint, of the same weight and assay as the imperial rupee, with the head of the British sovereign on the obverse. Imperial service troops are maintained, consisting of both cavalry and infantry, with transport. The state is traversed by the Delhi branch of the Rajputana railway, and a small amount of the land revenue has been carried out by an English civilian.

The state was founded by Pratap Singh (1740–1701), a Rajput of ancient lineage, and increased by his adopted son Bakhtawar Singh. The latter joined the British against the Mahattars, and in 1803, after the battle of Laswari (Nov. 1), signed a treaty of offensive and defensive alliance with the British government. In 1811, owing to his armed intervention in Jaipur, a fresh engagement was made, prohibiting him from political intercourse with other states without British consent. In 1857 the raja Biml Singh sent a force of Musalmans and Rajputs to relieve the British garrison in Agra; the Musalmans, however, deserted, and the rest were defeated by the mutineers.

The City of Alwar has a railway station on the Rajputana line, 98 m. from Delhi; pop. (1901) 56,771, showing a steady increase. It stands in a valley overflowing by a fortress 1,000 ft. above. It is surrounded by a rampart and moat, with five gates, and contains fine palaces, temples and tombs. The water-supply is brought from a lake 9 m. distant. It has a high school, affiliated to the Allahabad university; and a school for the sons of nobles, founded to commemorate the Diamond Jubilee of Queen Victoria. The Lady Dufferin hospital is under the charge of an English lady doctor, with two female assistants.
ELYATTES—AMADÍS DE GAULA

ELYATTES, king of Lydia (609–550 B.C.), the real founder of the Lydian empire, was the son of Sadyattes, of the house of the Myrmidones. For several years he continued the war against Milletus begun by his father, but was obliged to turn his attention to the Medes and Babylonians. On the 28th of May 555, during a battle on the Halys between him and Cyaxares, kings of Media, an eclipse of the sun took place; hostilities were suspended, peace concluded, and the Halys fixed as the boundary between the two kingdoms. Alyattes drove the Cimmerii (see Scythia) from Asia, subdued the Carians, and took several Ionian cities (Smyrna, Colophon). He was succeeded by his son Croesus. His tomb still exists on the plateau between lake Gygaea and the river Hermus to the north of Sardis—a large mound of earth with a substructure of huge stones. It was excavated by Spiegelthaler in 1854, who found that it covered a large vault of flat-cut marble blocks approached by a flat-roofed passage of the same stone from the south. The sarcophagus and its contents had been removed by early plunderers of the tomb, all that was left being some broken alabaster vases, pottery and charcoal. On the summit of the mound were large phalli of stone.

ELYPIUS, a Greek writer on music whose works, with those of six others, were collected and published with a commentary and explanatory notes (Antiquae Musicae Autores Sopiem, Amstel., 1652), by Mark Melchomius (1650–1711). He is said to have written a treatise Before Euclid and Ptolemy, and a novel on Cassander, which precedes his Introduction to Music between those of Nicomachus and Gaudentius. The work consists solely of a list of symbols of the various scales and modes, and is probably only a fragment.

ELYPIUS OF ANTIOCH, a geographer of the 4th century, who was sent by the emperor Julian into Britain as first prefect, and was afterwards commissioned to rebuild the temple of Jerusalem. Among the letters of Julian are two (29 and 30) addressed to Alypius; one inviting him to Rome, the other thanking him for a geographical treatise, which no longer exists.

See also Ammianus Marcellinus, xxi, 2, 2.

ELYTES, the midwife toad, first discovered by P. Demours in 1741, on the border of a small pond in the Jardin des Plantes, in the very act of parturition which has rendered it famous, and described as Petit crapaud mâle accoucheur de sa femelle, Alytes obstetricans is of special interest as the first known example of paternal solicitude in Batrachians, and although many no less wonderful cases of nursing instinct have since been revealed to us, it remains the only one among European forms.

