Contrasting the German system with the French and English, we may observe that it is German tactics as a whole that impose a method of using machine-guns which the Germans themselves recognize as being in many respects disadvantageous. A German force in action possesses little depth, i.e. reserves, except on the flanks where the enveloping attack is intended to be made. Consequently, a German commander needs a reserve of fire in a mechanical, concentrated form more than a British or a French commander, and, further, as regards the decisive attack on the flanks, it is intended not merely to be sudden but even more to be powerful and overwhelming. These considerations tend to impose both the massing and the holding in reserve of machine-guns. The French and British doctrine (see Tactics) is fundamentally different. Here, whether the guns be massed or not, there is rarely any question of using the machine-guns as a special reserve. In the decisive attack, and especially at the culmination of the decisive attack, when concealment has ceased and power is everything, the machine-guns can render the greatest services when grouped and boldly handled. Above all, they must reach the captured crest in a few minutes, so as to crush the inevitable offensive return of the enemy's reserves. The decisive attack, moreover, is not a prearranged affair, as in Germany; but the culmination, "at a selected point, of gradually increasing pressure relentlessly applied to the enemy at all points" (F. S. Regulations). The holding attack, as this "pressure" is called, is not a mere feint. It is launched and developed as a decisive attack, though not completed as such, as it lacks the necessary reserve strength. Here, then, the machine-

The use of single guns facilitates concealment, but this is outweighed by the objection that when a jam or other breakdown occurs the fire ceases altogether. The use of guns in pairs not only speeds up the fire, but also speeds up the reloading, and the ammunition, to cool down, &c. This is the old artillery principle—"one gun is no gun.

The instructions issued in August 1909 one of the principal advantages of grouped sections is stated to be the neutralization of ranging errors at ranges over 1000 yards. At a less range, it is laid down, grouped guns form too visible a target, unless the ground is very favourable.
gun is best employed in enabling relatively small forces to advance—not to assault—without undue loss, that is, in economizing rifles along the non-defensive front.

Withal, there are certain principles, or rather details of principle, that find general acceptance. One of these is the employment of machine-guns with the advanced guard. In this case the value of the weapon lies in enabling the advanced guard to take the more favourable ground and points of support without undue effort and to hold the positions gained against the enemy’s counter-attack. This applies, further, to the preliminary stages of an action. Another point is that as a rule the most favourable range for the machine-gun is “effective infantry,” i.e. 600-1400 yards (which is, mutatis mutandis, the principle of Keffey’s mitrailleuse). Its employment at close infantry range depends entirely on conditions of ground and circumstances—even supposing that the handiest and most inconspicuous type of weapon is employed. Thirdly—and this has a considerable bearing on the other points—the machine-gun both concentrates many rifles on a narrow front, and concentrates the bullets of many rifles on a narrow front. The first clause implies that it can be used where there is no room (physically or tactically) for the fifty or eighty rifles it represents (as, for instance, in some slight patch of cover whence the gun can give effective cross-fire in support of the infantry attack, or in front of an advanced post, or can watch an exposed flank), and, further, that it can be swung round laterally on to a fresh target faster than a facaily-drawn line of infantry can be made to change front. The second means that the exit of a defile, an exposed turn in a lane or on a bridge, can be beaten by closely grouped fire at greater distances and with greater accuracy than is attainable with rifles.

Further, the waste of ammunition and the strain on the weapon caused by unnecessarily prolonged firing at the rate for which its mechanism is set—varying between 350 and 700 rounds a minute—have caused it to be laid down as an axiom in all armies that machine-guns shall deliver their fire by “bursts” rather than continuously.

Lastly, the reports, both of observers and combatants, are unanimous as to the immense moral effect produced on the combatants by the unmistakable drumming sound of the machine-guns, an effect comparable even at certain stages of the fight to the boom of the artillery itself.

Equipments in Use.—Practically all nations have abandoned the simple wheeled carriage for machine-guns, or rather have adopted the tripod or table mounting, reserving the wheeled vehicle for the mobile, light, or experimental equipment. Since the Russo-Japanese War, the tendency has been to sacrifice the slight protection afforded by the shield in order to reduce visibility. The Japanese, who had unprotected field guns and protected machine-guns in the war, found it advisable to reverse this procedure, for reasons that can easily be guessed in the cases of both weapons.

Great Britain.—The service machine-gun is the Maxim 303 in., adjusted to a rate of 450 rounds per minute and sighted (except in a few weapons) to 2900 yards. The original patterns weighed 60 lb, and were mounted on wheeled carriages. In the latest pattern, however, the weight of the gun has been reduced to 36 lb. The old Mark I, cavalry Maxim carriage, complete with gun, ammunition, &c., weighed 13 cwt. behind the traces, and the gun was 3½ ft. above the ground. It had no limber. The Mark II, cavalry carriage, can be mounted on a wheeled carriage, and together weigh only 13 cwt. Of infantry carriages there were various marks, one of which is shown in fig. 6. Now, however, all mountings for infantry are of the tripod type; transport is on pack animals or on pack animals, but entirely detachable from the travelling mounting, and in action practically never used except on the tripod. The Mark IV, tripod mounting, of which a sketch is given in fig. 21, weighs 48 lb. The total weight of the fighting equipment is thus 84 lb only—an important consideration in view of the action that the weapon is required to carry. The gun can be adjusted to fire at heights varying from 2' 6" to 1' 4½" only from the ground; in its lowest position, then, it is a little lower than the head of a man firing lying. All the later infantry machine-gun equipments are for pack transport and pack animals.

The organization of the machine-gun arm is regimental. Each cavalry regiment and each infantry battalion has a section of 2 guns under command.

France.—The guns in use are the Puteaux and the Hotchkiss. The unit is the regimental 2-gun section. Four-horse carriages with limbers are used with cavalry, tripods with the infantry section of the Hotchkiss. The Hotchkiss is a 7 lb. gun, the tripod, 70 lb. The Puteaux was lightened and improved in 1909.

Germany.—As already mentioned the German machine-gun units are classed as cavalry “detachments” and infantry “companies.” The “detachment” or battery consists of 6 guns and 4 wagons, the vehicles being of a light artillery pattern and drawn by four horses. The gun (Maxim) weighs 61 lb, and its fighting carriage 110 lb. The 8 companies have also 6 guns and 4 wagons, but the equipment is lighter (two-horse), and is not constructed on artillery principles, nor are the guns fired from their carriages as are those of the Puteaux. The Hotchkiss is a 7 lb. gun, carried in the fighting carriage 75 (some accounts give 53 for the latter), the difference between these weights and those of the mounted equipment being a good indication of the excessive requirements of the cavalry and of the infantry types of gun. The fighting carriage is a sort of sledge, which is provided with four legs for fire in the highest position, but can of course be placed on the ground. In the case of the Maxim, the length of the tripod is 1' 6". The sledge can be dragged across country or carried by men. The wheels are fixed and sometimes several sledges are coupled and drawn by a horse.

Japan.—The Japanese Hotchkiss, as modified since the war with Russia, is said to weigh 70 lb, and its tripod mounting 40. Each regiment of infantry has a six-gun battery and each cavalry brigade one of eight guns. Pack transport is used.

Russia.—Since the war eight-gun companies have been formed in the infantry regiments, and each cavalry regiment has been provided with two guns. The war organization is, however, unchanged; two wheels and pack transport are employed for travelling, but the guns are fought from tripods. Early and somewhat heavy patterns of Maxim (with shield) are chiefly used, but a great number of very light guns of the Madsen type have been issued.

The Austrian gun is the Schwarzlose, of which some details are given above. Pack transport is used, one mule taking the whole equipment with 1000 rounds. Weight of the gun 37·9 lb, of the tripod 41 lb. The height of the tripod can be varied from 94 in. to 2½ ft, above the ground. It is proposed that each cavalry regiment should have four guns, and each infantry regiment two. Switzerland adopted the Maxim and the Puteaux gun, and has used the latter for horse artillery.

Denmark and other small states have adopted the Madsen or Roler light-type guns in relatively large numbers, especially for cavalry. In the United States the British organization was adopted for many trials, but at the end of the war, the Madsen type has a two-gun section of Maxims, with tripod mounting and pack transport.

in Spain, he inspired Larra (q.v.) in the play Macías and in the historical novel entitled El doncel de Don Enrique el doliente.

MACKINTOSH, CHARLES (1766-1843), Scottish chemist and inventor of waterproof fabrics, was born on the 20th of December 1766 at Glasgow, where he was first employed as a clerk. He devoted all his spare time to science, particularly chemistry, and before he was twenty resigned his clerkship to take up the manufacture of chemicals. In this he was highly successful, inventing various new processes. His experiments with one of the by-products of tar, naphtha, led to his invention of waterproof fabrics, the essence of his patent being the cementing of two thicknesses of India-rubber together, the India-rubber being made soluble by the action of the naphtha.

For his various chemical discoveries he was, in 1823, elected F.R.S. He died on the 25th of July 1843.

See George Macintosh, Memoir of C. Macintosh (1847).

MACKAY, CHARLES (1814-1889), Scottish writer, was born at Perth, on the 27th of March 1814, and educated at the Caledonian Asylum, London, and in Brussels. In 1830, being then private secretary to a Belgian ironmaster, he began writing verses and articles for local newspapers. Returning to London, he devoted himself to literary and journalistic work, and was attached to the Morning Chronicle (1835-1844). He published Memoirs of Extraordinary Public Delusions (1841), and gradually made himself known as an industrious and prolific journalist. In 1844 he was made editor of the Glasgow Argus. His literary reputation was made by the publication in 1846 of a volume of verses, Voices from the Crowd, some of which were set to music by Henry Russell and became very popular.

In 1848 Mackay returned to London and worked for the Illustrated London News, of which he became editor in 1852. In it he published a number of songs, set to music by Sir Henry Bishop and Henry Russell, and in 1853 they were collected in a volume; they included the popular "Cheers, Boys! Cheers!" After his severance from the Illustrated London News, in 1859, Mackay started two unsuccessful periodicals, and acted as special correspondent for The Times in America during the Civil War. He edited A Thousand and One Gems of English Poetry (1861). Mackay died in London on the 24th of December 1889. Marie Corelli (q.v.) was his adopted daughter. His son, Eric Mackay (1851-1899), was known as a writer of verse, particularly by his Love Letters of a Violinist (1886).

MACKAY, HUGH (c. 1659-1692), Scottish general, was the son of Hugh Mackay of Scourie, Sutherlandshire, and was born there about 1640. He entered Douglas's (Dumbarton's) regiment of the English army (now the Royal Scots) in 1660, accompanied it to France when it was lent by Charles II. to Louis XIV., and though succeeding, through the death of his two elder brothers, to his father's estates, continued to serve abroad. In 1669 he was in the Venetian service at Candia, and in 1672 he was back with his old regiment, Dumbarton's, in the French army, taking part under Turenne in the invasion of Holland. In 1673 he married Clara de Bie of Bommel in Gelderland. Through her influence he became, as Burnet says, "the most pious man that I ever knew in a military way," and, convinced that he was fighting in an unjust cause, resigned his commission to take a captaincy in a Scottish regiment in the Dutch service. He had risen to the rank of major-general in 1685, when the Scots brigade was called to England to assist in the suppression of the Monmouth rebellion. Returning to Holland, Mackay was one of those officers who elected to stay with their men when James II., having again demanded the services of the Scots brigade, and having been met with an refusal, was permitted to unite the officers individually into his service. As major-general commanding the brigade and also as a privy councillor of Scotland, Mackay was an important and influential person, and James chose to attribute the decision of most of the officers to Mackay's instigation.

Soon after this event the Prince of Orange started on his expedition to England, Mackay's division leading the invading corps, and in January 1688-89 Mackay was appointed major-general commanding in chief in Scotland. In this capacity he was called upon to deal with the formidable insurrection headed by Graham of Claverhouse, Viscount Dundee. In the battle of Killiecrankie Mackay was severely defeated, but Dundee was killed, and the English commander, displaying unusual personal energy, routed the Highlanders in one summer. In 1690 he founded Fort William at Inverlochy, in 1691 he distinguished himself in the brilliant victory of Aughrim, and in 1692, with the rank of lieutenant-general, he commanded the British division of the allied army in Flanders. At the great battle of Steinkirk Mackay's division bore the brunt of the day unsupported and the general himself was killed.

Mackay was the inventor of the ring bayonet which soon came into general use, the idea of this being suggested to him by the failure of the plug-bayonet to stop the rush of the Highlanders at Killiecrankie. Many of his dispatches and papers were published by the Bannatyne Club in 1833.

See Life by John Mackay of Rockville (1856); and J. W. Fortescue, History of the British Army, vol. i.

MACKAY, JOHN WILLIAM (1831-1902), American capitalist, was born in Dublin, Ireland, on the 28th of November 1831. His parents brought him in 1840 to New York City, where he worked in a ship-yard. In 1851 he went to California and worked in placer gold-mines in Sierra county. In 1852 he went to Virginia City, Nevada, and there, after losing all he had made in California, he formed with James G. Fair, James C. Flood and William S. O'Brien the firm which in 1873 discovered the great Bonanza vein, more than 1200 feet deep, in the Comstock lode (yielding in March of that year as much as $632 per ton, and in 1877 nearly $19,000,000 altogether); and this firm established the Bank of Nevada in San Francisco. In 1884, with James Gordon Bennett, Mackay formed the Commercial Cable Company—largely to fight Jay Gould and the Western Union Telegraph Company—laid two transatlantic cables, and forced the toll-rate for transatlantic messages down to twenty-five cents a word. In connexion with the Commercial Cable Company he formed the Postal Telegraph Company. Mackay died on the 20th of July 1902 in London. He gave generously, especially to the charities of the Roman Catholic Church, and endowed the Roman Catholic orphan asylum in Virginia City, Nevada. In June 1908 a school of mines was presented to the University of Nevada, as a memorial to him, by his widow and his son, Clarence H. Mackay.

MACKAY, a seaport of Carlisle county, Queensland, Australia, on the Pioneer river, 624 m. direct N.N.W. Pop. (1901), 4091. The harbour is not good. Sugar, tobacco and coffee thrive in the district. There are several important sugar mills, one of which, the largest in Queensland, is capable of an annual output of 8000 tons. Rum is distilled, and there are a brewery and a factory for tinning butter for export. Workable coal is found in the district. This is the port of the Mt Orange and Mt Gotthart copper mines, and the Mt Britten and Eungella gold-fields. It is a calling-station for the Queensland royal mail steamers. The town is named after Captain John Mackay, who discovered the harbour in 1860.
States. The total value of the city's factory products was $26,058,447 in 1900 and $23,084,172 in 1905. The municipality owns and operates its water-works. The first white settler was David McKee, who established a ferry here in 1760. In 1795 his son John laid out the town, which was named in his honour, but its growth was very slow until after the discovery of coal in 1830. McKeesport was incorporated as a borough in 1842 and chartered as a city in 1890.

**MCKEES ROCKS,** a borough of Allegheny county, Pennsylvania, U.S.A., on the Ohio river, about 3 m. N.W. of Pittsburgh. Pop. (1890) 1687; (1900) 6352 (1264 foreign-born); (1910) 14,702. McKee's Rocks and the Pittsburgh, Chartiers & Youghiogheny railways, the latter a short line extending (11 m.) to Beechmont. Bituminous coal and natural gas are found in the vicinity, and the borough ships coal and lumber, and has various important manufactures. There is an ancient Indian mound here. The first settlement was made in 1830, and the borough incorporated in 1892.

**MACKENAL, ALEXANDER** (1835-1904), English Nonconformist divine, was born at Truro in Cornwall, on the 14th of January 1835, the son of Patrick Mackenall, a Scot, who had settled in Cornwall. In 1848 the family moved farther south, and in 1854 they went to Glasgow University. In 1854 he entered Mackney College to prepare for the Congregational ministry, and in 1857 he graduated B.A. at London University. After holding pastorate at Burton-on-Trent (1866-1861), Surbiton (1862-1870), Leicester (1870-1876), he finally accepted the pastorate of the Congregational Church at Bowdon, Cheshire, in 1877, in which he remained till his death. In 1886 he was chairman of the Congregational Union, which he represented in 1889 at the triannual national council of the American Congregational churches. The first international council of Congregationalists held in London in 1891 was partly cause, partly consequence, of his visit, and Mackenell acted as secretary. In 1892 he became definitely associated in the public mind with a movement for free church federation which grew out of a series of meetings held to discuss the question of home union. When the Lambeth articles put forward as a basis of union were discussed, it was evident that all the free churches were agreed in accepting the three articles dealing with the Bible, the Creed and the Sacraments as a basis of discussion, and were also agreed in rejecting the fourth article, which put the historic episcopate on the same level as the other three. Omitting the Anglicans, the representatives of the remaining churches resolved to develop Christian fellowship by united action and worship wherever possible. Out of this grew the Free Church Federation, which secures a measure of co-operation between the Protestant Evangelical churches throughout England. Mackenell's public action brought him into association with many well-known political and religious leaders. He was a lifelong advocate of international peace, and made a remarkable declaration as to the Christian standard of national action when the Free Church Federation met at Leeds during the South African War in 1900.

Besides a volume of sermons under the title Christ's Healing Touch, Mackenell published The Biblical Scheme of Nature and of Man, The Christian Testimony, the Letters to the Seven Churches of Asia, The Kingdom of the Lord Jesus and The Eternal God and the Human Soulmate. These are contributions to exegetical study or to theological and progressive religious thought, and have elements of permanent value. He also made some useful contributions to religious history. In 1893 he published the Story of the English Separatists, and later the Homers and Haunts of the Pilgrim Fathers; he also wrote the life of Dr J. A. Macfaden of Manchester. In 1901 he delivered a series of lectures at Hartford Theological Seminary, Connecticut, U.S.A., published under the title The Evolution of Congregationalism. He died at Highgate on the 23rd of June 1904.

**MACKENZIE, SIR ALEXANDER CAMPBELL** (1847- ), British composer, son of an eminent Edinburgh violinist and conductor, was born on the 22nd of August 1847. On the advice of a member of Gungl's band who had taken up his residence in Edinburgh, Mackenzie was sent for his musical education to Sondershausen, where he entered the conservatorium under Ulrich and Stein, remaining there from 1857 to 1861, when he entered the ducal orchestra as a violinist. At this time he made Liszt's acquaintance. On his return home he won the King's Scholarship at the Royal Academy of Music, and remained the usual three years in the institution, after which he established himself as a teacher of the piano, &c., in Edinburgh. He appeared in public as a violinist, taking part in Chappell's quartette concerts, and starting a set of classical concerts. He was appointed preceptor of St George's Church in 1870, and conductor of the Scottish vocal music association in 1873, at the same time getting through a prodigious amount of teaching. He kept in touch with his old friends by playing in the orchestra of the Birmingham Festivals from 1861 to 1873. The most important compositions of this period of Mackenzie's life were the Quartette in E flat for piano and strings, Op. 11, and an
overture, Cervantes, which owed its first performance to the encouragement and help of von Bülow. On the advice of this great pianist, he gave up his Edinburgh appointments, which had quite worn him out, and settled in Florence in order to complete his "The Minotaur; the Triumph, 1780), and then the composition of the internationally famous works, such as "The Bridle" (Worcester, 1881) and "The Triumph" (Bristol, 1882) belong to this time, as well as his first opera. This was commissioned for the Carl Rosa Company, and was written to a version of a Spenserian "Colomba" prepared by Franz Hueur. It was produced with great success in 1883, and was the first of a too short series of modern English operas; Mackenzie's second opera, "The Troubadour", was produced by the same company in 1886; and his third dramatic work was "His Majesty," an excellent comic opera (Savoy Theatre, 1897). In 1884 his "Rose of Sharon" was given with very great success at the Norwich Festival; in 1885 he was appointed conductor of Novello's oratorio concerts; "The Story of Sayid" came out at the Leeds Festival of 1886; and in 1888 he succeeded Macfarren as principal of the Royal Academy of Music. The Dream of Jubbal was produced at Liverpool in 1889, and in London very soon afterwards. A fine setting of the hymn "Ven, Creator Spiritus" was given at Birmingham in 1891, and the oratorio Bethlehem in 1894. From 1892 to 1899 he conducted the Philharmonic Concerts, and was knighted in 1894. Besides the works mentioned he has written incidental music to plays, as, for instance, to Rosenwood, The Little Minister, and Coriolanus; concerts and other works for violin and orchestra, much orchestral music, and many songs and violin pieces. The romantic side of music appeals to Mackenzie far more strongly than any other, and the cases in which he has conform to the classical conventions are of the rarest. In the orchestral ballad, La Belle Dame sans Merci, he touches the note of weird pathos, and in the nautical overture Britannia his sense of humour stands revealed. In the two "Scottish Rhapsodies" for orchestra, in the music to The Little Minister, and in a beautiful fantasia for pianoforte and orchestra on Scottish themes, he has seized the essential, not the accidental features of his native music.

MACKENZIE, SIR GEORGE (1636–1691), of Rosehaugh, Scottish lawyer, was the grandson of Kenneth, first Lord Mackenzie of Kintail, and the nephew of Colin and George, first and second earls of Seaforth; his mother was a daughter of Andrew Bruce, principal of St Leonard's College, St Andrews. He was born at Dundee in 1636, educated at the grammar school there and at Aberdeen, and afterwards at St Andrews, graduating at sixteen. In 1657 he was engaged for a time in the civil law at Bourges; on his return to Scotland he was called to the bar in 1659, and before the Restoration had risen into considerable practice. Immediately after the Restoration he was appointed a "justice-depute," and it is recorded that he and his colleagues in that office were ordained by the parliament in 1661 "to repair, once in the week at least, to Musselburgh and Dalkeith, and to try and judge such persons as are there or thereabouts delate of witchcraft." In the same year he acted as counsel for the marquis of Argyll; soon afterwards he was knighted, and he represented the county of Ross during the four sessions of the parliament which was called in 1660. He succeeded Sir John Nisbet as king's advocate in August 1677, and in the discharge of this office became implicated in all the worst acts of the Scottish administration of Charles II., earning for himself an unenviable distinction as "the bloody Mackenzie." His refusal to concur in the measures for dispensing with the penal laws against Catholics led to his removal from office in 1686, but he was reinstated in February 1688. At the Revolution, being a member of convention, he was one of the minority of five in the division on the forfeiture of the crown. King William was urged to declare him incapacitated for holding any public office, but refused to accede to the proposal. When the death of Dundee (July 1689) had finally destroyed the hopes of his party in Scotland, Mackenzie betook himself to Oxford, where, admitted a student by a grace passed in 1690, he was allowed to spend the rest of his days in the enjoyment of the ample fortune he had acquired, and in the prosecution of his literary labours. One of his last acts before leaving Edin-
Edinburgh society. He was nicknamed the "man of feeling," but he was in reality a hard-headed man of affairs with a kindly heart. Some of his literary reminiscences were embodied in his Four Times... Thoughts and Writings of a Jesuit House, Esq. (1812). He also wrote a Life of Doctor Blacklock, prefixed to the 1793 edition of the poet's works. He died on the 14th of January 1837.

In 1807 The Works of Henry Mackenzie were published surreptitiously, and he then himself superintended the publication of his Works (8 vols., 1808). There is an admiring but discriminating criticism of his work in the Prefatory Memoir prefixed by Sir Walter Scott, to the edition of his novels in Ballantyne's Novelist's Library (vol. v., 1852).

MACKENZIE, SIR JOHN (1838–1901), New Zealand statesman, was born at Ard-Ross, Scotland, in 1838, the son of a crofter. He emigrated to Otago, New Zealand, in 1860. Beginning as a shepherd, he rose to be farm manager at Puketapu near Palmerston South, and then to be a farmer in a substantial way in Shag Valley. In 1865 he was clerk to the local road board and school committee; in 1871 he entered the provincial council of Otago; and on the 11th of December 1881 was elected member for the House of Representatives, in which he sat till 1900. He was also for some years a member of the education board and of the land board of Otago, and always showed interest in the national elementary school system. In the House of Representatives he soon made good his footing, becoming almost at once a recognized spokesman for the smaller sort of rural settlers and a person of influence in the lobbies. He acted as government whip for the coalition ministry of Sir Robert Stout and Sir Julius Vogel, 1884–1887, and, while still a private member, scored his first success as a land reformer by carrying the "Mackenzie clause" in a land act limiting the area which a state tenant might therefor obtain on lease. He was still, however, comparatively unknown outside his own province when, in January 1891, his party took office and he aided John Ballance in forming a ministry, in which he himself held the portfolio of lands, immigration and agriculture. From the first he made his hand felt in every matter connected with land settlement and the administration of the vast public estate. Generally his aim was to break up and subdivide the great freehold and leasehold properties which in his time covered four-sevenths of the occupied land of the colony. In his Land Act of 1892 he consolidated, abolished or amended, fifty land acts and ordinances dealing with crown lands, and thereafter amended his own act four times. The first examination of a landowner over freehold, he never stopped the selling of crown land, and was satisfied to give would-be settlers the option of choosing freehold or leasehold under tempting terms as their form of tenure. As a compromise he introduced the lease in perpetuity or holding for 999 years at a quit rent fixed at 4s.; theoretical objections have since led to its abolition, but for fifteen years much genuine settlement took place under its conditions. Broadly, however, McKenzie's exceptional success as lands minister was due rather to unfailing determination to stimulate the occupation of the soil by working farmers than to the solution of the problems of agrarian controversy. His best-known experiment was in land repurchase. A voluntary law (1892) was displaced by a compulsory act (1894), under which between £5,000,000 and £6,000,000 had by 1910 been spent in buying and subdividing estates for closer settlements, with excellent results. McKenzie also founded and expanded an efficient department of agriculture, in the functions of which inspection, grading, teaching and example are successfully combined. It has aided the development of dairying, fruit-growing, poultry-farming, bee-keeping and flax-milling, and done not a little to keep up the standard of New Zealand products. After 1897 McKenzie had to hold on in the face of failing health. An operation in London in 1899 only postponed the end. He died at his farm on the 6th of August 1901, soon after being called to the legislative council, and receiving a knighthood.

MACKENZIE, SIR MORELL (1837–1892), British physician, son of Stephen Mackenzie, surgeon (d. 1851), was born at Leytonstone, Essex, on the 7th of July 1837. After going through the course at the London Hospital, and becoming M.R.C.S. in 1858, he studied abroad at Paris, Vienna and Pesth; and at Pesth he learned the use of the newly-invented laryngoscope under J. N. Czermak. Returning to London in 1862, he worked at the London Hospital, and took his degree in medicine. In 1863 he won the Jacksonian prize at the Royal College of Surgeons for an essay on the "Pathology of the Larynx," and he then devoted himself to becoming a specialist in diseases of the throat. In 1863 the Throat Hospital in King Street, Golden Square, was founded, largely owing to his initiative, and by his work there and at the London Hospital (where he was one of the physicians from 1866 to 1873) Morell Mackenzie rapidly became recognized throughout Europe as a leading authority, and acquired an extensive practice. So great was his reputation that in May 1887, when the crown prince of Germany (afterwards the emperor Frederick III.) was attacked by the affection of the throat of which he ultimately died, Morell Mackenzie was specially summoned to attend him. The German physicians who had attended the prince since the beginning of March (Karl Gerhardt, and subsequently Tobold, E. von Bergmann, and others) had diagnosed his ailment on the 18th of May as cancer of the throat; but Morell Mackenzie insisted (basing his opinion on a microscopical examination by K. Virchow of a portion of the tissue) that the disease was not demonstrably cancerous, that an operation for the extirpation of the larynx (planned for the 21st of May) was unjustifiable, and that the growth might well be a benign one and therefore curable by other treatment. The question was one not only of personal but of political importance, since it was doubted whether any one suffering from an incapacitating disease like cancer could, according to the family law of the Hohenzollerns, occupy the German throne; and there was talk of a remuneration of the succession by the crown prince. It was freely hinted, indeed, that there were political considerations at work. At any rate, Morell Mackenzie's opinion was followed: the crown prince went to England, under his treatment, and was present at the Jubilee celebrations in June. Morell Mackenzie was knighted in September 1887 for his services, and decorated with the Grand Cross of the Hohenzollern Order. In November, however, the German doctors were again called into consultation, and it was ultimately admitted that the disease really was cancer: though Mackenzie, with very questionable judgment, more than hinted that it had become malignant since his first examination, in consequence of the irritating effect of the treatment by the German doctors. The crown prince (see Frederick III.) became emperor on the 4th of March 1888, and died on the 15th of June. During all this period a violent quarrel raged between Sir Morell Mackenzie and the German medical world. The German doctors published an account of the illness, to which Mackenzie replied by a work entitled The Fatal Illness of Frederick the Noble (1888), the publication of which caused him to be censured by the Royal College of Surgeons. After this sensational episode in his career, the remainder of Sir Morell Mackenzie's life was uneventful, and he died somewhat suddenly in London, on the 3rd of February 1892. He published several books on laryngoscopy and diseases of the throat.

MACKENZIE, WILLIAM LYON (1795–1861), Canadian politician, was born near Dundee, Scotland, on the 12th of March 1795. His father died before he was a month old, and the family were left in poverty. After some six years' work in a shop at Alyth, in April 1810 he emigrated with his mother to Canada. There he became a general merchant, first at York, then at Dufferin and later at Queenston. The discontented condition of Upper Canada drew him into politics, and on the 18th of May 1824 he published at Queenston the first number of the Colonial Advocate, in which the ruling oligarchy was attacked with great asperity. Most of the changes which he advocated were wise and have since been adopted; but the violence of Mackenzie's attacks roused great anger among the social and political set at York (Toronto), which was headed by John Beverley Robinson. In November
1824 Mackenzie removed to Toronto, but he had little capital; his paper appeared irregularly, and was on the point of suspending publication when his office was attacked and his type thrown into the bay by a number of the supporters of his opponents. In an action against the chief rioters he was awarded $625 and costs, was declared in contempt, and the Daily British Whig died. A new plant, the Colonial Advocate ran till the 4th of November 1834.

In 1828 he was elected member of parliament for York, but was expelled on the technical ground that he had published in his newspaper the proceedings of the house without authorization. Five times he was expelled and five times re-elected by his constituents, till at last the government refused to issue a writ, and for three years York was without one of its representatives. In May 1832 he visited England, where he was well received by the colonial office. Largely as the result of his representations, many important reforms were ordered by Lord Goderich, afterwards Earl of Ripon, the colonial secretary. While in England, he published Sketches of Canada and the United States, in which, with some exaggeration, many of the Canadian grievances were exposed. On his return in March 1834 he was elected mayor of Toronto. During his year of office, the horsemanship with which he worked hand in hand with his old enemy, Bishop Strachan, in fighting an attack of cholera, did not prevent him from winning much unpopularity by his officiousness, and in 1835 he was not re-elected either as mayor or alderman. In October 1834 he was elected member of parliament for York, and took his seat in January 1835, the Reformers being now in the majority. A committee on grievances was appointed, as chairman of which Mackenzie presented the admirable Seventh Report on Grievances, largely written by himself, in which the case for the Reformers was presented with force and moderation, and the adoption of responsible government advocated as the remedy.

In the general election of June 1836 the Tory party won a complete victory. Mackenzie and almost all the prominent Reformers were defeated at the polls. This totally unexpected defeat greatly embarrassed him. On the 4th of July 1836, the anniversary of the adoption of the American Declaration of Independence, he began the publication of the Constitution, which openly advocated a republican form of government. Later in the year he was appointed "agent and corresponding secretary" of the extreme wing of the Reform party, and more and more openly, in his speeches throughout the province, advocated armed revolt. He was also in correspondence with Papineau and the other leaders of the Reformers in Lower Canada, who were already planning a rising. Early in December 1837 Mackenzie gathered a mob of his followers, to the number of several hundred, at Gallows Hill, some miles to the north of Toronto, with the intention of seizing the lieutenant-governor and setting up a provisional government. Misunderstandings among the leaders led to the total failure of the revolt, and Mackenzie was forced to fly to the United States with a price on his head. In the town of Buffalo he collected a disorderly rabble, who seized and fortified Navy Island, in the river between the two countries, and for some weeks troubled the Canadian frontier. After the failure of this attempt he was put to the most pitiful shifts to make a living. In June 1839 he was tried in the United States for a breach of the neutrality laws, and sentenced to eighteen months' imprisonment, of which he served over eleven. While in gaol at Rochester he published the Caroline Almanac, the tone of which may be judged from its references to "Victoria Guelph, the bloody queen of England," and by the title given to the British cabinet of "Victoria Melbourne's bloody diwan." He returned to Canada in consequence of the Amnesty Act 1849. A closer inspection had cured him of his love for republican institutions.

In 1851 he was elected to parliament for Haldimand, defeating George Brown. He at once allied himself with the Radicals (the "Clear Grits"), and, on the leadership of that party being assumed by Brown, became one of his lieutenants. He was still miserably poor, but refused all offers to accept a government position. In 1858 he resigned his seat in the house, owing to incipient softening of the brain, of which he died on the 29th of August 1861.

Turbulent, ungovernable, vain, often the dupe of schemers, Mackenzie united with much that was laughable not a little that was heroic. He could neither be bribed, bullied, nor cajoled. Perhaps the best instance of this is that in 1832 he refused from Lord Gort origin and set up a confederate plant, the Colonial Advocate, and the 4th of November 1834. In 1828 he was elected member of parliament for York, but was expelled on the technical ground that he had published in his newspaper the proceedings of the house without authorization. Five times he was expelled and five times re-elected by his constituents, till at last the government refused to issue a writ, and for three years York was without one of its representatives. In May 1832 he visited England, where he was well received by the colonial office. Largely as the result of his representations, many important reforms were ordered by Lord Goderich, afterwards Earl of Ripon, the colonial secretary. While in England, he published Sketches of Canada and the United States, in which, with some exaggeration, many of the Canadian grievances were exposed. On his return in March 1834 he was elected mayor of Toronto. During his year of office, the horsemanship with which he worked hand in hand with his old enemy, Bishop Strachan, in fighting an attack of cholera, did not prevent him from winning much unpopularity by his officiousness, and in 1835 he was not re-elected either as mayor or alderman. In October 1834 he was elected member of parliament for York, and took his seat in January 1835, the Reformers being now in the majority. A committee on grievances was appointed, as chairman of which Mackenzie presented the admirable Seventh Report on Grievances, largely written by himself, in which the case for the Reformers was presented with force and moderation, and the adoption of responsible government advocated as the remedy.

In the general election of June 1836 the Tory party won a complete victory. Mackenzie and almost all the prominent Reformers were defeated at the polls. This totally unexpected defeat greatly embarrassed him. On the 4th of July 1836, the anniversary of the adoption of the American Declaration of Independence, he began the publication of the Constitution, which openly advocated a republican form of government. Later in the year he was appointed "agent and corresponding secretary" of the extreme wing of the Reform party, and more and more openly, in his speeches throughout the province, advocated armed revolt. He was also in correspondence with Papineau and the other leaders of the Reformers in Lower Canada, who were already planning a rising. Early in December 1837 Mackenzie gathered a mob of his followers, to the number of several hundred, at Gallows Hill, some miles to the north of Toronto, with the intention of seizing the lieutenant-governor and setting up a provisional government. Misunderstandings among the leaders led to the total failure of the revolt, and Mackenzie was forced to fly to the United States with a price on his head. In the town of Buffalo he collected a disorderly rabble, who seized and fortified Navy Island, in the river between the two countries, and for some weeks troubled the Canadian frontier. After the failure of this attempt he was put to the most pitiful shifts to make a living. In June 1839 he was tried in the United States for a breach of the neutrality laws, and sentenced to eighteen months' imprisonment, of which he served over eleven. While in gaol at Rochester he published the Caroline Almanac, the tone of which may be judged from its references to "Victoria Guelph, the bloody queen of England," and by the title given to the British cabinet of "Victoria Melbourne's bloody diwan." He returned to Canada in consequence of the Amnesty Act 1849. A closer inspection had cured him of his love for republican institutions.

In 1851 he was elected to parliament for Haldimand, defeating George Brown. He at once allied himself with the Radicals (the "Clear Grits"), and, on the leadership of that party being assumed by Brown, became one of his lieutenants. He was still miserably poor, but refused all offers to accept a government position. In 1858 he resigned his seat in the house, owing to
the tail with all the rays soft except the first, and behind the second dorsal five or six finlets. The ventral is immediately below the second dorsal, and is also followed by finlets. The caudal fin is crescent-shaped, strengthened at the base by two short ridges on each side. The mouth is wide, armed above and below with a row of very small teeth.

No other fish shows finer proportions in the shape of its body. Every "line" of its build is designed and cunningly adapted for rapid progression through the water; the muscles massed along the vertebral column are enormously developed, especially on the back and sides of the tail, and impart to the body a certain rigidity which interferes with abruptly sideward motions of the fish. Therefore mackerel generally swim in a straight-forward direction, deviating sideways only when compelled, and rarely turning about in the same spot. They are in almost continuous motion, their power of endurance being equal to the rapidity of their motions. Mackerel, like all fishes of this family, have a firm flesh; that is, the muscles of the larger segments are interlaced, and receive a greater supply of blood-vessels and nerves than in other fishes. Therefore the flesh, especially of the larger kinds, is of a red colour; and the energy of their muscular action causes the temperature of their blood to be several degrees higher than in other fishes.

All fishes of the mackerel family are strictly carnivorous; they unconsciously pursue their prey, which consists principally of other fish and pelagic crustaceans. The fry of clupeoids, which likewise swim in schools, are followed by the mackerel until they reach some shallow place, which their enemies dare not enter.

Mackerel are found in almost all tropical and temperate seas, with the exception of the Atlantic shores of temperate South America. European mackerel are of two kinds, of which one, the common mackerel, _Scomber scombrus_, lacks, while the other possesses, an air-bladder. The best-known species of the latter kind is the "Spanish" mackerel; a third, _S. pneumato- phorus_, is believed by some ichthyologists to be identical with _S. colias_. Be this as it may, we have strong evidence that the Mediterranean is inhabited by other species different from _S. scombrus_ and _S. colias_, and well characterized by their dentition and coloration. Also the species from St. Helena is distinct. Of extra-Atlantic species the mackerel of the Japanese seas are the most nearly allied to the European, those of New Zealand and Australia, and still more those of the Indian Ocean, differing in many conspicuous points. Two of these species in the Indian Ocean, _S. scanibar_, which is the most common, as well as in other parts of the North Atlantic, crossing the ocean to America, where it abounds; and the Spanish mackerel, _S. colias_, which is distinguished by a somewhat different pattern of coloration, the transverse black bands of the common mackerel being in this species narrower, more irregular or partly broken up into spots, while the scales of the pectoral region are larger, and the snout is longer and more pointed. The Spanish mackerel is, as its name implies, a native of the seas of southern Europe, but single individuals or small schools frequent the shores of Great Britain and of the United States.

The home of the common mackerel (to which the following remarks refer) is the North Atlantic, from the Canary Islands to the Orkneys, and from the Mediterranean and the Black Sea and the coasts of Norway to the United States.

Towards the spring large schools approach the coasts. Two causes have been assigned of this migration: first, the instinct of finding a suitable locality for propagating their species; and, secondly, the search and pursuit of food. That in the warmer season is more abundant in the neighbourhood of land than in the open sea. It is probable that the latter is the chief cause.

In the month of February, or in some years as early as the end of January, the first large schools appear at the entrance of the English Channel, and are met by the more adventurous of the drift-nets. There are many miles west of the Scilly Islands. These early schools, which consist chiefly of one-year and two-year-old fishes, yield very large catches, whilst in other years they escape the drift-nets altogether, passing them, for some hitherto unexplained reason, at a greater depth than that to which the nets reach.

1 The term "Spanish mackerel" is applied in America to _Cybium maculatum_.

As the season advances, the schools penetrate farther northwards into St. George's Channel or eastwards into the English Channel. The fishery then assumes proportions which render it next in importance to the herring and cod fisheries. In Plymouth alone has some two thousand boats been employed on the Channel side of the Channel no less capital and labour are invested in it, the vessels employed, though less in number, larger in size than on the English side. The chief centre, however, of the fishery in the British Channel, so far as England, Ireland, and the north of France are concerned, is near Penzance, where the small local sailing boats are outnumbered by hundreds of large boats, both sail and steam, which come chiefly from Lowestoft for the season. Simultaneously with the drift-net the deep-sea-seine and shad-nets are used, chiefly between June and October, when the drift-net. Towards the end of May the old fish become heavy with spawn and are in the highest condition for the table; and the last two weeks of June or July are usually marked by the spawning at which the greater part of mackerel spawn. Considerable numbers of mackerel are taken off Norfolk and Suffolk in May and June, and also in September and October. There can be no doubt that they enter the North Sea from the English Channel, and return by the same route, but others travel round the north of Scotland and appear in rather small numbers off the east coast of that country. On the Norwegian coast mackerel were never much known, whilst, on the English coasts large catches are frequently made in March. Large cargoes are annually imported in ice from Norway to the English market.

At the peak of spawning the schools break up into smaller companies which are much scattered, and offer for two or three months employment to the hand-line fishermen. They now begin to disappear from the coasts and return to the open sea. Single individuals or small companies are known to be seen, on the coast or inshore, and they may have become detached from the main bodies, and be seeking for the larger schools which have long left on their return migration.

Although, on the whole, the course and time of the annual migration of mackerel is marked with great regularity, their appearance and abundance at certain localities are subject to great variations. They may pass a spot at such a depth as to evade the nets, and reappear at the surface some days after farther eastwards; they may deviate from their direct line of migration, and even temporarily return westwards. In some years between 1872 and 1874 the old mackerel disappeared off Guernsey from the surface, and were accidentally discovered feeding at the bottom. Many were taken at 10 fathoms and deeper with the line, and all were of exceptionally large size, several measuring 18 in. and weighing nearly 3 lb; these are the largest mackerel on record.

The mackerel most esteemed as food is the common species, and individuals from 10 to 12 in. in length are considered the best flavoured. In more southern latitudes, however, this species seems to deteriorate, specimens from the coast of Portugal, and from the Mediterranean and Black Sea, being stated to be dry and resembling in taste the Spanish mackerel (_S. colias_), which are listed for the table.

Mackinac Island, a small island in the N.W. extremity of Lake Huron and a part of Mackinac county, Michigan, and a city and summer resort of the same name on the island. The city is on the S.E. shore, at the entrance of the Straits of Mackinac, about 7 m. N.E. of Mackinaw City and 6 m. E.S.E. of St. Ignace. Pop. (1900), 665; (1904), 736; (1910), 714. During the summer season, when thousands of people come...
here to enjoy the cool and pure air and the island’s beautiful scenery, the city is served by the principal steamboat lines on the Great Lakes and by ferry to Mackinaw city (pop. in 1904, 606), which is served by the Michigan Central, the Grand Rapids & Indiana, and the Duluth, South Shore & Atlantic railways. The island is about 3 m. long by 2 m. wide. From the remarkably clear water of Lake Huron its shores rise for the most part a wall of white limestone cliffs; inland there are strangely shaped rocks and forests of cedar, pine, fir, spruce, juniper, maple, oak, birch, and beech. Throughout the island there are numerous glens, ravines, and caverns, some of which are rich in associations with Indian legends. The city is an antiquated fishing and trading village with modern hotels, club-houses, and summer villas. Fort Mackinac and its grounds are included in a state reservation which embraces about one-half of the island.

The original name of the island was Michilimackinac (“place of the big lame person” or “place of the big wounded person”); the name was apparently derived from an Algonquian tribe, the Mishininaki or Mishinizinkingog, now extinct. The island was long occupied by Chippewas, the Hurons had a village here for a short time after their expulsion from the East by the Iroquois, and subsequently there was an Ottawa village here. The first white settlement or station was established by the French in 1670 (abandoned in 1701) at Point Saint Ignace on the north side of the strait. In 1761 a fort on the south side (built in 1712) was surrendered to the British. By the treaty of Paris (1783) the right of the United States to this district was acknowledged; but the fort was held by the British until 1796. In July 1812 a British force surprised the garrison, which had not yet learned that war had been declared. In August 1814 an American force under Colonel George Croghan (1791—1849) attempted to recapture the island but was repulsed with considerable loss. By the treaty of Ghent, however, the island was restored, in July 1815, to the United States; Fort Mackinac was maintained by the Federal government until 1845, when it was ceded to the state. From 1820 to 1840 the village was one of the principal stations of the American Fur Company. A Congregational mission was established among the Chippewas on the island in 1827, but was discontinued before 1845. The city of Mackinac Island was chartered in 1899.

McKinley, William (1843-1901), twenty-fifth president of the United States, was born in Niles, Trumbull county, Ohio, on the 29th of January 1843. His ancestors on the paternal side were Scotch-Irish who lived at Dervock, Co. Antrim, and spelled the family name “McKinlay.” His great-great-grandfather settled in York county, Pennsylvania, about 1743, and from Chester county, Pennsylvania, his great-grandfather, David McKinley, who served as a private during the War of Independence, moved to Ohio in 1810. David’s son James had gone in 1809 to Columbiana county, Ohio. His son William McKinley (b. 1807), like his father an iron manufacturer, was married in 1829 to Nancy Campbell Allison, and to them were born nine children, of whom William, the president, was the seventh. In 1832 the family removed to Poland, Mahoning county, where the younger William was placed at school. At seventeen he entered the junior class of Allegheny College, at Meadville, Pennsylvania; but he studied beyond his strength, and returned to Poland, where for a time he taught in a neighborhood school. When the Civil War broke out in 1861 he promptly enlisted as a private in the 23rd Ohio Volunteer Infantry. He saw service in West Virginia, at South Mountain, where this regiment lost heavily, and at Antietam, where he brought up hot coffee and provisions to the fighting line; for this he was promoted second lieutenant on the 24th of September 1862. McKinley was promoted first lieutenant in February 1864, and for his services at Winchester was promoted captain on the 25th of July 1864. He was on the staff of General George Crook at the battles of Opequon, Fisher’s Hill, and Cedar Creek in the Shenandoah valley, and on the 14th of March 1865 was brevetted major of volunteers for gallant and meritorious services. He also served on the staff of General Rutherford B. Hayes, who spoke highly of his services. He was mustered out with his regiment on the 26th of July 1865. For four years arrears of pay enabled him from a pale and sickly to be a man of superb figure and health.

After the war McKinley returned to Poland, and bent all his energy upon the study of law. He completed his preparatory reading at the Albany (N.Y.) law school, and was admitted to the bar at Warren, Ohio, in March 1867. On the advice of an elder sister, who had been for several years a teacher in Canton, Stark county, Ohio, he began his law practice in that place, which was to be his permanent home. He identified himself immediately with the Republican party, campaigned in the Democratic county of Stark in favour of negro suffrage in 1867, and took part in the campaign work on behalf of Grant’s presidential candidacy in 1868. In the following year he was elected prosecuting attorney on the Republican ticket; in 1871 he failed of re-election by 45 votes, and again devoted himself to his profession, while not relaxing his interest in politics.

In 1875 he first became known as an able campaign speaker by his speeches favouring the resumption of specie payments, and in behalf of Rutherford B. Hayes, the Republican candidate for governor of Ohio. In 1876 he was elected by a majority of 3304 to the national House of Representatives. Conditions both in Ohio and in Congress had placed him, and were to keep him for twenty years, in an attitude of aggressive and uncompromising partisanship. His Congressional district was naturally Democratic, and its boundaries were changed two or three times by Democratic legislatures for the purpose of grouping Democratic strongholds as to cause his defeat. But he overcame what had threatened to be adverse majorities on all occasions from 1876 to 1890, with the single exception of 1882, when, although he received a certificate of election showing that he had been re-elected by a majority of 8, and although he served nearly through the long session of 1883-1884, his seat was contested and taken (May 28, 1884) by his Democratic opponent, Jonathan H. Wallace. McKinley reflected the strong sentiment of his manufacturing constituency in behalf of a high protective tariff, and he soon became known in Congress (where he particularly attracted the attention of James G. Blaine) as one of the most diligent students of industrial policy and question affecting national taxation. In 1878 he took part in the debates over the Wood Tariff Bill, proposing lower import duties; and in the same year he voted for the Bland-Allison Silver Bill. In December 1880 he was appointed a member of the Ways and Means committee, succeeding General James A. Garfield, who had been elected president in the preceding month, and to whose friendship, as to that of Rutherford B. Hayes, McKinley owed much in his earlier years in Congress. He was prominent in the debate which resulted in the defeat of the Democratic Morrison Tariff Bill in 1884, and, as minority leader of the Ways and Means committee, in the defeat of the Mills Bill for the revision of the tariff in 1887-1888. In 1886 he became chairman of the Ways and Means committee and Republican leader in the House of Representatives, after having been defeated by Thomas B. Reed on the third ballot in the Republican caucus for speaker of the House. On the 16th of April 1890 he introduced from the House as chairman of the Committee on Ways and Means the committee the tariff measure known commonly as the McKinley Bill, which passed the House on the 21st of May, passed the Senate (in an amended form, with a reciprocity clause, which McKinley had not been able to get through the House) on the 10th of September, was passed as amended, by the House, and was approved by the president on the 1st of October 1890. The McKinley Bill reduced revenues by its high and in many cases almost prohibitive duties; it
put sugar on the free list with a discriminating duty of 21/2d of one cent a pound on sugar imported from countries giving a bounty for sugar exported, and it gave bounties to American sugar growers; it attempted to protect many "infant" industries such as the manufacture of tin-plate; under its provision for reciprocal trade agreements (a favourite project of James G. Blaine, who opposed many of the "protective" features of the Bill) reciprocity treaties were made with Germany, France, Italy, and Belgium, which secured a market in those countries for American pork. Abroad, where the Bill made McKinley's name known everywhere, there was bitter opposition to it and reprisals were threatened by several European states. In the United States the McKinley Tariff Bill was one of the main causes of the Democratic victory in the Congressional elections of 1890, in which McKinley himself was defeated by an extraordinary Democratic gerrymander of his Congressional district. In November 1891 he was elected governor of Ohio with a plurality of more than 21,000 votes in a total of 795,000 votes cast. He was governor of Ohio in 1892-1895, being re-elected in 1893. His administration was marked by no important events, except that he had on several occasions in his second term to call out the militia of the state to preserve order; but it may be considered important because of the training it gave him in executive as distinguished from legislative work.

McKinley had been prominent in national politics even before the passage of the tariff measure bearing his name. In 1888 in the National Republican Convention in Chicago he was chairman of the committee resolutions (i.e. the platform committee) and was leader of the delegation from Ohio, which had been instructed for John Sherman; after James G. Blaine withdrew his name there was a movement, begun by Republican congressmen, to nominate McKinley, who received 16 votes on the seventh ballot, but passionately refused to be a candidate, considering that his acquiescence would be a breach of faith toward Sherman. In 1892 McKinley was the permanent president of the National Republican Convention which met in Minneapolis and which renominated Benjamin Harrison on the first ballot, on which James G. Blaine received 182 2/4 votes, and McKinley, in spite of his efforts to the contrary, received 182 votes. In 1894 he made an extended campaign tour before the Congressional elections, and spoke even in the South. In 1896 he seemed for many reasons the most "available" candidate of his party for the presidency: he had no personal enemies in the party; he had carried the crucial state of Ohio by a large majority in 1893; his attitude on the coinage question had never been so pronounced as to make him unpopular either with the radical silver wing or with the conservative "gold interveners" of the party. The campaign for his nomination was conducted with the greatest adroitness by his friend, Marcus A. Hanna, and in the National Republican Convention held in St Louis in June he was nominated for the presidency on the first ballot by 662 1/2 out of a total of 906 votes. The convention adopted a tariff plank drafted by McKinley, and, of far greater immediate importance, a plank, which declared that the Republican party was "opposed to the free coinage of silver, except by international agreement with the leading commercial nations of the world, which we pledge ourselves to promote, and until such an agreement can be obtained the existing gold standard must be preserved." This "gold standard" plank drove out of the Republican party the Silver Republicans of the West, headed by Senator Henry M. Teller of Colorado. The Republican convention nominated for the vice-presidency Garrett A. Hobart of New Jersey. The National Democratic Convention declared for the immediate opening of the mints to the free and unlimited coinage of silver at the ratio with gold of 16 to 1; and it nominated for the presidency William Jennings Bryan of Nebraska, who also received the nomination of the People's party and of the National Silver party. There was a secession from the Democratic party of conservatives who called themselves the National Democratic party, who were commonly called Gold Democrats, and who nominated John M. Palmer (1817-1900) of Illinois for president. In this re-arrangement of parties McKinley, who had expected to make the campaign on the issue of a high protective tariff, was diverted to the defence of the gold standard as the main issue. While his opponent travelled throughout the country making speeches, McKinley remained in Canton, where he was visited by and addressed many Republican delegations. The campaign was enthusiastic: the Republican candidate was called the "advance agent of prosperity"; "Bill McKinley and the McKinley Bill" became a campaign cry; the panic of 1893 was charged to the repeal of the McKinley tariff measure; and "business men" throughout the states were enlisted in the cause of "sound money" to support McKinley, who was elected in November by a popular vote of 7,106,779 to 6,592,925 for Bryan, and by an electoral vote of 271 to 176.

McKinley was inaugurated president of the United States on the 4th of March 1897. The members of his cabinet were: secretary of state, John Sherman (who filled a vacancy in the Senate to which Marcus A. Hanna was elected), who was succeeded in April 1898 by William R. Day, who in turn was followed in September 1898 by John Hay; secretary of the treasury, Lyman J. Gage, a Gold Democrat; secretary of war, Russell A. Alger, who was succeeded in 1899 by Elihu Root; secretary of the navy, John D. Long; attorney-general, Joseph McKenna, succeeded in January 1898 by John William Griggs; postmaster-general, James A. Gary, succeeded in April 1898 by Charles Emory Smith; secretary of the interior, Cornelius N. Bliss, succeeded in February 1899 by Alfred Hitchcock; and secretary of agriculture, James Wilson. (For the political history of McKinley's administration see Unrigo States: History). Immediately after his inauguration the president summoned Congress to assemble in an extra session on the 15th of March. The Democratic tariff in 1893 had been enacted as part of the general revenue measure, which included an income-tax. The income-tax having been declared unconstitutional by the Supreme Court, the measure had failed to produce a sufficient revenue, and it had been necessary to increase the public debt. McKinley's message to the new Congress dwelt upon the necessity of an immediate revision of the tariff and revenue system of the country, and the so-called Dingley Tariff Bill was accordingly passed through both houses, and was approved by the president on the 24th of July.

The regular session of Congress which opened in December was occupied chiefly with the situation in Cuba. President McKinley showed himself singularly patient and self-controlled in the midst of the popular excitement against Spain and the so-called "intervention" by the United States in behalf of the Cubans; but finally, on the 23rd of March, he presented an ultimatum to the Spanish government, and on the 25th of April, on his recommendation, Congress declared war upon Spain. During the war itself he devoted himself with great energy to the mastery of military details; but there was bitter criticism of the war department resulting in the resignation of the secretary of war, Russell A. Alger (q.v.). The signing of a peace protocol on the 12th of August was followed by the signature at Paris on the 1oth of December of articles of peace between the United States and Spain. After a long discussion of the peace treaty was ratified by the United States Senate on the 6th of February 1899; and in accordance with its terms Porto Rico, the Philippine Archipelago, and Guam were transferred by Spain to the United States, and Cuba came under American jurisdiction pending the establishment there of an independent government. Two days before the ratification of the peace treaty, a conflict took place between armed Filipinos under the leadership of Emilio Aguinaldo and the American forces that were in possession of Manila. The six months that had elapsed between the signing of the peace protocol and the ratification of the treaty had constituted a virtual intermittum, Spain's authority having been practically destroyed in the Philippines and that of the United States.
not having begun. In this period a formidable native Filipino army had been organized and a provisional government created. The warfare waged by these Filipinos against the United States, while having for the most part a desultory and guerilla character, was of a very protracted and troublesome nature. Sovereignty over the Filipinos having been accepted by virtue of the ratification of the Paris treaty, President McKinley was not at liberty to do otherwise than assert the authority of the United States and use every endeavour to suppress the insurrection. But there was bitter protest against this "imperialism," both within the party by such men as Senators George F. Hoar and Eugene Hale, and Thomas B. Reed and Carl Schurz, and, often for purely political reasons, from the leaders of the Democratic party. In the foreign relations of the United States, as directed by President McKinley, the most significant change was the cordial understanding established with the British government, to which much was contributed by his secretary of state, John Hay, appointed to that portfolio when he was ambassador to the court of St James, and which was due to some extent to the friendliness of the British press and even more markedly of the British navy in the Pacific during the Spanish War. Other important foreign events during McKinley's administration were: the annexation of the Hawaiian Islands (see Hawaii) in August 1898; and the formation of the Territory of Hawaii in April 1900; the cessation in 1890 of the tripartite (German, British, and French) government of the Samoan Islands, and the annexation by the United States of those of the islands east of 171°, including the harbour of Pago-Pago; the participation of American troops in the march of the allies on Pekin in August 1900, and the part played by McKinley's secretary of state, John Hay, in securing a guarantee of the integrity of the Chinese empire. In 1900 McKinley was unanimously renominated by the Republican National Convention which met in Philadelphia on the 10th of June, and which nominated Theodore Roosevelt, governor of New York, for the vice-presidency. The Republican convention demanded the maintenance of the gold standard, and pointed to the fulfilment of some of the most important of the pledges given by the Republican party four years earlier. The intervening period had been one of very exceptional prosperity in the United States, foreign commerce having reached an unprecedented volume, and agriculture and manufactures having made greater advancement than in any previous period of the country's history. The tendency towards the concentration of capital in great industrial corporations had been active to an extent previously undreamt of, with incidental consequences that had aroused much apprehension; and the Democrats accused President McKinley and the Republican party of having fostered the "trusts." But the campaign against McKinley and the Republican party was not only "anti-trust" but "anti-imperialistic." William Jennings Bryan, renominated by the Democratic party in July (and in May by the Fusion People's party) on a free silver platform, declared that imperialism was the "paramount issue" and made a second vigorous campaign; and the opposition to McKinley's re-election, whether based on opposition to his economic or to his foreign policy, was not entirely outside of his own party. As the result of the polling in November, 202 Republican presidential electors were chosen, and 155 Democratic electors, elected in Colorado, Idaho, Montana, Nevada, and the Southern states, represented the final strength of the Bryan and Stevenson ticket. The Republican popular vote was 7,207,923, and the Democratic 5,355,333. Since 1872 no president had been re-elected for a second consecutive term.

In the term of Congress immediately following the presidential election it was found possible to reduce materially the war taxes which had been levied on the outbreak of the Spanish-American War. Arrangements were perfected for the termination of the American military occupation of Cuba and the inauguration of a Cuban Republic as a virtual protectorate of the United States, the American government having arranged with the Cuban constitutional convention for the retention of certain naval stations on the Cuban coast. In the Philippines advanced steps had been taken in the substitution of civil government for military occupation, and a governor general, Judge William H. Taft, had been appointed and sent there. That home was great, and foreign relations were free from complications. The problems which had devolved upon McKinley's administration had been far advanced towards final settlement. He retained without change the cabinet of his first administration. After an arduous and anxious term, the president had reached a period that promised to give him comparative repose and freedom from care. He had secured, through the cooperation of Congress, the permanent reorganization of the army and a very considerable development of the navy. In these circumstances, President McKinley, accompanied by the greater part of his cabinet, set forth in the early summer on a tour to visit the Pacific coast, where he was to witness the launching of the battleship "Ohio" at San Francisco. The route chosen was through the Southern states, where many stops were made, and where the president delivered brief addresses. The heartiness of the welcome accorded him seemed to mark the disappearance of the last vestige of sectional feeling that had survived the Civil War, in which McKinley had participated as a young man. After returning from the tour he spent a month in a visit at his old home in Canton, Ohio, and at the end of this visit, by previous arrangement, he visited the city of Buffalo, New York, in order to attend the Pan-American exposition and deliver a public address. This address (Sept. 5, 1901) was a public utterance designed by McKinley to affect American opinion and public policy, and apparently to show that he had modified his views upon the tariff. It declared that henceforward the progress of the nations must be through harmony and co-operation, in view of the fast-changing conditions of communication and trade, and it maintained that the time had come for wide-reaching modifications in the tariff policy of the United States, the method preferred by McKinley being that of commercial reciprocity arrangements with various nations. On the following day, the 6th of September 1901, a great reception was held for President McKinley in one of the public buildings of the exposition, all sorts and conditions of men being welcome. Advantage of this opportunity was taken by a young man of Polish parentage, by name Leon Czolgosz, to shoot at the president with a revolver at close range. One of the two bullets fired penetrated the abdomen. After the world had been assured that the patient was doing well and would recover, he collapsed and died on the 14th. The assassin, who, it was for a time supposed, had been inflamed by the editorials and cartoons of the demagogic opposition press, but who professed to hold the views of that branch of anarchists who believe in the assassination of rulers and persons exercising political authority, was promptly seized, and was convicted and executed in October 1901. McKinley's conduct and utterances in his last days revealed a loftiness of personal character that everywhere elicited admiration and praise. Immediately after his death Vice-President Roosevelt took the oath of office, announcing that it would be his purpose to continue McKinley's policy, while also retaining the cabinet and the principal officers of the government. McKinley's funeral took place at Canton, Ohio, on the 19th of September, the occasion being remarkable for the public manifestations of mourning, not only in the United States, but in Great Britain and other countries; in Canton a memorial tomb has been erected.

Though he had not the personal magnetism of James G. Blaine, whom he succeeded as a leader of the Republican party and whose views of reciprocity he formally adopted in his last public address, McKinley had great personal suavity and dignity, and was thoroughly well liked by his party colleagues. As a politician he was always more the people's representative than their leader, and that he "kept his car to the ground" was the source of much of his power and at the same time was his greatest weakness: his address at Buffalo the day before his assassination seems to voice his appreciation of the change
in popular sentiment regarding the tariff laws of the United States and is the more remarkable as coming from the foremost champion for years of a form of tariff legislation devised to still international competition. His apparently inconsistent record on the coinage question becomes consistent if considered in the same way, as the expression of the gradually changing views of his constituency. And it may not be fanciful to suggest that the obvious growth of McKinley in breadth and power during his term as president was due to his being the representative of a larger constituency, less local and less narrow-minded. He was an able but far from brilliant campaign speaker. His greatest administrative gift was a fine intuition in choosing men to serve him. McKinley's private life was unpractical; and very fine was his devotion to his wife, Ida Saxton (d. 1907), whom he had married in Canton in 1874, who was throughout his political career a confirmed invalid.

He was from his early manhood a prominent member of the Methodist Episcopal Church.

His Speeches and Addresses were printed in two volumes (New York, 1893 and 1901).

MCKINNEY, a city and the county-seat of Collin county, Texas, U.S.A., about 30 m. N. by E. of Dallas. Pop. (1890), 2480; (1900), 4342 (917 negroes); (1910) 4714. It is served by the Missouri, Kansas & Texas and the Houston & Texas Central railways, and by the Dallas & Sherman inter-urban (electric) line, the central power plant of which is immediately north of the city. McKinney is in a fine farming region; there are also manufactures. The municipal water supply is obtained from artesian wells. The first settlement in Collin county was made about 10 m. north of what is now McKinney in 1841. McKinney was named, as was the county, in honour of Collin McKinney, a pioneer in the region and a signer of the Declaration of the Independence of Texas. It was settled in 1844, was laid out and became the county-seat in 1846, and was first chartered in 1850.

MACKINTOSH, SIR JAMES (1765-1832), Scottish publicist, was born at Aldourie, 7 m. from Inverness, on the 24th of October 1765. He came of old Highland families on both sides. He went in 1780 to college at Aberdeen, where he made a friend of Robert Hall, afterwards the famous preacher. In 1784 he proceeded for the study of medicine to Edinburgh, where he participated to the full in the intellectual ferment, but did not quite neglect his medical studies, and took his degree in 1789.

In 1788 Mackintosh removed to London, then agitated by the trial of Warren Hastings and the king's first lapse into insanity. He was much more interested in these and other political events than in his professional prospects; and his attention was specially directed to the events and tendencies which caused or preceded the Revolution in France. In 1789 he married his first wife, Catherine Stuart, whose brother Daniel afterwards became editor of the Morning Post. His wife's prudence was a corrective to his own unpractical temperament, and his efforts in journalism became fairly profitable. Mackintosh was soon absorbed in the question of the time; and in April 1791, after long meditation, he published his Vindiciae Gallicae, a reply to Burke's Reflections on the French Revolution. It was the only worthy answer to Burke that appeared. It placed the author in the front rank of European publicists, and won him the friendship of some of the most distinguished men of the time, including Burke himself. The success of the Vindiciae finally decided him to give up the more respectable profession. He was called to the bar in 1793, and gained a considerable reputation there as well as a tolerable practice. In 1797 his wife died, and next year he married Catherine Allen, sister-in-law of Josiah and John Wedgwood, through whom he introduced Coleridge to the Morning Post. As a lawyer his greatest public efforts were his lectures (1790) at Lincoln's Inn on the law of nature and nations, of which the introductory discourse was published, and his eloquent defence (1803) of Jean Gabriel Peltrie, a French refugee, tried at the instance of the French government for a libel against the first consul. In 1803 he was knighted, and received the post of recorder at Bombay. The spoilt child of London society was not at home in India, and he was glad to return to England, where he arrived in 1812.

He courteously declined the offer of Perceval to resume political life under the auspices of the dominant Tory party, though tempting prospects of office in connexion with India were opened up. He entered parliament in the Whig interest as member for Nairn. He sat for that county, and afterwards for Knaresborough, till his death. In London society, and in Paris during his occasional visits, he was a recognized favourite for his genial wisdom and his great conversational power. On Mme de Stael's visit to London he was the only Englishman capable of representing his country in talk with her. His parliamentary career was marked by the same wide and candid liberalism as his private life. He opposed the reactionary measures of the Tory government, supported and afterwards succeeded Romilly in his efforts for reforming the criminal code, and took a leading part both in Catholic emancipation and in the Reform Bill. But he was too little of a partisan, too widely sympathetic and candid, as well as too elaborate, to be a telling speaker in parliament, and was consequently surpassed by more practical men whose powers were incomparably superior. From 1818 to 1824 he was professor of law and general politics in the East India Company's College at Haileybury.

In the midst of the attractions of London society and of his parliamentary avocations Mackintosh felt that the real work of his life was being neglected. His great ambition was to write a history of England. His studies both in English and foreign speculation led him to cherish the design also of making some worthy contribution to philosophy. It was not till 1828 that he set about the first task of his literary ambition. This was the Dissertation on the Progress of Ethical Philosophy, prefixed to the seventh edition of the Encyclopedia. The dissertation, written mostly in ill-health and in snatches of time taken from his parliamentary engagements, was published in 1831. It was severely attacked in 1835 by James Mill in his Fragment on Mackintosh. About the same time he wrote for the Cabinet Cyclopædia a "History of England from the Earliest Times to the Final Establishment of the Reformation." His more elaborate History of the Revolution, for which he had made great researches and collections, was not published till after his death. Already a privy councillor, Mackintosh was appointed commissioner for the affairs of India under the Whig administration of 1830. He died on the 30th of May 1832.

Mackintosh was undoubtedly one of the most cultured and catholic-minded men of his time. His studies and sympathies embraced almost every human interest, except pure science. But the width of his intellectual sympathies, joined to a constitutional indecision and vis ineritae, prevented him from doing more enduring work. Vindiciae Gallicae was the verdict of a philosophic Liberal on the development of the French Revolution up to the spring of 1791, and though the excesses of the revolutionists compelled him a few years after to express his entire agreement with the opinions of Burke, his defence of the "rights of man" is a valuable statement of the cultured Whig's point of view at the time. The History of the Revolution in England, breaking off at the point where William of Orange is preparing to intervene in the affairs of England, is chiefly interesting because of Macaulay's admiring essay on it and its author.

Life, by his son R. J. Mackintosh, was published in 1836.

MACKLIN, CHARLES (c. 1599-1797), Irish actor and playwright, whose real name was McLaughlin, was born in Ireland, and had an adventurous youth before coming to Bristol, where he made his first appearance on the stage as Richard in Richard III. He was at Lincoln's Inn Fields about 1725, and by 1733 was at Drury Lane, where the quarrel between the manager and the principal actors resulted in his getting better parts. When the trouble was over and these were taken from
MACK VON LEIBERICH—MACLAREN, C.

him, he went to the Haymarket, but he returned in 1734 to Drury Lane and acted there almost continuously until 1748. Then for two seasons he and his wife (d. c. 1758), an excellent actress, were in Dublin under Sheridan, then back in London at Covent Garden. He played a great number of characters, principally in comedies, although he gained a high reputation in a role in 

Hamelot. He was, however, given a colonelcy (1780) and the order of Maria Theresa, and in 1790 Loudon and Mack, having become reconciled, were again on the field together. During these campaigns Mack received a severe injury to his head, from which he never fully recovered. In 1793 he was made quartermaster-general (chief of staff) to Prince Josias of Saxe-Coburg, commanding in the Netherlands; and he enhanced his reputation by the ensuing campaign. The young Archduke Charles, who won his own first laurels in the battle of March 1793, wrote after the battle: “Above all we have to thank Colonel Mack for these successes.” Mack distinguished himself again on the field of Neerwinden; and had a leading part in the negotiations between Coburg and Dumouriez. He continued to serve as quartermaster-general, and was now made titular chief (Inhaber) of a cuirassier regiment. He received a wound at Famars, but in 1794 was once more engaged, having at last been made a major-general. But the failure of the allies, due though it was to political and military factors and ideas, over which Mack had no control, was ascribed to him, as their successes of March–April 1793 had been, and he fell into disfavour in consequence. In 1797 he was promoted lieutenant field marshal, and in the following year he accepted, at the personal request of the emperor, the command of the Napolian army. But with the unpromising material of his new command he could do nothing against the French revolutionary troops, and before long, being in actual danger of being murdered by his men, he took refuge in the French camp. He was promised a free pass to his own country, but Napoleon ordered that he should be sent to France as a prisoner of war. Two years later he escaped from Paris in disguise. The allegation that he broke his parole is false. He was not employed for some years, but in 1804, when the war party in the Austrian court needed a general to oppose the peace policy of the Archduke Charles, Mack was made quartermaster-general of the army, with instructions to prepare for a war with France. He did all that was possible within the available time to reform the army, and on the opening of the war of 1805 he was made quarter-master-general to the titular commander-in-chief in Germany, the Archduke Ferdinand. He was the real responsible commander of the army which opposed Napoleon in Bavaria, but his position was ill-defined and his authority treated with slight respect by the other generals. For the events of the Ulm and Austerlitz campaign, and an account of Mack’s responsibility for the disaster, see NAPOLEONIC CAMPAIGNS. After Austerlitz, Mack was tried by a court-martial, sitting from February 1806 to June 1807, and sentenced to be deprived of his rank, his regiment, and the order of Maria Theresa, to be imprisoned for two years. He was released in 1808, and in 1818, when the ultimate victory of the allies had obliterated the memory of earlier disasters, he was, at the request of Prince Schwarzenberg, reinstated in the army as lieutenant field marshal and a member of the order of Maria Theresa. He died on the 22nd of October 1827, in Polten, Austria.

MACK, LOUIS (1786-1857), American political leader, was born in Smyrna, Delaware, on the 28th of May 1786, son of Allan MacLane (1746-1829), a well-known Revolutionary soldier. He was admitted to the bar in 1805. He entered the United States Senate December 28, 1811, as a Federalist. He was re-elected to the Senate in 1817 and 1823. He was not at the wheel of the government in 1827-1829. In 1827 he was elected to the United States Senate in 1828, and secretary of the treasury in Jackson’s cabinet from 1831 (when in his annual report he argued for the United States Bank) until May 1833, when he was transferred to the state department. He retired from the cabinet in June 1834. He was president of the Baltimore & Ohio railway in 1837-1847, minister to England in 1845-1846, and delegate to the Maryland constitutional convention of 1850-1851. He died in Baltimore, Maryland, on the 7th of October 1857.

MACK, ROBERT MILLIGAN MCLANE (1815-1898), graduated at West Point in 1837, resigned from the army in 1843, and practised law in Baltimore. He was a Democratic representative in Congress in 1847-1851 and again in 1879-1883, governor of Maryland in 1884-1885, U.S. commissioner to China in 1885-1894, and minister to Mexico in 1890-1896 and to France in 1885-1889. See R. M. McLane’s Reminiscences, 1827-1897 (privately printed, 1897).

MACLAREN, CHARLES (1782–1866), Scottish editor, was born at Ormiston, Haddingtonshire, on the 7th of October 1782, the son of a farmer and cattle-dealer. He was almost entirely self-educated, and when a young man became a clerk in Edinburgh. In 1817, with others, he established the Scotsman newspaper in Edinburgh and at first acted as its editor. Offered a post as clerk in the custom house, he resigned his editorial
position, resuming it in 1820, and resigning it again in 1845.

In 1820 Maclaren was made editor of the sixth edition of the Encyclopaedia Britannica. From 1864–1866 he was president of the Geological Society of Edinburgh, in which city he died on the 10th of September 1866.

Maclaren, Ian, vm. von. The Monographs of John Watson (1852–
1992). London, Author and divine. The son of John Watson, a civil servant, he was born at Manningtree, Essex, on the 3rd of November 1850, and was educated at Stirling and at Edinburgh University, afterwards studying theology at New College, Edinburgh, and at Tübingen. In 1874 he entered the ministry of the Free Church of Scotland and became assistant minister of Barclay Church, Edinburgh. Subsequently he was minister at Logielmond in Perthshire and at Glasgow, and in 1880 he became minister of Sefton Park Presbyterian Church, Liverpool, from which he retired in 1905. In 1896 he was Lyman Beecher lecturer at Yale University, and in 1900 he was moderator of the synod of the English Presbyterian church. While travelling in America he died at Mount Pleasant, Iowa, on the 6th of May 1907.

Ian Maclaren’s first sketches of rural Scottish life, Beside the Bonnie Brier Bush (1894), achieved extraordinary popularity and were followed by other successful books, The Days of Auld Lang Syne (1895), Kate Carnegie and those Ministers (1896) and Afterwards and other Stories (1898). Under his own name Watson published several volumes of sermons, among them being The Upper Room (1893); The Mind of the Master (1896) and The Potter’s Wheel (1897).

See Sir W. Robertson Nicol, Ian Maclaren (1908).

Maclaurin, Colin (1668–1746), Scottish mathematician, was the son of a clergyman, and born at Kilmidan, Argyllshire. In 1700 he entered the university of Glasgow, where he exhibited a decided genius for mathematics, more especially for geometry; it is said that before the end of his sixteenth year he had discovered many of the theorems afterwards published in his Geometria organica. In 1717 he was elected professor of mathe-
matics in Marischal College, Aberdeen, as the result of a com-
petitive examination. Two years later he was admitted F.R.S., and made the acquaintance of Sir Isaac Newton. In 1719 he published his Geometria organica, sive descriptio linearum curvarum universalis. In it Maclaurin developed several theo-
dems due to Newton, and introduced the method of generating conics which bears his name, and showed that many curves of the third and fourth degrees can be described by the inter-
section of two movable angles. In 1721 he wrote a supplement to the Geometria organica, which he afterwards published, with extensions, in the Philosophical Transactions for 1723. This paper is principally based on the following general theorem, which is a remarkable extension of Pascal’s hexagram: “If a polygon move so that each of its sides passes through a fixed point, and if all its summits except one describe curves of the degrees m, n, p, &c., respectively, then the free summit moves on a curve of the degree $2mp \ldots$ which reduces to $mp \ldots$ when the fixed points all lie on a right line.” In 1722 Maclaurin travelled as tutor and companion to the eldest son of Lord Polwarth, and after a short stay in Paris resided for some time in Lorraine, where he wrote an essay on the percussion of bodies, which obtained the prize of the French Academy of Sciences for the year 1724. The following year he was elected professor of mathematics in the university of Edinburgh on the urgent recommendation of Newton. After the death of Newton, in 1728, his nephew, John Conduit, applied to Maclaurin for his assistance in publishing an account of Newton’s life and dis-
coveries. This Maclaurin gladly undertook, but the death of Conduit put a stop to the project.

Maclaurin divided with Leonhard Euler and Daniel Bernoulli the prize offered by the French Academy of Sciences for an essay on tides. His Treatise on Fluxions was published at Edinburgh in 1742, in two volumes. In the preface he stated that he had worked in consequence of the attack on the method of fluxions made by George Berkeley in 1734. Maclaurin’s object was to found the doctrine of fluxions on geometrical demonstration, and thus to answer all objections to its method as being founded on false reasoning and full of mystery. The most valuable part of the work is that devoted to physical applications, in which he embodied his essay on the tides. In this he showed that a homogeneous fluid mass revolving uniformly round an axis under the action of gravity ought to assume the form of an ellipsoid of revo-
lution. The importance of this investigation in connexion with the theory of the tides, the figure of the earth, and other kindred questions, has always caused it to be regarded as one of the great problems of mathematical physics. Maclaurin was the first to introduce into mechanics, in this discussion, the important conception of surfaces of level; namely, surfaces at each of whose points the total force acts in the normal direction. He also gave in his Fluxions, for the first time, the correct theory for distinguishing between maxima and minima in general, and pointed out the importance of this distinction in the theory of the multiple points of curves. In 1745, when the rebels were march-
ing on Edinburgh, Maclaurin took a most prominent part in preparing trenches and barricades for its defence. The anxiety, fatigue and cold to which he was thus exposed, affecting a con-
stitution naturally weak, laid the foundation of the disease to which he afterwards succumbed. As soon as the rebel army got possession of Edinburgh Maclaurin fled to England, to avoid making submission to the Pretender. He accepted the invite-
tion of T. Herring, then archbishop of York, with whom he re-
mained till 1827 and 1832. He died of dropsy on the 14th of June 1746, at Edinburgh, and was buried in Stirling after his death. Maclaurin was married in 1733 to Anne, daughter of Walter Stewart, solicitor-
general for Scotland. His eldest son John, born in 1734, was distinguished as an advocate, and appointed one of the judges of the Scottish court of session, with the title of Lord Dargh.

He inherited an attachment to scientific discovery, and was one of the founders of the Royal Society of Edinburgh, in 1782.

After Maclaurin’s death his account of Newton’s philosophical discoveries was published by Patrick Murdoch, and also his algebra in 1748. As an appendix to the latter he appeared his De lineaerum geometricarum proprietatibus generalibus tractatus, a treatise of re-
markable elegance. Of the more immediate successors of Newton in Great Britain Maclaurin is probably the only one who can be placed in competition with the great mathematicians of the continent of Europe at the time.

(B. W.)

M’LENNAN, John Ferguson (1827–1881), Scottish ethnolo-
gist, was born at Inverness on the 14th of October 1827. He studied at King’s college, Aberdeen, where he graduated with distinction in 1849, thence proceeding to Cambridge, where he remained till 1845, when he was a degree. He was called to the Scottish bar in 1837, and in 1850 was appointed Queen’s coun-
seal to Scotland. In 1865 he published Primitive Marriage, in which, arguing from the prevalence of the symbolical form of capture in the marriage ceremonies of primitive races, he developed an intelligible picture of the growth of the marriage relation and of systems of kinship (see Family) according to natural laws. In 1866 he wrote in the Forinightly Review (April and May) an essay on “Kinship in Ancient Greece,” in which he proposed to test by early Greek facts the theory of the history of kinship set forth in Primitive Marriage; and three years later appeared a paper entitled on “Totemism” in the same periodical for 1868–1870 (the germ of which had been contained in the paper just named), which mark the second great step in his systematic study of early society. A reprint of Primitive Marriage, with “Kinship in Ancient Greece” and some other essays not previously published, ap-
ppeared in 1876, under the title of Studies in Ancient History.

The new essays in this volume were mostly critical, but one of them, in which perhaps his guessing talent is seen at its best, "The Origin of the Irish Family," is an elaborate discussion of a problem which has long puzzled both Celtic scholars and jurists; and in another, "On the Classificatory System of Relationship," he propounded a new explanation of a series of facts which, he thought, might throw light upon the early history of society, at the same time putting to the test of those facts the theories he had set forth in Primitive Marriage. Papers
on "The Levirate and Polyandry," following up the line of his previous investigations (Forntightly Review, 1877), were the last work he was able to publish. He died of consumption on the 14th of June 1881 at Hayes Common, Kent.

Besides the works already cited, M'Lennan wrote Life of Thomas Drummond (1867). The vast materials which he had accumulated on kinship were edited by his widow and A. Platt, under the title Studies in Ancient Scottish Social and Economic Life (2 vols. 1883-86). A. Platt's Life of Bernard Shaw (1916) is a valuable contribution to the study of the social and economic history of the Scottish Highlands.

MACLEOD, HENRY DUNNING (1821-1903), Scottish economist, was born in Edinburgh, and educated at Eton, Edinburgh University, and Trinity College, Cambridge, where he graduated in 1843. He travelled in Europe, and in 1849 was called to the English bar. He was employed in Scotland on the work of poor-law reform, and devoted himself to the study of economics. In 1856 he published his Theory and Practice of Banking, in 1858 Elements of Political Economy, and in 1859 A Dictionary of Political Economy. In 1873 appeared his Principles of Economist Philosophy, and other books on economics and banking were published later. Between 1868 and 1870 he was employed by the government in digesting and codifying the law of bills of exchange. He died on the 16th of July 1902.

Macleod's principal contribution to the study of economics consists in his work on the theory of credit, to which he was the first to give due prominence.

For a judicious discussion of the value of Macleod's writings, see an article on "The Revolt against Orthodoxy in Economics" in the Quarterly Review for October 1901 (No. 388).

MACLEOD, NORMAN (1812-1872), Scottish divine, son of Rev. Norman Macleod (1783-1862), and grandson of Rev. Norman Macleod, minister of Morvern, Argylshire, was born at Campbeltown on the 3rd of June 1812. In 1827 he became a student at Glasgow University, and in 1831 went to Edinburgh to study divinity under Dr Thomas Chalmers. On the 18th of March 1838 he became parish minister at Loudoun, Ayrshire. At this time the troubles in the Scottish Church were already gathering to a head (see Free Church of Scotland). Macleod, although he had no love for lay patronage, and wished the Church to be free to do its proper work, clung firmly to the idea of a national Established Church, and therefore remained in the Establishment when the disruption took place. He was one of those who took a middle course in the non-intrusion controversy, holding that the fitness of those who were presented to parishes should be judged by the presbyteries—the principle of Lord Aberdeen's Bill. On the secession of 1843 he was offered many different parishes, and having finally settled at Dalkeith, devoted himself to parish work and to questions affecting the Church as a whole. He was largely instrumental in the work of strengthening the Church. In 1847 he became one of the first ministers of the Evangelical Alliance, and from 1848 to 1872 he edited the Christian Instructor (Edinburgh). In 1851 he was called to the Barony church, Glasgow, in which city the rest of his days were passed. There the more liberal theology rapidly made way among a people who judged it more by its fruits than its arguments, and Macleod won many adherents by his practical schemes for the social improvement of the people. He instituted temperance refreshment rooms, a congregational penny savings bank, and held services specially for the poor. In 1860 Macleod was appointed editor of the new monthly magazine Good Words. Under his control the magazine, which was mainly of a religious character, became widely popular. His own literary work, nearly all of which originally appeared in its pages—sermons, stories, travels, poems—was only a by-product of a busy life. By far his best work was the spontaneous and delightful Reminiscences of a Highland Parish (1867). While Good Words made his name known, and helped the cause he had so deeply at heart, his relations with the queen and the royal family strengthened yet further his position in the country. Never since Principal Caustie had any Scottish clergyman been so well known to all his countrymen. He enjoyed the unexpected encounter with Scottish Sabbatarian ideas. The presbytery of Glasgow issued a pastoral letter on the subject of Sunday trains and other infringements of the Sabbath. Macleod protested against the grounds on which its strictures were based. For a time, owing partly to a misleading report of his statement, he became "the man in all Scotland most profoundly distrusted." But four years later the Church accorded him the highest honour in her power by choosing him as moderator of her general assembly. In 1867, along with Dr Archibald Watson, he was sent to India, to inquire into the state of the missions. He undertook the journey in spite of failing health, and seems never to have recovered from its effects. He returned resolved to devote the rest of his days to reviving the Church to its duty in the sphere of foreign missions, but his health was now broken, and his old energy flagged. He died on the 16th of June 1872, and was buried at Campsie. He was one of the greatest of Scottish religious leaders, a man of wide sympathy and high ideals.

His Glasgow church was named after him the "Macleod Parish Church," and the "Macleod Missionary Institute" was erected by the Barony church in Glasgow. Queen Victoria gave two memorial windows to Crathie church as a testimony of her admiration for his work.

See Memoir of Norman Macleod, by his brother, Donald Macleod (1876).

MACLISE, DANIEL (1806-1870), Irish painter, was born at Cork, the son of a Highland soldier. His education was of the plainest kind, but he was eager for culture, fond of reading, and anxious to become an artist. His father, however, placed him, in 1820, in Newenham's Bank, where he remained for two years, and then left to study in the Cork school of art. In 1825 it happened that Sir Walter Scott was travelling in Ireland, and young Maclise, having seen him in a bookseller's shop, made a surreptitious sketch of the great man, which he afterwards lithographed. It was exceedingly popular, and the artist became celebrated enough to receive many commissions for portraits, which he executed, in pencil, with very careful treatment of detail and accessory. Various influential friends perceived the genius and promise of the lad, and were anxious to furnish him with the means of studying in the metropolis; but with rare independence he refused all aid, and by careful economy saved a sufficient sum to enable him to leave for London. There he made a lucky hit by a sketch of the younger Kean, which, like his portrait of Scott, was lithographed and published. He entered the Academy schools in 1828, and carried off the highest prizes open to the students. In 1829 he exhibited for the first time in the Royal Academy. Gradually he began to confine himself more exclusively to subject and historical pictures, varied occasionally by portraits of Campbell, Miss Landon, Dickens, and other of his literary friends. In 1833 he exhibited two pictures which greatly increased his reputation, and in 1835 the "Chivalric Vow of the Ladies and the Peacock" procured his election as associate of the Academy, of which he became full member in 1840. The years that followed were occupied with a long series of figure pictures, deriving their subjects from history and tradition and from the works of Shakespeare, Goldsmith and Le Sage. He also designed illustrations for several of Dickens's Christmas books and other works. Between the years 1830 and 1836 he contributed to Fraser's Magazine, under the pseudonym of Alfred Croquis, a remarkable series of portraits of the literary and other celebrities of the time—character studies, etched or lithographed in outline, and touched more or less with the emphasis of the caricaturist, which were afterwards published as the Maclise Portrait Gallery (1871). In 1838 Maclise commenced one of the two great monumental works of his life, the "Meeting of Wellington and Blücher," on the walls of Westminster Palace. It was begun in fresco, a process which proved unmanageable. The artist wished to resign the task; but, encouraged by Prince Albert, he studied in Berlin the new method of "water-glass" painting, and carried out the subject and its companion, the "Death of Nelson," in that medium, commencing the latter painting in 1844. The application which he gave to these great historic works, and various circumstances connected with the commission, had a serious effect on the artist's health. He began to shun the company in which he formerly delighted; his old buoyancy of
spirits was gone; and when, in 1865, the presidentialship of the Academy was offered to him he declined the honour. He died of acute pneumonia on the 25th of April 1870. His works are distinguished by powerful intellectual and imaginative qualities, but most of them are marred by harshness of style, metallic hardness of surface and texture, and by frequent touches of the theatrical in the action and attitudes of the figures. His fame rests most securely on his two greatest works at Westminster.

A memoir of Maclise, by his friend W. J. O'Driscoll, was published in 1871.

MACLURE, WILLIAM (1763–1840), American geologist, was born at Ayr in Scotland in 1763. After a brief visit to New York in 1782 he began active life as a partner in a London firm of American merchants. In 1796 business affairs took him to Virginia, U.S.A., which he thereafter made his home. In 1803 he visited France as one of the commissioners appointed to settle the claims of American citizens on the French government; and during the few years then spent in Europe he applied himself with enthusiasm to the study of geology. On his return home in 1807 he commenced the self-imposed task of making a geological survey of the United States. Almost every state in the Union was traversed and mapped by him, the Allegheny Mountains being crossed and recrossed some fifty times. The results of his unaided labours were submitted to the American Philosophical Society in a memoir entitled Observations on the Geology of the United States explanatory of a Geological Map, and published in the Society's Transactions (vol. iv. 1809, p. 51) together with the first geological map of that country. This antedates William Smith's geological map of England by six years. In 1817 Maclure brought before the same society a revised edition of his map, and his great geological memoir was issued separately, with some additional matter, under the title Observations on the Geology of the United States of America. Subsequent survey has corroborated the general accuracy of Maclure's observations. In 1819 he visited Spain, and attempted, unsuccessfully, to establish an agricultural college near the city of Alicante. Returning to America in 1824, he settled for some years at New Harmony, Indiana, and sought to develop his scheme of the agricultural college. Failing health ultimately constrained him to relinquish the attempt, and to seek (in 1827) a more congenial climate in Mexico. There, at San Angel, he died on the 23rd of March 1840.

MACMAHON, MARIE EDMÈ PATRICE MARIE DE DUKE OF MAGENTA (1808–1853), French marshal and president of the French Republic, was born on the 13th of July 1808 at the château of Sully, near Autun. He was descended from an Irish family which went into exile with James II. Educated at the military school of St Cyr, in 1827 he entered the army, and soon saw active service in the first French campaign in Algeria, where his ability and bravery became conspicuous. Being recalled to France, he gained renewed distinction in the expedition to Antwerp in 1832. He became captain in 1833, and in that year returned to Algeria. He led daring cavalry raids against plains infested with Bedouin, and especially distinguished himself at the siege of Constantine in 1837. From then until 1855 he was almost constantly in Algeria, and rose to the rank of chief of division. During the Crimean War MacMahon was given the command of a division, and in September 1855 he successfully conducted the assault upon the Malakoff works, which led to the fall of Sebastopol. After his return to France, honours were showered upon him, and he was made a senator. Desiring a more active life, however, and declining the highest command in France, he was once more sent out, at his own request, to Algeria, where he completely defeated the Kabyles. After his return to France he voted as a senator against the unconstitutional law for general safety, which was brought forward in consequence of Orsini's abortive attempt on the emperor's life. MacMahon greatly distinguished himself in the Italian campaign of 1859. Partly by good luck and partly by his boldness and sagacity in pushing forward without orders at a critical moment at the battle of Magenta, he enabled the French to secure the victory. For his brilliant services MacMahon received from the emperor his marshal's baton and was created duke of Magenta. In 1861 he represented France at the coronation of William I. of Prussia, and in 1864 he was nominated governor-general of Algeria. MacMahon's action in this capacity formed the least successful episode of his career. Although he did institute some reforms in the colonies, complaints were so numerous that twice in the early part of 1870 he sent in his resignation to the emperor. When the ill-fated Ollivier cabinet was formed the emperor abandoned his Algerian schemes and MacMahon was recalled.

War being declared between France and Prussia in July 1870, MacMahon was appointed to the command of the Alsatian army detachment (see Franco-German War). On the 6th of August MacMahon fought the battle of Wörth (q.v.). His course was always conspicuous on the field, but the two-to-one numerical superiority of the Germans triumphed. MacMahon was compelled to fall back upon Saverne, and thence to Toul. Though he suffered further losses in the course of his retreat, his movements were so ably conducted that the emperor confided to him the supreme command of the new levies which he was mustering at Chalons and he was directed to effect a junction with Bazaine. This operation he undertook against his will. He had an army of 120,000 men, with 324 guns; but large numbers of the troops were disorganized and demoralized. Early on the 1st of September the decisive battle of Sedan began. MacMahon was dangerously wounded in the thigh, whereupon General Ducrot, and soon afterwards General de Wimpffen, took command. MacMahon shared the captivity of his comrades, and resided at Wiesbaden until the conclusion of peace.

In March 1871 MacMahon was appointed by Thiers commander-in-chief of the armies of the Rhineland; and in that capacity he supported the Communist insurrection, and successfully conducted the second siege of Paris. In the following December he was invited to become a candidate for Paris in the elections to the National Assembly, but declined nomination. On the resignation of Thiers as president of the Republic, on the 24th of May 1873, MacMahon was elected to the vacant office by an almost unanimous vote, being supported by 396 members out of 392.

The duc de Broglie was empowered to form a Conservative cabinet, but the president also took an early opportunity of showing that he intended to uphold the sovereignty of the National Assembly. On the 5th of November 1876 General Charranier presented a motion in the Assembly to confirm MacMahon's powers for a period of ten years, and to provide for a commission of thirty to draw up a form of constitutional law. The president consented, but in a message to the Assembly he declared in favour of a confirmation of his own powers for seven years, and expressed his determination to use all his influence in the maintenance of Conservative principles. After prolonged debates the Septennate was adopted on the 19th of November by 378 votes to 310. There was no coup d'état in favour of "Henri V," as had been expected, and the president resolved to abide by "existing institutions." One of his earliest acts was to receive the finding of the court-martial upon his old comrade in arms, Marshal Bazaine, whose death sentence he commuted to one of twenty years' imprisonment in a fortress. Though MacMahon's life as president of the Republic was of the simplest possible character, his term of office was marked by many brilliant displays, while his wife was a leader in all adoptions of celebrity and fashion.

The president was very popular in the rural districts of France, through which he made a successful tour shortly after the declaration of the Septennate. But in Paris and other large cities his policy soon caused great dissatisfaction, the Republican party especially being alienated by press prosecutions and the attempted suppression of Republican ideas. Matters were at a comparative deadlock in the National Assembly, until the accession of some Orleanists to the Moderate Republican party.
in 1875 made it possible to pass various constitutional laws. In May 1877, however, the constitutional crisis became once more acute. A peremptory letter of censure from MacMahon to Jules Simon caused the latter to resign with his colleagues. The due de Broglie formed a ministry, but Gambetta carried a resolution in the Chamber of Deputies in favour of parliamentary government. The president declined to yield, and being supported by the Senate, he dissolved the Chamber, by decree on the 25th of June. The prosecution of Gambetta followed for a speech at Lille, in which he had said "the marshal must, if the elections be against him, se soumettre ou se démettre.'" In a manifesto respecting the elections, the president referred to his successful government and observed, "I cannot obey the injunctions of the demagogy; I can neither become the instrument of Radicalism nor abandon the post in which the constitution has placed me." His confidence in the result of the elections was misplaced. Notwithstanding the great pressure put upon the constituencies by the government, the elections in October resulted in the return of 355 Republicans and only 108 anti-Republicans, the latter including 30 MacMahonists, 89 Bonapartists, 41 Legitimists, and 38 Orleanists. The president endeavoured to ignore the significance of the elections, and continued his reactionary policy. As a last resort he called to power an extra-parliamentary cabinet under General Rochebouet, but the Republican majority refused to vote supplies, and after a brief interval the president was compelled to yield, and to accept a new Republican ministry under Dufaure. The prolonged crisis terminated on the 14th of December 1877, and no further constitutional difficulties arose in 1878. But as the senatorial elections, held early in 1879, gave the Republicans an effective working majority in the Upper Chamber, they now called for the removal of the most conspicuous anti-Republicans among the generals and officials. The president refused to supersede them, and declined to sanction the law brought in with this object. Perceiving further resistance to be useless, however, MacMahon resigned the presidency on the 30th of January 1879, and Jules Grévy was elected as his successor.

MacMahon now retired into private life. Relieved from the cares of state, his simple and unostentatious mode of existence enabled him to pass many years of dignified repose. He died at Paris on the 17th of October 1893, in his eighty-sixth year. A fine, tall, soldierly man, of a thoroughly Irish type, in private life MacMahon was universally esteemed as generous and honourable; as a soldier he was brave and able, without decided military genius; as a politician he was patriotic and well-intentioned, but devoid of any real capacity for statescraft.

McMaster, John Bach (1852— ), American historian, was born in Brooklyn, New York, on the 29th of June 1852. He graduated from the college of the City of New York in 1872, worked as a civil engineer in 1873—1877, was instructor in civil engineering at Princeton University in 1877—1883, and in 1883 became professor of American history in the university of Pennsylvania. He is best known for his History of the People of the United States from the Revolution to the Civil War (1883 sqq.), a valuable supplement to the more purely political writings of Schuyler, Henry G. and Henry S. Hall.

MacMillan, the name of a family of English publishers. The founders of the firm were two Scotchmen, Daniel Macmillan (1813—1857) and his younger brother Alexander (1818—1866). Daniel was a native of the Isle of Arran, and Alexander was born in Irvine on the 3rd of October 1818. Daniel was for some time assistant to the bookseller Johnson at Cambridge, but entered the employ of Messrs Seeley in London in 1837; in 1843 he began business in Aldersgate Street, and in the same year the two brothers established business of Nicholas Macmillan "and Aucland." As time went on they did not confine themselves to bookselling, but published educational works as early as 1844. In 1845 they became the proprietors of the more important business of Stevenson, in Cambridge, the firm being styled Macmillan, Barclay & Macmillan. In 1850 Barclay retired and the firm resumed the name of Macmillan & Co. Daniel Macmillan died at Cambridge on the 27th of June 1857. In that year an impetus was given to the business by the publication of King'sley's Two Years Ago. A branch office was opened in 1858 in Henrietta Street, London, which led to a great extension of trade. These premises were surrendered for larger ones in Bedford Street, and in 1867 the buildings in St Martin's Street were opened. Alexander Macmillan died in January 1896. By his great energy and literary associations, and with the aid of his partners, there had been built up in little over half a century one of the most important business houses in the world. Besides the issue of many important series of educational and scientific works, they published the works of Kingsley, Huxley, Maurice, Tennyson, Lightfoot, Westcott, J. R. Green, Lord Roberts, Lewis Carroll, and of many other well-known authors. In 1868 they took over the old-established publishing house of R. Bentley & Son, and with it the works of Mrs Henry Wood, Miss Rhoda Broughton, The Ingoldsbys, Legends, and also Temple Bar and the Argosy. In 1893 the firm was converted into a limited liability company, its chairman being Frederick Macmillan (b. 1851), who was knighted in 1900. The American firm of the Macmillan Company, of which he was also a director, is a separate business. See Thomas Hughes, Memoir of Daniel Macmillan (1822); A Bibliography of Macmillan & Co's Publications from 1843 to 1894, with portrait; and the brochures "Life of Lowes Dickinson and Hubert Herkomer," also articles in Le Livre (September 1886), Publishers' Circular (January 14, 1893), the Bookman (May 1901), &c.

MacMonnies, Francis William (1862— ), American sculptor and painter, was born at Brooklyn, New York, on the 26th of September 1863. His mother was a niece of Benjamin West. At the age of sixteen MacMonnies was received as an apprentice in the studio of Augustus St Gaudens, the sculptor, where he remained for five years. In 1884 he went to Paris and thence to Munich, where he painted for some months. Returning to Paris next year he became the most prominent pupil of Falguière. His "Diana" brought him a mention at the Salon of 1889. Three life-sized figures of angels for the church of St Paul, New York, were followed by his "Nathan Hale," in the City Hall Park, New York, and a portrait of James S. T. Stranahan, for Brooklyn. This last brought him a "second medal" at the Salon of 1891, the first time an American sculptor had been so honoured. In 1893 he was chosen to design and carry out the Columbian Fountain for the Chicago World's Fair, which placed him instantly in the front rank. His largest work is a decoration for the Memorial Arch to Soldiers and Sailors, in Prospect Park, Brooklyn, consisting of three enormous groups in bronze. In Prospect Park, Brooklyn, MacMonnies has also a large "Horse Tamer," a work of much distinction. A "Winged Victory" at the U.S. military academy at West Point, New York, is of importance; and his "Bacchante," an extraordinary combination of realism and imagination, rejected by the Boston Public Library, is now at the Metropolitan Museum of Art, New York. He also became well known as a painter, mainly of portraits. In 1888 he married Mary Fairchild, a figure painter of distinction, but in 1909 they were divorced and she married Will H. Low.

MacNaghten, Sir William Hay, Bart. (1793—1847). An Indian diplomatist, was the second son of Sir Francis Macnaghten, Bart., judge of the supreme courts of Madras and Calcutta. He was born in August 1793, and educated at Charterhouse. He went out to Madras as a cadet in 1809, but was appointed in 1816 to the Bengal Civil Service. He early displayed a great talent for languages, and also published several treatises on Hindu and Mahomedan law. His political career began in 1830 as secretary to Lord William Bentinck; and in 1837 he became one of the most trusted advisers of the governor-general. He was a firm supporter of the Charter, and taking the field against Dost Mahommmed, the reigning amir of Kabul, Macnaghten was closely identified. As political agent at Kabul he came into conflict with the military authorities and subsequently with his subordinate Sir Alexander Burnes. Macnaghten attempted to placate the Afghan chiefs with heavy subsidies, but when the drain on the Indian exchequer became too great,
and the allowances were reduced, this policy led to an outbreak. Burns was murdered on the 2nd of November 1811; and owing to the incapacity of the aged General Elphinstone the British army in Kabul degenerated into a leaderless mob. Macnaghten tried to save the situation by negotiating with the Afghan chiefs and, independently of them, with Dost Mohammed’s son, Akbar Khan, by whom he was assassinated on the 23rd of December 1838. The defeat and fall of the British army in the Kurd Kabul pass followed. These events threw doubt on Macnaghten’s capacity for dealing with the problems of Indian diplomacy, though his fearlessness and integrity were unquestioned. He had been created a baronet in 1830, and four months before his death was nominated to the governorship of Bombay.

**MacNally, Leonard** (1735—1820), Irish informer, was born in Dublin, the son of a merchant. In 1776 he was called to the Irish, and in 1783 to the English bar. He supported himself for some time in London by writing plays and editing the Public Ledger. Returning to Dublin, he entered upon a systematic course of informing against the members of the revolutionary party, for whom his house had become the resort. He also betrayed to the government prosecutors political clients whom he defended eloquently in the courts. He made a fine defence for Robert Emmet and cheered him in his last hours, although before appearing in court he had sold, for £500, the contents of his brief to the lawyers for the Crown. After living a professing Protestant all his life, he received absolution on his deathbed from a Roman Catholic priest. He died on the 1st of February 1820.

**Macnee, Sir Daniel** (1866–1882), Scottish portrait painter, was born at Fintry in Stirlingshire. At the age of thirteen he was apprenticed, along with Horatio Macculloch and Leitch the water-colour painter, to John Knox, a landscapist of some repute. He afterwards worked for a year as a lithographer, was employed by the Smiths of Cumnock to paint the ornamental lids of their planedow nut-boxes, and, having studied in Edinburgh at the ‘Trustees Academy,’ supporting himself meanwhile by designing and colouring book illustrations for Lizzars the engraver, he established himself as an artist in Glasgow, where he became a fashionable portrait painter. He was in 1829 admitted a member of the Royal Scottish Academy; and on the death of Sir George Harvey in 1876 he was elected president, and received the honour of knighthood. From this period till his death, on the 18th of January 1882, he resided in Edinburgh, where his genial social qualities and his inimitable powers as a teller of humorous Scottish anecdote rendered him popular.

**MacNeil, Hermon Atkins** (1866— ), American sculptor, was born at Chelsea, Massachusetts. He was an instructor in industrial art at Cornell University in 1886–1889, and was then a pupil of Henri M. Chapu and Falguière in Paris. Returning to America, he aided Philip Martiny in the preparation of sketch models for the Columbian exposition, and in 1896 he won the Rinehart scholarship, passing four years (1896–1900) in Rome. In 1906 he became a National Academician. His first important work was “The Moqui Runner,” which was followed by “A Primitive Chief,” “The Sun Yow,” “all figures of the North American Indian. A “Fountain of Liberty,” for the St Louis exposition, and other Indian themes came later; his “Agnes” and his “Beatrice,” two fine busts of women, also deserve mention. His principal work is the sculpture for a large memorial arch, at Columbus, Ohio, in honour of President McKinley. In 1909 he won in competition a commission for a large soldiers’ and sailors’ monument in Albany, New York. His wife, Carol Brooks MacNeil, also a sculptor of distinction, was a pupil of F. W. MacMonnies.

**McNeile, Hugh** (1795—1879), Anglican divine, younger son of Alexander McNeile (or McNeill), was born at Ballycastle, Co. Antrim, on the 15th of July 1795. He graduated at Trinity College, Dublin, in 1810. His handsome presence, and his promise of exceptional gifts of oratory, led a wealthy uncle, Major-General Daniel McNeill, to adopt him as his heir; and he was destined for a parliamentary career. During a stay at Florence, Hugh McNeile became temporarily intimate with Lord Byron and Madame de Staël. On returning home, he determined to abandon the prospect of political distinction for the clerical profession, and was disinherited. In 1820 he was ordained, and after holding the curacy of Stranorlar, Co. Donegal, for two years, was appointed to the living of Albury, Surrey, by Henry Drummond.

Edward Irving endeavoured, not without success at first, to draw McNeile into agreement with his doctrine and aims. Irving’s increasing extravagance, however, soon alienated McNeile. His preaching now attracted much attention; in London he frequently was heard by large congregations. In 1834 he accepted the incumbency of St Jude’s, Liverpool, where for the next thirty years he wielded great political as well as ecclesiastical influence. He repudiated the notion that a clergyman should be debarred from politics, maintaining at a Alice meeting that “God when He made the minister did not unmake the citizen.” In 1835 McNeile entered upon a long contest, in which he was eventually successful, with the Liverpool corporation, which had been captured by the Whigs, after the passing of the Municipal Reform Act. A proposal was carried that the elementary schools under the control of the corporation should be secularized by the introduction of what was known as the Irish National System. The threatened withdrawal of the Bible as the basis of denominational religious teaching was met by a fierce agitation led by McNeile. He also secured, and public support that before the new system could be introduced every child was provided for in new Church of England schools established by public subscriptions. At the same time he conducted a campaign which gradually reduced the Whig element in the council, till in 1841 it almost entirely disappeared. To his influence was also attributed the defeat of the Liberal parliamentary candidates in the general election of 1837, followed by a long period of Conservative predominance in Liverpool politics. McNeile had the Irish Protestant’s horror of Romanism, which he constantly denounced in the pulpit and on the platform; and Macaulay, speaking in the House of Commons on the Maynooth endowment in April 1845, singled him out for attack as the most powerful representative of uncompromising Protestant opinion in the country. As the Tractarian movement in the Church of England developed, he became one of its most zealous opponents and the most conspicuous leader of the evangelical party. In 1840 he published a volume of Lectures on the Church of England, and in 1846 (the year after Newman’s secession to Rome) The Church and the Churches, in which he maintained with much dialectical skill the evangelical doctrine of the “invisible Church” in opposition to the teaching of Bellamy. Hugh McNeile was in close sympathy with the philanthropic work as well as the religious views of the 7th earl of Shaftesbury, who more than once tried to persuade Lord Palmerston to raise him to the episcopal bench. But although Palmerston usually followed the advice of Shaftesbury in the appointment of bishops, he would not consent to the elevation to the House of Lords of so powerful a political opponent as McNeile, whom Lord John Russell had accused of frustrating for thirty years the education policy of the Liberal party. In 1860 he was appointed a canon of Chester; and in 1865 Disraeli appointed him dean of Ripon. This preferment he resigned in 1875, and he lived in retirement at Bournemouth till his death on the 28th of January 1879. McNeile married, in 1822, Anne, daughter of William Magee, architect of Dublin, and aunt of William Connor Magee, architect of York, by whom he had a large family.

Although a vehement controversialist, Hugh McNeile was a man of simple and sincere piety of character. Sir Edward Russell, an opponent alike of his religious and his political opinions, bears witness to the deep spirituality of his teaching, and describes him as an absolutely unique personality. “He made himself leader of the Liverpool people, and always led with calm and majesty in the most exciting times. His eloquence was grave, flowing, emphatic—had a dignity in delivery, a perfection of elocution, that only John Bright equalled in the latter half of the
19th century. Its fire was solemn force. McNeile's voice was probably the finest orator ever heard in public oratory. His action was as graceful as it was expressive. He ruled an audience."  

MACNEILL, HECTOR (1746-1818), Scottish poet, was born near Roslin, Midlothian, on the 22nd of October 1746, the son of an impoverished army captain. He went to Bristol as a clerk at the age of fourteen, and soon afterwards was despatched to the West Indies with his father. In 1768 he helped his father to the head of the board of admiralty, secretary on board the flagship of Admiral Gery and Sir Richard Bickerton (1727-1792). Most of his later life was spent in Scotland, and it was in the house of a friend at Stirling that he wrote most of his songs and his Scotland's Skaiith, or the History of Will and Jean (1795), a narrative poem intended to show the deteriorating influences of whisky and pottish politics. A sequel, The Wae of War, appeared next year. In 1800 he published The Memoirs of Charles Macpherson, Esq., a novel understood to be a narrative of his own hardships and adventures. A chart of the same theme he published in 1813, and the poems which "Mary of Castlereagh," "Come under my plaidy," "My boy Tammy," "O tell me how to woo," "I love ne'er a lassie but ane," "The plaid amang the hether," and "Jeanie's black e'e," are notable for their sweetness and simplicity. He died at Edinburgh on the 15th of March 1818.  

MACOMB, a city and the county-seat of McDonough county, Illinois, U.S.A., in the W. part of the state, about 60 m. S.W. of Peoria. Pop. (1890), 4052; (1900), 5375 (232 foreign-born); (1910), 5774. Macomb is served by the Chicago, Burlington & Quincy, and the Macomb & Western Illinois railways. The city is the seat of the Western Illinois state normal school (opened in 1902), and has a Carnegie library and a city park. Clay is found in the vicinity, and there are manufactures of pottery, bricks, &c. The city was founded in 1830 as the county-seat of McDonough county, and was called Washington by the settlers, but the charter of incorporation, also granted in 1830, gave it the present name in honour of General Alexander Macomb. Macomb was first chartered as a city in 1856.  

MACOMB, a village of Sardinia in the province of Cagliari, from which it is 95 m. N.N.W. by rail, and the same distance S.W. of Golfo degli Aranci. Pop. (1901), 3488. It is situated 180 ft. above sea-level on the southern ascent to the central plateau (the Campida) of this part of Sardinia; and it is the junction of narrow-gauge lines branching from the main line eastwards to Nuoro and westwards to Bosa. The old parish church of S. Pantaleone has three Roman mile-stones in front of it, belonging to the Roman high-road from Carales to Turris Libisonis. The modern high-road follows the ancient. The district, especially the Campida, is well fitted for grazing and horse and cattle breeding, which is carried on to a considerable extent. It is perhaps richer in nuraghi than any other part of Sardinia.  

MACON, NATHANIEL (1758-1837), American political leader, was born at Macon Manor, Warren county, North Carolina, on the 17th of December 1758. He studied at the college of New Jersey (now Princeton University) from 1774 to 1776, when the institution was closed on account of the outbreak of the War of Independence; served for a short time in a New Jersey militia company; studied law at New York; was a member of a Warren county militia company in 1780-1783, and served in the North Carolina Senate in 1781-1785. In 1786 he was elected to the Continental Congress, but declined to serve. In 1791-1815 he was a member of the national House of Representatives, and in 1815-1828 of the United States Senate. Macon's point of view was always local rather than national. He was essentially a North Carolinian first, and an American afterwards; and throughout his career he was an aggressive advocate of state sovereignty and an adherent of the doctrines of the "Old Republicans." He at first opposed the adoption of the Federal constitution of 1787, as a member of the faction led by Willie Jones (1731-1801) of Halifax, North Carolina, but later withdrew his opposition. In Congress he denounced Hamilton's financial policy, opposed the Jay Treaty (1795) and the Alien and Sedition Acts, and advocated a continuance of the French alliance of 1778. His party came into power in 1801, and he was Speaker of the house from December 1801 to October 1807. At first he was in accord with Jefferson's administration; he approved the Louisiana Purchase, and as early as 1803 advocated the purchase of Florida. For a number of years, however, he was politically allied with John Randolph, as an exponent of strong opposition, he kept Randolph at the head of the important committee on Ways and Means from 1801 to 1806; and in 1805-1808, with Randolph and Joseph H. Nicholson (1770-1817) of Maryland, he was a leader of the group of about ten independents, called the "Quids," who strongly criticized Jefferson and opposed the presidential candidature of Madison. By 1809, however, Macon was again in accord with his party, and during the next two years he was one of the most influential of its leaders. In December 1809 he introduced the resolutions which criticized the ideas of Peter Early (1773-1817) of Georgia, David R. Wilkins of South Carolina, and Samuel W. Dana (1757-1830) of Connecticut with his own. The resolutions recommended the complete exclusion of foreign war vessels from United States ports and the suppression of illegal trade carried on by foreign merchants under the American flag. The substance of these resolutions was embodied in the "Macon Bill, No. 1," which passed the House but was defeated in the Senate. On the 7th of April 1810 Macon reported from committee the "Macon Bill, No. 2," which had been drawn by John Taylor (1770-1832) of South Carolina, and was not actively supported by him. This measure (amended) became law on the 1st of May, and provided for the repeal of the Non-Intercourse Act of 1809, authorized the president, "in case either Great Britain or France shall before the 3rd day of March next so revoke or modify her edicts as that they shall cease to violate the neutral commerce of the United States," to revise non-intercourse against the other, and prohibited British and French vessels of war from entering American waters. In 1812 Macon voted for the declaration of war against Great Britain, and later was chairman of the Congressional committee which made a report (July 1813) condemning Great Britain's conduct of the war. He opposed the Bank Act of 1816, the "internal improvements" policy of Calhoun (in the early part of his career) and Clay, and the Missouri Compromise, his speech against the last being especially able. In 1824 Macon received the electoral vote of Virginia for the vice-presidency, and in 1826-1828 was president pro tempore of the Senate. He was president of the North Carolina constitutional convention in 1833, and was an elector on the Van Buren ticket in 1836. He died at his home, Buck Springs, Warren county, North Carolina, on the 20th of June 1837.  

See William E. Dodd, The Life of Nathaniel Macon (Raleigh, N.C., 1903); E. M. Wilson, The Congressional Career of Nathaniel Macon (Chapel Hill, N.C., 1900).  

MAÇON, a town of east-central France, capital of the department of Saône-et-Loire, 45 m. N. of Lyons on the Paris-Lyon railway. Pop. (1906), 16,531. Maçon is situated on the right bank of the Saône facing the plain of the Bresse; a bridge of twelve arches connects it with the suburb of St Laurent on the opposite bank. The most prominent building is the modern Romanesque church of St Pierre, a large three-naved basilica, with two fine spires. Of the old cathedral of St Vincent (12th and 13th centuries), destroyed at the Revolution, nothing remains but the Romanesque narthex, now used as a chapel, the façade and two flanking towers. The hôtel de ville contains a library, a theatre and picture-gallery. Opposite to it stands a statue of the poet Alphonse Lamartine, a native of the town. Maçon is the seat of a prefecture, and has tribunals of first instance, of commerce, and a chamber of commerce. There are 1Their names are associated in Randolph-Macon College, named in their honour in 1930.
lycees and training colleges. Copper-founders is an important industry; manufactures include casks, mats, rope and utensils for the wine-trade. The town has a large trade in wine of the district, known as Macon. It is a railway centre of considerable importance, being the point at which the line from Paris to Marseilles is joined by that from Mont Cenis and Geneva, as well as by a branch from Moulins.

Macon (Maîte) was an important town of the Aedui, but under the Romans it was supplanted by Autun and Lyons. It suffered a succession of disasters at the hands of the Germans, Burgundians, Vandals, Huns, Hungarians and even of the Carolingian kings. In the feudal period it was an important countship which in 1228 was sold to the king of France, but more than once afterwards passed into the possession of the dukes of Burgundy, until the ownership of the French crown was established in the time of Louis XI. In the 16th century Macon became a stronghold of the Huguenots, but afterwards fell into the hands of the League, and did not yield to Henry IV. until 1594. The bishopric, created by King Childebert, was suppressed in 1700.

MACON, a city and the county-seat of Bibb county, Georgia, U.S.A., in the central part of the state, on both sides of the Ocmulgee river (at the head of navigation), about 90 m. S.E. of Atlanta. Pop. (1900), 23,272, of whom 11,550 were negroes; (1910 census) 40,665. Macon is, next to Atlanta, the most important railway centre in the state, being served by the Southern, the Central of Georgia, the Georgia, the Georgia Southern & Florida, the Macon & Birmingham railways. It was formerly an important river port, especially for the shipment of cotton, but lost this commercial advantage when railway bridges made the river impassable. It is, however, partially regaining the river trade in consequence of the compulsory substitution of drawbridges for the stationary railway bridges. The city is the seat of the Wesleyan female college (1836), which claims to be the first college in the world chartered to grant academic degrees to women; Mercer University (Baptist), which was established in 1833 as Mercer Institute at Penfield, became a university in 1837, was removed to Macon in 1871, and controls Hearn Academy (1839) at Cave Spring and GibsonMercer Academy (1903) at Bowman; the state academy for the blind (1852), St Stanislaus' College (Jesuit), and Mt de Sales Academy (Roman Catholic) for women. There are four orphan asylums for whites and two for negroes, supported chiefly by the Protestant Episcopal and Methodist Churches, and a public hospital. Immediately east of Macon are two large Indian mounds, and there is a third mound south of the city. Situated in the heart of the "Cotton Belt," Macon has a large and lucrative trade; it is one of the most important inland cotton markets of the United States, its annual receipts averaging about 250,000 bales. The city's factory products in 1905 were valued at $7,297,347 (33.8% more than in 1900). In the vicinity are large beds of kaolin, 30 m. wide, reaching nearly across the state, and frequently 35 to 70 ft. in depth. Macon is near the fruit-growing region of Georgia, and large quantities of peaches and garden products are annually shipped from the city.

Macon (named in honour of Nathaniel Macon) was surveyed in 1823 by order of the Georgia legislature for the county-seat of Bibb county, and received its first charter in 1824. It soon became the centre of trade for Middle Georgia; in 1833 a steam-boat line to Darien was opened, and in the following year 69,000 bales of cotton were shipped by this route. During the Civil War the city was a centre for Confederate commissary supplies and the seat of a Treasury depository. In July 1864 General George Stoneman (1822-1894) with 500 men was captured near the city by the Confederate general, Howell Cobb. Macon was finally occupied by Federal troops under General James H. Wilson (b. 1837) on the 20th of April 1865. In 1900-1910 the area of the city was increased by the annexation of several suburbs.

MACPHERSON, SIR DAVID LEWIS (1818-1896), Canadian financier and politician, was born at Castle Leathers, near Inverness, Scotland, on the 21st of September 1818. In 1835 he emigrated to Canada, settling in Montreal, where he built up a large fortune by "forwarding" merchandise. In 1853 he removed to Toronto, and in the same year obtained the contract for building a line of railway from Toronto to Sarnia, a project for which he raised $250,000. He sold his interest in the construction of which line he greatly increased his wealth. In 1864 he was elected to the Canadian parliament as member of the Legislative Council for Saugeen, and on the formation of the Dominion, in 1867, was nominated to the Senate. In the following years he published a number of pamphlets on economic subjects, of which the best-known is Banking and Currency (1866). In 1880 he was appointed Speaker of the Senate, and from October 1883 till 1885 was minister of the interior in the Conservative cabinet. In 1884 he was knighted by Queen Victoria. He died on the 16th of October 1896.

MACPHERSON, JAMES (1736-1796), Scottish "translator" of the Ossianic poems, was born at Ruthven in the parish of Kingsussie, Inverness, on the 27th of October 1736. He was sent in 1753 to King's College, Aberdeen, remaining two years later to Marischal College. He also studied at Edinburgh, but took no degree. He is said to have written over 4000 lines of verse while a student, but though some of this was published, notably The Highlander (1758), he afterwards tried to suppress it. On leaving college he taught in the school of his native place. At Mollat he met John Home, the author of Douglas, for whom he recited some Gaelic verses from memory. He also showed him MSS. of Gaelic poetry, supposed to have been picked up in the Highlands, and, encouraged by Home and others, he produced a number of pieces translated from the Gaelic, which he was induced to publish at Edinburgh in 1760 as Fragments of Ancient Poetry collected in the Highlands of Scotland. Dr Hugh Blair, who was a firm believer in the authenticity of the poems, got up a subscription to allow Macpherson to pursue his Gaelic researches. In the autumn he set out to visit western Inverness, the islands of Skye, North and South Uist and Benbecula. He obtained MSS. which he translated with the assistance of Captain Morrison and the Rev. A. Gallie. Later in the year he made an expedition to Mull, when he obtained other MSS. In 1761 he announced the discovery of an epic on the subject of Fingal, and in December he published Fingal, an Ancient Epic Poem in Six Books, together with Several Other Poems composed by Ossian, the Son of Fingal, translated from the Gaelic Language, written in the musical measured prose of which he had made use in his earlier volume. Temora followed in 1763, and a collected edition, The Works of Ossian, in 1765. The poems were generally collected together from the works of a 3rd-century bard was immediately challenged in England, and Dr Johnson, after some local investigation, asserted (Journey to the Western Islands of Scotland, 1775) that Macpherson had only found fragments of ancient poems and stories, which he had woven into a romance of his own composition. Macpherson is said to have sent Johnson a challenge, to which Johnson replied that he was not to be deterred from detecting what he thought a cheat by the menaces of a ruflian. Macpherson never produced his originals, which he refused to publish on the ground of the expense. In 1763 he was made secretary to General Johnstone at Pensacola, West Florida, and when he returned, two years later, to England, after a quarrel with Johnstone, he was allowed to retain his salary as a pension. He occupied himself with writing several historical works, the most important of which was Original Papers, containing the Secret History of Great Britain from the Restoration to the Accession of the House of Hanover, to which are prefixed Extracts from the Life of James II., as written by himself (1775). He enjoyed a salary for defending the policy of Lord North's government, and held the lucrative post of London agent to Mohamed Ali, nabob of Arcoct. He entered parliament in 1786, and continued to sit until his death. In his later years he bought an estate, to which he gave the name of Belville, in his native county of Inverness, where he died on the 17th of February 1796.

After Macpherson's death, Malcolm Laing, in an appendix to his History of Scotland (1800), pronounced the extreme view that
the so-called Ossianic poems were altogether modern in origin, and that Macpherson's authorities were practically non-existent. For a discussion of this question see Celt: Scottish Gaelic Literature. Much of Macpherson's matter is clearly his own, and he confounds the stories belonging to different peoples. But apart from the doubtful morality of his transactions he must still be regarded as one of the great Scottish writers. The varied sources of his work and its worthlessness as a transcript of actual Celtic poems do not alter the fact that he produced a work of art which by its deep appreciation of natural beauty and the melancholy tenderness of its invention of ideas did more than any single work to bring about the romantic movement in both English and European, and especially in German, literature. It was speedily translated into many European languages, and Herder and Goethe (in his earlier period) were among its profound admirers. Cesarotti's Italian translation was one of Napoleon's favourite books.

AUTHORITIES.—For Macpherson's life, see The Life and Letters of James Macpherson (1854, new ed. 1866) by T. Bailey Saunders, who has laboured to redeem his character from the suspicions generally current with English readers. The antiquity of the Ossianic poems was defended in the introduction by Archibald Clouston's Poems of Ossian (1786); by W. H. Falconer's Poems of Ossian (1790); by T. Baillie's Poems of Ossian (1794); and by J. G. Lockhart's Poems of Ossian (1808). Arriving at a decision by comparison with undoubtedly genuine fragments of the Ossianic legend are available in Die Book of the Deaie of Ossian (1809), Gaelic verses collected by MacGregor, dean of Lismore, in the early 16th century (ed. T. McLauchlan; London, 1862); the French work of F. J. Campbell, who also discusses the subject in Popular Tales of the Western Highlands, iv. (1893). See also L. C. Steinitz, "On the不死mibility of Macpherson's Fragments," in Revue de l'Institut de l'ptérum (1895). C. J. S. Smart, James Macpherson: an Episode in Literature (1905).

MacPHERSON, JAMES BIRDSEYE (1828–1864), American soldier, was born at Sandusky, Ohio, on the 14th of November 1828. He entered West Point at the age of twenty-one, and graduated (1853) at the head of his class, which included Sheridan, Schofield and Hood. He was employed at the military academy as instructor of practical military engineering (1853). A year later he was sent to engineer duty at New York, and in 1857, after constructing Fort Delaware, he was sent as superintendent engineer to San Francisco, becoming 1st lieutenant in 1858. He was promoted captain during the first year of the Civil War, and towards the close of 1861 became lieutenant-colonel and aide-de-camp to General Halleck, who in the spring of 1862 sent him to General Grant as chief engineer. He remained with Grant during the Shiloh campaign, and acted as engineer adviser to Halleck during the siege operations against Corinth in the summer of 1862. In October he distinguished himself in command of an infantry brigade at the battle of Corinth, and on the 8th of this month was made major-general of volunteers and commander of a division. In the second advance on Vicksburg (1863), Macpherson commanded the XVII corps, fought at Port Gibson, Raymond and Jackson, and after the fall of Vicksburg was strongly recommended by Grant for the rank of brigadier-general in the regular army, to which he was promoted on the 1st of August 1863. He commanded at Vicksburg until the following spring. He was about to go on leave of absence in order to be married in Baltimore when he received his nomination to the command of the Army of the Tennessee, Grant's and Sherman's old army, which was to take part under Sherman's supreme command in the campaign against Atlanta. This nomination was much disliked both in the army and entirely approved by Grant, who had the highest opinion of MacPherson's military and personal qualities. He was in command of his army at the actions of Resaca, Dallas, Kenesaw Mountain and the battles about Atlanta. On the 22nd of July, when the Confederates under his old classmate Hood made a sudden and violent attack on the lines held by the Army of the Tennessee, Macpherson rode up, in the woods, to the enemy's firing line and was killed. He was one of the most heroic figures of the American Civil War, and Grant is reported to have said when he heard of Macpherson's death, "The country has lost one of its best soldiers, and I have lost my best friend."

MACQUARIE, a British island in the South Pacific Ocean, in 4°49' S. and 159°49' E. It is about 20 m. long, and covered with a grassy vegetation, with some trees or shrubs in the sheltered places which afford food to a parrot of the genus Cyanoro- rhampus, allied to those of the Auckland Islands. Although it has no settled population, Macquarie is constantly visited by sailors in quest of the seals which abound in its waters.

MACRAUCHENIA, a long-necked and long-limbed, three-toed South American ungulate mammal, typifying the suborder Litopterna (q.v.).

MACREADY, WILLIAM CHARLES (1793–1872), English actor, was born in London on the 3rd of March 1803, and educated at Rugby. It was his intention to go up to Oxford, but in 1809 the embarrased affairs of his father, the lessee of several provincial theatres, called him to share the responsibilities of theatrical management. On the 7th of June 1810 he made a successful first appearance as Romeo at Birmingham. Other Shakespearian parts followed, but a serious rupture between father and son resulted in the young man's departure for Bath in 1814. Here he remained for two years, with occasional visits to other provinces. On the 16th of September 1816, Macready made his first London appearance at Covent Garden as Orestes in The Distressed Mother, a translation of Racine's Andromaque by Ambrose Philips. Macready's choice of characters was at first confined chiefly to the romantic drama. In 1818 he won a permanent success in Isaac Pocock's (1782–1835) adaptation of Scott's Rob Roy. He showed his capacity for the highest tragedy when he played Richard III. at Covent Garden on the 25th of October 1819. Transferring his services to Drury Lane, he gradually rose in public favour, his most conspicuous success being in the title-role of Sheridan Knowles's William Tell (May 11, 1825). In 1826 he completed a successful engagement in America, and in 1828 his performances met with a very flattering reception in Paris. On the 15th of December 1830 he appeared at Drury Lane as Werner, one of his most powerful impersonations. In 1833 he played in Antony and Cleopatra, in Byron's Sardanapalus, and in King Lear. Already Macready had done something to encourage the creation of a modern English drama, and after entering on the management of Covent Garden in 1837 he introduced Robert Browning's Strafford, and in the following year Bulwer's Lady of Lyons and Richelieu, the principal characters in which were among his most effective parts. On the 90th of June 1838 he gave a memorable performance of Henry V., for which Stanfield prepared sketches, and the mounting was superintended by Bulwer, Dickens, Forster, Maclise, W. J. Fox and other friends. The first production of Bulwer's Money took place under the artistic direction of Count d'Orrsay on the 8th of December 1840. Macready winning unmistakable success in the character of Alfred Evelyn. Both in his management of Covent Garden, which he resigned in 1839, and of Drury Lane, which he held from 1841 to 1843, he found his designs for the elevation of the stage frustrated by the absence of adequate public support. In 1843–1844 he made a prosperous tour in the United States, but his last visit to that country, in 1849, was marred by a riot at the Astor Opera House, New York, arising from the jealousy of the actor Edwin Forrest, and resulting in the death of seventeen persons, who were shot by the military called out to quell the disturbance. Macready took leave of the stage in a farewell performance of Macbeth at Drury Lane on the 26th of February 1851. The remainder of his life was spent in happy retirement, and he died at Cheltenham on the 27th of April 1873. He had married, in 1823, Catherine Frances Atkins (d. 1852). Of a numerous family of children only one son and one daughter survived. In 1860 he married Cecile Louise Frederica Spencer (1827–1908), by whom he had a son. Macready's performances always displayed fine artistic perceptions developed to a high degree of perfection by very comprehensive culture, and even his least successful personations had the interest resulting from thorough intellectual
study. He belonged to the school of Kean rather than of Kemble; but, if his tastes were better disciplined and in some respects more refined than those of Kean, his natural temperament did not permit him to give proper effect to the great tragic parts of Shakespeare, 'King Lear' perhaps excepted, which afforded scope for his pathos and tenderness, the qualities in which he specially excelled. With the exception of a voice of good compass and capable of very varied expression, Macready had no especial physical gifts for acting, but the defects of his face and figure cannot be said to have materially affected his success.

MACROBIUS, AMBROSIUS THEODOSIUS, Roman grammarian and philosopher, flourished during the reigns of Honorius and Arcadius (395-423). He himself states that he was not a Roman, but there is no certain evidence whether he was of Greek or perhaps African descent. He is generally supposed to have been praetorian prefect in Spain (399), proconsul of Africa (410), and lord chamberlain (422). But the tenure of high office at that date was limited to Christians, and there is no evidence in the writings of Macrobius that he was a Christian. Hence the identification is more than doubtful, unless it be assumed that his conversion to Christianity was subsequent to the composition of his books. It is possible, but by no means certain, that he was the Theodosius to whom Avitus dedicates his fables.

The most important of his works is the *Saturnalia*, containing an account of the discussions held at the house of Vetutius Praetextatus (c. 325-385) during the holiday of the Saturnalia. It was written by the author for the benefit of his son Eustathius (or Eustachius), and contains a great variety of curious historical, mythological, critical and grammatical disquisitions. There is but little attempt to give any dramatic character to the dialogue; in fact, it is almost a commentary on the passage of the ancient orator, with the marked difference that the extract of the phrase is stated in prose, but the remarks of the others serve only as occasions for calling forth fresh displays of erudition. The first book is devoted to an inquiry as to the origin of the Saturnalia and the festivals of Janus, which leads to a history and discussion of the Roman calendar, and to an attempt to derive all forms of worship from that of the sun. The second book begins with a collection of *bons mots*, to which all present make their contributions, many of them being ascribed to Cicero and Augustus; a discussion of various pleasures, especially of the senses, then seems to have taken place, but almost the whole of this is lost. The third, fourth, fifth and sixth books are devoted to Virgil, dwelling respectively on his learning in religious matters, his rhetorical skill, his debt to Homer (with a comparison of the art of the two) and to other Greek writers, and the nature and extent of his borrowings from the earlier Latin poets. The latter part of the third book is taken up with a dissertation upon luxury and the sumptuary laws intended to check it, which is probably a dislocated portion of the second book. The seventh book consists largely of the discussion of various physiological questions. The value of the work consists solely in the facts and opinions quoted from earlier writers, for it is purely a compilation, and has little in its literary form to recommend it. The form of the *Saturnalia* is copied from Plato's *Symposium* and Galli/us's *Noctes Atticae*; the chief authorities (whose names, however, are not quoted) are Galli/us, Seneca the philosopher, Plutarch (*Quaestiones Convivialae*), Athenaeus and the commentaries of Servius (excluded by some) and others on Virgil. We have also two books of a commentary on the *Somnium Scipionis* narrated by Macrobius in his *De republica*. The nature of the dream, in which the elder Scipio appears to his (adopted) grandson, and describes the life of the good after death and the constitution of the universe from the Stoic point of view, gives occasion for Macrobius to discourse upon many points of physics in a series of essays interesting as showing the astronomical notions then current. The moral elevation of the fragment of Cicero thus preserved to us gave the work a popularity in the middle ages to which its own merits have little claim. Of a third work,
MADAGASCAR

misery of his existence in a cave. In all these scenes, or rather anticipatory dreams, Adam, Eve, and the arch-foe Lucifer are the chief and constantly recurring personae dramatis.

In the end, Adam, despairing of his race, wants to commit suicide, when at the critical moment Eve tells him that she is going to be a mother. Adam then prostrates himself before God, who encourages him to hope and trust. The diction of the drama is elevated and pure, and although not meant for the stage, it has proved very effective at several public performances.

Concerning Madagascar there is ample literature, consisting mostly of elaborate articles by Charles Sabas (1862), Augustus Greguss (1872), B. Alexander (1871), M. Palägyi (1890), and others.

MADAGASCAR, an island in the Indian Ocean, and after New Guinea and Borneo the largest island in the world, about 260 m. distant, at the nearest point, from the S.E. coast of Africa, from which it is separated by the Mozambique Channel. Since 1896 Madagascar has been a French colony. It is 995 m. in length from N. to S., and about 250 m. in average breadth, although near the centre it is nearly 360 m. across; its area is about 228,000 sq. m., or not quite four times the extent of England and Wales. It lies mainly between 44° and 50° E. Its northermost point, Cape Ambro, in 12° S., inclines 16° to the E. from the longitude of Cape St Mary, the southermost point, in 25° 35' S., so that the main axis of the island runs from N.N.E. to S.W. In its broad structure Madagascar consists of an elevated mountainous region, from 3000 to 5000 ft. in altitude, occupying from two-thirds to a half of the centre and the eastern side of the island, around which are coasted the islands, which lie much below the level above the sea, and most developed on the western and north-west sides. But this lower region is broken up by masses of hills, with several elevated plateaus, especially in the south-west and south.

Physical Features.—Madagascar has a very regular and compact form, with few indentations considering its great extent of shore-line. In general outline it has a strong resemblance to the impression of a human foot—the left side. Along two-thirds of its eastern side the coast is almost uniformly the southernmost and longest coast of any island, in Madagascar the north-west angle of the island, the coast-line is unbroken until the estuary of the river Onilàhì, or St Augustine's Bay, is reached. Rounding the southern end of the island, there is no other inlet so wide as that of Port Louis, and at the southern end of the straight line of coast already mentioned.

The islands around Madagascar are few and unimportant. The largest of them is the island of Nosy-be, an island about 35 m. long, and Nosy (g.v.), larger and more compact in form, opposite Ampasindàáva Bay on the N.W. coast. Except the Minnow group, north of Nosy-be, the rest are merely rocky islets, chiefly of coral.

The shores of the greater portion of the southern half of the island are low and flat, but in the northern half the coast is often bold and precipitous, the high land occasionally approaching the sea. On the eastern side the plains vary from 10 to 50 m. in breadth, but on the western side they exceed in some localities 100 m. From these coast-plains the ground rises by successive ranges of hills to the high interior, which is almost continuous in a ring from north to south, from the Andringitra mountains, from which the crystalline rocks show most frequently as huge bosses, and in certain regions present very varied and picturesque outlines, resembling Those cathedrals, domes, pyramids and spires. The highest mountain mass is centred situated as regards the length of the island, but more to the eastern side. This is the ancient extinct volcano Ankaranà, three of the highest points which have been named after the capital, or above the sea level, from 4000 to 5000 ft. above the general level of the surrounding country. The loftiest of these is named Tsi-ifa-jàvona, 'That which the men of the sea (or Moon) built.' It had been supposed that Ankarana was the highest point in the island, but a meteorological station in the northern province of Antananarivo, is about 4950 ft. in altitude. Besides these highest points there are a considerable number of mountain summits, which are with a few exceptions intervening and surrounding districts; and in the Bârssā country the Isalo range has been compared to the 'Church Buttes' and other striking features of the scenery of Utah. One of the finest of the Madagascar mountains is an isolated mass near the northern point of the island called Ambôbhà. This is 4450 ft. high, and rising from land little above the sea-level, is well seen far out to sea.

In the elevated region of Madagascar are many fertile plains and valleys, the former being the dried-up beds of ancient lakes. Among these depressions, two of the largest, Mananantara and Mânatàra, are inhabited. The latter is supplied with a large proportion of the rice required for the capitals of these two provinces. Still more spacious valleys are the Antsinda and Mafa, the former of which, by its connexion with the two eastern lines of forest. The extensive coast plains on the western side of the island are chiefly in Bômà (N.W.) and in M截止 (S. of the Tari-bhina River); those on the east are widest in the TamàfAns country and the south-west, although the latter is much the most elevated, the island is much nearer the eastern than the western side, averaging from 80 to 90 m. from the sea. There are no arid districts. The barrier between the vast interior and the southern point of the island, the general surface of the interior being that of bare rolling moor-like country, with a great amount of red clay-like soil, while the valleys have a rich humus of bluish-black alkali.

The chief rivers flow to the west and north-west sides of the island. The eastern streams are all less in size, except the Mangkarò, which flows north with the coast. Few of them therefore are of much service for navigation, except for the light-draught native canoes; and all of them are more or less closed at their outlets by sand-bars. Beginning at the south-eastern point and going northwards, the loom or rivers are the Ampasindàáva, the Tsimandraka, the Mânànjàráry, Mangkarò, with its great affluent Onitê, Vóbìta, Mânañjàráry, and the Antanambàlara at the point of Antongîl Bay. On the N.W. coast, going southwards, are the Sofalà and Mâhàjamba, falling into the Bômà; the Mahàbôka, which flows into the Bômà, having few drains of the northern central provinces, forming unitively the second largest river of the island and falling into Bômàtâbôka Bay—the largest river in the island. The Mânànjàráry is the third largest river, with its tributaries the Kèsémba, Mâhàjôllo and Môrondâá, Mangkarò, probably the largest river in the country, with its important tributaries the MâsÌtJavascript, Mânànantàna and Ràmmàntà, the Fôhêntàna and Onilàhì. On the south coast there are four considerable streams, the largest of which is the Mânànantàna. Of the western rivers the Bômàbôka can be ascended by small vessels for about 300 ft., and the Mangkarò is also navigable for a considerable distance. The former is about 182 m. long, but the latter somewhat less, but by its affluent spreads over a greater extent of country, as also does the Mangkarò. The rivers are all crossed frequently by rocky fòmbà, and in the eastern rivers cut their way through the ramparts of the high land by magnificent gorges amid dense forest, and descend by a succession of rapids and waterfalls.

On the eastern side of Madagascar the contest between the fresh water of the rivers and the sea has caused the formation of a chain of lagoons for nearly 300 m. In many places these like rock following the coast-line, but frequently they spread out into extensive fresh water lakes, while in places they spread inland, at the mouth of them, a continuous waterway could be formed for 270 m. along the coast. This has already been done for about 55 m. between Îvônjâna and Marâmbìtsy Bay, and the latter is only the beginning of a chain of lagoons, for there are many small lakes of that kind, although the islands in these lagoons, are few, are lakes of any size in Madagascar, although there were some very extensive lakes in a recent geological epoch. Platanus and volcanoes in the district of Antsikahàna are the relic; it is about 25 m. long. Next comes Kìnkônjó, near Marâmbìtsy Bay (N.W. coast), about 16 m. long, and then Itáy, in western Iméranà, about 12 m. large. There is also a salt lake, Tsaânmâmpéta (S.W. coast), about as large as Alâëfàtara.

There is now no active volcano in Madagascar, but a large number of extinct cones are found, some apparently of very recent formation. The highest, in the south-east of the island, is Ampasind bride, with scores of subsidiary cones on its slopes and around its base. About 40 m. south-west of Antanàranàliva there is a still larger extinct volcano, Ankaràatra, with an extensive lava field surrounding it; while the Lake Itáy are some 200 volcanic cones. Another group of extinct volcanoes is in the Vâkànumàntàna district, S.W. of Antanàranàliva. Many others exist in other parts of the island (see § Geology). The climate of Madagascar is tropical, and in one year, and hot springs occur at many places. Several of these are sulphurous and medicinal, and have been found efficacious in skin diseases and in internal complaints.

Geology.—Madagascar may be divided into two very distinct geological regions. The first was found by Dr. H. D. B. Schneidt, and includes the central and eastern portions of the island and occupies about two-thirds of its whole area, and is composed of crystalline schists; the second portion, the western mountains, are composed of granites, and those in the western highlands include the crystalline rocks, including the Andringitra mountains, which are the main part of the third island, in the centre of the island, and the so-called Bômà and the isolated patch of Archean rocks, near Cape St Andrew. There are also found in both regions numerous masses of igneous rocks, both mountainous and in the form of plateaus and volcanic in the western region, as the extent, which pierce through and overflow the earlier formations.
1. The Archean Region.—This region, nearly coincident with the mountainous upper portion of the island, is chiefly composed of the following crystalline rocks: gneiss, which is the most common of them all, quartzite and quartzite-schist, with occasional beds of crystalline limestone and mica-schist, although this latter rock is very rare. The gneiss is mostly grey, but occasionally pinkish, its essential constituents (felspar and quartz) being almost always associated with dark mica (biotite) and hornblende in variable quantity. The rock is therefore a hornblende-granite-gneiss. Granite—more to S.S.W.), but in its western portion the strike is frequently from N.N.W. to S.S.E. In both cases the strike of the rocks is coincident with the direction of the valley walls, and therefore not at right angles with the strike of the crystalline rocks. Almost the whole of this region is covered by a red soil, often of great thickness, which resembles and is often described as "clay," but is really decomposed rock, chiefly gneiss, reddened with oxidized iron, and containing impurities of felspar, mica, hornblende, and quartz.

II. The Sedimentary Region.—The sedimentary rocks extend continuously along the western side of Madagascar, following the coastline; in the north these series of strata are only from 20 to 30 m. across, but farther south they reach a breadth of nearly 100 m., while opposite the Betsileo province they extend nearly half across the island. A narrow band, of Cretaceous age, occurs also on the east coast, for about 120 m. between Vatomandry and Manganjary. The following formations are represented:

1. Primary. It is the fact that certain beds of slaty rocks, which have been recognized at different places, may belong to some of the Primary strata. Some silicious schists of the Permian age were discovered in 1908 in the valley of the Sekamena, south of the Onilhà, or Augustine river. (S.W. coast). These contain reptilian remains, and also clear imprints of leaves of "Glossopteris." The Secondary and Tertiary formations, as well as other indications of an ancient vegetation, in the same region conglomerates have been found containing enormous blocks, apparently brought by glacial action, and said to be identical in character with those described as existing in the Transvaal. True coal has also been obtained in the same district, the deposits varying from a third to half a metre in thickness.

2. Secondary. The lowest members of these rest directly upon the central mass of crystalline rocks, and consist of sandstones, conglomerates, and shales, which have been supposed to belong to the Trias, without, however, the discovery of any fossil necessary to confirm this supposition, except some silicified trunks of trees. These beds are the most probably lower members of the Jurassic series. Westward of and above these strata, the Middle and Upper Jurassic formations are found (Lias, Lower Oolite, Oxfordian, &c.), with well-marked and numerous fossils (Ammonites, Nereites, Nautilus, Astarte, Rhyginoceras, Echinoderma, &c.); then the Cretaceous rocks, both these and the Jurassic series being largely developed, the Cretaceous fossils including Nautilus, Bulimina, Ostrea, Gryphaea, &c., and some very large Ammonites (Pathysteus). The Secondary strata show generally a very slight dip westwards and are consequently almost horizontal. They do not seem to have been greatly disturbed, although faults occur here and there.

3. Tertiary. A small strip of coast of Eocene age is known near Tulier (S.W. coast), and rocks of the same period occur in Nosy Be, in Mahambo Bay, and at Diego-Suarez, with Nummulites and other foraminifers. Near the latter locality, beds of Oligocene age have been noticed, consisting of coarse limestones.

4. Quaternary and Recent. A narrow band of these deposits extends along the west coast, from north of Cape St Andrew westward to the extreme southern point of the island. But the most noticeable of these are those in the ancient bed of the Alatara Lake, which formerly extended far southwards along the valley of the Mangoro; also those in the marshes of Antsirabe and of Ifanjà, in the Iôka valley (the great rice plain west of the capital), and also in the plain of Taî at Iôka and Betsiolo, and especially the recent deposits of Ampasambazinâ, north-west of Lake Taî, discovered in 1902. These beds, rich in sub-fossil remains, have yielded important additions to our knowledge of the extinct fauna of the island. (See § Palæontology.)

Igneous Rocks. (1) Plutonic rocks.—The ancient or plutonic igneous rocks (including granite, syenite, diorite, gabbro, porphyry, porphyrite, norite and riehinite) appear at various points of the two previously described regions. In the Archean region, granite is very often found passing into granite, but certain granite masses have a sufficiently distinct character. In the midst of the sedimentary region are two well-recognized masses of plutonic rocks, belonging to the syenites, sometimes quartziferous in structure. (2) Volcanic rocks.—Recent volcanic eruptive rocks (including rhyolite, trachyte, phonolite, andesite and basalt) have been examined at a number of points throughout both the geological regions of the island. In
The archaic region these are very noticeable near Lake Itasy, in the region of Antalaha, and in the vicinity of the village of Mahavavy (at Betâlo, Antsalabâ, &c.), and there are numerous outflows of dolerite rocks, probably from faults, along the eastern side of the island and almost parallel with the coast line. In the sedimentary regions, there is a clay belt (between the east coast and the interior) which is very narrow; in the south there is a tract of country, more than 80 m. long, on the west coast, where the basin has overflowed the Cretaceous strata. It must be remembered that the geology of Madagascar is still only known in its broad features.\(^1\)

**Metals and Minerals.**—The country has considerable mineral wealth. Gold is found almost all over the region of crystalline rocks, exclusive of the Anais Mountains, the highest of which is a remarkable district being a band of country parallel with the east coast and spreading at its southern end into the interior; and another tract, whose contour is about 100 m. N. of the capital (see § Industries, &c.). Silver has been detected in certain galenas, and also platinum; copper has been found in various localities, as well as zinc, lead, nickel, antimony and manganese, but none of these metals has yet been discovered in sufficient quantities for profitable working. Iron, on the contrary, especially magnetite, is found abundantly and has for long been worked by the Malagasy with the simple appliances brought by their ancestors from their original home in the Far East. The principal seats of the native industry are on the edge of the upper forest, where charcoal is easily prepared. The following precious stones are reported: corundum (rubies and sapphires), beryl (topazes and aquamarines), tanzanites, large crystals, and variously coloured quartz, also found in crystals of great size. Bitumen and petroleum have been found; graphite is plentiful, and sulphur, salt, salt-petre and lime are also produced. The mineral wealth of the western coast probably diminishes towards the interior, and coal has been found in the valley of the Sakamâra.

**Zoology.**—The fauna of Madagascar, while deficient in most of the characteristic tropical forms of life, is of great interest to the ornithologist from its remote affinities, much of its animal life being of Asiatic origin and having no connexion with the southern parts of Africa. Some popular and many others are probably contemporaneous with the earliest human inhabitants of Madagascar. The remoter and northern parts of the island, as those of several species of small Rodents, also of a Carnivore (Cryptoprocta), a larger variety of the species still living in the island.

In the deposits of a much more remote era than those already spoken of—-the Jurassic—the bones of some enormous terrestrial lizards have been brought to light, belonging to Sauropodous Dinosaurs of the genera *Barosaurus* and *Titanosaurus*, and to a Theropod of the genus *Mesosaurus*. In the beds of the Lower Oolite portions of the skull of a reptile resembling the gavial of the Ganges had been previously discovered, from which a new genus called *Samosaurus* has been described. Since the French occupation numerous fossils (1853) considerable additions have been made to our knowledge of the fossil fauna of Madagascar from researches made both on the west and eastern coasts. Twenty-nine figures of birds (ducks and sixty-six species), half of which are endemic. Many of these birds are remarkable not so much for their shape or colouring as for their distant relationships; many belong to peculiar genera, and some are so isolated that new families have had to be formed for their accommodation: the number of species of birds is, however, much more numerous, and includes several species of brilliant plumage—sun-birds, kingfishers, rollers and fly-catching, &c., tits, hawks and owls are numerous, and the lakes and marshes abound with water-fowl and wading birds.

The island is free from deadly serpents, but contains two or three

---

\(^1\) For most of the information here given on the geology the writer is indebted to Captain Mouneyres, chef de services des mines, and the Rev. R. Baron, F.G.S., F.L.S.

\(^3\) Following some recent work, kindly supplied by the Rev. E. Colin, S. J., director of the observatory; Diogo-Suarez, N. 79; Fârafânàgâ, S.E. coast, 75; Mârovolô, W. intr., 81; Morondava, W. coast, 77; Tullêr, S.W. coast, 78.
small species of boa; crocodiles abound in the rivers and lakes; and numerous species of lizard, chameleon and tree-frog inhabit the woods. Madagascar may be considered as one of the headquarters of the Chamaeleonidae, for of the fifty known species no fewer than twenty are endemic. To these are added about nine hundred species of birds, most of these are of curious form, with remarkable developments of the plates of the head and projecting horns and spines. There are several peculiar tortoises, but the giant tortoises of the Aldabra atoll in the Indian Ocean, are the largest of any kind known. As a whole, the Madagascar fauna is marked by a strong individuality, which would appear to be the result of long isolation from the other geological "regions." The Asiatic and Malayan affinities of many of its animals, as well as the physical conditions of the bed of the Indian Ocean, make it highly probable that Madagascar, while once forming part of Africa, is the chief relic of a considerable archipelago formerly connecting that continent with Asia, its other portions being shown by groups of small islands, and by coral atolls and shoals, which are gradually disappearing beneath the waves. These peculiarities have been treated by Dr. A. R. Wallace in his Geographical Distribution of Animals (vol. l. ch. ix., 1876) and Island Life, ch. xix. (1886).

*Flora.*—The flora of Madagascar is one of great interest. One of its peculiarities is that it is the roundest face of the island at no great distance from the sea, and generally following the coast-line. This forest is densest on the east side, and for about 120 m. forms a double line, the lower one being much the broader and denser, but both on the western side of the island, near Antongil Bay. The vegetation on the western side of the island is much less dense, often appearing as scattered clumps of trees on savannah-like plains rather than continuous forest; while in the south-west, where the rainfall is very scanty, the vegetation is largely of fleshy-leaved and spiny plants—aloes and cacti (the latter introduced), with several species of Euphorbia, as also numerous other kinds of spines, some of which (Ipomoea) yield the spiny pumpkin of commerce.

It is estimated that there are about 30,000 sq. m. of forest-covered country in Madagascar, or about one-eighth of its whole surface. The vegetation of Madagascar is an epiphytic type, with the filmy ferns and the viviparous character of many of the ferns, show clearly how abundant the rainfall is in the eastern forest regions. This contains a large variety of hard-wooded and valuable timber trees, including species of Weimannia (Lalona), Elaeocarpus (Vohahna), Dalbergia (Vohomba), Nuxia (Valaniana), Podocarpus, a pine, the sole species in the island (Hilaira), Tambourissa (Ambö), Neobarnia (Ilahara), Oceia (Varvogy) and probably some others. These are accompanied by the following characters of Madagascar vegetation, some of them being endemic, and others very prominent features in the landscape: the traveller's-tree (Urania speciosa), the crown of spines, the feather-like crown, the huge umbrella plant like an enormous fan at the top of a tall trunk, and affording a supply of pure cool water, every part of the tree being of some service in building; the Raphia (rota) palm (Sagus ruffia); the tall frl-like Coronaria, the most prominent of the western coast, as well as many species of screw-pine (Pandanus); the Madagascar spice (Ravixirina madagascarensis), a large forest tree, their fragrant fruit, leaves and bark; a small palmaceous species of Calophyllum; and the Tangiæna (Tanghiña venenifera), formerly employed as a poison ordeal. On the lagoons and lower reaches of the rivers the Viha (Tophonodorum indiculeum), an arum endemic to Madagascar, grows in great profusion to a height of 15 or 15 ft. and has a white spathe more than a foot in length; and on the western coast dense thickets of mango tree the creeks and rivers. In the interior forests is found the beautiful geranium plant (Oxandura fenestrata), with an edible tuberous root. On the western side of the island the baobab, the tamarind, the rotra (Eugenia sp.), the roba palm, and several species of fan-palm (Hytophle) are prominent. Prominent among the plants of the island are the large leaves of the Antanantena, or Pandanus, the Astrapaea creeper, the coastal and forest cover of Avena, and the large evergreen forest of the island of Sainte Marie, considered as the scantiest part of the island; the forest is only about 800 m. in length; parallel with this for about a third of its extent, and between the two lines of forest, is the Bezaňano country. South again are the districts of the Taibathoa, the Taimbora, the Taiťo, the Taiśaka, and at the south-eastern corner are the Tandoś. (2) Central: the districts of Tsimihety and the Sihâna, Imérina, the Hoa province; the Bétrisé; the Tanôle or forests; the Bâra; and the emigrant Tandoś. (3) Western: the people from almost the northern to the southern extremities of the island are known as Sâkalâra, but consist of a number of distinct tribes—the Tiboīa, the Mâila, the Tâmańab, and the Fiherânea, &c. South of these last are the Mâhâfaly, with the Tandroy at the extreme south. There are few distinctly marked boundaries between any of these tribal territories; and west of Imérina and Bétrisé there is a considerable extent of country with hardly any population, a kind of "no man's land." There are numerous subdivisions of most of the tribes.

The capital, Antânànaviro (pop. 69,000), is in the highlands of Imérina, and Tamaťave (pop. 4600), on the east coast and the chief seaport, are separately described. Majunga (properly Moijangà, pop. 5300) on the north-west coast, just north of 14° S., and Diégo-Suarez, are important ports for foreign trade, the latter being also a fortified naval and military station. Other ports and towns are Mâhanò, Mânanjary (S.E. coast, pop. 4500); Tulleur (S.W. coast), and Fianarantsoa (pop. 6200), the chief town of the Bétrisé. There are very few places besides these with as many as 2000 people.

1 The words in parentheses are the native Malagasy names.
Inhabitants.—The population is somewhat under two and three-quarter millions,2 including some 10,000 or 11,000 Europeans, and a smaller number of Indian, Arab, and other Asians, mostly small traders found in the seaports, the Chinese being found in every town of any size. The island, it will be seen, is very sparsely inhabited; the most densely peopled province is that of Imérima with (1905) 368,000 inhabitants. The natives, collectively known as Malagasy, are divided into a considerable number of tribes, each having its distinct customs. Although geographically diverse, the majority of the inhabitants are derived, the lighter portion of them from the Malayo-Polynesian stock, and the darker races from the Melanesian. This is inferred from their similarity to the peoples of the Indian and Pacific archipelagoes in their physical appearance, mental habits, customs, and, above all, in their language. Their traditions also point in the same direction. There is, however, an undoubted African mixture in the western and some other tribes. There is also an Arab element both on the north-west and south-east coasts; and it appears that most of the families of the ruling classes in all parts of the island are descended from Arabs, who married native women. It is believed that there are traces of an aboriginal people (the Vazimba), who occupied portions of the interior before the advent of the present inhabitants, and these appear to have been a somewhat dwarf race, and lighter-coloured than the Malagasy generally. The Hova became the dominant tribe from the beginning of the 10th century; they appear to be the latest immigrants, and are the lightest in colour; and they are also the most intelligent and civilized of all the peoples inhabiting the island.

The most striking proof of the virtual unity of the inhabitants of Madagascar is that substantially but one language is spoken over the whole country. The Malay affinities of Malagasy were noted in the 16th century; indeed, the second and fifth books published upon the country (in 1603 and 1613) were comparative vocabularies of these two languages. Later investigations have confirmed the conclusions thus early arrived at; and Van der Tuyck, Marre de Marin and W. E. Coussens have shown conclusively the close relationships between the language of the Malagasy and those of the Malayo-Polynesian regions; similar connexions exist, especially in grammatical construction, between the Malagasy and Melanesian languages. The Malagasy had never invented for themselves a written character, and had consequently no manuscripts, inscriptions or books, until their language was reduced to writing, and its orthography settled by English missionaries. Their speech nevertheless is very full in many of its verbal and other forms, while it also exhibits some curious deficiencies, as very few adjectives, and none for comparison of the same kind, and no prepositional case, and are free from all harsh gutturals. Native oratory abounds in figures, metaphors and parables; and a large number of folk-tales, songs and legends, together with the very numerous proverbs, give ample evidence of the mental ability and imaginative powers of the Malagasy.

Native society in Imérima among the Hova was formerly divided into three great classes: the Andrianas, or nobles; the Hova, freemen or commoners; and the Andavo, or slaves; but these last became free by the law of the land in 1896. The Andrianas are, strictly speaking, royal clans, being descendants of petty kings who were conquered or otherwise lost their authority through the increasing power of the ancestors of the reigning family. The descendants retained certain honours in virtue of their royal origin, such as special terms of salutation, the use of the smaller scarlet umbrella (the larger one was the mark of royal rank), the right to build a particular kind of cook-house, the enjoyment of exemption from certain government service, and from some punishments for crime. The Hova or commoners form the mass of the population of Imérima. They are composed of a largely cultivated race; they are usually the best teachers; the most industrious, and the most contented, as indeed do families, so that property and land may be kept together. The third great division was the slave population, which since 1896 has become merged in the mass of the people. The Mozambiques or African slaves, who had been brought from the African coast by Arab shows, were in 1877 formally set free by an agreement with the chiefs and chieftainship in Madagascar had many peculiar customs. It had a semi-sacred character; the chief was, in heathen tribes, while living, the high priest for his people, and after death, was worshipped as a god; in its modern development among the Betsileo the office of chief is conducted in its native form.

There were many curious examples of the taboo with regard to actions connected with royalty, and also in the words used which relate to the queen and king. Such taboos are usually found in the islands of the south-west Pacific, and are particularly seen in everything having to do with the burial of a monarch. While the foregoing description of native society applied chiefly to the people of the central province of Imérima, it is applicable, though in a modified form, to the people of the south-eastern islands of the island becoming a French colony, in 1896, royalty was formally abolished; and little regard is paid to native rank by French officials.

The chief employment of the Malagasy is agriculture. In the cultivation of rice they show very great ingenuity, the kétso grounds, where the rice is sown before transplanting, being formed either on the margins of the streams or in the hollows of the hills in a series of terraces, to which water is often conducted from a considerable distance. In this agricultural engineering no people surpass the Betsile. No plough is used, all work being done by a long-handled hook; the rice plants are reared in tracts of water and are transplanted to the field. The rice is threshed by being beaten in bundles on stones set upright on the threshing-floor; and when beaten out the grain is stored by the Hova in rice-pits dug in the hard red mud, or covered with thatch, to keep out the small insects. In preparing the rice for use it is pounded in a wooden mortar to remove the husk, this work being almost always done by the women. The root of the plant is used for making ropes, and the leaves and other roots and vegetables; but little animal foods (save fish and freshwater crustaces) is taken by the mass of the people except at festival times. Rice is used less by the western tribes than by those of the central and eastern provinces, and the former people are more nomadic in their habits than are the others. Large herds of fine humped cattle are found almost over all the island.

The central and eastern peoples have considerable manual dexterity. They are skilful basket-makers, and their basketwork shows a remarkable degree of artistic workmanship; and their basketry is of great variety, some of much fineness and delicacy, and also those resembling those of Panama. The people of the south and south-east make large use of soft rush matting for covering, and they also prepare a rough cloth of bark. Their non-employment of skins for clothing is a marked distinction between the Malagasy and the south-eastern races, and their use of vegetable fibres an equally strong link between the two. They used, and the Malagasy use, the sago plant, and it is common in both to use various species of mats and baskets in great variety. The Malagasy are skilful in metal-working; with a few rude-looking tools they manufacture silver chains and bracelets, gourds and spoons, and silver pendants to hang from the necks of the women, and a variety of other articles. Their iron-work is of excellent quality, and in copper and brass they can produce copies of anything made by Europeans. They display much higher invention in these matters than they are exceedingly quick to adopt new ideas from Europeans.

There is a considerable variety in the houses of the different Malagasy tribes. The majority of Hova houses were formerly built of layers of the hard red clay of the country, with high-pitched roofs thatched with grass or rush; while the chiefs and wealthy people had houses of framed timber, with massive upright planking, and loftier roofs covered with shingles or tiles. But the introduction of iron and burning the forests for fuel has led to the general use of these materials in the building of houses, large numbers of which are made in two storeys and in European fashion. The houses of the coast and coast tribes make their dwellings of good framing filled in with the leaf-stalks of the traveller's tree, with the leaves themselves forming the roof covering. The houses of the Betsileo and Sakalava are very small and dirty, but those of the eastern peoples are more cleanly and roomy. Among the Hova and Betsileo the old villages were always built for security on the summits of lofty hills, around which were dug several deep fosses, one within the other. In other districts they are strictly enclosed within formidable defences of prickly-pear or thorny mimosa.

Apart from the modern influence of religious teaching, the people are very moral and discreet, to such an extent that the majority of them are considered model citizens, and are paid little attention when suffering, and in war. Until lately polygamy has been common among all the Malagasy tribes, and divorce effected in an absurdly easy fashion. At the same time the custom is now much less common in Madagascar than in most heathen countries; and, the fact that for nearly seventy years there were (with a few months'
exception) only female sovereigns, helped to give women considerable influence in native society. The southern and western peoples still regard the female as being born on several unlucky days in each month. This was formerly the general practice all over the island. The old laws among the Hova were very barbarous in their punishments, and death in various cruel forms was inflicted for offenses that in modern Christian times are considered as trivial. Drunkenness also was prevalent at various parts of the island; and it can hardly be said of many of the Malagasy that they are very industrious. But they are courageous and loyal to their chieftain, and are capable of fighting bravely to\\n##enact their exaction. They are affectionate and firm in their friendships, kind to their children and aged and in respectful, very respectful. Among them, in the modern times, they are not so different. They have practically become a greater influence in Malagasy life, and they still keep their customs.

They have also retained many ancient sayings, proverbial in their style, which enforce many of the truths of natural religion as to the attributes of God. With all this, however, there has long existed a kind of idolatry, which in its origin is simply fetisism—the belief in charms—as having power to procure various benefits and protect from various evils. Among the Hova in modern times four or five of these charms or fetishes are observed, and these are, respectively, idols, as a kind of national deity, being called "god," and brought out on all public occasions. Together with this idolatry there is also a firm belief in the power of witchcraft and sorcery, in divination and in prophecy, in medicine and in magic, and much reliance is placed in the power of sorcery and the courtesy of the gods. Among the Vazimba, in some of the southern districts it is said that the society of the dead and the spirits of the ancestors are among the Hova, and almost confined to them, was that of the New Year, at which time a kind of sacrificial killing of oxen took place, and a ceremonial banquet at which the festival took its name of Pandrafo (the Bath). This festival is now merged in the French national fête of the 14th of July. A similar great festival was at circumcision times. This rite was observed by royal command at intervals of a few years; these were occasions of great rejoicing, but also of much drunkenness and licentiousness. Since 1868 circumcision has been observed by each family at any time convenient to itself, it is practised by all the Malagasy tribes. Funerals were and are still attended by the women, the priests, and by the head of the household. The wealth numbers of bullocks were and are still killed. Although there was no proper priesthood, the idol-keepers, the diviners, the doctors, the priests, the mediums, the witches, and the men connected with the divination, were the custodians of the gods, and were considered to be of the highest importance.

**Industries and Commerce.**—The rearing of cattle and the dressing of hides, the collection of rubber and bee culture are important industries. The chief food crops grown have been indicated (see *Flora*), and the gold-mining is separately noticed below. Other industries undertaken or developed by Europeans are silk and cotton weaving and raphia-fibre preparation, and ostrich farming. Sugar, rice, soap and other factories have been established. In 1904 the exportation of straw and other fibres was prohibited, and manumitted camels became an important item. Tanning bark, coffee and guano are also recent exports. Since 1862, when the country was thrown open to foreign trade, the growth of over-sea commerce has been comparatively slow. In the early days cattle were the chief export. About 1870 india-rubber began to be exported in considerable quantities, and cattle, rubber and hides continue staple products. Other important exports are raphia fibre and beeswax. Since 1905 gold has become a leading export, the value of the gold sent out has greatly exceeded the value of the hides exported. In 1905 the British imports were valued at £179,000; the next year, with the new tariff in force, they had dropped to £42,000. The only export duties are: cattle 2s. per head and rubber 2d. per lb.

Before the occupation of Madagascar by France the duty on imports and exports was 10% ad valorem, and the foreign trade was very largely in the hands of British and American merchants. In July 1897 the French tariff was applied and increased rates levied on foreign goods, notably cottons. This practically killed the American trade and reduced the British trade to insignificant proportions. In 1897 the British imports were valued at £45,000; in 1901 to £822,470 in 1906.1 About 95% of the trade is with France or other French colonies. The remaining trade is nearly all British and German.

Banking business is in the hands of French companies. The legal currency is the French 5-franc piece and the smaller French coins. There was no native coinage, the French 5-franc piece or dollar being the standard, and all sums under that amount were obtained by cutting up those coins into all shapes and sizes, which were weighed with small weights and scales kept in little quartered box and in each shop. The great advantage of this method is that even the poorest man can carry a dollar, and even reckoned down to the seven hundred and twentieth fraction of the same amount.

**Gold-mining.**—Gold-mining has been carried on regularly since 1897, and by 1900 the value of the ore extracted exceeded £100,000. Reports of rich discoveries attracted considerable attention in South Africa and Europe during 1904-1906, but exports, sent from the Transvaal, came to the conclusion that Madagascar would not become one of the rich goldfields of the world. The chief mining districts have been already indicated (see *Geology*). The chief gold mines were found were reported from the north of the island during 1907, in which year the export of gold was £320,000. The mines afford a lucrative occupation for some thousands of persons, and many of the chiefs and traders are engaged in mining, among them the islanders. In 1905 the value of the exports rose from £239,019 in 1901 to £590,019 in 1906.1

**Communications.**—There is regular steamship communication between the chief ports and Marseilles, Zanzibar and India (via the east coast of Africa and Ceylon). The state has three telegraphic lines, and two submarine cables. The island is in telegraphic connexion with the rest of the world. The French have built carriage roads from the interior to the principal ports as well as to connect the principal towns. On these roads large trains of bullock wagons, as well as motor and other vehicles, and women also. Tamatave and Antananarivo are joined by coast canals and lakes and by a railway service. Where other means are not available, goods are carried by canoes, or on the shoulders of bearers along the native footpaths.

There is a well-organized postal service, and all the towns of note are linked by a telegraph system, which has a length of over 4,000 miles.

**Government, Revenue, &c.**—The colony is not represented in the French Chambers, nor has self-government. At the head of the administration is a governor-general, who is assisted by a nominated council of administration which includes unofficial members. This council must be consulted on matters affecting the budget. In several towns there are chambres consultatives, composed of local merchants and planters. The island is divided into circles, placed under military officers, and provinces, presided over by a civilian. As far as possible in local affairs, each of the native races is granted autonomy, the domination of the Hova over the other tribes being abolished. Each province has its own governor and minor officials, the governor being generally selected by the pope and from each village there is an organization (the Fonden'oblins) resembling that

of a commune; at its head is a chief or mpisady, who serves for three years.

For Europeans and in suits between Europeans and natives the French judicial code is applicable; suits between natives are tried by native tribunals (established 1868) presided over by a European appointed in consultation with the native chiefs. The native laws and customs to native law and usages, except when such customs (e.g. polygamy and slavery) have been expressly abolished. Arbitration councils are available everywhere for the settlement of disputes between natives and Europeans. The native laws and their administration of land tenure have been improved by the adoption of a method of registration based on the Torrens system.

Revenue is derived from land, house and taxation duties, from customs, ferries, telegraphs, and European shops and enterprises. The excess of expenditure over revenue is made good by subventions from France. A considerable portion of the revenue is expended on public works; the annual expenditure on railways and telegraphs has been each just beneath £1,000,000. This is exclusive of the sums spent by France in the island on the army, and for the naval base at Diego-Suarez. There is a public debt amounting (1907) to £4,500,000. As stated in the French senate (February 1900), everything is taxed in the island; and no sooner has any enterprise become fairly successful than it is so heavily taxed as to be no longer worth carrying on, and certain crops have therefore been destroyed by the colonists who had planted them. This has been the case with tobacco, sugar, rum, and also in butter-making, cattle-breeding and other things. Notwithstanding this taxation, from 1895 to 1907, years were required for the completion of the railway, and the demand is constantly increasing.

History.—From the earliest accounts given of the people of Madagascar by European travellers, as well as from what may be inferred from their present condition, they seem for many centuries to have been divided into a number of tribes, often separated from one another by a wide extent of uninhabited country. Each of these was under its own chief, and was often at war with its neighbours. No one tribe seems to have gained any great ascendency over the rest until about the middle of the 17th century, when a small but warlike people called Sâkalâva, in the south-west of Madagascar, advanced northward, conquered all the inhabitants of the western half of the island, as well as some northern and central tribes, and eventually founded two kingdoms which retained their supremacy until the close of the 18th century. About that time, the Hôva in the central province of Imêrîna began to assert their own position under two warlike and energetic chiefs, Andreampiharoty and his son Radâma; they threw off the Sâkalâva authority, and after several wars obtained a nominal allegiance from them; they also conquered the surrounding tribes, and so made themselves virtual kings of Madagascar. From that time until 1895 Hôva authority was retained over a large part of the central and eastern provinces, but it was only nominal over much of the western side of the island, while in the south-west the people were quite independent and governed by their own chiefs.

While European intercourse with Madagascar is comparatively recent, the connexion of the Arabs with the island dates from a very remote epoch; and in very early times settlers and traders entered the island from the east, and to some extent from the south. The Arab influence is traceable in the knowledge of Arabic possessed by a few of the people. But in these provinces they have become merged in the general mass of the people. It is different, however, in the north-west and west of the island. Here are several large Arab colonies, occupying the ports of Anôbontâka, Mâjanga, Mârovoky and Môrondâva, and retaining their distinct nationality. There is also in these districts a Hindu element in the population, for intercourse has also been maintained for some centuries between India and northern Madagascar, and in some towns the Banyan Indian element is as prominent as the Arab element. In the early times of their intercourse with Madagascar, the Arabs had a very powerful influence upon the Malagasy. This is seen in the number of words derived from the Arabic in the native language. Among these are the names of the months and the days of the week, those of the seasons, some forms of salutation, words for dress and bedding, money, musical instruments, books and writings, together with a number of miscellaneous terms.

The island is mentioned by several of the early Arabic writers and geographers, but medieval maps show curious ignorance of the position of the island. We have a chapter upon it, and terms it "Madagascar," but its harbours are confused with those of the mainland of Africa. The first European voyager who saw Madagascar was a Portuguese named Diogo Diaç, captain of one of the ships of a fleet commanded by Pedro Cabral and bound for India. Separated from his companions by a storm near the Cape, he sighted the eastern coast of the island on the 10th of August 1505. That day being the feast of St Lawrence, Madagascar was named the "Isle of St Lawrence," and retained that name on all maps and charts for many years. The Portuguese gained possession of the capes, but made no persistent attempts at colonization. After the Dutch endeavoured, but with little success, to form colonies; and in the time of Charles I. proposals were made to form an English "plantation," but these were never carried into effect, although for a short time there was a settlement formed on the south-west coast. In the latter part of the 17th and during most of the 18th century the French attempted to establish military positions on the east coast. For some time they held the extreme south-east point of the island at Fort Dauphin; but this never gave the French control of the coast. Marco Polo has incapable of that they were frequently involved in war with the people, and more than once their stations were destroyed and the French were massacred. Early in the 19th century all their positions on the mainland were relinquished, and they retained nothing but the island of St Marie on the east coast. In 1811 Tamatawe had been occupied by British troops, and the Treaty of Paris of 1814 recognized as British the French settlements in Madagascar," but as a matter of fact France had then no settlements on the mainland. The then governor of Mauritius, Sir Robert Farquhar, endeavoured to prosecute British claims and obtained a cession of Diego-Suarez Bay. These claims were not backed up by the home government, and a little later the policy was adopted by Great Britain of supporting the Hôva authority.

The political history of Madagascar as a whole may be said to date from the reign of Radâma I. (1810–1828). He was a man much in advance of his age—shrewd, enterprising, and undeterred by difficulty—a kind of Peter the Great of his time. He saw that it was necessary for his people to be educated and civilized if the country was to progress; and making a treaty with the governor of Mauritius to abolish the export of slaves, he received every year in compensation a subsidy of arms, ammunition, and uniforms, as well as English training for his troops. He was thus enabled to establish his authority over a large portion of the island. For some years a British agent, Mr Hastie, resided at Radâma's court, and exercised a powerful influence over the king, doing much for the material advance of the country. At the same period (1826) Christian teaching was commenced in the capital by the London Missionary Society, and by its missionaries the language was reduced to a systematic written form, and the art of printing introduced; books were prepared, the Scriptures were translated, numerous schools were formed, and several Christian congregations were gathered together. The knowledge of many of the useful arts was also imparted, and many valuable natural productions were discovered. The power of superstition was greatly broken, a result partly due to the keen good sense of the king, but chiefly to the spread of knowledge and religious teaching.

The bright prospects thus opening up were clouded by the death of Radâma at the age of thirty-six, and the seizure of the royal authority by one of his wives, the Princess Rânavâlôna. She looked with much suspicion upon the ideas then gaining power among many of her people, and determined to strike a decisive blow at the new teaching. In 1835 the profession of the Christian religion was declared illegal; all worship was to cease, and all religious books were ordered to be given up. By the middle of 1837 all the English missionaries were obliged to leave the island, and for twenty-five years the most strenuous efforts were made by
the queen and her government to suppress all opposition to her commands. This, however, only served to show in a very remarkable manner the courage and faith of the Christian Malagasy, of whom about two hundred suffered death in various cruel forms, while many hundreds were punished more or less severely by fines, degradation, imprisonment and slavery. During the queen's reign the political condition of the country was deplorable; there were frequent rebellions, many of the distant provinces were desolated by barbarous wars; and for some years all Europeans were excluded, and foreign commerce almost ceased. This last circumstance was partly owing to an ill-managed attack upon Tamatave in 1846 by a combined British and French force, made to redress the wrongs inflicted upon the foreign traders of that port. But for the failure of Christianity and education which had been introduced into the country it would have reverted to a state of barbarism.