Alytes obstetricans is a small toad-like Batrachian, two inches in length, of dull greyish coloration, plum form with warty skin and large eyes with vertical pupils. Although toad-like it is not really related to the toads proper, but belongs to the family Discoglossidae, characterized by a circular, adherent tongue, teeth in the upper jaw and on the palate, short but distinct ribs on the anterior vertebrae, and convex-concave vertebrae. It inhabits France, Belgium, Switzerland, Western Germany (eastwards to the Weser), Spain and Portugal. A second species, Alytes cisternasii, occurs in Spain and Portugal.

Alytes is nocturnal and slow in its movements. It is thoroughly terrestrial, selecting for its retreat in the daytime holes made by small mammals, or interstices between stones. Towards evening it reveals its presence by a clear whistling note, which has often been compared to the sound of a little bell, or to a chime when produced by numerous individuals. The breeding season lasts throughout spring and summer, and the female is able to spawn two, three or even four times in the year. Pairing and oviposition take place on land; the male seize the female round the waist. The eggs are laid one by one among European forms, strings of many eggs, as if strung together by elastic filaments continuous with the gelatinous capsules. After impregnation, the male twists them round his legs and returns to his usual retreat, going about at night in order to feed himself and to keep up the moisture of the eggs, even resorting to a short immersion in the water during exceptionally dry nights. The development of the embryo within the egg takes about three weeks. 'When the time for

eclosion has come, the male enters the water with his burden; the larvae, in the full tadpole condition, measuring 14 to 17 millimetres, bite their way through their tough envelope, which is not abandoned by the father until all the young are liberated, and complete in the ordinary way their metamorphosis. The tadpoles grow to a large size considering that of the adult, the body equalling in size a sparrow's or even a small pigeon's egg, and they often remain more than a year in that condition.

ALZEY, a town of Germany, in the grand duchy of Hesse-Darmstadt, 18 m. S. of Mainz by rail. Pop. (1900) 6893. There are a Roman Catholic and two Protestant churches, several high grade schools and a teachers' seminary. Alzey has industries of dyeing and weaving, breweries, and does a considerable trade in wine. It is immortalized in the "Nibelungenlied" in the person of "Volker von Alzoe," the warrior who in the last part of the epic plays a part second only to that of Hagen, and who "was called the minstrel (spiltron) because he could fiddle." It became an Imperial city in 1277. In 1620 it was sacked by the Spaniards and French, and again burned by the French. Alzoe became a Roman Catholic priest during the Napoleonic wars, it passed in 1815 to the grand-duchy of Hesse-Darmstadt.

ALZOG, JOHANNE BAPTIST (1808–1878), German theologian, was born at Oihau, in Silesia, on the 29th of June 1808. He studied at Breslau and Bonn and was ordained priest at Cologne in 1834. In the following year he accepted the chairs of exegesis and church history at the seminary of Posen. He removed in 1844 to Hildesheim, where he had been appointed rector of the seminary. He became professor of church history at the university of Freiburg in the Breisgau in 1853 and held that post till his death on the 1st of March 1878. Together with Düllinger, Alzog was instrumental in convoking the famous Munich assembly of Catholic scholars in 1863. He also took part, with Bishops Hefele and Haseberg, in the preparatory work of the Vatican Council and voted in favour of the doctrine of papal infallibility but against the opportuneness of its promulgation. Alzog's fame rests mainly on his Handbuch der Universal-Kirchengeschichte (Mainz, 1841, often reprinted under various titles; Eng. trans. by Pabish and Byrne, A Manual of Church History, 4 vols, Cincinnati, 1874). Based upon the foundations laid by Möhler, this manual was generally accepted as the best exposition of Catholic views, in opposition to the Protestant manual by C. A. Hase, and was translated into several languages. Besides a host of minor writings on ecclesiastical subjects, and an active collaboration in the great Kirchenlexicon of Wetzer and Welte, Alzog was also the author of Grundriss der Patrologie (Freiburg, 1866, 4th ed. 1888), a scholarly work, though now superseded by that of O. Bardenhewer.

A full list of Alzog's writings is given in H. Hurter's Nomenclator litterarius recentioris theologae catholicae, vol. iii. For an account of his life see the funeral oration by F. X. Kraus, entitled: Gedächtnissrede auf Johannes Alzog (Freiburg, 1879).

AMADÍS DE GAULA. This famous romance of chivalry survives only in a Castilian text, but it is claimed by Portugal as well as by Spain. The date of its composition, the name of its author, and the language in which it was originally written are not yet settled. It is not even certain when the romance was first printed, for though the oldest known edition (a unique copy of which is in the British Museum) appeared at Saragosse in 1508, it is highly probable that Amadis was in print before this date: an edition is reported to have been issued at Seville in 1496. As it exists in Spanish, Amadís de Gaula consists of four books, the last of which is generally believed to be by the regidor de Medina del Campo, Garcí Rodríguez de Montalvo, whose name is given as the author in all editions of Amadís later than that of 1508, and as García Gutierrez de Montalvo in some editions of the Sergas de Esplandían. Montalvo alleges that the first three books were arranged and corrected by him from "the ancient originals," and a reference in the prologue to the siege of Granada points to the conclusion that the Spanish recast was made shortly after 1492; it is
possible, however, that the prologue alone was written after 1492, and that the text itself is older. The number of these “ancient originals” is not stated, nor is there any mention of the language in which they were composed; Montalvo's silence on the latter point might be taken to imply that they were in Castilian, but any such inference would be hazardous. Three books of *Amadís de Gaula* are mentioned by Pero Ferrás who was living in 1379, and there is evidence that the romance was current in Castile more than a quarter of a century earlier; but again there is no information as to the language in which they were written. Gomes Eannes de Azurara, in his *Chronica de D. Pedro de Menezes* (c. 1450), states that *Amadís de Gaula* was written by Vasco de Lobeira in the time of King Ferdinand of Portugal who died in 1383; as Vasco de Lobeira was knighted in 1385, it would follow that he wrote the elaborate romance in his earliest youth. This conclusion is untenable, and the suggestion that the author was Pedro de Lobeira (who flourished in the 15th century) involves a glaring anachronism. A further step was taken by the historian João de Barros, who maintained in an unpublished work dating between 1540 and 1550 that Vasco de Lobeira wrote *Amadís de Gaula* in Portuguese, and that his text was translated into Castilian; this is unsupported assertion. Towards the end of the 16th century Miguel Leite Ferreira, son of the Portuguese poet, Antonio Ferreira, declared that the original manuscript of *Amadís de Gaula* was then in the Archivo provincial de Asturias; and Lobo, *Amadís de Gaula* in Portuguese, which is alleged to have existed in the *Conde de Vimeiro’s library* as late as 1586, had vanished before 1756. In the absence of corroboration, these dubious details must be received with extreme reserve. A stronger argument in favour of the Portuguese case is drawn from the existing Spanish text. In *book I*, chapters 40 and 41, it is recorded that the Infante Alphonso of Portugal suggested a radical change in the narrative of Briolanja’s relations with Amadis. This prince has been identified as the Infante Alphonso who died in 1324, or as one who ruled the islands of Madeira and the Azores in 1326. Were either of these identifications established, the date of composition might be referred with certainty to the beginning of the 14th century or the end of the 13th. But both identifications are conjectural. Nevertheless the passage in the Spanish text undeniably lends some support to the Portuguese claim, and recent critics have inclined to the belief that *Amadís de Gaula* was written by João de Lobeira, a Galician knight who frequented the Portuguese court between 1258 and 1265, and to whom are ascribed two fragments of a poem in the *Colloqui Brancuti Compendium* (Nos. 240 and 242), which reappears with some unimportant variants in *Amadís de Gaula* (book II, chapter 13). The coincidence may be held to account in some measure for the traditional association of a Lobeira with the authorship of *Amadís de Gaula*; but, though curious, it warrants no definite conclusion being drawn from it. Against the Portuguese claim it is argued that the *Villancico* corresponding to João de Lobeira’s poem is an interpolation in the Spanish text, that Portuguese prose was in a rudimentary stage of development at the period when—*ex hypothesi*—the romance was composed, and that the book was very popular in Spain almost a century before it is even mentioned in Portugal. Lastly, there is the incontrovertible fact that *Amadís de Gaula* exists in Castilian, while it remains to be proved that it ever existed in Portuguese. As to its substance, it is beyond dispute that much of the text derives from the French romances of the Round Table; but the evidence does not enable us to say (1) whether it was pieced together from various French romances; (2) whether it was more or less literally translated from a lost French original; or (3) whether the first Peninsula adapter or translator was a Castilian or a Portuguese. On these points judgment must be suspended. There remains, however, with some hesitation in accepting Cervantes’ verdict on *Amadís de Gaula* of the “best of all the books of this kind that have ever been written.” It is the prose epic of feudalism, and its romantic spirit, its high ideals, its fantastic gallantry, its ingenious adventures, its mechanism of symbolic wonders, and its flowing style have entranced readers of such various types as Francis I. and Charles V., Ariosto and Montaigne.