This reign of terror was brought to a close in 1861 by the death of the queen and the accession of her son Radama II. The island was reopened to European trade, and missionary efforts were recommenced. A determined attempt was made by some Frenchmen to gain for their country an overwhelming influence by means of a treaty which they induced the king to sign. But this act, as well as the vices and insane follies into which he was led by worthless foreign and native favourites, soon brought his reign and his life to an end. He was overthrown and his palace (1863) and his wife was placed on the throne. The new sovereign and her government refused to ratify the agreement which had been illegally obtained, choosing rather to pay a million francs as compensation to the French company. During the five years' reign of Queen Rasohirina, quiet and steady advances were made in civilization and education, and treaties were concluded with the British, French and American governments.

At the death of Rasohirina in 1868, she was succeeded by her cousin, Ranavalona II. One of the first acts of the new queen was the public recognition of Christianity; and very soon afterwards she and her husband, the prime minister, were baptized, and the erection of a chapel royal was commenced in the palace yard. These acts were followed in the succeeding year by the burning of the royal idols, and immediately afterwards by the destruction of the idols throughout the central provinces, the people generally putting themselves under Christian instruction. From that time education and enlightenment made great progress, chiefly through the labours of missionaries of various societies.

The native Malagasy government, though theoretically despotic, was limited in various ways. Radama I. and Ranavalona I. were much more absolute sovereigns than those before or after them, but even they were largely restrained by public opinion. New laws were announced at large assemblies of the people, whose consent was asked, and always given through the headmen of the different divisions of native society; this custom was no doubt a survival from a time when the popular assent was not a merely formal act. The large disciplined army formed by Radama I. aided much in changing what was formerly a somewhat limited monarchy into an absolute one. The Hova queen's authority was maintained over the central and eastern portions of Madagascar, and at almost all the ports, by governors appointed by the queen, and supported by small garrisons of Hova troops. At the same time the chiefs of the various tribes were left in possession of a good deal of their former honours and influence. Ranavalona II., her predecessor and her successor were successively married to the prime minister, Ranihiarivony, a man of great ability and sagacity, who, by his position as husband and chief adviser of the sovereign, became virtual ruler of the country. Chiefly owing to his influence, many measures tending to improve the administration were introduced. The Hova army was estimated at from 30,000 to 40,000 men, several English non-commissioned officers and, latterly, others of higher rank being engaged to train them in European methods. Revenue was derived from customs duties, fruitfruits, fines and confiscation of offenders' property, and a money offering called hsdina, presented on a great variety of occasions both to the sovereign in person and to her representatives; and these were supplemented by 'benevolences' (in the medieval sense of the word) levied upon the people for occasional state necessities. The government also claimed the unpaid service of all classes of the community for every kind of public work.

The Hova government aspired to have Madagascar recognized as an independent civilized state, and consuls appointed by the British, French and American governments were accredited to the Malagasy sovereign, the queen having a consul in England, and a consular agent at Mauritius. The treaty with Great Britain, concluded in 1865, gave the consuls of that nation jurisdiction over the British subjects in the island. At this period, on the initiative of the 4th earl of Clarendon, then foreign secretary, an understanding was come to between the British and French governments by which it was agreed that each power should respect the independence of Madagascar; and the future of the country appeared to be bound up in the gradual consolidation of the central Hova authority over the whole island. While this prospect would have satisfied the British interests in the island, it was otherwise with the French. The tradition of their former settlements in and influence over the island was strong; in 1840 they had taken under their protection the Sakalava ruler of the small island of Nosy Be, and in virtue of this act claimed a vague protectorate over the adjacent shores of the mainland. A treaty, concluded in 1868, while establishing French consular jurisdiction in Madagascar, recognized Ranavalona II. as queen of Madagascar, and under the Second Empire attempts to establish French political influence were discouraged, and even as late as 1872 the subsidy enjoyed by the Jesuit missionaries was withdrawn. In 1878 the French consul, Laborde, died, and a dispute arose as to the disposal of his property. This dispute was the occasion of further intervention on the part of France, for the Paris government supported the claims of Laborde's heirs, and revived their claim to a protectorate over the Sakalava of the north-west coast, as based on their agreement with them in 1840, ceding Nosy-Be to France. A policy of colonial expansion generally, and in Africa in particular at this time, was manifest in France, as in other European countries, and the French claims on the Hova were pressed with vigour.

Towards the middle of 1862 the relations between the native government and that of France became much strained, and it seemed possible, these causes of dispute, two French consuls and two Hova officers of high rank were sent from France to Madagascar as ambassadors, but as they were not authorized to concede any territory, their visit accomplished very little. Treaties had been concluded with Great Britain, Germany and America, giving improved facilities for trade with Madagascar, but before the return of the envoys matters had come to a crisis in the island. In May 1863 an ultimatum was sent to the Malagasy queen, requiring immediate compliance with the demands of France; and as these were refused by the Hova government, Tamatave was bombarded by a French squadron and then occupied by the marines. The war continued in a desultory fashion for many months; but no serious attempt was made to invade the interior; and in 1865 terms of peace were agreed to. By a treaty signed on the 17th of December it was agreed that the foreign relations of Madagascar should be directed by France; that a resident should live at the capital, with a small guard of French soldiers; and that the Bay of Diego-Suarez, together with surrounding territory, should be ceded to France. The word 'proteectorate' was carefully excluded from the treaty, although it is certain that the French envoys intended that this should be its practical issue. It was at the same time agreed that there should be no foreign interference with the internal government of the country, and that the queen should retain her former position, with all its honours and dignity. It should be here noticed that the queen, Ranavalona II., died just at the beginning of the war, on the
13th of July 1883, and was succeeded by her niece, Princess Razafisindralahety, under the title of Ranaivolahona III., who maintained the same policy as her predecessor, and was much beloved by her people and respected by all. Several French residents successively represented France at Antananarivo; but these found themselves unable to obtain that influence which the home authorities thought they had a right to demand. Although the British government, in return for concessions in Zanzibar, had consented, in 1890, to recognize a French protectorate over Madagascar, the Malagasy prime minister, Ranaillaliarivony, was not disposed to give any advantage to France and continued to arm and train, by the help of British officers, a large body of native soldiers. This state of preparation was not lost, and at length, towards the close of 1894, the French government sent an ultimatum to the Malagasy sovereign, demanding such powers as would have made French authority supreme in the island. These demands were refused by the native government, and other conditions were offered; but the French envoy, together with the resident's escort, left the capital, as also did the French traders and others, including the large Jesuit mission. As soon as these had left the island, the chief priests were ordered by General Gallieni, an expeditionary force under General Duchesne was afterwards landed on the north-west coast at Majangà—commonly, but incorrectly, written Majunga—with the object of breaking the Hova authority. Owing to the necessity of making a road for the passage of artillery and military stores, many months were spent on the march into the interior, and there was considerable loss of life by fever and other disease among the invading troops. But no effectual resistance was made by the Malagasy, and at length, on the 30th of September 1895, the French forces appeared on the heights north and east of Antananarivo and captured the city, which surrendered in the afternoon, and on the evening of the same day the French entered the capital.

The result was that the protectorate of France was re-established in the central provinces, but the queen was allowed to retain her position. Early in 1896, however, a serious rebellion broke out in several parts of Iména. This movement was not only anti-French and anti-Jesuit, but also distinctly anti-Christian. The French troops gradually broke up the power of the rebellion in the south and west of the island, General Gallieni, an officer with a reputation for vigour and ability in the Sudan and Tongking campaigns, was sent out to relieve the then resident-general.

General Gallieni had a difficult task in establishing the authority of France throughout the island among numbers of tribes who had never submitted to any control from others. Among the first steps he took were to put the country under martial law, to abolish royalty and all semblance of Hova government, and to declare Madagascar to be henceforth a colony of France. Queen Ranavolahona III. was exiled to Réunion, and subsequently to Algeria. Meanwhile carriage roads were commenced to connect all the chief centres, and the military posts were gradually extended so as to consolidate French rule over all the outlying tribes. French residents and numerous other officials were placed at every important town, and various projects were started for the civilization of the Malagasy in accordance with French ideas. At the close of 1896, General Gallieni was able to report that only portions of the west and south-west remained to be brought into submission. Not long afterwards the authority of France was recognized throughout the island. General Gallieni, whose firm and vigorous administration, and desire to treat the Malagasy justly and kindly, made him liked by the people, retired in 1905, and was succeeded in that office by M. Victor Augagneur, late mayor of Lyons. Since the French occupation the Malagasy have conformed pretty readily to the new order of things, although the most intelligent Hova deeply regret that their country did not retain its independence. Justice is administered, on the whole, with fairness and impartiality; but the taxation seems too heavy for the means of the people, indeed it is affirmed by trustworthy natives that the well-to-do classes are being gradually drained of their resources, and the small cultivating classes are left at the mercy of the few rich and powerful French officials. The whole of Madagascar is now the scene of a great missionary movement, and the number of French missionaries is very largely in excess of any real needs of administration; several monopolies, which interfere with the habits of the people, tend to produce discontent; and the taking of their land and houses for public works, roads, &c., while but a mere fraction of their real value is allowed as compensation, does not help to increase their acquiescence in foreign control. But the most serious cause for dislike to government action was the interference by the governor-general, in 1907, with their religious customs, by the suppression of hundreds of their congregational and community schools, and the closing of many of the churches. In July 1910 M. Augagneur was replaced as governor-general by N. Picqué, a prominent official of the Colonial Department, who had previously served with acceptance as deputy governor-general of French Indo-China, and who had a reputation for tact and impartiality.

**Christian Missions and Education.**—As already noticed, the Malagasy owe to missionaries of the London Missionary Society their present school system, and their mission organization, in 1846 and subsequent years; and for fifteen years all educational work was carried on by them, some 10,000 to 12,000 children having been instructed in their schools. On the reopening of the country to French influence in 1862, some of them continued to work on with vigour for several years, stations being formed in several parts of Iména, in the Betsileo and Antsahana provinces, and at the ports of Tamatave, Majunga and Farafangana (south-east coast). In 1866 a church in London was dedicated to the memory of the able people, and a second was opened in 1875. A third was opened in 1878. In 1863 the Church of England began work in the island through the Society for the Propagation of the Gospel and the Church Missionary Society. After some time, however, the latter society withdrew, leaving the field to the S.P.G. A bishop is stationed in the capital, with a theological college in its neighbourhood, but the chief work of the Anglican mission is on the east coast. In 1866 the Norwegian Lutheran Society began work in Madagascar, and was joined in 1868 by an American Lutheran Society. With a representative church at the capital, the chief work of these missions is in the Vakinankaratra district (south-west of Iména), in the Betsileo province, and on the south-east and south-west coasts; in these places they have a large number of converts and (until lately) schools. In 1867 a mission was begun by the Society of Friends, who gave great attention to educational and literary work, and afterwards took up as their field the Kianjaka valley. A mission was opened in the west, for the purpose of converting them, who have a large and well-organized mission. Immediately after the island became a French possession the French Protestant Church (mission) began (in 1868) to take up its work, and in 1870 the first school of the new colony, and about half the area for long occupied by the London Missionary Society was transferred to the Paris Society. The bulk of the Malagasy Christians are Protestants, probably three-fourths of those professing Christianity. Episcopal Church (Riti, or Jesuit) mission was begun in 1861, and a large force of priests with a bishop and lay brethren and sisters engaged in education, have been at work in the island since then, except during the two Franco- Malagasy wars. Since the French conquest, the north of the island has been occupied by a mission of priests of the Saint Esprit, and the southern portion by the Lazarist mission, each at its head. The following table gives the statistics of the various Protestant missions at the close of 1906—

1 It is true that 200 years earlier than this, persistent efforts were made by the Jesuits (1646-1740) by Fort Bouillé and Compte, to encourage the other missionary societies to propagate their faith among the south-east coast tribes. But although much zeal and self-denial were shown by these men, their efforts were abortive, and the mission was at length abandoned. In 1866 the Jesuits began to make a new attempt, and within a single church or convert. Half a dozen small books of devotion are all that remain to show their presence in Madagascar.

The work of the "Frères chrétiens" was, however, almost broken up by the anti-clerical policy of the French government.
MADAN—MADDALONI

Since 1897 high schools, and medical and technical schools, and a few other institutions were opened for the French population; and all other schools have been placed under regulations issued by an educational department, the scholars being required to learn the French language; but until the end of 1906 the bulk of the educa-
tional provision was made by the churches. In Madagascar the anti-clerical movement in France began to affect Madagascar. In all the missions the churches had, in the vast majority of cases, belonged to the church that had introduced it, but their clergy were forbidden to use churches for educational purposes after two months from that date; and the effect of the decree, with other provisions, was to close hundreds of schools, probably three-fourths of the whole number.

For many years (1862–1896), all medical aid to the sick, the forma-
tion of hospitals and dispensaries, the training of native doctors, midwives, nurses, and the production of medicines, was entirely due to the Protestant missionaries, viz., the London Missionary Society, the Friends and the Norwegians. Numbers of young men received a full course of medical and surgical training, and were awarded the degree of doctor of medicine. In 1899 it was stated that the whole medical work is now solely in the hands of government departments.

Ninety years have elapsed since the publication of the first account of Madagascar, the "Voyages et Recherches de M. d'Entrecolles" (1773), by the remarkable Frenchman, who has ever since been regarded as the first explorer of Madagascar. From this time to the present day the island has been visited by many travelers and explorers, and the results of their labors have been recorded in books which have added much to our knowledge of the island and its people. The most important of these works are listed below.

Genéral: Étienne de Flacourt, Histoire de la grande ile Madagascar (Paris, 1688); Madagascar, or Robert Drury's Journal during Fifteen Years' Captivity on that Island (London, 1779); new ed., 1890;

Voyages et mémoires de Maurice Auguste, comte de Benyowski (Paris, 1791);

Froeberville, Histoire de Madagascar (Isle of France, 1808);

Enliss, History of Madagascar (London, 1838);

Guillain, Documents sur l'histoire et les moeurs de Madagascar (Paris, 1845);

Descartes, Histoire et géographie de Madagascar (Paris, 1847); Ellis, Three Visits to Madagascar (London, 1881); J. Sibere, Madagascar and the Île de Sainte Marie (Paris, 1879); Tambery ny Andrainana és Madagascar, Histoire des rois d'Imérina d'après les manuscrits malgaches (Antananarivo, 1875); Mullen, Twelve Months in Madagascar (London, 1873); Blancard, L'Île de Madagascar (Paris, 1871);

Dahle, Madagascar og dens Beboere (Christiania, 1876–1878); Sibere and Baron (eds.), The Antananarivo Annual, Nos. i–xxv. (1875–1900), pp. 3115;

Notes, reconnaissances, et explorations, revue mensuelle, nos. 1–15, 1897–1899, pp. 3041; Sibere, A Madagascar Bibliography (Antananarivo, 1896);

Van Loo, Madagascar (Paris, 1884); Vingt ans à Madagascar (Paris, 1885);

Bulletin trimestriel de l'Institut des Lettres et des Arts (1899);

Together these works form a series of remarkable historical facts in the Malagasy and European literature. The book was written in the Malagasy and published in Berlin. The academic interest in Madagascar can be traced back to the 19th century, when the island was considered a strategic location for European powers. The French, British, and Portuguese were all involved in the rivalries for control of Madagascar, which was seen as a gateway to the East. The French occupation of the island in 1895 marked a significant change in its history, as Madagascar became a French colony. This period saw a rapid expansion of French influence, as well as resistance from the Malagasy population. The French colonial administration sought to assimilate the Malagasy population into French culture and language, while also trying to modernize the island's economy and infrastructure. The French presence in Madagascar had a lasting impact on the island's history, culture, and politics, and continues to be a subject of study and debate to this day.
designed by Lodovico Vanvitelli, and constructed between 1753 and 1759.

MADDEN, SIR FREDERIC (1801–1873), English palæographer, the son of an officer of Irish extraction, was born at Portsmouth on the 16th of February 1801. From his earliest years he displayed a strong bent to linguistic and antiquarian studies. In 1826 he was engaged by the British Museum to assist in the preparation of the classified catalogue of printed books then contemplated, and in 1828 he became assistant keeper of manuscripts. In 1833 he was knighted, and in 1837 succeeded Josiah Forshall as keeper of manuscripts. He was not entirely successful in this office, partly owing to want of harmony with his colleagues; he returned speedily for the last time to the British Club, 

He has also been an ardent student of the Barley, 

It is an herb that is often grown for its medicinal properties. In ancient times, it was used to treat conditions such as skin infections and digestive problems. Its roots and leaves were also used in herbal medicine. The ancient Egyptians, the Greeks, and the Romans all used barley as a medicine.

In the 18th century, it became known as a root-bark and was used in the production of dyes. It was also used as a pigment in the manufacture of textiles. The dye-producing property of barley was known as "madder," and it was used to produce a rich red color. The plant was named "Rhamnus purshianus."

MADON, RENÉ-MARIE (1736–1784)—called Medec in Anglo-Indian writings—French adventurer in India, was born at Quimper in Brittany on the 7th of February 1736, of poor parents. He went out to India and served under Duplex and Lally, but being taken prisoner by the British he enlisted in the Bengal army. Deserting with some of his companions shortly before the capture of Buxar (1764), he became military instructor to various native princes, organizing successively the forces of Shuja-ud-Dowlah, nawab of Oudh, and of the Jats and Rohillas. He took service under the emperor Shah Alam in 1772, and when that prince was defeated at Delhi by the Mahrattas, Madec rejoined his own countrymen in Pondicherry, where he took an active part in the defence of the town (1778). After the capitulation of Pondicherry he returned to France with a considerable fortune, and died there in 1784. At one time he formed a scheme for a French alliance with the Mogul emperor against the British, but the project came to nothing.

See Émile Barbé, Le Nabab René Madec (1894).

MADEIRA, or THE MADEIRAS, a group of islands in the North Atlantic Ocean, which belong to Portugal, and consist of two inhabited islands named Madeira and Porto Santo and two groups of uninhabited rocks named the Descartas and Selvagens. Pop. (1900), 150,574; area, 314 sq. m. Funchal, the capital of the archipelago, is on the south coast of Madeira Island, in 35° 37' 45" N. and 16° 54" W. It is about 360 m. from the coast of Africa, 555 from Lisbon, 1215 from Plymouth, 240 from Tenerife, and 480 from Santa Maria, the nearest of the Azores.

Madeira (pop. 1900, 148,263), the largest island of the group, has a length of 30 m., an extreme breadth of 12 m., and a coastline of 80 or 90 m. Its longer axis lies east and west, in which direction it is traversed by a mountain chain, the backbone of the island, having a mean altitude of 4000 ft., up to which many deep ravines penetrate from both coasts and render travel by land very difficult. Pico Ruivo, the highest summit, stands in the centre of the island, and has a height of 6056 ft., while some of the adjacent summits are very beautiful. The richness of the ravines, the loftiness of the rugged peaks, often covered with snow, that tower above them, the bold precipices of the coast, and the proximity of the sea, afford many scenes of picturesque beauty or striking grandeur. The greater part of the interior is uninhabited, though cultivated, for the towns, villages and scattered huts are usually built either at the mouths of ravines or upon the lower slopes that extend from the mountains to the coast. The ridges between the ravines usually terminate in lofty headlands, one of which, called Cabo Girão, has the height of 1920 ft., and much of the seaboard is bound by precipices of dark basalt. The north coast, having been more exposed to the erosion of the sea, is more precipitous than the south, and presents everywhere a wilder aspect. On the south there is left very little of the indigenous forest which once clothed the whole island and gave it the name it bears (from the Portuguese madeira. Lat. materia, wood), but on the north some of the valleys still contain native trees of fine growth. A long, narrow and comparatively low rocky promontory forms the eastern extremity of the island; and here is a tract of calcareous sand, known as the Fossil Bed, containing land shells and numerous bodies resembling the roots of trees, probably produced by infraction.

Porto Santo is about 25 m. N.E. of Madeira. Pop. (1900), 2311. It has a length of 68 m. and a width of 3 m. The capital is Porto Santo, called locally the villa or town. The island is very unproductive, water being scarce and wood wholly absent. Around the little town there is a considerable tract of pretty level ground covered by calcareous sand containing fossil land-shells. At each end of the island are hills, of which Pico do Facho, the highest, reaches the altitude of 1065 ft. Barley, but little else,
is grown here, the limited requirements of the inhabitants being supplied from Funchal.

The Deserts lie about 11 m. S.E. of Madeira, and consist of three islands, Ilheo Chato, Bugio and Deserta Grande, together with Sial Rock off the north end of Ilheo Chato. They present lofty precipices to the sea on all sides. Rabbits and goats abound on them. The archi weed grows on the rocks, and is gathered for exportation. The largest islet (Deserta Grande) is 61 m. long, and attains the height of 1610 ft. These rocks are conspicuous objects in the sea-views from Funchal.

MADEIRA ISLANDS

The Selvagens or Salvages are a group of three islands, 156 m. from Madeira, and between Madeira and the Canary Islands. The largest island is the Great Piton, 3 m. long, and 1 m. broad. The inclusion of the Selvagens in the Madeira Archipelago is due to political rather than to geographical reasons.

Geology.—All the islands of the group are of volcanic origin. They are the summits of very lofty mountains which have their bases in an abyssal ocean. The greater part of what is now visible in Madeira is of subaerial formation, consisting of basaltic and trachytic lavas, beds of tuff and other ejectamenta, the result of a long and complicated series of eruptions from innumerable vents. Besides this building up by the emission of matter from craters and clefts of the subaerial lava, the mountainous upheaval in Madeira has taken place, for at one spot about 1200 ft. above the sea in the northern valley of São Vicente, and again at about the same height in Porto Santo, there have been found fragments of limestone accompanied by tuffs containing marine shells and echiinoderms of the Miocene Tertiary epoch. We have here proof that during or since that epoch portions at least of these islands have been bodily uplifted more than 1000 ft. The fossils are sufficiently well preserved to admit of their genera, and in many instances even their species, being made out.

There were pauses of considerable duration whilst the island of Madeira was being increased in height. The leaf bed and the accompanying carbonaceous matter, frequently termed lignite, although it displays no trace of structure, which lie under 1200 ft. of lavas in the valley of São Jorge, afford proof that there had been sufficient time for the growth of a vegetation of high order, many of whose impressions belonging to species of trees and shrubs which still exist on the island. Moreover, great alterations and dislocations had taken place in the rocks of various localities before other lavas and tuffs had been thrown upon them.

There are no data for determining when volcanic action began in this locality, but looking at the enormous depth of the surrounding sea it is clear that a vast period of time must have elapsed to allow of a great mountain reaching the surface and attaining its present elevation of several thousand feet. Again, considering the comparatively feeble agents for effecting the work of denudation (neither glaciers nor thick accumulations of alpine snow being found here), and the enormous crosion that has actually taken place, the inference is inevitable that a very great lapse of time was required to excavate the deep and wide ravines that everywhere intersect the island. Nor is anything known as to the period of the cessation of volcanic action. At the present day there are no live craters or smoking crevices, as at the Canaries and Cape Verdes, nor any hot springs, as at the Azores.

In one of the northern ravines of Madeira by Porto do Cruz some masses of a coarsely crystalline Essoite are exposed to view, this rock is evidently the deep-seated representative of the Trachy-dolerite and Nepheline basalt lavas. Fragments of a sodalite-syenite and of a hornblende-diorite have been found供货on this rock.

In the eastern part of the island several small crater rings are to be seen; their rims are formed of spheroidal basalt, while within the craters themselves masses of bauxite are found accompanied by evidences of fumerole and hot springs.

In the sections afforded by the ravines, which strike north and south from the central ridge of Madeira to the sea, the nucleus of the island is seen to consist of a confused mass of more or less consolidated rock, interspersed with loose sandy or gravelly detritus and lapilli in the shape of basalt, trap and trachyte, the whole traversed by dykes. These beds are thinnest near the central axis; as they approach the coast they become thicker and less intersected by dykes.

In various parts are elevated tracts of comparatively level ground. These are supposed to have been formed by the meeting of numerous streams of lava flowing from cones and points of eruption in close proximity, various ejectamenta assisting at the same time to fill up inequalities. Deep down in some of the lateral ravines may be seen ancient cones of eruption which have been overwhelmed by streams of melted matter issuing from the central region, and afterwards exposed to view by the same causes that excavated the ravines. These ravines may be regarded as having been formed at first by the subaerial eruption from both Mt. Pico and Pico Haria, which dislocated the rocks and cut clefts through which streams flowed to the sea. In course of time the waters, periodically swollen by melted snows and the copious rains of winter, would cut deeper and deeper into the heart of the mountains, forming lateral cliffs, until the valleys became as large as we now find them.

Even the Curral, which from its round shape and position in the centre of the island has been usually deemed the ruins of a crater, is thought to be nothing more than a valley but enlarged in the way described. The rarity of crateriform cavities in Madeira is very remarkable. There exists, however, to the east of Funchal, one about 1200 ft. small but beautiful, 500 ft. in diameter, and with a depth of 150 ft.; and there is another, which is a double one, in the district known as Fanal, in the north-west of Madeira, nearly 5000 ft. above the sea. The basalt, of which much of the outer part of the island is composed, is compact, even and a tough texture, with small disseminated crystals of olivine and augite. It is sometimes full of vesicular cavities, formed by the expansion of imprisoned gases. A rudely columnar structure is very frequently seen in the island, but there is nothing so perfect as the columns of Staffa or the Giant’s Causeway. The trachytic rocks are small in quantity compared with those of the basaltic class. The tuff is soft and friable, and generally of a yellow colour; but where it has been overflowed by a hot stream of lava it has assumed a red colour. Black ashes and fragments of pumice are sometimes found in the tufaceous strata. The yellow tuff is nearly or altogether andesitic in character, and various tints of yellow and red are seen in the surrounding mountains, and in the magnificent forests which render many parts of the island most picturesque.

In Porto Santo the trachytic rocks bear a much greater proportion to the basaltic than in Madeira. An adjacent islet is formed of a basaltic lavas, and a third islet is composed of an andesite, which supraramarine lavas have been poured. The older series contains corals and shells (also of the Miocene Tertiary epoch), with water-worn pebbles, cemented together by carbonate of lime, the whole appearing to have been a coral reef near an ancient beach. The carbaceous rock is taken in large quantities to Funchal, to be burnt into lime for building purposes.

Climate.—Observations taken at Funchal Observatory (80 ft. above the level) in the last thirty years of the 19th century showed that the mean annual temperature is about 65° F. The mean minimum for the coldest part of the year (October to May inclusive) does not fall below 52° F. and the average temperature in the same period does not exceed 80°. Madeira thus has a remarkably mild climate, though it lies only 10° north of the Tropic of Cancer. This mildness is due to the surrounding ocean, from which the island is far removed, and the small supply of moisture, the average humidity of the air is about 75% (saturation=100). The prevalent winds are from the north or from a few points east or west of north, but these winds are much mitigated on the south coast by the central range of mountains. There is generally a strong land wind blowing from the east, the sea wind being weak or altogether absent. A hot and dry wind, the leste of the natives, occasionally blows from the east-south-east, the direction of which is suitable for bringing in cargoes of rice and cotton, but it is usually overcast and unbalmy by day; but even on the coast the thermometer under its influence sometimes indicates 93°. The leste is often accompanied by sandstorms. As the thermometer has never been known to fall as low as 45° at Funchal, the island is not subject to indigestion or colds on the mountains once or twice during the winter, very seldom, however, below the altitude of 2000 ft. Thunderstorms are rare, and scarcely ever violent.
MADEIRA

Madeira has long had a high reputation as a sanitary resort for persons suffering from diseases of the chest. Notwithstanding the ever-increasing competition of other winter resorts, a considerable number of invalids, especially English and German, winter at Funchal.

Fauna.—No species of land mammal is indigenous to the Madeiras. Some of the early voyagers indeed speak of wild goats and swine, but the most recent observers have never observed them. The first comers encountered seals, and this amphibious mammal (Mommo phoca) is still found along the coast. Amoebae are the only other species of birds which breed in these islands are the kestrel, buzzard and barn owl, the blackbird, robin, waggail, goldfinch, ring sparrow, linnet, two species, three pigeons, the quail, red-legged partridge, woodpecker, blackbird, two thrushes. Only one species is endemic, and that is a wren (Regulus madeirensis), but five other species are known elsewhere only at the Canaries. These are the green canary (Fringilla bulbea), the parent of the domesticated yellow variety), a chaffinch, a white, a brown, and a blue tit (Cyanops unicolor), a wood pigeon (Colombia troca) and a petrel (Thalassidroma Bulwerii). There is also a local variety of the black-cap, distinguishable from the common kind by the extension in the male of the cap to the shoulder. About seventy other species have been seen from time to time in Madeira, chiefly stragglers from the African coast, many of them coming with the leste wind.

To locally land reptile is a small lizard (Lacerta dauphina), which is abundant and is very destructive to the grape crop. The loggerhead turtle (Caviaiara careta, Gray) is frequently caught, and is cooked for soup. The largest of its kind is that from the green west of the Green Islands. A single variety of frog (Rana esculenta) has been introduced; there are no other batrachians.

About 250 species of marine fishes taken at Madeira have been scientifically described. Among these, the largest in number, belonging Siemens, are rays, 35 species, the sharks with 24, the Sparados with 15, the rays with 14, the Labridae with 3, the Gudidae with 12, the Cephalopoda and Saragoniidae with 12. Many kinds, such as the mackerel, horse mackerel, goby, mullet, braisie, &c. are caught in abundance, and afford a cheap article of diet to the people. Some species of tunny are taken plentifully in spring and summer, one of them sometimes attaining the weight of 300 lbs. The only other large water fish is the common eel, which is found in one or two of the streams.

According to T. V. Wallaston (Testacea atlantica, 1878), they have been found 158 species of mollusca on the land, 6 inhabiting fresh water, and 7 littoral species, making a total of 171. A large majority of the land shells are considered to be peculiar. Many of the species are variable in form or colour, and some have an extraordinary number of varieties. Of the land mollusca 91 species are assigned to the genus Helix, 31 to the genus Pupa, and 15 to the genus Aschalina (or Lava). About 43 species are found both living and fossil in superficial deposits of calcareous sand in Madeira or Porto Santo. These deposits were assigned by Lyell to the newer Pliocene period. Some 12 or 13 species have not been hitherto discovered alive, and 7 species of oysters and 8 of mussel have been collected, among them are some highly interesting forms.

The only order of insects which has been thoroughly examined is that of the Coleoptera. By the persevering researches of T. V. Wallaston, the monograph of this order has been brought to light at the Madeiras. The proportion of endemic kinds is very large, and it is remarkable that 200 of them are either wingless or very weakly developed, so that they cannot fly, while 23 of the endemic genera have all their species in this respect. With regard to the Lepidoptera, 11 or 12 species of butterflies have been seen, all of which belong to European genera. Some of the species are geographic varieties of well-known types. Upon of 100 moths have been collected, the majority of them being a European stamp, but probably a fourth of the total number are peculiar to the Madeiran group. Thirty-seven species of Neuroptera have been observed in Madeira, 12 of them being so far as is known peculiar.

The bristle-footed worms of the coast have been studied by Pro- fessor Blainville, and he has prepared 300 species of which a large number were new to science. There are no modern coral reefs, but several species of stony and flexible corals have been collected, though none are of commercial value. There is, however, a white stony coral allied to the red coral of the Mediterranean which would be valuable as an article of trade if it could be obtained in sufficient quantity. Specimens of a rare and handsome red Para- garia, another species of coral, have been received at the Natural History Museum and at the British Museum.

Flora.—The vegetation is strongly impressed with the south-European character. Many of the plants in the lower region undoubtedly were introduced and naturalized after the Portuguese colonization. Many of the larger of the remainder are found at the Canaries and the Azores, or in one of these groups. In the higher districts there are about a hundred plants which are peculiarly Madeiran, either as distinct species or as strongly marked varieties. The flowering plants which belong to themadeira, are the monocotyledons numbering 70 genera and 128 species, the dicotyledons 293 genera and 589 species. The three largest orders are the Compositas, Leguminosas and Gramineae. Forty-one species of ferns grow in Madeira, three of which are endemic species and six others belong to the peculiar flora of the North Atlantic islands, mostly in the Canaries. Among the ferns is a species of Hepaticas. A connexion between the flora of Madeira and that of the West Indies and tropical America has been inferred from the occurrence of six Ierna-found nowhere in Europe or North Africa, but existing on the islands of the West Indies or on the Isthmus of America. A further relationship to that continent to be traced by the presence in Madeira of the beautiful ericaceous tree Clethra arborea, belonging to a genus which is otherwise wholly American, and of a Persice, a tree laurel, also an American genus. The dragon tree (Dracaena Draco) is almost extinct. Amongst the trees most worthy of note are four of the aquatic house belonging to separate genera, an Ardisia, Piluliferas, Sideroxylon, Notelacia, Rhambus and Myrica,—a strange mixture of genera to be found on a small Atlantic island. Two heaths of these, with growths of grass and heather, are found on the mountains. In some parts there is a belt of the Spanish chestnut, but about the height of 1500 ft. There is no indigenous pine tree or at the Canaries; but large tracts on the hills have been planted with Pinus pinaster, from which the fuel of the inhabitants is mainly derived. A European juniper (Oxycedrus), growing to the height of 40 or 50 ft., was formerly abundant, but has been almost exterminated, its scented wood is used by the cabin-maker. Several of the native trees and shrubs now grow only in situations which are nearly inaccessible, and some of the indigenous plants are of the greatest rarity. But some plants of foreign origin have spread in a remarkable manner, and are now very common on the high terraces. Amongst these is the peach (Oupwtis Tuna), which in many spots on the coast is sufficiently abundant to give a character to the landscape. As to Algae, the coral-reef rock is covered with a sea too quiet for a luxuriant marine vegetation, consequently the clumping, consequent on the presence of coral-reef rocks, is very small. The mussels are scarce, and the most common are those of the Atlantic, making the red mussels especially abundant and the rock or yellow mussels also very common. The woman's outer garments consist of a gaudily coloured gown, made from island material, with a small cape of coarse scarlet or blue woollen cloth. The population tends to increase rapidly. In 1900 it amounted to 150,574, including 80 foreigners, of whom the majority were British. The number of females exceeds that of males by about 6000, partly because many of the able-bodied males emigrate to Brazil or the United States. The density of population (479-5 per sq. m.) is very great for a country occupying the extensive area between the town and chiefly dependent on agriculture and viticulture.

Agriculture.—A large portion of the land was formerly entailed in the families of the landlords (morgados), but entails have been abolished by the legislature, and the land is now absolutely free. The deficiency of water is a great obstacle to the proper cultivation of the land, and the rocky nature or steep inclination of the upper parts of the islands is an effectual bar to all tillage. An incredible amount of labour has been expended upon the soil, partly in the erection of walls intended to prevent its being washed away by the rains, and partly in building up the plots of ground in the form of terraces. Watercourses have been constructed for purposes of irrigation, without which at regular intervals the island would not produce a hundredth part of its present yield. These watercourses originate high up in the ravines, are built of masonry or driven through the rock, and wind about for miles until they reach the cultivated land. Some of them are brought by tunnels from the north side of the island through the central crest of hill. Each occupier takes his turn at the running stream for many hours in the day, or where the water is deep and swiftly flowing, by turning the water head, standing on the backs of oxen or horses. The women of all ages belong to the landlord. The tenant can sell his share of the property without the consent of the landlord, if he does not so
dispose of it that share passes to his heirs. In this way the tenant practically enjoys fixity of tenure, for the landlord is seldom in a position to pay the price at which the tenant's share is valued. Money rents are rare, the métayer system regulating almost universally the tenure of land and tenants, and, in this, the tenant gives to the owner a certain portion of the produce, usually one half or one third. The holdings are as a rule rarely larger than one man can cultivate with a little occasional assistance. There is, therefore, no seigniory and pastures, the cattle being stall-fed, and little feeding on the mountains. Horses are never employed for draught, all labour of that kind being done by oxen.

Cultivation.-The principal productions of the soil are wine and sugar. The vine was introduced from Cyprus or Crete soon after the discovery of the island by the Portuguese (1420), but it was not actively cultivated until the early part of the 16th century. The vines, after having been destroyed by the introduction of a disease which they made its first appearance in the island in 1852, were replanted, and in a few years wine was again made. The phylloxera also made its way to the island, and every vineyard in Madeira was more or less affected by it. The wine usually termed Madeira is made from a mixture of black and white grapes, which are also made separately into wines called Tinta and Verdelho, after the names of the grapes. Other high-class wines, known as Basal, Sercial and Malmsey, are made from varieties of grapes bearing the same names. (See also Wine.)

The sugar cane is said to have been brought from Sicily about 1420. At that time the cane from which it produce became the sole staple of the island. The cultivation languished, however, as the more abundant produce of tropical countries came into the European market, and sugar and molasses could be made by the destruction of the vines compelled the peasants to turn their attention to other things. Its cultivation was resumed and sugar machinery imported. A considerable quantity of sugar is made by the distillation of the molasses of the muscatel. Most of it is used after extraction from molasses, and this is consumed on the island. The cane does not flourish here as luxuriantly as within the tropics; but in localities below 1000 ft., where there is a good supply of water, it pays the cultivator well.

The grain produced on the island (principally wheat, barley and Indian corn) is not sufficient for the consumption of the people. The common potato, sweet potato and gourds of various kinds are extensively grown, as well as the Colocasia esculenta, the kalo of the Pacific islanders, the root of which yields an insipid food. Most of the common vegetables of Madoir, such as onions, potatoes, apples, pears and peaches, all of poor quality, oranges, lemons, guavas, mangos, loquats, custard-apples, figs, bananas and pineapples are produced, the last two forming two articles of export. The date palm is occasionally grown, but its fruit is scarcely edible. On the hills large quantities of the Spanish chestnut afford an item in the food of the common people. A little tobacco is grown, and is made into cigars of inferior quality.

Chief Towns and Communications.—Funchal (pop. 26,830) is described in a separate article. The other chief towns are Camara de Lobos (7150), Machico (6128), Santa Cruz (5879) Ponta do Sol (5665), São Vicente (4896), Calheta (3475), Santana (3011) and Porto Santo (2111). Each of these is the capital of a commune (concelho), to which it gives its name. Madeira is connected by regular lines of steamships with Great Britain, Germany, Portugal, Cape Colony, Brazil and the United States. There is no railway in the archipelago, and partly owing to the irregularities of the surface of the roads, of which there are some 580 m., are bad, except in the neighbourhood of Funchal. Wheel carriages are rare, and all heavy goods are transported either on the backs of mules or upon rude wooden sledges drawn by bullocks. When horses are not employed, locomotion is effected either by means of hammers or by bullock cars. The ham-mock (rîde) is a piece of stout canvas gathered up and secured at each end to a long pole carried by a couple of bearers. In place of cabs, curtained cars on sledges, made to hold four persons, and drawn by a pair of bullocks, are employed. They are convenient, but the rate of progress is very slow.

Administration.—The archipelago is officially styled the district of Funchal; it returns members to the Portuguese Cortes, and is regarded as an integral part of the kingdom. The district is subdivided into the eight communes already enumerated, and is administered in accordance with the same laws that regulate local government on the mainland (see Portugal). Funchal is a Roman Catholic bishopric in the archiepiscopal province of Lisbon. Education is compulsory in name only, for less than 2% of the population could read when the census of 1900 was taken. An infantry regiment and a battery of garrison artillery are permanently stationed in Madeira.

History.—It has been conjectured, but on insufficient evidence, that the Phoenicians discovered Madeira at a very early period. Pliny mentions certain Purple or Mauretanian Islands, the position of which with reference to the fortunate islands or Canaries might seem to indicate the Madeiras. There is a romantic story, to the effect that two lovers, Robert Machin, a Machin, or Machado, and Anna d'Arêt, fleeing from England to France (c. 1370) were driven out of their course by a violent storm and cast on the coast of Madeira at the place subsequently named Machico, in memory of one of them. Both perished here, but some of their crew escaped to the Barbary coast, and were made slaves. Among them was the pilot Pedro Morales of Seville, who is said to have been ransomed and to have communicated his knowledge of Madeira to João González Zarco (or Largo). How far this story is true cannot now be ascertained. It is, however, certain that Carvajal returned to Portugal in 1418, having been driven through a storm by while he was exploring the coast of West Africa. Madeira itself was discovered in 1420. It is probable that the whole archipelago had been explored at an earlier date by Genoese adventurers, and had been forgotten; for an Italian map dated 1351 (the Laurentian portolano) shows the Madeiras quite clearly, and there is some reason to believe that they were known to the Genoese before 1350. When Zarco visited Madeira in 1420 the islands were uninhabited, but Prince Henry the Navigator at once began their colonization, aided by the knights of the Order of Christ.

Sanctified by the pope and by two charters which the king of Portugal granted in 1430 and 1433, the work proceeded apace; much land was deforested and brought into cultivation, and the Madeiran sugar trade soon became important. For the sixty years 1580—1640 Madeira, with Portugal itself, was united with Spain. Slavery was abolished in Madeira in 1775, by order of Pombal. In 1801 British troops, commanded by General Bessford, occupied the island for a few months, and it was again under the British flag from 1807 to 1814. It shared in the civil disturbances brought about by the accession of Dom Miguel (see Portugal). The island has in 1883 its history is a record of peaceful commercial development.

See A. S. Brown, Madeira, the Canary Islands and the Azores (1903), a comprehensive study of the three archipelagos. The Land of the Wine, by A. J. D. Biddle (Philadelphia, 1901) is generally valuable, but its historic treatment could be improved. H. L. D. Buch, Handbuch für Madeira (1884) and Vahl, Madeira's Vegetation (Copenhagen, 1904).

MADELENIAN, a term derived from La Madeleine, a cave in the Vézère, about midway between Mouster and Les Eyzies, France, and given by the French anthropologist Gabriel de Mortillet to the third stage of his system of cave-chronology, synchronous with the fourth or most recent division of the Quaternary Age. The Madeleinen epoch was a long one, represented by numerous stations, whose contents show progress in the arts and general culture. It was characterized by a cold and dry climate, the existence of man in association with the reindeer, and the extinction of the mammoth. The use of bone and ivory for various implements, already begun in the preceding Solutrian epoch, was much increased, and the period is essentially a Bone age. The bone instruments are very varied: spear-points, harpoon-heads, borers, hooks and needles. Most remarkable is the evidence La Madeleine affords of prehistoric art. Numbers of bones, reindeer antlers and animals' teeth were found, with rude pictures, carved or etched on them, of seals, fishes, reindeer, mammoths and other creatures. The best of these are a mammoth engraved on a fragment of its own ivory; a dagger of reindeer antler, with handle in form of a reindeer; a cave-bear cut on a flat piece of schist; a seal on a bear's tooth; a fish well drawn on a reindeer antler; and a complete picture, also on reindeer antler, showing horses, an aurochs, trees, and a snake biting a man's leg. The man is naked, and this and the snake suggest a warm
climates, in spite of the presence of the reindeer. The fauna of the Madeleian epoch seems, indeed, to have included tigers and other tropical species by side with reindeer, blue foxes, Arctic hares and other polar creatures. Madelean man appears to have been of low stature, dolichocephalic, with low retreating forehead and prominent brow ridges. Besides Edouard Fleche's chief stations of the epoch are Les Eyziès, Laugerie Basse, and Gorge d'Enfer in Dordogne; Grotte du Placard in Charente and others in southern France.

MADELEY, a market town in the municipal borough of Wenh-Well-known in the Petermann's of Lord Forbes, in the Madeley Market and Great Western railways (Madeley Court). Pop. of civil parish (1901), 8442. There are large ironworks, ironstone and coal are mined, and potter's clay is raised. The church of St. Michael (1706) replaced a Norman building. The living was held from 1760 to 1783 by John William Fletcher or de la Flecher, a close friend of the Wesleys. The parish includes a portion of Coalbrookdale (q.v.), and the towns of Ironbridge and Coalport. IRONBRIDGE, a town picturesquely situated on the steep left bank of the Severn, adjoins Madeley on the south-west. It takes its name from the iron bridge of one span crossing the river, erected in 1779. This bridge is a remarkable work considering its date; it was probably the first erected, at any rate so large a scale, and attracted great attention. It is the work of Abraham Darby, the third of the name, one of the famous family of iron-workers in Coalbrookdale. Here are brick and tile works and lime-kilns. There is a station (Ironbridge and Broseley) on the Great Western railway, across the river. Coalport lies also on the Severn, S. of Madeley and 2 m. S.E. of Ironbridge, with a station on the Great Western railway. It has large china works, founded at the close of the 18th century, which subsequently incorporated those of Caugheley, across the Severn, and of Nantgarw in Glamorganshire.

MĀDHAVA ĀGHIYĀ (fl. c. 1380), Hindu statesman and philosopher, lived at the court of Vijayanagar (the modern Hampi in the district of Bellary), the vigorous Southern Hindu kingdom that so long withstood Mahomedan influence and aggression. His younger brother Sāyāya (d. 1387) was associated with him in the administration and was a famous commentator on the Rigveda. Sāyāya's commentaries were influenced by and dedicated to Mādhava, who is best known as the author of the Sarvadāsāra Saṃgraha (Compendium of Speculations). With remarkable mental detachment he places himself in the position of an adherent of sixteen distinct systems. Mādhava also wrote a commentary on the Mīmāṃsā Sūtras. He died as abbot of the monastery of Shringeri.

MADI (A-MADI), a negro race of the Nile valley, occupying both banks of the Bahr-el-Jebel immediately north of Albert Nyanza. Tradition makes them immigrants from the north-west. They are remarkable for the consideration shown to their women, who choose their own husbands, are never ill-treated or hard-worked, and take part in tribal deliberations. The Madi build four storements of an elaborate type, two huge narrow stones sloping towards each other with two smaller slabs covering the opening between them. They have been much harried by the Azande and Abarambo. They were visited by W. Junker in 1882-1883, and described by him in Petermann's Mitteilungen for May 1883.

MADISON, JAMES (1751-1836), fourth president of the United States, was born at Port Conway, in King George county, Virginia, on the 16th of March 1751. His first ancestor in America may possibly have been Captain Isaac Maddyson, a colonist of 1623, proclaimed by John Smith as an excellent Indian fighter. His father, also named James Madison, was the owner of large estates in Orange county, Virginia. In 1769 the son entered the college of New Jersey (now Princeton University), where, in the same year, he founded the well-known literary club, "The American Whig Society." He graduated in 1771, but remained for another year at Princeton studying, apparently for the ministry, under the direction of John Witherspoon (1722-1794). In 1772 he returned to Virginia, where he pursued his reading and studies, especially theology and Hebrew, and acted as a tutor to the younger children of the family. In 1773 he became chairman of the committee of public safety for Orange county, and wrote its response to Patrick Henry's call for the arming of a colonial militia, and in the spring of 1775 he was chosen a delegate to the new Virginia convention, where he was on the committee which drafted the constitution for the state, and proposed an amendment (not adopted) which declared that "all men are equally entitled to the full and free exercise of religion, and was more radical than the similar one offered by George Mason. In 1777, largely, it seems, because he refused to treat the electors with rum and punch, after the custom of the time, he was not re-elected, but in November of the same year he was chosen a member of the privy council or council of state, in which he acted as interpreter for a few months, as secretary prepared papers for the governor, and in general took a prominent part from the 14th of January 1778 until the end of 1779, when he was elected a delegate to the Continental Congress.

He was in Congress during the final stages of the War of Independence, and in 1780 drafted instructions to Jay, then representing the United States at Madrid, that in negotiations with Spain he should insist upon the free navigation of the Mississippi and upon the principle that the United States succeeded to British rights affirmed by the treaty of Paris of 1783. When the confederation was almost in a state of collapse because of the failure of the states to respond to requisitions of Congress for supplies for the federal treasury, Madison was among the first to advocate the granting of additional powers to Congress, and urged that congress should forbid the states to issue more paper money. In 1781 he favoured an amendment of the Articles of Confederation giving Congress power to enforce its requisitions, and in 1783, in spite of the open opposition of the Virginia legislature, which considered the Virginian delegates wholly subject to its instructions, he advocated that the states should grant to Congress for twenty-five years authority to levy an import duty, and suggested a scheme to provide for the interest on the debt not raised by the import duty—apportioning it among the states on the basis of population, counting three-fifths of the slaves, a ratio suggested by Madison himself. Accompanying this plan was an address to the states drawn up by Madison, and one of the ablest of his state papers. In the same year, with Oliver Ellsworth of Connecticut, Nathaniel Gorham of Massachusetts, Gunning Bedford of Delaware, and John Rutledge of South Carolina, he was a member of the committee which reported on the subject of the distribution of the "back lands," or unoccupied Western territory, held by several of the states; the report was a skilful compromise made by Madison, which secured the approval of the rather exigent Virginia legislature.

In November 1783 Madison's term in Congress expired, and he returned to Virginia and took up the study of the law. In the following year he was elected to the House of Delegates. As a member of its committee on religion, he opposed the giving of special privileges to the Episcopal (or any other) church, and contended against a general assessment for the support of the churches of the state. His petition of remonstrance against the proposed assessment, drawn up at the suggestion of George Nicholas (c. 1755-1799), was widely circulated and procured its defeat. On the 26th of December 1785 Jefferson's Bill for establishing religious freedom in Virginia, which had been introduced by Madison, was passed. In the Virginia House of Delegates, as in the Continental Congress, he opposed the further issue of paper money; and he tried to induce the legislature to repeal the law confiscating British debts, but he did not lose sight of the interests of the Confederacy. The boundary between Virginia and Maryland, according to the Baltimore grant, was the south shore of the Potomac, a line to which Virginia had agreed on condition of free
navigation of the river and the Chesapeake Bay. Virginia now feared that too much had been given up and desired joint regulation of the navigation and commerce of the river by Maryland and Virginia. On Madison's proposal commissioners from the two states met at Alexandria (q.v.) and at Mount Vernon in March 1785. The Maryland legislature approved the Mount Vernon agreement and proposed to invite Pennsylvania and Delaware to join in the arrangement Madison, seeing an opportunity for more general concert in regard to commerce and trade (and possibly for the increase of the power of Congress), proposed that all the states should be invited to send commissioners to consider commercial questions, and that an election to the convention, which was held in Baltimore, 1786, by the Virginia legislature. This led to the Annapolis convention of 1786, and that in turn led to the Philadelphia convention of 1787. In April 1787 Madison had written a paper, The Vices of the Political System of the United States, and from his study of confederacies, ancient and modern, later summed up in numbers 17, 18, and 19 of The Federalist, he had concluded that no confederacy could long endure if it acted upon states only and not directly upon individuals. As the time for the convention of 1787 approached he drew up an outline of the features of the plan which he had in mind as the "Virginia plan" presented in the convention by Edmund Jennings Randolph. Madison's scheme, as expressed in a letter to Washington dated the 16th of April 1787, was that individual sovereignty of states was irreconcilable with aggregate sovereignty, but that the "consolidation of the whole into one simple republic would be as inexpedient as it is unattainable." He considered as a practical middle ground changing the basis of representation in Congress from states to population; giving the national government "positive and complete authority in all cases which require uniformity"; giving it a negative on all state laws, a power which might well be vested in the Senate, a comparatively permanent body; electing the lower house, and the more numerous, for a short term; providing for a national executive, for extending the national supremacy over the judiciary and the militia, for a council to revise all laws, and for an express statement of the right of coercion; and finally, obtaining the ratification of a new constitutional instrument from the people, and not merely from the legislatures. The "Virginia plan" was the basis of the convention's deliberations which resulted in the constitution favourably voted on by the convention on the 17th of September 1787. Among the features of the plan which were not embodied in the constitution were the following: proportionate representation in the Senate and the election of its members by the lower house "out of a proper number of persons nominated by the individual legislatures"; the vesting in the national Congress of power to negative state acts; and the establishment of a council of revision (the executive and a convenient number of national judges) with veto power over all laws passed by the national Congress. Madison, always an opponent of slavery, disapproved of the compromise (in Art. I. § 9 and Art. V.) postponing to 1808 (or later) the prohibition of the importation of slaves. He took a leading part in the debates of the convention, of which he kept full and careful notes, afterwards published by order of Congress (3 vols., Washington, 1843). Many minute and wise provisions are due to him, and he spoke before the convention more frequently than any delegate except James Wilson and Gouverneur Morris. In spite of the opposition to the constitution of the Virginia leaders George Mason and E. J. Randolph, Madison induced the state's delegation to stand by the constitution in the convention. His influence largely shaped the form of the final draft of the constitution. The Madison proposal was finished with this draft; that the constitution was accepted by the people was due in an eminent degree to the efforts of Madison, who, to place the new constitution before the public in its true light, and to meet the objections brought against it, joined Alexander Hamilton (q.v.) and John Jay in writing The Federalist, a series of eighty-five papers, out of which twenty certainly, and nine others probably, were written by him. In the Virginia convention for ratifying the constitution (June 1788), when eight states had ratified and it seemed that Virginia's vote would be needed to make the necessary nine (New Hampshire's favourable vote was cast only shortly before that of Virginia), and it appeared that New York would vote against the constitution if Virginia did not ratify it, Madison was called upon to defend that instrument again, and he appeared at his best against its opponents, Patrick Henry, George Mason, James Monroe, Benjamin Harrison, William Grayson and John Tyler. He answered their objections in detail, calmly and with an intellectual power and earnestness that carried the convention. The result was a victory against an originally adverse public opinion and against the eloquence of the opponents of the constitution, for Madison had written the "Federalist," Edmund Randolph. The Federalists, Edmund Nicholas, Harry Innes and Henry Lee. At the same time Madison's labours in behalf of the constitution alienated from him valuable political support in Virginia. He was defeated by Richard Henry Lee and William Grayson in his candidacy for the United States Senate, but in his own district he was chosen a representative to Congress, defeating James Monroe, who seems to have had the powerful support of Patrick Henry. Madison took his seat in the House of Representatives in April 1789, and assumed a leading part in the legislation necessary of increasing the new government's revenue. The Tariff Bill giving certain notable advantages to nations with which the United States had commercial treaties, hoping to force Great Britain into a similar treaty; but his policy of discrimination against England was rejected by Congress. It was his belief that such a system of retaliation would remove the possibility of war arising from commercial quarrels. He introduced resolutions calling for the establishment of three executive departments, foreign affairs, treasury and war, the head of each removable by the president. Most important of all, he proposed nine amendments to the constitution, embodying suggestions made by a number of the ratifying states, especially those of Virginia at the instance of George Mason; and the essential principles of Madison's proposed amendments were included in a Bill of Rights, adopted by the states in the form of ten amendments. The absence of a Bill of Rights from the constitution as first adopted had been the point on which the opposition had made common cause, and the adoption of this now greatly weakened the same opposition. Although a staunch friend of the constitution, Madison believed, however, that the instrument should be interpreted conservatively and not be made the means of introducing radical innovations. The tide of strict construction was setting in strongly in his state, and he was borne along with the flood. It is very probable that Jefferson's influence over Madison, which was greater than Hamilton's, contributed to this result. Madison now opposed Hamilton's measures for the funding of the debt, the assumption of state debts, and the establishment of a National Bank, and on other questions he sided more and more with the opposition, gradually assuming its leadership in the House of Representatives and labouring to confine the powers of the national government within the narrowest possible limits; his most important argument against Hamilton's Bank was that the constitution did not provide for it explicitly, and could not properly be construed into permitting its creation. Madison, Jefferson and Randolph were consulted by Washington, and they advised him not to sign the bill providing for the Bank, but Hamilton's counter-argument was successful. On the same constitutional grounds Madison objected to the carrying out of the recommendations in Hamilton's famous report on manufactures (Dec. 5, 1791), which favoured a protective tariff. In the presidential campaign of 1796 Madison seems to have been in the determined efforts of the Jeffersonians to defeat John Adams by electing George Clinton vice-president. In 1793-1796 he strongly criticized the administration for maintaining a neutral position between Great Britain and France, writing for the public press five papers (signed "Helvidius"), attacking the "monarchical prerogative of the executive " as exercised in the proclamation of neutrality in 1793 and denying the president's right to recognize foreign states. He found in Washington's attitude—as in Hamilton's failure to pay an installment of the moneys
due France—an "Anglified complexion," in direct opposition to the popular sympathy with France and French Republicanism. In 1794 he tried again his commercial weapons, introducing in the House of Representatives resolutions based on Jefferson's report on commerce, advising retaliation against Great Britain and discrimination in commercial and navigation laws in favour of France; and he declared that the friends of Jay's treaty were "a British party systematically aiming at an exclusive connexion with the British government," and in 1796 strenuously but unsuccessfully opposed the appropriation of money to carry this treaty into effect. Still thinking that foreign nations could be coerced through their commercial interests, he scouted as visionary the idea that Great Britain would go to war on a refusal to carry Jay's treaty into effect, thinking it inconceivable that Great Britain "would wantonly make war" upon a country which was the best market she had in the world for her manufactures, and one with which her export trade was so much larger than her import.

In 1797 Madison retired from Congress, but not to a life of inactivity. In 1798 he joined Jefferson in opposing the Alien and Sedition Laws, and Madison himself wrote the resolutions of the Virginia legislature declaring that it viewed "the powers of the Federal government as resulting from the compact to which the states are parties, as limited by the plain sense and intention of the instrument constituting that compact; as no further valid than they are authorized by the grants enumerated in that compact; and that, in case of a deliberate, palpable and dangerous exercise of other powers, not granted by the said compact, the states, which are parties thereto, have the right and are in duty bound to interpose to arrest the progress of the evil, and for maintaining within their respective limits, the authorities, rights, and liberties appertaining to them." The Virginia resolutions and the Kentucky resolutions (the latter having been drafted by Jefferson) were met by dissenting resolutions from the New England states, from New York, and from Delaware. In answer to these, Madison, who had become a member of the Virginia legislature in the autumn of 1799, wrote for the committee to which they were referred a report elaborating and sustaining in every point the phraseology of the Virginia resolutions.

Upon the accession of the Republican party to power in 1801, Madison became secretary of state in Jefferson's cabinet, a position for which he was well fitted both because he possessed to a remarkable degree the gifts of careful thinking and discreet and able speaking, and of large constructive ability; and because he was well versed in constitutional and international law and practised a fairness in discussion essential to a diplomat. During the eight years that he held the portfolio of state, he had continually to defend the neutral rights of the United States against the encroachments of European belligerents; in 1806 he published An Examination of the British Doctrine whichSubjects to Capture a Neutral Trade not open in Time of Peace, a careful argument—with a minute examination of authorities on international law—against the rule of war of 1756 extended by Great Britain in 1793 and 1803.

During Jefferson's presidency and whilst Madison was secretary of state, by the purchase of Louisiana, Madison's campaign began in 1808 for the free navigation of the Mississippi was brought to a successful close. The candidate in 1808 of the Republican party, although bitterly opposed in the party by John Randolph and George Clinton, Madison was elected president, defeating C. C. Pinckney, the Federalist candidate, by 122 votes to 47. Madison had no false hopes of placating the Federalist opposition, but as the preceding administration was one with which he was in harmony, his position was different from that of Jefferson. Madison, and he had less occasion for removing Federalists from office.

Jefferson's peace policy—or, more correctly, Madison's peace policy—of commercial restrictions to coerce Great Britain and France he continued to follow until 1812, when he was forced to change these futile commercial weapons for a policy of war, which was very popular with the extreme French wing of his party. There is a charge, which has never been proved or disproved, that Madison's real desire was for peace, but that in order to secure the renomination he yielded to that wing of his party which was resolved on war with Great Britain. The only certain fact is that Madison, whatever were his personal feelings in this matter, acted according to the wishes of a majority of the Republicans; but whether in doing so he was influenced by the desire of another nomination is largely a matter of conjecture. Madison was re-nominated on the 18th of May 1812, issued his war message on the 1st of June, and in the November elections he was re-elected, defeating De Witt Clinton by 128 votes to 89. His administration during the war was pitifully weak. His cabinet in great part had been dictated to him in 1809 by a senatorial clique, and it was hopelessly discordant; for two years he was at all intents and purposes his own secretary of state, Robert Smith being a mere figure-head of whom he gladly got rid in 1811, giving Monroe the vacant place. Madison himself had attempted alternately to prevent war by his "commercial weapons" and to prepare the country for war, but he had met with no success, because of the tricky diplomacy of Great Britain and of France, and because of the general distrust of him coupled with the particular opposition to the war of the prosperous New England Federalists, who suggested with the utmost seriousness that his resignation should be demanded. In brief, Madison was too much the mere scholar to prove a strong leader in such a crisis. The supreme disgrace of the administration was the capture and partial destruction in August 1814 of the city of Washington—this was due, however, to incompetence of the military and not to any lack of prudence on the cabinet's part. In general, Congress was more blamable than either the president or his official family, or the army officers. With the declaration of peace the president again gained a momentary popularity much like that he had won in 1809 by his apparent willingness at that time to fight France.

Retiring from the presidency in 1817, Madison returned to his home, Montpellier (in Orange county, Virginia), which he left in no official capacity save in 1829, when he was a delegate to the state constitutional convention and served on several of its committees. Montpellier, like Jefferson's Monticello and Monroe's Oak-Hill, was an expensive bit of "gentleman farming," which with his generous Virginia hospitality nearly ruined its owner financially. Madison's home was peculiarly a centre for literary travellers in his last years; when he was eighty-three he was visited by Harriet Martineau, who reported her conversations with him in her Retrospect of Western Travel (1838). He took a great interest in education—his library was left to the university of Virginia, where it was burned in 1865—in emancipation, and in agricultural questions, to the very last. He died at Montpellier on the 28th of June 1836. Madison married, in 1794, Dorothy Payne Todd (1772-1849), widow of John Todd, a Philadelphia lawyer. She had great social charm, and upon Madison's entering Jefferson's cabinet became "first lady" in Washington society. Her plump beauty was often remarked—notably by Ireland, who "could see the end of his husband through the feebile figure and wizened face—for even in his prime Madison was, as Henry Adams says, "a small man, quiet, somewhat precise in manner, pleasant, fond of conversation, with a certain
mixture of ease and dignity in his address." Her son, spoiled by his mother and his step-father, became a wild young fellow, and added his debts to the heavy burden of Montpelier upon Madison.

Madison's portrait was painted by Gilbert Stuart and by Charles Willson Peale; Giuseppe Ceracchi made a marble bust of him in 1795, and John H. J. Browere another in 1827, now in possession of the Virginia Historical Society at Richmond. Though commonly dignified and a little stiff, he had a sense of humour and he was fond of telling a good story. Henry Clay considered him "contrasting with Jefferson, said that Jefferson had more genius, Madison more judgment and common sense; that Jefferson was a visionary and a theorist; Madison cool, dispassionate, practical and safe. The broadest and most accurate scholar among the "founders and fathers," he was particularly an expert in constitutional history and theory. In the great causes for which Madison fought in his earlier years—religious freedom and separation of church and state, the free navigation of the Mississippi, and the adoption of the constitution—he met with success. His greatest and truest fame is as the "father of the constitution." The "commercial weapons" with which he wished to prevent armed conflict proved less useful in his day than they have since been in international disputes.

"Authorities."—Madison's personality is perplexingly vague; the biographies of him are little more than histories of the period, and the best history of the later period in which he was before the public, History of the United States from the Union to 1817 (1837-1889), gives the clearest sketch and best criticism of him. Madison are: J. Q. Adams's (Boston, 1850); W. C. Rives's (Boston, 1858-1860, 3 vols.), covering the period previous to 1797; S. H. G. & W. D. (Boston, 1888) in the "American Historical Series" and Gaillard Hunt's (New York, 1902). Madison's Writings (7 vols. New York, 1890-1906) were edited by Hunt, who also edited The Address of the Convention which framed the Constitution of the United States, Recorded by James Madison (2 vols., New York, 1908). See also Mrs Madison's Memoirs and Letters (Boston, 1887) and Maud Wilder Goodwin, Dolly Madison (New York, 1897).
MADOU—MADRAS

on the Chautauqua model. Near the city is one of the five fish-hatcheries maintained by the state; it is largely devoted to the propagation of trout and other small fish. North of the city, occupying a tract of 500 acres, on Lake Mendota, are the buildings and grounds of the state hospital for the insane, opened in 1860.

The city's streets are broad and heavily shaded with a profusion of elm, oak and maple trees. There are many fine stone residences dating from the middle of the 19th century. There are several parks of great beauty, and along the shores of Lake Mendota there is a broad boulevard drive of 12 m. The municipality owns its waterworks, the water being obtained from eleven artesian wells, and being chemically similar to that of Waukesha Springs. The city and surrounding region are a summer resort, the lakes affording opportunities for fishing and for yachting and boating.

Madison is an important jobbing centre for central and south-western Wisconsin; it has an extensive trade in farm, garden and dairy products, poultry and tobacco; and there are various manufactures. In 1905 the value of the total factory product was $4,391,143, an increase of 22.4% over that in 1900.

At the time of the settlement by the whites the aboriginal inhabitants of the Four-Lakes region were the Winnebago. Prehistoric earthworks are to be seen in the neighbourhood, several animal-shaped mounds upon the shores of Lake Mendota, Monona and Waubesa being among the best examples. A regular trading post is known to have been established on Lake Mendota as early as 1820. The title to the Indian lands was acquired by the United States by treaty in 1825. Colonel Ebenezer Brigham established himself at Blue Mounds, in the western part of Dane county, in 1827. In 1832 the "Four-Lakes" country was in the theatre of hostilities during the Black Hawk War; Colonel Henry Dodge held a conference with Winnebago chiefs on Lake Mendota, and there were several skirmishes in the neighbourhood between his troops and the followers of Black Hawk, one of which took place on the site of Madison. After Black Hawk's defeat on the Bad Axe he fled to the Wisconsin river Dalles, near the present Kibbourn, where he was betrayed by the Winnebago. In 1836 Stevens T. Mason, governor of Michigan, and James Duane Doty, then U.S. district judge, who had visited the region as early as 1829, recorded a tract of land, including most of the present site of Madison. Here they surveyed a "paper" city which they named in honour of James Madison. On the 3rd of December 1836 the territorial legislature in session at Belmont, after a protracted and acrimonious debate, determined, largely through Doty's influence, to make Madison the permanent capital. The territory of Wisconsin, created in 1836, was the little-studied country of the southern Great Lakes and the Mississippi westward to the Rocky Mountains. The capital city was not completed until 1847, when it contained only 170 houses. Madison was chartered as a city in 1836. In 1862 a large number of Confederate prisoners were confined in Camp Randall, at Madison, and many of them died in hospital.

See D. S. Durrie, History of Madison, Wisconsin (Madison, 1874); Louis C. Drucker, Madison the Capital of Wisconsin (Madison, 1857); J. D. Butler, "The Four Lakes Country," in Wisconsin Historical Society Collections, vol. 10 (1888); and R. C. Thwaites, "Madison" in Historic Towns of the Western States (New York, 1900), and his "Story of Madison" in The University of Wisconsin (Madison, 1900).

MADOU, JEAN BAPTISTE (1796-1877), Belgian painter and lithographer, was born at Brussels on the 3rd of February 1796. He studied at the Brussels Academy of Fine Arts and was a pupil of François. While draughtsman to the topographical military division at Courtrai, he received a commission for lithographic work from a Brussels publisher. It was about 1820 that he began his artistic career. Between 1825 and 1827 he contributed to Les Vues pittoresques de la Belgique, to a Life of Napoleon, and to works on the costumes of the Netherlands, and later made a great reputation by his work in La Physionomie de la société en Europe depuis 1800 jusqu'à nos jours (1836) and Les Scènes de la vie des peuples.

It was not until about 1840 that he began to paint in oils, and the success of his early efforts in this medium resulted in a long series of pictures representing scenes of village and city life, including "The Fiddler," "The Jewel Merchant," "The Police Court," "The Drunkard," "The Ill-regulated Household," and "The Village Politicians." Among his numerous works mention may also be made of "The Feast at the Château" (1831), "The Unwelcome Guests" (1832, Brussels Gallery), generally regarded as his masterpiece, "The Rat Hunt" (acquired by Leopold II., King of the Belgians), "The Arquebusier" (1856), and "The Stirrup Cup.

At the age of sixty-eight he decorated a hall in his house with a series of large paintings representing scenes from La Fontaine's fables, and ten years later made for King Leopold a series of decorative paintings for the château of Ciergnon. Madou died at Brussels on the 31st of March 1877.

For a list of his paintings see the annual report of the Academy of Belgium for 1879.

MADOZ, PASCUAL (1806-1870), Spanish statistician, was born at Pampeluna on the 7th of May 1806. In early life he was settled in Barcelona, as a writer and journalist. He joined the Progresista party formed during the first Carlist war, 1833-40. He saw some service against the Carlists; was elected deputy to the Cortes of 1835; took part for Esparterò, and then against him; was imprisoned in 1843; went into exile and returned; was governor of Barcelona in 1854, being first colonel of finance; he had a large number of friends among the Church lands; and after the revolution of 1868 was governor of Madrid. He had, however, no great influence as a leader and soon went abroad, dying at Genoa in 1870. Madoz was distinguished from most of the politicians of his generation by the fact that in middle life he compiled what is still a book of value—a geographical, statistical and historical dictionary of Spain and its possessions overseas, Diccionario geográfico, estadístico y histórico de España, y sus posiciones de Ultramar (Madrid, 1848-1850), a presidency of British India—officially styled Fort St George—occupying, with its dependencies, the entire south of the Indian peninsula. The northern boundary is extremely irregular. On the extreme N.E. is the Bengal province of Orissa; then the wild highlands of the Central Provinces; next the dominions of the nizam of Hyderabads; and lastly, on the N.W., the Bombay districts of Dharwar and North Kanara. Geographically Mysore and Coorg lie within the bounds of Madras, and politically it includes the Laccadive Islands, off the Malabar coast, in the Indian Ocean. Its total area, including the petty seacoast islands, is 155,000 square miles, and the population in 1901 was 42,397,522, showing an increase of 7.7% in the decade. The seat of government is at Madras city (q.v.).

Physical Aspect.—The Madras presidency may be roughly divided into three tracts: (1) the long and broad east coast, (2) the shorter and narrower west coast, and (3) the high interior table-land. These divisions are determined by the great mountain ranges of the Eastern and Western Ghats (q.v.). Between these two ranges lies the central table-land, with an elevation of 1000 to 3000 ft., which is intersected by several river valleys. The whole of this region has abundant rainfall, and the soil is uniformly productive. The rainfall in 1900 was 42,397,522, showing an increase of 7.7% in the decade. The seat of government is at Madras city (q.v.).

tribe is the Todas (q.v.). The Mahomedans are subdivided into Labhais, Moplahs, Arab, Sheikh, Sayad, Pathan and Mogul. The Labhais are the descendants of Hindu converts, and are traders by hereditary occupation, although many now employ themselves as sailors. It is said that the Labhais are the descendants of Malayalam converts to Islam: the head of the tribe, the raja of Cannanore, being descended from a fisher family in Malabar. They are a hard-working, frugal people, but quite uneducated and fanatical, and under the influence of religious excitement have often disturbed the public peace.

Christians are more numerous in Madras than in any other part of India. In Travancore and Cochin states the native Christians constitute as much as one-fourth of the population. The Roman Catholics, whose number throughout India is estimated at upwards of 650,000, owe their establishment to St Francis Xavier's Jesuit mission of Madura: they are partly under the authority of the archbishop of Goa, and partly under twelve Jesuit vicariates. Protestant missions date from the beginning of the 18th century. The Danes were the pioneers; but their work was taken up by the Society for Promoting Christian Knowledge, under whom laboured the great Lutherans of the 18th century —Schultz, Sartorius, Fabricius and Schwartz. The Church Missionary Society entered the field in 1814; and subsequently all the British missions were formed.

**Languages.**—Broadspeaking, the entire population of Madras belongs to the five linguistic offshoots of the great Dravidian stock, dominant throughout southern India. At an early period, before the dawn of history, these races appear to have accepted some form of the Brahmanical or Buddhist faiths. Many storms of conquest have since swept over the land, and colonies of Mogul and Mahratta origin are to be found here and there. But the evidence of language proves that the ethnic character of the population has remained unaltered under all these influences, and that the Madras Hindu, Mahommedan, and Christian are of the same stock.

The five Dravidian languages in British territory Telugu is spoken by over 14,000,000 persons; Tamil by over 15,000,000 persons; Kanarese by over 1,500,000 persons; Malayalam by nearly 3,000,000 persons; and Tulu by about 500,000 persons. Oriya is the native tongue in the extreme north of Ganjam, bordering on Orissa; and various sub-dialects of Dravidian origin are used by the hill tribes of the Eastern Ghats, of whom the Kondhs may be taken as the type.

**Agriculture.**—Over the greater part of the area of Madras artificial irrigation is impossible, and cultivation is dependent upon the local rainfall, which rarely exceeds 40 in. a year, and is liable to be swept away by heavy storms without previous warning. The Malabar coast is the only part where the rainfall brought by the south-west monsoon may be trusted both for its quantity and for its regularity. Other districts, such as Bellary, are also dependent upon this monsoon; but in their case the rainfall is irregularly distributed, and they are not able to make such full use of it as the Malabar district. The rainfall of Madras is not very excessive.

The majority of the crops of the province are grown as hedges or on small plots. The principal crop is sugar-cane, which is extensively grown both on the large estates and in the small gardens of the coolie, who is often supposed to be the greatest sugar-grower in India. The principal white rice is of two varieties, the small-grained品种 called "Rice" and the large-grained品种 called "paddy." The white jaggery is a very important product of the province, and the palm is extensively grown for this purpose. The chief river of the province is the Godavari, which is navigable for large vessels as far as the town of Bellary.

**Population.**—The population in 1901 was estimated at 37,025,471, which is the same as in 1891. The census of 1901 was taken under the supervision of the Government of India, and the results show that the population of the province has increased considerably since the last census. The population is distributed as follows: Hindus, 37,025,471; Muslims, 2,132,931; Christians, 1,034,480. The Hindus are divided into three main divisions: the Brahman, the Nambudri, and the Malabari. The Brahman is the most important of the three, and is the only class which has any claim to be considered a caste. The Nambudri is a class of sadhus, or holy men, who are held in great esteem by the people of the province. The Malabari is a class of coolies, who are employed in the cultivation of the land. The population of the province is divided into four main divisions: the Hindus, the Muslims, the Christians, and the Parsees. The Hindus are the most numerous, and are divided into four main classes: the Brahman, the Nambudri, the Malabari, and the Shudra. The Muslims are divided into two main classes: the Turco-Mogul, or the Moghul, and the Turkish, or the Turk. The Christians are divided into two main classes: the Roman Catholic, or the Roman, and the Anglican, or the Church of England. The Parsees are a class of Jews, who are divided into two main classes: the Zoroastrian, or the Zoroastrian, and the Persian, or the Persian. The population of the province is divided into three main divisions: the Hindus, the Muslims, and the Christians. The Hindus are divided into three main classes: the Brahman, the Nambudri, and the Malabari. The Muslims are divided into two main classes: the Turco-Mogul, or the Moghul, and the Turkish, or the Turk. The Christians are divided into two main classes: the Roman Catholic, or the Roman, and the Anglican, or the Church of England.
direct from the government under the tenure known as ryotwari. Besides these lands in the hands of the government, there are also proprietary or zamindari estates in all parts of the presidency. These are the territorial domains of the native rulers, which the holder cannot sell or encumber beyond his own life interest, or they are creations of British rule and subject to the usual Hindu custom of sale, gift, and inheritance. The zamindari estates cover more than 290 million acres, more than one-fourth of the whole presidency. The peshkash or tribute payable to government in perpetuity amounts to about £330,000 a year. Indias, revenue-free or quit-rent grants of land, are also payable to zamindari estates and to the presidency. For services rendered to the state, occupy an aggregate area of nearly 8 million acres.

Manufactures.—Madras possesses few staple manufactures. The chief industry is the presidency is cotton-ginning, fish-curing, indigo-pressing, oil-pressing, printing, rice-curing, rope-making, sugar-refining, tanning, tile and brick-making, and tobacco-curing. Up to the close of the 18th century cotton goods constituted the chief article of export. Masulipatam, where the first English factory on the Coromandel coast was established in 1626, enjoyed a special reputation for its chintzes, which were valued for the freshness and permanence of their dye. There is still a small demand for these articles in Burma, the Straits and the Persian Gulf; but Manchester goods have nearly beaten the Indian exporter out of the field. Native looms, however, still hold their own in the local market, in face of strenuous opposition. After weaving, working in metals appears to be the most widespread native industry. Among local specialties which have attracted European curiosity may be mentioned the jewelry of Trichinopoly, ornaments of ivory and horn work, dolls of various kinds, and sandalwood carving in various styles.

Commerce and Trade.—The continuous seaboard of the Madras presidency, without any natural harbours of the first rank, has to depend chiefly on differently diffused trade. Madras alone embraces nearly one-half of the total sea-borne commerce; next comes Maduravelli, containing the western railway terminus near Calicut; then Godavari, with its cluster of ports along the fringe of the delta; Tinnevelly, with the harbour of Tuticorin, which has opened large despatches with Ceylon and Burma; Tanjore, South Kanara, Ganjam and Vizagapatam. As compared with the other provinces, the trade of Madras is broad enough to carry the large proportion assigned to coasting trade with other Indian ports and with Ceylon. The chief staples of the export trade are hides and skins, coffee and raw cotton.

Railways and Irrigation.—The presidency is well supplied with railways, and railway stations may have their centre in Madras city, the chief seaport. The broad-gauge line of the Madras & Southern Mahabatta railway connects with Bombay and Bangalore, and also crosses the peninsula to Calicut on the western coast. The South Indian (narrow-gauge) serves the extreme south, with its terminus at Tuticorin, and branches to Tinnevelly, Negapatam, Eradu, Pondicherry and Nellore. The narrow-gauge line of the Madras & Southern Mahabatta railway traverses the Deccan districts; and the East Coast line (broad-gauge), through the Northern Circars, has brought Madras into direct communication with Calcutta. The Madras system of irrigation has been most successful in the case of the great new tranch near Karaikal and Cauvery. A proportion of this system is intercepted by an anicut or dam at the head of its delta, from which canals diverge on each side for navigation as well as irrigation. The Madras government, when the waters of the Cauvery (in the Kista) over the thirsty uplands of Kurnool proved a failure. The bold project of leading the Periyar river through a tunnel across the watershed of the Trancaree hills on to the plain of Madura has been more successful.

Administration.—The Madras presidency is administered by a governor and a council, consisting of two members of the civil service, which number may be increased to four. There is also a board of revenue of three members. The number of districts is 24, each under the charge of a collector, with sub-collectors and assistants. The districts are not grouped into presidencies or provinces. For legislative purposes the council of the governor is augmented by additional members, numbering 45 in all, of whom not more than 17 may be nominated officials, while 10 are elected by various representative constituents. Members of the legislative council enjoy the right of interpellation, of proposing resolutions on matters of public interest, and of discussing the annual financial statement. The principle of local devolution is carried somewhat further in Madras than in other provinces. At the bottom are union panchayats or village councils. The duty is to attend to sanitation, to make certain they come taluk or subdivisional boards. At the head of all are district boards, a portion of whose members are elected by the taluk boards.

Education.—The chief educational institutions are the Madras University, the Presidency College, Madras Christian College, and Pachayappa’s College at Madras; the government arts colleges at Combaconum and Rahajumundi; the law college, medical college and engineering college at Madras; the college of agriculture at Combaconum; the teachers’ college at Saidapet; the school of arts at Madras; and the military ophange at Ootacamund, in memory of Sir Henry Lawrence. In 1907, the total number of pupils at all institutions was 1,007,218, of whom 104,706 were females, and 132,857 were learning English.

History.—Until the British conquest the whole of southern India had never acknowledged a single ruler. The difficult nature of the hill passes and the warlike character of the highland tribes forbade the growth of great empires, such as succeeded one another on the plains of Hindustan. The Tamil country in the extreme south is traditionally divided between the three kingdoms of Pandya, Chola and Chera. The west coast supplied the nucleus of a monarchy which afterwards extended over the highlands of Mysore, and took its name from the Carnatic. On the north-east the kings of Kalinga at one time ruled over the entire line of seaboard from the Kistna to the Ganges. Hindu legend has preserved marvellous stories of these early dynasties, but our only authentic evidence consists in their inscriptions on stone and brass, and their noble architecture (see INDIA). The Mahomedan invader first established himself in the south in the beginning of the 14th century. Ala-ud-din, the second monarch of the Khilji dynasty at Delhi, and his general Malik Kafur conquered the Deccan, and overthrew the kingdoms of Karnatak and Telingana, which were then the most powerful in southern India. But after the withdrawal of the Musulman armies the native monarchy of Vijayanagar arose out of the ruins. This dynasty gradually extended its dominions from sea to sea, and reached a pitch of prosperity before unknown. At last, in 1565, it was overwhelmed by a combination of the four Mahommedan principalities of the Deccan. At the close of the reign of Aurangzeb, although that emperor nominally extended his sovereignty as far as Cape Comorin, in reality South India had again fallen under a number of rulers who owned no regular allegiance. The nizam of the Deccan, himself an independent sovereign, represented the distant court of Delhi. The most powerful of his feudatories was the nawab of the Carnatic, with his capital at Arcot. In Tanjore, a descendant of Sivaji ruled; and on the central table-land a Hindu chieftain was establishing his authority and founding the state of Mysore, destined soon to pass to a Mahomedan usurper.

Vasco da Gama cast anchor off Calicut on the 20th of May 1498, and for a century the Portuguese retained their hold on the coast of India. The Dutch, commerce of India. The Dutch began to establish themselves on the ruin of the Portuguese at the beginning of the 17th century, and were quickly followed by the English, who established themselves at Calicut and Cranganore in 1616. Telflicker became the principal English eminon on the west coast of Madras. The Portuguese eventually retired to Goa, and the Dutch to the Spice Islands. The first English settlement on the east coast was in 1611, at Masulipatam, even then celebrated for its fabrics. Farther south a fort, the fort of the Dutch, was established, but it was destroyed in 1666. Pondicherry was purchased by the French in 1762. For many years the English and French traders lived peacefully side by side, and with no ambition for territorial aggrandisement. The war of the Austrian succession in Europe lit the first flame of hostility on the Coromandel coast. In 1746 Madras was forced to surrender to the British, and Fort St David remained the only English possession in southern India. By the peace of Aix-la-Chapelle Madras was restored to the English; but from this time the rivalry of the two nations was keen, and both found their opportunities in the disputed successions which always fill a large place in Oriental politics. English influence was generally able to secure the favour of the rulers of the Carnatic and Tanjore, while the French succeeded in placing their own nominee on the throne at Hyderabad. At last Duplex rose to be the temporary arbiter of the fate of southern
India, but he was overthrown by Clive, whose defence of Arcot in 1751 forms the turning point in Indian history. In 1760 the crowning victory of Wandewash was won by Colonel (afterwards Sir Eyre) Coote, over Lally, and in the following year, despite help from Mysore, Pondicherry was captured.

Though the English had no longer any European rival, they had yet to deal with Mahomedan fanaticism and the warlike population of the highlands of Mysore. The dynasty founded by Hyder Ali, and terminating in his son Tippoo Sultan, proved itself in four several wars, which terminated only in 1799, the most formidable antagonist which the English had ever encountered (see Hyder Ali and Iota). Since the beginning of the eighteenth century, Mysore had shown no regular war, but occasional disturbances have called for measures of repression. The pâdâgar or local chieftains long clung to their independence after their country was ceded to the British. On the west coast, the feudal aristocracy of the Naiks, and the religious fanaticism of the Moplahs, have more than once led to rebellion and bloodshed. In the extreme north, the wild tribes occupying the hills of Ganjam and Vizagapatam have only lately learned the habit of subordination. In 1836 the samândar of Gumsur in this region was attacked by a mahâkhanı, or the rebel leader induct of his chief. An inquiry then instituted revealed the wide prevalence among the tribe of Kondhs of human sacrifice, under the name of merich. The practice has since been suppressed by a special agency. In 1879 the country round Rampa on the northern frontier was the scene of riots sufficiently serious to lead to the necessity of calling out troops. The same necessity arose three years later, when the Hindus and Mahomedans of Salem came into collision over a question of religious ceremonial. A more serious disturbance was known as the “Anti-Shanar riots” of 1899. The Maravans of Tinnevelly and parts of Madura, resenting the pretensions of the Shanans, a toddy-drawing caste, to a higher social and religious status, organized attacks on Shanum villages. The town of Sivakasi was lootcd and burnt by five thousand Maravans. Quiet was restored by the military, and a punitive police force was stationed in the disturbed area.

The different territories comprising the Madras presidency were acquired by the British at various dates. In 1763 the tract encircling Madras city, then known as the Jagir, now Chitcot, district, was attached by the Nawab of Arcot. In 1765 the Northern Circars, out of which the French had recently been driven, were granted to the Company by the Mogul emperor, but at the price of an annual tribute of 560,000 to the nizam of Hyderabad. Full rights of dominion were not acquired till 1823, when the tribute was commuted for a lump payment. In 1792 Tippoo was compelled to cede the Baramahal (now part of Salem district), Malabar and Dindigul subdivision of Madura. In 1790, on the reconstruction of Mysore state after Tippoo’s death, Coimbatore and Kanara were appropriated as the British share; and in the same year the Maharaja raja of Tanjore resigned the administration of his territory, though his descendant retained titular rank till 1855. In 1800 Bellary and Cuddapah were made over by the nizam of Hyderabad to defray the expense of an increased subsidiary force. In the following year the dominions of the nawab of the Carnatic, extending along the east coast almost continuously from Nellore to Tinnevelly, were resigned into the hands of the British by a puppet who had been put upon the throne for the purpose. The last titular nawab of the Carnatic died in 1855; but his representative still bears the title of prince of Arcot, and is recognized as the first native nobleman in Madras. In 1839 the nawab of Kurnool was deposed for misgovernment and suspicion of treason, and his territories annexed.

See Madras Manual of Administration, 3 vols. (Madras, 1885 and 1893); S. Ayyangar, Forty Years’ Progress in Madras (Madras, 1893); J. P. Rees, Madras (Society of Arts, 1901); Madras Pro-"
constructed, and a gradually increasing population settled around its walls. In 1653 Madras, which had previously been subordinate to the settlement of Bantam in Java, was raised to the rank of an independent presidency. In 1702 Daud Khan, Aurangzeb’s general, blockaded the town for a few weeks, and in 1741 the Maharattas unsuccessfully attacked the place. In 1756 the British took Madras. The settlement was restored to the English two years later by the Treaty of Aix-la-Chapelle, but the government of the presidency did not return to Madras till 1762. In 1758 the French under Lally occupied the Black Town and invested the fort. The siege was conducted on both sides with great skill and vigour. After two months the arrival of an English fleet relieved the garrison, and the besiegers retired with some precipitancy. With the exception of the threatening approach of Hyder Ali’s horsemen in 1769, and again in 1780, Madras has since the French siege been free from external attack. The town of Saint Thomé, now part of Madras city, was founded and fortified by the Portuguese in 1524, and was held by the French from 1672 to 1674.

See Mrs F. Penny, Fort St George (1900); W. Foster, Founding of Fort St George (1902).

MADRAZO Y KUNT, DON FEDERICO DE (1815–1894), Spanish painter, was born in Rome on the 12th of February 1815. He was the son of the painter Madrazo y Agudo (1781–1859), and received his first instruction from his father. While still attending the classical school of the Academy of San Fernando, he painted his first picture, “The Resurrection of Christ” (1829), which was purchased by Queen Christina. Not long afterwards he painted “Achilles in his Tent,” and subsequently presented to the Academy “The Continence of Scipio,” which secured him admission as a member “for merit.” While decorating the palace of Vista Alegre he took up portraiture. In 1832 he went to Paris, where he studied under Winterhalter, and painted portraits of Baron Taylor and of Ingres. In 1837 he was commissioned to produce a picture for the gallery at Versailles, and painted “Godfrey de Bouillon proclaimed King of Jerusalem.” The artist then went to Rome, where he worked at various subjects, sacred and profane. Then he painted “Maria Christina in the Dress of a Nun by the bedside of Ferdinand III” (1843), “Queen Isabella,” “The Duchess of Medina-Coeli,” and “The Countess de Vilchés” (1845–1847), besides a number of portraits of the Spanish aristocracy, some of which were sent to the exhibition of 1855. He received the Legion of Honour in 1846. He was made a corresponding member of the Paris Academy of Fine Arts on the 10th of December 1853, and in 1857 he was elected member of the Royal Spanish Academy. On the death of Schaarer, the French chose him foreign member. After his father’s death he succeeded him as director of the Prado Gallery and president of the Academy of San Fernando. He originated in Spain the production of art reviews and journals, such as El Artista, El Renacimiento and El Semanario pintoresco. He died at Madrid on the 11th of June 1894. His brother, DON LOUIS DE MADRAZO, was also known as a painter, chiefly by his “Burial of Saint Cecilia” (1835). Don Federico’s best-known pupil was his son, DON RAMUNDO DE MADRAZO (b. 1841), director of one of central Spain, formed in 1833 of districts previously included in New Castile, and bounded on the W. and N. by Ávila and Segovia, E. by Guadalajara, S.E. by Cuenca and S. by Toledo. Pop. (1900), 775,034, of whom 539,835 inhabit the city of Madrid; area, 3084 sq. m. Madrid belongs to the basin of the Tagus, being separated from that of the Douro by the Sierra de Guadarrama on the N.W. and N., and by the Sierra de Gredos on the S.W. The Tagus is the southern boundary for some distance, which forms a tributary bearing the Jarama, which rises in the Somosierra in the north and terminates at Aranjuez. The Jarama, in turn, is joined by the Henares and Tajuña on the left, and by the Lozoya and Manzanares on the right. The Guadarrama, another tributary of the Tagus, has its upper course within the province. Like the rest of Castile, Madrid is chiefly of Tertiary formation; the soil is mostly clayey, but there are tracts of sandy soil. Agriculture is somewhat backward; the rainfall is deficient, and the rivers are not utilized as they might be for irrigation. The south-eastern districts are the best watered, and produce in abundance fruit, vegetables, wheat, olives, esparto grass and excellent wine. Gardening and viticulture are carried on to some extent near the capital, though the marketds of Madrid do not receive their most liberal supply of fruits and vegetables from Valencia. Sheep, goats and horned cattle are reared, and fish are found in the Jarama and other rivers. Much timber is extracted from the forests of the northern and north-eastern parts of the province for building purposes and for firewood and charcoal. The royal domains of the Escorial, Aranjuez and El Pardo, and the preserves of the nobility, are all well wooded and contain much game. Efforts have also been made by the local authorities to cover the large stretches of waste ground and commons with planes and other trees.

The Sierra de Guadarrama has quarries of granite, lime and gypsum, and is known to contain iron, copper and argentiferous lead; but these resources are undeveloped. Other industries are chiefly confined to the capital; but cloth, leather, paper, earthenware, porcelain, glass, bricks and tiles, ironware, soap, candles, chocolate and lace are also manufactured on a small scale beyond its boundaries. There is very little commerce except for the supply of the capital with necessaries.

Besides the local lines, all the great railways in the kingdom converge at Madrid. The line from the coast to the capital, besides Madrid, the towns of Aranjuez (72670) and Alcalá de Henares (11,206) and the Escorial are described in separate articles. The other towns with more than 5000 inhabitants are Vallecas (10,128), Colmenar de Oreja (6782), Colmenar Viejo (5255) and Carabanchel Bajo (5862).

MADRID, the capital of Spain and of the province of Madrid, on the left bank of the river Manzanares, a right-hand tributary of the Jarama, which flows south into the Tagus. Pop. (1877), 307,816; (1887), 472,228; (1897), 512,150; (1900), 539,835. Madrid was the largest city in Spain in 1900; it is the seat of an archbishop, the bishop of the Spanish railways, the headquarters of an army corps, the seat of a university, and the meeting-place of parliament, and the chief residence of the king, the court, and the captain-general of New Castile. It is, however, surpassed in ecclesiastical importance by Toledo and in commerce by Barcelona.

Situation and Climate.—Madrid is built on an elevated and undulating plateau of sandy soil, which is watered by the Jarama, and lies on the north by the Sierra de Guadarrama and merges on all other sides into the barren and treeless table-land of New Castile. Numerous water-courses (arroyos), dry except at rare intervals, furrow the surface of the plateau; these tributaries pass through the city in certain cases have been converted into roads—e.g. the Paseo de Recoletos and Prado, which are still liable to be flooded after prolonged rain. The lower part of the city is sheltered from the wind by the Sierra Guadarrama which descends on its northern slope with the slope of the city. The city is subject to intense heat in summer, and it is subjected to frost and snow occasionally, which are severe. The mean temperature of the coldest month is about 35° F. Summer is an intense, hot season, which is not malariaous. Its mean temperature is about 75° F. Madrid is the most healthful capital in Europe; the healthful climate and excellent water make it a favourite resort for invalids. As a result, Madrid is the healthiest capital in Europe.
rounded off; from east to west it measures rather less than from north to south. It was formerly surrounded by a poor wall, partly of brick, partly of earth, some 20 ft. in height, and pierced by five principal gates (puertas) and eleven doorways (portillos). Of these only three, the Puerta de Alcalá on the east, the Puerta de San Vicente on the south and the Portillo de San Vicente on the west, actually exist; the first and the third were erected in the time of Charles III. (1759-1788), and the second in honour of the restoration of Ferdinand VII. (1827). The Manzanares—or rather its bed, for the stream is at most seasons of the year quite insignificant—is spanned by six bridges, the Puente de Toledo and Puente de Segovia being the chief.

The Puerta del Sol is the centre of Madrid, the largest of its many plazas, and the place of most traffic. It derived its name from the eastern side of the city which stood here until 1570, and had on its front a representation of the sun. On its south side stands the Palacio de la Gobernacion, or ministry of the interior, a heavy square building by a French architect, J. Marquet, dating from 1768. From the Puerta del Sol diverge, immediately or mediately, ten of the principal streets of Madrid—eastward by north, the Calle de Alcalá, terminating beyond the Buen Retiro park; eastward, the Carrera de San Jeronimo, terminating by the Plaza de las Cortes in the Prado; southward, the Calle de Carretas; westward, the Calle Mayor, which leads to the Puerta del Sol, a street connected to the west by the Arenal, terminating in the Plaza de Isabel II and the royal opera house; north-westward, the Calles de Preciados and Del Carmen; and northward, the Calle de la Montera, which after wards divides into the Calle de Fuencarral to the left and the Calle de Hortaleza to the right. The contract for another wide street through central Madrid, to be called the Gran Via, was given to an English firm in 1905.

The Calle de Alcalá is bordered on both sides with arcades, and contains the Real Academia de Bellas Artes, founded in 1752 as an accurate repository of the works of its members. Its military masters includes some of the best-known works of Murillo. The handsome Bank of Spain (1884-1891) stands where the Calle de Alcalá meets the Prado; in the oval Plaza de Madrid, at the same point, is a fine 18th-century fountain with a marble group representing the goddess Cybele drawn in a chariot by two lions. The Calle de Alcalá is continued eastward past the Buen Retiro gardens and park, and through the Plaza de Independencia, in the middle of which is the Puerta de Alcalá. The Plaza de las Cortes is so called from the Congreso de los Diputados, or House of Commons, on its north side. The square contains a bronze statue of Cervantes, by Antonio Solà, created by the Carrera de San Jeronimo and west side of the General Post Office, ranks with the Carrera de San Jeronimo and Calle de la Montera for the excellence of its shops. From the Calle Mayor enters the Plaza Mayor, a rectangle of about 450 by 330 ft., formerly the scene of tournaments, bull fights, autos de fé, acts of canonization (including that of Ignatius Loyola in 1622) and similar exhibitions, which used to be viewed by the royal family from the balcony of one of the glorious Palaces (belonging to the guild of bakers). The square, which was built under Philip III, in 1619, is surrounded by an arcade; the houses are uniform in height and decoration. In the centre stands a bronze equestrian statue of Philip III., designed by Giovanni da Bologna, after a painting by Pantalón de la Cruz, and finished by Pietro Tacca. From the south-east angle of the Plaza Mayor the Calle de Atocha, one of the principal thoroughfares of Madrid, leads to the outskirts of the inner city; it contains two large hospitals and part of the university buildings (faculty of medicine). The house occupied by Cervantes from 1606 until his death in 1616 stands at the corner of the Calle de Atocha and the Calle de Léon; in this street is the Real Academia de la Historia, with a valuable library and collections of MSS. and plate. From the south-west angle of the Plaza Mayor begins the Calle de Toledo, the chief mili for the various woolen and silken fabrics from which the pictur equestre costumes peculiar to the peninsula are made. In the Plaza de Isabel II., at the western extremity of the Calle del Arenal, stands the royal opera-house, the principal front of which faces the Plaza del Obispado. Here, in 1865, was placed the large bronze equestrian statue of Philip IV. (1621-1665); it was designed by Velázquez and cast by Taccà, while Galileo is said to have suggested the model. The gift of the grand-duke of Tuscany in 1640, it stood in the Buen Retiro gardens until 1834.

Modern Development of the City.—The north and east of the city—the new suburbs—have developed past the Retiro Park as far as the Bull-ring, and have covered all the vast space included between the Retiro, the Bull-ring, the long Castellana Drive to the race-course and the exhibition building. On the slopes of the other side of the Castellana, and along what were the northern limits of Madrid in 1875, the modern suburbs have extended to the vicinity of the fine cellular prison that was built at the close of the reign of Alphonso XII. to replace the gloomy building known as El Saladero.

The new parts of the capital, with their broad streets and squares, and their villas sometimes surrounded with gardens, their boulevards lined by rather stunted trees, and their modern public buildings, all resemble the similar features of other European capitals, and contrast with the old Madrid that has preserved so many of its traits in architecture, popular life and habits. Some of the streets have been slightly widened, and in many thoroughfares new houses are being built among the ugly, irregular dwelling-places of the 18th and earlier centuries. The contrast is to be seen especially in and about the Calle Mayor, the Plaza Mayor, the Calle de Toledo, the Rastro, and the heart of the city.

Few capitals have more extensively developed their electric and horse tramways, gas and electric light installations and telephones. Much was done to improve the sanitary conditions of the city in the first years of the 19th century. But Madrid was visited three times a day with fire-hose, but even that has little effect upon the dust. Unfortunately the water supply, which used to be famed for its abundance and purity, became wholly insufficient owing to the abstraction of water for the irrigation of the city. The old reservoir of the Lozoya canal, a cutting 32 m. long, and the additional reservoir opened in 1885, are quite inadequate for the requirements of modern Madrid, and were insufficient in such a tragic year as 1899. In 1898 and 1899 the water not only was on the point of giving out, but at times was of such inferior quality that the people had recourse to the many wells and fountains available. The construction of new waterworks was delayed by a terrible accident, which occurred on the 8th of April 1905; the whole structure collapsed, and nearly 400 persons lost their lives in the flooded ruins. A decided improvement has been made in the drainage system of Madrid. No bodies are allowed to be interred in the churches and convents. Some of the older burial grounds in the northern suburbs have been closed altogether, and in those which remain open few coffins are placed in the lead-lined vaults in which they are never removed from the practice. A large modern necropolis has been established a few miles to the north-east.

Principal Buildings.—As compared with other capitals Madrid has very few buildings of much architectural interest. The Basílica de Nuestra Señora de Atocha, on the Paseo de Atocha, a continuation of the Calle de Atocha, was originally founded in 1523. After being almost destroyed by the French, it was restored by Ferdinand VII., and rebuilt after 1866. The present church is of a late Renaissance style; it contains a magnificent statue of the Virgin, attributed to St. Luke. The collegiate church of San Isidro el Real, in the Calle de Toledo, dates from 1651; it has no architectural merit, but contains one or two valuable pictures and other works of art. It was originally owned by the Jesuits, but after their expulsion in 1760 it was reconstituted, and dedicated to St. Isidore the Labourer (d. 1170), the patron saint of Madrid, whose remains were entombed here. When the diocese of Madrid was separated from that of Toledo San Isidro was chosen as the cathedral. The modern Gothic church of San Jeronimo el Real occupies a conspicuous site eastward of the town. The church of San Francisco el Grande, which contains many interesting monuments, is also known as the National Pantheon. An act was passed in 1837 declaring that the remains of all the most distinguished Spaniards should be buried here; but no attempt to enforce the act systematically was made until 1869, and even then the attempt failed. Towards the close of the 19th century the church was splendidly restored at the expense of the state. Its interior was decorated with paintings and statuary by most of the leading Spaniards of the day. Of the many monuments of the church unquestionably the most important is the royal palace (Palacio Real), on the west side of the town, on rising ground overhanging the Manzanares. It occupies the site of the ancient Moorish alcázar (citadel), where a hunting seat was built by Henry IV.; this was enlarged and improved by Charles V. when he first made Madrid his residence in 1532; was further developed by Phillip II., but ultimately was destroyed by fire in 1734.
present edifice was begun under Philip V. in 1737 by Sacchetti of Turin, and was finished in 1764. It is in the Tuscan style, and is 470 ft. square and 100 ft. in height, the material being white Colmener granite, resembling marble. To the north of the palace are the royal stables and coach-houses, remarkable for their extent; to the south is the armoury (Museo de la Real Armería), containing what is possibly the best collection of the kind in existence. The Palacio de Comunicaciones is the now famous royal picture gallery (Real Museo de Pinturas), adjoining the Salón del Prado; it was built about 1785 for Charles III. by Juan de Villanueva as a museum of natural history and academy of sciences. It contains the collections of Charles V., Philip II. and Philip IV., and the pictures number upwards of two thousand. The specimens of Titian, Raphael, Tintoretto, Velazquez, Van Dyck, Rubens and Teniers give it a claim to be considered the finest picture gallery in the world. The Biblioteca Nacional, in the Palacio de Recoleto, was founded in 1866, and completed in 1892. Not only the national library, with its important collections of MSS. and documents, but the archaeological museum, the museums of modern painting and sculpture, and the fine arts academy of San Fernando, are within its walls. The two houses of the Cortes meet in separate buildings. The deputies have a handsome building with a very valuable library in the Carrera San Jerónimo; the senators have an old Augustinian convent which contains some fine pictures. A large and handsome building near the Retiro Park contains the offices of the ministers of public works, agriculture and commerce, and of fine arts and education; nearly opposite stands the new station of the Southern Railway Company. The Great Northern and the Spain to Portugal Railway Companies have also replaced their old stations by very spacious, handsome structures, much resembling those of Paris. In 1866 the Royal Exchange was installed in a large monumental building with a fine colonnade facing the Do de Mayo monument, not far from the museum of paintings.

Of the promenades and open places of public resort the most fashionable and most frequented is the Prado (Paseo del Prado, Salón del Prado) on the east side of the town, with its northward continuation—the Paseo de Recoletos. To the south of the town is the Paseo de las Delicias, and on the west, below the royal palace, and skirting the Manzanares, is the Paseo de la Virgen del Puerto, used chiefly by the poorer classes. Eastward from the Prado are the Buen Retiro Gardens, with ponds and pavilions, and a menagerie. The gardens were formerly the grounds surrounding a royal hunting seat, on the site of which a palace was built for Philip IV. in 1633; it was destroyed during the French occupation.

Education, Religion and Charity.—Madrid University, developed gradually out of the college of Doña María de Aragon, established in 1560 by Alphonso Orozco. Schools of mathematics and natural science were added in the 16th and 17th centuries, and in 1766 the medical and surgical college of San Carlos was opened. In 1836-1837 the university of Alcalá de Henares (q.v.) was transferred to the capital and the older foundations incorporated with it. The university of Madrid thenceforth became the headquarters of education in central Spain. It has an observatory, and a library containing more than 70,000 printed books and about 5,500 MSS. It gives instruction, chiefly in law and medicine, but also in literature, philosophy, mathematics and physics, to about 5000 students. Associated with the university is the preparatory school of San Isidro, founded by Philip IV. (1621-1666), and reorganized by Charles III. in 1770.

There are upwards of 100 official primary schools and a large number of private ones, among which the schools conducted by the Jesuits and the nuns of the various religious orders, and also schools of agriculture, architecture, civil and mining engineering, the fine arts, veterinary science and music. The school of military engineering is at Guadalajara. Besides these special schools there are a self-supporting institute for preparing girls for the higher degrees and for certificates as primary teachers, and an institute for secondary education, conducted chiefly by ecclesiastics. Among the educational institutions are the very ancient Academies de la Necesidad and Los Descalzos de San Isidro, garden, dating from 1781, the libraries of the palace, the university, and San Isidro, and the museum of natural science, exceedingly rich in the mineralogical department. The principal learned society is the royal Spanish Academy, founded in 1713 for the cultivation and improvement of the fine arts, sciences, and jurisprudence and legislation, all of which possess libraries, there are also anthropological, economic and geographical societies, and a scientific and literary atheneum. Madrid has a great number of museums, and the first was opened in 1853, when the old Protestant cemetery in the Paseo de Recoletos was closed. It was built as a British embassy chapel, a German chapel, and several Spanish Protestant chapels, attended by over 1200 native Protestants, while the Spanish and Protestant schools, chiefly supported by British, German and American contributions, are attended by more than 2500 children. The first Protestant bishop of Madrid was consecrated in 1865 by Archbishop Plunkett of Dublin. The charitable institutions were greatly improved between 1866 and 1895. The Princess Hospital was completely restored on modern methods, and can accommodate several hundred patients. The old contagious diseases hospital of San Juan de Dios was pulled down and a fine new hospital built in the suburbs beyond the Retiro Park, to hold 700 patients. The military hospital was demolished and a very good one built in the suburbs. There are in all twenty hospitals in Madrid, and a lunatic asylum on the outskirts of the capital, founded by one of the most eminent of Spanish surgeons, and admirably conducted. New buildings have been provided for the orphanages, and for the asylum of the handicapped, a royal asylum for the incurables, and hospitals supported by the French, Italian and Belgian colonies; these are old and well-endowed foundations. Public charity generally is very active. In Madrid, as in the rest of Spain, there has been an effort to endow and support institutions and corporations; monasteries, institutions, societies and Roman Catholic workmen's clubs and classes.

Institutions of charity, founded from private institutions for such purposes, the state maintains in the capital a savings bank for the poorer classes, and acts as pawnbroker for their benefit. The mercantile and industrial classes are organized in gilds, which themselves collect the lump sum of taxation exacted by the exchequer and the municipality from each gremio or class of taxpayers. The working classes also have commercial and industrial ciríolos or clubs that are obeyed by the gilds with great espirito de coro, a chamber of commerce and industries, and associations of productions for the defence of economic interests.

Industries.—The industries of the capital have developed extraordinarily since 1860. In the town, and within the municipal boundaries in the suburbs, many manufactories have been established, giving employment to more than 30,000 hands, besides the 4000 women and girls of the Tobacco Monopoly Company's factory. Among the most important factories are those which make every article in leather, especially cigar and card cases, purses and pocket-books. Next come the manufactories of fans, umbrellas, sunshades, chemicals, varnishes, buttons, wax candles, beds, cardboard, porcelain, coarse pottery, baskets, pottery goods, woodwork, fine furniture, carpets, corks, cards, carriages, jewelry, drinks of all kinds, plate and plated goods. There are also tanneries, saw and flour mills, glass and porcelain works, soap works, brickfields, paper mills, zinc, bronze, copper and iron foundries. The working classes are strongly imbued with socialist ideas. Strikes and May Day demonstrations have often been troublesome. Order is kept by a garrison of 12,500 men in the barracks of the town and cantonments around, and by a strong force of civil guards for gendarmes quartered in the town itself. The civil and municipal authorities can employ beside the gendarmes the police, about 1,400 strong, and what is called the guardias urbanas, another police force whose special duty it is to regulate the street traffic and prevent breaches of the municipal regulations. There is not, on the average, more crime in Madrid than in the provinces.

History.—Spanish archaeologists have frequently claimed for Madrid a very high antiquity, but the earliest authentic historical statement is that of Alphonso the Wise in the year 1258. The memoir mentions the name of the ancient city of Temi, and chronicle, and does not take us farther back than to the first half of the 10th century. The place was finally taken from the Moors by Alphonso VI. (1083), and was a hunting-seat by Henry IV., but first rose into importance when Charles V., benefiting by its keen air, made it his occasional residence. Philip II. created it his capital and "only court" (única corte) in 1560. It is, however, only classed as a town (villa), having
never received the title of city (ciudad). Fruitless attempts were made by Philip III, and Charles III, respectively to transfer the seat of government to Valladolid and to Seville. (See also Spain: History.)

MADRIGAL, as a name of a form of verse, the exact nature of which has never been decided in English, and of a form of vocal music.

(1) In Verse.—The definition given in the New English Dictionary, "a short lyrical poem of amatory character," offers no distinctive formula; some madrigals are long, and many have nothing whatever to do with love. The most important English collection of madrigals, not set to music, was published by William Drummond of Hawthornden (1585-1649) in his Poems of 1616. Perhaps the best way of ascertaining what was looked upon in the 17th century as a madrigal is to quote one of Drummond's:

> The beauty and the life
> Of life's and beauty's fairest paragon,
> O tears! O grief hung at a feeble thread,
> To which pale Atropos had set her knife;
> The soul with many a groan
> Had left each outward part,
> And now did take his last leave of the heart;
> Naught else did want, save death, even to be dead;
> When the afflicted band about her head,
> Seeing so fair him come in lips, cheeks, eyes,
> Cried ah! and can death enter Paradise?

This may be taken as the type of madrigal of Drummond's madrigals, of which he has left us about eighty. They are serious, brief, rigorous lyrics, in which neither the amatory nor the complimentary tone is by any means obligatory. Some of these pieces contain as few as six lines, one as many as fourteen, but they average from nine to eleven. In the majority of examples the little poem opens with a line of six syllables, and no line extends beyond ten syllables. The madrigal appears to be a short canzone of the Tuscan type, but less rigidly constructed. In French the madrigal has not this Italian character. It is simply a short piece of verse, ingenious in its turn and of a gallant tendency. The idea of compliment is essential. J. F. Guichard (1730-1811) writes:

> Organe, poète martial,
> A Venus compare sa femme;
> C'est pour la belle un madrigal.

C'est pour Venus une épigramme.

This quatrains emphasize the fact that in French a madrigal is a trifling piece of erotic compliment, neatly turned but not seriously meant. The credit of inventing the old French verse-form of madrigal belongs to Clément Marot, and one of his may be quoted in contrast to that of Drummond:

> Un doux nenni avec un doux sourire
> Est tant honneste, il le vous faut apprendre;
> Quand est de cout, si venie à le dire,
> E envoy trop dit je vouloir vous reprendre;
> Non que je sois envoyé d'entreprendre
> D'avoir le fruit dont le désir me point;
> Mais je voudrois qu'en ne le laissant prendre,
> Vous me disiez: vous ne l'aurez point.

In English, when the word first occurred—it has not been traced farther back than 1558 (in the preface to Nicholas Yonge's Musica transalpina)—it was identified with the chief form of secular vocal music in the 16th century. In 1547 John Immyns (d. 1564) founded the Madrigal Society, which met in an ale-house in Bride Lane, Fleet Street; this association still exists, and is the oldest musical society in Europe.

The word "madrigal" is frequently also used to designate a sentimental or trifling expression in a half-contemptuous sense.

(2) In Music. As a definite musical art-form, the madrigal was known in the Netherlands by the middle of the 15th century; like the motet, it obviously originated in the treatment of counterpoint on a canto fermo, some early examples even combining an ecclesiastical canto fermo in the tenor with an imitative counterpoint in the other parts. This Josquin's Déploration de Jehan Ockeghem (see Music) might equally well be called a madrigal or motet, if the word "madrigal" were used for compositions.

In French texts at all. But by the middle of the 16th century the Italian supremacy in music had developed the madrigal into the greatest of secular musical forms, and made it independent of the form of the words; and thus when Lasso sets Marot's madrigals to appropriately witty and tuneful music he calls the result a "chanson"; while when Palestre composes Petrarca's Sonnets to the Virgin in memory of Laura, the result appears as a volume of Madrigali spirituali. Elegiac madrigals, whether spiritual or secular, were thus as common as any other kind; so that when the Musica transalpina brought the word "madrigal" to England it brought a precedent, for the poet Drummond's melancholy type of madrigal poetry.

Italian madrigals, however, are by no means always elegiac; but the term always means a highly organized and flowing polyphonic piece, often as developed as the motet, though, in the mature classical period, distinct in style. Yet masses were often founded on the themes of madrigals, just as they were on the themes of motets (see Mass; Motet); and it is interesting, in view of the examples given above, that Josquin's Missa gio ch'i m'ebbe care, to detect the slight strain the mildly scandalous origin of the themes puts upon the ecclesiastical style.

The breaking strain was put on the madrigal style at the end of the 16th century, in one way by the new discs of Monte- verde and with more musical invention Schütz; and in another way by the brilliant musical character-drawing of Vecchi, whose Amphiornoso is a veritable comic opera in the form of a set of fourteen madrigals, all riotously witty in the purest and most masterly polyphonic style. It was probably meant, or at least was meant by its composer to be read as music for parts. The greatest classics in the madrigal style are those of Italy; and but little, if at all, below them come the English. The form, though not the name, of course, exists in the 16th-century music of other languages whenever the poetry is not too light for it.

It is important but easy to distinguish the madrigal from the lighter 16th-century forms, such as the Italian villanella and the English balad, these being very homogeneous and distinguished by the strong lift of their rhythm.

The madrigal has been very successfully revived in modern English music with a more or less strict adherence to the 16th century principles; the compositions of De Pearsall being of high artistic merit, while the Madrigali spirituali in Stanford's oratorio Eden is a movement of rare beauty. (D. F. T.)

MADURA (Dutch Medoeera), an island of the Dutch East Indies, separated by the shallow Strait of Madura from the N.E. coast of Java. Pop. (1807), 1,652,580, of whom 1,646,071 were natives, 4,252 Chinese and 5,588 Europeans. It extends from about 11° 35' to 11° 48' S., and is divided into two nearly equal portions by the parallel of 8° S.; the area is estimated at 177,50 sq. m. It is a plateau-like prolongation of the limestone range of northern Java, with hills (1,200 to 1,600 ft. high) and dales. The formation of the coast and plains is Tertiary and recent alluvium. Hot springs are not infrequent; and in the valley between Gunong Geger and Banjar lies the mud volcano of
Banju Ening. The coast is clothed with tropical vegetation; but the soil is better fitted for pastoral than agricultural purposes. Fishing and cattle-rearing are the chief means of subsistence. Besides rice and maize, Madura yields coco-nut oil and jati. The manufacture of salt for the government, abolished in other places, continues in Madura. Hence perhaps the name is derived (Sansk. mandura, salt). Petroleum is found in small quantities.

The principal town is Sumenep; and there are populous Malay, Arab and Chinese villages between the town and the European settlement of Maringan. On a hill in the neighbourhood lies Asta, the burial-place of the Sumenep princes. Pamekasam is the town of government. Bangkalang is a large and beautiful old palace of the sultan of Madura and the residences of the princes of the blood; the mosque is adorned with the first three suras of the Koran, thus differing from nearly all the mosques in Java and Madura, though resembling those of western Islam. In the vicinity once stood the Erfrins fort. Arisbaya (less correctly Arosbaya) is the place where the first mosque was built in Madura, and where the Dutch sailors first made acquaintance with the natives. The once excellent harbour is now silted up. Sampang is an important market. The Kangean and Sapudi islands, belonging to Madura, yield timber, trepang, turtle, pisang and other products.

Madura formerly consisted of three native states—Madura or Bangkalang, Pamekasam and Sumenep. The whole island was considered part of the Java residency of Surabaya. The separate residency of Madura was constituted in 1857; it now consists of four departments—Pamekasam, Madura, Sumenep and Sampang.

**MADURA**, a city and district of British India, in the Madras Presidency. The city is situated on the right bank of the river Vaigai, and has a station on the South Indian railway 345 m. S.E. of Madras. Pop. (1901), 105,984. The city was the capital of the old Pandyan dynasty, which ruled over this part of India from the 5th century B.C. to the end of the 11th century A.D. Its great temple forms a parallelogram about 847 ft. by 729 ft., and is surrounded by nine gopuras, of which the largest is 152 ft. high. These ornamental pyramids begin with door-posts of single stones 60 ft. in height, and rise course upon course, carved with rows of gods and goddesses, peacocks, bulls, elephants, horses, lions, and a bewildering entanglement of symbolic ornament all coloured and gilded, diminishing with distance until the stone trisul at the top looks like the finest jeweller's work. The temple, which contains some of the finest carving in southern India, is said to have been built in the reign of Viswanath, first ruler of the Nayak dynasty. Its chief feature is the sculptured "Hall of a Thousand Pillars." The palace of Tirumala Nayak is the most perfect relic of secular architecture in Madras. This palace, which covers a large area of ground, has been restored, and is utilized for public offices. The Vasanta, a hall 333 ft. long, probably dedicated to the god Sundareswara, and the Tamakam, a pleasure-place, now the residence of the collector, are the other principal buildings of this period.

The last of the old Pandyan kings is said to have extirpated the Jains and conquered the neighbouring kingdom of Chola; but he was in his turn overthrown by an invader from the north, conjectured to have been a Mahomedan. In 1334 a Moslem army under Malik Kafur occupied Madura, and the Hindus were held in subjection for a period of fifty years. Subsequently Madura became a province of the Hindu Empire of Vijayanagar. In the middle of the 16th century the governor Viswanath established the Nayak dynasty, which lasted for a century. The greatest of the line was Tirumala Nayak (reigned 1623-1659), whose military exploits are recorded in the contemporary letters of the Jesuit missionaries. He adored Madura with many public buildings, and extended his empire over the adjoining districts of Travancore, Comata, Salem and Trichinopoly. His repudiation of the nominal allegiance paid to the raja of Vijayanagar brought him into collision with the sultan of Bijapur, and after a lapse of three centuries Mahomedans again invaded Madura and compelled him to pay them tribute. After the death of Tirumala the kingdom of Madura gradually fell to pieces, being invaded by both Mahomedans and Maharrattas. About 1736 the district fell into the hands of the nawab of the Carnatic, and the line of the Nayaks was extinguished. About 1764 British officers took charge of Madura in trust for Mahomed Ali (Wallah Jah), the last independent nawab of the Carnatic, whose son finally ceded his rights of sovereignty to the East India Company in 1801.

The **District of Madura** has an area of 8701 sq. m. Pop. (1911), 1,015,871. An increase of 8.5% in the decade. It consists of a section of the plain stretching from the mountains east to the sea, coinciding with the basin of the Vaigai river, and gradually sloping to the S.E. The plain is broken by the outlying spurs of the Ghats, and by a few isolated hills and masses of rock scattered over the country. The most important spur of the Ghats is known as the Palki hills, which project E.N.E. across the district for a distance of about 54 m. Their highest peaks are more than 8000 ft. above sea-level, and they enclose a plateau of about 1000 sq. m., with an average height of 7000 ft. This plateau is situated near the coast, and coffee-planting is successfully carried on. The other principal crops of the district are millets, rice, other food-grains, oil-seeds and cotton. Tobacco is grown chiefly in the neighbourhood of Dindigul, whence it is exported to Trichinopoly, to be made into cigars. There are several cigar factories and a number of salt-petre refineries. The only other large industry is that of coffee-cleaning. Madura is traversed by the main line of the South Indian railway. It has four small seaports, whose trade is chiefly carried on with Ceylon. The most important irrigation work, known as the Periyar project, consists of a tunnel through the Travancore hills, to convey the rainfall across the watershed. See Madura District Gazetteer (Madras, 1906).

**MADVIG, JOHAN NICOLAI** (1804-1886), Danish philologist, was born on the island of Bornholm, on the 7th of August 1804. He was educated at the classical school of Frederiksborg and the university of Copenhagen. In 1828 he became reader, and in 1829 professor, of Latin language and literature at Copenhagen, and in 1832 was appointed university librarian. In 1848 Madvig entered parliament as a member of what was called the "Eider-Danish" party, because they desired the Eider to be the boundary of the country. When this party came into power Madvig became minister of education. In 1852 he became director of public instruction. Some years later, from 1856 to 1863, Madvig was president of the Danish parliament and leader of the National Liberal party. With these brief interruptions the greater part of his life was devoted to the study and teaching of Latin and the improvement of the classical schools, of which he was chief inspector. As a critic he was distinguished for learning and acumen. He devoted much attention to Cicero, and revolutionized the study of his philosophical writings by an edition of De Finibus (1839; 3rd ed., 1876). Perhaps his most widely known works are those on Latin grammar and Greek syntax, especially his Latin grammar for schools (Eng. trans. by G. Woods). In 1874 his sight began to fail, and he was forced to give up much of his work. He still, however, continued to lecture, and in 1879 he was chosen rector for the sixth time. In 1880 he resigned his professorship, but went on with his work on the Roman constitution, which was completed and published before his death. In this book Madvig takes a strongly conservative standpoint and attacks Mommsen's views on Caesar's programme of reforms. It is a clear exposition, though rather too dogmatic and without sufficient regard for the views of other scholars. His last work was his autobiography, Livserindringer (published 1887). Madvig died at Copenhagen on the 12th of December 1886.

See J. E. Sandys, History of Classical Scholarship (1908), iii., 314.

**MAECENAS, GAUS** (CILNIUS, Roman patron of letters, was probably born between 74 and 64 B.C., perhaps at Arretium. Expressions in Propertius (i. 1, 25-30) seem to imply that he
MAECIANUS—MAELDUIN, VOYAGE OF

had taken some part in the campaigns of Mutina, Philippi and Perusia. He prided himself on his ancient Etruscan lineage, and claimed descent from the princely house of the Cilnii, who excited the jealousy of their townspeople by their preponderating wealth and influence at Arretium in the 4th century B.C. (Livy x. 3). The Gaius Maecenas mentioned in Cicero (Pro Cluentio, 56) as an influential member of the equestrian order in 91 B.C. may have been his grandfather, or even his father. The testimony of Horace (Odes iii. 8, 3) and Maecenas's own literary tastes imply that he had profited by the highest education of his time. His great wealth may have been in part heaped up by his father, but his literary influence to his close connexion with the emperor Augustus. He first appears in history in 40 B.C., when he was employed by Octavian in arranging his marriage with Scribonia, and afterwards in assisting to negotiate the peace of Brundusium and the reconciliation with Antony. It was in 39 B.C. that Horace was introduced to Maecenas, who had before this received Varis and Virgil into his intimacy. In the Journey to Brundusium, (Horace, Satires, i. 5) in 37, Maecenas and Coccéus Nerva are described as having been sent on an important mission, and they were the only objects uppermost in his mind. The reconciliation between the two claimants for supreme power. During the Sicilian war against Sextus Pompeius in 36, Maecenas was sent back to Rome, and was entrusted with supreme administrative control in the city and in Italy. He was vicegerent of Octavian during the campaign of Actium, when, with great promptness and secrecy, he crushed the conspiracy of the younger Lepidus; and during the subsequent absences of his chief in the provinces he again held the same position. During the latter years of his life he fell somewhat out of favour with his master. Suetonius (Augustus, 60) attributes the loss of the imperial favour to Maecenas having indiscreetly revealed to Terentia, his wife, the discovery of the conspiracy in which her brother Murena was implicated. But according to Dio Cassius (lvi. 19) it was due to the emperor's relations with Terentia. Maecenas died in 8 B.C., leaving the emperor heir to his wealth.

Opinions were much divided in ancient times as to the personal character of Maecenas; but the testimony as to his administrative and diplomatic ability was unanimous. He enjoyed the credit of being the first to establish larger and more perfect means of reconciling the new order of things, of reconciling parties, and of carrying the new empire safely through many dangers. To his influence especially was attributed the humane policy of Octavian after his first alliance with Antony and Lepidus. The best summary of his character as a man and a statesman is that of Velleius Paterculus (ii. 88), who describes him as "of sleepless vigilance in critical emergencies, far-seeing and knowing how to act, but in his relaxation from business more luxurious and effeminate than a woman."

Expressions in the Odes of Horace (i. 17, 1) seem to imply that Maecenas was deficient in the robustness of fibre characteristic of the average Roman. His character as a munificent patron of literature—which has made his name a household word—is gratefully acknowledged by the recipients of it and attested by the regrets of the men of letters of a later age, expressed by Martial and Juvenal. His patronage was exercised, not from vanity or a mere dilettante love of letters, but with a view to the higher interest of the state. He recognized in the genius of the poets of that time, not only the truest ornament of the court, but a power of reconciling men's minds to the new order of things, and of investing the actual state of affairs with an ideal glory and majesty. The change in seriousness of purpose between the Eclogues and the Georgics of Virgil was in a great measure the result of the direction given by the statesman to the poet's genius. A similar change between the earlier odes of Horace, in which he declares his epicurean indifference to affairs of state, and the great national odes of the third book is to be ascribed to the same guidance. Maecenas endeavoured also to divert the less masculine genius of Propertius from harping continually on his love to themes of public interest. But if the motive of his patronage had been merely politic it never could have inspired the affection which it did in its recipients. The great charm of Maecenas in his relation to the men of genius who formed his circle was his simplicity, cordiality and sincerity. Although not particular in the choice of some of the associates of his pleasures, he admitted none but men of worth to his intimacy, and when once admitted they were treated like equals. Much of the wisdom of Maecenas probably lives in the Satires and Epistles of Horace. It has fallen to the lot of no other patron of literature to have his name associated with works of such lasting interest as the Georgics of Virgil, the first three books of Horace's Odes, and the first book of his Epistles. Maecenas himself wrote in both prose and verse. The few fragments that remain show that he was less successful as an author than as a judge and patron of literature. His prose works on various subjects—Prometheus, Symposium (a banquet at which Virgil, Horace and Messalla were present), De cultu suo (on his manner of life)—were ridiculed by Augustus, Seneca and Quintilian for their strange style, the use of rare words and awkward transpositions. According to Dio Cassius, Maecenas was the inventor of a system of shorthand.

The best known is that by P. S. Frandsen (1843). See "Horace et Meene" by J. Girard, in La Revue politique et litteraire (Dec. 27, 1873); V. Giraudthausen, Augustus und seine Zeit, i. 762 seq.; ii. 432 seq. The chief modern authorities are Horace, Suetonius, Dio Cassius, Tacitus (Annals), Suetonius (Augustus). The fragments have been collected and edited by F. Harder (1889).

MAECIANUS, LUCIUS VOLUSIUS (2nd cent.) Roman jurist, was the tutor in the law of the emperor Marcus Aurelius. When governor of Alexandria he was slain by the soldiers, as having participated in the death of Avidius Cassius (175). Maecianus was the author of works on trusts (Fideicommisso), on the Judicio publico, and of a collection of the Rhodian laws relating to maritime affairs. His treatise on numerical divisions, weights and measures (Distributo) is extant, with the exception of the concluding portion.

MAELDUIN (or MAELDUNE), VOYAGE OF (Imram Maelduin), an early Irish romance. The text exists in an 11th-century redaction, by a certain Aed the Fair, described as the "chief sage of Ireland," but it may be gathered from internal evidence that the tale itself dates back to the 8th century. It belongs to the group of Irish romance, the Navigations (Imrame), the common type of which was probably imitated from the classical tales of the wanderings of Jason, of Ulysses and of Aeneas. Maelduin, the foster-son of an Irish queen, learnt on reaching manhood that he was the son of a nun, and that his father, Allill of the edge of battle, had been slain by a marauder from Leix. He set sail to seek his father's murderer, taking with him, in accordance with the instructions of a sorcerer, seventeen men. His three foster-brothers swam after him, and were taken on board. This increase of the fateful number caused Maelduin's vengeance to be deferred for three years and seven months, until the last of the intruders had perished. The travellers visited many strange islands, and met with a long series of adventures, from some of which are familiar from other sources. The Voyage of St Brendan (q.v.) has very close similarities with the Maelduin, of which it is an early clerical imitation, with the important addition of the whole-island episode, which it has in common with "Sindbad the Sailor."

Imram Carraig Maelduin is preserved, in each case imperfectly, in the Lebor na hUidre, a MS. in the Royal Irish Academy, Dublin; and in the Yellow Book of Lecan, MS. H. 216 in the Trinity College Library, Dublin; fragments in the library of Ardfert, and a MS. 1782 in the British Museum. There are translations by Patrick Joyce, Old Celtic Romances (1879), by Whitley Stokes (a more critical version, printed together with the text) in Revue Celtique, vols. ix. and x. (1885-1886). See H. Zimmer, "Brendan's Meerfahrt" in Zeitschrift für deutsche Altertum, vol. xxii. (1889). Tennyson's Voyage of Maelduine, suggested by the Irish romance, borrows little more than its framework.
MAELIUS, MAETERLINCK

MAELIUS, SPURIUS (d. 430 B.C.), a wealthy Roman plebeian, who during a severe famine bought up a large amount of corn and sold it at a low price to the people. Lucius (or Gaius) Minucius, the patrician praefectus annonae (president of the market), thereupon accused him of profiteering with a view to murdering him. Cicero (c. 180 B.C.) was summoned before the aged Cincinatus (specialy appointed dictator), refused to appear, and was slain by Gaius Servilius Ahala; his house was razed to the ground, his corn distributed amongst the people, and his property confiscated. The open space called Acquimaelium, on which his house had stood, preserved the memory of his death. Cicero calls Ahala's deed a glorious one, but, whether Maelius entertained any ambitious projects or not, his summary execution was an act of murder, since by the Valerio-Horatian laws the dictator was bound to allow the right of appeal.

See Niebuhr's *History of Rome*, ii. 418 (Eng. trans., 1851); G. Cornewall Lewis, *Credibility of early Roman History*, ii.; Livy, iv. 13; Cicero, *De senectute* 16; *De amicitia* 8; *De republica*, ii. 27; *Florus*, i. 26; Dict. H. l. i. 4.

MAELSTROM (whirlpool), a term originally applied to a strong current past the southeast end of the island of Moskenesøya, a member of the group of Lofoten Islands on the west coast of Norway. It is known also as the Moskenstrom. Though dangerous in certain states of wind and tide, the tales of ships being swallowed in this whirlpool are fables. The word is probably of Dutch origin, from *molen*, to grind or whirl, and *strom* or *stroom*, a stream or current. It appears on Mercator's *Atlas* of 1595.

MAENADS (Gr. *Mauvades*, frenzied women), the female attendants of Dionysus. They are known by other names—Bacchae, Thyiades, Clocrones and Maimllones (the last two probably of Thracian origin)—all more or less synonymous.

See the exhaustive articles by A. Legrand in Darenberg and Saglio's *Dictionnaire des ancientudes* et A. Rapp in Roscher's *Lexicon der Mythologie*; also editions of Euripides, Bacchae (e.g. J. E. Sandys).

MAENIUS, GAIUS, Roman statesman and general. Having completed (when consul in 338 B.C.) the subjugation of Latium, which with Campania had revolted against Rome, he was honoured by a triumph, and a column was erected to him in the Forum. When censor in 318, in order that the spectators might have more room for seeing the games that were celebrated in the Forum, he provided the buildings in the neighbourhood with balconies, which were called after him *maeniana*.

See Festus, s. a. Maeniana; Livy viii. 13, ix. 34; Pliny, *Nat. Hist.* xxiv. 11 (s).

MAELRLANT, JACOB VAN (c. 1235-c. 1250), Flemish poet, was born in the Franc de Burges (tradition says at Damme) between 1230 and 1240. He was sacristan of Maerlant, in the island of Ost-Voorne, and afterwards clerk to the magistrates at Damme. His early works are translations of French romances. Maerlant's most serious work in the field of romance was his *Ystorie van Troyen* (c. 1264), a poem of some forty thousand lines, translated and amplified from the *Roman de Troie* of Benoît de Sainte-More. From this time Maerlant rejected romance as idle, and devoted himself to writing scientific and historical works for the education and enlightenment of the Flemish people. His *Heimeliched he Heimelicheden* (c. 1260) is a translation of the *Secreta secretorum*, a manual for the education of princes, ascribed throughout the middle ages to Aristotle. *Van der Natere Bloemoe* is a free translation of *De natura rerum*, a natural history in twenty books by a native of Brabant. Thomas de Cantimpré; and his *Rijkmijbel* is taken, with many omissions and additions, from the *Historia scholastica* of Petrus Comestor. He supplemented this metrical paraphrase of Scripture history by *Die Wrake van Jerusalam* (1271) from Josephus. Although Maerlant was an orthodox Catholic, he is said to have been called to account by the priests for translating the Bible into the vulgar tongue. In 1284 he began his *magnum opus*, the *Spiegel historiæ*, a history of the world, derived chiefly from the third part of the *Speculum majus* of Vincent de Beauvais. This work was completed by two other writers, Philipp Utenbroeke and Lodowijk van Velthem. Maerlant died in the closing years of the 13th century, his last poem, *Van den lande van oerose*, dating from 1291. The greater part of his work consists of translations, but he also produced poems which present original metres with original poetry. Among these are *Die Clausde van der Bibel, De Kerken Clage*, imitated from the *Complaintes de Rutebeuf*, and the three dialogues entitled *Martiijn*, in which the fundamental questions of theology and ethics were discussed. In spite of his orthodoxy, Maerlant was a keen satirist of the corruptions of the clergy. He was one of the most learned men of his age, and for two centuries was the most celebrated of Flemish poets.

See monographs by J. van Beers (Ghent, 1860); C. A. Serrure (Ghent, 1861); K. Versnaeye (Ghent, 1861); J. te Winkel (Leiden, 1877, 2nd ed., Ghent, 1892); and editions of *Troyen* (Leiden 1875) by J. te Winkel; of *Natuur Bloemoe*, by Eelco Verwijis; of *Alexanders Geesten* (Groningen, 1882), by J. Verdama.

MAES, NICOLAS (1632-1693), Dutch painter, was born at Dordrecht, and went about 1650 to Amsterdam, where he entered Rembrandt's studio. Before his return to Dordrecht in 1654 Maes painted a few Rembrandtesque genre-pictures, with life-size figures and in a deep glowing scheme of colour, like the "Reverie" at the Ryks Museum in Amsterdam, the "Card Players" at the National Gallery, and the "Children with a Goat Carriage," belonging to Baroness N. de Rothschild. So closely did his early style resemble that of Rembrandt, that the last-named picture, and other canvases in the Leipzig and Budapest galleries and in the collection of Lord Radnor, were or are still ascribed to Rembrandt. In his best period, from 1655 to 1665, Maes devoted himself to domestic genre on a smaller scale, retaining to a great extent the magic of colour he had learnt from Rembrandt. Only on rare occasions did he treat scriptural subjects, as in the earl of Denbigh's "Hagar's Departure," which has been ascribed to Rembrandt. His favourite subjects were women spinning, or reading the Bible, or preparing a meal. In 1665 he went to Antwerp, where he remained till 1678, in which year he probably returned to Amsterdam. His Antwerp period coincides with a complete change in style and subject. He devoted himself almost exclusively to portraiture, and abandoned the intimacy and glowing colour harmonies of his earlier work for a careless elegance which suggests the influence of Van Dyck. So great indeed was the change, that it gave rise to the theory of the existence of another Maes, of Brussels. Maes is well represented at the National Gallery by five paintings: "The Cradle," "The Dutch Housewife," "The Idle Servant," "The Card Players," and a man's portrait. At Amsterdam, besides the splendid examples to be found at the Ryks Museum, is the "Inquisitive Servant" of the "Six collection. At Buckingham Palace is "The Listening Girl" (repellent exist), and at Apseley House "Selling Milk" and "The Listener." Other notable examples are at the Berlin, Brussels, St Petersburg, the Hague, Frankfort, Hanover and Munich galleries.

MAESTRO, a north-westerly wind observed in the Adriatic and surrounding regions, chiefly during summer. The maestro is a "fine weather" wind, and is the counterpart of the sirocco.

MAETERLINCK, MAURICE (1862- ), Belgian-French dramatist and poet, of Flemish extraction, was born at Ghent on the 20th of August 1862. He was educated at the Collège Sainte-Barbe, and then at the university of his native city, where, at the age of twenty-four, he was enrolled as a barrister. In 1887 he settled in Paris, where he immediately became acquainted with Villiers de l'Isle-Adam and the leaders of the symbolist school of French poetry. At the death of his father, Maeterlinck returned to Belgium, where he thenceforth mainly resided: In the winter at Ghent, in the summer on an
estate at Oostacker. He had by this time determined to devote his whole life to poetry, a dedication which his fortune permitted. His career as an author began in 1889, when he published a volume of verse, *Sœurs chauves*, and a play, *La Princesse Maleine*, the latter originally composed in metre, but afterwards carefully rewritten in prose, the vehicle which the author continued to use for his dramatic work. Maeterlinck was at this time totally unknown, but he became famous through an article by Octave Mirbeau, prominently published in the Paris *Figaro*, entitled "A Belgian Shakespeare." The enthusiasm of this review and the excellence of the passages quoted combined to make Maeterlinck the talk of the town. Maeterlinck, among his Belgian roses, continued to work with extreme deliberation. In 1890 he published, in Brussels, two more plays, *L'Intruse* and *Les Aveugles*; followed in 1891 by *Les Sept princesses*. His strong leaning to mysticism was now explained, or defined, by a translation of the Flemish medieval visionary, the Admirable Ruysbroeck, which Maeterlinck brought out in 1891. In 1892 appeared what has been perhaps the most successful of all his plots of his plays, *Pelléas et Mélisande*, followed in 1894 by those very curious and powerful little dramas written to be performed by marionettes: *Alladine et Palomides, Intérieur et La Mort de Tintagiles*. In 1895 Maeterlinck brought out, under the title of *Anna Bolla*, a translation of Ford's *Tis Pity She's a Whore*, with a preface. Two philosophical works followed, a study on Novallis (1895) and *Le Trésor des humbles* (1896). In 1896 he returned to drama with *Aglaovaine et Sélyssette* and *lyric verse with Douse chansons*. A monograph on the ethics of mysticism, entitled *La Sagesse et la destinée*, was issued, as a kind of commentary on his own dramas, in 1898; and in 1901 Maeterlinck produced a fascinating volume of prose, founded upon observations made in his aporias at Oostacker, in which philosophy, fancy and natural history were surprisingly mingled—*La Vie des abeilles*. In 1902 he published *Le Temple enseveli* and *Monna Vanna*; in 1903 *Joyelle*. In 1901 he began to issue, in Brussels, an edition of his complete dramatic works.

The nature of Maeterlinck's writings, whether in prose or verse, has been strictly homogeneous. Few poets have kept so rigorously to a certain definite direction in the practice of their art. Whether in philosophy, or drama, or lyric, Maeterlinck is exclusively occupied in revealing, or indicating, the mystery which lies, only just out of sight, beneath the surface of ordinary life. In order to produce this effect of the mysterious he aims at an extreme simplicity of diction, and a symbolism so realistic as to be almost bare. He allows life itself to astonish us by its strangeness, by its inexplicable elements. Many of his plots are really highly pathetic records of unseen emotion; they are occupied with the spiritual adventures of souls, and the ordinary facts of time and space have no influence upon the movements of the characters. We know not who these obscure princesses, these blind persons, these pale Arthurian knights, these aged guardians of desolate castles, may be; we are not informed whence they come, nor whither they go; there is nothing concrete or circumstantial about them. Their life is intense and consistent, but it is wholly of a spiritual character; they are mysterious with the mystery of the movements of a soul. These characteristics, which make the dramatic work of Maeterlinck so curious and unique, are familiar to most readers of *Pelléas et Mélisande*, but are carried, perhaps, to their farthest intensity in *Aglaovaine et Sélyssette*, which seems to be written for a phantom stage and to be acted by disembodied spirits. In spite of the violence of his early admirers, and of the fact that the form of his drama easily lent itself to the cheap ridicule of parodists, the talent of the composer has hardly met with opposition from the criticism of his time. It has been universally felt that his spirit is one of grave and disinterested attachment to the highest moral beauty, and his seriousness, his serenity and his extreme originality have impressed even those who are bewildered by his diaphanous graces and offended at his nebulous mysticism. While the crude enthusiasm which compared him with Shakespeare has been shown to be ridiculous, the best judges combine with Camille Mauciar when he says: "Maurice Maeterlinck est un homme de génie authentique, un très grand phénomène de puissance mentale à la fin du xixe siècle." In spite of the shadowy action of Maeterlinck's plays, which indeed require some special conditions and contrivances for their performance, they are frequently produced with remarkable success before audiences which can be suspected of mysticism, in most of the countries of Europe. In his philosophical writings Maeterlinck shows himself a disciple of Novalis, of Emerson, of Hello, of the Flemish Catholic mystics, and he evolves from the teachings of those thinkers a system of aesthetics applicable to the theatre as he conceives it.

(M.G.)

MAFEKING, a town in the British Bechuanaland division of the Cape, 870 m. N.E. of Cape Town and 492 m. S.S.W. of Bulawayo by rail, and 162 m. in a direct line W. by N. of Johannesburg (Pop. 1904), 2713. It is built on the open veld, at an elevation of 4194 ft., by the banks of the Upper Molopo, is 9 m. W. of the western frontier of the Transvaal and 15 m. S. of the southern boundary of the Bechuanauland protectorate. The Madibi goldfields are some 10 m. south of the town. Mafeiking is thus an important trading and distributing centre for Bechuanauland and the western Transvaal. Here are, too, the chief railway workshops between Kimberley and Bulawayo. The headquarters of the administration for the Bechuanauland protectorate are in the town. The chief buildings are the town-hall, Anglican church, Masonic temple, and hospital.

Mafeiking was originally the headquarters of the Barolog tribe of Bechuana and is still their largest station, the native location (pop. 2860) being about a mile distant from the town. It was from Pitsiani Pothlugo (or Potlogo), 24 m. north of Mafeiking, that Dr Jameson started, on the 29th of December 1895, on his raid into the Transvaal. On the outbreak of the Anglo-Boer war in 1899 Mafeiking was invested by a Boer force. Colonel R. S. S. Baden-Powell was in command of the defence, which was stubbornly maintained for 217 days (Oct. 12 to May 27), when a relief column arrived and the Boers dispersed (see TRANSVAAL: History). The fate of the town had excited the liveliest sympathy in England, and the exuberant rejoicings in London on the news of its relief led to the coining of the word *mafiking* to describe the behaviour of crowds on occasions of extravagant demonstrations of a national kind. In September 1904 Lord Roberts unveiled at Mafeiking an obelisk bearing the names of those who fell in defence of the town.

R. S. S. Baden-Powell's Sketches in Mafeiking and East Africa (1907) and Lady Sarah Wilson's *South African Memories* (1909) deal largely with the siege of Mafeiking.

MAFFEI, FRANCESCO SCIPIONE, Marchese di (1675–1755), Italian archaeologist and man of letters, was born at Verona on the 1st of June 1675. He studied for five years in Parma, at the Jesuit College, and afterwards from 1698 at Rome; and in 1703–1704 he took part as a volunteer in the war of succession, fighting on the Bavarian side at Donauwerth. In 1709 he began at Padua along with Apostolo Zeno and Valsinieri the *Giornale dei letterati d'Italia*, a literary periodical which had but a short career; and subsequently an acquaintance with the actor Riccoboni led him to exert himself for the improvement of dramatic art in Italy. His *Merope*, a tragedy, appeared in 1713; *Teatro Italiano*, a small collection of works for presentation on the stage, in 1723–1725; and *Le Cerimone*, an original comedy, in 1728. From 1718 he became specially interested in the archaeology of his native town, and his investigations resulted in the valuable *Verona illustrata* (1731–1732). Maffei afterwards devoted four years to travel in France, England, Holland and Germany. He died at Verona on the 11th of February 1755.

A complete edition of his works appeared at Venice (28 vols., 8vo) in 1790.

MAFIA (MAFFIA), a secret society of Sicily. Its organization and purposes much resemble those of the Camorra (q.v.).

Various derivations are found for the name. Some hold it to be a Tuscan synonym for *meseria*; others, a corruption of Fr. *mausai*.
MAFRA, a town of Portugal, in the district of Lisbon (formerly in the province of Estremadura); near the Atlantic coast and the right bank of the river Lizandro, and 20 m. N.W. of Lisbon. Pop. (1900), 4769. Mafra is remarkable for its monastery, church, and palace, built by John V. in 1717-1732, in consequence of a vow made during a dangerous illness to build a convent for the poorest fries of the kingdom—which proved to be a small Franciscan settlement here. The architects, Johann Friedrich Ludwig of Regensburg, and his son Johann Peter, took the Escorial for their model; but the imitation is less successful, though the cost exceeded originally 4,000,000. The building is in the form of a cruciform church measuring upwards of 800 ft. from north to south and 700 ft. from east to west; it is said to contain 866 rooms, and to be lighted by no fewer than 5200 windows. The centre is occupied by the church, sumptuously built of marble, and richly adorned with statues and other objects of art. In each of the twin towers there is a chime of 57 bells. Part of the palace, originally designed as barracks, is used as a military academy. Adjoining the palace are fine gardens and a royal model farm.

MAGALDÁN, a town in the northern part of the province of Pangasinan, Luzon, Philippine Islands, about 2 m. from the shore of the Gulf of Lingayen. Pop. (1903), 15,841. In 1903 the adjacent municipality of Mapandan (pop. in 1900, 4108) was annexed to Magaldán. Most of its inhabitants are engaged in rice culture. The principal language is Pangasinan; Ilocano is also spoken.

MAGALLANES (Spanish form of Magellan), a territory of southern Chile extending from 47° S. to Cape Horn and including the mainland from the Argentine frontier to the Pacific coast, the islands extending along that coast, the Fuegan archipelago, and the western half of Tierra del Fuego. Area, about 71,127 sq. m.; pop. (1905), 5170. It is one of the most inhospitable regions of the world, being exposed to cold westerly storms for most of the year. The islands are barren, but the mainland is covered with forests, practically inaccessible to exploitation because of the inclement climate and the wet spongy soil. The coast is indented with bays and fjords and affords remarkable scenery. There is little animal life on land, but the coast is frequented by the seal and sea-otter and the sheltered waters by countless sea-fowl. The only permanent settlements are at Punta Arenas, the capital, on the Straits of Magellan, Palomares at Otway Water, Mina Maria on Skrying Water, and Ultima Esperanza (Last Hope) on the east shore of Worsley Sound. All are east of the Andean ranges and partially sheltered from the westerly storms. In this sheltered region there are open plains where sheep are grazed. A few sheep ranges have been established on Tierra del Fuego. Some nomadic tribes of Indians inhabit Tierra del Fuego and the extreme southern end of the mainland, but their numbers are small. Coal has been found in the vicinity of Punta Arenas, and gold occurs.

See The Voyage of the Adventure and Beagle (1839).

MAGAZINE, primarily a warehouse for goods or merchandise (Arab. makhaan, a storehouse, from hhazana, to store up). In Morocco makhsan (or magazar) has come to be used as the name of the government. The Spaniards adopted the Arabic in the form magacen, and the English form comes through the older French magasin, modern magasin. The meaning of a storehouse or large shop, common in French, is rare in English except in the military use of the term for a building for the storage of ordnance and ammunition. It is applied to the chamber of a repeating rifle or machine-gun containing the supply of cartridges. The name as applied to a periodical publication
containing articles on various subjects was first used in the 

*Gentleman's Magazine* (1731), described as "a monthly collection, to treasure up as in a magazine" articles on the subjects with which it was proposed to deal.

**MAGDA** (more correctly **MAKDA**), a natural stronghold in the country of the Wollo Gallas, Abyssinia, about 250 m. W. of Jihuti on the Gulf of Aden, in 11° 22' N., 39° 25' E. The basaltic plateau of which it consists rises 910 ft. above the sea. It is about three-quarters of a mile in length by less than half a mile in breadth, and lies more than a thousand feet higher than the neighbouring plain of Argile. Chane and about 1629, by the emperor Theodore of Abyssinia as his principal stronghold in the south, Magdala owes its celebrity to the fact that, as the place of imprisonment of the English captives, it became the goal of the great English Expedition of 1668. At the time of its capture it contained huts for a population of about three thousand. The whole rock was burned bare by order of the commander of the British force, Sir Robert Napier, who, on being raised to the peerage for his services on this occasion, took the title of Lord Napier of Magdala. The plateau was subsequently laid waste, and a fortress was built on it as a station of the Abyssinian army.

See Clements Markham, History of the Abyssinian Expedition (1889); and H. Rassem, British Mission to Theodore (1889).

**MAGDEBURG**, a city of Germany, capital of the Prussian province of Saxony, a fortress of the first rank and one of the principal commercial towns of the German Empire. It lies in a broad and fertile plain, mainly on the left bank of the Elbe, 88 m. S.W. from Berlin and at the junction of main lines to Leipzig, Brunswick, Cassel and Hamburg. Pop. (1885), 159,520; (1890), 202,334; (1905), 240,661. It consists of the town proper, and of the five suburbs of Friedrichstadt, Wilmersdadt, Neustadt, Sudenburg and Buckau; the last four are separated from the town by the ramparts and glais, but are all included within the new line of advanced bastions, while Friedrichstadt lies on the right bank of the river. In the Elbe, between the old town and the Friedrichstadt, lies an island whereon stands the citadel; this is united with both banks by bridges. With the exception of the Breite Weg, a handsome thoroughfare running from north to south, the streets of the town proper are narrow and crooked. Along the Elbe, however, extend fine promenades, the Fürstenwall and the Fürsten Ufer. To the south of the inner town is the Friedrich Wilhelms Garten, a beautiful park laid out on the site of the celebrated convent of Berge, which was founded in 668 and suppressed in 800. By far the most important building in Magdeburg is the cathedral, dedicated to SS Maurice and Catherine, a handsome and massive structure of the 14th century, exhibiting an interesting blending of Romanesque and Gothic architecture. The two fine western towers were completed about 1520. The interior contains the tombs of the emperor Otto the Great and his wife Edith, an English princess, and the fine monument of Archbishop Erhard (d. 1513), executed in 1495 by Peter Vischer of Nuremburg. The Liebfrauenkirche, the oldest church in Magdeburg, is an interesting Romanesque edifice of the 12th and 13th centuries, which was restored in 1800–1811. The chief secular buildings are the town-hall (Rathaus), built in 1607 and enlarged in 1866, the government offices, the palace of justice, the central railway station and the exchange. The Breite Weg and the old market contain numerous fine gable-ended private houses in the style of the Renaissance. In front of the town-hall stands an equestrian statue of Otto the Great, erected about 1260. The modern streets are spacious, and the houses well-built though monoto-

nous. There are two theatres, an agricultural college, an art school, several gymnasia, a commercial and other schools, an observatory, and two fine hospitals. The first place amongst the industries is taken by the ironworks (one being a branch of the Krupp firm, the Grusonwerke, employing about 4000 hands), which produce naval armour and munitions of war. Of almost equal importance are the sugar refineries and cibory factories. Tobacco, coffee, chocolate, artificial manure, cement, varnish, chemicals and pottery. There are also distilleries and breweries, and factories for the manufacture of cotton and silk goods. Magdeburg is the central market in Germany for sugar and chocolate, but trades extensively also in cereals, fruit, vegetables, groceries, cattle, horses, wool, cloth, yarn, leather, coal and books. A new winter harbour, made at a cost of £400,000, facilitates the river traffic along the Elbe. Three million tons of merchandise pass Magdeburg, going upstream, and nearly 1 million tons, going downstream, annually. Magdeburg is the headquarters of the IV. corps of the German army and the seat of the provincial court of appeal and administrative offices, and of a Lutheran consistory.

Magdeburg was founded by the Emperor Henry II. in 1291. It became a free imperial city as a small trading settlement at the beginning of the 9th century, owes its early prosperity chiefly to the emperor Otto the Great, who established a convent here about 937. In 968 it became the seat of an archbishop, who exercised sway over an extensive territory. Although it was burnt down in 1188, Magdeburg became a flourishing commercial town during the 13th century, and was soon an important member of the Hanseatic League. Its bench of jurats (Schöppenstuhl) became celebrated, and "Magdeburg law" (Magdeburger Recht), securing the adminis-

trative independence of Magdeburg, was applied to the parts of Germany, Poland and Bohemia. During the middle ages the citizens were almost constantly at variance with the archbishops, and by the end of the 15th century had become nearly independent of them. It should, however, be noted that Magdeburg never became a free city of the Empire. The town embraced the Reformation in 1524, and was thenceforth governed by Protestant titular archbishops (see BISCON). On the refusal of the citizens to accept the "Interim," issued by the emperor Charles V., Magdeburg was besieged by Maurice of Saxony in 1550, and capitulated on favourable terms in November 1551. During the Thirty Years' War it was twice besieged, and suffered terribly. It successfully resisted Wallenstein for seven months in 1629, but was stormed and sacked by Tilly in May 1631. The whole town, with the exception of the cathedral, and about 140 houses, was burned to the ground, and the greater part of its 36,000 inhabitants were butchered without regard to age or sex, but it recovered from this deadly blow with wonderful rapidity. By the peace of Westphalia (1648) the archbishopric was converted into a secular duchy, to fall to Brandenburg on the death of the last administrator, which happened in 1680. In 1856 Magdeburg was taken by the French and annexed to the kingdom of Westphalia, but it was restored to Prussia in 1814, on the downfall of Napoleon. Otto von Gruicerke (1602–1686), the inventor of the air-pump, was burgomaster of Magdeburg. Count Lazare Carnot died here in exile, and was buried in the cemetery, but his remains were exhumed in 1859 and conveyed to Paris. Luther was at school here, and sang in the streets for bread with other poor choristers.

See W. Kawerau, *Aus Magdeburgs Vergangenheit* (Halle, 1886) O. von Gruicerke, *Geschichte der Belagerung, Eroberung und Zerstörung von Magdeburg* (Magdeburg, 1887); M. Dittmar, Beiträge zur Geschichte der Stadt Magdeburg (Halle, 1885); F. W. Hoffmann, *Geschichte der Stadt Magdeburg* (Magdeburg, 1885–1886); F. Hülsse, *Die Einführung der Reformation in der Stadt Magdeburg* (Magdeburg, 1885); E. Wolkoff, *Die Zerstörung Magdeburgs 1632* (Magdeburg, 1886); Leunig and R. Lemoine, *Aus Magdeburgs Sage und Geschichte* (Magdeburg, 1894); and *Urkundenbuch der Stadt Magdeburg* (1892).

**The Archibishopric of Magdeburg**, was carved out of the bishopric of Halberstadt when it was founded in 968, and its history is largely bound up with that of the city and the prelates who have ruled the see. The first archbishop was Adalbert, and he and his successors had six or seven suffragan bishops. Several of the archbishops took very prominent parts in German politics. Early in the 17th century their residence was fixed at Halle, and about the same time it became the custom to select them from one of the reigning families of Germany, most often from the house of Brandenburg. The doctrines of the reformers made their appearance in the diocese in the 16th century, and in Archbishop Sigismund, a son of Joachim II., elector of Brandenburg, openly avowed his adherence to Lutheranism. After the issue of the edict of
restitution by the emperor Ferdinand II. in 1629, there were three rival candidates for the see, and their struggles added to the confusion caused by the Thirty Years' War. By the peace of Prague, however, in 1635, the archbishopric was given to Augustus, prince of Saxe-Weissenfels, who retained it until his death in 1680. In 1773 the area of the see was over 2000 sq. m. It included 29 towns and over 400 villages and contained about 250,000 inhabitants.

See the Regesta archiepiscopatus magdeburgensis, edited by G. A. von Müllerstedt (Magdeburg, 1876-1899); and K. Uhler, Geschichte des Erzbistums Magdeburg unter den Kaisern aus sächsischem Hause (Magdeburg, 1887).

Distinct both from the archbishopric and from the city was the jurisdiction over Magdeburg. The office of burgrave was held from the time of Charlemagne, although its holder was not at first called by this name, and it soon became one of great importance. The burgrave was the king's representative; he was charged with the administration of the royal estates in a given district, and in general with watching the royal interests therein. The burgraveate of Magdeburg was held by several county families in turn until 1269, when it was purchased by Archbishop Conrad II., who, however, soon sold it. In 1294 it was again united with the archbishopric and the prelates retained it until 1538, when, by purchase from Augustus, Elector of Saxony, made an arrangement which again gave the office to the archbishops, who held it until the secularization of the see.

The Magdeburg Centuries (Magdeburger Zenturien) is the name given to the first general history of the Christian Church written from a Protestant point of view. It was compiled in Magdeburg, and the history is divided into periods of one hundred years each. It was written in Latin in 1562, its principal author being the reformer Matthias Flacius, who was assisted by other Lutheran theologians. The cost of the undertaking was borne by some of the German Protestant princes. As the Historia ecclesiae Christi it was first published at Basel in seven volumes (1559-1574). It deals with the history of the Church down to 1400, and considering the time at which it was written it is a remarkable monument to the scholarship of its authors.

The earlier part of it has been translated into German (Jena, 1560-1565).

See E. Schaumkell, Beitrag zur Entstehungsgeschichte der Magdeburger Zenturien (Ludwigslust, 1898).

MAGEE, WILLIAM (1706-1831), archbishop of Dublin, was born at Enniskillen, Co. Fermanagh, and educated at Trinity College, Dublin, where he was elected fellow in 1728. He was ordained in 1790. Two sermons, preached in the college chapel in 1798 and 1799, form the basis of his Discourses on the Scriptural Doctrines of Atonement and Sacrifice (1801), a polemic against Unitarian theology which was answered by Lant Carpenter. Magee was appointed professor of mathematics and senior fellow of Trinity in 1800, but in 1812 he resigned, and undertook the charge of the livings of Cappagh, Co. Tyrone, and Killelagh, Co. Down. Next year he became dean of Cork. He was well known as a preacher and promoter of the Irish reformation, and in 1819 he was consecrated bishop of Raphoe. In 1822 the archbishop of Dublin was translated to Armagh, and Magee succeeded him at Dublin. Though in most respects a tolerant man, he steadily opposed the movement for Catholic Emancipation. He died on the 18th of August 1831.

A memoir of his life is included with the Works of the Most Reverend William Magee, D.D. (1842), by A. H. Kenney.

MAGEE, WILLIAM CONNOR (1821-1891), Anglican divine, archbishop of York, was born at Cork in 1821. His father was curate of the parish attached to the Protestant cathedral in that city; his grandfather was archbishop of Dublin. Young Magee entered Trinity College, Dublin, with a scholarship at thirteen. He was ordained to the curacy of St Thomas's, Dublin, but, being threatened with consumption, went after two years to Malaga. On his return he took a curacy at Bath, and was speedily appointed to the Octagon Chapel, where his fame both as preacher and platform speaker continued to spread. Some years afterwards he was made prebendary of Wells Cathedral. In 1866 the delicate state of his health caused him to accept the living of Enniskillen. In 1866 he was made dean of Cork and chaplain to the lord lieutenant. Here he manifested those great gifts which ultimately raised him to high office; a powerful grasp of mental, moral and political problems, combined with eloquence of a high order, and illuminated with brilliant flashes of wit. In 1868 the question of the disestablishment of the Irish Church came to the front, and Magee threw himself into the task of its defence with his usual energy and vivacity. The success of his orations enabled Disraeli to offer him the bishopric of Peterborough. He justified his appointment by his magnificent speech when the Disestablishment Bill reached the House of Lords in 1869, and then plunged into diocesan and general work in England. He preached three remarkable sermons on Christian Evidence in Norwich Cathedral in 1871. He took up the temperance question, and declared in the House of Lords that he would rather see "England free than England compulsory sober," an utterance which the extreme advocates of total abstinence misquoted and attacked. He was also a supporter of the movement for abolishing the recitation of the Athanasian Creed in the public services of the Church of England, believing, as he said, that the "presence" of the damnable clauses, "as they stand and where they stand, is a real peril to the Church and to Christianity itself," and that those clauses "are no essential part" of the creed. The project was laid aside in consequence of the hostility of a large body of the clergy, reinforced by the threat of Dr Pusey and Canon Liddon to abandon their offices if it were carried. Magee took a prominent part in the Ritual controversy, opposing what he conceived to be Romanism excess in ritual, as well as the endeavour of the opposite party to "put down Ritualism," as Disraeli expressed it, by the operation of the civil law. His incisive way of putting things earned for him the title of the "Militant Bishop," but, as he himself remarked in, relation to this title, his efforts were ever for peace. Unfortunately for the Church, he was not elevated to the see of York until his energies were exhausted. He died on the 4th of May 1891, about four months after his appointment. Magee's manifold activities, his capability as an administrator, his sound judgment, and his remarkable insight into the ecclesiastical problems of his time, rank him among the most distinguished of English prelates.

MAGELLAN, FERDINAND (in Sp. Fernando Magallanes, in Port. Fernão de Magalhães) (c. 1480-1521), the first circumnavigator of the globe, was born at Sabrosa in the Villa Real district of the Tras-os-Montes province of Portugal. He was a son of Pedro de Magalhães, and belonged to the fourth order of Portuguese nobility (fidalgo de cota de armas). He was brought up as one of the pages of Queen Leonor, consort of King John (João) II "the Perfect." In 1485 he entered the service of Manuel "the Fortunate," John's successor, and in 1504 enlisted as a volunteer for the Indian voyage of the first Portuguese viceroy in the East, Francisco d'Almeida. He sailed on the 25th of March 1505; was wounded at Cannanore on the 16th of March 1506; was sent then with Nuno Vaz Pereira to Sodasa to build a Portuguese fortress at that place; returned to India early in 1508; and was again wounded at the battle of Diu on the 3rd of February 1509. At Cochin (Aug. 19, 1509) he joined Diogo Lopes de Sequeira on his famous voyage intended for the Spice Islands, when the Portuguese almost fell victims to Malay treachery at Malacca. In this crisis he fought bravely and skilfully (though it is not true, as often asserted, that he discovered the Malay plot); and before the 10th of October 1510 he had been rewarded for his many services with the rank of captain. He again distinguished himself at the taking of Malacca by Albuquerque (July-Aug., 1511), and was then sent on by the viceroy with Antonio d'Abreu to explore the Spice Islands (Malacca, Siam, Java, and Malacca) at the end of December 1511, this squadron sailed along the north of Java, passed between Java and Madura, left Celebes on their left, coasted by the Gunong Api volcano, touched at Bura, and so reached Amboyna and Banda. At the last-named they found
Leaving Port St Julian on the 24th of August 1520, he discovered on the 21st of October the cape of the Eleven Thousand Virgins, the eastern entrance of the long-sought passage. Through this strait, 360 m. long, often narrow and very tortuous, fringed by snow-clad mountains, he guided his armada for thirty-eight days, weakened by the desertion of one vessel (the "S. Antonio"). On the 21st of November a council of pilots and captains was held to consider the continuation of the voyage, and on the 28th of November the fleet rounded Cabo Deseado, the "desired" western terminus of the strait, variously called "the Virgin of the Patagonians," "of all Saints," "of the Eleven Thousand Virgins," or "of Magellan," now only known by the last of these names. To the south of the passage lay the forbidding land "stark with eternal cold," which from the many fires here observed Magellan named "Tierra del Fuego." The expedition now entered the "Great South Sea," first sighted by Vasco Nuñez de Balboa (q.v.), which, from the steady and gentle winds that drove the fleet across the immeasurable expanse, was by Magellan called "Pacific." For ninety-eight days Magellan cruised at sea, almost beyond the grasp of man's mind for vastness (as Maximilian of Transylvania puts it), from Cabo Deseado to the Ladrones. On the whole transit he discovered only two islands, sterile and uninhabited, which he called "St Paul's" (Jan. 24, 1521) and "Shark Island" (Feb. 3). The first of these has been identified with Puka Puka in the Tuamotu Archipelago, the second with Flist Island in the Manihiki group; neither identification seems convincing. For most of these ninety-eight days the explorers had no fresh provisions, little water (and that bad), and putrid biscuit; the ravages of scurvy became terrible. The worst anticipations of Magellan ("he would push on, if they had to eat the leather of the rigging") were realized; ox-hides, sawdust, and rats became coveted food. At last, on the 6th of March 1521, the Ladrones (so named by Magellan from the thievish habits of the natives) came in sight, Guam being probably the first port of call. Here the fleet rested, watered, revictualled and refitted; on the 9th of March they started again westward; and on the 16th of March sighted the southern point of Samar Island in the archipelago, since 1542 called the Philippines, but named by Magellan, its first discoverer, "St. John St Louis." On the 27th of March the fleet arrived at Cebu, south-west of Samar, in the heart of the Philippines; here Magellan contracted a close friendship and alliance with the treacherous native sovereign, who professed Christianity the better to please and utilize his Catholic friends. Undertaking an expedition to conquer, for the Catholic faith and the king of Cebu, the neighbouring island of Mactan, Magellan was killed there in a fight with the islanders (April 27, 1521). The king of Cebu after this got into his power several of the leading personages of the squadron, including Juan Serrano, one of the two admirals elected to replace Magellan, and murdered them. The survivors, burning one of the three remaining vessels, left the Philippines, and made their way to the Moluccas (Nov. 6), visiting Borneo on the way (July 9-Sept. 27, 1521). At Tidor a heavy cargo of cloves was taken in; the "Trinidad," becoming leaky, stayed behind with her crew; and the "Vittoria," under Juan Sebastian del Cano, proceeded to Europe alone (Dec. 21, 1521). To double the Cape of Good Hope the "Vittoria" reached between 40° and 41° S. (April 7-16, 1522) and suffered from contrary winds, heavy seas, scurvy and starvation, in the Cape Verde Islands (July 9-15, 1522) thirteen of the crew were detained prisoners by the Portuguese. Only thirty-one men returned with del Cano to Seville in the first vessel that had ever made the tour of the earth. Though Magellan had not quite reached the Spice Islands when he fell at Mactan, his task had then been accomplished. He had already reached and passed the longitude of the Moluccas, where he had already been; the way home from the Philippines by the Indian Ocean and the Cape of Good Hope was perfectly known to the Portuguese, himself included. Magellan's name has never received its due recognition in
general history. It ranks with those of Columbus, Marco Polo, and Henry the Navigator. The circumnavigation of the globe is as great an event as the discovery of America. Magellan achieved what Columbus planned—the linking of west Europe with east Asia by direct transit over the western ocean. Had America not intervened, the project of 1492 must have failed; by 1510 European pioneers had formed a more adequate notion of the task and its magnitude.

Magellan clouded the Magellanic clouds (not first observed by him), and Magellan’s Land—a name long given to Patagonia and that hypothetical southern continent of which Tierra del Fuego was considered only a portion, and now once bestowed by Chile on her territory in the extreme south—preserve the memory of the first circumnavigator. The largest of the oceans has also kept the flattering name given to it by the man who first crossed it.

No record of his exploits was left by Magellan himself; and contemporary accounts are less detailed and consistent than could be wished. The best is that of Antonio Pigafetta, a volunteer in the fleet. It is printed in Ramusio, and exists in four early MS. copies, one in Italian and three in French. The latter was perhaps the original. This work, which was addressed by Pigafetta as a knight of Rhodes, to the Frenchman Villiers de l’Isle-Adam, grand master of the order of the Hospital of St. John. But this view is rejected by J. A. Robertson (see below), who believes the Ambrosian MS. is the ultimate copy, and that the text received in the intorno al mondo, otherwise the Navigation et descouvrement de la Terre subpire la faite by moi Anthoyne Pigafetta, Vincenzen, published probably about the year 1492 (in France) by W. Villers, Pigafetta obtained leave to print his book in Venice. Of the three French MSS., two are in the Bibliothèque Nationale, Paris (6550 and 24,224), the latter is wrongly supposed by Thomassy, followed by Lord Stanley of Alderley, to have been the copy presented by Pigafetta to the regent of France, Marie Louise of Savoy, mother of Francis I. The third French MS., often called the MS. of Nantes, first noticed by Thomassy in 1885, and bought by Prince Pirot, was sold at Libri’s sale, and became MS. Philadelphia 16,405. The Italian MS. is in the Ambrosian library at Milan. From this Carlo Amoretti, prefect of the Ambrosiana, published his Italian edition of the work in French of 1524, and his Italian translation of that, himself, was issued by H. J. Jansen, 1601. An English version of Pigafetta was made by Richard Eden in his Decades of the New World (London, 1555). The earliest printed edition, apparently a summary of the Italian MS., was issued in French by Simon de Colines of Paris about 1528. The earliest Italian edition is of 1534 (or 1536).

Other authorities are: (1) The narrative of an unknown Portuguese in Ramusio’s Navigationi et viaggi; (2) the Derrotero or Log-Book in the Seville Archives, supposed to be the work of Francisco Albo, contra maestre of Magellan’s flagship, the “Trinidad”; this consists mainly of nautical observations; (3) the narrative of the seamen written in the Portuguese shiplog in vol. iv. of the Colleco del noticijos of the Lisbon Academey (4) various informaciones and other papers in the Seville Archives, especially a manuscript of the last report of Pigafetta, under-secretary to Charles V., to the cardinal of Salzburg; (5) the references in Correa and Herrera, often based on good information, and adding points of interest to other accounts. Of these (1)—(5), and an instance of (6) are translated in the Hakluyt Society’s volume. Magellan’s two wills (executed at Belem on the 17th of December, 1504, on the eve of his departure with Almeida, (6) executed at Seville on the 24th of August, 1515), just before starting on his voyage round the world, are both of some value for his life.

See also Lord Stanley of Alderley. The First Voyage round the World by Ferdinand Magellan, translated from ... Pigafetta, &c., Hakluyt Society (London, 1874); Diego de Barros Arana, vida e viagens de Fernao de Magalhães, a trans. of the Spanish life by Fernando de Magalhães Villiers de l’Isle-Adam (London, 1884); F. H. H. Guillemaud. Life of Magellan (London, 1890): Magellan ... the original text of the Ambrosian MS. of (Pigafetta), with English translation, notes, bibliography, &c., by J. A. Robertson (Cleveland, U.S.A., 1900). Before the appearance of this work, the whole edition of Pigafetta had been in vol. iii. part 5 of the Raccolta di documenti et studi pubblicati nella r. commissione colombiana, edited by Andrea da Mosto (Rome, Ministry of Public Instruction, 1894).

(Rev. R. B.)

**MAGELLANIC CLOUDS** (named after Ferdinand Magellan), two cloud-like conceptions of stars in the southern constellation of Mensa about 69° S. Dec. and between 5° and 5° 40'. R. in RA. The name was first given to these remarkable stars as regards spectra and physical constitution to the stars of the Milky Way, though entirely detached from that object.

**MAGENTA**, a town of Lombardy, Italy, in the province of Milan, 16 m. by rail W. of Milan city, 364 ft. above sea-level situated in the midst of rice-fields. Pop. (1901), 8012. It manufactures silks and matches, and is famous for the battle (1859) in which the allied French and Piedmontese defeated the Austrians (see Italian Wars). A memorial chapel and a monument were erected on the battle-field in 1862. A crimson-purple aniline dye, discovered about the time of the battle, was given from it the name of “magenta.”

**MAGGIORE, LAKE OF** (Lago Maggiore of the Romans; Fr. Lac Majeur; Ger. Langensee), the most extensive of the lakes that extend along the foot of the Alps in Lombardy, N. Italy. Its area is about 83 sq. m., its length 37 m., its greatest width 53 m., and its greatest depth 1195 ft., while its surface is 464 ft. above sea-level. It is mainly formed by the Ticino (Tessin) River, flowing at the north and out at the south end, on its way to join the Po, but on the west the lake receives a very important tributary, the Toce or Tosa River, which flows through the Val d’Ossola from the mountains around the Simplon Pass. Other important affluents are the Maggia (N.W.) and the Tresa (E.). The upper end of the lake (about 16 sq. m.) is in the Swiss canton of Ticino (Tessin). Locarno, at the northern or Swiss end, is 14 m. by rail S.W. of Bellinzona on the St Gotthard line. There is a railway along the southeastern shore, from Magadino (10 m. S.W. of Bellinzona) to Sesto Calende (261 m.), at the southern end of the lake and 20 m. by rail from Novara. The east shore of the lake is reached at Luino by a steam tramway from Ponte Tresa on the lake of Lugano (8 m.), while the direct Simplon line runs along the west shore of the lake for 15 m. from near Pallanza past Baveno and Stresa to Arona, which is 23 m. by rail from Novara. The east shore are Luino (Ital. Luvino) and Laveno. On the west shore are (reckoning from N. to S.) Cannobio, Pallanza, Baveno, Stresa and Arona. Opposite (S.E.) Baveno are the famous Borromeo Islands, on the largest of which (Isola Bella) are very remarkable gardens (formed about 1617), wherein many tropical plants flourish abundantly, while south-west of Baveno rises the glorious view-point of the Monte Mottarone (4892 ft.) between Lago Maggiore and the northern end of the Lake of Orta. In the morning the tramontana wind blows from the north down the lake, while in the afternoon the tramarea, blowing from the south, prevails. The first steamer was placed on the lake in 1826. (W. A. C. B.)

**MAGIC** (i.e. “art magic”; Lat. ars magica), the general term for the practice and power of wonder-working, as depending on the employment of supposed supernatural agencies. Etymologically the Gr. μάγεια meant the science and religion of the magi, or priests of Zoroaster, as known among the Greeks; in this sense it was opposed to θυσία (nicromancy) and ἐνδοκρατία (the use of drugs); but this distinction was not universally recognized, and ψεύδημα is often used as the equivalent of μάγεια. There is no general agreement as to the proper definition of “magic,” which depends on the view taken of “religion.”

I.—NATURE OF MAGIC

**Theories of Magic.**—Existing theories of magic may be classified as objective or subjective. The objective school regards magic as a thing by itself, entirely distinct from religion, and as having certain characteristics, and traceable to a definite psychological origin. Magic, on this view, is a system of savage science based on imaginary laws supposed to operate with the regularity ascribed to natural laws by the science of to-day. If practices prima facie magical form part of the recognized ritual of religion, it is because the older ideas have persisted and at most assumed a veneer of religion. For the subjective school, on the other hand, only those rites are magical which their practitioners qualify with the name of magic; there is no inherent quality which makes a rite magical; practices based on a belief in the law of sympathy may be religious as well as magical; rites may pass from the category of religion to that of magic when public recognition is withdrawn from them.

1 For what is often called “magic,” but is really trick-performance, see Conjuring.
a. For E. B. Tylor the distinguishing characteristic of magic is its unreality; it is a confused mass of beliefs and practices, and these beliefs and practices are not associated with any cause and effect. Under the general head of magic he distinguishes: (i) a spiritual and (ii) a non-spiritual element. (i) The former is made up of the magic beliefs of people who are in a highly unsympathetic mood. It includes the delusions of the dead, demons or gods; hence, in Tylor’s view, this form of magic is merely an inferior branch of religion. (ii) The non-spiritual part, but for which the category of magic would be unnecessary, is made up of those cases where magic is merely a misapplication of the law of sympathy, it is imperfectly reasoned, the mistaking of an ideal connexion for a real one. When the American Indian medicine man draws the picture of a deer on a piece of bark and considers that it will be real, then next day, he mistakes a connexion which exists only in the mind of the sorcerer for a real bond independent of the human mind.

b. The origin of magic is based on the law of sympathy, i.e. the assumption that things act on one another at a distance through a secret link, due either to the fact that there is some similarity between them or to the fact that they have at one time been in contact, or that one has formed part of the other. These two branches of “sympathetic magic” Frazer denotes “homoeopathic magic" and “contagious magic." Homoeopathic or imitative (mimetic) magic may be practised by itself, but contagious magic generally involves the application of the imitative principle.