**AMADOU,** a soft tough substance used as tinder, derived from *Polyergus* *fomentarius*, a fungus belonging to the group Basidiomycetes and somewhat resembling a mushroom in manner of growth. It grows upon old trees, especially the oak, ash, or elm. The fungus is cut into slices and then steeped in a solution of nitrate. Amadou is prepared on the continent of Europe, chiefly in Germany, but the fungus is a native of Britain. *Polyergus igniarius* and other species are also used, but yield an inferior product.

**AMAKUSA,** an island belonging to Japan, 26 1/2°. long and 13 1/2°. in extreme width, situated about 32°. 20' N., and 130°. E. long, on the west of the province of Higo (island of Klushiu), from which it is separated by the Yatsushiro-kai. It has no high mountains, but its surface being very hilly—four of the peaks rising to a height over 500 ft.—the natives resort to the terrace system of cultivation with remarkable success. A number of the heads of the Christians executed in connexion with the Shimabara rebellion in the first half of the 17th century were buried on this island. Amakusa produces a little coal and fine kaolin, which was largely used in former times by the potters of Hirado and Satsuma.

**AMAL,** the name of the noblest family among the Ostrogoths, and that from which nearly all their kings were chosen.

**AMALARIO** (d. 531), king of the Visigoths, son of Alaric II., was chanced upon when his father fell in battle against Clovis, king of the Franks (507). He married Clothilda, daughter of Clovis; but his disputes with her, he being an Arian and she a Catholic, brought on him the death of his wife. Alaric II. was killed in a Franks’ invasion, in which he lost his life in 534.

**AMALASUNTHA** (d. 533), daughter of Theoderic, king of the Ostrogoths, was married in 525 to Eucharic, an Ostrogoth of the old Amal line, who had previously been living in Spain. Her husband died, apparently in the early years of her marriage, leaving her with two children, Athalaric and Matasuntha. On the death of her father in 526, she succeeded him, acting as regent for her son, but being herself deeply imbued with the old Roman culture, she gave to that son’s education a more refined and literary turn than suited the ideas of her Gothic subjects. Conscious of her unpopularity she banished, and afterwards put to death, three Gothic nobles whom she suspected of intriguing against her rule, and at the same time opened negotiations with the emperor Justinian with the view of removing herself and the Gothic treasure to Constantinople. Her son’s death in 534 made but little change in the posture of affairs. Amalasuntha, now queen, with a view of strengthening her position, made her cousin Theodahad partner of her throne (not, as sometimes stated, her husband, for his wife was still living). The choice was unfortunate. Theodahad, notwithstanding avarish of literary culture, was a coward and a scoundrel. He fostered the disaffection of the Goths, and either by his orders or with his permission, Amalasuntha was imprisoned on an island in the Tuscan lake of Bolsena, where in the spring of 535 she was murdered in her bath.

The letters of Cassiodorus, chief minister and literary adviser of Amalasuntha, and the histories of Procopius and Jordanes, give us our chief information as to the character of Amalasuntha.
AMALEKITES—AMALRIC

AMALEKITES, an ancient tribe, or collection of tribes, in the south and south-east of Palestine, often mentioned in the Old Testament as foes of the Israelites. They were regarded as a branch of the Edomites (Gen. xxxvi. 12, see EDOM), and appear to have numbered among their divisions the Kenites. When the Israelites were journeying from Egypt to the land of Canaan, the Amalekites are said to have taken advantage of their weak condition to harry the stragglers in the rear, and as a judgment for their hostility it was ordained that their memory should be blotted out from under heaven (Deut. xxv. 17-19).