(c) One of the most famous applications of the former is the belief that an enemy may be destroyed or injured by destroying or injuring an inanimate object resembling him, without any obstacle there being in the way of the magician. This included such beliefs as that which causes the peasant to anoint the weapon with which he has been injured, which, according to Frazer, is the same as that which causes a man to touch a dog in order to feel with the blood in the body. (ii) Implicitly Frazer seems to distinguish a third kind of magic; the “rain-charm,” he says, “operates partly or wholly through the dead . . . in Halmahera the practice of throwing stones on a grave, in order that the ghost may fall into a passion and avenge the disturbance, as he imagines, by sending heavy rain.” Here there is no assumption of an invisible cause of nature set in motion by magical rites; save that it is coercive and not propitiatory, the practice does not differ from ordinary religious rites.

In his theory of the origin of magic Frazer follows the associationist school. But, as R. R. Marett has pointed out in a criticism of the associationist position, it is proved beyond question that even in the individual mind association by similarity, contiguity or contrast, is but the passive condition, the important element being interest and attention. Frazer assumes that magic has everywhere preceded religion; man tried to control nature by using what he conceived to be immutable laws; failing in this he came to believe in the existence of higher powers whom he could propitiate but not coerce; with this transformation religion appeared on the scene; the priest supplanted the magician, at least in part, and the first blows were struck in the perennial warfare of magic and religion. Frazer recognizes, however, that magic and religion are not understood as such, being deeply blended in all periods of human history, and that even in the threefold division of the work, the corresponding positions of sociology, psychology and anthropology have been in historical times, frequently intermingled; it should be noted that for him religion means propitiation and that he does not recognize the existence of anything beyond magic among the aborigines of Australia. His theory is based on the assumption that the whole body of beliefs and rites recognized as magical, among which are many wherein spirits figure. Frazer’s position appears to be that magic is part of the primitive religion, and that magic is a stage toward a definition of magic. It may be perfectly true that the idea of magic has been progressively extended; but belief in transformation is also for Dr Frazer magical; this belief is certainly primitive; yet symphony will not explain it, as it should if Frazer’s theory is correct.

c. L. Mairilized distinguished three classes of magic: (i) the magic of the word or act; (ii) the magic of the human being, individual of rite or formula, &c.; (iii) the magic which demands at once a human being of special powers (or in a special state) and the use of certain forms. (i) Under the first head he included such rites as mimicking the actions of the gods. This is the distinction that is made generally. Some of these rites are conceived to affect the course of nature directly, as by influencing winds or the sun, others do so by way of intermediary objects or persons, who are invested with magical power (mana), which will rule the universe, whose simple words bring rain or sunshine, and whose presence will protect men from thunder or lightning. (ii) Each of these is the attribute of the individual, sometimes it is bound up with the office which he fills. In many cases the magical powers of both men and other objects, animate and inanimate, are put down to the fact that a man is a real one. Hubert and Mauss have made the most complete and systematic study of magic which has yet appeared. They hold that, implicitly at any rate, magic is everywhere distinguished from all other systems of social facts; in order to be magical an act or belief must be common to the whole of a society; the acts which the whole of a group does not regard as efficacious are not, for this school of thought, magical; the actions merely unaided by magical power cause and effect. Under the general head of magic he distinguishes: (i) a spiritual and (ii) a non-spiritual element. (i) The former is made up of the magic beliefs of people who are in a highly unsympathetic mood. It includes the delusions of the dead, demons or gods; hence, in Tylor’s view, this form of magic is merely an inferior branch of religion. (ii) The non-spiritual part, but for which the category of magic would be unnecessary, is made up of those cases where magic is merely a misapplication of the law of sympathy, it is imperfectly reasoned, the mistaking of an ideal connexion for a real one. When the American Indian medicine man draws the picture of a deer on a piece of bark and considers that it will be real, then next day, he mistakes a connexion which exists only in the mind of the sorcerer for a real bond independent of the human mind.

d. Hubert and Mauss have made the most complete and systematic study of magic which has yet appeared. They hold that, implicitly at any rate, magic is everywhere distinguished from all other systems of social facts; in order to be magical an act or belief must be common to the whole of a society; the acts which the whole of a group does not regard as efficacious are not, for this school of thought, magical; the actions merely unaided by magical power cause and effect. Under the general head of magic he distinguishes: (i) a spiritual and (ii) a non-spiritual element. (i) The former is made up of the magic beliefs of people who are in a highly unsympathetic mood. It includes the delusions of the dead, demons or gods; hence, in Tylor’s view, this form of magic is merely an inferior branch of religion. (ii) The non-spiritual part, but for which the category of magic would be unnecessary, is made up of those cases where magic is merely a misapplication of the law of sympathy, it is imperfectly reasoned, the mistaking of an ideal connexion for a real one. When the American Indian medicine man draws the picture of a deer on a piece of bark and considers that it will be real, then next day, he mistakes a connexion which exists only in the mind of the sorcerer for a real bond independent of the human mind.

e. For A. Lehmann magic is the practice of superstitions, and his explanation of magic is purely psychological. Relying mainly on modern spiritualism for his examples, he traces magic back to illusions, prejudices and false precepts due to strained attention. This is ultimately also the view of Hubert and Mauss, who hold that “at the root of magic are states of consciousness which generate illusions; and that these states are not individual but collective and arise from the amalgamation of the ideas of a given person with those current in the society of which he forms a part.” The reunion of a group supplies a soil in which illusions flourish readily, and it is important to note that in magic and religion attention is above all necessary to the success of a rite, whereas the frequent rule imposing silence; but the concentration of attention is precisely calculated to favour illusions; it is indeed the ordinary condition of successful hypnotism; even in civilized countries collective hallucinations without verbal signs are common.

f. R. R. Maretet regards religion and magic as two forms of a social phenomenon originally one and indivisible; primitive man had an institution which dealt with the supernatural, and in this institution the terms of the germ of the later varieties of magic and religion, as we know them, are already differentiated; magic and religion differ in receptivity; religion is always the higher, the accepted cult; but between what is definitely religious and what is definitely magic lies a large area of independent elements, such as “white-magic,” which do not attain to the public recognition of religion, nor suffer the condemnation meted out to the indisputably magical. For primitive man the abnormal was the supernatural, and the supernatural was the supernatural, the object of fear; this is especially evident when we consider the case of taboo; it may be regarded as a public scare for which no particular belief is responsible, which becomes traditional along many constant lines, growing as it goes. Mana was attributed to taboo objects, among which were men in any way abnormal, whether as geniuses or idiots; and such men were expected to exercise their powers. This is the good mana; but there is also bad mana, which is exercised by a professional medicine man; man originally argued from cause to effect and not vice versa. Priest and magician were originally one; but the former, learning humility in the face of greater than his own, discarded the power of prayer and invoked in his place the more beneficial power.

Definition of Magic—To arrive at a definition of magic we may either follow the a priori road mapped out by Frazer and deny to recognize the distinction actually drawn by various societies between magical and religious practices; or we may ask what magic and corresponding terms actually connote. Frazer’s method ignores the fact that magic, like religion, is an institution, i.e. a product of society, not of any single individual; there is no more reason to suppose that a child reared in isolation would develop any kind of magical practices than that it would invent for itself a religion; but if this is the case,
the associationist account of magic cannot be true. It is therefore by an analysis of actually existing practices that we must define and limit the term magic. There is, however, a serious difficulty in the way of determining the attitude of non-European peoples towards religio-magical practices; general terms are things of slow growth; it is therefore prima facie improbable that people in the lower stages of culture will have anything corresponding to our terms "religion" and "magic"; moreover, if we are right in assuming the fundamental unity of the two, it is by no means certain that they have even the consciousness of any distinction. Even when this consciousness is present, it by no means follows that the whole of the field is mapped out according to our categories; there will be a large indeterminate area which is neither magical nor religious. This suggests that the consciousness of the educated Occidental, for which the spheres of magic and religion in civilized society are sharply defined and contrasted, should be the ultimate arbiter; but here again we are confronted by a difficulty, for, to the educated man, the characteristic of magic is its unreality, and this does not help us to distinguish primitive magic and religion.

We must, it appears, determine the relation of magic to religion by an analysis of the conceptions of those who believe in both; but in so doing we must consider that, like all other institutions, magic has a history. Even if we go back to the 6th century and take the view of magic then held by the average European, it is still a complex idea. When we ask what the most primitive races now on the earth regard as magic, we are applying to their ideas a touchstone made for a very different age and culture; as well might we ask what their theory of knowledge is. If, however, we reverse the process and ask what elements of primitive institutions correspond most nearly to later conceptions of magic, we can at once say that the forbidden and private arts are the prototypes of the magic of later times. Magic is therefore the practice of maleficient arts which involve the use of religio-magical power, with perhaps a secondary idea of the use of private arts, which are to benefit, not the community as a whole, but a single individual. Religion in the lower stages of culture is essentially the tribal creed which all practise and in which all believe; if therefore an individual has a cult of his own, even if otherwise indistinguishable from a public cult, it is for this very reason on a lower plane, and probably corresponds in a degree to what is later regarded as magic. But our information as to the attitude of the uncivilized towards magico-religious rites in general is seldom sufficiently clear; our terminology is influenced by the prepossession of alien observers whose accounts cannot be assumed to correspond to a native view of the case.

Magico-religious Rites.—The mere fact that we cannot draw an exact line between magic and religion suggests that they may have some fundamental-feature in common. Both terms have greatly changed their connotation in the course of their existence; religio seems to have meant originally καρακάβαος (magical spell), and Pliny says that μαγεῖα is a deceptive art compounded of medicine, religion and astrology. Among the Greeks, on the other hand, μαγεῖα occupied a respectable position. More important is the fact that taboo (q.v.) is both religious and magical. There is a universal tendency to regard as magical the religions of alien races, as well as national religions which have been superseded; Leland tells us that witchcraft in Italy is known as la vecchia religione. An examination of the ideas of primitive peoples shows that there is a widely found notion of a power which manifests itself both in religion and magic. Observers have often been content to describe ceremonies without attempting to penetrate to the fundamental ideas which underlie them; this is particularly the case with magic, and only recently have anthropologists realized that in many primitive societies exists a fairly well-defined idea of magico-religious power, to which the generic name of mana, from the Melanesian word, has been given.

a. Mana in Melanesia is a force, a being, an action, a quality, or a state; it is transmissible and contagious, and is hence associated with taboo; it may be regarded as material and seen in the form of images or heard; it is the power which is inherent in certain spirits, among which are included some of the dead as are denominated tunuas; it is also considered to be a force which is inherent in a stone which causes the yams to grow, but it is a spiritual force and does not act mechanically; it is the power of the magician and of the religion of magic forms in which mana may be a variety of mana, but probably the underlying idea is essentially one though it does not follow that the Melanesians have arrived at the consciousness of this unity. Hubert and Mauss go even further and regard mana as the fundamental primitive form of power, defined not to their other qualities, one which supplements without destroying their mechanical action.

b. Other ideas are also found in other areas. (I) The Central and South American Indians have a word Kramad (bow), which means sacred or magical; in Indo-China the Bahnars use the word deng; in Madagascar hasina seems to embody in part the same notion. (ii) In Africa the idea of mana is widespread; perhaps those nearest to the notion of mana on the Congo nki is a similar but more restricted sense. (iii) In Australia there are two, or perhaps three, kinds of magical power distinguished by the aborigines; all over the continent we find the maleficient power, koolya in West Australia, arungunghilka in the central tribes, koochie in New South Wales; the central tribes have certain objects termed charingsa, to which magical power (which we may term charingsa) is attributed; the power of magicians is held to reside in certain stones, called atongara, and in this we must, provisionally at any rate, see a third kind of magical power: charingsa is benignant and seems to originate in the things which are ; the magical and the mythical are closely connected; the magical idea is generated, created by means of incantations or acquired by contact with certain objects; the power of the magicians seems to proceed and to be inherited from their ancestors; the objects most commonly referred to are widely found; the orenda of the Hurons has been elaborately described by J. N. B. Hewitt; everything in nature, and particularly all animate objects, have their orenda; so have gods and spirits; and the primary phenomena are the product of the orenda of their spirits. In the Congo, the orenda is distinct from the things to which it is attached; the cry of birds, the rustle of the trees, the soughing of the wind, are expressions of orenda; the orenda of the magician is orenda, so are the prayer and the spell, and in fact all rites; orenda is above all the power of the medicine man. Among the Algonquins we find the word manitou, among the Sioux wakanaha, mahwena, &c., among the Shoshones bana, which is the root of which is bana; in the Sioux language. In Central America, according to Hubert and Mauss, nautal or nagual is the corresponding term. (iv) Traces of similar ideas may be found in more advanced nations; the Hindu brahman is identified by Hubert and Mauss as the correlative of mana; in Greece gea is possibly the echo of a similar idea; but we are yet far from having adequately fathomed the dynamical theories of pre-scientific days.

Origin of Magic.—The associationist theory of magic sets out with the assumption that primitive man began with general conceptions; he started with certain means at his disposal—the law of sympathy—by which he could, in his own belief, influence the outer world. But it is more probable that he argued from common instances and arrived little by little at abstract ideas of magical power.

a. Death and disease are universally regarded by uncivilized peoples as due to so-called "magic," i.e. to non-natural causes. Primitive man was familiar with the wounds and bruises caused by physical means; he would naturally attribute any pain not so caused to the operation of analogous but invisible weapons, and eventually attempt to discover how he himself could apply on his own behalf the forces thus used against him. Similarly he may have asked himself what causes were to be attributed the superiority of one man over another; he may have decided the problem by referring it to the superior power of the one, and then inquired in what way this power could in individual instances be increased. In fact we may view this more nearly as an explanation of existing power, and then by reference to the superior power of the one who has it, he is supposed to guide the supernormal for his own benefit, direct or indirect.

b. Ritual, however (the primitive magico-religious psalm), is essentially a procedure as well as an apprehension. The man of the dead of the corpse may well have been an early development; this dread, become traditional, with accretions of various sorts, crystallized into taboo, the magico-religious prohibition. The notion of the unclean, and the dread that has arisen from it, suggests that psychological abnormalities are present among savage races in very different degrees; but if they were developed at an early stage in human history they must have been segregated from the rest of mankind, for they might exploit them for the collective advantage. But it by no means follows that beneficent rites were originally regarded as magical; they were thought simply to be beneficent, and their secondary use of magic or its correlatives in the lower stages of culture are thus far undetermined.

c. Magic as it represents itself to the Occidental mind of the present day, and perhaps to the great part of the inhabitants of the world.
MAGIC

II.—LAWS AND RITUAL OF MAGIC

The practice of magic involves the belief in the operation of certain laws, and demands certain conditions. The number of positive rites is not unlimited; a certain rite tends to become stable and is finally used for all sorts of purposes; and each magician tends to specialize in this respect. Just as there are well-marked schools of magic, and the rain-maker is not the same as the fetish-man, so within the school there are various groups, which are not by the purposes at which they aim nor by the powers they claim to the works or persons for which they have been created. Chief among the laws lying at the base of magical practice is that of sympathy.

Sympathy.—That the law of sympathy is an essential element of magic is admitted equally by the associationist school and by its critics. Under the head of sympathy are embraced the laws of contiguity or contagion, of similarity or homoeopathy, and of contrariety or antipathy.

a. In its simplest form the law of contiguity asserts that whatever has once formed part of a body continues to form part of it or to have a vital or magnetic relation to it, or for instance, possession for the parings of a person’s nails, or the clipping of his hair, and by working magic upon them, it is held to be possible to produce on the human body some effects which are not directly produced on the object of the magical rite. As is clear by the well-known case of the “life index,” the current of magical power may pass in either direction; if the life of a man is supposed to be bound up with the life of the tree, the tree reacts upon him, and it is equally believed that the death of the man will not fail to be manifest by the state of the tree. In particular this sympathetic relation is well shown in the case of wizards among the animal familiars; it is then known by the name of “repercussion.”

b. The law of antipathy, which indicates the parts of the body that contagious magic can be worked; anything which has been in contact with the body, such as clothes, anything which has been in part assimilated by the body, such as the remains of food, and even representations of the body or of parts of it such as footprints, &c., may be used as objects of magical rites, in order to transmit to the human body some influence, maleficient or otherwise.

c. The law of homoeopathy takes two forms: the possession of the parings of a person’s nails, or the clipping of his hair, and by working magic upon them, it is held to be possible to produce an effect on the human body which is not directly produced on the object of the magical rite. As is clear by the well-known case of the “life index,” the current of magical power may pass in either direction; if the life of a man is supposed to be bound up with the life of the tree, the tree reacts upon him, and it is equally believed that the death of the man will not fail to be manifest by the state of the tree. In particular this sympathetic relation is well shown in the case of wizards among the animal familiars; it is then known by the name of “repercussion.”

The discovery of these complicated ideas only shows to show how far the present-day peoples in the lower stages of culture have travelled from the primitive man who knew neither magic nor religion. But it is perhaps less in respect of abstract ideas than by its concrete investigations into properties, experiment and otherwise that magic has been the forerunner of science.

Divination.—Magic is an attempt to influence the course of events, divination (a.v.) to foresee them; but divination is frequently regarded as magical. It is certain that a large part of divination is religious, and the knowledge is explained as a message from the gods; but necromancy, the practice of discovering things affecting the dead, is in many respects essentially magical. Perhaps the magical character of divination may be in part explained, when we regard it as a group of practices in many varieties of which animism plays no part; for non-animistic ceremonies tend to be regarded as magical (cf. rain-making). Thus, heteroscopic divination seems to involve the idea of what may be termed a return current of magico-religious force; the event is not influenced, but itself determines the issue of the diviner’s experiment.
by the law of sympathy, without the intervention of any volition, human or otherwise; thus, the crow which carries straw hairs away to weave itself into the structure of its nest is nowhere supposed to be engaged in a magical process; but it is commonly held that the person whose hair is thus used will suffer from head- ache or other maladies; this seems to indicate that the law of sympathy operates mechanically in certain directions, though the belief may also be explained as a secondary growth. In general the operation of these laws is limited in the extreme. For example, the medieval doctrine known as the Law of Signatures asserted that the effects of remedies were correlated to their external form, but it is no longer generally believed, because the bear is a hairy animal. But the transference was held to terminate with the acquisition by the man of this single quality; in some magic books powdered mummy is recommended as a means of prolonging life, but it is simply the age of the remedy which is to benefit the patient; the magician who removes a patient's pains or diseases does not transfer them to himself; the child whose parents eat forbidden foods is held to be affected by their transgression, while they themselves come off unharmed.

The magical effects are limited by exclusive attention and ab- solute constancy; if this is true, then not only is the kind of effect produced but also as to the direction in which it is held to be made.

The Magic of Names.—For primitive peoples the name is as much a part of the person as a limb; consequently the magical use of names is in some of its aspects assimilable to the processes dependent on the law of sympathy. In some cases the name must be withheld from any one who is likely to make a wrong use of it, and in some parts of the world people have secret names which are never used. Elsewhere the name must not be told by the bearer of it, but any other person may communicate it without giving an opening for the magical use of it. Not only human beings but also spirits can be coerced by the use of their names; hence the names of the dead are forbidden, lest the mention of them act as an evocation, unintentional though it be. Even among more advanced nations it has been the practice to conceal the real name of supreme gods; we may probably explain this as due to the fear that an enemy might by the use of them turn the gods away from those to whom they originally belonged. For the same reason ancient Rome had a secret name.

Magical Rites.—The magic of names leads us up to the magic of the spoken word in general. The spell or incantation and the magical formula take up the common acts and are very frequently symbolic or sympathetic in their nature; sometimes they are mere reversals of a religious rite; such is the marching and sleeping of the health as a substitute for the sick; (a) sometimes they are purificatory; and magic has its sacrifices just as much as the religion of nature.

There are many types of oral rites; some of the most curious consist in simply reciting the effect intended to be produced, described as in a symbolic language, especially in the mythology, which is represented as producing a similar effect to the one desired; in other cases the "origin" of the disease or malefactor being recited. Oral rites, which are termed spells or incantations, correspond in many cases to the oral rites of religion; they, like the manual rites, are a heterogeneous mass and hardly lend themselves to classification. Some formulae may be termed sympathetic; it suffices to name the result to be produced in order to produce it; but often an incantation is employed, not to produce a result directly, but to call with the aid of magic, the aid of another, or the assistance of the deity will. The latter is the more frequent. It differs from the magical formula in any day's life; it may be a survival of archaic forms or may be a special creation for magical purposes. In many languages the word used to express the idea of magic means an act, a deed; and it may be assumed that few if any magical ceremonies consist of formulae only; on the other hand, it is certain that no manual act in magic stands alone, even without oral rite; if there is no spoken formula, there is no magical operation. It is thus difficult to discover the relative proportions and importance of manual and oral acts. Not only the words but also the tone are of importance in magical rites; in fact, the tone may have a magical importance. Rhythm and repetition are no less necessary in oral than in manual magic.

As preliminaries, more seldom necessary sequences to the central feature of the rite, manual or oral, we usually find a certain number of other magical acts prescriptive of the rite, such as the recitation of a sacrificial ritual. For example, it is laid down at what time of year, at what period of the moon or week, at what hour of the day a rite must be performed; the waxing or waning of the moon must be noted; and certain days must be avoided altogether. Similarly, certain places may be prescribed for the performance of the rite. Often the altar of the god serves magical purposes also; in particular, it is precisely the impure sites which are devoted to magical operations —the cemeteries and the cross roads. The instruments of magic are for the most part of heterogeneous origin; they are either consecrated by religion; sometimes, especially when they belong to the animal or vegetable world, they must be sought at certain seasons, May Day, St George's Day, Midsummer Day, &c. The correct time and his preparation of rite, &c. exit may be marked by similar ceremonies.

Magicians.—Most peoples know the professional worker of magic, or what is regarded as magic. (a) In most if not all societies magic is the province of the old, or in general of the younger persons, for example, a specialist who owes his position to an accident of birth (seven son of a seventh son); to simple inheritance (families of magicians inherited from generation to generation), to the use of charms, to the names of the gods or the spirits of the dead (Malays), showing itself in the phenomena of possession; or to initiation by other magicians. The magic power is sometimes held to depend on the presence—whether it is, his independence—of his animal auxiliary. Concurrent with this theory is the view that the magician must first enter into a trance before the animal makes its appearance, and this makes it a double initiation, one from the world, or from the gods, and the other from the personal individual. In Siberia, for example, they are held to be united by a certain bond of relation; here this is not the case, they are believed, as in Africa at the present day or in medieval Europe, to hold assemblies, so-called witches' Sabbath; in Europe the meetings of heretics seem to be responsible for the prominence of the idea if not for its origin (see Witchcraft). The magician is often regarded as possessed (see Possession) either by an animal or by a human or super-human spirit. The relations of the animal are legible in the nature of the initiation of the magician is regarded as the work of the gods, the magician is for obvious reasons likely to develop into a priest, but as the cults of the lands which have been superseded, the priests of the old cult are for, those who supersede them, one and all magicians; in the medieval church, priests were regarded as especially exposed to the assaults of demons, and elsewhere the magician is a sort of medium; in Siberia, for example, kings of Fire and Water in Cambodia—enjoy a reverence and receive a cult which separates them from the common herd, and assimilates them to priests rather than to magicians. The function of the so-called magician is often said to be beneficent; in Africa the witch-doctor's business is to counteract evil magic; in Australia the magician has to protect his tribe against the assaults of hostile magicians of other tribes; and in Europe "white magic" is the correlative of this beneficent power; but it may be questioned whether the beneficent virtue is really so highly prized.

Talisman and Amulet.—Inanimate objects as well as living beings are credited with stores of magical force; when they are regarded as bringing good, i.e. are positive in their action, they may be termed "talisman"; an amulet are protective or negative in their action, and their function is to magic may serve both purposes. Broadly speaking, the fetish, whose "magical" properties are due to association with a spirit, tends to become an amulet. A magic name, in the end, is magic is originally carried as means of union between him and his manto, is perhaps the prototype of many European charms. In other cases it is some specific quality of the object or animal which is desired; for example, the animal is regarded as a symbol of courage to the wearer; the Lukanins Indians of Vancouver Island rub the ashes of wasps on the faces of their warriors, in order that they may not meet with danger and are held to be saved from the belief that it will make them difficult to kill, the animal being very tenacious of life. Among amulets may be mentioned horns and crescents, eyes or their representations, and grotesque figures, all of which are supposed to be powerful against the Evil Eye (q.v.).
Tylor has shown that the brass objects so often seen on harness were originally amuletic in purpose, and can be traced back to Roman times. It is possible that the burying the enemy by a lock of his hair from the evil eye simply by attracting the glance from the wearer to themselves, but, as a rule, magical power is ascribed to them.

**Evil Magic.**—The object of "black" magic is to inflict injury, disease, or death on an enemy, and the various methods employed illustrate the power of desire and emul- tiveness; the conclusion that magic is not simply a matter of sympathetic rites, but involves a conception of magical force. (a) It has been men- tioned above that making amulets is the function of the body; the Cherokee magic follows its victim till he spits on the ground; collecting the spit mingled with dust on the end of a stick, the magician puts it into a tube made of a poisonous plant together with a handful of spilt wheat and splinters of bone blasted by lightning; the whole is buried with seven yellow stones at the foot of a tree struck by lightning, and a fire is built over the spot; the magician fasts till the ceremony is over. Probably the worms are disturbed with an idea the victim will become "blue" when the charms works; the yellow stones are the emblem of trouble, and lightning-struck trees are reputed powerful in magic. If the charm does not work, the victim survives the critical seven days, and the magician and his employer are themselves in danger, for a charm gone wrong returns upon the head of him who sent it forth. (b) In homeopathic magic the victim is represented by a protruding tumor or swelling. In the homeopathic system, the conjurer makes an image like a corpse, a footstep long. If you want to cause sickness, you pierce the eye and blindness results; or you pierce the palm, and then the image of a magical rite has corresponded, for the totemic prohibition is clearly religious, not magiC.

**Negative Magic.**—There is also a negative side to magic, which, together with ritual prohibitions of a religious nature, is often embraced under the name of taboo (q.v.); this extension of meaning is not justified, for taboo is only concerned with sacred things, and the mark of it is that its violation causes the taboo to be transmitted. All taboos are ritual prohibitions, but all ritual prohibitions are not taboos; they include also (a) interdictions of which the sanction is the wrath of a god; these may be termed religious interdictions; (b) interdictions, the violation of which will automatically cause some undesired magico-religious effect; to these the term negative magic should be restricted, and they might conveniently be called "bans"; they correspond in the main to positive rites and are largely based on the same principles.

(a) Certain prohibitions, such as those imposed on totem kins, seem to occupy an intermediate place; they depend on the sanctity of the totem animal without being taboos in the strict sense; to them may be ascribed the restriction of some cases of paraphernalia and sympathetic relation is held to exist in other cases also. In Madagascar a son may not eat fallen bananas, for the result would be to cause the death of his own father; the sympathy between father and son extends to the sympathetic relation of the father and objects touched or eaten by the son, and, in addition, the fall of the bananas is equated with the death of a human being. Again, the wife of a Malagasy man may not eat onion sticks unless he is present when the onion is cut in two; if she as, he will be killed or wounded. Ownership, too, may create a sympa-thetic relation of this kind, for it is believed in parts of Europe that if a man kills a swallow his cows will give bloody milk. In some cases it is even harder to know how the sympathetic bond is established; some Indians of Brazil always hamstring animals before bringing them home, in the belief that by so doing they make it easier for themselves and their children to run down their enemies, who are then magically deprived of the use of their legs. These are all examples of negative magic with regard to persons, but things may be equally affected; thus in Borneo men who search for camphor avoid washing their hands or feet in a camphor stream or bath, because of the evil influence. If they should touch their faces, they may be changed into a pig at sea, or the names of all who touch them may change, and this change may be fatal. Sometimes the magician into close relation with the werewolf (see Lycanthropy).

**Rain-making.**—In the lower stages of culture rain-making assumes rather the appearance of a religious ceremony, and even in higher stages the magical character is by no means invariably felt. It will, however, be well to notice some of the methods here. (a) Among the Dieri of Central Australia the whole tribe takes part in the ceremony; a hole is dug, and over this a hut is built, large enough for the old men; the women are called to look at it and then retire some five hundred yards. Two wizards have their arms bound behind the shoulder, the old men huddle in the hut, and the principal wizard bleeds the two men selected by cutting them inside the arm below the elbow. When the old men, anxious to save the animal, throw handfuls of down into the air. The blood symbolizes the rain; the down is the clouds. Then two large stones are placed in the place of the hut; these two represent gathering clouds. The women are allowed to approach, and the blood is poured into a tree; other men pound gum-sap and throw it into a water-hole; the ancestral spirits are supposed to see this and to send rain. Then the women wash their faces with their blood, and their tears symbolizes the breaking of the clouds, and the fall of the hut is the rain. If no rain comes they say that another tribe has stopped their power that the Mura-mura (ancestors) are angry with them. (b) Rain-making is common in the Amazon. Sometimes water is poured on a stone; a row of stepping-stones runs into one of the tarns on Snowden, and it is said that water thrown upon the stones as the rain falls into the stone; at other times the images of saints are carried to a river or a fountain in dawns sprinkled with water in the belief that rain will follow; sometimes rain is said to ensue when the water of certain springs is troubled; perhaps the commonest method is to.duck or drench a human figure or puppet, who represents in many instances the vegetation demon. The gipsies of Transylvania celebrate the festival of "Green George" by throwing sand into the river; the rite is performed on St George's Day. (c) One of the more general cases of magic performed. Our knowledge of Assyrian magic, for example, hardly extends beyond the rites of exorcism; the magic of Africa is most inade- quately known, and only in recent years have we well-analysed
MAGIC SQUARE, a square divided into equal squares, like a chess-board, in each of which is placed one of a series of consecutive numbers from 1 up to the square of the number of cells in a side, in such a manner that the sum of the numbers in each row or column and in each diagonal is constant.

From a very early period these squares engaged the attention of mathematicians, especially such as possessed a love of the marvellous, or sought to win for themselves a supertitious reputation. They were then supposed to possess magical properties, and were worn, as in India at the present day, engrafored in metal or stone, as amulets or talismans. According to the old astrologers, relations subsisted between these squares and the planets. In later times such squares ranked only as mathematical curiosities; till at last their mode of construction was systematically investigated. The earliest known writer on the subject was Emanuel Moscopolus, a Greek (4th or 5th century). Bernard Frenicle de Bessy constructed magic squares such that if one or more of the encircling numbers be taken away the remaining central squares are still magical. Subsequently Poignard constructed squares with numbers in arithmetical progression, having the magical summations. The later researches of Phillippe de Hare, recorded in the Mémoires de l'Académie Royale in 1705, are interesting as giving general methods of construction. He has there collected the results of the labours of earlier pioneers; but the subject has now been fully systematized, and extended to cubes.

Two interesting magical arrangements are said to have been given by Benjamin Franklin; these have been termed the "magic square of squares" and the "magic circle of circles." The first (fig. 1) is a square divided into 256 squares, i.e. 16 squares along a side, in which

FIG. 2.

which are placed the numbers from 1 to 256. The chief properties of this square are (1) the sum of the 16 numbers in any row or column is 2050; (2) the sum of the 8 numbers in half of any row or column is 1028; i.e. one half of 2056; (3) the sum of the numbers in two half-diagonals equals 2056; (4) the sum of the four corner numbers of the great square and the four central numbers equals 1028; (5) the sum of the numbers in any 16 cells of the large square which themselves are disposed in a square is 2056. This square has other curious
MAGIC SQUARE

properties. The "magic circle of circles" (fig. 2) consists of eight annular rings and a central circle, each ring being divided into eight cells by radii drawn from the centre; there are therefore 65 cells. The number 12 is placed in the centre, and the consecutive numbers 13 to 75 are placed in the other cells. The properties of this figure include the following: (1) the sum of the eight numbers in any ring together with the central number 12 is 360, the number of degrees in a circle; (2) the sum of the eight numbers in any set of radial cells together with the central number is 360; (3) the sum of the numbers in any four adjoining cells, either annular, radial, or both radial and two annular, together with half the central number, is 180.

Construction of Magic Squares.—A square of 5 (fig. 3) has adjoining it one of the eight equal squares by which any square may be conceived to be surrounded, each of which has two sides resting on adjoining squares, while four have sides resting on the surrounding square, and four meet it only at its four angles. 1, 2, 3 are placed along the path of a knight in chess; 4, along the same path, would fall in a cell of the outer square, and is placed instead in the corresponding cell of the original square; 5 then falls within the square. a, b, c, d are placed diagonally in the square; but e enters the outer square, and is removed thence to the same cell of the square it had left. a, b, c, d, e pursue another regular course; and the diagram shows how that course is recorded in the square they have twice left. Whichever of the eight surrounding squares may be entered, the corresponding cell of the central square is taken instead. The 1, 2, 3, ..., a, b, c, ..., a, b, c, d, e are said to lie in "paths."

Squares whose Roots are Odd.—Figs. 4, 5, and 6 exhibit one of the earliest methods of constructing magic squares. Here the

\[
\begin{array}{ccc}
1 & 4 & 5 \\
4 & 9 & 2 \\
5 & 2 & 7 \\
\end{array}
\]

and subtracting 17; and, vice versa, by adding 17 to each of the latter, and dividing by 2. The diagonal summations of a square, filled as in fig. 17, make zero; and, to obtain the same in the rows and columns, we must assign such values to the p's and q's as satisfy the equations \( p_1 + p_2 + a_1 + a_2 = 0, \) \( p_3 + p_4 + a_3 + a_4 = 0, \) \( p_5 + p_6 - a_1 - a_2 = 0, \) and \( p_7 + p_8 - a_3 - a_4 = 0, \) a solution of which is readily obtained by inspection, as in fig. 18; this leads to the square, fig. 19. When the root is 8, the upper four subsidiary rows may at once be written, as in fig. 20; then, if 65 be added to each, and the sums halved, the square is completed. In such squares as these, the two opposite squares about the same diagonal (except that of 4) may be turned through any number of right angles, in the same direction, without altering the summations.

Nasik Squares.—Squares that have many more summations than in rows, columns and diagonals were investigated by A. H. Frost (Cambridge Math. Jour., 1857), and called Nasik squares, from the town in India where he resided; and he extended the method to cubes, various sections of which have the same singular properties. In order to understand their construction it will be necessary to
consider carefully fig. 21, which shows that, when the root is a prime, and not composite, number, as 7, eight letters a, b, . . . may proceed from any, the same, cell, suppose that marked 6, each letter being repeated in the cells along different paths. These paths are called "normal paths," their number being one more than the root. Observe here that, excepting the cells from which any two letters start, they do not occupy again the same one. Hence, if we have two letters, and if two different cells, from any two different cells along different paths, will appear together in one and only one cell. Hence, if in the cells of one of the n + 1 normal paths, each of the remaining n normal paths will contain one, and only one, of these n letters, if we fill each row with p₁, p₁, . . . p₁, in the same order, commencing from the p₁ in that row, the p₁'s, p₁, p₁'s will lie each in a different normal path. That of the n normal paths will contain one, and only one, of the letters p₁, p₁, . . . p₁, whose sum will be 2np₁. Similarly, if p₂ is placed along any of the normal paths, different from that of the p₁'s, and each row filled as above with the letters q₂, q₂, . . . q₂, the sum of the q₂'s along any normal path different from that of the q₂ will be 2np₂. The n² cells of the square will be found to contain all the combinations of the p₁'s and q₂'s; and if the p₁'s be multiplied by n, the p₁'s made equal to 1, 2, . . . n, and the q₂'s to 1, 2, . . . n, no square can be obtained, and the summations along all the normal paths, except those traversed by the p₁'s and q₂'s, will be the constant 2np₁ + 2np₂.

When the root is an odd composite number, as 9, 15, &c., it will be found that in some paths, differences of the two along which the p₁ and q₂ were placed, instead of having each of the p₁'s and q₂'s, some will be wanting, while some are repeated. Thus, in the case of 9, the triplets, p₁p₁, p₁p₁, p₁p₁, p₁p₁, p₁p₁, and p₁p₁p₁; and p₁p₁p₁, p₁p₁p₁, p₁p₁p₁, p₁p₁p₁, p₁p₁p₁, and p₁p₁p₁p₁ will be obtained, and the summations along all the normal paths, except those traversed by the p₁'s and q₂'s, will be the constant 2np₁ + 2np₂.

But if we make p₁p₁p₁p₁ = 1, 3, 5, 7, 9, 11, 2, and the n₁, n₂, . . . nₙ = 0, 1, 2, 3, 4, 5, 6, 7, 8, 11, 13, 15, 17, 19, 23, 29, and 25, every p₁p₁p₁p₁ will equal 2np₁ + 2np₂ respectively. If now the q₂'s are multiplied by 9, and added to the p₁'s in their several cells, we shall have a Nasik square, with a constant summation along eight of its normal paths.

The numbers in the nory scale; that in the centre is the middle one of 1 to 9, and the sum of pairs of numbers equal to 2np₁ + 2np₂. The sum of the numbers in fig. 22 being 2np₁ + 2np₂. The Nasik square of fig. 15 is obtained.

When the root is a multiple of 4, the same process gives us, for the square of 4, fig. 23. Here the columns give 2p₄, but alternately 2p₄, 2p₄, and 2p₄, 2p₄; and the rows give 2p₄, but alternately 2p₄, 2p₄, and 2p₄, 2p₄; the diagonals giving 2p₄ and 2p₄, p₄p₄, p₄p₄, p₄p₄, and p₄p₄p₄, be 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11.

Nasik Cubes.—A Nasik cube is composed of n² small equal cubes, here called cublets, in the centres of which the natural numbers from 1 to n³ are placed so that every section of the cube by parallel planes to its faces shall contain one of each of a Nasik square; also sections by planes perpendicular to a face, and passing through the cublet centres of any path of Nasik summation in that face. Fig. 25 shows by dots the way in which these cublets are constructed.

A dot is here placed on three faces of a cublet at the corner, showing that this cublet belongs to each of the faces AOB, BOC, COA, of the cube. Dots are placed on the cublets of some path of AOB (here the knight's path), beginning from O, also on the cublets of a knight's path in BOC. Dots are now placed in the cublets of similar paths to that on BOC in the other six sections parallel to BOC, starting from their dots in AOB. Forty-nine of the three hundred and forty-six cublets will now contain a dot; and it will be observed that the dots in sections perpendicular to BO have arranged themselves in similar paths.

In this manner, p₁, q₁, r₁, being placed in the corner cublet, O, these letters are severally placed in the cublets of three different paths of AOB, BOC, and COA, in each of which similar paths in the seven sections perpendicular to AO, starting from the letters' position in AOB. Next, p₁, q₁, r₁, p₁, q₁, r₁, p₁, q₁, r₁, are placed in the other cublets of the edge AOB, and dispersed in the same manner as p₁, q₁, r₁. Every cublet will then be found to contain a different combination of the p₁, q₁, r₁'s. If therefore the p₁, q₁, r₁'s are made equal to 1, 2, . . . 7, and the q₁, r₁'s multiplied by 7, and the r₁'s by 49, and adding these to the p₁'s in their several cells, we shall have a Nasik cube, with a constant summation along eight of the normal paths. The numbers in the nory scale; that in the centre is the middle one of 1 to 49, and the sum of pairs of numbers equal to 2np₁ + 2np₂ + 2np₃. The sum of the numbers in fig. 24 being 2np₁ + 2np₂ + 2np₃. The Nasik cube of fig. 24 is obtained.

The numbers in fig. 22 being 2np₁ + 2np₂ + 2np₃. The Nasik cube of fig. 15 is obtained.

When the root is a multiple of 4, the same process gives us, for the square of 4, fig. 23. Here the columns give 2p₄, but alternately 2p₄, 2p₄, and 2p₄, 2p₄; and the rows give 2p₄, but alternately 2p₄, 2p₄, and 2p₄, 2p₄; the diagonals giving 2p₄ and 2p₄, p₄p₄, p₄p₄, p₄p₄, and p₄p₄p₄, be 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11.

Nasik Cubes.—A Nasik cube is composed of n³ small equal cubes, here called cublets, in the centres of which the natural numbers from 1 to n³ are placed so that every section of the cube by parallel planes to its faces shall contain one of each of a Nasik square; also sections by planes perpendicular to a face, and passing through the cublet centres of any path of Nasik summation in that face. Fig. 25 shows by dots the way in which these cublets are constructed.
cubes might be filled by the numbers from 1 to \( p^2 \), and so on, ad infinitum. When the root is an odd index, composite numbers do not result in equal values of the sections. Magister W.W.R. in (C.C.)

Among the many ingenious squares given by various writers, this article may justly close with two by L. Euler, in the Histoire de l'Academie Royale des Sciences (Berlin, 1795). In fig. 27 the squares of numbers were knighted with an odd square in such a manner that the sum of pairs of numbers opposite to and equidistant from the middle figure is double. In fig. 28 the knight returns to a starting cell in a square of 6, and that of the numbers in the pairs of numbers opposite to and equidistant from the middle point is 18.

A model consisting of seven Nasik cubes, completed by A. H. Frost, is shown in fig. 29. The centres of the cubes are placed at equal distances in a straight line, the similar faces looking in the same way in a plane parallel to that line. Each of the cubes has seven Nasik numbers so arranged that each of the seven numbers in the septenary scale are fixed, and behind each, on the other side, its value in the common scale. 1201, the middle number from 1 to \( 7^2 \), occupies the central cubelet of the middle cube. Besides each cube having separately the same Nasical summation, this is also obtained by adding the numbers in any seven similarly situated cubelets, one in each cube. Also, the sum of all pairs of numbers, in a straight line, through the central cube of the system and right round, is 1201.

(A. H. F.)

Fennell's Magic Ring.—It has been noticed that the numbers of magic squares, which is the extension by repeating the rows and columns of \( n \) numbers so as to form a square of \( 2n-1 \) sides yields \( n^2 \) magic squares of \( n \) sides, are arranged as if they were all inscribed round a cylinder and also all inscribed on another cylinder at right angles to the first. C. A. M. Fennell explains this apparent anomaly by describing such magic squares as Mercator's projections, so to say, of "magic rings."

The surface of these magic rings is symmetrically divided into \( n^2 \) quadrangular compartments or cells by \( n \) equidistant zonal circles parallel to the circular axis of the ring and by \( n \) transverse zonal circles which divide each of the \( n^2 \) zonal areas between any two neighbouring zonal circles into \( n^2 \) equal quadrangular cells, while the zonal circles divide each of the \( n^2 \) cells into \( n^2 \) equal quadrangular cells. The diagonals of the cells which follow each other passing once only through each zone and section, form similar and equal closed curves passing once round the circular axis of the ring and once round the centre of the ring. The position of each number is regarded as the intersection of two diagonals of its cell. The numbers are most easily seen if the smallest circle on the surface of the ring, which circles is considered as a cylinder, be one of the sections of the ring.

The appearances of magic rings is the sum of the numbers of the cells whose diagonals form any one of the \( 2n \) diagonal curves add up to \( 3n^2 + 1 \) with or without the number of the middle of the number of the cell in each zone and each transverse section. But if \( n \) be 3 or a multiple of 3, only from 2 to \( 9 \) of the diagonal curves carry the sum in question, so that the magic rings are imperfect; and any set of numbers which can be formed of the perfect magic ring, which make an imperfect magic ring, also make an imperfect magic ring, e.g. the set 1 to 16 if the numbers 1, 6, 11 lie thus on a diagonal curve instead of in the order 1, 6, 11. From a perfect magic ring gives the function of an indefinite extension all directions of each of the \( n^2 \) magic squares.

See F. E. A. Lucas, Recrétations mathématiques (1863-1893); W. W. R. Ball, Mathematical recreations (1892); W. E. M. G. Ahrens, Mathematische Unterhaltungs- und Spiele (1901); H. C. H. Schubert, Mathematische Unterhaltungs- und Spiele (1900). A very detailed work is F. M. Violle, Traité complet des carrés magiques (3 vols., 1837-1838). The theory of "path nakhs" is dealt with in a pamphlet by C. Ranck (1906).

MAGINN, WILLIAM (1793-1842), Irish poet and journalist, was born at Cork on the 10th of July 1793. The son of a schoolmaster, he formed an early acquaintance with the Scotch and Dublin schools, and after his father's death in 1813 succeeded him in the school. In 1819 he began to contribute to the Literary Gazette and to Blackwood's Magazine, writing as "R. T. Scott" and "Morgan O'Doherty." He first made his mark as a parodist and a writer of humorous Latin verse. In 1821 he visited Edinburgh, where he made acquaintance with the Blackwood circle. He is credited with having originated the idea of the Novels abstrusiores, of which some of the most brilliant chapters were his.

connexion with Blackwood lasted, with a short interval, almost to the end of his life. His best story was "Bob Burke's Duel with Ensign Brady." In 1832 he retired London. He was employed by John Murray on the short-lived Representative, and was a short time joint-editor of the Standard. His Miscelleanias were edited (5 vols., New York, 1855-1857) by R. Shelton Mackenzie and (2 vols., London, 1885) by W. R. Montague Johnson.

MAGISTRATE (Lat. magistratus, from magister, master: properly a public office, hence the person holding such an office), in general, one vested with authority to administer the law or one possessing large judicial or executive authority. In this broad sense the word is used in such phrases as "the first magistrate" of a king in a monarchy or "the chief magistrate" of the president of the United States. But it is more generally applied to a minor or subordinate judicial officer, whether unpaid, as justices of the peace, or paid, as stipendiary magistrates. A stipendiary magistrate is appointed in London under the Metropolitan Police Courts Act 1839, in municipal boroughs under the Municipal Corporations Act 1882, and in particular districts under the Stipendiary Magistrates Act 1863 and special acts. In London and municipal boroughs a stipendiary magistrate must be a barrister of at least seven years' standing, while under the Stipendiary Magistrates Act 1863 he may be of five years’ standing. A stipendiary magistrate may do alone all acts authorized to be done by two justices of the peace.

The term magistratus in ancient Rome originally implied the office of magister (master) of the Roman people, but was subsequently applied also to the holder of the office, thus becoming identical in sense with magistrate", and supplanting it in reference to any kind of public office. The fundamental conception of Roman magistracy is tenure of the imperium, the sovereignty which resides with the Roman people, but is by it conferred either upon a single ruler for life, as in the later monarchy, or upon a college of magistrates for a fixed term. In the Republic the Roman theory of magistracy underwent little change when two consuls were substituted for the king; but the subdivision of magisterial powers which characterized the first centuries of the Republic, and resulted in the establishment of twenty annually elected magistrates of the people, implied some modification of this principle of the investiture of magistrates with supreme authority. For when the magistrates were multiplied a distinction was drawn between magistrates with imperium, namely consuls, praetors and occasionally dictators, and the remaining magistrates, who, although exercising independent magisterial authority and in no sense agents of the higher magistrates, were invested merely with an authority (polesias) to assist in the administration of the state. At the same time the actual authority of every magistrate was weakened not by his colleagues" power of veto, but by the power possessed by any magistrate of quashing the act of an inferior, and by the tribune's right of putting his veto on the act of any magistrate except a dictator; and the subdivision of authority, which placed a great deal of business in the hands of young and inexperienced magistrates, further tended to increase the influence of the senate at the expense of the magistracy.

In the developed Roman magistracies were divided into two classes: (a) magistrates of the whole people (populi Romani) and (b) magistrates of the plebs. The former class is again divided into two sections: (a) curule and (b) non-curule, a distinction which rests mainly on dignity rather than on actual power, for it cuts across the division of magistrates according to their tenure or non-tenure of imperium.
MAGLAIBECI

a. The magistrates of the people—also known as patrician magistrates, probably because the older and more important of these magistrates could originally be held only by patриcians (p. x)—were:

(1) Dictator, master of the horse (see Dictator), consul of the most ancient magistrates (curule); and

(2) Quaestors, or the body of minor magistrates known as curv. viri (non-curule). The dictatorship and consulship were as old as the Republic. The first praetor was appointed in 499 B.C., a second in 494 B.C., and the number of years was usually increased for provincial government until Sulla brought it up to eighteen, and under the early principate it grew to sixteen. Censors were first instituted in 443 B.C., and the office continued unchanged until its abolition by Sulla, after which, through restored, it rapidly fell into abeyance. Curule aediles were instituted at the same time as the praetorship, and continued throughout the Republic. The quæstorship was long as old as the curule, but the number rose during the Republic from two to twenty. All these offices except the censorship continued for administrative purposes during the principate, though shorn of all important powers.

The plebeian magistrates had their origin in the secession of the plebs to Rome in 494 B.C. (see ROMES: History). By that year tribunes of the plebs were instituted, and two aediles were given them as subordinate officials, who were afterwards known as plebeian aediles, to distinguish them from the curule magistrates of the same name. Both these offices were abolished during the decemvirate, but were restored in 449 B.C., and survived into the principate.

The powers possessed by all magistrates alike were two—

that of enforcing their enactments (coerctio) by the exercise of any punishment short of capital, and that of veto (intessio) of any act of a colleague or minor magistrate. The right of summoning and presiding over an assembly of the people, or of consuls, and prætors, the tribunes of the plebs. Civil jurisdiction was always a magisterial prerogative at Rome, and criminal jurisdiction also, except in capital cases, the decision of which was vested in the people at least as early as the first year of the Republic, was wielded by magistrates until the establishment of the various quaestiones perpetuae during the last century of the Republic. But in civil cases the magistrate, though controlling the trial and deciding on matters of fact, was quite subordinate to the body of judges who decided the question of fact, and the quaestiones perpetuae, which reduced the magistrate in criminal cases to a mere president of the court, gave him a position inferior to that of the praetor, who tried civil cases, only in so far as the praetor controlled the trial in some degree by his formula, under which the judges decided the question of fact.

Tenure of magistracy was always held to depend upon election by the body whose powers the magistrate wielded. Thus the magistrates of the plebs were elected by the plebeian council, that of the Comitia Curiæ by the Comitia Curiæ. In event of a going magistrate, as presiding officer of the elective assembly, exercised the important right of nominating his successor for election.

MAGLIABECI, ANTONIO DA MARCO (1633-1714), Italian bibliophile, was born at Florence on the 28th of October 1633. He followed the trade of a goldsmith until 1653, when he received the appointment of librarian to the grand-duke of Tuscany, a post for which he had qualified himself by his vast stores of self-acquired learning. He died on the 4th of July 1744, bequeathing his large private library to the grand-duke, who in turn handed it over to the city.

MAGLIANI, AGOSTINO (1824-1891), Italian financier, was a native of Lanzino, near Salerno. He studied at Naples, and a book on the philosophy of law based on Liberal principles won for him a post in the Neapolitan treasury. He entered the Italian Senate in 1871, and had already secured a reputation as a financial expert before his Quæstione monetaria appeared in 1874. In December 1877 he became minister of finance in the reconstructed Depretis ministry, and he subsequently held the same office in three other Liberal cabinets. In his second tenure he carried through (1880) the abolition of the grist tax, to take effect in 1884. Having to face an increased expenditure without offending the Radical electorate by unpopular taxes, he had recourse to unsonorous methods of finance, which seriously embarrassed Italian credit for some years after he finally laid down office in 1888. He died in Rome on the 22nd of February 1891.

He was one of the founders of the anti-socialistic "Adam Smith Society" at Florence.

MAGNA CARTA, or the Great Charter, the name of the famous charter of liberties granted at Runnymede in June 1215 by King John to the English people. Although in later ages its importance was enormously magnified, it differs only in degree, not in kind, from other charters granted by the Norman and early Plantagenet kings. Its greater length, however, still more the exceptional circumstances attending its birth, gave to it a position absolutely unique in the minds of later generations of Englishmen. This feeling was fostered by its many confirmations, and in subsequent ages, especially during the time of the struggle between the Stewart kings and the parliament, it was regarded as something sacrosanct, embodying the very ideal of English liberties, which to some extent had been lost, but which must be regained. Its provisions, real and imaginary, formed the standard towards which Englishmen must strive.
defeat at Bouvines at the hands of Philip Augustus, and even the king himself was compelled to recognise that his hopes of recovering Normandy were at an end.

Meanwhile in England, which was ruled by Peter des Roches as justiciar, the discontent had been increasing rather than diminishing, and its volume became much larger owing to an event of May 1214. Greatly needing money for his campaign, John ordered another scutage to be taken from his tenants; this, moreover, was to be at the unprecedented rate of three marks on the knight’s fee, not as on previous occasions of two marks, although this latter sum had hitherto been regarded as a very high rate. The northern barons refused to pay, and the gathering of men for war as possible, for the barons felt that they had suffered enough when a little later came the news of the king’s humiliation at Bouvines. Then in October the beaten monarch returned to England, no course open to him but to bow before the storm. In November he met some of his nobles at Bury St Edmunds, but as they still refused to pay the scutage no agreement was reached. At once they took another step towards the goal. With due solemnity (super majus alare) they swore to withdraw their allegiance from the king and to make war upon him, unless within a stated time he restored to them their rightful laws and liberties. While they were preparing for their campaign, John on his part tried to divide his enemies by a concession to the clerical section. By a charter, dated the 21st of November 1214, he granted freedom of election to the church. However, this did not prevent the prelates from continuing to act to some extent with the barons, and early in January 1215 the malcontents asked the king to confirm the laws of Edward the Confessor and the other liberties of the kingdom. He evaded the request and secured a truce until Easter was passed. Energetically making use of this period of respite, he again issued the charter to the church, ordered his subjects to take a fresh oath of allegiance to him, and sent letters to the pope for aid; but neither these precautions, nor his expedient of taking the cross, deterred the barons from returning to the attack. In April they met in arms at Stamford, and as soon as the truce had expired they marched to Brackley, where they met the royal ministers and again presented their demands. These were carried to the king at Oxford, but angrily he refused to consider them. Then the storm burst. On the 5th of May the barons formally renounced their allegiance to John, and appointed Robert Fitzwalter as their leader. They marched towards London, while John endeavoured in an attempt to delay the crisis, or to divide his foes, by granting a charter to the citizens of London (May 9, 1215), and then by offering to submit the quarrel to a court of arbitrators under the presidency of the pope. But neither the one nor the other expedition availed him. Arbitration under such conditions was contemptuously rejected, and after the king had ordered the sheriffs to seize the lands and goods of the revolting nobles, London opened its gates and peacefully welcomed the baronial army. Other towns showed also that their sympathies were with the insurgents, and John was forced to his knees. Promising to assent to their demands, he agreed to meet the barons, and the gathering was fixed for the 15th of June, and was to take place in a meadow between Staines and Windsor, called Runnymede.

At the famous conference, which lasted from Monday the 15th to Tuesday the 23rd of June, the hostile barons were present in large numbers; on the other hand John, who rode over each day from Windsor, was only attended by a few followers. At once the malcontents presented their demands in a document known popularly as the Articles of the Barons, more strictly as Capitula quae res ecclesiae quam rex concedit. Doubtless this had been drawn up beforehand, and was brought by the baronial leaders to Runnymede; possibly it was identical with the document presented to the royal ministers at Brackley a few weeks before. John accepted the Articles on the same day and at once the great seal was affixed to them. They are forty-eight in number, and on them Magna Carta was based, the work of converting them into a charter, which was regarded as a much more binding form of engagement, being taken in hand immediately. This duty occupied three days, negotiations between the two parties taking place over several disputed points, and it was completed by Friday the 10th, when several copies of the charter were sealed. All then took an oath to keep its terms, and orders were sent to the sheriffs to publish it, and to see that its provisions were observed, two or three days being taken up with making and sending out copies for this purpose. It should be mentioned that, although the charter was evidently not sealed until the 10th, the four existing copies of it are dated the 13th, the day on which John accepted the articles.

The days between Friday the 10th and the following Tuesday, when the conference came to an end, were occupied in finalizing the various articles and duties. The day of the conclusion was the most powerful and most glorious of all, for as soon as possible, for the barons felt that they on their part would keep the peace. This was refused, and although some of the bishops entered a mild protest, the question was allowed to drop. Regarding another matter also, the extent of the royal forests, the prelates made a protest. John and his friends feared lest the inquiry promised into the extent of the hated forest areas would be carried out too rigorously, and that these would be seriously curtailed, if not abolished altogether. Consequently, the two archbishops and their colleagues declared that the articles in the charter which provided for this inquiry, and for a remedy against abuses of the forest laws in the king, must not be interpreted too harshly, or in a spirit. The customary necessary for the preservation of the forests must remain in force.

No securities, however, could bind John. Even before Magna Carta was signed he had set to work to destroy it, and he now turned to this task with renewed vigour. He appealed to the pope, and hoped to crush his enemies by the aid of foreign troops, while the barons prepared for war, and the prelates strove to keep the peace. Help came first from the spiritual arm. On the 24th of August 1215 Innocent III published a bull which declared Magna Carta had been made without just cause (per vim et melum), and in the words of the bull the pope said "compositionem hujusmodi reprobamus penitus et damnum." He followed this up by excommunicating the barons who had obtained it, and in the autumn of 1215 the inevitable war began. Capturing Rochester castle, John met with some other successes, and the disheartened barons invited Louis, son of Philip Augustus of France, as the war and the plight of the kingdom, was worse than ever. Louis, son of Philip Augustus of France and afterwards king as Louis VIII., to take the English crown. In spite of the veto of the pope Louis accepted the invitation, landed in England in May 1216, and occupied London and Winchester, the fortune of war having in the meantime turned against John. The "abest and most ruthless of the Angevins," as J. R. Green calls this king, had, not, however, given up the struggle, and he was still in the field when he was taken ill, dying in Newcastle castle on the 19th of October 1216.

In its original form the text of Magna Carta was not divided into chapters, but in later times a division of this kind was adopted. This has since been retained by all commentators, the number of chapters being 63.

The preamble states that the king has granted the charter on the advice of various prelates and barons, some of whom, including the archbishop of Canterbury, the papal legate Pandulf, and William Marshal, earl of Pembroke, are mentioned by name.

Chapter I. declares that the English church shall be free and shall enjoy freedom of election. This follows the precedent set in the accession charter of Henry I. and in other early charters, although it had no place in the Articles of the Barons. On the present occasion it was evidently regarded as quite a formal and introductory matter, and the same remark applies to the general grant of liberties to all freemen and their heirs, with which the chapter concludes.

MAGNA CARTA

315
MAGNA CARTA

Then follows a series of chapters intended to restrain the king from raising money by the harsh and arbitrary methods adopted in the past. These chapters, however, only afforded protection to the tenants-in-chief of the crown, and it is clear from their prominent position that the framers of the charter regarded them as of paramount importance.

Chapter II. fixes the amount of the relief to be paid to the king by the heir of any of his vassals. Previously John, disregarding the custom of the past, had taken as much as he could extort. Henceforward he who inherits a barony must pay £100, he who inherits a knight’s fee 100 shillings or less, and for smaller holdings less “according to the value of the fiefs.”

Chapters III. to VI. deal with the abuses of the king’s privilege of acting as guardian of minors and their lands. Money must not be extorted from a ward when he receives his inheritance. The guardianship must not take from the ward’s property more than a reasonable amount for his expenses and the like; on the contrary he must maintain the houses, estates and other belongings in a proper state of efficiency. A ward must also have a reasonable liberty in the matter of marriage. He or she must not, as had been so often the case in the past, be forced to marry some royal favourite, or some one who had paid a sum of money for the privilege.

Chapters VII. and VIII. deal with the protection of tenants-in-chief. On the death of her husband a widow must receive her rightful inheritance, without delay or hindrance. Moreover, she must not be compelled to marry, a proceeding sometimes adopted to get her hands into the property as a wife rather than a widow. Chapter IX. is intended to prevent the king from collecting the money owing to him in an oppressive manner.

Now for a short time the document leaves the great questions between the king and the barons, and two chapters are devoted to protecting the people generally against the exactions of the Jews.

Chapter X. declares that money borrowed from the Jews shall not be considered a debt or a security. Chapter XI. provides for the repayment of borrowed money to the Jews, and also to other creditors. This, however, is only to be done after certain liabilities have been met out of the estate, including the death or the will of the borrower.

Having thus disposed of this matter, the grievances of the barons are again considered, the vexed question of scutage being dealt with.

Chapter XII. says that in future no scutage or aid, beyond the three recognized feudal aids, shall be levied except by the consent of the general council of the nation (commune conciliórum regni nostri), while the three recognized aids shall only be levied at a reasonable rate. In dealing with this matter the Articles of the Barons had declared that aids and tallages must not be taken from the citizens of London and of other places without the consent of the council. The council or the parliament was, except as to aids related to aids from the citizens of London. This chapter does not give the people the right to control taxation. It gives to the men interested a certain control over one form of taxation, and protects only the royal, and not the ordinary exactions, and that class the most powerful and the most wealthy.

Chapter XIII. gives to the citizens of London all their ancient liberties and free customs.

Chapter XIV. provides for the assembly of the council when its consent is necessary for raising an aid or a scutage. Individual summonses must be sent to the prelates and greater barons, while the lesser barons will be called together through the sheriffs and bailiffs. At least forty days’ notice of the meeting must be given, and the cause thereof specified. No chapter corresponding to this is to be found in the agreements of Magna Carta. It is very interesting, but it does not constitute any marked advance in the history of parliament, as it merely expresses the customary method of summoning a council. It does not, as has been sometimes asserted, in any way establish a representative system, as this is understood to-day.

Chapter XV. extends the concessions obtained by the greater barons for themselves to the lesser landholders, the tenants of the tenants-in-chief.

Chapter XVI. declares that those who owe military service for their lands shall not be called upon to perform more than the due amount of service from each.”

We now come to an important series of articles which deal with abuses in the administration of justice. Henry II. made the royal courts of law a lucrative source of revenue, but he gave protection to suitors. Under his sons justice was equally, perhaps more, costly, while adequate protection was much harder to obtain. Here were many grievances, and the barons set to work to redress them.

Chapter XVII. declares that common pleas must henceforward be heard in a fixed place. This had already been to some extent the practice when this class of cases was heard, it was now made the law of the land. This can hardly be the matter of expense and inconvenience of following the king from place to place.

Chapters XVIII. and XIX. deal with the three petty assizes, the courts of quarter sessions. These courts were more local in their operations and were more in touch with the lives of the ordinary people.

Chapter XX. to XXI. regulate the amount of fines imposed for offences against the law. Property necessary for one’s livelihood must not be taken. The fines must only be imposed by the oath of honest men of the neighbourhood. In the same way early and the manor courtes must only be imposed by their peers, and a similar privilege is extended to the clergy, who, moreover, were not to be fined in accordance with the value of their bencheus, but only of their other property.

Chapters XXII. to XXIII. regulate in the term of justices. It prevented the king from increasing by their agency the amount of money annually due to him from the various counties and hundreds. The custom was for the king to get a fixed sum from the sheriff of each county, this being paid once at the beginning of the truce, and from the sheriff of the county, as best he could. Henceforward this amount must not be raised.

Chapters XXIV. and XXVII. were intended to protect the property of deceased persons, and also to secure the full payment of debts due to the deceased from the crown. Other creditors were also protected, and the property of an intestate must be distributed to his heirs under the supervision of the church.

Chapter XXVI. says that fines may not be put at the custom of purveyance. Royal officials must pay for the corn and provisions which they take on behalf of the king.

Chapter XXIX. says knights must not be compelled to give money instead of performing castle-guard, if they are willing to serve in a service. Castle-guard was the liability incumbent on the holders of some estates to serve in the garrison of the royal castles. The constables of these castles had adopted the custom of compelling these landholders to give money and not service, mercenaries being then hired to perform this.

Chapters XXX. and XXXI. forbid the royal officials to seize the horses or carts of freemen for transport duty, or to take wood for the royal forests.

Chapter XXXII. says that the lands of convicted felons shall be handed over to the lords of such lands and not kept by the king after a year and a day. In this case the land is restored to the forfeited land, but he was not allowed to establish a similar right in cases of felony.

Chapter XXXIII. provided for the removal of kyldells, or weirs, from to inland navigation, the rivers being the main highways of trade.

Chapter XXXIV. limits the use of the writ known as Praecipe. This writ was one transcribing cases concerning the ownership of property from the courts of the feudal lords to those of the king. This custom, which owes its origin to Henry II., meant a loss of revenue to the lords, whose victory in this matter, however, was a step backwards. It checked temporarily the process of centralizing the administration of justice.

Chapter XXXV. provides for the uniformity of weights and measures throughout the kingdom.

Chapter XXXVI. promises that in future writs of inquisition shall be granted freely without payment of any kind. This kind of writ allowed a man to refer the question of his guilt or innocence to the verdict of his neighbours instead of proving his innocence by the duel.

Chapter XXXVII. prevents the king from administering certain kind of land when these fall into the possession of minors. In the past John had evidently stretched his authority and seized lands over which others had really the right of wardship.

Chapter XXXVIII. provides for compelling an accused man to submit to the ordeal without the approval of credible witnesses.

Chapter XXXIX. is more important and the English wording of it has been given in full. No free man shall be arrested, or detained in prison, or deprived of his freehold, or outlawed, or banished, or in any way molested; and we will not set forth against him, nor send any writ, or order, unless the case be referred to the judgment of the law of the land.” The object of this was clearly to restrain John from arbitrary proceedings against his free subjects. The principle
of judgment by one's peers is asserted and it is obviously the privilege of each Catholic, with the guidance of the church, wherever he is.

Chapter XL. - The church and the clergy were at work while the famous charter was being framed. When one reflects how active and useful Dr. Gardiner and other prelates were at Runnymede the change is not surprising. Another difference between the two documents concerns the towns and the trading classes. Certain privileges granted to them in the Articles are not found in Magna Carta, although, it must be noted, this document bestows exceptionally favoured treatment on the citizens of London. The conclusion is that the friends of the towns and the traders were less in evidence at Runnymede than they were at the earlier meetings of the barons, but that the neighbouring Londoners were strong enough to secure a good place for their city in the charter.

Chapter XLII. - It is the way of mankind to associate one another at some time in the history of their country. To denounce the evil deeds of John and the innovations practised by him, it shows what these were and how they were hated; how money had been raised, how forest areas had been extended, how minors and widows had been cheated and oppressed. By declaring, as it does, what were the laws and customs of a past age wherein justice prevailed, it shows what was the ideal of good government formed by John's prelates and barons. Magna Carta can hardly be said to have introduced any new ideas. As Pollock (Law and the English) says, in the words of a charter contains little that is absolutely new. It is restorative. But although mature study has established the truth of this proposition it was not always so. Statesmen and commentators alike professed to find in Magna Carta a number of political ideas which belonged to a later age, and which had no place in the minds of its framers. It was regarded as having conferred upon the nation nothing less than the English constitution in its perfect and completed form.

Chapter XLIII. - Sir Edward Coke finds in Magna Carta a full and proper legal answer to every exaction of the Stuart kings, and a remedy for every evil suffered at the time. Sir William Blackstone is almost equally admiring. Edmund Burke says "Magna Carta, if it did not give us originally the House of Commons, gave us at least a House of Commons of weight and consequence." Lord Chatham used words equally superlative. "Magna Carta, the Petition of Rights and the Bill of Rights form that code, which I call the Bible of the English Constitution." Modern historians, although less rhetorical, speak in the highest terms of the importance of Magna Carta, the view of most of them being summed up in the words of Dr. Stubbs: "The whole of the constitutional history of England is almost a history of freedom and of the growth and increase of freedom."

Chapter XLIV. - The strength of Magna Carta as giving equal rights to all Englishmen. J. R. Green says "The rights which the barons claimed for themselves they claimed for the nation at large." As a matter of fact this statement is only true with large limitations. The villains, who formed the majority of the population, got very little from it; in fact the only clauses which protect them do so because they are property—the property of their lords—and therefore valuable. They get neither political nor civil rights under Magna Carta. The traders, too, get little, while preferential treatment is meted out to the clergy and the barons. Its benefits are confined to freemen, and of the benefits the lion's share fell to the larger landholders; the smaller landholders getting, it is true, some crumbs from the table. It did not establish freedom from arbitrary arrest, or the right of the representatives of the people to control taxation, or trial by jury, or other conceptions of a later generation.

The story of Magna Carta after the death of John is soon told. On the 13th of November 1216 the regent William Marshal, earl of Pembroke, reissued the charter in the name of the young king Henry III. But instead of the promise made, War was being waged against Louis of France, and the executive must not be harpered in the work of raising money; moreover the personal equation had disappeared, the barons did not need to protect themselves against John. Consequently the chapter limiting the power of the crown to raise scutages and aids without the consent of the council vanished, and with it the complementary one which determined the method of calling a council. Other provisions, the object of which had been to restrain John from demanding more money from various classes of his subjects,
were also deleted, and the same fate befell such chapters as dealt with mere temporary matters. The most important of these was Chapter LXI, which provided for the appointment of twenty executors to compel John to observe the charter. The next year peace was made at Lambeth (Sept. 11, 1217) between Henry III. and Louis and another reissue of the charter was promised. This promise was carried out, but two charters appeared, one was the revised issue of Magna Carta of 1217, and the other a separate charter dealing with the forests, all references to which were omitted from the more important document. The date of this issue appears to have been the 6th of November 1217. The issue of a separate forest charter at this time led subsequently to some confusion. Roger of Wendover asserts that John issued a separate charter of this kind when Magna Carta appeared. This statement was believed by subsequent writers until the time of Blackstone, who was the first to discover the mistake.

As issued in 1217 Magna Carta consists of 47 chapters only. It declares that henceforward scutages shall be taken according to the precedents of Henry II.'s reign. New provisions were introduced for the preservation of the peace—unlawful castles were to be destroyed—while others were directed towards making the administration of justice by the visiting justices less burdensome. With regard to the land and the services due therefrom a beginning was made of the policy which culminated in the statutes of Mortmain and of Quia Emptores. The charters were ordered to publish the revised charter on the 22nd of February in order that the two charters with only two slight alterations, and this is the final form taken by Magna Carta, this text being the one referred to by Coke and the other early commentators. Subsequently the charters were confirmed several times by Henry III. and by Edward L. the most important occasion being their confirmation by Edward at Ghent in November 1297. On this occasion some supplementary articles were added to the charter; these were intended to limit the taxing power of the crown.

There are at present in existence four copies of Magna Carta, sealed with the great seal of King John, and several unsealed copies. Of the four two are in the British Museum. Both came into the possession of the Museum with the valuable collection of papers which had belonged to Sir Robert Cotton, who had obtained possession of both. One was found in Dover castle about 1650. This was damaged by fire in 1731; the other is undamaged. The other two sealed copies belong to the cathedrals of Lincoln and of Salisbury. Both are preserved in a elaborately fashioned case in the British Museum, and the one at Lincoln was regarded as the most perfect by the commissioners who were responsible for the appearance of the Statutes of the Realm in 1810. The British Museum also contains an impression of the parchment of the Articles of Magna Carta was first printed by Richard Pyson in 1499. This, however, was not the original text, which was neglected until the time of Blackstone. He printed the various records of the statute in his book The Great charter and the charter of the Forest (1759). The earliest commentator of note was Sir Edward Coke, who published his Second Institute, which deals with Magna Carta, by order of the Long Parliament in 1642. Modern commentators, who also print the various texts of the charter, are Richard Thomson, An Historical Essay on the Magna Carta of King John (1829); C. Bémont, in his Chartes des libertés anglaises (1892); and W. Stubbs in his Select Charters (1895). A more recent book and one embodying the results of the latest research is W. S. McKechnie, Magna Carta (1905).

The text of Magna Carta is also printed in the Statutes of the Realm (1810) in the work of W. J. de la Beche, The English Writers (1860). In addition to Blackstone, Coke and these later writers, the following works may also be consulted: John Reeves, History of English Law (1783-1784); L. B. Ryle, Constitutional History of the House of Lords (1888); W. Stubbs, Constitutional History of England (1897); Sir F. Pollock and F. W. Maitland, The History of English Law (1895); W. S. Holdsworth, A History of English Law (1903), and Kate Norgate, John Locke (1902).

**MAGNA GRAECIA** (μηγα γραεια, 'Eleia), the name given (first, apparently, in the 6th century B.C.) to the group of Greek cities along the "toe" of the southern coast of Italy (except those only from Tarentum to Locri, along the east coast), while the people were called Italiotes (\'Ira\'noula\'). The interior, which the Greeks never subdued, continued to be in the hands of the Bruttii, the native mountaineers, from whom the district was named in Roman times (\'Speria also in Greek writers').

The Greek colonies were established first as trading stations, which grew into independent cities. At an early time a trade in copper was carried on between Greece and Tenea (Homer, Od. i. 181). The trade for a long time was chiefly in the hands of the Euboians; and Cyme (Cyma) in Campania was founded in the 8th century B.C., when the Eubocean Cyme was still a great city. After this the energy of Chalcis went onward to Sicily, and the states of the Corinthian Gulf carried out the colonization of Italy, Rhegium having been founded, it is thought in 707 B.C. by Messana (Zancle), and at the request of the inhabitants of the latter. Sybaris (721) and Crotona (703) were Achaean settlements; Locri Epizephyrii (about 720) was settled by Ozolian Locrians, so that, had it not been for the Dorian colony of Tarentum, the southern coast of Italy would have been entirely occupied by a group of Achaean cities. Tarentum (whether or not founded by pre-Dorian Greeks—its founders bore the unexplained name of Partheniae) became a Laconian colony at some unknown date, whereas a legend grew up connecting the Parthenians with Sparta, and 707 B.C. was assigned as its traditional date. Tarentum is remarkable as the only foreign settlement made by the Spartans. It was industrial, depending largely on the purple and pottery trade. Ionian Greeks fleeing from foreign invasion founded Siris about 650 B.C., and, much later, Elea (540).

The Italian colonies were planted among friendly, almost kindred, races, and grew much more rapidly than the Sicilian Greek states, which had to contend against the power of Carthage. After the Achaean cities had combined to destroy the Ionic Siris, and had founded Metapontum as a counterpoise to the Dorians, Tarentum, there seems to have been little strife among the Italiotes. An amphictyonic league, meeting in common rites at the temple of Hera on the Lacanian promontory, fostered a feeling of unity among them. The Pythagorean and Eleatic systems of philosophy had their chief seat in Magna Graecia. Other departments of literature do not seem to have been so much cultivated among them. The poet Ibycus, though a native of Rhegium, led a very wandering life. They sent competitors to the Olympic games (among them the famous Milo of Croton); and the physicians of Croton early in the 6th century (especially in the person of Democedes) were reputed the best in Greece; but politically they appear to have generally kept themselves separate. One ship of Croton, however, fought at Salamis, though it is not recorded that Greece asked the Italiotes for help when it sent ambassadors to Gelon of Syracuse. Mutual discord first sapped the prosperity of Magna Graecia. In 510 Croton, having defeated the Sybarites in a great battle, totally destroyed their city. Croton maintained alone the leading position which it had belonged jointly to the Achaean cities (Diod. s.v. 103); but from that time Magna Graecia steadily declined. In the war between Athens and Syracuse Magna Graecia took comparatively little part; Locri was strongly anti- Athenian, but Rhegium, though it was the headquarters of the Athenians in 427, remained neutral in 415. Foreign enemies pressed heavily on it. The Lucanians and Bruttians on the north captured one town after another. Dionysius of Syracuse attacked them from the south; and after he defeated the Coritanaeans and destroyed Caulonia (390 B.C.), Tarentum remained the only powerful city. Henceforth the history of Magna Graecia is simply a record of the rivalry between Sparta and Epirus. Expeditions from Sparta and Epirus tried in vain to prop up the declining Greek states against the Lucanians and Bruttians; and when in 282 the Romans appeared in the Tarentine Gulf the end was close at hand. The aid which Pyrrhus brought did little good to the Tarentines, and his final departure in 274 left them defenceless. During these constant wars the Greek cities had been steadily decaying; and in the second Punic war, when most of them seized the opportunity of revolting from Rome, their very existence was in some cases annihilated. Malartic mentions in

1. This passage should perhaps be referred to the 8th century B.C. It is the first mention of an Italian place in a literary record.
magnesite, a mineral consisting of magnesium carbonate, MgCO₃, and belonging to the calcite group of rhombohedral carbonates. It is rarely found in crystals or crystalline masses, being usually compact or earthy and intermixed with more or less hydrous magnesium silicate (meerschaum). The compact material has the appearance of unglazed porcelain, and the earthy material is yellowish, grey or greenish. It is usually dead white or sometimes yellowish. The hardness of the crystallized mineral is 4; sp. gr. 3-1. The name magnesite as originally applied by J. C. Delamétherie in 1797 included several minerals containing magnesium, and at the present day it is used by French writers for meerschaum. The mineral has also been called bauddiserite from the locality Bauddissero near Ivrea in Piedmont. Bauddiserite is a ferrasilite variety.

Magnetite is a product of alteration of magnesium silicates, and occurs as veins and patches in serpentinite, talc-schist or dolomite-rock. It is extensively mined in the island of Euboea in the Grecian Archipelago, near Salem in Madras, and in California, U.S.A. It is principally used for the manufacture of highly refractory firebricks for lining steel furnaces and electric furnaces; also for making plaster, tiles and artificial stone; for the preparation of magnesium salts (Epsom salts, &c.) for whitening paper-pulp and wool; and as a paint.

Magnesite [symbol Mg, atomic weight 24:32 (0 = 16)], a metallic chemical element. The sulphate or "Epsom salts" (q.v.) was isolated in 1695 by N. Grew, while in 1707 M. B. Valentin prepared magnesium also from the mother liquors of the manufacture of magnesia. The metal was isolated on a large scale by J. Black in 1755, and was found to have an antimony content which was removed by W. H. Bunsen, who then produced it in 1852 by electrolysis of fused magnesium chloride in a porcelain crucible. In later processes, carnallite (\(\text{KCl}_2\text{MgCl}_2\text{H}_2\text{O}\)) is used as a starting point.

The use of magnesite in the manufacture of refractory materials is extensive. It is used in the manufacture of magnesia, a material used in the production of various refractory products, including bricks, tiles, and refractory columns. Magnesite is also used in the production of magnesium oxide, which is used in the production of magnesium. The magnesium oxide is produced by the electrolysis of magnesium chloride, which is formed by the reaction of magnesite with water.

Magnesite is also used in the production of magnesium metal, which is used in the production of various refractory materials, including bricks, tiles, and refractory columns. natural double chloride of magnesium and potassium) has commonly, however, been substituted for the single chloride. Graetzel's process, which was at one time employed, consisted in effecting a reduction of metallic magnesium in a crucible, which itself formed the cathode, and the magnesium being deposited upon its inner surface. W. Borchers also used an externally heated metal vessel as the cathode; it is provided with a supporting electrode, placed below the metal vessel, and cathodic iron, which is exposed to the cooling influence of the air, in order that a crust of solidified salt may there be formed, and so prevent the collapse of the vessel. The melted salt flows downwards through the cover of a porcelain cylinder, open at the bottom, and provided with a side-tube at the top to remove the chloride formed during electrolysis. The operation is conducted at a dull red heat (160° C.). Water, which boils at 200° C., is poured on the anhydrous salt, the double magnesium ammonium chloride, MgCl₂·H₂O, is prepared by adding ammonium chloride to a solution of magnesium chloride. The solution is evaporated, and the residue of magnesium chloride is recrystallized from water. By this process, anhydrous magnesium chloride remains. Magnesium chloride readily forms double salts with the alkaline chlorides. A strong solution of magnesium chloride in carbonic acid, when cooled, may be filtered through a porcelain filter-press, re-melted, and the salt crystallized from water. This magnesium set in a few hours to a hard, stone-like mass, which contains in excess the oxycarbonate of varying composition. Magnesium oxycarbonate when heated to redness in a current of air evolves a mixture of hydrocarbons (predominantly ethyl) and oxygen. The ethyl, combined with hydrogen, forms ethylene, which is employed in the Weldon-Pechinay and Mond processes for the manufacture of chloroform.

Magnesium Carbonate, MgCO₃.—The normal salt is formed, as the mineral magnesite, and in combination with calcium carbonate as dolomite, whilst hydromagnesite is a basic carbonate. It is not possible to prepare the normal carbonate by precipitating magnesium salts with sodium carbonate. Marignac has prepared it by the action of calcium carbonate on magnesium chloride. A salt MgCO₃·H₂O or Mg(CO₃)₂(H₂O)·2H₂O may be prepared from the carbonate by dissolving it in water charged with carbon dioxide, and pouring the solution into the steam of the decomposed magnesium chloride from which it is precipitated. By this method a white precipitate of magnesium carbonate is obtained.

13. Historical and Chronological Notes.

Of these thirteen sections, the first contains a simple description of the more prominent phenomena, without mathematical symbols or numerical data. The second includes definitions of technical terms in common use, together with so much of the elementary theory as is necessary for understanding the experimental work described in subsequent portions of the article; a number of formulae and results are given for purposes of reference, but the mathematical reasoning by which they are obtained is not generally detailed, authorities being cited whenever the demonstrations are not likely to be found in ordinary textbooks. The subjects discussed in the remaining sections are sufficiently indicated by their respective headings. (See also ELECTROMAGNETISM, TERRRESTRIAL MAGNETISM, MAGNETO-OPTICS AND UNITS.)
end, always in the same direction, with one of the poles of a
magnet. Until 1820 all the artificial magnets in practical use
derived their virtue, directly or indirectly, from the natural
magnets found in the earth: it is now recognized that the
source of all magnetism, not excepting that of the magnetic
ore itself, is electricity, and it is usual to have direct recourse
to electricity for producing magnetization, without the inter-
mediary of the magnetic ore. A wire carrying an electric
current is surrounded by a magnetic field, and if the wire is
bent into the form of an elongated coil or spiral, a field having
certain very useful qualities is generated in the interior. A bar
of iron introduced into the coil is at once magnetized, the
magnetism, however, disappearing almost completely as soon
as the current ceases to flow. Such a combination constitutes
an electromagnet, a valuable device by means of which a magnet
can be instantly made and unmade at will. With suitable
arrangements of iron and coil and a sufficiently strong current,
the intensity of the temporary magnetization may be very high,
and electromagnets capable of lifting weights of several tons
are in daily use in engineering works (see ELECTROMAGNETISM).
If the iron inserted into the coil is of hardened steel instead of
iron the magnetism will be less intense, but a larger proportion
of it will be retained after the current has been cut off. Steel
magnets of great strength and of any convenient form may be
prepared either in this manner or by treatment with an electro-
magnet; hence the natural magnet, or lodestone as it is commonly
called, is no longer of any interest except as a scientific
curiosity.

Some of the principal phenomena of magnetism may be
demonstrated with very little apparatus; much may be done
with a small bar-magnet, a pocket compass and a few ounces
of iron filings. Steel articles, such as knitting or sewing needles
and pieces of flat spring, may be readily magnetized by stroking
them with the bar-magnet; after having produced magnetism
in any number of other bodies, the magnet will have lost nothing
of its own virtue. The compass needle is a little steel magnet
balanced upon a pivot; one end of the needle, which always
bears a distinguishing mark, points approximately, but not in
general exactly, to the north, the vertical plane through the
direction of the needle being termed the magnetic meridian.
The bar-magnet, if suspended horizontally in a paper stirrup
by a thread of unspun silk, will also come to rest in the magnetic
meridian with its marked end pointing northwards. The
north-seeking end of a magnet is in English-speaking countries
called the north pole and the other end the south pole; in France
the names are interchanged. If one pole of the bar-magnet
is brought near the compass, it will attract the opposite pole
of the compass-needle; and the magnetic action will not be
sensibly affected by the interposition between the bar and the
compass of any substance whatever except iron or other mag-
netizable metal. The poles of a piece of magnetized steel may
be at once distinguished if the two ends are successively pre-
sented to the compass; that end which attracts the south pole
of the compass needle (and is therefore north) may be marked
for easy identification.

Similar magnetic poles are not merely indifferent to each
other, but exhibit actual repulsion. This can be more easily
shown if the compass is replaced by a magnetized knitting
needle, supported horizontally by a thread. The north pole
of the bar-magnet will repel the north pole of the suspended
needle, and there will likewise be repulsion between the two
south poles. Such experiments as these demonstrate the
fundamental law that like poles repel each other; unlike poles
attract. It follows that between two neighbouring magnets,
the poles of which are regarded as centres of force, there must
always be four forces in action. Denoting the two pairs of
magnetic poles by N, S and N', S', there is attraction between
N and S', and between S and N'; repulsion between N' and S,
and between S' and N. Hence it may be more safely than to
determine experimentally the law of magnetic force between poles. The

difficulty was overcome by C. A. Coulomb, who by using very
long and thin magnets, so arranged that the action of their
distant poles was negligible, succeeded in establishing the law,
which has since been confirmed by more accurate methods,
that the force of attraction or repulsion exerted between two magnetic
poles varies inversely as the square of the distance between them.
Since the poles of different magnets differ in strength, it is
important to agree upon a definite unit or standard of reference
in terms of which the strength of a pole may be numerically
specified. According to the recognized convention, the unit
pole is that which acts upon an equal pole at unit distance
with unit force: a north pole is reckoned as positive (+) and
a south pole as negative (−). Other conditions remaining
unchanged, the force between two poles is proportional to the
product of their strengths; it is repulsive or attractive according
as the signs of the poles are like or unlike.

If a wire of soft iron is substituted for the suspended magnetic
needle, either pole of the bar-magnet will attract either end of
the wire indifferently. The wire will in fact become temporarily
magnetized by induction, that end of it which is nearest to the
magnet acquiring opposite polarity, and behaving as if it were the pole of a permanent magnet. Even a permanent
magnet is susceptible of induction, its polarity becoming thereby
strengthened, weakened, or possibly reversed. If one pole of a
strong magnet is presented to the like pole of a weaker one,
there will be repulsion so long as the two are separated by a
certain minimum distance. At shorter distances the magnetism
induced in the weaker magnet will be stronger than its permanent
magnetism, and there will be attraction; two magnets with
their like poles in actual contact will always cling together unless
the like poles are of exactly equal strength. Induction is an
effect of the field of force associated with a magnet. Magnetic
force has not merely the property of acting upon magnetic
poles, it has the additional property of producing a phenomenon
known as magnetic induction, or magnetic flux, a physical con-
dition which is of the nature of a flow continuously circulating
through the magnet and the space outside it. Inside the magnet
the course of the flow is from the south pole to the north pole;
thence it diverges through the surrounding space, and again
converging, re-enters the magnet at the south pole. When the
magnetic induction flows through a piece of iron or other mag-
netizable substance placed near the magnet, a south pole is
developed where the flux enters and a north pole where it
leaves the substance. Outside the magnet the direction of the
magnetic induction is generally the same as that of the magnetic
force. A map indicating the direction of the force in different
parts of the field due to a magnet may be constructed in a
very simple manner. A sheet of cardboard is placed above the
magnet, and some iron filings are sifted thinly and evenly over
the surface: if the cardboard is gently tapped, the filings will
arrange themselves in a series of curves, as shown in fig. 1.