An allusion to this appears in the account of Israel's defeat on the occasion of the attempt to force a passage from Kadesh through Horamath, evidently into Palestine (Num. xiv. 43-45. cp. Deut. i. 44-46). The statements are obscure, and elsewhere Horamath is the scene of a victory over the Canaanites by Israel (Num. xxi. 1-3), or by the tribes Judah and Simeon (Judg. i. 17). The question is further complicated by the account of Joshua's overthrow of Amalek appearing in 1 Sam. xxxi. 2-4. The event was commemorated by the erection of the altar "Yahweh-nissi" ("Yahweh my banner" or "memorial"), and rendered even more memorable by the utterance, "Yahweh hath sworn: Yahweh will have war with Amalek from generation to generation" (Ex. xviii. 8-16, on its present position, see Exodus [Book]). The same sentiment recurs in Yahweh's command to Saul to destroy Amalek utterly for its hostility to Israel (1 Sam. xvi.), and in David's retaliatory expedition when he distributed among his friends the spoil of the "enemies of Yahweh" (xxx. 26). Saul himself, according to one tradition, was slain by an Amalekite (1 Sam. xiv. 24, see xxv. 4), and a similar spirit appears among the prophecies ascribed to Balaam: "Amalek, first (or chief) of nations, his latter end will be destruction" (Num. xxiv. 20).

The district of Amalek lay to the south of Judah (cp. 1 Chron. iv. 42 seq.), probably between Kadesh and Horamath (cp. Gen. xiv. 7; 1 Sam. xv. 7, xvii. 8), and the interchange of the ethnic with "Canaanites" and "Amorites" suggests that the Amalekites are merely one of Israel's traditional enemies of the older period. Hence we find them taking part with Ammonites and Midianites (Judg. iii. 13, vi. 3), and their king Agag slain by Samuel as a sacrificial offering (1 Sam. xv. 9), was by a byword for old-time might and power (Num. xxiv. 7). Even in one of the Psalms (lxxxxiii. 7) Amalek is mentioned among the enemies of Israel—just as Greek writers of the 6th century of this era applied the old term Scythians to the Goths (Nóldëke)—and the traditional hostility between Saul and Amalek is reflected still later in the book of Esther where Haman the Agagite is pitied against Mordecai the Benjamite.

Twice Amalek seems to be mentioned as occupying central Palestine (Judg. v. 14, xii. 15), but these passages are not certain. The name is celebrated in Arabian tradition, but the statements regarding them are confused and conflicting, and for historical purposes are practically worthless, as has been proved by Th. Nòldeke (Ueber die Amalékiten, Göttingen, 1864). On the biblical data, see also E. Meyer, Die Israeliten (Index, i.e.).

AMALFI, a town and archiepiscopal see of Campania, Italy, in the province of Salerno, from the town of which name it is distant 12 m. W.S.W. by road, on the N. coast of the Gulf of Salerno. Pop. (1901) 6681. It lies at the mouth of a deep ravine, in a sheltered situation, at the foot of Monte Corrato (4314 ft.), in the centre of splendid coast scenery, and is in consequence much visited by foreigners. The cathedral of S. Andrea is a structure in the Lombard-Norman style, of the 11th century; the façade in black and white stone was well restored in 1801; the bronze doors were executed at Constantinople before 1066. The campanile dates from 1270. The interior is also fine, and contains ancient columns and sarcophagi. The conspicuous Capuchin monastery on the W., with fine cloisters (partly destroyed by a landslip in 1896) is now used as an hotel. Amalfi is first mentioned in the 6th century, and soon acquired importance as a naval power; to the 9th century it was allied with Venice and Gaeta the Italian trade with the East, and in 848 its fleet went to the assistance of Pope Leo IV, against the Saracens.

It was then an independent republic with a population of some 70,000, but in 1131 it was reduced by King Roger of Sicily. In 1135 and 1137 it was taken by the Pisans, and rapidly declined in importance, though its maritime code, known as the Tavole Amalfitane, was recognized in the Mediterranean until 1576. In 1345 a large part of the town was destroyed by an inundation, and its harbour is now of little importance. Its industries too, have largely disappeared, and the paper manufacture has lost ground since 1861.