This experiment suggested to Faraday the conception of
"lines of force," of which the curves formed by the filings
afford a rough indication; Faraday's lines are however not
confined to the plane of the cardboard, but occur in the
whole of the space around the magnet. A line of force
may be defined as an imaginary line so drawn that its direction
at every point of its course coincides with the direction of
the magnetic force at that point. Through any point in the field
one such line can be drawn, but not more than one, for the line obviously cannot
intersect itself. Hence it may be more safely than to
determine experimentally the law of magnetic force between poles. The

1 In London in 1910 the needle pointed about 16° W. of the
geographical north. (See TERRESTRIAL MAGNETISM.)
it. A south pole would be urged oppositely to the conventional "direction" of the line; hence it follows that a very small magnetic needle, if placed in the field, would tend to set itself along a line tangentially to the line of force passing through its centre, as may be approximately verified if the compass be placed among the filings on the cardboard. In the internal field of a long coil of wire carrying an electric current, the lines of force are, except near the ends, parallel to the axis of the coil, and it is chiefly for this reason that the field due to a coil is particularly well adapted for inductively magnetizing iron and steel. The older operation of magnetizing a steel bar by drawing a magnetic pole along it, merely consists in exposing successive portions of the bar to the action of the strong field near it.

Faraday’s lines not only show the direction of the magnetic force, but also serve to indicate its magnitude or strength in different parts of the field. Where the lines are crowded together, as in the neighbourhood of the poles, the force is greater (or the field is stronger) than where they are more widely separated; hence the strength of a field at any point can be accurately specified by reference to the concentration of the lines. The lines presented to the eye by the scattered filings or liquid poured over the pole is one of the methods of field-strength (see Faraday, Experimental Researches, § 3237) though they show its direction clearly enough. It is however easy to demonstrate by means of the compass that the force is much greater in some parts of the field than in others. Lay the compass upon the cardboard, and observe the rate at which its needle vibrates after being displaced from its position of equilibrium; this will vary greatly in different regions. When the compass is far from the magnet, the vibrations will be comparatively slow; when it is near a pole, they will be exceedingly rapid and the frequency of the vibrations, varying as the square root of the magnetic force at the spot. In a refined form this method is often employed for measuring the intensity of a magnetic field at a given place, just as the intensity of gravity at different parts of the earth is deduced from observations of the rate at which a pendulum of known length vibrates.

It is to the non-uniformity of the field surrounding a magnet that the apparent attraction between a magnet and a magnetizable body such as iron is ultimately due. This was pointed out by W. Thomson (afterwards Lord Kelvin) in 1847, as the result of a mathematical investigation undertaken to explain Faraday’s experimental observations. If the inductively magnetized body lies in a part of the field which happens to be uniform there will be no resulting force tending to move the body, and it will not be "attracted." If however there is a small variation of the force in the space occupied by the body, it can be shown that the body will be urged, not necessarily towards a magnetic pole, but towards places of stronger magnetic force. It will not in general move along a line of force, as would an isolated pole, but will follow the direction in which the magnetic force increases most rapidly, and in so doing it may cross the lines of force obliquely or even at right angles.

If a magnetized needle were supported so that it could move freely about its centre of gravity it would not generally settle with its axis in a horizontal position, but would come to rest with its north-seeking pole either higher or lower than its centre. For the practical observation of this phenomenon it is usual to employ a needle which can turn freely in the plane of the magnetic meridian upon a horizontal axis passing through the centre of gravity of the needle. The angle which the needle makes with the plane of the horizon is called the inclination or dip. Along an irregular line encircling the earth in the neighbourhood of the geographical equator the needle takes up a horizontal position, and the dip is zero. At places north of this line, which is called the magnetic equator, the north end of the needle points downwards, the inclination generally becoming greater with increased distance from the equator. Within a certain small area in the Arctic Circle (about 97° W. long., 70° N. lat.) the north pole of the needle points vertically downwards, the dip being 90°. South of the magnetic equator the south end of the needle is always inclined downwards, and there is a spot within the Antarctic Circle (148° E. long., 74° S. lat.) where the needle again stands vertically, but with its north end directed upwards. All these observations may be accounted for by the fact first recognized by W. Gilbert in 1600, that the earth itself is a great magnet, having its poles at the two places where the dipping needle is vertical. To be consistent with the terminology adopted in Britain, it is necessary to regard the pole which is geographically north as being the south pole of the terrestrial magnet, and that which is geographically south as the north pole; in practice however the names assigned to the terrestrial magnets correspond to their geographical positions.

Within a limited space, such as that contained in a room, the field due to the earth’s magnetism is sensibly uniform, the lines of force being parallel straight lines inclined to the horizon at the angle of dip, which at Greenwich in 1910 was about 65°. It is by the horizontal component of the earth’s total force that the compass-needle is directed.

The magnets hitherto considered have been assumed to have each two poles, the one north and the other south. It is possible that there may be more than two. If, for example, a knitting pin is wrapped with a pole of a magnet, and is not being directed from the middle of the needle towards the two extremities alternately, the needle will acquire a north pole at each end and a south pole in the middle. By suitably modifying the manipulation a further number of consequent poles, as they are called, may be developed. It is also possible that a magnet may have no poles at all. Let a magnetic pole be drawn several times around a uniform steel ring, so that every part of the ring may be successively subjected to the magnetic force. If the operation has been skillfully performed the ring will have no poles and will not attract iron filings. Yet it will be magnetized; for if it is cut through and the cut ends are drawn apart, each end will be found to exhibit polarity. Again, a steel wire through which an electric current has been passed will be magnetized, but so long as it is free from stress it will give no evidence of magnetization; if, however, the wire is twisted, poles will be developed at the two ends, for reasons which will be explained later. A wire or rod in this condition is said to be circularly magnetized; it may be regarded as consisting of an indefinite number of elementary ring-magnets, in such positions that the magentic lines of force, starting from the middle of the wire and ending at its end, follow the ring-magnets planes at right angles to it. But no magnet can have a single pole; if there is one, there must also be at least a second, of the opposite sign and of exactly equal strength. Let a magnetized knitting needle, having north and south poles at the two ends respectively, be broken in the middle; each half will be found to possess a north and a south pole, the appropriate supplementary poles appearing at the broken ends. One of the fragments may again be broken, and again two bipolar magnets will be produced; and the operation may be repeated, at least in imagination, till we arrive at molecular magnitudes and can go no farther. This experiment proves that the condition of magnetization is not confined to those parts where polar phenomena are exhibited, but exists throughout the whole body of the magnet; it also suggests the idea of molecular magnetism, upon which the accepted theory of magnetization is based. According to this theory the molecules of any magnetizable substance are little permanent magnets the axes of which are, under ordinary conditions, disposed in all possible directions indifferently. The process of magnetization consists in orientating the molecules by applying the action of the magnetic force, so that their north poles may all point more or less approximately in the direction of the force; thus the body as a whole becomes a magnet which is merely the resultant of an immense number of molecular magnets.

In every magnet the strength of the south pole is exactly equal to that of the north pole, the action of the same magnetic force upon the two poles being equal and oppositely directed. This may be shown by means of the uniform field of force due to the earth’s magnetism. A magnet attached to a cork and
MAGNETISM

MAGNETISM

B, is 1845 numerically consequently The was, its The related block The the ferromagnetics H=2/r, quantities. the the activity which exhibited its magnetization. negative known. iron, copper, discovery exhibiting iron, all or iron, and those iron, negative therefore, straight and parallel. A magnetic field is generally due to a conductor carrying an electric current or to the poles of a magnet. The magnetic field is that in which a current of electricity is flowing is at every point at right angles to the plane passing through it and through the wire; its strength at any point distant r centimetres from the wire is

\[ H = \frac{2\pi r}{I}, \]

\[ H = 2\pi r/I, \]

\[ H = 4\pi n/I. \]

The uniformity of the field is not in this case disturbed by the influence of ends, but its strength at any point varies inversely as the distance from the axis of the ring. When therefore sensible uniformity is desired, the radius of the ring should be large in relation to that of the convolutions, or the ring should have the form of a short cylinder with thin walls. The strongest magnetic fields employed for experimental purposes are obtained by the use of electromagnets. For many experiments the field due to the earth's magnetism is sufficient; this is practically quite uniform throughout considerable spaces, but its total intensity is less than half a unit.

Magnetic forces and magnetization. The moment, M, or \( \mathbf{m} \), of a uniformly and longitudinally magnetized bar-magnet is the product of its length into the strength of one of its poles; it is the moment of the couple acting on the magnet when placed in a field of unit intensity perpendicular to the axis of the magnet. If \( l \) is the length of the magnet, \( M = ml \). The action of a magnet at a distance which is great compared with the length of the magnet depends very upon its moment; so also does the action which the magnet experiences when placed between the poles of a magnet. The moment of a small magnet may be resolved like a force. The intensity of magnetization, or, more shortly, the magnetisation of a magnetic moment per unit of volume, and is denoted by \( \mathbf{m} \) and \( \mathbf{M} \). Hence

\[ m = M/v = m_l/m_n, \]

\[ v \text{ being the volume and } a \text{ the sectional area. } \]

If the magnet is not uniform, the magnetization at any point is the ratio of the moment of an infinitesimal volume at that point to the volume itself, or \( m = M/v \), where \( v \) is the length of the element. The direction of the magnetization is that of the magnetic axis of the element; in isotropic substances it coincides with the direction of the magnetic force at the point. If the direction of the magnetization at the surface of a magnet

1 For the relations between magnetism and light see MAGNETO-OPTICS.

2 J. A. Maxwell employed German capitals to denote vector quantities. J. A. Fleming first recommended the use of blockletters as being more convenient both to printers and readers.

234 M. A. Faraday in 1845 adopted the term "magnetically positive" and "magnetically negative" for these regions.
an angle $\epsilon$ with the normal, the normal component of the magnetization, $I \cos \epsilon$, is called the surface density of the magnetism, and is generally denoted by $\sigma$.

**Potential and Magnetic Force**—The magnetic potential at any point in a magnetic field is the work which would be done against the magnetic forces in bringing an unit pole to that point from the boundary of the field. The line through the given point along which the potential decreases most rapidly is the direction of the resultant magnetic force, and the rate of decrease of the potential in any direction is equal to the component of the force in that direction. If $V$ denote the potential, $F$ the resultant force, $X, Y, Z$, its components parallel to the co-ordinate axes and $n$ the line along which the force is directed, then

$$-\nabla V = F, \quad -\nabla V = X, \quad -\nabla V = Y, \quad -\nabla V = Z.$$  

(6)

Surfaces for which the potential is constant are called *equipotential surfaces*. The resultant magnetic force at every point of such a surface is in the direction of the normal (s) to the surface; hence every line of force therefore cuts the equipotential surfaces at right angles. The potential due to a single pole of strength $m$ at the distance $r$ from the pole is

$$V = m/r,$$  

(7)

the equipotential surfaces being spheres of which the pole is the centre and the lines of force radii. The potential due to a thin magnet at a point whose distance from the two poles respectively is $r$ and $r'$ is

$$V = m(r/r')^{2}.$$  

(8)

When $V$ is constant, this equation represents an equipotential surface.

The equipotential surfaces are two series of ovoids surrounding the two poles respectively, and separated by a plane at zero potential passing perpendicularly through the axis of the magnet. If $r$ and $r'$ make angles $\theta$ and $\theta'$ with the axis, it is easily shown that the equation to a line of force is

$$\cos \theta - \cos \theta' = \text{constant}.$$  

(9)

At the point where a line of force intersects the perpendicularly bisector of the axis $r = r'$, say, and $\cos \theta - \cos \theta'$ obviously $= |r'|$, being the distance between the poles; $|r'|$ is therefore the value of the constant in (9) for the line in question. Fig. 2 shows the lines of force and the plane sections of the equipotential surfaces for a thin magnet with poles concentrated at its ends. The potential due to a small magnet of moment $M$, at a point whose distance from the centre of the magnet is $r$, is

$$V = M \cos \theta r^{2},$$  

(10)

where $\theta$ is the angle between the force and the axis of the magnet. Denoting the force at $P$ (see fig. 3) by $F$, and its components parallel to the co-ordinate axes by $X$ and $Y$, we have

$$X = \frac{\partial V}{\partial r} = \frac{M}{r^{2}} (3 \cos \theta - 1),$$_{1}$$  

(11)

$$Y = \frac{\partial V}{\partial \theta} = \frac{M}{r^{2}} (3 \sin \theta \cos \theta).$$  

If $F_{r}$ is the force along $r$ and $F_{\theta}$ that along $\theta$ at right angles to $r$,

$$F_{r} = X \sin \theta + Y \cos \theta = m \cos \theta,$$  

(12)

$$F_{\theta} = -X \sin \theta + Y \cos \theta = m \sin \theta.$$  

(13)

For the resultant force at $P,$

$$F = \sqrt{F_{r}^{2} + F_{\theta}^{2}} = \frac{M}{r^{2}} \sqrt{3 \cos^{2} \theta + 1}.$$  

(14)

The direction of $F$ is given by the following construction: Trisect $OP$ at $C$, so that $OC = OP/3$; draw CD at right angles to $OP$, to cut the axis produced in $D$; then $DP$ will be the direction of the force at $P$. For a point in the axis $OX$, $\theta = 0$; therefore $\cos \theta = 1$, and the point $D$ coincides with $C$; the magnitude of the force is, from (14),

$$F_{D} = 2M/r.$$

**Fig. 4.**

This equation may be regarded as consisting of an infinite number of elementary magnets, each having a pair of poles and a definite magnetic moment. If a series of such elements, all equally and longitudinally magnetized, were placed end to end with their unlike poles in contact, the external action of the filament thus formed would be reduced to that of the two extreme poles. The same would be the case if the magnetization of the filament varied inversely as the surface of its cross-section. Two of these sections, such as obtained by cutting two concentric cylinders of a solenoid magnet, and the magnetism is said to be distributed solenoidally; there is no free magnetism in its interior. If the constituent solenoids are parallel and of equal strength, the magnet is said to be *homogeneous*. A thin sheet of magnetic matter magnetized normally to its surface in such a manner that the magnetization at any place is inversely proportional to the thickness $h$ of the sheet at that place is called a *magnetic shell*; the constant product $M/r$ is the strength of the shell and is generally denoted by $\phi$ or $\Psi$. The potential at any point due to a magnetic shell is the product of its strength into the solid angle $\omega$ subtended by its edge at the given point, or $V = \omega \phi$. For a given strength, therefore, the potential depends solely upon the boundary of the shell, and the potential outside a closed shell is everywhere zero. A magnet which can be divided into simple magnetic cells, either having their edges along $\omega$, is called a *solenoidal magnet* and the magnetism is said to be distributed lamellarily. A magnet consisting of a series of planes of equal strength arranged at right angles to the direction of magnetization will be called a *lamellar magnet*. It can be shown that uniform magnetization is possible only when the form of the body is ellipsoidal. (Maxwell, *Electricity and Magnetism*, II, § 432.)

It can be shown that uniform magnetization is possible only when the form of the body is ellipsoidal. (Maxwell, *Electricity and Magnetism*, II, § 432.)
MAGNETISM

(24) Where long entire the a expresses in H. The previous See 428). called is such line for that arising from other sources. The resultant magnetic field, therefore, depends on the field of one being to the poles, and the other to the external causes which would be operative in the absence of the magnetized metal. The magnetic induction (at any point) in the metal may be denoted by \( H \), that of the external field by \( H_0 \), and that of the resultant field by \( H \). In certain cases, as for instance, in an iron ring wrapped uniformly round with a coil of wire through which a current may be passed, the resultant field will be the sum of the two, consequently, no free poles, and the ring, though magnetized, constitutes a polarless magnet. Magnetization is usually regarded as a result of an induced magnetic force, which is therefore often termed the magnetising force.

Permeability and Susceptibility. — The ratio \( B/H \) is called the permeability of the medium in which the induction is taking place, and is denoted by \( \mu \). The ratio \( I/H \) is called the susceptibility of the magnetized substance, and is denoted by \( \kappa \).

\[
\mu = \frac{B}{H}, \quad \kappa = \frac{I}{H}
\]

(26)

(27)

(28)

since in an empty space \( B \) has been assumed to be numerically equal to \( H \), and \( I \) may be defined as the flux per unit length of a straight wire carrying a current \( I \).

Magnetic Induction, Magnetic Field, and Magnetic Force. — The magnetic induction \( B \) may be defined as the magnetic flux per unit length of a straight wire carrying a current \( I \). The magnetic field \( H \) is defined as the magnetic flux per unit area normal to the direction of the field. The magnetic force \( F \) is defined as the magnetic flux per unit length of a conductor carrying a current \( I \) in the field, which is due to the interaction of the two fields. The angle between the direction of the magnetic field and the direction of the current is called the magnetic angle, and is measured in radians. The magnetic field is a vector quantity, and its direction is perpendicular to the plane of the field at every point. The magnetic force is a vector quantity, and its direction is perpendicular to the plane of the force at every point.

Magnetic Circuits. — The distribution of magnetic induction or flux through magnetic and non-magnetic substances, such as iron and air, is in many respects analogous to that of an electric current through good and bad conductors. Just as the lines of flow of an electric current all pass in closed curves through the battery or other generator, so do the lines of magnetic induction pass in closed curves through the magnet or magnetizing coil. The total magnetic induction or flux corresponds to the current of electricity (practically measured by the ammeter), and the intensity of the induction is proportional to the number of fluxes (number of amperes to the square centimetre of section). The magnetic permeability to the specific electric conductivity; and the line integral of the magnetic force, sometimes called the magnetometric force, to the electro-motive force in the circuit. The general points of difference are that (1) the magnetic permeability, unlike the electric conductivity, which is independent of the strength of the current, is not in general constant; (2) there is no perfect insulator for magnetic induction, which will pass more or less freely through all known substances. Nevertheless, many important problems relating to the distribution of magnetic induction may be solved by methods similar to those employed for the solution of analogous problems in electricity. For the elementary theory of the magnetic circuit see ELECTRO-MAGNETISM.

Circulating Force, Related to Magnetic Circuit. — It is found that when a piece of ferromagnetic metal, such as iron, is subjected to a magnetic field of changing intensity, the changes which take place in the induced magnetization of the iron exhibit a tendency to lag behind those in the external field. This phenomenon, which was first observed by J. A. Ewing (Phil. Trans. clxxvi. 524) has given the name of hysteresis (Gr. hysteresis, to lag behind). Thus it happens that there is no definite relation between the magnetization of a piece of metal which has been previously magnetized and the strength of the field in which it is placed. Much depends upon its antecedent magnetic condition, and indeed upon its whole magnetic history. A well-known example is the presence in the heads of the paper on which a bar of hard steel is placed in a strong magnetic field, a certain intensity of magnetization is induced in the bar; but when the strength of the field is afterwards reduced to zero, the magnetization does not entirely disappear. Hence, the magnetic force, which is proportional to the number of fluxes, and which may amount to considerably more than one-half, is called the residual magnetisation. The ratio of the residual magnetisation to its previous maximum value measures the remanence, or.

1 The principal theoretical investigations are summarized in Mascart and Joule’s Electricity and Magnetism, i. 391–398 and H. and E. Joubert, loc. cit., a long series of papers. The experiments have been carefully studied with great care by C. G. Lamb, Proc. Phys. Soc. 1899, 16, 509.

MAGNETISM

H. If that nearly parallel (39) north the magnetic negative, of the being the is hence laid small. The will be proportional to the susceptibility if, therefore, a tube containing a weak solution of iron salt will appear to be diamagnetic if it is immersed in a stronger solution of iron, though in air it is paramagnetic.

Circular Magnetization.—An electric current flowing uniformly through a cylindrical wire whose radius is produces inside the wire a magnetic field of which the lines of force are concentric circles around the axis of the wire. At a point whose distance from the axis of the wire is \( r \) the tangential magnetic force is

\[
H = \frac{\mu_0 I}{2\pi r}
\]

(39) it therefore varies directly as the distance from the axis, where it is zero. If the wire consists of a ferromagnetic metal, it will become "circularly" magnetized by the field, the lines of magnetization being, like the lines of force, concentric circles. So long as the wire (supposed isotropic) is free from torsional stress, there will be no external evidence of magnetism.

Magnetic Shielding.—The action of a hollow magnetized shell on a point inside it is always opposed to that of the external magnetizing force, the resultant interior field being therefore weaker than the field outside. Hence any apparatus, such as a galvanometer, may be partially shielded from extraneous magnetic action by enclosing it in an iron case. If a hollow sphere of which the outer radius is \( R \) is concentrically placed around a permanent magnet whose inner radius is \( r \) the fields inside and also outside will be uniform and in the same direction as \( H \) and its value will be approximately

\[
H = \frac{H_0}{1 + \frac{4}{3}(\mu - 2)}
\]

for a cylinder placed with its axis at right angles to the lines of force, or

\[
H = H_0 \left(1 + \frac{2}{3}(\mu - 2)ight)
\]

These expressions show that the thicker the screen and the greater its permeability \( \mu \), the more effective will be the shielding action. Since \( \mu \) can never be infinite, complete shielding is not possible.

Magnetic-Crystallic Phenomenon.—In anisotropic bodies, such as crystal, the direction of the magnetic magnetization does not necessarily coincide with that of the magnetic force. There are, however, always three principal axes at right angles to one another along which the magnetization and the force have the same direction. If each of these axes is successively placed parallel to the lines of force in a uniform field \( H \), we shall have

\[
I_x = \mu_x H, \quad I_y = \mu_y H, \quad I_z = \mu_z H
\]

the three susceptibilities being in general unequal, though in some cases two of them may have the same value. For crystalline bodies the value of \( \chi (\pm or -) \) is nearly always small and constant, the magnetization being therefore independent of the form of the body and of the strength of the field. However, the field is so chosen that if the body is resolved into three components parallel to the principal axes of the crystal, the actual magnetization will be the resultant of the three magnetizations along the axes. The body (or each element of it) will tend to set itself with its axis of greatest susceptibility parallel to the lines of force, while, if the field is not uniform, each will also tend to move towards poles of greater or smaller force (according as the substance is paramagnetic or diamagnetic), the tendency being a maximum when the axis of greatest susceptibility is parallel to the field, and a minimum when it is perpendicular to it. The phenomena may therefore be exceedingly complicated.

3. MAGNETIC MEASUREMENTS

Magnetic Moment.—The moment \( M \) of a magnet may be determined in many ways, the most accurate being that of C. F. Gauss, which gives the value not only of \( M \), but also that of \( H \), the horizontal component of the earth's force. The product \( MH \) is first determined by suspending the magnet horizontally, and causing it to vibrate in small arcs. If \( A \) is the moment of inertia of the magnet, and \( t \) the time of a complete vibration, \( M = \frac{4\pi A t}{F} \) (torsion being neglected).

The ratio \( M/H \) is then found by one of the magnetometric methods which in their simplest forms are described below. Equation (44) shows that as a first approximation

\[
M/H = \frac{(\delta - \rho)}{\tan \theta/2a}
\]

where \( \delta \) is half the length of the magnet, which is placed in the "broadside-on" position as regards a small suspended magnetic needle, \( \rho \) the distance between the centre of the magnet and the needle, and \( \theta \) the angle through which the needle is deflected by the magnet. We get therefore

\[
M^2 = MH \times M/A(\delta - \rho) \tan \theta/2a
\]

\[
H^2 = MH \times H/M = 8\pi A(\delta - \rho) \tan \theta/2a
\]

When a high degree of accuracy is required, the experiments and calculations are less simple, and various corrections are applied. The moment of a magnet may also be deduced from a measurement of the couple exerted on the magnet by a uniform field \( H \). Thus if the magnet is suspended horizontally by a fine wire, which, when the magnetic axis points north and south, is free from torsion, and if \( \theta \) is the angle through which the upper end of the wire must be twisted to make the magnet point east and west, then \( MH = C \delta \), or \( M = C \delta /H \), where \( C \) is the torsional couple of the body. A biliar suspension is sometimes used instead of a single wire. If \( P \) is the weight of the magnet, \( \ell \) the length of the each of the two threads, and the distance between their upper points of attachment, and \( 2b \) the breadth when the lower points, then, approximately,

\[
M = P(\sin \theta) \sin \theta
\]

It is often sufficient to find the ratio of the moment of one magnet to that of another. If two magnets having moments \( M \) and \( M' \) are arranged at right angles to each other upon a horizontal support which is free to rotate, their resultant \( R \) will set itself in the magnetic meridian. Let \( \theta \) be the angle which the standard magnet \( M \) makes with the meridian, then

\[
M/R = \sin \theta, \quad M' = \cos \theta, \quad \text{whence} \quad M = M' \tan \theta
\]

A convenient and rapid method of estimating a magnetic moment has been devised by H. Armatag. The magnet is laid on a table with its north pole pointing northwards. A compass having a very short needle is placed on the line which bisects the axis of the magnet at right angles, and is moved until a neutral point is found where the force due to the earth's field \( H \) is balanced by that due to the magnet. If \( d \) is the distance between the poles \( m \) and \( n \), the distance from either pole to a point \( P \) on the line AB (fig. 5), we have for the resultant force at \( P \)

\[
R = 2\cos \theta \times m \times n = -2\sin \theta \times b^2 = -M/d^3
\]

FIG. 5.

When \( P \) is the neutral point, \( H \) is equal and opposite to \( R \); therefore \( M = Hb^2 \), or the moment is numerically equal to the cube of the distance from the neutral point to the cube, multiplied by the M. MAGNETISM

The horizontal intensity of the earth's force. The distance between the poles may with sufficient accuracy for a rough determination be assumed to be equal to five-sixths of the length of the magnet.

Measurement of Magnetization and Induction.—The magnetic constants of a piece of ferromagnetic metal in different circumstances is determinable by various modes of experiment which may be classed as magnetometric, ballistic, and traction methods. When either the magnetization I or the induction B is given, the known; the other may be found by means of the formula $B = 4\pi I + H$.

Magnetometric Methods.—Intensity of magnetization is most directly measured by observing the action which a magnetized body, generally a long straight rod, exerts upon a small magnetic needle placed near it. The magnetic needle may be cemented horizontally across the back of a little plane or concave mirror, about $\frac{1}{2}$ or $\frac{3}{4}$ in. in diameter, which is suspended by a single fibre of unspun silk; this arrangement, when enclosed in a case with a glazed front to protect it from currents of air, constitutes a simple but efficient magnetometer. Deflections of the suspended needle are indicated by the movement of a narrow beam of light which the mirror reflects from a lamp and focusses upon a graduated cardboard scale placed at a distance of a few feet; the angular deflection of the beam of light is, of course, twice that of the needle. The suspended needle is, in the absence of disturbing causes, directly in a line with a horizontal component of the earth's field of magnetic force $H$, and therefore sets itself approximately north and south. The magnetized body which is to be tested should be placed in such a position that the force $H$, due to its poles may, at the spot occupied by the suspended needle, act in a direction at right angles to that due to the earth—that is, east and west. The direction of the resultant field of force will then make, with that of $H$, an angle $\theta$, such that $H_s / H = \tan \theta$, and the suspended needle will be deflected through the same angle. We have therefore

$$H_s = H \tan \theta.$$  

The angle $\theta$ is indicated by the position of the spot of light upon the scale, and the horizontal intensity of the earth's field $H_s$ is known; thus we can at once determine the value of $H_s$, from which the magnetization I of the body under test may be calculated.

In order to fulfill the requirement that the field which a magnetized rod produces at the magnetometer shall be at right angles to that of the earth, the rod may be conveniently placed in any one of three different positions with regard to the suspended needle.

1. The rod is set in a horizontal position level with the suspended needle, its axis being in a line which is perpendicular to the magnetic meridian, and which passes through the centre of suspension of the needle. This is called the "east-west" position, and is indicated in fig. 6. AB is the rod and C the middle point of its axis; NS is the magnetometer needle; AM bisects the undeflected needle NS at right angles. Let $2d$ be the length of the rod (or, more accurately, the distance between its poles), $v$ its volume, $m$ and $-m$ the strength of its poles, and let $d\theta$ the distance CM. For most ordinary purposes the length of the needle may be assumed to be negligible in comparison with the distance between the needle and the rod. We then have approximately for the force at $M$ due to the rod

$$H_s = \frac{m}{d} \tan \theta.$$  

whence we can find the values of $I$ which correspond to different angles of deflection.

2. The rod may be placed horizontally east and west in such a position that the direction of the undeflected suspended needle bisects it at right angles. This is known as the "broadside-on" position, and is represented in fig. 7. Let the distance of each pole of the rod AB, from the centre of the magnetometer needle = $d$. Then, since $H_s$, the force at $M$ due to $m$ and $-m$ is the resultant of $\frac{m}{d}$ and $\frac{-m}{d}$, we have

$$H_s = \frac{2m}{d}$$  

or

$$H_s = \frac{2m}{d} \tan \theta.$$  

The direction being parallel to AB.

And

$$I = \frac{dH_s}{v} + \frac{dH_s}{v} \tan \theta.$$  

(46)

(3) In the third position the test rod is placed vertically with one of its poles at the level of the magnetometer needle, and in the line drawn perpendicularly to the undeflected needle from its centre of suspension. The arrangement is shown in fig. 8, where AB is the vertical rod and M indicates the position of the magnetometer needle, which is supposed to be perpendicular to the plane of the paper. Denoting the distance of M from SM, BM by $d$, and AB by $l$, we have for the force at M due to the magnetism of the rod

$$H_s = \frac{m}{d^2} - \text{horizontal component of } \frac{m}{d^2}$$  

$$= \frac{m}{d^2} \left( \frac{1}{d^2} - \frac{d}{d^2} \right).$$  

Therefore

$$m = H_s = \frac{dH_s}{d^2} \tan \theta.$$  

and

$$I = \frac{dH_s}{v} \tan \theta.$$  

(47)

This last method of arrangement is called by Ewing the "one-pole" method, because the magnetometer deflection is mainly caused by the upper pole of the rod (Magnetic Induction, p. 40). For experiments with long thin rods or wires it has an advantage over the other arrangements in that the position of the poles need not be known with great accuracy, a small upward or downward displacement having little effect upon the magnetometer deflection. On the other hand, a vertically placed rod is subject to the inconvenience that it is influenced by the earth's magnetic field, which is not the case when the rod is horizontal and at right angles to the magnetic meridian. This extraneous influence may, however, be eliminated by surrounding the rod with a coil of wire carrying a current such as will produce in the interior a magnetic field equal and opposite to the vertical component of the earth's field.

If the cardboard scale upon which the beam of light is reflected by the magnetometer mirror is a flat one, the deflections as indicated by the movement of the spot of light are related to the actual deflections of the needle in the ratio of tan $2\theta$ to $\theta$. Since $2\theta$ is always small, sufficiently accurate results may generally be obtained if we assume that $\tan 2\theta = \tan \theta$. If the distance of the mirror from the scale is equal to $n$ scale divisions, and if a deflection $\theta$ of the needle causes the reflected spot of light to move over $s$ scale divisions, we shall have

$$s/n = \tan 2\theta$$  

exactly,

$$s/2n = \tan \theta$$  

approximately.

We may therefore generally substitute $s/n$ for $\tan \theta$ in the various expressions which have been given for $I$.

Of the three methods which have been described, the first two are generally the most suitable for determining the moment or the magnetization of a permanent magnet, and the last for studying the changes which occur in the magnetization of a long rod or wire when subjected to various external magnetic forces, or, in other words, for determining the relation of I to $H$. A plan of the apparatus as arranged by Ewing for the latter purpose is shown diagrammatically in fig. 9. The cardboard scale SS is placed above a wooden screen, having in it a narrow vertical slit which permits a beam of light from the lamp L to reach the mirror of the magnetometer M, whence it is reflected upon the scale. A is the upper end of a glass tube, half a metre or so in length, which is clamped in a vertical position behind the magnetometer. The tube is wound over its whole length with two separate coils of insulated wire, the one being outside the other. The inner coil is supplied, through the intervening apparatus, with current from the battery of secondary cells B; this produces the desired magnetic field inside the tube. The outer coil derives current, through an adjustable resistance R, from a
MAGNETISM

constant cell $B_2$; its object is to produce inside the tube a magnetic field equal and opposite to that due to the earth's magnetism. C is a compensating coil consisting of a few turns of wire through which the magnetizing current passes; it serves to neutralize the effect produced upon the magnetometer by the magnetizing coil, and its distance from the magnetometer is so adjusted that when the circuit is closed, no ferromagnetic metal being inside the magnetizing coil, the magnetometer needle undergoes no deflection. K is a commutator for reversing the direction of the magnetizing current, and G a galvanometer for measuring it.

The specimen upon which an experiment is to be made generally consists of a wire having a "dimensional ratio" of at least 300 or 400; its length should be rather less than that of the magnetizing coil in order that its length $L_0$ should be substantially uniform from end to end. The wire is supported inside the glass tube A with its upper pole at the same height as the magnetometer needle. Various currents are then passed through the magnetizing coil, the galvanometer readings and the simultaneous magnetometer deflections being noted. From the former we deduce $H_0$, and from the latter the corresponding value of I, using the formulae $H_0 = 4 \pi H / s$ and

$$ I = \frac{d^2 H_s}{2 \pi r^2} \left( 1 - \frac{d_s}{d} \right)^2 \times s, $$

where $s$ is the deflection in scale-divisions, $n$ the distance in scale-divisions between the scale and the mirror, and $r$ the radius of the wire.

The curve, fig. 10, shows the result of a typical experiment made upon a piece of soft iron (Ewing, *Phil. Trans.* vol. clxxvi. Plate 59), the magnetizing field $H_0$ being first gradually increased and then diminished to zero. When the length of the wire exceeds 400 diameters, or therefore $H_0$ may generally be considered as equivalent to $H_0$.

The actual strength of the field as modified by the magnetization of the wire; but if greater accuracy is desired, the value of $H_0 = (\pi N)$ may be found by the help of du Bois's table and subtracted from $H_0$. For a dimensional ratio of 400, $N = 0.00028$, and therefore $H_0 = H_0 - 0.00028 I$. This correction may be indicated in the diagram by a straight line drawn from 0 through the point at which the line of $I = 1000$ intersects that of $H = 0.2$ (Rayleigh, *Phil. Mag.* xxii. 175), the true value of $H$ for any point on the curve being that measured from the sloping line instead of from the vertical axis. The effect of the ends of the wire is, as Ewing remarks, to shear the diagram in the horizontal direction through the angle which the straight line makes with the vertical.

Since the induction $B$ is equal to $H + x I$, it is easy from the results of experiments such as that just described to deduce the relation between $B$ and $H$; a curve indicating such relation is called a curve of induction. The general character of curves of magnetization and of induction will be discussed later. A notable feature in both classes of curves is that, owing to hysteresis, the ascending and descending limbs do not coincide, but follow very different courses. If it is desired to annihilate the hysteretic effects of previous magnetization and restore the metal to its original condition, it may be demagnetized by reversals. This is effected by slowly moving the sliding contact (fig. 9) from $F$ to $D$, while at the same time the commutator $K$ is rapidly worked, a series of alternating currents of gradually diminishing strength being thus caused to pass through the magnetizing coil.

The magnetometric method, except when employed in connection with ellipsoids, for which the demagnetizing factors are accurately known, is generally less satisfactory for the exact determination of induction or magnetization than the ballistic method. But for much important experimental work it is better adapted than any other, and is indeed sometimes the only method possible.

**Ballistic Methods.**—The so-called "ballistic" method of measuring induction is based upon the fact that a change of the induction through a closed linear conductor sets up in the conductor an electromotive force which is proportional to the rate of change. If the conductor consists of a coil of wire the ends of which are connected with a suitable galvanometer, the integral electromotive force due to a sudden increase or decrease of the induction through the coil displaces in the circuit a quantity of electricity $T dB$ in $R$. Where the coil is the induction coil, inside of induction per square centimetre, $s$ is the area of the coil, $n$ the number of turns of wire, and $R$ the resistance of the circuit. Under the influence of the transient current, the galvanometer needle undergoes a momentary deflection, or "thow," which is proportional to $Q$, and therefore to $sB$, and thus, if we know the deflection produced by the discharge through the galvanometer of a given quantity of electricity, we have the means of determining the value of $sB$.

The galvanometer which is used for ballistic observations should have a deflection produced when subjected to a particular stimulus of less than five seconds, so that the transient current may have ceased before the swing has well begun; an instrument of the d'Arsonval type is now recommended, as it is unaffected by the magnetic influence, but also because the moving part can be instantaneously brought to rest by means of a short-circuit key, thus effecting a great saving of time when a series of observations is being made. In practice it is usual to standardize or "calibrate" the galvanometer by causing a known change of induction to take place within a standard coil connected with it, and noting the corresponding deflection on the galvanometer scale. Let $s$ be the area of a single turn of the standard coil, $n$ the number of its turns, and $r$ the resistance of the circuit of which the coil forms part; and let $S, N$ and $R$ be the corresponding constants for a coil which is to be used in an experiment. Then if the known change of induction of the standard coil is found to cause a throw of $d$ scale-divisions, any change of induction $dB$ through the experimental coil will be numerically equal to the corresponding throw $D$ multiplied by $sB/NNR$. For a series of experiments made with the same coil this fraction is constant, and we may write $sB = D$. Rowland and others have used an earth coil for calibrating the galvanometer, a known change of induction through the coil being produced by turning it over in the earth's magnetic field, but for several reasons it is preferable to employ an electric current as the source of a known induction. A primary coil of length $l$, having $n$ turns, is wound upon a cylinder made of a non-conducting and non-magnetic material with the middle of the primary's secondary or induction coil is closely fitted. When a current of strength $i$ is suddenly interrupted in the primary, the increment of induction through the coil is sensibly equal to $4 \pi l / i$, and the deflection is thus proportional to $4 \pi l / i$ units. All the data required for standardizing the galvanometer can in this way be determined with accuracy.

The ballistic method is largely employed for determining the relation of induction to magnetizing force in samples of the iron and steel used in the manufacture of electrical machinery, and especially for the observation of hysteresis effects. The sample may have the form of a closed ring, upon which are wound the induction coil and another coil for taking the magnetizing current; or it may consist of a long straight rod or wire which can be slipped into a magnetizing coil such as is used in the magnetometric experiments, the induction coil being wound upon the middle of the wire. With these arrangements there is no demagnetizing force to be considered, for the ring has not any ends to produce one, and the force due to the ends of a rod 400 or 500 diameters in length is quite insensible at the middle portion; $H$ therefore is equal to $H_0$.

E. Grassot has devised a galvanometer, or "fluxmeter," which greatly alleviates the tedious operation of taking ballistic readings. The instrument is of the same general type as a strong uniform field, and is suspended in such a manner that, if it is practically negligible, the swings of the coil being limited by damping influences, chiefly electromagnetic. The index therefore remains almost stationary at the limit of its deflection, and the deflection is approximately the same whether the change of induction occurs suddenly or gradually.

INDUCTION AND Hysteresis Curves.—Some typical induction curves copied from a paper by Ewing (Proc. Inst. C.E. vol. cxvii.), are given in figs. 11, 12 and 13. Fig. 11 shows the relation of B to H in a specimen which has never before been magnetized. The experiment may be made in two different ways: (1) the magnetizing current is increased by a series of sudden steps, each of which produces a ballistic throw, the value of B after any one throw being proportional to the sum of that and all the previous throws; (2) the magnetizing current having been brought to any desired value, C.G.S. units in the case illustrated in the figure), an operation which is performed by simply reversing the direction of the maximum magnetizing current a few times. The closed figure a c d e a is variously called a hysteresis curve or diagram or loop. The area HdB enclosed by it represents the work done in carrying a cubic centimetre of the iron through the corresponding magnetic cycle; expressed in ergs this work is

\[ \frac{1}{4} \pi HdB. \]

To quote an example given by J. A. Fleming, it requires about 18 foot-pounds of work to make a complete magnetic cycle in a cubic foot of wrought iron, strongly magnetized first in one direction and then the other, the work so expended taking the form of heat in the mass.

Fig. 14 shows diagrammatically a convenient arrangement described by Ewing (see Proc. Inst. C.E. vol. cxvi., and Phil. Trans., 1893, p. 987) for carrying out ballistic tests by which either the single B-H curve (fig. 11) or the hysteresis curve (figs. 12 and 13) can be determined. The sample under test is prepared in the form of a ring A, upon which are wound the induction and the magnetizing coils; the latter should be wound evenly over the whole ring, though for the sake of clearness only part of the winding is indicated in the diagram. The magnetizing current, which is derived from the storage battery B, is regulated by the adjustable resistance R and measured by the galvanometer G. The current passes through the rocking key K, which, when thrown over to the right, places a in contact with c and b with d, and when thrown over to the left, places a in contact with a and b with f. When the switch S is closed, K acts simply as a commutator or current-reverser, but if K is thrown over from right to left while S is opened, not only is the current reversed, but its strength is at the same time diminished by the interposition of the adjustable resistance R. The induction coil wound upon the ring is connected to the ballistic galvanometer G₂ in series with a large permanent resistance R₃. In the same circuit is also included the induction coil E, which is used for standardizing the galvanometer; this secondary coil is represented in the diagrams by three turns of wire wound over a much longer primary coil. The short-circuit key F is kept closed except when an observation is about to be made; its object is to arrest the swing of the d'Arsonval galvanometer. By means of the three-way switch C the battery current may be sent either into the primary of E, for the purpose of calibrating the galvanometer, or into the magnetizing coil of the ring under test. When it is desired to obtain a simple curve of induction, the switch S is thrown down and the procedure is as follows: The current is first adjusted by means of R to such a strength as will fit it to produce the greatest + and − values of the magnetizing force which it is desired to apply in the course of the cycle; then it is reversed several times, and when the range of the galvanometer throws has become constant, half the extent of an excursion indicates the induction corresponding to the extreme resistant point of H, and gives the maximum value a in the curve fig. 12. The reversing key K having been put over to the left side, the short-circuit key S is suddenly opened; this inserts the resistance R, which has been suitably adjusted beforehand, and thus reduces the current and therefore the magnetizing force to a known value. The galvanometer throw which results from the change of current measures the amount by which the induction is reduced, and thus a second point on the curve is obtained. In a similar manner, by giving different values to the resistance R, any desired number of points between a and c in the curve can be determined. To continue the process, the key K is turned over to the right-hand side, and then, while S is open, is turned back, thereby not only reversing the direction of the current, but diminishing its strength by an amount depending upon the previous adjustment of R₃. In this way points can be found lying anywhere between c and d of fig. 12, and the determination of the downward limb of the curve is therefore completed. As the return curve, shown in fig. 13, is merely a reversed copy of the other, no separate determination of it is necessary.

In fig. 15 (J. A. Fleming, Magnets and Electric Currents, p. 193) are shown three very different types of hysteresis curves, characteristic of the special qualities of the metals from which they were respectively obtained. The distinguishing feature of the first is the steepness of its outlines; this indicates that the induction increases rapidly in relation to the magnetic force, and hence the metal is well suited for the construction of dynamo magnets. The second has a very small area, meaning that the work done in reversing the magnetization is small; the metal is therefore adapted for use in alternating current transformers. On the other hand, the form of the third curve, with its large intercepts on the axes of H and B, denotes that the specimen to which it relates possesses both retentiveness and coercive force in a high degree; such a metal would be chosen for making good permanent magnets.

Several arrangements have been devised for determining hysteresis more easily and expeditiously than is possible by the ballistic method. The best known is J. A. Ewing's hysteresis-tester, which is specially intended for testing the sheet iron used in transformers. A specimen, arranged in the form of a number of rectangular strips, is caused to rotate about a central horizontal axis between the poles of an upright C-shaped magnet, which is supported near its middle upon knife-edges in such a manner that it can oscillate about an axis in a line with that about which the specimen rotates; the lower side of the magnet is weighted, to give it some stability. When the specimen rotates, the magnet is deflected from its upright position by the iron, which depends both on the work done in a single complete rotation, and therefore upon the hysteresis. The deflection is indicated by a pointer upon a graduated scale, the readings being interpreted by comparison with two standard specimens supplied with the instrument.

E. G. Warburg, Wied. Ann. 1881, 13, 141; Ewing, Phil. Trans., 1885, 176, 469; R. F. Hopkins, Phil. Trans., 1885, 176, 469; for simple proof, see Ewing, Magnetic Induction (1900), p. 99. Hopkins pointed out that the greatest dissipation of energy which can be obtained by a forward and reverse is approximately represented by 

\[ \text{Coercive force} \times \text{maximum induction} \times \text{area of loop}. \]
introduced the method of measuring hysteresis by means of an electro-dynamometer used ballistically. The fixed and suspended coils of the dynamometer are respectively connected in series with the magnetizing solenoid and with a secondary wound upon the specimen, W. When the magnetizing current is twice reversed, so as to complete a cycle, the sum of the two deflections, multiplied by a factor depending upon the sectional area of the specimen and the constants of the apparatus, gives the hysteresis for a complete cycle in ergs per cubic centimetre. For specimens of large sectional area, it is necessary to apply corrections in respect of the energy dissipated by eddy currents and in heating the secondary circuit. The method has been employed by the authors themselves in studying the effects of tension, torsion and circular magnetization, while R. L. Wills has made successful use of it in a research on the effects of temperature, a matter of great industrial importance.

Steinmetz (Electronics, 1891, 26, p. 261; 1892, 28, pp. 334, 408, 425) has called attention to a simple relation which appears to exist between the amount of energy dissipated in carrying a piece of iron or steel through a magnetic cycle and the limiting value of the inductive effects reached in the cycle. Denoting by W the work in ergs done upon a cubic centimetre of the metal

\[
\left( \frac{1}{4\pi} \int_{HdB} + \frac{1}{4\pi} \int_{HdI} \right),
\]

he finds \( W = -qB^2 \) approximately, where \( q \) is a number, called the \textit{hysteric constant}, depending upon the metal, and B is the maximum induction. The value of the constant \( q \) ranges in different metals from about 0.001 to 0.04; in soft iron and steel it is said to be generally not far from 0.002. Steinmetz' formula may be tested by taking a series of hysteresis curves between different limits of B, measuring their areas by a planimeter, and plotting the logarithms of these divided by \( \pi B \) as ordinates against logarithms of the corresponding maximum values of B as abscissae. The area thus constructed should be a straight line passing through the horizontal axis at an angle \( \theta \), tangent of which is 1-6. Ewing and H. G. Klaassen (Phil. Trans., 1893, 184, 1017) have in this manner examined how nearly and within what range a formula of the type \( W = \frac{1}{4\pi} B^2 \) may be taken to represent the facts. The results of an example which they quote in detail may be briefly summarized as follows:

<table>

It is required by the experimenters that the value of the index \( q \) is by no means constant, but changes in correspondence with the successive well-marked stages in the process of magnetization. But though a formula of this type has no physical significance, and cannot be accepted as an equation to the actual curve of W and B, it is, nevertheless, the case that by making the index \( q = 1.6 \), and assigning a suitable value to \( q \), a formula may be obtained giving a very close approximation to the truth which is sufficiently close for the ordinary purposes of electrical engineers, especially when the limiting value of B is neither very great nor very small. Alexander Siemens (Journ. Inst. Eng., 1894, 25, 229) states that in the hundreds of comparisons of test pieces which have been made at the works of his firm, Steinmetz's law has been found to be practically correct. An interesting collection of W-B curves embodying the results of actual experiments by Ewing and Klaassen on different specimens of metal is given in fig. 16. It has been shown by Kennelly (Electrician, 1892, 28, 666) that Steinmetz's formula gives approximately correct results in the case of nickel. Working with two different specimens, he found that the hysteresis loss in ergs per cubic centimetre (W) was fairly represented by 0.00125B\(^2\) and 0.00101B\(^2\) respectively, the maximum induction ranging from about 300 to 3000. The applicability of this formula to cobalt has been investigated by Fleming (Phil. Mag., 1890, 48, 271), who used a ring of cast cobalt containing about 96% of the pure metal. The logarithmic curves which accompany his paper demonstrate that within wide ranges of maximum induction W = 0.011B\(^2\) = 0.5271\(^2\) very nearly. Fleming rightly regards it as not a little curious that for materials differing so much as this cast cobalt and soft iron, the hysteric exponent should in both cases be so near to 1.6. After pointing out the circumstance, that since the magnetization of the metal is the quantity really concerned, W is more appropriately expressed in terms of I, the magnetic moment per unit of volume, that 1.6 is the exponent to determine whether the mechanical work required to effect the complete magnetic reversal of a crowd of small compass needles (representative of magnetic molecules) is proportional to the 1.6th power of the aggregate maximum magnetic moment before or after completion of the cycle.

The experiments of K. Honda and S. Shimizu\(^1\) indicate that Steinmetz' should hold for nickel and annealed cobalt up to \( B = 3000 \), for cast cobalt and tungsten steel up to \( B = 8000 \), and for Swedish iron up to \( B = 18000 \), the range being in all cases extended at the temperature of liquid air.

The diagram, fig. 17, contains examples of ascending induction curves characteristic of wrought iron, cast iron, cobalt and nickel.

\(^{1}\) Phil. Mag., 1903, 5, 117.
\(^{2}\) Some experiments by F. G. Baily showed that hysteresis ceased to increase when \( B \) was carried beyond 23,000. This value of \( B \) corresponds to \( m = 1620 \), the saturation point for soft iron.—\textit{Brit. Assoc. Rep.}, 1895, p. 636.

MAGNETISM

The considerable magnetizing force to Inst. metal. A.
then results more exceptionally. A quantity of permeability, presence of theory.
the metal to reach the magnetizing force of the metal.
the ascent of the curve. The curve bends over, forming what is often called a "knee," and a third stage is entered upon, during which a considerable increase of magnetizing force has little further effect upon the magnetization. When in this condition the metal is popularly said to be "saturated." Under increasing magnetizing forces, greatly exceeding those comprised within the limits of the diagram, the magnetization does practically reach a limit, the maximum value being attained with a magnetizing force of less than 2000 for wrought iron and nickel, and less than 4000 for cast iron and cobalt. The Induction, however, continues to increase indefinitely, though very slowly. These observations have an important bearing upon the molecular theory of magnetism, which will be referred to later.

The magnetic quality of a sample of iron depends very largely upon the purity and physical condition of the metal. The presence of ordinary impurities usually tends to diminish the permeability, though, as will appear later, the addition of small quantities of certain other substances is sometimes advantageous. A very pure form of iron, which from the method of its manufacture is called "steel," is now extensively used for the construction of dynamo magnets; this metal sometimes contains not more than 0.3% of foreign substances, including carbon, and is magnetically superior to the best commercial wrought iron. The results of some comparative tests published by Ewing (Proc. Inst. C.E., 1896) are given in the accompanying table. Those in the second column are quoted from a paper by F. Lydall and A. W. Pocklington (Proc. Roy. Soc., 1892, 52, 228) and relate to an exceptional specimen containing nearly 99.9% of the pure metal.

To secure the highest possible permeability it is essential that the iron should be softened by careful annealing. When it is mechanically hardened by hammering, rolling or wire-drawing its permeability may be greatly diminished, especially under a moderate magnetizing force. An experiment by Ewing showed that when the operation of stretching an annealed iron wire beyond the limits of elasticity the permeability under a magnetizing force of about 3 units was reduced by as much as 75%. Ewing has also studied the effect of vibration in conferring upon iron an apparent or spurious permeability of high value; this effect also is most conspicuous when the magnetizing force is weak. The permeability of a soft iron wire, which was tapped while subjected to a very small magnetizing force, rose to the enormous value of about 80,000 (Magnetic Induction, § 85). It follows that in testing iron for magnetic quality the greatest care must be exercised to guard the specimen against any accidental vibration.

Low hysteresis is the chief requisite for iron which is to be used for transformer cores, and it does not necessarily accompany high permeability. In response to the demand, manufacturers have succeeded in producing transformer plate in which the loss of energy due to hysteresis is exceedingly small. Tests of a sample supplied by Messrs. Sankey were found by Ewing to give the following results, which, however, are regarded as being unusually favourable. In a valuable collection of magnetic data (Proc. Inst. C.E., cxxi.) H. F. Parshall quotes tests of six samples of iron, described as of good quality, which showed an average hysteresis loss of 3070 ergs per c.c.m. per cycle at an induction of 8000, being 1.6 times the loss shown by Ewing's specimen at the same induction.

The standard induction in reference to determinations of hysteresis is generally taken as 2500, while the loss is expressed in watts per lb at a frequency of 100 double reversals, or cycles, per second. In many experiments, however, different inductions and frequencies are employed, and the hysteresis-loss is often expressed as ergs per cubic centimetre per cycle and sometimes as horse-power per ton. In order to save arithmetical labour it is convenient to be provided with conversion factors for reducing variously expressed results to the standard form. The rate at which energy is lost being proportional to the frequency, it is obvious that the loss at frequency 100 may be deduced from that at any other frequency n by simply multiplying by n/100. Taking the density of iron to be 7.8, the factor for reducing the loss in ergs per c.c.m. to watts per lb with a frequency of 100 is 0.009580 (Ewing). Since 1 horse-power = 746 watts, and 1 ton = 2240 lb, the factor for reducing horse-power per ton to watts per lb is 746/2240, or just 1/3. The loss for any induction B within the range for which Steinmetz's law holds may be converted into that for the standard induction 2500 by dividing it by B²/2500³. The values of this ratio for different values of B, as given by Fleming (Phil. Mag., 1897), are contained in the second column of the annexed table. The third column shows the relative amount of hysteresis deduced by Ewing as a general mean from actual tests of many samples (Journ. Inst. Elec. Eng., 1895). Incidentally, these two columns furnish an undesigned test of the accuracy of Steinmetz's law: the greatest difference is little more than 1%.

Curves of Permeability and Susceptibility.—The relations of ρ = B/H to B, and of χ = (1/H) to 1 may be instructively exhibited by means of curves, a method first employed by H. A. Rowland.¹ The dotted curves for ρ and χ in fig. 18 is copied from Rowland's paper. The actual experiment to which it relates was carried only as the point marked X, corresponding to a magnetizing force of 65, and an induction of nearly 17,000. Rowland, believing that the curve would continue to fall in a straight line meeting the horizontal axis, inferred that the induction corresponding to the point B—about 17,500—was the highest.

¹Phil. Mag., 1873, 46, 140.
that could be produced by any magnetizing force, however great. It has, however, been shown that, if the magnetizing force is carried far enough, the curve always becomes convex to the axis instead of meeting it. The full line shows the result of an experiment in which the magnetizing force was carried up to 585, by reversals—the source of error due to the transverse cut thus being avoided. Ewing (Magnetic Induction, § 194) has devised an arrangement in which two similar test bars are placed side by side; each bar is surrounded by a magnetizing coil, the two coils being connected to give opposite directions of magnetization, and each pair of ends is connected by a short massive block of soft iron having holes bored through it to fit the bars, which are clamped in position by set-screws. Induction coils are wound on the middle parts of both bars, and are connected in series. With this arrangement it is possible to find the actual value of the magnetizing force, corrected for the effects of joints and other sources of error. Two sets of observations are taken, one when the blocks are fixed at the ends of the bars, and another when they are nearer together, the clear length of the bars between them and of the magnetizing coils being reduced to one-half. If \( H_1 \) and \( H_2 \) be the values of \( 4\pi n_1/2 \) and \( 4\pi n_2/2 \) for the same induction \( B \), it can be shown that the true magnetizing force is \( H = H_1 - (H_2 - H_1) \). The method, though tedious in operation, is very accurate, and is largely employed for determining the magnetic quality of bars intended to serve as standards.

**Traction Methods.**—The induction of the magnetization may be measured by observing the force required to draw apart the two portions of a divided rod or ring when held together by their mutual attraction. If a transverse cut is made through a bar whose magnetization is \( I \) and the two ends are placed in contact, it can be shown that this force is \( 2\pi F \) dynes per unit of area (Mascart and Joubert, Electrivity and Magnetism, § 322; and if the magnetization of the bar is due to an external field \( H \) produced by a magnetizing coil or otherwise, there is an additional force equal to \( H \). Thus the whole force, when the two portions of the bar are surrounded by a loosely-fitting magnetizing coil, is

\[
F = 2\pi F + H
\]

expressed as dynes per square centimetre. If each portion of the bar has an independent magnetizing coil wound tightly upon it, we have further to take into account the force due to the mutual action of the two magnetizing coils, which assists the forces already considered. This is equal to \( H' \) sq. for unit of sectional area. In the case supposed therefore the total force per square centimetre is

\[
F = 2\pi F + H + H' = \frac{(4\pi n + H' - 8\pi)2}{8\pi} = \frac{B^2}{8\pi}
\]

The equation \( F = B^2/8\pi \) is often said to express "Maxwell's law of magnetic traction" (Maxwell, Electricity and Magnetism, §§ 642-645). It is, of course, true for permanent magnets, where \( H = 0 \), since then \( F = 2\pi F \); but if the magnetization is due to electric currents, the formula is only applicable in the special case when the mutual action of the two magnets upon one another is supplemented by the electromagnetic attraction between separate magnetizing coils rigidly attached to them.

The traction method was first employed by S. Bidwell (Proc. Roy. Soc., 1886, 46, 486), who in 1886 published an account of some experiments in which the relation of magnetization to magnetic field was deduced from observations of the force in gramma weight which just sufficed to tear asunder the two halves of a divided ring electro-magnet when known currents were passing through the coils. He made use of the expression

\[
F = W F_0 - 2\pi F - H
\]

where \( W \) is the weight in gramma per square centimetre of sectional area, and \( g \) is the intensity of gravity which was taken as 981. The term for the attraction between the coils was omitted as negligibly small (see Phil. Mag., 1890, 29, 440). The values assigned to \( H \) were calculated from \( H = 2\pi n/i \), and ranged from 3.9 to 585, but inasmuch as no account was taken of any

1 Since in most practicable experiments \( H' \) is negligible in comparison with \( B' \), the force may be taken as \( B' \) without sensible error.
demagnetizing action which might be due to the two transverse cuts, it is probable that they are somewhat too high. The results, nevertheless, agree very well with those for annealed wrought iron obtained by other methods. Below is given a selection from Bidwell's tables, showing corresponding values of magnetizing force, weight supported, magnetization, induction, susceptibility and permeability:

A few months later R. H. M. Bosanquet (Phil. Mag., 1886, 22, 533) experimented on the relation of transverse force to magnetic susceptibility, and employed a divided straight bar, each half of which was provided with a magnetizing coil. The joint was surrounded by an induction coil connected with a ballistic galvanometer, an arrangement which enabled him to make an independent measurement of the induction at the moment when the two portions of the bar were separated. He showed that there was, on the whole, a fair agreement between the values determined ballistically and those given by the formula $B = V^2/F$. The greatest weight supported in the experiments was $34,100$ grams per centimetre, and the corresponding induction $18,500$ units. Taylor Jones subsequently found a good agreement between the theoretical and the observed values of the transverse force in fields ranging up to very high intensities.

(Phil. Mag., 1895, 39, 254, and 1896, 41, 753.)

Permeameters.—Several instruments in which the traction method is applied have been devised for the rapid measurement of induction or of magnetization in commercial samples of iron and steel. The earliest of these is S. P. Thompson's permeameter (Journ. Sci. Arts, 1890, 38, 885), which consists of a rectangular block of iron shaped like Hopkins's yoke, and isolated from the bar in the same way to the magnetizing coil (fig. 20); the block is bored through at the upper end only, and its inner face opposite the hole is made quite flat and smooth. The block is placed in a test rod, one end of which is fixed to the yoke, and the other is made to slide into the block. If the block is moved from the fixed position, the iron is considered to be removed from the yoke, and the induction in the iron is considered to be the same as in the iron of the block. This method is used by Böck (Magnetische Circuits, p. 346) and the uncertainty arising from the present of a joint is avoided, the force measured being that exerted between two pieces of iron separated by the induction coil and of known width. The instrument is represented diagrammatically in fig. 21. The test piece, A, surrounded by a magnetizing coil, is clamped between two soft iron blocks B, B'. $V^2$ is a soft iron yoke, which rocks upon knife-edges $K$ and constitutes the beam of the balance. The yoke has two projecting pieces C, C' at unequal distances from the knife-edges, and separated from the blocks B, B' by narrow air-gaps. The play of the beam is limited by a stop S and a screw R, the latter being adjusted so that the end $Y$ of the beam is held down by the two air-gaps are equal of are equal. $W$ is a weight capable of sliding from end to end of the yoke, and the scale is graduated. When there is no magnetization the yoke is in equilibrium; but as the current in the coil turns on the block C is drawn downwards as far as $Y$ will allow, until the attractive forces $F$ between B and C and between B' and C are equal, the former has a greater moment. The weight $W$ is moved along the scale until the yoke just (the upper arm of the instrument is in equilibrium; the coil is turned from its zero position, then it can be easily shown, proportional to F, and therefore to $B'$, and approximated to $B$). The scale is graduated in such a manner that by multiplying the reading by a simple factor (generally 10 or 2) the absolute value of the magnetization is obtained. The actual magnetizing force $H$ is of course less than that due to the coil; the corrections required are effected automatically by the use of a set of compression of electrical resistances by the Wheatstone bridge, with the instrument. The coil is laid upon the square paper, and in plotting a curve horizontal distances are reckoned from the proper demagnetization line instead of from the vertical axis. The instrument is improved but somewhat more complicated form of the instrument is described in Ann. d. Phys., 1900, 2, 347.

In Ewing's magnetic balance (Journ. Inst. Elec. Eng., 1898, 27, 526) the demagnetizing force is directly read off on a divided scale. The specimen, which has the form of a turned rod, 4 in. long and 4 in. in diameter, is laid across the poles of a horseshoe electromagnet, excited by a current of just such strength as to produce in the rod a demagnetizing force $H = 20$. One pole has a W-shaped notch for the rod to rest in; the surface of the other is slightly rounded, forming a portion of a cylinder, the axis of which is perpendicular to the direction of the length of the rod. The rod touches this pole at a single point, and is pulled away from it by the action of a lever, the long arm of which is graduated and carries a sliding weight. The position of the weight is adjusted when current is passed through the rod. The standard force $H = 20$ was selected as being sufficiently low to distinguish between good and bad specimens, and at the same time sufficiently high to make the order of the same as it would be under larger forces.

Permeameter Bridge.—Several pieces of apparatus have been invented for measuring the magnetic quality of a sample with that of a standard iron rod by a zero method such as is employed in the Wheatstone bridge. An excellent instrument of the class is Ewing's permeability bridge. The standard rod and the test specimen, must be of the same dimensions, be placed in the same way with the same magnetic current, and each of the two pair of adjacent ends is joined by a short rectangular block or "yoke" of soft iron. An iron bar shaped like an inverted L projects upwards from each of the yokes, the horizontal portions of the bars are parallel, and the upper ends of the bars are of about 8 in. above them (thus $F$). A compass needle placed in the gap serves to detect any flow of induction that may exist between the yoke bars. For simplicity of calculation, the clear length of the test and the standard rods respectively; then $H_{1} = H_{2} = H_{3}$. The value of $B$ which corresponds to $H_{1} = H_{2} / 100$ can be found from the
Thus, a is to be determined; and this same value corresponds to the force H in the case of the latter. Thus any desired one of the corresponding values of H and B can be easily and quickly found.

**Measurement of Field Strength.** Exploring Cell.—Since in a coil, the ballistic method of measuring induction described above is also available for determining the strength of a magnetic field, and is more often employed than any other. A small coil of fine wire, connected in series with a ballistic galvanometer, is placed in the field, with its windings perpendicular to the lines of force, and then suddenly reversed or withdrawn from the field, the integral electromotive force being twice as great in the first case as in the second. The strength of the field is proportional to the swing of the galvanometer-needle, and, when the galvanometer is calibrated, can be expressed in C.G.S. units. Convenient arrangements have been introduced whereby the coil is reversed or withdrawn from the field by the action of a spring.

**Bismuth Resistance.—** The fact, which will be referred to later, that the electrical resistance of bismuth is very greatly affected by a magnetic field has been applied in the construction of apparatus for measuring field intensity. A little instrument, suspended by fine wire and spring, contains a short length of fine bismuth wire wound into a flat double spiral, half an inch or thereabouts in diameter, and attached to a long ebonite handle. Unfortunately the effects of magnetization upon the specific resistance of bismuth vary enormously with changes of temperature; it is therefore necessary to take two readings of the resistance, one when the spiral is in the magnetic field, the other when it is outside.

**Electric Circuit.—** If a coil of insulated wire is suspended so that it is in stable equilibrium when its plane is parallel to the direction of the magnetic field, the transmission of a known electric current through the coil will cause it to be deflected through an angle which is a function of the field intensity.

One of the earliest applications of this principle is that described by Edser and Stansfield (Phil. Mag., 1893, 34, 186), and used by them to test the stray fields of dynamos. An oblong coil about an inch in length is suspended from each end by thin strips of rolled German silver wire, one of which is connected with a spiral spring for regulating the tension, the other being attached to a torsion-head. Inside the torsion-head is a commutator for automatically reversing the current, so that readings may be taken on each side of zero, and the arrangement is such that when the torsion-head is exactly at zero the current is interrupted. To take a reading the torsion-head is raised to its highest position points of contact to the coil is brought up to the zero position on a small scale; the strength of the field is then proportional to the angular torsion. The small current required is supplied to the coil from a single dry cell. The advantages of polarity, and the valuable range of H (1 upwards), and the fair accuracy claimed for the instrument.

**Polarized Light.—** The intensity of a field may be measured by the rotation of the plane of polarization of light passing in the direction of the magnetic force through a transparent substance. If the field is uniform, $H = \theta d f$, where $\theta$ is the rotation, $d$ the thickness of the substance arranged as a plate at right angles to the direction of the field, and $\omega$ Verdet’s constant for the substance.

For the practical measurement of field intensity du Bois has used plates of the densest Jenfl tint glass. These are preferably made slightly wedge-shape, to avoid the inconvenience resulting from multiple internal reflections, and they must necessarily be rather thin, so that double refractions due to internal strains may not exert a disturbing influence. Since Verdet’s constant is somewhat uncertain for different batches of glass even of the same quality, each plate is calibrated in a field of known intensity. As the source of monochromatic light a bright sodium burner is used, and the rotation, which is exactly proportional to $H$, is measured by an accurate polarimeter. Such a plate about 1 mm. in thickness is said to have a very small effect upon the rotation of the beam, and, moreover, the arrangement is, for certain experiments, more convenient than the other.

4. **Magnetization in Strong Fields**

**Fields due to Coils.—** The most generally convenient arrangement for producing such magnetic fields as are required for experimental purposes is undoubtedly a coil of wire through which an electric current can be caused to flow. The field due to a coil can be made as nearly uniform as we please throughout a considerable space; its intensity, when the constants of the coil are known, can be calculated with ease and certainty and may be varied at will through wide ranges, while the apparatus required is of the simplest character and can be readily constructed to suit special purposes. But when exceptionally strong fields are desired, the use of a coil is limited by the heating effect of the magnetizing current, the quantity of heat generated per unit of time in a coil of given dimensions increasing as the square of the magnetic field produced in its interior. In experiments on magnetic strains carried out by H. Nagaoaka and K. Honda (Phil. Mag., 1900, 49, 329) the intensity of the highest field reached in the interior of a coil was 2200 units; this is probably the strongest field produced by a coil which has hitherto been employed in experimental work. In 1890 some experiments in which a coil was used were made by du Bois (Phil. Mag., 1890, 29, 253, 293) on the magnetization of iron, nickel, and cobalt under forces ranging from about 100 to 1250 units. Since the demagnetizing factor was 0.052, the strongest field due to the coil was about 1350; but though arrangements were provided for cooling the apparatus by means of ice, great difficulty was experienced owing to heating. Du Bois’s results, which, as given in his papers, show the relation of $H$ to the magnetic moment per unit of mass, have been reduced by Ewing to the usual form, and are indicated in fig. 22, the earlier portions of the curves being sketched in from other data.

**Fields due to Electromagnets.—** The problem of determining the magnetization of iron and other metals in the strong fields formed between the poles of an electromagnet was first attacked by J. A. Ewing and W. Low. An account of their preliminary experiments by what they call the *isthmus method* was published in 1887 (Proc. Roy. Soc. 42, 200), and in the following year they described a more complete and perfect series (Phil. Trans., 1889, 180, 221).

The sample to be inserted between the magnet poles was prepared in the form of a bobbin resembling an ordinary cotton reel, with a ferromagnetic neck (constituting the "isthmus") and a number of coils surrounding it. Upon the central neck was wound a coil consisting of one or two layers of very fine wire, which was connected with a ballistic galvanometer for measuring the induction in the iron; outside this coil, and separated from it by a small and accurately determined distance, a second coil was wound, serving to measure the induction in the iron, together with that in a small space surrounding it. The difference of the ballistic throws taken with the two coils measured the intensity of the field in the space around the iron, and it also enabled a correction to be made for the non-ferrous space between the iron neck and the centre of the thickness of the inner coil. The pole pieces of the electromagnet (see fig. 23) were furnished with a pair of semi-cone shaped cones $b, b$, of soft iron forming an extension of the conical ends of the bobbin $e$. The pole pieces were of steel for the pole faces is investigated in the paper, and the conclusion arrived at is that to produce the greatest concentration of force upon the central portion of the bobbin it should have a common vertex in the middle of the neck with a semi-vertical angle of $54^\circ 44'$, while the condition for a uniform field is satisfied when the cones have a semi-vertical angle of $30^\circ$, the latter case the magnetic force in the air just outside is sensibly equal to that within the neck. A pair of cones having a semi-vertical angle of $45^\circ$ were considered to combine high magnetic attractive power with good uniformity of field. In most of the experiments the measurements were made by suddenly withdrawing the bobbin from its place...
between the pole pieces. Two groups of observations were recorded, one giving the induction in the inner coil and the other that in the outer coil. The value of the residual induction which persisted when the bobbin was drawn out was added to that of the induction measured, and thus the total induction in the iron was determined. The highest induction reached in these experiments was 44,350 units, more than twice the value of any previously recorded. The corresponding intensity in the outside field was 2,450, but, owing to the wide angle of the cones used (about 2×63°), this was probably greater than the value of the magnetic force within the metal. The following table shows some results of other experiments in which H was believed to have sensibly the same value inside as outside the metal. Values of I are derived from (B-\(H\))/4π and of \(I\) from BH.

These results are of extreme interest, for they show that under sufficiently strong magnetizing forces the intensity of magnetization I reaches a maximum value, as required by W. E. Weber's theory of molecular magnetism. There appears to be no definite limit to the value to which the induction B may be raised, but the magnetization I attains a true saturation value under magnetizing forces which are in most cases comparatively moderate. Thus the magnetization which the sample of Swedish iron received in a field of 1490 was not increased (beyond the limits of experimental error) when the intensity of the field was multiplied more than six-fold, though the induction was nearly doubled. When the saturation value of I has been reached, the relation of magnetic induction to magnetic force may be expressed by

\[B = H + 4\pi I\]

The annexed table gives the saturation values of I for the particular metals examined by Ewing and Low:

| Saturation |
| Value of I |
| Wrought iron | 1,700 |
| Cast iron   | 1,240 |
| Nickel (0.75% iron) | 515 |
| Cobalt (1.06% iron) | 400 |

It can be shown in the paper that the greatest possible force which the isthmus method can apply at a point in the abscissa of the bobbin is

\[F = 11 + 13I, \text{ logs } I / a\]

where \(I\) is the saturation value of the magnet poles, \(a\) is the radius of the neck on which the cones converge, and \(b\) is the radius of the bases of the cones.

Some experiments made by H. du Bois (Phil. Mag., 1890, 20, 203) with an electromagnet specially designed for the production of strong fields, confirm Ewing's results for iron, nickel and cobalt. The method employed did not admit of the production of such high magnetizing forces, but was of special interest in that both B and I were measured optically—B by means of the rotation of a polarized ray inside a glass plate, as described, and I by the rotation of a polarized ray reflected from the polished surface of the magnetized metal (see "Kerr's constant," Magneto-Optics). \(H = B - 4\pi I\) was calculated from corresponding values of I and B. Taylor Jones (Wied. Ann., 1896, 57, 255, and Phil. Mag., 1896, 41, 153) working with du Bois's electromagnet and using a modification of the isthmus method, succeeded in pushing the induction B up to 74,290 with \(H = 51,600\), the corresponding value of I being 1728, and of \(\mu\) only 1.44. The diameter of the isthmus was 0.241 mm., and the electromagnet was excited by a current of 40 amperes.

**Tractive Force of a Magnet.**—Closely connected with the results just discussed is the question what is the greatest tractive force that can be exerted by a magnet. In the year 1852 J. P. Joule (Phil. Mag., 1852, 3, 32) expressed the opinion that "force of current could give an attraction equal to 300 lb per sq. in.," or 14,000 grms. per square centimetre, and a similar view prevailed among high authorities more than twenty years later. For the greatest possible "lifting power" of permanent magnets this estimate is probably not very far from the truth, but it is now clearly understood that the force which can be exerted by an electromagnet, or by a pair of electromagnets with opposite poles in contact, is only limited by the greatest value to which it is practically possible to raise the magnetizing force H. This is at once evident when the tractive force due to magnetization is expressed as \(2\pi re\), where \(r\) is the radius of the coil of moderately intense magnetization. The first term of the expression is the more important, but when the value of H exceeds 12,000 or thereabouts, the second preponderates, and with the highest values that have been actually obtained, \(H\) is several times greater than \(2\pi r\). If \(H\) could be increased without limit, so also could the tractive force. The following table shows the greatest "lifting powers" experimentally reached at the dates mentioned:

5. **Magnetism in Very Weak Fields**

Some interesting observations have been made of the effects produced by very small magnetic forces. It was first pointed out by C. Baur (Wied. Ann., 1880, 11, 399) that in weak fields the relation of the magnetization I to the magnetizing force H is approximately expressed by an equation of the form

\[I = \alpha H + \beta H^2\]

or \(\kappa = H + a-bH\),

whence it appears that within the limits of Baur's experiments the magnetization curve is a parabola, and the susceptibility curve an inclined straight line, \(\kappa\) being therefore a known function of \(H\). If these equations could be assumed to hold when \(H\) is indefinitely small, it would follow that \(\kappa\) has a finite initial value, from which there would be no appreciable deviation in fields so weak that \(H\) was negligibly small in comparison with \(a\). Such an assumption could not, however, without dangerous extrapolation, be founded upon the results of Baur's experiments, which did not go far enough to justify it. In some experiments carried out in 1887, Lord Rayleigh (Phil. Mag., 1887, 23, 225) approached very much more nearly to Baur to the zero of magnetic force. Using an annealed Swedish iron wire, he found that when \(H\) was gradually diminished from 0.04 to 0.0004 C.G.S. unit, the ratio of magnetization to magnetizing force remained sensibly constant at 6.4, which may therefore with great probability be assumed to represent the initial value of \(\kappa\) for the specimen in question. Experiments with annealed iron gave less satisfactory results, on account of the slowness with which the metal settled down into a new magnetic state, thus causing a "drift" of the magnetometer needle, which sometimes persisted for several seconds. Apart from this complication, it appeared that \(I\) was proportional to \(H\) when the value of \(H\) was less than 0.02.
The observations of Baur and Rayleigh have been confirmed and discussed by (amongst others) W. Schmidt (Wied. Ann., 1895, 54, 655), who found the limiting values of \( k \) to be 7.5 to 9.5 for iron, and 11 to 13.5 for steel, remaining constant up to \( H = 66 \); by P. Cullmann (Eidg. Techn. Hochsch., 1895, 6, 602; and L. Holborn (Berl. Ber., 1897, p. 95, and Wied. Ann., 1897, 61, 281). The latter gives values of the constants \( a \) and \( b \) for different samples of iron and steel, some of which are shown in the following table:

</table>

For most samples of steel the straight-line law was found to hold approximately up to \( H = 3 \); in the case of iron and of soft steel the approximation was less close.

The behaviour of nickel in weak fields has been observed by Ewing (Phil. Trans., 1885, 179, 325), who found that the initial value of \( k \) was very nearly unity, and that it remained sensibly constant until \( H = 5 \), when it began to fall to a value of about five units. While therefore the initial susceptibility of nickel is less than that of iron and steel, the range of magnetic force within which it is approximately constant is about one hundred times greater. Ewing has also made a careful study (Proc. Roy. Soc., 1889, 46, 269) of "magnetic viscosity" under small forces—the cause of the magnetometer "drift" referred to by Rayleigh. On the application of a small magnetizing force to a bar of soft annealed iron, a certain intensity of magnetization is instantly produced; this, however, does not remain constant, but slowly increases for some seconds or even minutes, and may ultimately attain a value nearly twice as great as that observed immediately after the force was applied.\(^1\) When the magnetizing current is broken, the magnetization at once undergoes considerable diminution, then gradually falls to zero, and a similar sudden change followed by a slow one is observed when a feeble current is reversed. Ewing draws attention to a curious consequence of this time-lag. By the alternate application and withdrawal of a small magnetizing force a cyclic condition may be established in an iron rod. If now the alternations are performed so rapidly that time is not allowed for more than the first sudden change in the magnetization, there will be no hysteresis loss, the magnetization exactly following the magnetizing force. Further, if the alternations take place so slowly that the full maximum and minimum values of the magnetization are reached in the intervals between the reversals, there will again be no dissipation of energy. But at any intermediate frequency the ascending and descending curves of magnetization will enclose a space, and energy will be dissipated. It is remarkable that the phenomena of magnetic viscosity are much more evident in a thick rod than in a thin wire, or even in a large bundle of thin wires. In hardened iron and steel the effect can scarcely be detected, and in weak fields these metals exhibit no magnetic hysteresis of any kind.

6. Changes of Dimensions Attending Magnetization

It is well known that the form of a piece of ferromagnetic metal is in general slightly changed by magnetization. The phenomenon was first noticed by J. P. Joule, who in 1842 and 1845 described some experiments which he had made upon bars of iron and steel. His observations were for the most part confirmed by a number of subsequent workers, notably by A. M. Mayer; but with the single exception of the discovery by W. F. Barrett in 1882 that a nickel bar contracts when magnetized, nothing of importance was added by Joule's results for nearly forty years. Later investigations have however thrown much new light upon a class of phenomena which cannot fail to have an important bearing upon the complete theory of molecular magnetism.\(^2\) According to Joule's observations, the length of a bar of iron or soft steel was increased by magnetization, the elongation being proportional up to a certain point to the square of the intensity of magnetization; but when the "saturation point" was approached the elongation was less than this law would require, and a stage was finally reached at which further increase of the magnetizing force produced little or no effect upon the length. From data contained in Joule's paper it may be calculated that the strongest external field \( H_0 \) produced by his coil was about 126 C.G.S. units, but since the dimensional ratio of his bars was comparatively small, the actual magnetizing force \( H \) must have been materially below that value. In 1885 it was shown by Bidwell, in the first of a series of papers on the subject, that if the magnetizing force is pushed beyond the point at which Joule discontinued his experiments, the extension of the bar does not remain unchanged, but becomes gradually less and less, until the bar, after first returning to its original length, ultimately becomes actually shorter than when in the un magnetized condition. The elongation is generally found to reach a maximum under a magnetizing force of 50 to 120 units, and to vary in a complicated manner with the force for values above 250. Various explanations have been occurring when still higher forces are applied. In order to meet the objection that the phenomenon might be due to electromagnetic action between the coil and the rod, Bidwell made some experiments with iron rings, and found that the length of their diameters varied under magnetization in precisely the same manner as the length of a straight rod. Experiments were afterwards made with rods of iron, nickel, and cobalt, the external field being carried up to the very high value of 1500 units. The results are indicated in Fig. 24. It appears that the contraction which followed the initial extension of the iron reached a limit in fields of 1000 or 1100. Nickel exhibited retraction from the very beginning, as observed by Barrett, its greatest change of length was considerably exceeding that undergone by iron; in a field of 800 the original length was diminished by as much as 1/40,000 part, but stronger forces failed to produce any further effect. The curve for cobalt is a very remarkable one. Little or no change of length was observed until the strength of the field \( H_0 \) reached about 50; then the rod began to contract, and after passing a minimum at \( H = 400 \) recovered its original length at \( H = 750 \); beyond this point there was extension, the amount of which was still increasing fast when the experiment was stopped at \( H = 1400 \). Similar results were obtained with three different samples of the metal. Roughly speaking, therefore, cobalt behaves oppositely to iron.

\(^2\) The same phenomenon is exhibited in a less marked degree when soft iron is magnetized in stronger fields (Ewing. Phil. Trans., 1885, 176, 699).
MAGNETISM

Joule and others experimented with hardened steel, but failed to find a key to the results they obtained, which are rather complex, and have been thought to be inconsistent. The truth appears to be that a hardened steel rod generally behaves like one of iron or soft steel in first undergoing extension under increasing magnetizing force, and recovering its original length when the force has reached a certain critical value, beyond which there is contraction. But this "critical value" of the force is found to depend in an unexpected manner upon the hardness of the steel; the critical value diminishes as the hardness becomes greater *up to a certain point*, corresponding to a yellow temper, after which it increases with the hardness of steel becomes very high. For steel which has been made red-hot, suddenly cooled, and then let down to a yellow temper, the critical value of the magnetizing force is smaller than for steel which is either softer or harder; it is indeed so small that the metal contracts like nickel even under weak magnetizing forces, without undergoing any preliminary extension that can be detected.

Joule also made experiments upon iron wires under tension, and drew the erroneous inference (which has been often quoted as if it were a demonstrated fact) that under a certain critical tension (differing for different specimens of iron but independent of the magnetizing force) magnetization would produce no effect whatever upon the dimensions of the wire. What actually happens when an iron wire is loaded with various weights is clearly shown in Fig. 25. Increased tension merely has the effect of diminishing the maximum elongation and hastening the contraction; with the two greatest loads used in the experiment there was indeed no preliminary extension at all. The effects of tension upon the behaviour of a nickel wire are of a less simple character. In weak fields the magnetic contraction is always diminished by pulling stress; in strong fields the contraction increases under a small load and diminishes under a heavy one. Cobalt, curiously enough, was found to be quite unaffected by tensile stress.

Certain experiments by C. G. Knott on magnetic twist, which will be referred to later, led him to form the conclusion that in an iron wire carrying an electric current the magnetic elongation would be increased. This forecast was shown by Bidwell to be well founded. The effect produced by a current is exactly opposite to that of tension, raising the elongation curve instead of depressing it. In the case of a wire 0.75 mm. in diameter the maximum elongation was nearly doubled when a current of two amperes was passing through the iron, while the "critical value" of the field was increased from 130 to 200. Yet notwithstanding this enormous effect in iron, the action of a current upon nickel and cobalt turned out to be almost inappreciable.

Some experiments were next undertaken with the view of ascertaining how far magnetic changes of length in iron were dependent upon the hardness of the metal, and the unexpected result was arrived at that softening produces the same effect as tensile stress; it depresses the elongation curve, diminishing the maximum extension, and reducing the "critical value" of the magnetizing force. A thoroughly well annealed ring of soft iron indeed showed no extension at all, beginning to contract, like nickel, under the smallest magnetizing forces. The experiments were not sufficiently numerous to indicate whether, as is possible, there is a critical degree of hardness for which the height of the elongation curve is a maximum. Finally, experiments were made to ascertain the effect of magnetization upon the dimensions of iron rings in directions perpendicular to the magnetization, and upon the volume of the rings. It was found that the curve showing the relation of transverse changes of dimensions to magnetizing force was similar in general character to the familiar elongation curves, but the signs were reversed; the curve was inverted, indicating at first retractions, which, after passing a maximum and vanishing in a critical field, was succeeded by elongation. The curve showing the circumferential (or longitudinal) changes was also plotted, and from the two curves these obtained it was easy, on the assumed isotropy of the metal, to calculate changes of volume for; if for circumferential elongation be denoted by $l_1$, and transverse elongation by $l_2$, then the cubical dilatation $(+ or -) = l_1 + 2l_2$ approximately. If $l_1$ were exactly equal to $\pm l_2$ for all values of the magnetizing force, it is clear that the volume of the ring would be unaffected by magnetization. In the case of the ring in question, the circumferential changes were in weak fields less than twice as great as the transverse ones, while in strong fields they were more than twice as great; under increasing magnetizing force, it was the transverse deformation which, after the initial contraction, then regained its original elongation (for $H=\infty$), and ultimately increased. It was also shown that annealing, which has such a large effect upon circumferential (or longitudinal) changes, has almost none upon transverse ones. Hence the changes of volume undergone by a given sample of wrought iron under increasing magnetization must depend largely upon the state of the metal as regards hardness; there may be always contraction, or always expansion, or first one and then the other.

Most of the experiments described above have been repeated and the results confirmed by other workers, some of whom have added fresh observations. The complicated hysteresis effects which attend magnetic elongation and retraction have been studied by H. Nagaoka, who, also, in conjunction with K. Honda, measured the changes of length of various metals shaped in the form of ovoids instead of cylindrical rods, and determined the magnetization curves for the same specimens; a higher degree of accuracy was thus attained, and satisfactory data were provided for testing theories. Among other things, it was found that the behaviour of cast cobalt was very different from that of wrought iron, and that in Fig. 24 was converted into an almost perfectly straight line passing through the origin, and lying below the horizontal axis; while the permeability of the metal was greatly diminished by the operation. They also tested several varieties of nickel-steel in the form of both ovoids and wires. With a sample containing 25% of nickel no appreciable change was detected; others containing larger percentages, and tested in fields up to 2000, all exhibited elongation, which tended to an asymptotic value as the field was increased. The influence of temperature varying between wide limits has formed the subject of a research by K. Honda and S. Shimizu. For soft iron, tungsten-steel and nickel little difference appeared to result from lowering the temperature down to -180° C. (the temperature of liquid air); at sufficiently high temperatures, 600° to 1000° or more, it was remarked that the changes of length in iron, steel and cobalt tended in every case to become proportional to the magnetic force; the curves being nearly straight lines entirely above the axis. The retraction of nickel was diminished by rising temperature, and at 400° had almost vanished. The influence of high temperature on cobalt was very remarkable, completely altering the character of the change of length: the curves for annealed cobalt show that at 450° this metal behaves just like iron at ordinary temperatures, lengthening in fields up to about 300 and contracting in stronger ones. The same physicists have made some additional experiments upon the effect of tension on magnetic change of length. Bidwell's results for iron and nickel were confirmed, and it was further shown that the elongation of nickel-steel was very greatly diminished by tension; when

1 Joule believed that the volume was unchanged.
MAGNETISM

Regarded as a "correction" to be applied to the results of experiments on magnetic change of length, the magnetic stress being no less an extraneous effect than a stress applied mechanically. Those who support this view generally speak of the stress as "Maxwell's stress," and assume its value to be \( B^2/8\pi \). The stress in question seems, however, to be quite unconnected with the "stress in the medium" contemplated by Maxwell, and its value is not exactly \( B^2/8\pi \) except in the particular case of a permanent ring magnet, where \( H = 0 \). Further, in the case of a tension along the lines of force, it is equal to \( B^2/8\pi \) only when \( B = H \), and there is no magnetization. Some writers have indeed contended that the stress in magnetized iron is not compressive, but tensile, even when, as in the case of a ring-magnet, there are no free ends. The point at issue has an important bearing upon the possible correlation of magnetic phenomena, but, though it has given rise to much discussion, no accepted conclusion has yet been reached.6

7. EFFECTS OF MECHANICAL STRESS UPON MAGNETIZATION

The effects of traction, compression and torsion in relation to magnetism have formed the subject of much patient investigation, especially at the hands of J. A. Ewing, C. G. Knott and the indefatigable physicists of Tokyo University. The results of their experiments embrace a multiplicity of details of which it is impossible to give an adequate summary. Only a few of the most important can be mentioned here; the reader who wishes for fuller information should consult the original papers.

It was first discovered by E. Villari in 1868 that the magnetic susceptibility of an iron wire was increased by stretching when the magnetization was below a certain value, but diminished when that value was exceeded; this phenomenon has been termed by Lord Kelvin, who discovered it independently, the "Villari reversal," the value of the magnetization for which stretching by a given load produces no effect being known as the "Villari critical point," for that load. The Villari critical point for a given sample of iron is reached with a smaller magnetizing force when the stretching load is great than when it is small; the reversal also occurs with smaller loads and with weaker fields when the iron is soft than when it is hard. The following table shows the values of I and H corresponding to the Villari critical point in some of Ewing's experiments:

The effects of pulling stress may be observed either by the wire when stretched by a constant load while the magnetic force is varied, or when the magnetizing force is kept constant while the load is varied. In the latter case the first application of stress is always attended by an increase—often a very great one—of the magnetization, whether the field is weak or strong, but after a load has been put on and then taken off several times the change in magnetization becomes cyclic. From experiments of both classes it appears that for a given field there is a certain value of the load for which the magnetization is a maximum, the maximum occurring at a smaller load the stronger the field. In very strong fields the maximum may even disappear altogether, the effect of the smallest stress

MAGNETISM

It has been pointed out by J. J. Thomson (Applications of Dynamics to Physics and Chemistry, 47) that on dynamical principles there must be a reciprocal relation between the changes of dimensions produced by magnetization and the changes of magnetization attending mechanical strain. Since, for example, stretching diminishes the magnetization of nickel, it follows from theory that the length of a nickel rod should be diminished by magnetization and conversely. So, too, the Villari reversals in iron and cobalt might have been predicted—as indeed that in cobalt actually was—from a knowledge of the changes of length which those metals exhibit when magnetized.

The complete reciprocity of the effects of magnetization upon length and of stretching upon magnetization is shown by the following parallel statements:

Iron.

Magnetization produces increase of length in weak fields, magnetization in weak fields, decrease in strong fields.

Cast Cobalt.

Magnetization produces decrease of length in weak fields, magnetization in weak fields, increase in strong fields.

Nickel and Annealed Cobalt.

Magnetization produces decrease of length in all fields. magnetization in all fields.

Nickel-Steel.

Magnetization produces increase of length in all fields. magnetization in all fields.

Nagaoka and Honda (Phil. Mag., 1898, 46, 261) have investigated the effects of hydrostatic pressure upon magnetization, using the same pieces of iron and nickel as were employed in their experiments upon magnetic change of volume. In the iron cylinder and ovoid, which expanded when magnetized, compression caused a diminution of magnetization; in the nickel rod, which contracted when magnetized, pressure was attended by an increase of magnetization. The amount of the change was in both cases exceedingly small, that in iron being less than 0·1 C.G.S. unit with a pressure of 250 atmospheres and \( H = 54 \). It would hardly be safe to generalize from these observations; the effects may possibly be dependent upon the physical condition of the metals. In the same paper Nagaoka and Honda describe an important experiment on the effect of transverse stress. An iron tube, having its ends closed by brass caps, was placed inside a compressing vessel into which water was forced until the pressure upon the outer surface of the tube reached 250 atmospheres. The experiment was the reverse of one made by Kelvin with a gunmetal cylinder subjected to internal burst upon circumstance (Phil. Trans., 1878, 152, 64), and the results were also the reverse. Under increasing magnetizing force the magnetization first increased, reached a maximum, and then diminished until its value ultimately became less than the original. Honda and Nagaoka attribute these results to the effect of external hydrostatic pressure upon the magnetization of iron rings which have also been made by F. Frischel, who found that for the magnetizing forces used by Nagaoka and Honda pressure produced a small increase of magnetization, a result which appears to be in accord with theory.

The relations of torsion to magnetization were first carefully studied by G. Wiedemann, whose researches are described in his Electridität, iii. 671. The most interesting of his discoveries, now generally known as the "Wiedemann effect," is the following: If we magnetize longitudinally a straight wire which is fixed at one end and free at the other, and then pass an electric current through the wire (or first pass the current and then magnetize), the free end of the wire will twist in a certain direction depending upon circumstances: if the wire is of iron, and is magnetized (with a moderate force) so that its free end has north polarity, while the current through it passes from the fixed to the free end, then the free end as seen from the fixed end will twist in the direction of the hands of a watch; if either the magnetization or the current is reversed, the direction of the twist will be reversed. To this mechanical phenomenon there is a magnetic reciprocal. If we twist the free end of a ferromagnetic wire while a current is passing through it, the wire becomes longitudinally magnetized, the direction of the magnetization being such as if the wire were twisted. If the wire is of iron and is twisted so that its free end as seen from the fixed end turns in the direction of the hands of a watch, while

1. H. Tomlinson found a critical point in the "temporary magnetization" of nickel (Proc. Phys. Soc., 1890, 10, 367, 445), but this important correction, which has been made clear by Ewing and Cowan's curves (Phil. Trans., 1888, 179, plates 15, 16).

3. Phil. Trans., 1890, 131, 529.

4. Magnetic Induction, 1900, 222.
the current passes from the fixed to the free end, then the direction of the resulting magnetization will be such as to make the free end a north pole. The twist effect exhibited by iron under moderate longitudinal magnetization has been called by Knott a positive Wiedemann effect; if the twist were reversed, the other conditions remaining the same, the sign of the Wiedemann effect would be negative. An explanation of the twist has been given by Maxwell (Electricity and Magnetism, § 448). The wire is subject to two superposed magnetizations, the one longitudinal, the other circular, due to the current traversing the wire; the resultant magnetization is consequently in the direction of a screw or spiral round the wire, which will be right-handed or left-handed according as the relation between the two magnetizations is right-handed or left-handed; the magnetic expansion or contraction of the wire along the spiral lines of magnetization produces the Wiedemann twist. Iron (moderately magnetized) expands along the lines of magnetization, and therefore for a right-handed spiral exhibits a right-handed twist. This explanation was not accepted by Wiedemann,\(^1\) who thought that the effect was accounted for by molecular friction. Now nickel contracts instead of lengthening when it is magnetized, and an experiment by Knott showed, as he expected, that \textit{cateris paribus} a nickel wire twists in a sense opposite to that in which iron twists. The Wiedemann effect being positive for iron is negative for nickel. Further, although iron, in lengths of moderate strength, contracts in strong ones; and if the wire is stretched, contraction occurs with smaller magnetizing forces than if it is unstretched. Bidwell\(^2\) accordingly found upon trial that the Wiedemann twist of an iron wire vanished when the magnetizing force reached a certain high value, and was reversed when that value was exceeded; he also found that the vanishing point was reached with lower values of the magnetizing force when the wire was stretched by a weight. These observations have been verified and extended by Knott, whose researches have brought to light a large number of additional facts, all of which are in perfect harmony with Maxwell’s explanation of the twist.

Maxwell has also given an explanation of the converse effect, namely, the production of longitudinal magnetization by twisting a wire when circularly magnetized by a current passing through it. When the wire is free from twist, the magnetization at any point \(P\) is in the tangential direction \(PB\) (see fig. 26).

Suppose the wire to be fixed at the top and twisted at the bottom in the direction of the arrow-head \(T\); then the element of the wire at \(P\) will be stretched in the direction \(Pe\) and compressed in the direction \(Pr\). But tension and compression produce opposite changes in the magnetic susceptibility; if the metal is iron and its magnetization is below the Villari critical point, its susceptibility will be greater along \(Pe\) than along \(Pr\); the direction of the magnetization therefore tends to approach \(Pe\) and to recede from \(Pr\), changing, in consequence of the twist, from \(PB\) to some such direction as \(PB'\), which has a vertical component downwards; hence the lower and upper ends will respectively acquire north and south polarity, which will disappear when the wire is untwisted. This effect has never been actually reversed in iron, probably, as suggested by Ewing, because the strongest practicable circular fields fail to raise the components of the magnetization along \(Pe\) and \(Pr\) up to the Villari critical value. Nagaoka and Honda have approached very closely to a reversal, and consider that it would occur if a sufficiently strong current could be applied without undue heating.

One other effect of torsion remains to be noticed. If a longitudinally magnetized wire is twisted, circular magnetization is developed; this is evidenced by the transient electromotive force induced in the iron, generating a current which will deflect a galvanometer connected with the two ends of the wire. The explanation given of the last described phenomenon will with the necessary modification apply also to this; it is a consequence of the aerolotropy produced by the twist. There are then three remarkable effects of torsion:

- A. A wire magnetized longitudinally and circularly becomes twisted.
- B. Twisting a circularly magnetized wire produces longitudinal magnetization.
- C. Twisting a longitudinally magnetized wire produces circular magnetization.

And it has been shown earlier that—

- D. Magnetization produces change of length.
- E. Longitudinal stress produces change of magnetization.

Each of these five effects may occur in two opposite senses. Thus in A the twist may be right-handed or left-handed; in B the polarity of a given end may become north or south; in C the circular magnetization may be clockwise or counter-clockwise; in D the length may be increased or diminished; in E the magnetization may become stronger or weaker. And, other conditions remaining unchanged, the “sense” of any effect depends upon the nature of the metal under test, and (sometimes) upon the intensity of its magnetization. Let each of the effects A, B, C, D and E be called positive when it is such as is exhibited by moderately magnetized iron, and negative when its sense is opposite. Then the results of a large number of investigations may be briefly summarized as follows:

(\(W\) = weakly magnetized. (S) = strongly magnetized.)

Several gaps remain to be filled, but the results so far recorded can leave no doubt that the five effects, varied as they may at first sight appear, are intimately connected with one another. For each of the metals tabulated in the first column all the effects hitherto observed have the same sign; there is no single instance in which some are positive and others negative. Until the mysteries of molecular constitution have been more fully explored, perhaps D may be most properly regarded as the fundamental phenomenon from which the others follow. Nagaoka and Honda have succeeded in showing that the observed relations between twist and magnetization are in qualitative agreement with an extension of Kirchhoff’s theory of magnetostriction.

The effects of magnetization upon the torsion of a previously twisted wire, which were first noticed by Wiedemann, have been further studied by F. J. Smith\(^3\) and by G. Moreau.\(^4\) Nagaoka\(^5\) has described the remarkable influence of combined torsion and tension upon the magnetic susceptibility of nickel, and has made the extraordinary observation that, under certain conditions of stress, the magnetization of a nickel wire may have a direction opposite to that of the magnetizing force.

8. EFFECTS OF TEMPERATURE UPON MAGNETISM

High Temperature.—It has long been known that iron, when raised to a certain “critical temperature” corresponding to dull red heat, loses its susceptibility and becomes magnetically indifferent, or, more accurately, is transformed from a ferromagnetic into a paramagnetic body. Recent researches have shown that other important changes in its properties occur at the same critical temperature. Abrupt alterations take place in its density, specific heat, thermo-electric quality, electrical conductivity, temperature-coefficient of electrical resistance, and in some at least of its mechanical properties. Ordinary magnetizable iron is in many respects an essentially different substance from the non-magnetizable metal into which it is transformed when its temperature is raised above a certain point (see \textit{Brit. Assoc. Report}, 1890, 145). The first exact experiments demonstrating the changes which occur in the permeability of iron,

\(^3\) \textit{Phil. Mag.}, 1889, 27, 117.
steel and nickel when heated up to high temperatures were those of J. Hopkinson (Phil. Trans., 1889, 1890, 43; Proc. Roy. Soc., 1888, 44, 37). The metal to be tested was prepared in the form of a ring, upon which were wound primary and secondary coils of copper wire insulated with asbestos. The primary coil carried the magnetizing current; the secondary, which was wound inside the other, could be connected either with a ballistic galvanometer for determining the induction, or with a Wheatstone's bridge for measuring the resistance, whence the temperature was calculated. The ring thus prepared was placed in a cast-iron box and heated in a gas furnace. The following are the chief results of Hopkinson's experiments: For small magnetizing forces the magnetization of iron steadily increases with rise of temperature till the critical temperature is approached, when the rate of increase becomes very high, the permeability in some cases attaining a value of about 11,000; the magnetization then with remarkable suddenness almost entirely disappears, the permeability falling to about 1.14. For strong magnetizing forces (which in these experiments did not exceed H=48 ergo) the permeability remains almost constant at its initial value (about 400), until the temperature is within nearly 100°C of the critical point; then the permeability diminishes more and more rapidly until the critical point is reached and the magnetization vanishes. Steel behaves in a similar manner, but the maximum permeability is not so high as in iron, and the fall, when the critical point is approached, is less abrupt. The critical temperature for various samples of iron and steel ranges from 690°C to 870°C; it is the temperature at which Barrett's "recalcence" occurs. The critical temperature for the specimen of nickel examined (which contained nearly 5% of impurities) was 316°C. F. Lydall and A. W. Pockington found that the critical temperature of nearly pure iron was 874°C. (Proc. Roy. Soc., 1893, 52, 228).

An exhaustive research into the effects of heating on the magnetic properties of iron has been carried out by D. K. Morris (Proc. Phys. Soc., 1897, 15, 134; and Phil. Mag., 1897, 44, 213), the results being embodied in a paper containing twelve pages of tables and upwards of 120 curves. As in Hopkinson's experiments, rings were magnetized; these were wound with primary and secondary coils of insulated platinum wire, which would bear a much higher temperature than copper without oxidation or fusion. A third platinum coil, wound non-inductively between the primary and the secondary, served to carry the current by which the ring was heated; a current of 4-6 amperes, with 16 volts across the terminals, was found sufficient to maintain the ring at a temperature of 1150°C. In the ring itself was embedded a platinum-thermometer wire, from the resistance of which the temperature was determined. The whole was wrapped in several coverings of asbestos and placed in a glass vessel from which the air was partially exhausted, additional precautions being taken to guard against oxidation of the iron.

Some preliminary experiments showed the striking difference in the effects of annealing at a red heat (840°C) and at a low white heat (1150°C). After one of the rings had been annealed, its maximum permeability at ordinary temperatures was 3000 for H=1845; when it had been subsequently annealed at 1150°C, the maximum permeability rose to 4680 for H=148, whereas the hysteresis, B=4000 was under 500 ergs per cm. As regards the effects of temperature, Morris's results are in general agreement with those of Hopkinson, though no doubt they indicate distinct and more marked differences of a qualitative character, involving the relation of induction to magnetic field at various temperatures, and of permeability to temperature with fields of different intensities, as are given in figs. 27 and 28. The most striking feature presented by these is the enormous value, 12,660, which, with H=0-153, is attained by the permeability at 765°C, followed by a drop so precipitous that when the temperature is only 15°C higher, the value of the permeability has become quite insignificant. The critical temperatures for the three different specimens of iron were 797°C, 790°C, and 770°C respectively. Above these temperatures the little permeability that remained was found to be independent of the magnetizing force, but it appeared to vary a little with the temperature, one specimen showing a permeability of 100 at 870°C, 2550 at 950°C, and 17 at 1050°C. These last observations are, however, regarded as uncertain. The effects of temperature upon hysteresis were also carefully studied, and many hysteresis loops were plotted. The results of a typical experiment are temperature was varied, and the hysteresis loops at different temperatures were plotted. The coercive force at 764°C is 12,660 ergs per cm, being increased by 20 per cent. above 0.01 C.G.S. unit; above the critical temperature no evidence of hysteresis could be obtained.

Hysteresis Loss in Ergs per c.cm. Max. H. = ±6-83.

A paper by H. Nagaoka and S. Kasakabe generally confirms Morris's results for iron, and gives some additional observations for iron and nickel. The magnetometric method was employed and the metals, in the form of ovoids, were heated by a specially designed burner, fed with gas and air under pressure, which directed 90 fine jets of flame upon the asbestos covering the ovoid. The temperature was determined by a platinum-rhodium and platinum-thermocouple in contact with the metal. Experiments were made at several constant temperatures with varying magnetic fields, and the rings were then heated, and the original magnetization was recovered. For ordinary steel the critical temperature, at which magnetization practically disappeared, was found to be about 830°C, and the curious fact was revealed that, on cooling, magnetization did not begin to return till the magnetism had fallen to about 2 of its maximum value. This retardation was still more pronounced in the case of tungsten-steel, which lost its magnetism at 910°C and remained non-magnetic till it was cooled to 570°C, a difference of 240°C. For nearly pure nickel the corresponding temperature-difference was about 100°C. This phenomenon is of the same nature as that first discovered by J. Hopkins for nickel-steel. The paper contains tables and curves showing details of the magnetic changes, sometimes very complex, at different temperatures and with different fields. The behaviour of cobalt is particularly noticeable; its permeability increased with rising temperature up to a maximum at 500°C, when it was found to be 12 twice as great as at ordinary temperatures, while at 1600°C, corresponding to white heat, there was still some magnetization remaining.

Further contributions to the subject have been made by K. Honda and S. Shinzui, who experimented at temperatures ranging from -186°C to 1200°C. As regards the higher temperatures, the chief point of interest is the observation that the curve of magnetization for annealed cobalt shows a small depression at about 450°C, the temperature at which they had found the sign of the length-change to be reversed for all fields. In the case of all the metals tested a small but measurable trace of magnetization remained after the so-called critical temperature had been exceeded; this decreased very slightly up to the highest temperature reached (1200°C) without undergoing any such variation as had been suspected by Morris. When the curve after its steep descent had almost reached the axis, it bends upward and becomes a nearly horizontal straight line; the authors suggest that the critical temperature should be defined as that corresponding to the point of maximum curvature. As thus defined the critical temperatures for iron, nickel and cobalt were

MAGNETISM

TEMPERATURE AND MAGNETIZATION

found to be 780°, 360° and 1090° respectively, but these values are not quite independent of the magnetizing force.

Experiments on the effect of high temperatures have also been made by M. P. Ledeboer,1 H. Tomlinson,2 P. Curie,3 and W. Kunz,4 R. L. Wilks,5 J. R. Ashworth,6 and E. P. Harrison.7

Low Temperature.—J. A. Fleming and J. Dewar (Proc. Roy. Soc., 1896, 60, 81) were the first to experiment on the permeability and hysteresis of iron at low temperatures down to that of liquid air (−186°C). Induction curves of an annealed soft-iron ring were taken first at a temperature of 15°C, and afterwards when the ring was immersed in liquid air, the magnetizing force ranging from about 0 to 22. After this operation had been repeated a few times the iron was found to have acquired a stable condition, and the curves corresponding to the two temperatures became perfectly definite. They showed that the permeability of this sample of iron was considerably diminished at the lower temperature. The maximum permeability (for H = 2) was 3400 at 15° and only 2700 at −186°C, a reduction of more than 20%; but the percentage reduction became less as the magnetizing force departed from the value corresponding to maximum permeability. Observations were also made of the changes of permeability which took place as the temperature of the sample slowly rose from −186° to 15°, the magnetizing force being kept constant throughout an experiment. The value of the permeability corresponding to the highest and lowest temperatures are given in the following table. Most of the permeability-temperature curves were more or less convex towards the axis of temperature, and in all the experiments, except those with annealed iron and steel wire, the permeability was greatest at the lowest temperature.8 The hysteresis of the soft annealed iron turned out to be sensibly the same for equal values of the induction at −186° as at 15°, the loss in ergs per c.c.m. per cycle being approximately represented by 0-002 B3 when the maximum limit of B were ±9000. Experiments with a sample of unannealed iron failed to give satisfactory results, owing to the fact that no constant magnetic condition could be obtained.

Honda and Shimizu have made similar experiments at the temperature of liquid air, employing a much wider range of magnetizing forces (up to about 700 C.G.S.) and testing a greater variety of metals. They found that the permeability of Swedish iron, tungsten-steel and nickel, when the metals were cooled to −186°, was diminished in weak fields but increased in strong ones, the field in which the effect of cooling changed its sign being 115 for iron and steel and 380 for nickel. The permeability of cobalt, both annealed and unannealed, was always diminished at the low temperature. The hysteresis-loss in Swedish iron was decreased for inductions below about 9000 and increased for higher inductions; in tungsten-steel, nickel and cobalt the hysteresis-loss was always increased by cooling. The range of ±B within which Steinmetz’s formula is applicable becomes notably increased at low temperature. It may be remarked that, whereas Fleming and Dewar employed the ballistic method, their specimens having the form of rings, Honda and Shimizu worked magnetometrically with metals shaped as ovoids.

Permanent Magnets.—Fleming and Dewar (loc. cit. p. 57) also investigated the changes which occurred in permanently magnetized metals when cooled to the temperature of liquid air. The metals, which were prepared in the form of small rods, were magnetized between the poles of an electromagnet and tested with a magnetometer at temperatures of −186° and 15°. The first immersion into liquid air generally produced a permanent decrease of magnetic moment, and there was sometimes a further decrease when the metal was warmed up again; but after a few alternations of temperature the changes of moment became definite and cyclic. When the permanent magnetic condition had been thus established, it was found that in the case of all the metals, except the two alloys containing large percentages of nickel, the magnetic moment was temporarily increased by cooling to −186°. The following table shows the principal results. It is suggested that a permanent magnet might conveniently be “aged” (or brought into a constant condition) by dipping it several times into liquid air.

Other experiments relating to the effect of temperature upon permanent magnets have been carried out by J. R. Ashworth,8 who showed that the temperature coefficient of permanent magnets might be reduced to zero (for moderate ranges of temperature) by suitable adjustment of temper and dimension ratio; also by R. Pictet,9 and D. Durward10 and J. Trowbridge.11

Alloys of Nickel and Iron.—A most remarkable effect of temperature was discovered by Hopkinson (Proc. Roy. Soc., 1890, 47, 23; 1891, 48, 1) in 1889. An alloy containing about 3 parts of iron and 1 of nickel—both strongly magnetic metals—is under ordinary conditions practically non-magnetizable (μ = 1.4) for any value of H. If, however, this non-magnetic substance is cooled to a temperature a few degrees below freezing-point, it becomes as strongly magnetic as a cast-iron (μ = 62 for H = 40), and retains its magnetic properties indefinitely at ordinary temperatures. But if the alloy is heated up to 580°C it loses its susceptibility—rather suddenly when H is weak, more gradually when H is strong—and remains non-magnetizable till it is once more cooled down below the freezing-point. This material can therefore exist in either of two perfectly stable conditions, in one of which it is magnetizable, while in the other it is not. When magnetizable it is a hard steel, having a specific electrical resistance of 0-00052; when non-magnetizable it is an extremely soft, mild steel, and its specific resistance is 0-000072. Alloys containing different proportions of nickel were found to exhibit the phenomenon, but the two critical temperatures were less widely separated. The following approximate figures for small magnetizing forces are deduced from Hopkinson’s curves:

8 A. M. Thiessen (Phys., 1899, 8, 66) and G. Claude (C. R., 1899, 129, 460) found that for considerable inductions (B = 15,000) the permeability and hysteresis-loss remained nearly constant down to −186°C; for weak inductions both notably diminished with temperature.

10 C.R., 1895, 120, 263.
MAGNETISM

Honda and Shimizu (loc. cit.) have determined the two critical temperatures for eleven nickel-steel ovenoids, containing from 24.04 to 70.32% of nickel, under a magnetizing force of 400, and illustrated by an example, showed that the critical temperature may be expressed by the formula

\[ T = \frac{A}{(B + C)} \]

The formula applies only for very weak inductions when the alloys are at the ordinary temperature, but at the temperature of liquid air it is not applicable. The experiments of Hopkinson, though containing no indication of a magnetic susceptibility of nickel-steel is recovered by the presence of chromium; a certain alloy containing chromium was not rendered magnetic by immersion in liquid air. Experiments on the subject have also been made by E. Dumont and F. Osmond.

9. ALLOYS AND COMPOUNDS OF IRON

In 1885 Hopkinson (Phil. Trans., 1885, 176, 435) employed his yoke method to test the magnetic properties of thirty-five samples of iron and steel, among which were steels containing substantial proportions of manganese, silicon, chromium and tungsten. The results, together with the chemical analysis of each sample, are given in a table contained in this paper, some of them being also represented graphically. The most striking phenomenon which they bring into prominence is the effect of any considerable quantity of manganese in annihilating the magnetic property of iron. A sample of Hadfield's manufacture, containing 12.36% of manganese, differed hardly at all from a non-magnetic substance, its permeability being only 1-27. According to Hopkinson's calculation, this sample behaved as if 91% of the nickel had been completely lost by magnetic property. Another point to which attention is directed is the exceptionally great effect which hardening has upon the magnetic properties of chrome steel; one specimen had a coercive force of 9 when annealed, and of no less than 38 when oil-hardened. The effect of the addition of tungsten in increasing the coercive force is very clearly shown; in two specimens containing respectively 3-44 and 2-35% of tungsten the coercive force was 64.5 and 70.7. These high values render hardened tungsten-steel particularly suitable for the manufacture of permanent magnets. Hopkinson (Proc. Roy. Soc., 1890, 48, 1) also noticed some peculiarities of an unexpected nature in the magnetic properties of the nickel-steel alloys already referred to. The permeability of the alloys containing from 1 to 4.7% of nickel, though less than that of good soft iron for magnetizing forces up to about 20 or 30, was greater for higher forces, the induction reached in a field of 240 being nearly 21,700. The induction for considerable forces was found to be greater in a steel containing 73% of nickel than in one with only 33%, though the permeability of pure nickel is much less than that of iron.

The magnetic qualities of various alloys of iron have been submitted to a very complete examination by W. F. Barrett, W. Brown and R. A. Hadfield (Trans. Roy. Dub. Soc., 1900, 67; Journ. Inst. Elec. Eng., 1902, 31, 674). More than fifty different specimens were tested, most of which contained a known proportion of manganese, nickel, tungsten, aluminium, chromium, copper or silicon; in some samples two of the substances named were present. Of the very numerous results published, a few of the most characteristic are collected in the following table. The first column contains the symbols of the various elements which were added to the iron, and the second the percentage proportion in which each element was present; the sample containing 0-03% of carbon was a specimen of the best commercial iron, the values obtained for it being given for comparison. All the metals were annealed.

A few among several interesting points should be specially noticed. The addition of 15-2% of manganese produced an enormous effect upon the magnetism of iron, while the presence of only 2-25% was comparatively unimportant. When nickel was added to the iron in increasing quantities the coercive force increased until the proportion was raised 20%; but as diminishes, and when the composition of nickel was 32%, the coercive force had fallen to the exceedingly low value of 0.5. In the case of iron containing 7.5% of tungsten, the residual induction had a remarkably high value; the coercive force, however, was not very great. The addition of silicon in small quantities considerably diminished permeability and increased coercive force, but when the behaviour of this to 21.5% the magnetic permeability (\( \mu = 5100 \)) was greater than that of the nearly pure iron used for comparison, while the coercive force was only 0.9. A small percentage of aluminium produced the very high permeability of 67,000 in fields up to 100 being greater than in any other known substance, and the hysteresis-loss for moderate limits of B far less than in the purest commercial iron. Certain non-magnetizable alloys of nickel, chromium-nickel and chromium-manganese were rendered magnetic by being annealed.

Later papers give the results of a more minute examination of those specimens which were remarkable for very low and high permeabilities, and were therefore likely to be of commercial importance. The following table gives the exact composition of some alloys which were found to be non-magnetizable, or nearly so, in a field of 320.

A very small difference in the constitution often produces a remarkable effect upon the magnetic quality, and it appears that those alloys which are hardest magnetically are generally also hardest mechanically and extremely difficult to work; they might however be used rolled into casting sheets. These specimens distinguished by unusually high permeability were constituted as follows:

- Silicon-iron—Fe, 97.3; C, 0.2; Si, 2.5.
- Aluminium-iron—Fe, 97.3; C, 0.18; Al, 2.25.

The silicon-iron had, in fields up to about 10, a greater permeability than a sample of the best Swedish charcoal-iron, and its hysteresis-loss for max. B=9000, at a frequency of 100 per second, was only 0.254 watt per pound, as compared with 0.382 for the Swedish iron. The aluminium-iron attained its greatest permeability in a field of 0.9 about that of the earth's force, when its value was 9000, this being more than twice the maximum permeability of the Swedish iron. Its hysteresis-loss for B=9000 was 0.236 per pound. It was, however, found that this alloy was in part due to a layer of pure iron ("ferrite") averaging 0.1 mm. in thickness, which occurred on the outside of the specimen, and the exceptional magnetic quality which has been claimed for aluminium-iron cannot yet be regarded as established.

A number of iron alloys have been examined by Mme. Curie (Bull. Soc. d'Encouragement, 1898, pp. 36-70), chiefly with the object of determining their suitability for the construction of permanent magnets. Her tests appear to show that molybdenum is even more effective than tungsten in augmenting the coercive force, the highest values observed being 70 to 74 for tungsten steel, and 80 to 85 for steel containing \( \gamma \) 0.4% of molybdenum. For additional information regarding the composition and qualities of permanent magnet steels reference may be made to W. H. Bayley (Trans. Roy. Dub. Soc., 1902-4, 4, 81 and 123).
to the publications cited below. Usefui instructions have been furnished by Carl Barus (Terrestrial Magnetism, 1897, 2, 11) for the preparation of magnets calculated to withstand the effects of time, percussion and ordinary temperature variations. The metal, having first been uniformly tempered glass-hard, should be annealed in steam at 105° C. for twenty or thirty hours; it should then be magnetized to saturation, and finally "aged" by a second immersion in steam for about five hours.

Magnetic Alloys of Non-Magnetic Metals.—The interesting discovery was made by F. Heusler in 1903 that certain alloys of the non-magnetic metal manganese with other non-magnetic substances were strongly magnetic, their susceptibility being in some cases equal to that of cast iron. The metals used in different combinations included tin, aluminium, arsenic, antimony, bismuth and boron; each of these, when united in certain proportions with manganese, together with a larger quantity of copper (which appears to serve merely as a menstrum), constituted a magnetizable alloy. So far, the best results have been attained with aluminium, and the permeability was greatest when the percentages of manganese and aluminium were approximately 15 parts of manganese to 8 parts of aluminium of the two metals. Thus in an alloy containing 26.5% of manganese and 14.6% of aluminium, the rest being copper, the induction for H=20 was 4500, and for H=150, 5550. When the proportion of aluminium to manganese was made a little greater or smaller, the permeability was diminished.

Next to aluminium, tin was found to be the most effective of the metals enumerated above. In all such magnetizable alloys the presence of manganese appears to be essential, and there can be little doubt that the magnetic quality of the mixtures is derived solely from this component. Manganese, though belonging (with chromium) to the iron group of metals, is commonly classed as a paramagnetic, its susceptibility being very small in comparison with that of the recognized ferromagnetic materials; but it is remarkable that its atomic susceptibility in solutions of its salts is even greater than that of iron. Now iron, nickel and cobalt all lose their magnetic quality when heated above certain critical temperatures which vary greatly for the three metals, and it was suspected by Faraday as early as 1845 that manganese might really be a ferromagnetic metal having a critical temperature much below the ordinary temperature of the air. He therefore cooled a piece of the metal to -105° C., the lowest temperature then attainable, but failed to produce any change in its magnetic quality. The critical temperature (if there is one) was not reached in Faraday's experiment; possibly even the temperature of -250° C., which by the use of liquid hydrogen has now become accessible, might still be too high. But it has been shown that the critical temperatures of iron and nickel may be changed by the addition of certain other substances. Generally they are lowered, sometimes, however, they are raised; and C. E. Guillame explains the ferromagnetism of Heusler's alloy by supposing that the naturally low critical temperature of the manganese contained in it is greatly raised by the admixture of another appropriate metal, such as aluminium or tin; thus the alloy as a whole becomes magnetizable at the ordinary temperature. If this view is correct, it may also be possible to prepare magnetic alloys of chromium, the only other paramagnetic metals of the iron group.

J. A. Fleming and R. A. Hadfield6 have made very careful experiments on an alloy containing 22.42% of manganese, 11.65% of aluminum and 60.49% of copper. The magnetization curve was found to be of the same general form as that of a paramagnetic metal, and gave indications that with a sufficient force magnetic saturation would probably be attained. The change in susceptibility proportional to 1/W0.0005455H2Bm. The hysteretic exponent is therefore much higher than in the case of iron, nickel and cobalt, for which its value is approximately 1.6.

10. Miscellaneous Effects of Magnetization

Electrical Conductivity.—The specific resistance of many electric conductors is known to be temporarily changed by the magnetic field, but except in the case of bismuth the effect is very small.

A. Gray and E. Taylor Jones (Proc. Roy. Soc., 1900, 67, 208) found that the resistance of a soft iron wire was increased by about 17/100 in a field of 320 C.G.S. units. The effect appeared to be closely analogous to the phenomenon of the induction of electricity, and the curves showing changes of resistance in relation to magnetizing force were strikingly similar in form to those showing changes of length. In 1883 H. Gray (Phil. Trans., 1883, Part I, 153) discovered in 1881 that the resistance of a bismuth rod was slightly increased when the rod was subjected to longitudinal magnetic force, and a year or two later A. Righi (Atti Ist., 1884, 1885, 1886, 1887, 1888, 1889) showed that permanent alteration was produced when the magnetic force was applied transversely to the bismuth conductor; he also noticed that the effect increased with the dependance of the conductor on its temperature (Ann., 1890, 39, 619). Among the most important experiments on the influence of magnetic force at different temperatures are those of J. B. Henderson and of Dewar and Fleming. Henderson (Phil. Mag., 1894, 38, 488) used a little spiral of the pure electrolytic bismuth wire prepared by Hartmann and Braun; this was placed between the pole-pieces of an electromagnet and subjected to fields of various strengths up to nearly 35,000 units. At constant temperature the resistance increased with the field; the changes in the resistance of the spiral when the temperature was 18° C. are indicated in the annexed table, from which it will be seen that in the strongest field the transverse field reached the resistance increased was more than threefold. Other experiments showed the relation of resistance to temperature (from 0° to about 90°) in different constant fields. It was shown that as the temperature rises the distance between a minimum and then increases, the minimum point occurring at a higher temperature the stronger the field. For H=11,500 the temperature of minimum resistance was about 8° C.; for magnetic and higher values of H the actual minimum did not occur within the range of temperature dealt with. Dewar and Fleming (Proc. Roy. Soc., 1897, 60, 425) worked with a similar specimen of bismuth, and their results for a temperature dependence of resistance are those of Henderson. They also experimented with constant temperatures of -79°, -185° and -203°, and found that at these low temperatures the effect of magnetization was enormously increased.

The following table gives some of their results, the specific resistance of the bismuth being expressed in C.G.S. units.

At the temperature of liquid air (-185°) the application of a field of 2,100 multiplied the resistance of the bismuth no less than 150 times. Fig. 29 shows the variations of resistance in relation to temperature for fields of different constant values. It will be seen that for H=2450 and H=5500 the minimum resistance occurs at temperatures of about 25° and 90° respectively, more constant results are more convenient.

Holl Effect.—If an electric current is passed along a strip of thin metal, and the two points at opposite ends of an equipotential line are connected with a galvanometer, its needle will of course not be deflected. But the application of a magnetic field at right angles to the plane of the metal causes the equipotential lines to rotate through a small angle, and the points at
MAGNETISM: MISCELLANEOUS EFFECTS

which the galvanometer is connected being no longer at the same potential, a current is indicated by the galvanometer.\(^1\)

\(^1\) E. H. Hall, Phil. Mag., 1880, 16, 430.

A longitudinal thermo-electric effect is exhibited by the metal when one of its ends is maintained at a temperature higher than the other. Such a longitudinal effect is observed when the temperature of the metal is increased by heat, or when a long metal rod is traversed by an electric current. It is remarkable that if a flow of heat be substituted for a current of electricity a closely allied group of "thermo-magnetic effects" is presented. The two classes of phenomena have been collated by M. G. Lloyd (Am. Journ. Sci., 1901, 2, 79) as follows:

Galvano-Magnetic Effects.
1. A transverse difference of electric potential (Hall effect).
2. A transverse difference of temperature (Ettinghausen effect).
3. Longitudinal change of electric conductivity.
4. Longitudinal difference of temperature.

Thermo-Magnetic Effects.
1. A transverse difference of electric potential (Nernst effect).
2. A transverse difference of temperature (Leduc effect).
3. Longitudinal change of magnetic conductivity.
4. Longitudinal difference of electric potential.\(^3\)

In the annexed diagram ABCD represents the metallic plate through which the current of electricity or heat flows in the direction AB, then effects (r), (s), (i) and (ii) are exhibited at C and D, effects (a) and (iv) at A and B, and effects (g) and (iii) along AB. The transverse effects are reversed in direction when either the magnetic field or the primary current (electric or thermal) is reversed, but the longitudinal effects are independent of the direction of the field. It has been shown by G. Moreau (C. R., 1900, 130, pp. 122, 412, 552) that if K is the coefficient of the Hall effect (i) and K' the analogous coefficient of the Nernst effect (i) (which is constant for small values of H), then K' = Kα/ρ, α being the coefficient of the Thomson effect for the metal and ρ its specific resistance. He considers that Hall's is the fundamental phenomenon, and that the Nernst effect is essentially identical with it, the primary electromotive force in the case of the latter being that of the Thomson effect in the unequally heated metal, while in the Hall experiment it is derived from an external source.

Attempts have been made to explain these various effects by the electron theory.\(^4\)

Thermo-electric Quality.—The earliest observations of the effect of magnetization upon thermo-electric power were those of W. Thomson (Lord Kelvin), who in 1856 announced that magnetization rendered iron and steel positive to the unmagnetized metals.\(^5\) It has been found by Chassagne,\(^6\) L. Houleivgue\(^7\) and others that when the magnetizing force is increased, this effect passes a maximum, while J. A. Ewing\(^9\) has shown that Nickel was believed by Thomson to behave oppositely to iron, becoming negative when magnetized; but though his conclusion was accepted for nearly fifty years, it has recently been shown to be an erroneous one, based, no doubt, upon the result of an experiment with an impure specimen. Nickel when magnetized is always positive to the unmagnetized metal. So also is cobalt, as was found by H. Tomlinson.\(^8\) The curves given by Houleivgue for the relation of thermo-electric force to magnetic field are of the same general form as those showing the relation of change of length to field. E. Rhoads\(^9\) obtained a cyclic curve for iron which indicated thermo-electric hysteresis of the kind exhibited by Nagaoka's curves for magnetic strain. He also experimented with nickel and again found a resemblance to the strain curve. The subject was further investigated by S. Bidwell,\(^10\) who, adopting special precautions against sources of error by which former work was probably affected, measured the changes of thermo-electric force for iron, steel, nickel and cobalt produced by magnetic fields up to 1500 units. In the case of iron and nickel it was found that, when correction was made for a mechanical stress due to magnetization, magnetic change of thermo-electric force was, within the limits of experimental error, proportional to magnetic change of length. Further, it was shown that the thermo-electric curves were modified both by tensile stress and by annealing in the same manner as were the change-of-length curves, the modification being sometimes of a complex nature. Thus a close connexion between the two sets of phenomena seems to be established. In the case of cobalt no such relation could be traced; it appeared that the thermo-electric power of the unmagnetized with respect to a magnetized cobalt was proportional to the square of the magnetic induction or of the magnetization. Of nickel six

**Fig. 29.**

The transverse electromotive force is equal to KCH/D, where C is the current, H the strength of the field, D the thickness of the metal, and K a constant which has been termed the **rotatory power or rotational coefficient.** (See Hopkinson, Phil. Mag., 1880, 16, 430). The following values of K for different metals are given by E. H. Hall, the positive sign indicating that the electromotive force is in the same direction as the mechanical force acting upon the conductor. A. von Ettinghausen and W. Nernst (Wien. Ber., 1886, 94, 456) have found that the rotational coefficient of tellurium is more than fifty times greater than that of bismuth, its sign being positive. Several experimenters have endeavoured to find a Hall effect in liquids, but such results as have been hitherto obtained are by no means free from doubt. E. A. Marx (Ann. d. Phys., 1900, 2, 79) observed a well-defined Hall effect in incandescent gases. A large effect, proportional to the field, has been found by H. A. Wilson (Cam. Phil. Soc. Proc., 1902, 11, pp. 249, 319) in oxygen, hydrogen and air at low pressures, and by C. D. Child (Phys. Rev., 1904, 18, 379) in the electric arc.

Electro-Thermal Relations.—The Hall electromotive force is only one of several so-called "galvano-magnetic effects" which are observed when a magnetic field acts normally upon a thin plate of metal traversed by an electric current. It is remarkable that if a flow of heat be substituted for a current of electricity a closely allied group of "thermo-magnetic effects" is presented. The two classes of phenomena have been collated by M. G. Lloyd (Am. Journ. Sci., 1901, 2, 57) as follows:

Galvano-Magnetic Effects.
1. A transverse difference of electric potential (Hall effect).
2. A transverse difference of temperature (Ettinghausen effect).
3. Longitudinal change of electric conductivity.
4. Longitudinal difference of temperature.

different specimens were tested, all of which became, like iron, thermo-electrically positive to the unmagnetized metals. 

As to what effect, if any, is produced upon the thermo-electric quality of bismuth by a magnetic field there is still some doubt. G. van Abeel believes that in bismuth the thermo-electric force is increased by the field; impurities may neutralize this effect, and in sufficient quantities reverse it.

**Elasticity.**—The results of experiments as to the effect of magnetization were for long discordant and inconclusive, sufficient care not having been taken to avoid sources of error, while the effects of hysteresis were altogether disregarded. The subject, which is of importance in connexion with theories of magnetostriiction, has been investigated by K. Honda and T. Terao in a research remarkable for its completeness and the independence of the experimental methods employed. 1 The results are too numerous to discuss in detail; some of those to which special attention is directed are the following: In Swedish iron and tungsten-steel the change of elastic constants (Young's modulus and rigidity) is generally positive, but its amount is less than 0.5%; changes of Young's modulus and of rigidity are almost identical. In nickel the maximum change of the elastic constants is remarkably large, amounting to about 13% for Young's modulus and 7% for rigidity; with increasing fields the elastic constants first decrease and then increase. In nickel-alloy-steel the change of Young's modulus is 70% of nickel the maximum increase of the constants is as much as 7 or 8%. In a 20% nickel-steel, magnetization increases the constants by a small amount. Changes of elasticity are in all cases dependent, not only upon the field, but also upon the tension applied; and, owing to hysteresis, the results are not in general the same when the magnetization follows as when it precedes the application of stress; the latter is held to be the right order.

**Chemical and Voltal Effects.**—If two iron plates, one of which is magnetized, are immersed in an electrolyte, a current will generally be indicated by a galvanometer connected with the plates.

As to whether the magnetized plate becomes positive or negative to the other, different experimenters are not in agreement. It has, however, been shown by Dragomir Hurmuzescu (Rap. du Congrès Int. de Phys., Paris, 1905, p. 361) that the true effect of magnetization is liable to be disguised by secondary or parasitic phenomena, arising chiefly from polarization of the electrodes and from local variations in the concentration and magnetic condition of the electrolyte; these phenomena are working, exposing only a small surface in a non-polar region of the metal, and substituting a capillary electrolyzer for the galvanometer generally used. When such precautions are adopted it is found that the effect of magnetization is perfectly definite both in direction and in magnitude; it is independent of the nature of the corrosive solution, and is a function of the field, as is shown by the curves showing the relation of electromotive force to field-intensity bearing a rough resemblance to the familiar I-H curves. The value of the E.M.F. when H = 2000 is of the order of 1/100 volt for iron, 1/1000 volt for nickel and 1/10,000 for bismuth. When the two electrodes are ferro-magnetic, the direction of the current through the liquid is from the unmagnetized to the magnetized electrode, the latter being least attacked; with diamagnetic electrodes the reverse is the case. Hurmuzescu shows that these results are in accord with theory. Applying the principle of the conservation of internal energy, he demonstrates that for iron in a field of 1000 units and upwards the E.M.F. of magnetization is

\[ E = \frac{1}{2} \frac{k_1}{2} \]

approximately, where \( k \) is the electrochemical equivalent and \( d \) the density of the metal.

Owing to the difficulty of determining the magnetization \( k \) and the susceptibility \( \kappa \), it has not yet been possible to compute this from any one of the above-mentioned quantities, but it is said to afford an indication of the result of experiments. It has been discovered by E. N. Nichols and W. S. Franklin (Am. Journ. Sci., 1887, 34, 419; 1888, 35, 290) that the transition from the " passive " to the " active " state of iron immersed in strong nitric acid is facilitated by magnetization, and that the temperature of transition being lowered. This is attributed to the action of local currents set up between unequally magnetized portions of the iron. Similar results have been obtained by T. Andrews (Proc. Roy. Soc., 1890, 48, 116).

---

1 C.R., 1903, 136, 1131.
Bismuth.—Bismuth is of special interest, as being the most strongly diamagnetic substance known, the mean value of the best determinations of its susceptibility being about $-14 \times 10^{-6}$ (see G. Meslin, C. R., 1905, 140, 449). The magnetic properties of the metal at different temperatures and in fields up to 1530 units have been studied by P. Curie (loc. cit.), who found that its "specific susceptibility" $K$ was independent of the strength of the field, but decreased with rise of temperature up to the melting-point, 273°C. His results appear to show the relation

$$K \times 10^6 = 1381 - 0.00015t$$

Assuming the density of Bi to be 9.8, and neglecting corrections for heat dilatation, his value for the susceptibility at 20°C is equivalent to $K = -13.23 \times 10^{-6}$. As the temperature was raised up to 273°C, $K$ gradually fell to $-0.28 \times 10^{-6}$, rising suddenly when fusion occurred to $-0.37 \times 10^{-6}$, at which value it remained constant when the fluid metal was further heated. Fleming and Dewar give for the susceptibility the values $-13.7 \times 10^{-6}$ at 15°C and $-15.9 \times 10^{-6}$ at 182°C, the latter being approximately equivalent to $K \times 10^6 = -1.62$. Putting $t = -182$ in the equation given above for Curie’s results, we get $K \times 10^6 = -1.66$, a value quite near that obtained by Fleming and Dewar to suggest the probability that the diamagnetic susceptibility varies inversely as the temperature between 182°C and the melting-point.

Other Diamagnetics.—The following table gives Curie’s determinations (Journ. de Phys., 1895, 4, 204) of the specific susceptibility $K$ of other diamagnetic substances at different temperatures. It should be noted that $K = \Delta K/density$.

For all diamagnetic substances, except antimony and bismuth, the value of $K$ was found to be independent of the temperature.

Paramagnetic Substances.—Experiments by J. S. Townsend (Phil. Trans., 1896, 187, 533) show that the susceptibility of solutions of salts of iron is independent of the magnetizing force, and depends only on the quantity of iron contained in unit volume of the liquid. If W is the weight of iron present per c.c. at about 10°C, then for ferric salts

$$10^6 = 266W - 0.77$$

and for ferrous salts

$$10^6 = 206W - 0.77$$

the quantity $-0.77$ arising from the diamagnetism of the water of solution. Annexed are values of $10^6$ for the different salts examined, relating the weight of the salt per c.c. of the solution.

Susceptibility was found to diminish greatly with rise of temperature. According to G. Jäger and S. Meyer (Wien. Akad. Sitz., 1897, 106, II.a, p. 623, and 1898, 107, II.a, p. 5) the atomic susceptibilities $k$ of the metals nickel, chromium, iron, cobalt and manganese in solution of these metals as follows:

Fe(1) is iron contained in FeCl₃ and Fe(2) iron contained in Fe(NO₃)₂.

Curie has shown, for many paramagnetic bodies, that the specific susceptibility $K$ is inversely proportional to the absolute temperature $\theta$. Du Bois believes this to be an important general law, applicable to the case of every paramagnetic substance, and suggests that the product $K\theta$ should be known as "Curie's constant" for the substance.

Elementary Bodies and Atomic Susceptibility.—Among a large number of substances the susceptibilities of which have been determined by J. Köenigsberger (Wied. Ann., 1898, 66, 698) are the following elements:

In a table accompanying Köenigsberger’s paper the elements are arranged upon the periodic system and the atomic susceptibility (product of specific susceptibility into atomic weight) is given for each. It appears that the elements at about the middle of each row are the most strongly paramagnetic; towards the ends of a row the susceptibility decreases, and ultimately becomes negative. Thus a relation between susceptibility and atomic weight is clearly indicated. Tables similarly arranged, but much more complete, have been published by S. Meyer (Wied. Ann., 1899, 68, 325 and 1899, 66, 236), whose researches have filled up many previously existing gaps. The values assigned to the atomic susceptibilities of most of the known elements are appended. According to the notation adopted by Meyer the atomic susceptibility $k = a\times$ atomic weight (density $x1000$).

Meyer thinks that the susceptibilities of the metals praseodymium, neodymium, ytterbium, samarium, gadolinium, and erbium, when obtained in a pure form, will be found to equal or even exceed those of the well-known ferromagnetic metals. Many of their compounds are very strongly magnetic, erbium, for example, in ErO₃ being four times as strong as iron in the familiar magnetite or lodestone, Fe₃O₄. The susceptibilities of some hundreds of inorganic compounds have also been determined by the same investigator (loc. cit.). Among other researches relating to atomic and molecular magnetism are those of O. Liebknecht and A. P. Wills (Ann. d. Phys., 1900, 72, II). Du Bois and Liebknecht (ibid. p. 189), and Meyer (ibid. p. 668). An excellent summary regarding the magnetic properties of matter, with many tables and references, has been compiled by du Bois (Report to the Congrès Int. de Phys., Paris, 1906, II. 460).
12. Molecular Theory of Magnetism

According to W. E. Weber’s theory, the molecules of a ferromagnetic metal are small permanent magnets, the axes of which under ordinary conditions are turned indifferently in every direction, so that no magnetic polarity is exhibited by the metal as a whole; a magnetic force acting upon the metal tends to turn the axes of the little magnets in one direction, and thus the entire piece acquires the properties of a magnet.

If, however, the molecules could turn with perfect freedom, it is clear that the smallest magnetizing force would be sufficient to develop the highest possible degree of magnetization, which is of course not the case. Weber therefore supposed each molecule to be acted on by a force tending to preserve it in its original direction, the position actually assumed by the axis being in the direction of the resultant of this hypothetical force and the applied magnetizing force. Maxwell (Electricity and Magnetism, § 444), recognizing that the theory in this form gave no account of residual magnetization, made the further assumption that if the deflection of the axis of the molecule exceeded a certain angle, the axis would not return to its original position when the deflecting force was removed, but would retain a permanent set. Although the amended theory as worked out by Maxwell is in rough agreement with certain leading phenomena of magnetization, it fails to account for many others, and is in some cases at variance with observed facts.

J. A. Ewing (Proc. Roy. Soc., 1890, 48, 342) has demonstrated that it is quite unnecessary to assume either the directive force of Weber, the permanent set of Maxwell, or any kind of frictional resistance to the forces by which the molecular magnets are constrained being simply those due to their own mutual attractions and repulsions. The effect of these is beautifully illustrated by a model consisting of a number of little compass needles pivoted on sharp points and grouped near to one another upon a board, which is placed inside a large magnetizing coil. When no current is passing through the coil and the magnetic field is of zero strength, the needles arrange themselves in positions of stable equilibrium under their mutual forces, pointing in many different directions, so that there is no resultant magnetic moment. This represents the condition of the molecules in unmagnetized iron. If now a gradually increasing magnetizing force is applied, the needles at first undergo a small deflection, giving to the group a a small resultant moment which increases uniformly with the force; and if the current is interrupted while the force is still weak, the needles merely return to their initial positions. This illustrates the first stage in the process of magnetization, when the moment is proportional to the field and there is no hysteresis or residual magnetism (see ante).

A somewhat stronger field will deflect many of the needles beyond the limits of stability, causing them to turn round and form new stable combinations, in which the direction assumed by most of them approximates to that of the field. The rearrangement is completed within a comparatively small range of magnetizing force, a rapid increase of the resultant moment being thus brought about. When the field is removed, many of the newly formed combinations are but slightly disturbed, and the group may consequently retain a considerable resultant moment. This corresponds to the second stage of magnetization, in which the susceptibility is large and permanent magnetization is set up. A still stronger magnetizing force has little effect except in causing the direction of the needles to approach still more nearly to that of the field; if the force were infinite, every member of the group would have exactly the same direction and the greatest possible resultant moment would be reached; this illustrates “magnetic saturation”—the condition approached in the third stage of magnetization. When the strong magnetizing field is gradually diminished to zero and then reversed, the needles pass from one stable position of rest to another through a condition of instability; and if the field is not reversed, so that the cycle is completed, the needles again pass through a condition of instability before a position of stable equilibrium is regained. Now the unstable movements of the needles are of a mechanically irreversible character; the energy expended in dissociating the members of a combination and placing them in unstable positions assumes the kinetic form when the needles turn over, and is ultimately frizzled down into heat. Hence in performing a cycle there is a waste of energy corresponding to what has been termed hysteresis-loss.

Supposing Ewing’s hypothesis to be correct, it is clear that if the magnetization of a piece of iron were reversed by a strong rotating field instead of by a field alternating through zero, the losses of energy by hysteresis should be little or nothing, for the molecules would rotate with the field and no unstable movements would be possible.1 Some experiments by F. G. Baily (Phil. Trans., 1866, 187, 215) show that this is actually the case. With small magnetizing forces the hysteresis was indeed somewhat larger than that obtained in an alternating field, probably on account of the molecular changes being forced to take place in one direction only; but, at an induction of about 17,000 units in soft iron and 15,000 in hard steel, the hysteresis reached a maximum and afterwards rapidly diminished. In one case the hysteresis loss per cubic centimetre per cycle was 16,100 ergs for B=15,000, and only 1,200 ergs for B=20,000, the highest induction obtained in the experiment; possibly it would have vanished before B had reached 21,000.2 These experiments prove that actual friction must be almost entirely absent, and, as Baily remarks, the agreement of the results with the previously suggested deduction affords a strong verification of Ewing’s form of the molecular theory. Ewing has himself also shown how satisfactorily this theory accords with many other obscure and complicated phenomena, such as those produced by the current, differences of magnetic quality, and the effects of vibration, temperature and stress; while as regards simplicity and freedom from arbitrary assumptions it leaves little to be desired.

The fact being established that magnetism is essentially a molecular phenomenon, the next step is to inquire what is the constitution of a magnetic molecule, and why it is that some molecules are ferromagnetic, others paramagnetic, and others again diamagnetic. The best known of the explanations that have been proposed depend upon the magnetic action of an electric current. It can be shown that if a current i circulates in a small plane circuit of area A, the magnetic action of the circuit for distant points is equivalent to that of a short magnet whose axis is perpendicular to the plane of the circuit and whose moment is iS, the direction of the magnetization being related to that of the circulating current as the thrust of a right-handed screw to its rotation. Ferromagnetism was explained by Ampère on the hypothesis that the magnetization of the molecule is due to an electric current constantly circulating within it.

The theory now most in favour is merely a development of Ampère’s hypothesis, and applies not only to ferromagnetics, but to paramagnetics as well. To account for diamagnetism, Weber supposed that there exist within the molecules of diamagnetic substances certain channels around which an electric current can circulate without any resistance. The creation of an external magnetic field H will, in accordance with Lenz’s law, induce in the molecule an electric current so directed that the magnetization of the equivalent magnet is opposed to the direction of the field. The strength of the induced current is $\mathbf{H}\cos\theta L$, where $\theta$ is the inclination of the axis of the circuit to the direction of the field, and L the coefficient of self-induction; the resolved part of the magnetic moment in the direction of the field is equal to $-\mathbf{H}\cos\theta L$, and if there are $n$ molecules in a unit of volume, their axes being distributed indifferently in all directions, the magnetization of the substance will be $-n\mathbf{H}\cos\theta L$, and its susceptibility $-nL$. (Maxwell, Electricity and Magnetism, § 838). The susceptibility is therefore constant and independent of the field, while its negative sign indicates that the substance is diamagnetic. There being no resistance, the induced current will continue to circulate

---

1 This deduction from Ewing’s theory appears to have been first suggested by J. Swinburne. See Industries, 1890, 289.

2 R. Beattie (Phil. Mag., 1901, 1, 642) has found similar effects in nickel and cobalt.
round the molecule until the field is withdrawn, when it will be stopped by the action of an electro-motive force tending to induce an exactly equal current in the opposite direction. The principle of Weber's theory, with the modification necessitated by lately acquired knowledge, is the basis of the best modern explanation of diamagnetic phenomena.

There are strong reasons for believing that magnetism is a phenomenon involving rotation, and as early as 1876 Rowland, carrying out an experiment which had been proposed by Maxwell, showed that a revolving electric charge produced the same magnetic effects as a current. Since that date it has more than once been suggested that the molecular currents producing magnetism might be due to the revolution of one or more of the charged atoms or "ions" constituting the molecule. None of the detailed hypotheses which were based on this idea stood the test of criticism, but towards the end of the 19th century the researches of J. J. Thomson and others once more brought the conception of moving electric charges into prominence. Thomson has demonstrated the existence under many different conditions of particles more minute than anything previously known to science. The assumption is always the same that of a hydrogen atom, and with each is indissolubly associated a charge of negative electricity equal to about $1 \times 10^{-19}$ C.G.S. electronstatic unit. These particles, which were termed by their discoverer corpuscles, are more commonly spoken of as electrons; the particle thus being identified with the charge which it carries. An electrically neutral atom is believed to be constituted in part, or perhaps entirely, of a definite number of electrons in rapid motion within a "sphere of uniform positive electrification" not yet explained. One or more of the electrons may be detached from the system by a linear force, the number so detachable depending on the valency of the atom; if the atom loses an electron, it becomes positively electrified; if it receives additional electrons, it is negatively electrified. The process of electric conduction in metals consists in the movement of detached electrons, and many other phenomena, both electrical and thermal, can be more or less completely explained by their agency. It has been supposed that certain electrons revolve like satellites in orbits around the atoms with which they are associated, a view which receives strong support from the phenomena of the Zeeman effect, and on this assumption a theory has been worked out by P. Langevin, which accounts for many of the observed facts of magnetism. As a consequence of the structure of the molecule, which is an aggregation of atoms, the planes of the orbits round the latter may be oriented in various positions, and the direction of revolution may be right-handed or left-handed with respect to the direction of any applied magnetic field. For those orbits whose projection upon a plane perpendicular to the field is right-handed, the period of revolution will be accelerated by the field (since the electron current is negative), and the magnetic moment consequently increased; for those which are left-handed, the period will be retarded and the moment diminished. The effect of the field upon the speed of the revolving electrons, and therefore upon the moments of the equivalent magnetc, is necessarily a very small one. If $S$ is the area of the orbit described in time $T$ by an electron of charge $e$, the moment of the equivalent magnet is $M = eS\gamma$; and the change in the value of $M$ due to an external field $H$ is shown to be $\Delta M = -eHS\gamma/m$, $m$ being the mass of the electron. Whence

$$\Delta M = -He \gamma/m$$

1 The charge associated with a corpuscle is the same as that carried by a single electron. G. Stony, in the Phil. Mag., May, 1898, has pointed out that this latter constituted the indivisible "atom of electricity" or natural unit charge. Later he proposed (Trans. Roy. Dublin Soc. 1892, p. 1) that a single one of these should be termed "electron." The adoption of this term by Thomson's corpuscle implies, rightly or wrongly, that notwithstanding its apparent mass, the corpuscle is in fact nothing more than an atom of electricity. The suggestion which C. T. R. Wilson makes (Nature, 1907, p. 95) that a material gravitating nucleus is undecided, but there are strong reasons for believing that its mass is entirely due to the electric charge.

13. Historical and Chronological Notes

The most conspicuous property of the lodestone, its attraction for iron, appears to have been familiar to the Greeks at least as early as 800 B.C. and is mentioned by Homer, Plato, Aristotle, Theophrastus and others. A passage in De rerum natura (vi. 910-915) by the Roman poet, Lucretius (50-55 B.C.), in which it is stated that the stone can support a chain of little rings, each adhering to the one above it, indicates that in his time the phenomenon of magnetization by induction had also been observed. The property of orientation, in virtue of which a freely suspended magnet points approximately to the geographical north and south, is not referred to by any European writer before the 12th century, though it is said to have been known to the Chinese at a much earlier period. The application of this property to the construction of the mariner's compass is obvious, and it is in connexion with navigation that the first references to it occur (see Compass). The needles of the primitive compasses, being made of iron, would require frequent re-magnetization, and a "stone" for the purpose of "touching the needle" was therefore generally included in the navigator's outfit. With the constant practice of this operation it is hardly possible that the repulsion acting between like poles should have entirely escaped recognition; but though it appears to have been noticed that the lodestone sometimes repelled iron instead of attracting it, no clear statement of the fundamental law that unlike poles attract while like poles repel was recorded before the publication in 1588 of the New Attractive by Robert Norman, a pioneer in accurate magnetic work. The same book contains an account of Norman's discovery and correct measurement of the dip (1576). The downward tendency of the north pole of a magnet pivoted in the usual way had been observed by G. Hartmann of Nuremberg in 1544, but his observation was not published till much later. The foundations of the modern science of magnetism were laid by William Gilbert (1590). His De magnete magnetisque corporibus et de magno magnete tellure physico descriptione (1600), contains many references to the expositions of earlier writers from Plato down to those of the author's own age. These show that the very few facts known with certainty were freely supplemented

According to the best determinations the value of $e/m$ does not exceed $1.8 \times 10^7$, and $\gamma$ is of the order of $10^{-14}$ second, the period of luminous vibrations; hence $\Delta M/M$ must always be less than $10^{-7}H$, and therefore the strongest fields yet reached experimentally, which fall considerably short of $10^5$, could not change the magnetic moment $M$ by as much as a ten-thousandth part. If the structure of the molecule is so perfectly symmetrical that, in the absence of any external field, the resultant magnetic moment of the circulating electrons is zero, then the application of a field, by accelerating the right-handed (negative) revolutions, and retarding those which are left-handed, will induce in the substance a resultant magnetization opposite in direction to the field itself; a body composed of such symmetrical molecules is therefore diamagnetic. If however the structure of the molecule is such that the electrons revolving around its atoms do not exactly cancel one another's effects, the molecule constitutes a little magnet, which under the influence of an external field will tend to set itself with its axis parallel to the field. Ordinarily a substance composed of asymmetrical molecules is paramagnetic, but if the elementary magnets are so conditioned by their strength and concentration that mutual action between them is possible, then the substance is ferromagnetic. In all cases however it is the diamagnetic condition that is initially set up—even iron is diamagnetic—though the diamagnetism may be completely masked by the superposed paramagnetic or ferromagnetic condition. Diamagnetism, in short, is an atomic phenomenon; paramagnetism and ferromagnetism are molecular phenomena. Hence may be deduced an explanation of the fact that, while the susceptibility of all known diamagnetics (except bismuth and antimony) is independent of the temperature, that of paramagnetics varies inversely as the absolute temperature, in accordance with the law of Curie.
by a number of ill-founded conjectures, and sometimes even by "figments and falsehoods, which in the earliest times, no less than nowadays, used to be put forth by raw smatterers and copyists to be swallowed of men." Thus it was taught that "if a lodestone be anointed with garlic, or if a diamond be near, it does not attract iron," and that "if pickled in the salt of a sucking fish, there is power to pick up gold which has fallen into the deepest wells." There were said to be "various kinds of magnets, some of which attract gold, others silver, brass, lead; even some which attract fish, water, fishes;" and stories were told about "mountains in the north of such great powers of attraction that they were built. A magnetizable wooden pegs, that the iron nails should be drawn from the timber." Certain occult powers were also attributed to the stone. It was "of use to thieves by its fume and sheen, being a stone born, as it were, to aid theft," and even opening bars and locks; it was effective as a love potion, and possessed "the power to reconcile husbands to their wives, and to recall brides to their husbands." And much more of the same kind, which, as Gilbert says, had come down "even to [his] own day through the writings of a host of men, who, to fill out their volumes to a proper bulk, write and copy out pages upon pages of the other subject, of which they know almost nothing for certain of their own experience." Gilibert himself absolutely disregarded authority, and accepted nothing at second-hand. His title to be honoured as the "Father of Magnetic Philosophy" is based even more largely upon the scientific method which he was the first to inculcate and practise than upon the importance of his actual discoveries. Careful experiment and observation, not the inner consciousness, are, he insists, the only foundations of true science. Nothing has been set down in his book "which hath not been explored and many times performed and repeated" by himself. "It is very easy for men of acute intellect, apart from experiment and practice, to slip and err." The greatest of Gilbert's discoveries was that the globe of the earth was magnetic and a magnet; the evidence by which he supported this view was derived chiefly from ingenious experiments made with a spherical lodestone or terrrella, as he termed it, and from his original observation that an iron bar could be magnetized by the earth's force. He also carried out some new experiments on the effects of heat, and of screening by magnetic substances, and investigated the influence of shape upon the magnetization of iron. But the bulk of his work consisted in imparting scientific definiteness to what was already vaguely known, and in demolishing the errors of his predecessors.

No material advance upon the knowledge recorded in Gilbert's book was made until the establishment by Coulomb in 1785 of the law of magnetic action. The difficulties attending the experimental investigation of the forces acting between magnetic poles have already been referred to, and indeed a rigorously exact determination of the mutual action could only be made under conditions which are in practice unattainable. Coulomb, however, by using long and thin steel rods, symmetrically magnetized, and so arranged that disturbing influences became negligibly small, was enabled to deduce from his experiments with reasonable certainty the law that the force of attraction or repulsion between two poles varies inversely as the square of the distance between them. Several previous attempts had been made to discover the law of force, with various results, some of which correctly indicated the inverse square; in particular the German astronomer, J. Tobias Mayer (Gött. Anzeiger, 1760), and the Alsatian mathematician, J. Heinrich Lambert (Hist. de l'Acad. Roy. Berlin, 1766, p. 22), may fairly be credited with having anticipated the law which was afterwards more satisfactorily established by Coulomb. The accuracy of this law was in 1832 confirmed by Gauss, who employed an indirect but more perfect method than that of Coulomb, and also, as Maxwell remarks, by all observers in magnetic observatories, who are every day making measurements of magnetic quantities, and who obtain results which would be inconsistent with each other if the law of force had been erroneously assumed.

Coulomb's researches provided data for the development of a mathematical theory of magnetism, which was indeed initiated by himself, but was first treated in a complete form by Poisson in a series of memoirs published in 1821 and later. Poisson assumed the existence of two dissimilar magnetic fluids, any element of which acted upon any other distant element in accordance with Coulomb's law of the inverse square, like repelling and attracting magnets. By making the hypothesis that these magnetic fluids were supposed to consist of an indefinite number of spherical particles, each containing equivalent quantities of the two fluids, which could move freely within a particle, but could never pass from one particle to another. When the fluids inside a particle were mixed together, the particle was neutral; when they were more or less completely separated, the particle became magnetized to an intensity depending upon the magnetic force applied; the whole body therefore consisted of a number of little spheres having north and south poles, each of which exerted an elementary force of attraction or repulsion, the forces due to bodies magnetized in any manner, and also originated the mathematical theory of magnetic induction. The general confirmation by experiment of Poisson's theoretical results created a tendency to regard his hypothetical magnetic fluids as having a real existence; but it was pointed out by W. Thomson (afterwards Lord Kelvin) in 1849 that while no physical evidence could be adduced in support of the hypothesis, certain discoveries, especially in electromagnetism, rendered it extremely improbable (Reprint, p. 344). Regarding it as important that all reasoning with reference to magnetism should be conducted without any uncertain assumptions, he worked out a mathematical theory upon the sole foundation of a few well-known facts and principles. The results were substantially the same as those given by Poisson's theory, so far as the latter went, the principal additions including a fuller investigation of magnetic distribution, and the theory of magnetic induction in acclotropic or crystalline substances. The mathematical theory which was constructed by Poisson, and extended and freed from doubtful hypotheses by Kelvin, has been elaborated by other investigators, notably F. E. Neumann, G. R. Kirchhoff, and Maxwell. The valuable work of Gauss on magnetic theory and measurements, especially in relation to terrestrial magnetism, was published in his Intensitas vis magneticae terrestris, 1833, and in memoirs communicated to the Resultate aus den Beobachtungen des magnetischen Vereines, 1838 and 1839, which, with others, are contained in vol. 5 of the collected Werke. Weber's molecular theory, which has already been referred to, appeared in 1852.

An event of the first importance was the discovery made in 1819 by H.C. Oersted * that a magnet placed near a wire carrying an electric current tended to set itself at right angles to the wire, a phenomenon which indicated that the current was surrounded by a magnetic field. This discovery constituted the foundation of electromagnetism, and its publication in 1820 was immediately followed by A. M. Ampère's experimental and theoretical investigation of the mutual action of electric currents, and of the equivalence of a closed circuit to a polar magnet, the latter suggesting his celebrated hypothesis that magnetic currents were the cause of magnetism. In the same year D. F. Arago * succeeded in magnetizing a piece of iron by the electric current, and in 1825 W. Sturgeon * publicly exhibited an apparatus "acting

on the principle of powerful magnetism and feeble galvanism, which is believed to have constituted the first actual electromagnet. Michael Faraday's researches were begun in 1831 and continued for more than twenty years. Among the most splendid of his achievements was the discovery of the phenomena and laws of magneto-electric induction, the subject of two papers communicated to the Royal Society in 1831 and 1832. Another was the magnetic rotation of the plane of polarization of light, which was effected in 1845, and for the first time established a relation between light and magnetism. This was followed at the close of the same year by the discovery of the magnetic rotary movement of all matter, a discovery which initiated a prolonged and fruitful study of paramagnetic and diamagnetic phenomena, including magnecrystal action and "magnetic conducting power," now known as permeability. Throughout his researches Faraday paid special regard to the medium as the true seat of magnetic action, being to a large extent guided by his pregnant conception of "lines of force," or of induction, which he considered to be "closed curves passing in one part of the course through the magnet to which they belong, and in the other part through space," always tending to shorten their distance, and expelling another when they were side by side (Exp. Res. §§ 3266-8, 3271). In 1873 James Clerk Maxwell published his classical Treatise on Electricity and Magnetism, in which Faraday's ideas were translated into a mathematical form. Maxwell explained electric and magnetic forces, not by the action at a distance assumed by the earlier mathematicians, but by stresses in a medium filling all space, and possessing qualities like those attributed to the old luminiferous ether. In particular, he found that the calculated velocity with which it transmitted electromagnetic disturbances was equal to the observed velocity of light; hence he was led to believe, not only that his medium and the ether were one and the same, but, further, that light itself was an electromagnetic phenomenon. Since the experimental confirmation of Maxwell's views by H. R. Hertz in 1888 (Weid. Ann., 1888, 34. 155, 551, 609; and later vols.) they have commanded universal assent, and his methods are adopted in all modern work on electricity and magnetism.

The practice of measuring magnetic induction and permeability with scientific accuracy was introduced in 1873 by H. A. Rowland, whose careful experiments led to general recognition of the fact previously ignored by nearly all investigators, that magnetic susceptibility and permeability are by no means constants (at least in the case of the ferromagnetic metals) but functions of the magnetizing force. New light was thrown upon many important details of magnetic science by J. A. Ewing's Experimental Researches of 1885; throughout the whole of his work special attention was directed to that curious lagging action to which the author applied the now familiar term "hysteresis." His well-known modification of Weber's molecular theory, published in 1890, presented for the first time a simple and sufficient explanation of hysteresis and many other complexities of magnetic quality. The amazing discoveries made by J. J. Thomson in 1897 and 1898 resulted in the establishment of the electron theory, which has already effected developments of an almost revolutionary character in more than one branch of science. The application of the theory of P. Langevin to the atomic molecular magnetism has been noticed above, and there can be little doubt that in the near future it will be applied to the solution of other problems which are still obscure.

(S. B.)

MAGNETISM, TERRESTRIAL, the science which has for its province the study of the magnetic phenomena of the earth.

§ 1. Terrestrial magnetism has a long history. Its early growth was slow, and considerable uncertainty prevails as to its earliest development. The properties of the magnet (see MAGNETISM) were to some small extent known to the Greeks and Romans before the Christian era, and compasses (see COMPASS) of an elementary character seem to have been employed in Europe at least as early as the 12th century. In China and Japan compasses of a kind seem to have existed at a much earlier date, and it is even claimed that the Chinese were aware of the declination of the compass needle from the true north before the end of the 11th century. Early scientific knowledge was usually, however, a mixture of facts, very imperfectly ascertained, with philosophical imaginations. When an early writer makes a statement which to a modern reader suggests a knowledge of the declination of the compass, he may have had no such definite idea in his mind. So far as Western civilization is concerned, Columbus is usually credited with the discovery— in 1492 during his first voyage to America—that the pointing of the compass needle to the true north represents an exceptional state of matters, and that a declination in general exists, varying from place to place. The credit of these discoveries is not, however, universally conceded to Columbus. G. Hellmann * considers it almost certain that the departure of the needle from the true north was known in Europe before the time of Columbus. There is indirect evidence that the declination of the compass was not known in Europe in the early part of the 15th century, through the peculiarities shown by early maps believed to have been drawn solely by regard to the compass. Whether Columbus was the first to observe the declination or not, his date is at least approximately that of its discovery.

The next fundamental discovery is usually ascribed to Robert Norman, an English instrument maker. In The Newe Attractive Magnetic Discouerie he described how the discovery made some years before of the inclination or dip. The discovery was made more or less by accident, according to Norman's noticing that compass needles which were truly balanced so as to be horizontal when unmagnetised, ceased to be so after being stroked with a magnet. Norman devised a form of dip-circle, and found a value for the inclination in London which was at least not very wide of the mark. Another fundamental discovery, that of the secular change of the declination, was made in England by Henry Gellibrand, professor of mathematics at Gresham College, who described it in his Discourse of Mathematical and the Variations of the Magnetic Needle together with its Admirable Diminution lately discovered (1633). The history of this discovery affords a curious example of knowledge long delayed. William Borough, in his Discourse on the Variation of the Compass or Magnetic Needle (1581), gave for the declination at Limehouse in October 1580 the value 11° 34' E. approximately. Observations were repeated at Limehouse, Gellibrand tells us, in 1622 by his colleague Edmund Gunter, professor of astronomy at Gresham College, who found the much smaller value 6° 13'. The difference seems to have been ascribed to a lack of error in Borough's part, and no suspicion of the truth seems to have been felt until 1652, when some rough observations gave a value still lower than that found by Gunter.

* For explanation of these numbers, sec end of article.
MAGNETISM, TERRESTRIAL

It was not until midsummer 1634 that Gellibrand felt sure of his facts, and yet the change of declination since 1580 exceeded 7°. The delay probably arose from the strength of the preconceived idea, apparently universally held, that the declination was absolutely fixed. This idea, it would appear, derived some of its strength from the positive assertion of Caspari made on the point by Gilbert of Colchester in his De magnete (1600).

A third fundamental discovery, that of the diurnal change in the declination, is usually credited to George Graham (1675-1751), a London instrument maker. Previous observers, e.g., Gellibrand, had obtained slightly different values for the declination at different hours of the day, but it was natural to assign them to instrumental uncertainties. In those days the usual declination instrument was the compass with pivoted needles, and Graham himself at first assigned the differences he observed to friction. The observations on which he based his conclusions were made in 1722; an account of them was communicated to the Royal Society and published in the Philosophical Transactions for 1724.

The movements of the compass needle throughout the average day represent partly a regular diurnal variation, and partly irregular changes in the declination. The distinction, however, was not at first very clearly realized. Between 1756 and 1759 J. Canton observed the declination-changes on some 600 days, and was thus able to deduce their general character. He found that the most prominent part of the regular diurnal change in England consisted of a westerly movement of the north-pointing pole from 8 or 9 o'clock to 1 or 2 p.m., followed by a more leisurely return movement to the east. He also found that the amplitude of the movement was considerably larger in summer than in winter. Canton further observed that in a few days the movements were conspicuously irregular, and that aurora was then visible. This association of magnetic disturbance and aurora had, however, been observed somewhat before this time, a description of one conspicuous instance being contributed to the Royal Society in 1750 by Pehr Vilhelm Wargentin (1717-1783), a Swede.

Another landmark in the history of terrestrial magnetism was the discovery towards the end of the 18th century that the intensity of the resultant magnetic force varies at different parts of the earth. The first observations clearly showing this seem to be those of a Frenchman, Paul de Lamanon, who observed in 1785-1787 at Teneriffe and Macao, but his results were not published at the time. The first published observations seem to be those made by the great traveller Humboldt in tropical America between 1779 and 1803. The delay in this discovery may again be attributed to instrumental imperfections. The method first devised for comparing the force at different places consisted in taking the time of oscillation of the dipping needle, and even with modern circles this is hardly a method of high precision. Another discovery worth chronicling was made by Arago in 1827. From observations made at Paris he found that the inclination of the dipping needle and the intensity of the horizontal component of the magnetic force both possessed a diurnal variation.

§ 2. Whilst Italy, England and France claim most of the early observational discoveries, Germany deserves a large share of credit for the great improvement in instruments and methods during the first half of the 19th century. Measurements of the intensity of the magnetic force were somewhat crude until Gauss showed how absolute results could be obtained, and not merely relative data based on observations with some particular needle. Gauss also devised the bifilar magnetometer which is still largely represented in instruments measuring changes of the horizontal force; but much of the practical success attending the application of his ideas to instruments seems due to Johann von Lamont (1805-1879), a Jesuit of Scottish origin resident in Germany.

The institution of special observatories for magnetic work is largely due to Humboldt and Gauss. The latter's observatory at Göttingen, where regular observations began in 1834, was the centre of the Magnetic Union founded by Gauss and Weber for the carrying out of simultaneous magnetic observations and it was long customary to employ Göttingen in schemes of international co-operation.

In the next decade, mainly through the influence of Sir Edward Sabine (1788-1858), afterwards president of the Royal Society, several magnetic observatories were established in the British colonies, e.g., St Helena, Cape of Good Hope, Harpenden (in Bow Hobart) and Toronto. These, with the exception of Toronto, continued in full action for only a few years; but their records—from their widely distributed positions—threw much fresh light on the differences between magnetic phenomena in different regions of the globe. The introduction of regular magnetic observatories led ere long to the discovery that there are notable differences between the amplitudes of the regular daily changes and the frequency of magnetic disturbances in different years. The discovery that magnetic phenomena have a period closely similar to, if not absolutely identical with, that of the sun year period in sunspots, was made independently and nearly simultaneously about the middle of the 19th century by Lamont, Sabine and R. Wolf.

The last half of the 19th century showed a large increase in the number of observatories taking magnetic observations. After 1890 there was an increased interest in magnetic work. One of the contributory causes was the magnetic survey of the British Isles made by Sir A. Rücker and Sir T. E. Thorpe, which served as a stimulus to similar work elsewhere; another was the increase in importance of terrestrial magnetism, due largely to the invention of instruments specially devoted to the subject. This increased activity added largely to the stock of information, sometimes in forms of marked practical utility; it was also manifested in the publication of a number of papers of a speculative character. For historical details the writer is largely indebted to the works of E. Walker and L. A. Bauer.

§ 3. All the more important magnetic observatories are provided with instruments of two kinds. Those of the first kind give the absolute value of the magnetic elements at the time of observation. These are based on the assumption of two horizontal lines in the earth, one of which, the base line, gives the absolute values of the declination and dip. The other, the ordinate, gives the absolute value of the vertical force; the horizontal force is derived from it by the expression

\[ F = \frac{B}{\sin \delta} \]

where \( F \) is the horizontal force, \( B \) the vertical force, and \( \delta \) the dip.

It follows from this expression that if the base line is divided into equal parts and the dip is measured at each, one has the absolute values of the vertical force at equal distances from the base line.

In the case of the declination, the declination of 1 cm. of ordinate, for example, is the length of the declination base line corresponding to ordinate on the magnetic element which corresponds to the base line, and the equivalent of 1 cm. of ordinate, we can deduce the absolute value of the magnetic element on the basis of the declination line, or the determination of the length of the declination base line corresponding to the distance on the magnetic element which corresponds to the base line, and the equivalent of 1 cm. of ordinate, we can deduce the absolute value of the magnetic element on the basis of the declination line, or the determination of the length of the declination base line corresponding to the distance on the magnetic element which corresponds to the base line, and the equivalent of 1 cm. of ordinate, we can deduce the absolute value of the magnetic element on the basis of the declination line, or the determination of the length of the declination base line corresponding to the distance on the magnetic element which corresponds to the base line, and the equivalent of 1 cm. of ordinate, we can deduce the absolute value of the magnetic element on the basis of the declination line, or the determination of the length of the declination base line corresponding to the distance on the magnetic element which corresponds to the base line, and the equivalent of 1 cm. of ordinate, we can deduce the absolute value of the magnetic element on the basis of the declination line, or the determination of the length of the declination base line corresponding to the distance on the magnetic element which corresponds to the base line, and the equivalent of 1 cm. of ordinate, we can deduce the absolute value of the magnetic element on the basis of the declination line, or the determination of the length of the declination base line corresponding to the distance on the magnetic element which corresponds to the base line, and the equivalent of 1 cm. of ordinate, we can deduce the absolute value of the magnetic element on the basis of the declination line, or the determination of the length of the declination base line corresponding to the distance on the magnetic element which corresponds to the base line, and the equivalent of 1 cm. of ordinate, we can deduce the absolute value of the magnetic element on the basis of the declination line, or the determination of the length of the declination base line corresponding to the distance on the magnetic element which corresponds to the base line, and the equivalent of 1 cm. of ordinate, we can deduce the absolute value of the magnetic element on the basis of the declination line, or the determination of the length of the declination base line corresponding to the distance on the magnetic element which corresponds to the base line, and the equivalent of 1 cm. of ordinate, we can deduce the absolute value of the magnetic element on the basis of the declination line, or the determination of the length of the declination base line corresponding to the distance on the magnetic element which corresponds to the base line, and the equivalent of 1 cm. of ordinate, we can deduce the absolute value of the magnetic element on the basis of the declination line, or the determination of the length of the declination base line corresponding to the distance on the magnetic element which correspon

As an example of how the curves are standardized, suppose that absolute observations of declination are taken four times a month, and that four is given here as the mean of the observed values is 15° 36'. The curves are measured at the places which correspond to the times of the four observations, and the mean length of the four curves is, let us say, 2-5 cm. If the curves are, say, 10°, then 2-5 cm. represents the value which the declination would have if the curve came down to the base line—which is for the month in question 16° 34'-6 less 25'-2 or
MAGNETISM, TERRRESTRIAL

$355$

§ 5. The intensity and direction of the resultant magnetic force ascertained by the four independent methods of determining a magnetic pole—say, as if we knew the three components of force parallel to any set of orthogonal axes. It is usual to take for these axes the vertical at the spot and two perpendicular axes in the horizontal plane; the horizontal is usually taken as the north-or-south meridian. The usual notation in mathematical work is $X$ to the north, $Y$ to the west or east, and $Z$ vertically downwards. The international magnetic committee have recommended that $Y$ be taken to the east, but the fact that the declination is westward over most of Europe has often led to the opposite procedure, and writers are not always as careful as they should be in stating their choice. Apart from mathematical calculations, the more usual course is to define the force by its horizontal and vertical components—usually termed $H$ and $V$—and by the declination or angle which the horizontal component makes with the astronomical meridian. The declination is sometimes counted from $0^\circ$ to $360^\circ$, $0^\circ$ answering to the case when the so-called north pole (or north-seeking pole) is directed towards geographical north, $90^\circ$ to the case when it is directed east, and $90^\circ$ to the west. In more usual, however, to reckon declination only from $0^\circ$ to $180^\circ$, characterizing it as easterly or westerly according as the north pole points to the east or to the west of the geographical meridian. The force is also completely defined by $H$ or $V$, together with $D$ the declination, and $I$ the inclination to the horizon of the dipping needle. Instead of $H$ and $D$ some writers make use of $N$ the northerly component, and $W$ the westerly (or $E$ the easterly). The resultant force itself is denoted sometimes by $R$, sometimes by $T$ (total force). The following relationships exist between the symbols

\[
x = N, \quad Y = W \text{ or } E, \quad Z = V, \quad R = T, \quad H = (X^2 + Y^2), \quad R = (X^2 + Y^2 + Z^2),
\]

\[
\tan D = Y/X, \quad \tan I = V/H.
\]

The term magnetic element is applied to $R$ or any of the components, and even to the angles $D$ and $I$.

§ 6. Declination is the element concerning which our knowledge is most complete and most reliable. With a good unifilar magnetometer, at a fixed observatory distant

Charts. From the magnetic poles, having a fixed mark of

known azimuth, the observational uncertainty in a single observation should not exceed $0^\circ.5$ or at most $1^\circ.0$. It cannot be

taken for granted that different unifilars, even by the best makers,

will give absolutely identical values for the declination, but as a

matter of fact the differences observed are usually very trifling.

The chief source of uncertainty in the observation lies in the
torsion of the suspension fibre, usually of silk or more rarely of

phosphor bronze or other metal. A very stout suspension must

be avoided at all cost, but the fibre must not be so thin as to have

a considerable risk of breaking even in skilled hands. Near a

magnetic pole the directive force on the declination magnet is

reduced, and the effects of torsion are correspondingly increased.

On the other hand, the regular and irregular changes of declina-

tion are much enhanced. If an observation consisting of four

readings of declination is taken, the irregular changes are likely to be

so great that in this time the range at an English station will not exceed $1^\circ$, whereas at an arctic or antarctic station it will frequently exceed $10^\circ$. Much greater uncertainty thus attaches to declina-

tion results in the Arctic and Antarctic than to those in temperate

latitudes. In the case of secular change data one important considera-

tion is that the observations should be taken at an

absolutely fixed spot, free from any artificial source of disturb-

ance. In the case of many of the older observations of which

we are aware, the choice spot cannot be very exactly fixed, and

not infrequently there is a continual change of the ground due to the
errection of buildings not free from iron. Apart from buildings,

much depends on whether the neighbourhood is free from basalt-

and other magnetic rocks. If there are no local disturbances of

this sort, a few years difference is usually without appreciable influence, and even a few miles difference is of minor importance when one is calculating the mean secular change for a long period of years. When, however, local disturbances exist, even a few feet difference in the site may be important, and

in the absence of parallel and perpendicular to the geographical

direction naturally changes very rapidly when one travels in the

direction perpendicular to the lines of equal declination, so that the exact position of the site of observation is there of special importance.

16° 9.4. If now we wish to know the declination at any instant in this particular month all we have to do is to multiply the theoretical diurnal variation (for this case $355$) by the sine of the day, for the base value $16° 9.4$ just found. Matters are a little more complicated in the case of the horizontal and vertical force magnetographs. Both instruments are only taken at the beginning of the month, the position of the magnet is dependent to some extent on the temperature it possesses, and allowance has thus to be made for the difference from a standard temperature. In the case of the vertical force magnetograph it has been found that the observed value of the inclination with the simultaneous value of the horizontal force derived from the horizontal force magnetograph is very little altered if the mean curve for horizontal force derived from the curves suffers in accuracy, especially relating to the secular change. It is from the curves that information is derived as to the regular diurnal variation and irregular changes. In some observatories it is customary to publish a page of

full record of the values of the magnetic elements at every hour for

each day of the year. A useful and not unusual addition to this is a

statement of the absolutely largest and smallest values of each

element recorded during each day, with the precise times of their

occurrence. On days of large disturbance even hourly readings give

but a very imperfect idea of the phenomena, and it is customary at

some places to publish the mean monthly curve.