AMALGAM, the name applied to alloys which contain mercury. It is said by Andreas Libavius to be a corruption of málalge; in the alchemists the form algamola is also found. Many amalgams are formed by the direct contact of a metal with mercury, sometimes with absorption, sometimes with evolution, of heat. Other methods are to place the metal and mercury together in dilute acid, to add mercury to the solution of a metallic salt, to place a metal in a solution of mercuric nitrate, and to electrolyse a metallic salt using mercury as the negative electrode. Some amalgams are liquids, especially when containing a large proportion of mercury; others assume a crystalline form. In some cases definite compounds have been isolated from amalgams which may be regarded as mixtures of one or more of such compounds with mercury in excess. In general these compounds are decomposable by heat, but some of them, such as those of gold, silver, copper and the alkali metals, even when heated above the boiling point of mercury retain mercury and leave residues of definite composition. Tin amalgam is used for "silvering" mirrors, gold and silver amalgam in gilding and silversmithing. The name was given to mercuric compounds, such as an amalgam of zinc and tin for the rubbers of electrical machines; the zinc plates of electric batteries are amalgamated in order to reduce polarization.

AMALRIC, the name of two kings of Jerusalem.

Amalric I, king from 1162 to 1174, was the son of Fulc of Jerusalem, and the brother of Baldwin III. He was twice married: by his first wife, Agnes of Edessa, he had issue a son and a daughter, Baldwin IV. and Sibylly, while his second wife, Maria Commena, bore him a daughter Isabella, who ultimately married the Lusignan prince, crusading ally of the Hospitallers. When Isabella was replaced by his third wife, the throne was disputed by his sons. One was succeeded by his brother Amalric II, the other by his son Baldwin IV. with the aid of the Hospitallers (1174 to 1183).

Amalric II, king from 1183 to 1191, was the son of Fulc of Jerusalem, and the brother of Baldwin III. He was twice married: by his first wife, Agnes of Edessa, he had issue a son and a daughter, Baldwin IV. and Sibylly, while his second wife, Maria Commena, bore him a daughter Isabella, who ultimately married the Lusignan prince, crusading ally of the Hospitallers. When Isabella was replaced by his third wife, the throne was disputed by his sons. One was succeeded by his brother Amalric II, the other by his son Baldwin IV. with the aid of the Hospitallers (1174 to 1183).

Amalric II, king from 1183 to 1191, was the son of Fulc of Jerusalem, and the brother of Baldwin III. He was twice married: by his first wife, Agnes of Edessa, he had issue a son and a daughter, Baldwin IV. and Sibylly, while his second wife, Maria Commena, bore him a daughter Isabella, who ultimately married the Lusignan prince, crusading ally of the Hospitallers. When Isabella was replaced by his third wife, the throne was disputed by his sons. One was succeeded by his brother Amalric II, the other by his son Baldwin IV. with the aid of the Hospitallers (1174 to 1183).
AMALRIC—AMANA

he who set William of Tyre to work. He was perhaps still more of a lawyer: his delight was in knotty points of the law, and he knew the Assises better than any of his subjects. The Church had some doubts of him, and he laid his hands on the Church. William of Tyre was once astonished to find him questioning, on a bed of sickness, the resurrection of the body; and his taxation of clerical goods gave umbrage to the clergy generally. But he maintained the independence of his kingdom with the resources which he owed to the Church; and he is the last in the fine list of the early kings of Jerusalem.

William of Tyre is our original authority: see xix. 2-3 for his sketch of Amalric. Röhrich narrates the reign of Amalric I., Geschichte des Königreichs Jerusalem, c. xvii—xviii.

Amalric II., king from 1197 to 1205, was the brother of Guy of Lusignan. He had been constable of Jerusalem, but in 1194, on the death of his brother, he became king of Cyprus, as Amalric I. He married Isabella, the daughter of Amalric I. by his second marriage, and became king of Jerusalem in right of his wife in 1197. In 1198 he was able to procure a five years’ truce with the Mahomedans, owing to the struggle between Saladin’s brothers and his sons for the inheritance of his territories. The truce was disturbed by raids on both sides, but in 1204 it was renewed for six years. Amalric died in 1205, just after his son and just before his wife. The kingdom of Cyprus passed to Hugh, his son by an earlier marriage, while that of Jerusalem passed to Maria, the daughter of Isabella by her previous marriage with Conrad of Montferrat. (E. BR.)

AMALRIC (Fr. AMANUI) OF BENA (d. c. 1204—1207), French theologian, was born in the latter part of the 12th century at Bena, a village in the diocese of Chartres. He taught philosophy and theology at the university of Paris and enjoyed a great reputation as a subtle dialectician; his lectures developing the philosophy of Aristotle attracted a large circle of hearers. In 1204 his doctrines were condemned by the university, and, on a personal appeal to Pope Innocent III., the sentence was ratified, Amalric being ordered to return to Paris and recant his errors. His death was caused, it is said, by grief at the humiliation to which he had been subjected. In 1209 ten of his followers were burnt before the gates of Paris, and Amalric’s own body was exhumed and burnt and the ashes given to the winds. The doctrines of his followers, known as the Amalricians, were formally condemned by the fourth Lateran Council in 1215. Amalric appears to have derived his philosophical system from Eriquena (q.v.), whose principles he developed in a one-sided and strongly pantheistic form. Three propositions only can with certainty be attributed to him: (1) that God is all; (2) that every Christian is bound to believe that he is a member of the body of Christ, and that this belief is necessary for salvation; (3) that the love of God can commit no sin. These three propositions were further developed by his followers, who maintained that God revealed Himself in a threefold revelation, the first in Abraham, marking the epoch of the Father; the second in Christ, who began the epoch of the Son; and the third in Amalric and his disciples, who inaugurated the era of the Holy Ghost. Under a true belief everyone could commit no sin, the Amalricians indulged in every excess, and the sect does not appear to have long survived the death of its founder.

AMALTEO, the name of an Italian family belonging to Oderzo, Treviso, several members of which were distinguished in literature. The best known are three brothers, Geronimo (1507—1574), Giambattista (1524—1573) and Cornelio (1530—1603), whose Latin poems were published in one collection under the title Trism Fratrum Amaltheorum Carmina (Venice, 1627; Amst., 1689). The eldest brother, the poet, was a celebrated physician; the second, Giambattista, accompanied a Venetian embassy to England in 1554, and was secretary to Pius IV. at the council of Trent; the third, Cornelio, was a physician and secretary to the republic of Ragusa.

AMALTEO, POMPONIO (1505—1584), Italian painter of the Venetian school, was born at San Vito in Friuli. He was a pupil and son-in-law of Pordenone, whose style he closely imitated. His works consist chiefly of frescoes and altar-pieces and many of them (e.g. in the church of Santa Maria de’ Battisti, at San Vito) have suffered greatly from the ravages of time.

AMALTHEA, in Greek mythology, the foster-mother of Zeus. She is sometimes represented as the goat which suckled the infant-god in a cave in Crete, sometimes as a nymph of uncertain parentage (daughter of Oceanus, Haemonius, Olen, Melisseus), who brought him up on the milk of a goat. This goat having broken off one of her horns, Amalthea filled it with flowers and fruits and presented it to Zeus, who placed it together with the goat amongst the stars. According to another story, Zeus himself broke off the horn and gave it to Amalthea, promising that it would supply whatever she desired in abundance. Amalthea gave it to Achelous (her reputed brother), who exchanged it for his own horn which had been broken off in his contest with Hercules for the possession of Delaines. Appearing to an ancient mythology, the owners of the horn were many and various. Speaking generally, it was regarded as the symbol of inexhaustible riches and plenty, and became the attribute of various divinities (Hades, Gaea, Demeter, Cybele, Hermes), and of rivers (the Nile) as fertilizers of the land. The term “horn of Amalthea” is applied to a fertile district, and an estate belonging to Titus Pomponius Atticus was called Amaltheum. Cretan coins represent the infant Zeus being suckled by the goat; other Greek coins exhibit him suspended from its teats or carried in the arms of a nymph or a goat on which he is seated.