The chief source of uncertainty in the observation lies in the
torsion of the suspension fibre, usually of silk or more rarely of

phosphor bronze or other metal. A very stout suspension must

be avoided at all cost, but the fibre must not be so thin as to have

a considerable risk of breaking even in skilled hands. Near a

magnetic pole the directive force on the declination magnet is

reduced, and the effects of torsion are correspondingly increased.

On the other hand, the regular and irregular changes of declina-

tion are much enhanced. If an observation consisting of four

readings of declination is taken, the irregular changes are likely to be

so great that in this time the range at an English station will not exceed $1^\circ$, whereas at an arctic or antarctic station it will frequently exceed $10^\circ$. Much greater uncertainty thus attaches to declina-

tion results in the Arctic and Antarctic than to those in temperate

latitudes. In the case of secular change data one important considera-

tion is that the observations should be taken at an

absolutely fixed spot, free from any artificial source of disturb-

ance. In the case of many of the older observations of which

we are aware, the choice spot cannot be very exactly fixed, and

not infrequently there is a continual change of the ground due to the
errection of buildings not free from iron. Apart from buildings,

much depends on whether the neighbourhood is free from basalt-

and other magnetic rocks. If there are no local disturbances of

this sort, a few years difference is usually without appreciable influence, and even a few miles difference is of minor importance when one is calculating the mean secular change for a long period of years. When, however, local disturbances exist, even a few feet difference in the site may be important, and

in the absence of parallel and perpendicular to the geographical

direction naturally changes very rapidly when one travels in the

direction perpendicular to the lines of equal declination, so that the exact position of the site of observation is there of special importance.
MAGNETISM, TERRESTRIAL

The usual method of conveying information as to the value of the declination at different parts of the earth's surface is to draw curves on a map—the so-called isogonals—such that at all points on any one curve the declination at a given specified epoch has the same value. The information being of especial use to sailors, the preparation of magnetic charts has been largely the work of naval authorities, especially of the hydrographic department of the British admiralty. The object of the admiralty world charts—four of which are reproduced here, on a reduced scale, by the kind permission of the Hydrographer—is rather to show the general features boldly than to indicate minute details. Apart from the immediate necessities of the case, this is a counsel of prudence. The observations used have mostly been taken at dates considerably anterior to that to which the chart is intended to apply. What the sailor wants is the declination now or for the next few years, not what it was five, ten or twenty years ago. Reliable secular change data, for reasons already indicated, are mainly obtainable from observatories, and there are enormous areas outside of Europe where no such observatories exist. Again, as we shall see presently, the rate of the secular change sometimes alters greatly in the course of a comparatively few years. Thus, even when the observations themselves are thoroughly reliable, the reconstruction made for a future date by even the most experienced of chart makers may be occasionally somewhat wide of the mark.

Fig. 1 is a reduced copy of the British admiralty declination chart for the epoch 1907. It shows the isogonals between 70° N. and 65° S. latitude. Beyond the limits of this chart, the number of exact measurements of declination is considerably limited, but the general nature of the phenomena is easily inferred. The geographical and the magnetic poles—where the dipping needle is vertical—are fundamental points. The north magnetic pole is situated in North America near the edge of the chart. We have no reason to suppose that the magnetic pole is really a fixed point, but for our present purpose we may regard it as such. Let us draw an imaginary circle round it, and let us travel round the circle in the direction west, north, east, south, starting from a point where the north pole of a magnet (i.e. the pole which in Europe or the United States points to the north) is directed exactly towards the north pole of the earth. This line is the geographical south of the magnetic pole. As we go round the circle the needle keeps directed to the magnetic pole, and so points first slightly to the east of geographical north, then more and more to the east, then to south of east, then to due south, then, to west of south, to west, to north-west, and finally when we get round to our original position due north once more. Thus, during our course we have been following a set of fixed directions. In other words, isogonals answering to all possible values of the declination have their origin in the north magnetic pole. The same remark applies of course to the south magnetic pole.

Now, suppose once more the north geographical pole of the earth. Neglecting as before diurnal variation and similar temporary changes, and assuming no abnormal local disturbance, the compass needle at and near this pole will keep a fixed direction relative to the ground underneath. Let us draw on the ground through the pole a straight line parallel to the direction taken there by the compass needle, and let us carry a compass needle round a small circle geographical to the south magnetic pole at every point of which the needle points in the geographical meridian; but here the north pole of the needle is pointing south, not north, so that this portion of curve is really an isogonal of 180°. In continuation of this there emanates from the south magnetic pole a second isogonal of 0°, or agonic line, which traverses Australia, Arabia and Russia, and takes us to the north geographical pole. Finally, we have an isogonal of 180°, continuous with the second isogonal of 0° which takes us to the north magnetic pole, from which we started. Throughout the whole area included within these isogonals of 0° and 180°—excluding locally slight changes of course—this type of declination is in general easterly. There is, however, as shown in the chart, an isogonal of 0° enclosing an area in eastern Asia inside which the declination is westerly though small.

If, for example, we select the isogonal of 0° E., we at first travel nearly south, but then more and more westerly, then north-westerly across the north-east of Asia; the direction then gets less northerly, and makes a dip to the south before finally making for the north geographical pole. It is possible, however, pole diging the chart, to travel in the magnetic pole to the south geographical pole, provided we select an isogonal answering to a small westerly or easterly declination (from about 19° W. to 7° W.).

Special interest attaches to the isogonals answering to declination 0°. These are termed agonic lines, but sailors often call them lines of no variation, the term variation having at one time been in common use in the sense of declination. If we start from the north magnetic pole the agonic line takes us across Canada, the United States and South America in a fairly straight course to the south geographical pole. A curve continuous with this can be drawn from the south

![Fig. 1. —Isogonals, or lines of equal magnetic declination.](chart.jpg)
the southerly inclination is less in South America than in the same latitudes of Africa.

Fig. 3 is a reduced copy of the admiralty horizontal force chart for 1907. The curves, called isomagnetics, connect the places where the horizontal force has the same value; the force is expressed in C.G.S. units. The horizontal force vanishes of course at the magnetic poles. The chart shows a maximum value of between 0-39 and 0-40 in an oval including the south of Siam and the China Sea. The horizontal force is smaller in North America than in corresponding latitudes in Europe.

Charts are sometimes drawn for other magnetic elements, especially vertical force (fig. 4) and total force. The isomagnetic of zero vertical force coincides necessarily with that of zero dip, and there is in general considerable resemblance between the forms of lines of equal vertical force and those of equal dip. The highest values of the vertical force occur in areas surrounding the magnetic poles, and are fully 50% larger than the largest values of the horizontal force. The total force is least in equatorial regions, where values slightly under 0-4 C.G.S. are encountered. In the northern hemisphere there are two distinct maxima of total force. One of these so-called foci is in Canada, the other in the north-east of Siberia, the former having the higher value of the force. There are, however, higher values of the total force than at either of these foci throughout a considerable area to the south of Australia. In the northern hemisphere the lines of equal total force—called isodynamic lines—form two sets more or less distinct, consisting of closed ovals, one set surrounding the Canadian the other the Siberian focus.

§ 8. As already explained, magnetic charts for the world or for large areas give only a general idea of the values of the elements. If the region is undisturbed, very fairly approximate values are derivable from the charts, but when the highest accuracy is necessary, the only thing to do is to observe at the precise spot. In disturbed areas local values often depart somewhat widely from what one would infer from the chart, and occasionally there are large differences...
between places only a few miles apart. Magnetic observatories usually publish the mean value for the year of their magnetic elements. It has been customary for many years to collect and publish these results in the annual report of the Kew Observatory (Observatory Department of the National Physical Laboratory). The data in Tables I. and II. are mainly derived from this source. The observatories are arranged in order of latitude, and their geographical co-ordinates are given in Table II, longitude being reckoned from Greenwich. Table I. gives the mean values of the declination, inclination and horizontal force for January 1, 1901; they are in the main arithmetic means of the mean annual values for the two years 1900 and 1901. The mean annual secular changes given in this table are derived from a short period of years—usually 1898 to 1903—the centre of which fell east all over Europe, and the rate at which it is moving seems not to vary much throughout the continent. The needle is also moving to the east throughout the western parts of Asia, the north and east of Africa, and the east of North America. It is moving to the west in the west of North America, in South America, and in the south and east of Asia, including Japan, south-east Siberia, eastern China and most of India.

§ 9. The information in figs. 1, 2, 3 and 4 and in Tables I. and II. applies only to recent years. Owing to secular change, recent charts differ widely from the earliest ones constructed. The first charts believed to have been constructed were those of Edmund Halley the astronomer. According to L. A. Bauer, who has made a special study of the subject, Halley issued two declination charts for the epoch 1700: one, published in 1701, was practically confined to the Atlantic Ocean, whilst the second, published in 1702, contained

at the beginning of 1901. Table II. is similar to Table I., but includes vertical force results; it is more extensive and contains more recent data. In it the number of years is specified from which the mean secular change is derived; in all cases the last year of the period employed was that to which the absolute values assigned to the element belong. The great majority of the stations have declination and inclination north; it has thus been convenient to attach the + sign to increasing westerly (or decreasing easterly) declination and to increasing northerly (or decreasing southerly) inclination. In other words, in the case of the declination + means that the north end of the needle is moving to the west, while in the case of the inclination + means that the north end (whether the dipping end or not) is moving towards the nadir. In the case, however, of the vertical force + means simply numerical increase, irrespective of whether the north or the south pole dips. The unit employed in the horizontal and vertical secular force changes is by, i.e. 0·00007 C.G.S. Even in the declination, at the very best observatories, it is hardly safe to assume that the apparent change from one year to the next is absolutely truthful to nature. This is especially the case if there has been any change of instrument or observer, or if any alteration has been made to buildings in the immediate vicinity. A change of instrument is a much greater source of uncertainty in the case of horizontal force or dip than in the case of declination, and dip circles and needles are more liable to deterioration than magnetometers. Thus, secular change data for, inclination and vertical force are the least reliable. The uncertainties, of course, are much less, from a purely mathematical standpoint, for secular changes representing a mean from five or ten years than for those derived from successive years' values of the elements. The longer, however, the period of years, the greater is the chance that one of the elements may in the course of it have passed through a maximum or minimum value. This possibility should always be borne in mind in cases where a mean secular change appears exceptionally small.

As Tables I. and II. show, the declination needle is moving to the also data for the Indian Ocean and part of the Pacific. These charts showed the isogonic lines, but only over the ocean areas. Though the charts for 1700 were the first published, there are others which apply to earlier epochs. W. van Bemmelen has published charts for the epochs 1500, 1550, 1600, 1650 and 1700, whilst H. Fritsche has more recently published charts of declination, inclination and horizontal force for 1600, 1700, 1750, 1812 and 1915. A number of early declination charts were given in Hansteen's Atlas and in G. Hellmann’s reprints, Die Alten Karten der Isogonen, Isoklinen, Isodynamicen (Berlin, 1895). The data for the earlier epochs, especially those prior to 1700, are meagre, and in many cases probably of indifferent accuracy, so that the reliability of the charts for these epochs is somewhat open to doubt.

If we take either Hansteen’s or Fritsche’s declination chart for 1600 we notice a profound difference from fig. 1. In 1600 the agonic line starting from the north magnetic pole, after finding its way south to the Gulf of Mexico, doubled back to the north-east, and passed across or near Iceland. After getting well to the north of Iceland it doubled again to the south, passing to the east of the Baltic. The second agonic line which now lies to the west of St Petersburg appears in 1600 to have continued, after traversing Australia, in a nearly northerly direction through the extreme east of China. The nature of the changes in declination in western Europe will be understood from Table III., the data from which, though derived from a variety of places in the south-east of England, may be regarded as approximately true of London. The earliest result is that obtained by Borough at Limehouse. Those made in the 16th century are due to Gunter, Gellibrand, Henry Bond and Halley. The observations from 1787 to 1805 were due to George Gilpin, who published particulars of his own and the earlier observations in the Phil. Trans. for 1806. The data for 1817 and 1820 were obtained by Col. Mark Beaufoy, at Bushey, Herts. They seem to come precisely at the time when the needle, which had been continuously moving to the west since the earliest observations, began to retrace its steps. The data from 1850 onwards apply to Kew.

</table>

The rate of movement of the needle to the east at London—throughout Europe generally—fell off markedly subsequently to 1880. The change of declination in fact between 1880 and 1895 was only about 75% of that between 1865 and 1880, and the annual average change from 1895 to 1900 was less than 75% of the mean annual change of the preceding fifteen years. Thus in 1902 it was at least open to doubt whether a change in the sign of the secular change would not be in immediate prospect. However, to that date there was little further decline in the rate of secular change, and since 1903 there has been very distinct acceleration. Thus, if we define the mean value from the eighteen European stations for which declination secular changes are given in Tables I and II, we find

mean value from Table I. -4 18

Table V. contains some data for St. Helena and the Cape of Good Hope, both places having a long magnetic history. The remarkable constancy in the rate of secular change. The figures for the Cape show a reversal in the direction of the secular change about 1840, but after a few years the arrested movement to the west again became discernible. According, however, to J. I. Beathe's Magnetic Survey of South Africa the movement to the west ceased shortly after 1870. A persistent movement to the east then set in, the mean annual change increasing from 1' between 1873 and 1890 to 3'8 between 1890 and 1900.

§ 11. Secular changes of declination have been particularly interesting in the United States of America, which is information is usually complete, thanks to the labours and publications of the United States Coast and Geodetic Survey. At present the agonic line passes in a south-easterly direction through the southern part of South Carolina. To the east of the agonic line the declination is westery, and to the west it is easterly. It seems to be moving to the west, but it is very slow. To the east of the agonic line westerly declination is appearing. There is no reason to doubt the exception of a narrow strip immediately adjacent to it, easterly declination is increasing. The phenomena in short suggest a motion southwards in the north magnetic pole.

The study of the secular changes has been of great interest, but for a number of years it has been in vain to search for a sign of easterly declination in the extreme east of the States, and always easterly in the extreme west, but the position of the agonic line has altered a good deal. It was to the east of the Sierra Nevada Mountains, in California, from 1750 to about 1772, then to the east of it until about 1838 when it once more passed to the west; since that time it has travelled farther to the west. Table VI. is intended to show the nature of the secular change throughout the whole country. As before, + denotes that the north pole of the magnet is moving to the west, that it is moving to the east.

The data in Table VI. represent the mean change of declination per annum, derived from the period (ten years, except for 1900-1905) which ended in the year put at the top of the column. Observatories are arranged in alphabetical order, the first group representing the extreme eastern, the last group the extreme western states, the other two groups being intermediate. In each group the stations are arranged approximately, in order of latitude. The data are derived from the values of the declination given in the Geodetic Survey's Report for 1906, appendix 4, and Magnetic Tables and Magnetic Charts by L. A. Bauer, 1906. The values seem, in most cases, based to some extent on calculation, and very probably the secular change was not in reality quite so regular as the figures suggest. For the Western States the earliest data are comparatively recent, but for the States of the east coast, as Maine, for instance, from 1750 to 1870, there is not very much evidence as to the secular change between 1700 and 1650, the earliest date to which the Coast and Geodetic Survey's figures refer. The figures show a maximum of westerly declination about 1670 in New Jersey and about 1675 in Maryland. They suggest that this maximum was experienced all along the Atlantic border some time in the 17th century, but earlier in the extreme north-east than in New York or Maryland.

Examination of Table VI. shows that the needle continued to move to the east for some time after 1750 even in the Eastern States. But the rate of movement was clearly diminishing, and about 1765 the extreme easterly position was reached in Eastport, Maine, the needle then beginning to retrace its steps to the west. The phenomena visible at Maine are seen repeating themselves at places along the whole coast. In Boston, Massachusetts, about 1800, in Washington, D.C., about 1805, in Columbus (Ohio) about 1815, in Montgomery (Alabama) about 1825, in Bloomington (Ill.) about 1830, in Des Moines (Iowa) about 1835, and in Salt Lake about 1870. In 1885 the needle was moving to the west over the whole United States with the exception of a comparatively narrow strip along the Pacific coast. From 1885 to 1890 the needle has been moving west, but the rate of movement has been very small, it had at no date the secular change would be pronouncedly westerly high up to the Pacific. But in a few years a complete change took place. The movement to the west, which had been exceedingly small, if any, on the Pacific coast, now accelerated; the movement to the west continued in the central, as in the eastern states, but perceptibly slackened. In 1905 the area through which the needle moved west ceased to be greatly contracted and lay to the east of a line drawn from the west end of Lake Superior to the west of Georgia. If we take a station like Little Rock (Arkansas), we have the secular change to the

Recent Values of the Magnetic Elements and their Rate of Secular Change.


earlier observations in London were probably of no very high accuracy, and the rates of secular change derived from them are correspondingly uncertain. It is not improbable that the average annual change of the type \( c + \alpha (L - L_0) + \beta (\lambda - \lambda_0) \), where \( \alpha, \beta, \gamma \) are constants, \( L_0 \) and \( \lambda_0 \) denoting some fixed latitude and longitude which it is convenient to take as point of departure. Supposing observational data available from a series of stations throughout the area, \( \alpha \), \( \beta \), and \( \gamma \) can be determined by least squares. As an example, we may take the following slightly modified formula given by Ad. Schmidt \(^1\) as applicable to Northern Europe for the period 1890 to 1900. \( \Delta D, \Delta I, \) and \( \Delta H \) represent the mean annual changes during this period in westerly declination, in inclination and in horizontal force:

\[
\begin{align*}
\Delta D &= -5.29 - 0.071(L - 50) + 0.033(\lambda - 10) \\
\Delta I &= -1.55 + 0.010(L - 50) + 0.036(\lambda - 10) \\
\Delta H &= +335 + 0.029(L - 50) - 0.035(\lambda - 10)
\end{align*}
\]

Longitude \( \lambda \) is here counted positive to the east. The central position assumed here (lat. 50°, long. 10°E) falls in the north of

Bavaria. In the case of the horizontal force unity represents 17. Schmidt found the above formulæ to give results in very close agreement with the data at the eight stations which he had employed in determining the constants. These stations ranged from Pavlovsk to Perpignan, and from Stonyhurst to Ekaterinburg in Siberia. Formulæ involving the second as well as the first powers of \( L - L_0 \) and \( \lambda - \lambda_0 \) have also been used, e.g., by A. Tanakadate in the Magnetic Survey of Japan.

Formulae are also wanted to show how the value of an element, or the rate of change of an element, at a particular place has varied throughout a long period. For comparatively short periods it is best to use formulae of the type \( E = a + b t + c P \), where \( E \) denotes the value of an element \( t \) years subsequent to some convenient epoch; \( a, b, c \) are constants to be determined from the observational data. For longer periods formulae of the type \( E = a + b \sin (m1 + n) \), where \( a, b, m, n \) are constants, have been used by Schott and others with considerable success. The following examples, due to G. W. Littlehales, will suffice for illustration:

Declination (West) \( = 14° - 63 + 15° \sin \sin (0 - 61 - (t - 180)) + 77° - 8 \)
Inclination (South) \( = 49° - 11 + 8° - 75 \sin \sin (0 - 8 - 180) + 34° - 3 \).

Here \( t \) denotes the date. It is perhaps hardly necessary to point out that the extension of any of these empirical formulae—whether to places outside the surveyed area, or to times not included in the period of observation—is fraught with danger, which increases rapidly the further the extra-polation is pushed.

Table VII.—Inclination (nothery) and Horizontal Force at London.

Table VIII.—Diurnal Inequality of Declination, mean from whole year (+ to West).

The curve is being described in the clockwise direction. This, according to Bauer's own investigation, is the normal mode of description. Schott and Littlehales have found, however, a considerable number of cases where it is difficult to say whether the motion is clockwise or not, while some of the results for the coasts of the Pacific it was clearly anti-clockwise. Frisch's dealing with the secular changes from 1600 to 1885—as given by his calculated values of the magnetic elements—at 204 points of intersection of the lines of latitude and longitude. It is true that in three cases in which the motion was unmistakably clockwise, while in twenty-one cases it was clearly the opposite.

§ 14. All the magnetic elements at any ordinary station show a regular variation in the polar day. To determine this, the irregular changes, means of the hourly readings must be formed making use of a number of days. The amplitude of the diurnal change usually varies considerably with the season of the year. Thus a diurnal inequality derived from all the days of the year combined, or from a smaller number of days selected equally from all the months of the year, can give only the average effect throughout the year. Also unless the hours of maxima and minima at a given station are but slightly variable with the season, the result obtained by combining data from all the months of the year may be a hybrid which does not very closely resemble the phenomena in the months of the individual months. This remark applies in particular to the declination at places within the tropics. One consequence is obviously to make the range of diurnal inequality the best.

Tables VIII. to X. give mean diurnal inequalities derived from all the months of the year combined, the figures representing the algebraic excess of the hourly value over the mean for the twenty-four hour mean. The \( + \) sign denotes in Table VIII. that the north end of the needle is to the west of its mean position for the day; in Tables IX. to XI. it denotes that the element—the dip being the north or south as indicated—is numerically in excess of the twenty-four hour mean. The letter " a " denotes that all days have been included except, as a rule, those characterized by specially large disturbances. The letter " q " denotes that the results are derived from a limited number of days selected as being specially quiet.

i.e., free from disturbance. In all cases the aperiodic or non-cyclic element—indicated by a difference between the values found for the first and second midnights of the day—has been eliminated in the usual way, i.e. by treating it as accumulating at a uniform rate throughout the twenty-four hours. The years from which the data were derived are indicated. The algebraically greatest and least of the hourly values are printed in heavy type; the range thence derived is given at the foot of the tables.

When comparing results from different stations, it must be remembered that the disturbing forces required to cause a change of $t$ in declination and in dip vary directly, the former as the horizontal force, the latter as the total force. Near a magnetic pole the horizontal force is relatively very small, and this accounts, at least partly, for the difference between the declination phenomena at Jan Mayen and South Victoria Land on the one hand and at Kolaba, Batavia and Mauritius on the other. There is, however, another cause, already alluded to, viz. the variability in the type of the diurnal inequality in tropical stations. With a view to illustrating this point Table XII. gives diurnal inequalities of declination for June and December for a number of stations lying between 45° N. and 45° S. latitude. Some of the results are represented graphically in fig. 6, plus ordinates representing westerly deflection. At the northmost station, Toronto, the difference between the two months is mainly a matter of amplitude, the range being much larger at midsummer than at midwinter. The conspicuous phenomenon at both seasons is the rapid swing to the west from 8 or 9 a.m. to

1 or 2 p.m. At the extreme southern station, Hobart—at nearly equal latitude—the great diurnal movement is to the east, and so in the opposite direction to that in the northern hemisphere, but it again takes place nearly the same hours in June (midwinter) as in December. If, however, we take a tropical station such as Trivandrump or Kolaba, the phenomena in June and December are widely different in type. At Trivandrump—situated near the magnetic equator in India—we have in June the conspicuous forenoon swing to the west seen at Toronto, occurring it is true slightly earlier in the day; but in December at the corresponding hours the needle is actually swinging to the east, just as it is doing at Hobart. In June the diurnal inequality of declination at tropical stations—whether to the north of the equator like Trivandrump, or to the south of it like Batavia—is on the whole of the general type characteristic of temperate regions in the northern hemisphere; whereas in December the inequality at these stations resembles that of temperate regions in the southern hemisphere. Comparing the inequalities for June in Table XII. amongst themselves, and those for December amongst themselves, one can trace a gradual transformation from the phenomena seen at Toronto to those seen at Hobart. At a tropical station the change from the June to the December type is probably in all cases more or less gradual, but at some stations the transition seems pretty rapid.

§ 15. In the case of the horizontal force there are, as Table IX. shows, two markedly different types of diurnal inequality. In the one type, exemplified by Pavlovsk or Greenwich, the force is below its mean value in the middle of the day; it has a principal minimum about 10 or 11 a.m., and morning and evening maxima, the latter usually the largest. In the other type, exemplified by Kolaba or Batavia, the horizontal force is above its mean in the middle of the day.
MAGNETISM, TERRESTRIAL

365
day, and has a maximum about 11 a.m. The second type may be regarded as the tropical type. At tropical stations, such as Kolaba, Batavia, Manila and St. Helena, the type is practically the same in summer as in winter, and is the same whether the station is north or south of the equator. Similarly, what we may call the temperate type is seen—with comparatively slight modifications—both in summer and winter at stations such as Greenwich or Pavlovsk. In winter, it is true, the pronounced daily minimum is a little later and the early morning maximum is relatively more important than in summer. There is not, as in the case of the declination, any essential difference between the phenomena at temperate stations in the northern and southern hemispheres.

![Fig. 6](image_url)

With diminishing latitude, there is a gradual transition from the temperate to the tropical type of horizontal force diurnal variation, and at stations whose latitude is under 45° there is a very appreciable variation in type with the season. The mean diurnal variation for the year at Tiflis in Table IX, really represents a struggle between the two types, in which the whole the temperate type prevails. If we take the diurnal variations at Tiflis for midsummer and midwinter, we find the former essentially of the temperate, the latter essentially of the tropical type. A similar contrast may be seen in the mean diurnal inequality for the year at the Cape of Good Hope, but there the tropical type on the whole predominates, and it prevails more at midwinter than at midsummer. Toronto and Hobart, though similar in latitude to Tiflis, show a closer approach to the temperate type. Still at both stations the hours during which the force is below its mean value tend to extend back towards midsummer, especially at midsummer. The amplitude of the horizontal force range appears less at intermediate stations, such as Tiflis, than at stations in either higher or lower latitudes. There is a very great difference in this respect between the north and the south of India.

In the case of the vertical force in higher temperate latitudes—at Pavlovsk for instance—the diurnal inequalities from "all" and from "quiet" days differ somewhat widely in amplitude and shape. The variation in type is distinct at Tiflis, though the evening maximum is always pre-eminent. Speaking generally, the time of the minimum, or principal minimum, varies much less with the season than that of the maximum. At Kew, for instance, on quiet days the minimum falls between all 7 a.m. and noon, in almost the months of the year, but the time of the maximum varies from about 4 p.m. in December to 7 p.m. in June. At Kolaba the time of the maximum is nearly independent of the season; but the minimum is positive to negative in the forenoon and negative to positive in the afternoon are some hours later in winter than in summer. At Batavia the diurnal inequality varies very little in type with the season, and there is little evidence of more than one maximum and minimum in the day. At Batavia, as at Kolaba, negative values occur near noon; but it must be remembered that while at Kolaba and more northern stations vertical force urges the north pole of a magnet downwards, the reverse is true of Batavia, as the dip is southerly. At St. Helena vertical force is below its mean value in the forenoon, but the change from to -+ occurs at noon, or but little later, both in winter and summer. At Good Hope the phenomena at midsummer are similar to those at Kolaba, the force being below its mean value from about 9 a.m. to 3 p.m. and above it throughout the rest of the day; but at midwinter the phenomena is a curious double period, the force being below its mean from 1 a.m. to 7 a.m. as well as from 11 a.m. to 3 p.m., and thus resembling the all-day annual results at Greenwich. At Hobart vertical force is below its mean value from 1 a.m. to 4 a.m. at midsummer, and from 4 a.m. to noon at midwinter; while the force is above its mean persistently throughout the afternoon both in summer and winter, there is at midwinter a well marked secondary minimum about 6 p.m., almost the same hour as that at which the maximum for the day is observed in summer.

§ 17. Variations of inclination are connected with those of horizontal and vertical force by the relation

\[ I = \frac{1}{2} \sin [V - 1^\circ] - H - 1^\circ].

Thus in temperate latitudes where V is considerably in excess of H, whilst diurnal changes in V are usually less than those in H, it is the latter which chiefly dominates the diurnal changes in inclination. When the H influence prevails, I has its highest values at hours when H is least. This explains why the dip is above its mean value near midday at stations in Table XI, from Pavlovsk to Port St. Maur. Near the magnetic equator the vertical force has the greater influence. This alone would tend to make a minimum dip in the late forenoon, and this minimum is accentuated owing to the altered type of the horizontal force diurnal variation, whose maximum now coincides closely with the minimum in the vertical force. This accounts for the prominence of the minimum in the diurnal variation of the inclination at Kolaba and Batavia, and the large amplitude of the range. Tiflis shows an intermediate type of diurnal variation; there is a minimum near noon, as in tropical stations, but the maximum is also below its mean level, long before and after it. The type really varies at Tiflis according to the season of the year. In June—as in the mean equality from the whole year—there is a well marked double period; there is a principal minimum at 2 a.m. and a secondary one about 4 a.m.; and a principal maximum about 9 a.m. and a secondary one about 6 a.m. In December, however, only a single period is recognizable, with a minimum about 8 a.m. and a maximum about 7 p.m. The type of diurnal inequality seen
MAGNETISM, TERRESTRIAL

3 66

at the Cape of Good Hope does not differ much from that seen at
Batavia. Only a single period is clearly shown. The maximum
occurs about 8 or 9 p.m. throughout the year. The time of the
minimum is more variable; at midsummer it occurs about II a.m.,
but at midwinter three or four hours later. At Hpbart the type
varies considerably with the season. In June (midwinter) a double
period is visible. The principal minimum occurs about 8 a.m., as
at the Cape. But, corresponding to the evening maximum seen at
the Cape, there is now only a secondary maximum, the principal
maximum occurring about I p.m. At midsummer the principal
maximum is found as at Kew or Greenwich about 10 or II a.m.,
the principal minimum about 4 p.m.
1 8. Even at tropical stations a considerable seasonal change
is usually seen in the amplitude of the diurnal inequality in at least
one of the magnetic elements. At stations in Europe, and generally
in temperate latitudes, the amplitude varies notably in all the
elements. Table XIII. gives particulars of the inequality range of
declination derived from hourly readings at selected stations,

variation in the range from April to August. Sometimes, as at Kew
and Greenwich, there is at least a suggestion of a secondary minimum
Manila and Trivandrum show a transition from
at midsummer.
the December minimum, characteristic of the northern stations,
to the June minimum characteristic of the southern, there being two
conspicuous minima in February or March and in November or
October. At St Helena there are two similar minima in May and
September, while a third apparently exists in December. It will be
noticed that at both Pavlovsk and Kew the annual variation in the
range is specially prominent in the quiet day results.
Table XIV. gives a smaller number of data analogous to those of
Table XIII., comprising inequality ranges for horizontal force,
vertical force and inclination. In some cases the number of years
from which the data were derived seems hardly sufficient to give
a smooth annual variation. It should also be noticed that unless
the same group of years is employed the data from two stations are
not strictly comparable. The difference between the all and quiet
day vertical force data at Pavlovsk is remarkably pronounced.
The general tendency in all the elements is to show a reduced
range at midwinter; but in some cases there is also a distinct
reduction in the range at midsummer. This double annual period
is particularly well marked at Batavia.
| 19. When discussing diurnal inequalities it is sometimes convenient to consider the components of the horizontal force in and
perpendicular to the astronomical meridian, rather than the horiIf

at any hour of
departures of H and
the
values, then 8N and 3W represent
the corresponding departures of N and
from their mean values.
In this way diurnal inequalities may be calculated for N and
when those for H and D are known. The formulae suppose 5D
to be expressed in absolute measure, i.e. i' of arc has to be replaced
by 0-0002909. If we take as an example a station at which H is

D).
words, employing 17 as unit of force, one replaces H5D by 5'38SD,
where SD represents declination change expressed as usual in
minutes of arc. In calculating diurnal inequalities for N and VV,
one ought, strictly speaking, to assign to H and
the exact mean
values belonging to these elements for the month or the year being
dealt with.
For practical purposes, however, a slight departure
from the true mean values is immaterial, and one can make use of a
constant value for several successive years without sensible error.
As an example, Table XV. gives the mean diurnal inequality for the
whole year in N and
at Falmouth, as calculated from the 12 years
1891 to 1902. The unit employed is l-yThe data in Table XV. are closely similar to corresponding Kew
data, and are presumably fairly applicable to the whole south of
England for the epoch considered. At Falmouth there is comparatively little seasonal variation in the type of the diurnal variation in either N or W. The amplitude of the diurnal range varies,
however, largely with the season, as will appear from Table XVI.,
which is based on the same 12 years as Table XV.
Diurnal inequalities in N and
lend themselves readily to the
construction of what are known as vector diagrams.
These are
curves showing the direction and intensity at each hour of the day
of the horizontal component of the disturbing force to which the
diurnal inequality may be regarded as due. Figs. 7 and 8, taken
from the Phil. Trans, vol. 2O4A, will serve as examples. They
refer to the mean diurnal inequalities for the months stated at
Kew (1890 to 1900) and Falmouth (1891 to 1902), thick lines relating
to Kew, thin to Falmouth.
NS and
represent the geographical
north-south and east- west directions; their intersection answers
to the origin (thick lines for Kew, thin for Falmouth). The line
from the origin to
represents the magnetic meridian. The line from
the origin to any cross the number indicating the corresponding
hour counted from midnight as o represents the magnitude and
direction at that hour of the horizontal component of the disturbing force to which the diurnal inequality may be assigned. The
cross marks the point whose rectangular co-ordinates are the values
of 5N and 5VV derived from the diurnal inequalities of these
elements. In figs. 7 and 8 the distances of the points N, E, S,
from their corresponding origin represents lo-y. The tendency
to form a loop near midnight, seen in the November and December

curves is characteristic of the winter months at Kew and Falmouth. The shape is less variable in summer than in winter; but even in summer the portion answering to the hours 6 p.m. to 6 a.m. varies a good deal. The object of presenting the Kew and Falmouth curves side by side is to emphasize the close resemblance between the magnetic phenomena at places in similar latitudes, though over 200 miles apart and exhibiting widely different ranges for their meteorological elements. With considerable change of latitude however the shape of vector diagrams changes largely.

§ 20. Any diurnal inequality can be analysed into a series of harmonic terms whose periods are 24 hours and submultiples thereof. The series may be expressed in either of the equivalent forms:

\[
\begin{align*}
& a_1 \cos (t+a_1 \cos \phi + a_2 \sin \phi + \ldots) \\
& c_1 \sin (t+a_2 \cos \phi + a_3 \sin \phi + \ldots)
\end{align*}
\]

In both forms \( t \) denotes time, counted usually from midnight, one hour of time being interpreted as \( 15^\circ \) of angle. Form (i) is that utilized in actually calculating the constants \( a, b, \ldots \) Once the \( a, b, \ldots \) constants are known, the \( c, a, \ldots \) constants are at once derivable from the formulae:

\[
\tan a_0 = a_0 \tan b_0 ; \quad c_0 = a_0 \sin a_0 \cos a_0 = \sqrt{(a_0^2 + b_0^2)}.
\]

The \( a, b, c, a \) constants are called sometimes Fourier, sometimes Bessel coefficients. By taking a sufficient number of terms a series can always be obtained which will represent any set of diurnal inequality figures; but unless one can obtain a close approach to the observational

The original observations also differ in reliability; thus the results are of somewhat unequal value. The mean results for Engelenburg's zones must naturally have some of the sources of uncertainty reduced; but then the fundamental idea represented by the arrangement in zones is open to question. The majority of the data in Table XVII. are taken from Engelenburg, but the phase angles have been altered so as to apply to westerly declination. The stations are arranged in order of latitude from north to south; in a few instances results are given for quiet days. The figures represent in all cases arithmetic means derived from the 12 monthly values. In the table, so far as is known, the local mean time of the observatory has been employed. This is a point requiring attention, because most observatories employ Greenwich time, or time based on Greenwich or some other national observatory, and any change in angle is absolutely unaltered. For the calculation of the values of the constants. The data for Victoria Land refer to the "Discovery's" 1902-1903 winter quarters, where the declination, taken westerly, was about 20° S.

As an example of the mean of the phase angles in Table XVII., take the ordinary day data for Kew. The times of occurrence of the maxima are given by \( t + 234° = 450° \) for the 24-hour term, \( t + 126° = 360° \) for the 12-hour term, and so on, taking an hour in time equivalent to 15°.

Thus the times of the maxima are:

- 24-hour term, 2 h. 24 m. p.m.; 12-hour term, 1 h. 47 m. a.m.
- 8-hour term, 4 h. 41 m. a.m., 0 h. 41 m. p.m., and 0 h. 41 m. p.m.
- 6-hour term, 0 h. 33 m. a.m. and p.m., and 6 h. 33 m. a.m. and p.m.

(From Phil. Trans.)

Fig. 7.
The minima, or extreme easterly positions in the waves, lie midway between successive maxima. All four terms, it will be seen, have maxima at some hour between oh. 30m. and 2h. 30m. p.m. They thus reinforce one another strongly from 1 to 2 p.m., accounting for the prominence of the maximum in the early afternoon.

November.

December.

Fig. 8.

The utility of a Fourier analysis depends largely on whether the several terms have a definite physical significance. If the 24-hour and 12-hour terms, for instance, represent the action of forces whose distribution over the earth or whose seasonal variation is essentially different, then the analysis helps to distinguish these forces, and may assist in their being tracked to their ultimate source. Suppose, for example, one had reason to think the magnetic diurnal variation due to some meteorological phenomenon, e.g. heating of the earth's atmosphere, then a comparison of Fourier coefficients, if such existed, for the two sets of phenomena would be a powerful method of investigation.

§ 21. Fourier coefficients of course often vary much with the season of the year. In the case of the declination this is especially true of the phase angles at tropical stations. To enter on details for a number of stations would unduly occupy space. A fair idea of the variability in the case of declination in temperate latitudes may be derived from Table XVIII, which gives monthly values for Kew derived from ordinary days of an 11-year period 1890-1900.

Fourier analysis has been applied to the diurnal inequalities of the other magnetic elements, but more sparingly. Such results are illustrated by Table XIX, which contains data derived from Kew from 1890 to 1900. Winter includes November to February, Summer May to August, and Equinox the remaining four months. In this case the data are derived from mean diurnal inequalities for the season specified. In the case of the c or amplitude coefficients the unit is in (for I inclination), and in for H and V (horizontal and vertical force). At Kew the seasonal variation in the amplitude is fairly similar for all the elements. The 24-hour and 12-hour terms tend to be largest near midsummer, and least near midwinter; but the 8-hour and 6-hour terms have two well-marked maxima near the equinoxes, and a clearly marked minimum near midsummer, in addition to one near midwinter. On the other hand, the phase angle phenomena vary much for the different elements. The 24-hour term, for instance, has its maximum earlier in winter than in summer and towards the vertical force, but the exact reverse holds for the inclination and the horizontal force.

MAGNETISM, TERRESTRIAL

369

effects of secular change and annual inequality. Eliminating the secular change, we arrive at an annual inequality, based on all days of the year including the highly disturbed. It is this annual inequality which appears under the heading \( s \). It is certainly very unlike the annual inequality derived in the usual way. Whether the difference is to be wholly assigned to the fact that highly disturbed days contribute in the one case, but not in the other, is a question for future research.

In the case of the inclination, Lizar found that in both hemispheres the dip (north in the northern, south in the southern hemisphere) was larger than the normal when the sun was in perihelion, corresponding to an enhanced value of the horizontal force in summer in the northern hemisphere.

In the case of annual inequalities, at least that of the declination, it is a somewhat suggestive fact that the range seems to become less as we pass from older to more recent results, or from shorter to longer periods of years. Thus far from Paris from 1821 to 1830 Arago deduced a range of \( 2^\circ \) 9'. Quarter days at Kew from 1890 to 1894 gave a range of \( 1^\circ \), while at Potsdam Ludeling got a range \( 3^\circ \) larger than that in Table XX, when considering the shorter period 1891-1899. Up to the present, few individual results, if any, can claim a very high degree of certainty. With improved instruments and methods it may be different in the future.

\( \text{§ 23. The inequalities in Table XX, may be analysed—as has in fact been done by Hann—in a series of Fourier terms, whose periods are the year and its submultiples. Fourier analysis can also be formed representing the annual variation in the amplitudes of the regular diurnal inequality, and its component 24-hour, 12-hour, &c., waves, or of the monthly cycle. To secure the highest theoretical accuracy, it would be necessary in calculating the Fourier coefficients to allow for the fact that the "months" from which the observational data are derived are not of uniform length, but differ, of course, by \( 1/12 \) of the year, but slightly displaced from the position they would occupy if the 12 months were exactly equal, and these displacements are usually neglected. The loss of accuracy cannot be but trivial, and the simplification is considerable.}

\[ P_1 \sin(t+\theta_1) + P_2 \sin(2t+\theta_2) + \ldots \]

where \( t \) is time counted from the beginning of the year, one month being taken as the equivalent of \( 30^\circ \). \( P_1, P_2 \) represent the amplitudes and \( \theta_1, \theta_2 \) the phase angles of the first two terms, whose periods are respectively 12 and 6 months. Table XXI gives the values of the coefficients in the case of the regular diurnal inequality for certain specified elements and periods at Kew and Falmouth. In the case of \( P_1 \) and \( P_3 \) the 'unit' is \( 1^\circ \) for D and 1, and \( \sqrt{2}/2 \) for H and V. M denotes the mean value of the range for the whole 365 days from the day of the year in question. The meaning of \( P_1/M \) and \( P_3/M \) both increase considerably as we pass from years of many to years of few sun spots. It is relatively considered the range of the regular diurnal inequality is more variable throughout the year when sun spots are few than when they are many.

The tendency to an earlier occurrence of the maximum as we pass from quiet days to ordinary days, or from years of sun spot minimum to years of sun spot maximum, which appears in the table, appears also in the case of the horizontal force—at least in the case of the annual term—both at Kew and Falmouth. The phenomena at the two stations show a remarkably close parallelism. At both, and this is true also of the absolute ranges, the maximum of the annual term falls in all cases nearer the summer, the maximum in midwinter. The maxima of the 6-month terms fall near the equinoxes. Allusion has already been made in § 14 to one point which requires fuller discussion. It is this that Kew, the general character of, say, the declination does not vary very much with the season, but still it does vary. The principal minimum of the year, for instance, occurs from one to two hours earlier in summer than in winter. Let us suppose for a moment that all the days of a month are exactly alike, the difference in type between successive months coming in per

\[ P_1 \sin(t+\theta_1) + P_2 \sin(2t+\theta_2) + \ldots \]

The Fourier series may be represented by

salts. Suppose further that having formed twelve diurnal inequalities from the days of the individual months of the year, we deduce a mean diurnal inequality for the whole year by combining these twelve inequalities and taking the mean. The hours of maximum and minimum being different for the twelve constituents, it is obvious that the resulting maximum will normally be less than the arithmetic mean of the twelve maxima, and the resulting minimum (arithmetically) less than the arithmetic mean of the twelve minima. The range—or algebraic excess of the maximum over the minimum—in the mean diurnal inequality for the year is thus normally less than the arithmetic mean of the twelve ranges from diurnal inequalities for the individual months. Furthermore, as we shall see later, there are differences in type not merely between the different months of the year, but even between the same months in different years. Thus the range of the mean diurnal inequality for, say, January based on the combined observations of 10 days, may be larger, and generally will be slightly less than the arithmetic mean of the ranges obtained from the Januarys separately. At Kew, for instance, taking the ordinary days of the years 1891-1899, the absolute ranges of declination from the 12 months treated independently was \( 8^\circ \) 52', the mean range from the 12 months of the year (the eleven Januaries being combined into one, Table XXII.—Annual Variation of Diurnal Inequality Range. Fourier Coefficients.

| Kew | D1 | 3.36 | 0.94 | 279° | 280° | 0.40 | 0.11 |
| Kew | D1 | 3.12 | 0.96 | 280° | 279° | 0.47 | 0.13 |
| Kew | D1 | 0.10 | 0.16 | 279° | 268° | 0.42 | 0.10 |
| Kew | D1 | 1.17 | 3.0 | 269° | 266° | 0.48 | 0.11 |
| Kew | D1 | 2.0 | 2.2 | 282° | 242° | 0.63 | 0.12 |
| Kew | D1 | 4.50 | 1.26 | 277° | 282° | 0.47 | 0.13 |
| Kew | D1 | 4.10 | 1.40 | 277° | 285° | 0.43 | 0.15 |
| Kew | D1 | 3.55 | 1.10 | 277° | 269° | 0.49 | 0.16 |
| Kew | D1 | 3.19 | 1.14 | 277° | 277° | 0.49 | 0.17 |

and so on was \( 8^\circ \) 44', but the mean range from the whole 4,000 odd days superposed was only \( 8^\circ \) 03'. Another consideration is that a diurnal inequality is usually based on hourly readings, and the range deduced is thus an under-estimate unless the absolute maximum and minimum both happen to come exactly at an hour. These considerations would alone suffice to show that the absolute range in individual days, i.e. the difference between the algebraically largest and least values of the element found any time during the 24 hours, must on the average exceed the
range in the mean diurnal inequality for the year, however this latter is formed. Other causes, moreover, are at work tending in the same direction. Even in central Europe, the magnetic curves for individual days of an ordinary month often differ widely amongst themselves, and show maxima and minima at different times of the day. In high latitudes, the variation from day to day is sometimes so great that mere eye inspection of magnetograph curves may leave one with but little idea as to the probable shape of the resultant diurnal curve for the month. Table XXII. gives the arithmetic mean of the absolute daily ranges from several stations. The values which it assigns to the year are the arithmetic mean of the 12 monthly values. The Mauritian data are for different periods, viz. declination 1875, 1880 and 1883 to 1900, and diurnal force 1883 to 1890, vertical force 1884 to 1890. The other data are all for the period 1890 to 1900. A comparison of the absolute ranges in Table XXII. with the inequality ranges for the same stations derivable from Tables VII. to X. is most instructive. At Mauritius the ratio of the absolute to the inequality range is for D 1.38, for H 1.76, and for V 1.19. At Pavlovsk the corresponding ratios are much larger, viz. 2.16 for D, 2.43 for H, and 2.05 for V. The declination data for Kew in Table XXII. illustrate other points. The first set of data are derived from all days of the year. The second omit the highly disturbed days. The third answer to the 5 days a month selected as typically quiet. The yearly mean absolute range from ordinary days at Kew in Table XXII. is 1.4 times the mean inequality range in Table VII.; comparing individual months the ratio of the absolute to the inequality range varies from 2.06 in January to 1.21 in June. Even confining ourselves to the quiet days at Kew, which are free from all but the most trifling disturbances, we find that the mean absolute range for the year is 1.20 times the arithmetic mean of the inequality ranges for the individual months of the year, and 1.22 times the range from the mean diurnal inequality for the year. In this case the ratio of the absolute to the inequality range varies from 1.55 in December to only 1.09 in May.

§ 25. The variability of the absolute daily range of declination is illustrated by Table XXII., which contains data for Kew derived from all days of the 11-year period 1890–1900. It gives the total number of times during the 11 years when the absolute range lay within the limits specified at the heads of the first nine columns of figures. The two remaining columns give the arithmetic means of the five largest and the five least absolute ranges encountered each month, the mean of the twelve monthly diurnal inequality ranges from ordinary days was only 8'-44, but the absolute range during the 11 years exceeded 20' on 492 days, 15' on 1196 days, and 10' on 2784 days, i.e. on 69 days out of every 100.

MAGNETISM, TERRESTRIAL

Ranges at Ekaterinburg are larger in 1892 than in 1893, the excess is trivial. The phenomena apparent in Table XXIV, are fairly representative; other stations and other periods associate large inequality range with high sun-sunspot frequency. The diurnal inequality range it should be noticed is comparatively little influenced by irregular disturbances. Coming to Table XXV, we have ranges of a different character. The absolute range at Kew on quiet days is strongly influenced by irregular disturbances in the range of diurnal inequality, and in its phenomena the very similar to those observed in Table XXIV. As we pass from left to right in Table XXV, the influence of disturbance increases. Simultaneously, with the parallelism with sun-spot frequency is less close. The entries relating to 1892 and 1894 become more and more prominent compared to those for 1893. The yearly range may depend on but a single magnetic storm, the largest disturbance of the year produced for the year of observation. Taking monthly ranges the values for 1894 are, speaking roughly, only half those for 1892 and 1894, and very similar to those of 1898, though the sun-spot frequency in the latter year was less than a third of that in 1893. Ekaterinburg data exactly analogous to those for Pavlovsk show a similar prominence in 1892 and 1894 as compared to 1893.

The phenomenon in Table XXIV, is fairly representative; other stations and other periods associate large inequality range with high sun-sunspot frequency. The diurnal inequality range it should be noticed is comparatively little influenced by irregular disturbances. Coming to Table XXV, we have ranges of a different character. The absolute range at Kew on quiet days is strongly influenced by irregular disturbances in the range of diurnal inequality, and in its phenomena the very similar to those observed in Table XXIV. As we pass from left to right in Table XXV, the influence of disturbance increases. Simultaneously, with the parallelism with sun-spot frequency is less close. The entries relating to 1892 and 1894 become more and more prominent compared to those for 1893. The yearly range may depend on but a single magnetic storm, the largest disturbance of the year produced for the year of observation. Taking monthly ranges the values for 1894 are, speaking roughly, only half those for 1892 and 1894, and very similar to those of 1898, though the sun-spot frequency in the latter year was less than a third of that in 1893. Ekaterinburg data exactly analogous to those for Pavlovsk show a similar prominence in 1892 and 1894 as compared to 1893.

The retirement of 1893 from first place, seen in the absolute ranges at Kew, Pavlovsk and Ekaterinburg, is not confined to the northern hemisphere. It is visible, for instance, in the amplitudes of the Batavia disturbance results. Thus though the variation from year to year in the amplitude of the absolute ranges is relatively not less but greater than that of the inequality ranges, and though the general tendency is for all ranges to be larger in many years in ranges with parallelism the changes between the changes in sun-spot frequency and in the ranges in the ranges in the ranges is not so marked as in absolute ranges and for disturbances as for the inequality ranges. § 27. The relationship between magnetic ranges and sun-spot frequency is the one of least interest. W. Wolf has employed a graphical method which has advantages, especially for tracing the general features of the resemblance, and is besides independent of any theoretical hypothesis. Taking time for the axis of abscissae, Ellis has two marks for its determination. For the sun-spot frequency, the other the inequality range of declination or of horizontal force at Greenwich. The value assigned in the magnetic curve to the ordinate or for any particular month represents a mean from 12 months of which it forms a central month, the object being to eliminate the regular annual variation in the diurnal inequality. The sun-spot data derived from Wolf and Wolfer were similarly treated. Ellis originally dealt with the period 1841 to 1877, but subsequently with the period 1878 to 1896, and his second paper gives curves representing the phenomena over the whole 56 years. This period covered five complete sun-spot periods, and the approximate synchronism of the maxima and minima, and the general parallelism of the magnetic and sun-spot changes is evident to the eye. Ellis' has also applied an analogous method to investigate the relationship between sun-spot frequency and the number and depth of days of magnetic disturbance at Greenwich. A decline in the number of the high magnetic sun-spot numbers may be inferred from the range of the inequality range. Another method, initiated by Professor Wolf of Zurich, lends itself more readily to the investigation of numerical relationships. He started by supposing an exact proportionality between corresponding changes in sun-spot frequency and magnetic range. This is expressed mathematically by the formula

\[ R = a + b S + c (1 + b/S) S, \]

where \( R \) denotes the magnetic range, \( S \) the corresponding sun-spot frequency, while \( a \) and \( b \) are constants. The constant \( a \) represents the range for zero sun-spot frequency, while \( b \) is the proportional increase in the range accompanying unit rise in sun-spot frequency. Assuming the formula to be true, one obtains from the observed values of \( R \) and \( S \) numerical values for \( a \) and \( b \), and can thus investigate whether or not the sun-spot influence is the one for the different magnetic elements and for different places. Of course, the usefulness of Wolt's formula depends largely on the accuracy with which it represents the facts. That it must be at least a rough approximation is evident in that disturbances in the ranges of diurnal inequality might be inferred from Ellis' curves. Several provisos should be noticed. The formula may apply with high accuracy, \( a \) and \( b \) being determined values, though two of these three might be applicable to more remote periods. There are only three or four stations which have continuous magnetic records extending even 50 years back, and, owing to temperature correction uncertainties, there may be no reason for the variation of the horizontal and vertical force are above criticism. Declination is less exposed to uncertainty, and there are results of experimental observations of declination before the era of photographic curves. A change, however, of \( S \) in declination has a significance which alters with the intensity of the horizontal force. During the period 1850–1900 horizontal force in England increased about 5%. So that the force required to produce a declination change of 10° in 1900 would in 1850 have produced a deflection of 20°. It must also be remembered that secular changes of declination must alter the angle between the needle and any disturbing force acting in a fixed direction. Thus a and \( b \) is rather to be anticipated, especially in the case of the declination. Wolf's formula has been applied by Rajna to the yearly mean declination range at Kew based on readings taken twice daily from 1836 to 1894, treating the whole period together, and then the period 1871 to 1894 separately. During two sub-periods, 1857–1850 and 1841–1850, Rajna's calculated values for the range differ very persistently in one direction from those observed; Wolf's formula was applied by C. Chree to these two periods separately. He also applied it to Greenwich inequality ranges for the years 1882 to 1896, treating the whole period and the last 32 years of it separately, and finally to all (a) and quiet (q) day Greenwich ranges from 1831 to 1866. The results of these applications of Wolf's formula appear in Table XXVI.

The Milan results are suggestive rather of heterogeneity in the material than of any decided secular change in a or \( b \) in the Greenwich data are suggestive of a gradual fall in a, and rise in b, at least in the case of the declination.

As explained above, a would represent the range in a year of no sun-spots, while \( b \) would represent the excess over this shown by the range in a year when Wolf's sun-spot frequency is 100. Thus

Historically, the values of a and b in Wolf's formula are used to calculate diurnal inequalities. The values provided in this table allow for the calculation of declination, inclination, horizontal force, and vertical force for various locations and time periods.

### Footnotes

1. The term "sun-spot" (S) refers to sunspots, which are temporary dark areas on the Sun's surface. The "sun-spot maximum" is the period when the number of sunspots is at its peak.

2. The term "quiet days" (Q) refers to days with minimal solar activity, which can affect the Earth's magnetic field.

3. The term "epoch" refers to a specific time period for which the data is calculated.

4. The table includes values for a and b in Wolf's formula, which are used to calculate diurnal inequalities. These values are crucial for understanding solar activity and its impact on Earth's magnetic field.

5. The data in Table XXVII is derived from observations made at various locations from 1875 to 1898, providing a comprehensive view of solar and terrestrial magnetic phenomena.

6. The table includes data for both years ending in 9 and 0, indicating a focus on solar cycles and their effects on Earth's magnetic field.

7. The data suggests that solar activity, as measured by sunspots and solar flares, has a significant impact on Earth's magnetic field, with periods of increased activity correlating with increased magnetic disturbances.

8. The term "solar cycle" refers to the roughly 11-year period during which sunspots and other solar activity vary, affecting Earth's magnetic field.

9. The table provides a snapshot of solar activity and its impact on Earth's magnetic field, with implications for understanding geomagnetic variations and their effects on technological and environmental systems.
small and might be accidental. In the case of D at Greenwich 1891 differed from the other years, and of two more recent years examined by Ellis, one, 1904, agreed with 1891. At Kew, on the average of the 11 years 1890 to 1900, the quiet-day mean annual value of declination exceeded the ordinary day value, but the apparent excess 0"-02 is too small to possess much significance.

Another property more recently discovered in quiet days is the non-cyclical change. This will be readily understood from the following data from the 11-year period 1890 to 1900 at Kew. The mean daily change for all days is calculated from the observed annual change.

<table>

</tbody>
</table>

Thus the changes during the representative quiet day differed from those of the average day. Before accepting such a phenomenon as natural, instrumental peculiarities must be carefully considered. The secular change is really based on the absolute instruments, the diurnal changes on the magnetographs, and the first idea likely to occur to a critical mind is that the apparent abnormal change on quiet days represents in reality change of zero in the magnetographs. If, however, the phenomenon were instrumental, it should appear equally on days other than quiet days, and we should thus have a shift of zero amounting in a year to over 1,000 in H and about 90 in I. Under such circumstances it would be continually drifting off the sheet. In the case of the Kew magnetographs, a careful investigation showed that any instrumental change occurred in the high magnetic range during which it did not reach a few tenths of a minute. In the case of the H and V magnetographs at Kew there is a slight drift, of instrumental origin, due to weakening of the magnets, but it is exceedingly small, and in the case of H is in the direction of the non-cyclical change on quiet days. It only remains to add that the hypothesis of instrumental origin was positively disproved by measurement of the curves on ordinary days.

It cannot be supposed that every quiet day agrees with the average quiet day in the order of magnitude, or even in the sign, of the non-cyclical change. In fact, in not a few months the sign of the non-cyclical change on the mean of the quiet days differs from that obtained for the average quiet day of a period of years. At Kew, between 1890 and 1900, the number of months during which the mean non-cyclical change for the five quiet days selected by the astronomer royal (Sir W. H. M. Christie) was plus, zero, or minus was as follows:

<table>
<thead>
<tr>
<th>Element</th>
<th>Number</th>
</tr>
</thead>
<tbody>
<tr>
<td>D</td>
<td>53</td>
</tr>
<tr>
<td>I</td>
<td>13</td>
</tr>
<tr>

<td>112</td>
</tr>
<tr>
<td>V</td>
<td>47</td>
</tr>
</tbody>
</table>

The + sign denotes westerly movement in the declination, and increasing dip of the north end of the needle. In the case of I and H the excess in the number of months showing the normal sign is overwhelming. The following mean non-cyclical changes on quiet days are from other sources:

<table>
<thead>
<tr>
<th>Element</th>
<th>Greenwich (1890-1893)</th>
<th>Falmonth (1898-1902)</th>
<th>Kolaba (1894-1901)</th>
</tr>
</thead>
<tbody>
<tr>

<td>+0.05</td>
<td>+0.07</td>
</tr>
<tr>
<td>H</td>
<td>-0.47</td>
<td>-0.59</td>
<td>-0.97</td>
</tr>
</tbody>
</table>

The results are in the same direction as at Kew, + meaning in the case of D movement to the west. As Falmonth, as at Kew, the non-cyclical change showed a tendency to be small in years of few sun-spots.

§ 30. In calculating diurnal inequalities from quiet days the non-cyclical change must be eliminated, otherwise the result would depend on the hour at which the "day" is supposed to commence. If the value recorded at the second midnight of the average day exceeds that at the first midnight by N, the elimination is effected by applying to each hourly value the correction N (1/24) for each of the 24 hours, where N is the hour counted from the first midnight (0 hours). This assumes the change to progress uniformly throughout the 24 hours. Unless this is practically the case—a matter difficult either to prove or disprove—the correction may not necessarily be what is assigned. This method has been employed in the previous tables. The fact that differences do exist between diurnal inequalities derived from quiet days and all ordinary days was stated explicitly in § 4, and is obvious in Tables VIII. to XI. An extreme case is represented by the data for Jan Mayen in these tables. Figs. 9 and 10 are vector diagrams for this station, for all and for quiet days during May, June and July 1883, according to data got out by Ludwig. As shown by the arrowway fig. 10 (quiet days) is in the main described in the normal or clockwise direction, but fig. 9 (all days) is described in the opposite direction. Ludwig found this peculiar difference between all and quiet days at all the north polar stations occupied in 1882-1883 except Kinga Fjord, where both diagrams were described clockwise.

In temparate latitudes the differences of type are much less, but still exist. A general increase in the quiet-day ordinates of declination in the case of declination may be derived from Table XXII., containing data for Kew, Greenwich and Param St. Maur.

The data for Greenwich are due to W. Ellis, those for Param St. Maur to T. Moureault. The ordinates range from the excess of all or ordinary day mean hourly value over the corresponding quiet day value in the mean diurnal inequality for the year. At Kew and Greenwich of extreme disturbance have been excluded from the Param St. Maur, but apparently not at Param St. Maur. The number of highly disturbed days at the three stations is, however, small, and their influence is not great. The differences disclosed in Table XXII. are of a systematic character which would not tend to disappear however long a period was utilized. In short, while the diurnal inequality from quiet days may be that most truly representative of undisturbed conditions, if the causes of disturbance are not the same at the two stations.

To go into full details respecting the differences between all and quiet days would occupy undue space, so the following brief summary of the differences observed in declination at Kew must suffice. While the inequality range is but little different for the two types of days, the mean of the hourly differences from the mean for the day is considerably reduced in the quiet days. The 24-hour term in the Fourier analysis is of smaller amplitude in the quiet days, and its phase angle is on the average about 6°-75 smaller than on ordinary days, implying a retardation of about 27 minutes in the time of maximum. The diurnal inequality range is more variable throughout the year. Quiet days than on ordinary days, and the same is true of the absolute ranges. The tendency to a secondary minimum in the range at midsummer is considerably more decided on ordinary than on quiet days. When the variation throughout the year in the diurnal inequality range is expressed in Fourier series, whose periods are the year and its submultiples, the 6-month term is notably larger for ordinary than for quiet days. Also the date of the maximum in the 12-month term is about three days earlier for ordinary than for quiet days. The exact size of the differences between ordinary and quiet day phenomena must depend to some extent on the criteria employed in selecting quiet days and in excluding disturbed days. This raises difficulties when it comes to comparing results at different stations.

For stations near together the difficulty is trifling. The astronomer royal's quiet days have been used for instance at Param St. Maur, Val Joyeux, Falmonth and Kew, as well as at Greenwich. But when stations are wide apart there are two obvious difficulties: first, the difference of local time; secondly, the fact that a day may be typically quiet at one station but appreciably disturbed at the other.

If the typical quiet day were simply the antithesis of a disturbed day, it would be natural to regard the non-cyclical change on quiet days as a species of recoil from some effect of disturbance. This view derives support from the fact, pointed out long ago by Sabine, that the horizontal force usually, though by no means always, is lowered by magnetic disturbances. Dr van Bemmelen who has examined all the diurnal and non-cyclical changes in quiet days not as disposed to regard this as a sufficient explanation. There are, however, difficulties in accepting this view. Thus, whilst the non-cyclical change is most prominent in the earlier years, the change appeared on the whole enhanced in years of sun-spot maximum, the difference between years such as 1892 and 1894 on the one hand, and 1890 and 1900 on the other, was by no means proportional to the apparent change of disturbance. Another clue appeared on the average non-cyclical change of declination was calculated at Kew for 207 days, selected as those of most marked irregular disturbance between 1890 and 1900, the sign actually proved to be the same as for the average quiet day of the period.

§ 31. A satisfactory definition of magnetic disturbance is about as difficult to lay down as one of heterodoxy. The idea in its generality seems to present no difficulty, but it is a very different matter when one comes to details. Amongst the chief disturbances recorded since 1890 are those of February 13-14 and August 12, 1892; July 20 and August 20, 1893; February 15, 1893; September 5, 1893; February 9-10, 1907; September 11-12, 1908 and September 25, 1909. On such days as these the oscillations shown by the magnetic curves are large and rapid, aurora is nearly always visible in temperate latitudes, earth-currents are prominent and there is intermixture—sometimes very serious—in the transmission of telegraphic messages both in overhead and underground wires. A day of this kind is usually characterized by its extreme scale and daily values, in each of which the curve shows practically no movement beyond the slow regular progression of the regular diurnal inequality. But between these two extremes there are an infinite variety of intermediate cases. The first serious attempt at a precise definition of disturbance seemed to be due to General Sabine \textsuperscript{31}. His method had once an extensive vogue, and still continues to be applied at some important observatories. Sabine regarded a particular observation as disturbed when it differed from the mean of the observations at that hour for the whole month by not less than a certain limiting value. His definition takes account only of the extent of the departure from the mean, whether the curve is smooth at the time or violently oscillating makes no difference. In dealing with a particular station Sabine laid down separate limiting values for each element. These limits were the same, irrespective of the season of the year or of the sun-spot frequency. A departure, for example, of 3\(^\text{rd}\) at Kew from the mean value of declination for the hour constituted a disturbance, whether it occurred in December in a year of sun-spot maximum, or in June in a year of sun-spot minimum, though the regular diurnal inequality range might be four times as large in the second case as in the first. The limiting values varied from station to station, the size depending apparently on several considerations not very clearly defined. Sabine stated the disturbances in each element into these limits, one tending to increase the element, the other tending to diminish it. He investigated how the numbers of the two classes varied throughout the whole year from September to September of the following year. He also took account of the aggregate value of the disturbances of one sign, and traced the diurnal and annual variations in these aggregate values. He thus got two sets of diurnal variations and two sets of annual variations of disturbance, the one set depending only on the number of the disturbed hours, the other set considering only the aggregate value of the disturbances. Generally the two species of disturbance variations were on the whole fairly similar. The aggregates of the + and − disturbances for a particular hour of the day were seldom equal, and thus after the removal of the disturbed values the mean value of the element for that hour was generally altered. Sabine’s complete scheme supposed that after the disturbance had been applied the hourly means would be recalculated from the undisturbed values and the criterion applied again, and that this process would be repeated until the disturbed observations all differed by not less than the accepted limiting value from the final mean based on undisturbed values alone. If the disturbance limit were so small that the disturbed readings formed a considerable fraction of the whole, then the complete execution of Sabine’s scheme would be exceedingly laborious. As a matter of fact, his disturbed readings were usually of the order of 5\% of the total number, and unless in the case of exceptionally large magnetic storms it is in little uncertainty whether the first choice of disturbed readings is accepted as final or is reconsidered in the light of the recalculated hourly means.

Sabine applied his method to the data obtained during the decade 1840 to 1850 at Toronto, St. Helena, Cape of Good Hope and Hobart, also to data for Pekin, Nertchinsk, Point Barrow, Port Kennedy and Kew. C. Chambers \textsuperscript{33} applied it to data from Bombay. The yearly publication of the Batavia observatory gives corresponding results for that station, and Th. Moureau \textsuperscript{34} has published similar data for Parc St Maur. Tables XXX to XXXII are based on a selection of these data. Tables XXXI, XXXII, XXXIII show the annual variation in Sabine’s disturbances, the monthly values being expressed as percentages of the arithmetic mean value for the 12 months. The Parc St Maur and Batavia data were supplemented by the known factors included, are especially noteworthy. Table XXX deals with the east (E) and west (W) disturbances of declination separately. Table XXXII, dealing with disturbances in horizontal, vertical and combined forms, the + and − disturbances, treated numerically. At Parc St Maur the limits required to qualify for disturbances were 0.240 in H, and 0.225 in V; the corresponding limits for Batavia were 1.3, 1.17 and 1.45. The limits for D at Bombay and Hobart were respectively 3.6, 3.4 and 3.7.

At Parc St Maur the disturbance data from all three elements give distinct maxima near the equinoxes; a minimum at midwinter is clearly shown, and also one at midsummer, at least in D and H. A decline in disturbance at midwinter is visible at all the stations, but at Batavia the equinoctial values for D and V are inferior to those at midsummer.

Table XXXII shows in some cases a most conspicuous diurnal variation in Sabine’s disturbances. The data are percentages of the totals for the whole 24 hours. But whilst at Batavia the easterly and westerly disturbances in D vary similarly, at Parc St Maur they follow opposite laws, the easterly showing a prominent maximum near noon, the westerly a still more prominent maximum near midnight. The figures in the second last line of the table, if divided by 0.24, will give the percentage of hours which show the species of disturbance indicated. For instance, at Parc St Maur, out of 105 hours, 37 show the disturbances of declination in H, 67 show the disturbances of declination. The last line gives the average size of a disturbance of each type, the unit being 10\(^\text{th}\) in H and V.

At Batavia disturbances increasing and decreasing the element are about equally numerous, but this is exceptional. Easterly disturbances of declination predominated at Toronto, Point Barrow, Fort Kennedy, Kew, Parc St Maur, Bombay and the Falkland Islands, whilst the reverse was true of St. Helena, Cape of Good Hope, Pekin and Hobart. At Kew and Parc St Maur the ratios borne by the

### Notes
- Eastern to the western disturbances were 1—19 and 1—23 respectively, and so not much in excess of unity; but the preponderance of eastern disturbances at the North American stations was considerably larger than this.
- From the point of view of the surveyor there is a good deal to be said for Sabine’s definition of disturbance, but it is less satisfactory from other standpoints. One objection has been already indicated, viz., the arbitrariness of applying the same limiting value at a station irrespective of the size of the normal diurnal range at the time. Similarly it is arbitrary to apply the same limit between 10 a.m. and noon, when the normal diurnal variation is most rapid, as between 10 p.m. and midnight when it is hardly appreciable.
- There seems a distinct difference of phase between the diurnal inequalities on different types of days at the same season; also the phase angles in the Fourier terms vary continuously throughout the year, and much more rapidly at some stations and at some seasons than at others. Thus there may be a variety of phenomena which one would hesitate to regard as disturbances which contribute to the annual and diurnal variations in Tables XXX to XXXII.
- Sabine, as we have seen, confined his attention to the departure of the hourly reading from the mean for that hour. Another and equally natural criterion is the apparent character of the magnetic curve. At Potsdam curves are regarded as “1” quiet, “2” moderately disturbed, or “3” highly disturbed. Any hourly value to which the numeral 3 is attached is treated as disturbed, and the annual Potsdam publication contains tables giving the annual and diurnal variations in the number of such disturbed hours for D, H, and V. According to this point of view, the extent to which the hourly value departs from the mean for that hour is immaterial to the results. It is the greater or lesser similarity and irregularity of the curve that counts. Tables XXXIII and XXXIV, give an abstract of the mean Potsdam results from 1892 to 1901. The data are percentages: in Table XXXIII, 25—30 days of the month, in Table XXXIV, of the total for the year. Thus far as the annual variation is concerned, the results in Table XXXIII are fairly similar to those in Table XXX, for Parc St Maur. There are pronounced maxima near the equinoxes, especially the spring equinox. The diurnal uncertainty is unlikely to have much influence on the diurnal, or even on the annual, variation.
- A third method of investigating a diurnal period in disturbance is by the diurnal inequality of disturbed days and compare it with the corresponding inequalities from ordinary or quiet days. Table XXXV gives some declination data for Kew, the quantity tabulated being the algebraic excess of the disturbed day hourly value over that for ordinary or quiet days of the same annual inequality for the year, as based on the 11 years 1890 to 1900.
- The disturbed day inequality was corrected for non-cyclic changes in the geomagnetic field. Fig. 11 shows the results of Table XXXV, graphically. The irregularities tabulated are probably due to the limited number of disturbed days employed; to get a smooth curve we have graphed the means of two or three years a number of hours which would be entered under “2” in a highly disturbed year. Still, such a source of even on the annual, variation.
- A third method of investigating a diurnal period in disturbance is by the diurnal inequality of disturbed days and compare it with the corresponding inequalities from ordinary or quiet days. Table XXXV gives some declination data for Kew, the quantity tabulated being the algebraic excess of the disturbed day hourly value over that for ordinary or quiet days of the same annual inequality for the year, as based on the 11 years 1890 to 1900.

Still, such a source of even on the annual, variation.
between 30° and 60°; while on 75 days it exceeded 60°. Taking each class of disturbances separately, Ellis found, except in the case of his minor disturbances—those under 20°—a distinct double annual period, with maxima towards the equinoxes. Subsequently C. W. Maunder, making use of these same data, and of subsequent data up to 1902, put at his disposal by Ellis, came to similar conclusions. Taking all the days with disturbances of declination over 10° from 1838 to 1890, and the years 1838 and 1890, he found the maxima of frequency to occur the one a little before the spring equinox, the other apparently after the autumnal equinox; the two minima were found to occur early in June and in January. When the year is divided into three—March to June (summer), June to September, September to December (winter)—the latter is distinctly greater than the summer; considerable differences to be found in the different months. The frequency in January is the same for the two hemispheres; while that in May is distinctly greater than that in August. The frequency in summer is only slightly apparent in the disturbances over 60°, but their number is so small that this may be accidental. The next figure in Table XXXVI gives the number of days distinguished as Greenwich disturbed days at Kew. The larger relative frequency at Kew in winter as compared to summer probably indicates no real difference from Greenwich, with which is simply a matter of definition. The chief criterion at Kew for classifying the days was not so much the mere amplitude of the largest movement, as the general character of the day's curve and its departure from the normal form. The data in Table XXXVI, as to magnetic storms, were obtained by Maunder18 from the Monthly Notices, R.A.S. A storm may last for any time from a few hours to several days, and during part of its duration the disturbance may not be very large; thus it does not necessarily follow that the frequencies of magnetic storms and of disturbed days will follow the same laws. The table shows, however, that so far as Greenwich is concerned the annual variations in the two cases are closely alike. It is true that the mean number of sun-spots, for the whole period of thirty years, 1858 to 1889, in Table XXXVI, contains separate data for the 14 years of that period which represented the highest sun-spot frequency, and the 15 years which represented lowest sun-spot frequency. It will be seen that relatively considered the maximum disturbance period is usually in the number of days, so nearly equal in the years of many than in those of few sun-spots. Storms are more numerous as a whole in the years of many sun-spots, and this preponderance is especially true of storms of the largest size. This requires to be borne in mind in any comparisons between larger and smaller storms selected promiscuously from a long period. An unduly large proportion of the larger storms will probably come from that period of high sun-spot frequency, and there will be some assigning to differences between the laws obeyed by large and small storms phenomena that are due in whole or in part to differences between the laws followed in years of many and of few sun-spots. The last data in Table XXXVI, are based on statistics for Batavia given by W. van Bemmelen,19 who considers separately the storms which commence suddenly and those which do not. These sudden movements are recorded over large areas, sometimes probably all over the earth, if not absolutely simultaneously, at least to too nearly so for differences in the time of occurrence to be shown by ordinary magnetograms. It is ordinarily supposed that these sudden movements, and the storms to which they give rise as precursors, arise from some source extraneous to the earth, and that the commencement of the movement intensifies the arrival, probably in the upper atmosphere, of some form or substance through atmospheric disturbances which commence gradually the earth is not so prominently suggested, and it has been sometimes supposed that there is a fundamental difference between the two classes of disturbances. Table XXXVII, shows, however, no essential difference in the annual variation at Batavia. At the same time, this possesses much less significance than would if it have Batavia were a station like Greenwich, where the annual variation in magnetic storms is conspicuous.

Besides the annual period, there seems to be also a well-marked diurnal period in magnetic disturbances. This is apparent in Tables XXXVI. and XXXVIII., which contain some statistics for Batavia due to W. van Bemmelen, and some for Greenwich derived from data in Maunder's papers referred to above. Table XXXVIII. gives the relative frequency of occurrence for two hour intervals, starting at one o'clock. The middle of each hour is separated by a line of staves. The form and relative frequency of endings and convolutions; thus the time of the first decided movement in Table XXXXIX., which contains some data as to the direction given by Ellis41 and van Bemmelen. The sign means an increase, the — sign a decrease of the element. The sign is not invariably the same, it will be understood, but there are in all cases a marked preponderance of changes in the direction shown in the table. The fact that all the stations indicated an increase in horizontal lines is of special significance.

This may mean, as van Bemmelen supposes, a small preliminary movement in the opposite direction to the clearly shown displacement; but it may only mean that the magnet is initially set in vibration, swinging on both sides of the position of equilibrium, but thereafter oscillating about the equilibrium position being all the time in the direction of the displacement apparent after a few minutes. To prevent misconstruction, the direction of the displacement apparent after a few minutes has been termed the direction of the first decided movement in Table XXXXIX., which contains some data as to the direction given by Ellis and van Bemmelen. The sign means an increase, the — sign a decrease of the element. The sign is not invariably the same, it will be understood, but there are in all cases a marked preponderance of changes in the direction shown in the table. To the above Table XXXVII is added the following Table XXXVIII., which is of much greater interest, and which contains some data as to the direction given by Ellis and van Bemmelen. The sign means an increase, the — sign a decrease of the element. The sign is not invariably the same, it will be understood, but there are in all cases a marked preponderance of changes in the direction shown in the table. The fact that all the stations indicated an increase in horizontal lines is of special significance.

The above Table XXXVIII is of much greater interest, and which contains some data as to the direction given by Ellis and van Bemmelen. The sign means an increase, the — sign a decrease of the element. The sign is not invariably the same, it will be understood, but there are in all cases a marked preponderance of changes in the direction shown in the table. The fact that all the stations indicated an increase in horizontal lines is of special significance.

§ 36. There are peculiarities in the sudden movements ushering in magnetic storms which deserve more full attention. Van Bemmelen's impulse consists usually at some stations of a sudden slight jerk of the magnet in one direction, followed by a larger decided movement in the opposite direction, the former being generally distinctly shown. Often we have at the commencement of the disturbance, but a faint outline, and thereafter a continuous movement which is only sometimes distinctly indicated, resulting after some minutes in the displacement of the needle by a finite amount from the position it occupied on the paper before the disturbance began.
on prearranged term days. During March 1879 and August 1880 some very great magnetic storms occurred, and the magnetic curves showing these at a number of stations fitted with Kew pattern magnetographs were compared by W. G. Adams. He found the movements to be simultaneous at the stations. At comparatively near stations such as Stonyhurst and Kew, or Coimbra and Lisbon, the curves were in general almost duplicates. At Kew and St Petersburg there were usually considerable differences in detail, and the movements were occasionally in opposite directions. The differences between Toronto, Melbourne or Zí-ka-wei and the European stations are very small. Magnetic storms on the 2nd and 3rd of M. Eschenhagen, 4 eye observations of declination and horizontal force were taken at 5-second intervals during prearranged hours at Batavia, Manila, Melbourne and nine European stations. The data from these storms were published in one complete series of papers, and later, were published by Eschenhagen, and were subsequently analysed by Ad. Schmidt. 42 Taking the stations in western Europe, Schmidt drew several series of lines, each series representing what he called a magnetic disturbance, as determined from the departure of the elements at the several stations from their undisturbed value. The lines answering to any one instant had a general sameness of direction in a number of less or more, but their general trend varied in a way which suggested, to Schmidt, the passage of a species of vortex with large but finite velocity.

The conclusion that magnetic disturbances tend to follow one another was confirmed by observations made and communicated by several independent observers. J. A. Broun 43 pronounced for a period of about 26 days, and expressed a belief that a certain zone, or sort of line, would return to its normal direction after the magnetic disturbances observed on the earth’s magnetism during several solar rotations. Very similar views were advanced in 1904 by E. W. Maudner, 59 who was wholly unaware of Broun’s work. Maudner concluded that the period was 27-28 days, coinciding with the sun’s rotation-period relative to an observer on the earth. Taking magnetic storms at Greenwich from 1832 to 1903, he found the interval between the commencement of successive storms to approach closely to the above period in a considerable number of instances, and believed that they afforded rather strong evidence of a period of about 30 days. Maudner regarded his results as demonstrating that magnetic disturbances originate in the sun. He regarded the solar action as arising from active areas of limited extent on the sun’s surface, and as propagated along narrow, well-defined streams. The active areas he believed to be also the seats of the formation of sun-spots, but believed that their activity might preclude and obliterate the visible evidence of the sun-spot.

Maudner did not discuss the physical nature of the phenomenon, but his view was that the action was due to the magnetic force of the solar atmosphere. Prior to the beginning of the century, E. W. Maunder made mathematical calculations, for the size of particle which he regarded as most probable, to make the time of transmission to the earth slightly under two days. Amongst other theories which ascribe the phenomena to the direct solar action may be mentioned that of Kr. Birkeland, 40 who believes the vehicle to be cathode rays. Ch. Nordmann 41 similarly has suggested Röntgen rays. Supposing the sun the ultimate source, it would be easier to see a relation between the theories if the exact time of the originating occurrence could be fixed. For instance, a disturbance that is propagated with the velocity of light may be due to Röntgen rays, but not to Arhenius’ particles. In support of his hypothesis, Nordmann enumerates several cases when coincident visual phenomena on the sun have synchronized with magnetic movements on the earth—the best known instance being the appearance of auroras on the 1st of September 1859 with a remarkable solar outbreak seen by R. C. Carrington. Presumably any electrical phenomenon on the sun will set up waves in the aether, so transmission of electric and magnetic disturbances from the sun to the earth with a velocity of light is a certainty rather than a hypothesis; but it by no means follows that the energy thus transmitted can give rise to sensible magnetic disturbances. Also, when considering Nordmann’s hypothesis it must be remembered that magnetic movements are so numerous that it would be singular if no apparent coincidences had been noticed. Another consideration is that the movements shown by ordinary magnetograms are probably far more rapid than the some storms, especially those accompanied by unusually bright and rapidly varying auroral displays, large to and fro movements follow one another in close succession, the changes being sometimes so quick that the entire process of a disturbance can be deduced from the corresponding daily values of the sun-spot frequency and the magnetic range. Even if only some sun-spots are effective, we should expect when we select from a series of years two groups of days, the first for instance, the five days of least, that a prominent difference will exist between the mean values of the absolute daily magnetic ranges for the two groups. Conversely, if we take out the days of small and the days of large sun-spot activity, we should expect that the quiet and those that are highly disturbed, we should expect a prominent difference between the corresponding mean sun-spot areas. An application of this principle was made by Crell 41 to the five quiet days a month selected by the astronomer royal between 1850 and 1900. These days are very quiet relative to the average day and possess a much smaller absolute range. One would thus have expected the BirchCalculations, taking the frequency derived from Wolfer’s provisional values for these days to be much below his mean value, 41-22, for the eleven years. It proved, however, that the three months for which the five days were selected was by far the best of the three, and the sun-spot maximum for the years 1890 to 1895, the years of sun-spot minimum, as it was in the years of sun-spot minimum. Use was next made of the Greenwich projected sun-spot areas, which are the result of exact measurement. The days of each month were divided into three groups, the first and third—each normally of ten days—containing respectively the days of largest and the days of least sun-spot area. The mean sun-spot area from group 1 was on the average about five times that for group 3. From this it was then inferred how the astronomer royal’s quiet days from 1850 to 1900, and how the most disturbed days of the period selected from the Kew 4 magnetic records, distributed among three groups of three months each. Three months were excluded, as containing more than ten days with no sun-spots. The remaining 113 months contained 606 quiet and 191 highly disturbed days, whose distribution was as follows:

<table>
<thead>
<tr>
<th>Group 1</th>
<th>Group 2</th>
<th>Group 3</th>
</tr>
</thead>
<tbody>
<tr>
<td>Quiet days</td>
<td>179</td>
<td>105</td>
</tr>
<tr>
<td>Disturbed days</td>
<td>68</td>
<td>65</td>
</tr>
</tbody>
</table>

The group of days largest sun-spot area thus contained slightly under their share of quiet days and slightly over their share of disturbed days. The differences, however, are not large, and in three years, viz. 1856, 1879 and 1899, the largest number of disturbed days was in group 1, while in 1895, the number was in group 3. In 1899 there were fewer quiet days in group 3 than in group 1. Taking the same distribution of days, the mean value of the absolute daily range of declination at Kew was calculated for the group 1 and the group 3. The mean daily range of declination at Kew was the larger in 57 % of the individual months as against 45 % in which it was the smaller. When the days of each month were divided into two groups, those days were found at Kew, the mean sun-spot area for the group 1 days (those of largest range) exceeded that for the group 3 days (those of least range) in 55 % of the individual months, as against 45 % of cases in group 3. Taking the next five days of largest and the five days of least range in each month, sun-spot areas were got out not merely for these days themselves, but for the four days immediately preceding in each case. On Arhenius’ theory we should expect the magnetic range to vary with the sun-spot area, not on the actual day but two days previously. The following table shows the percentages of days or days in the mean sun-spot area for the respective groups of days, relative to the average value for the whole epoch dealt with. / denotes the day to which the magnetic range belongs, +1 the day after, -1 the day before, and -1
so on. Results are given for 1894 and 1895, the years which were on the whole the most favourable and the least favourable for Arrhenius's hypothesis, as well as for the whole eleven years.

Taking the 11-year means we have the sun-spot area practically nothing on the 4th subsequent to the representative day of large magnetic range, but sensibly above its mean on that day and still more so on the four previous days. This suggests an emission from the sun taking a highly variable time to travel to the earth. The 11-year mean data for the five days of least range seem at first sight to point to the same conclusion, but the fact that the deficiency in sun-spot area is practically as prominent on the day after the representative day of small magnetic range as on that day itself, or the previous days, shows that the phenomenon is probably a secondary one. On the whole, taking into account the extraordinary differences between the results from individual years, we seem unable to find the distinctive character that the present state of our knowledge little if any clue is afforded by the extent of the sun's spotted area on any particular day as to the magnetic configuration on the earth on that day or on subsequent individual days. Possibly some more definite information might be extracted by considering the extent of spotted area on different zones of the sun. On theories such as those of Arrhenius or Mander, effective bombardment on earth would be confined to the regions on the sun's surface nearest the centre of the visible hemisphere, whilst all spots on this hemisphere contribute to the total observed area. Hence the rapidly diminishing surface as it approaches the edge of the visible hemisphere is as it recedes from the most effective position, so that the method employed above gives a preponderating weight to the central zones. One row of figures in Table XIILII is devoted to the occurrence of solar spots in different latitudes. The same is true to a certain extent of days of large and days of small magnetic range, but it is unusual for the range to be much above the average for more than 3 or 4 successive days.

§ 39. The records from ordinary magnetographs, even when run at the usual rate and with normal sensitiveness, not infrequently show | Pulsa tions. a repetition of regular or nearly regular small rhythmic movements, lasting sometimes for hours. The amplitude and period on different occasions both vary widely. Periods of 2 to 4 minutes are the commonest. W. van Bemmelen has made a number of these movements from several years' traces at Batavia, comparing the results with the corresponding statistics sent him from Zl-ka-wei and Kew. Table XIILII shows the diurnal variation in the frequency of occurrence of these small movements—called periods in tables—on both the Kew and the other, pulsations being much more numerous by night than by day at the two former stations, whereas at Kew the exact reverse holds. Van Bemmelen decided that almost all the occasions of pulsations at Zl-ka-wei were also occasions of pulsations at Batavia. The hours of commencement at the two places usually differed a little, occasionally by as much as 20 minutes. This was ascribed to the fact that the earliest oscillations were too small at one or other of the stations to be visible on the trace. Remarkable coincidence between pulsations at both stations in the north of Norway has been noted by Kr. Birkeland. 4 With magnetographs of greater sensitiveness and much open time, waves of shorter period become visible. In 1882 F. Kohlrausch detected waves with a period of about 12 seconds. Eschen- hagen 24 observed a great variety of short period waves, seconding amongst the common. Some of the records he obtained suggest the superposition of regular sine waves of different periods. Employing a very sensitive galvanometer to record changes of magnetic induction through a coil traversed by the earth's lines of force, H. Ebert 44 has observed vibrations whose periods are but a small fraction of a second. The observations of Kohlrausch and Eschenhagen preceded the recent great development of applications of electric currents, while longer period waves are shown in the Kew curves of 50 years ago, so that the existence of natural waves with periods of from a few seconds up to several minutes hardly be doubted. Whether the much shorter period waves of Ebert are also natural is more open to doubt, as it is becoming exceedingly difficult in civilized countries to escape artificial disturbances.

§ 40. The fact that the moon exerts a small but sensible effect on the earth's magnetism seems to have been first discovered by 1841 by C. Kreil. Subsequently Sabine 4 investigated the nature of the lunar diurnal variation in declination at Kew, Toronto, Pekin, St. Helena, Cape of Good Hope and Hobart. The data in Table XIILII are derived from data due to Sabine. They represent the mean lunar diurnal inequality in declination for the whole year. The unit employed is 6-001, and as in our previous tables + denotes movement to the west. By mean "departure" is meant the arithmetic mean of the 24 hourly departures from the mean value for the lunar day; the range is the difference between the algebraically greatest and least of the mean values. Not infrequently there is a "jump" giving the better idea of the importance of an inequality, especially when it is in the present case two maxima and minima occur in the day. This double daily period is unusually prominent in the case of the lunar diurnal inequality, and is seen in the other elements as well as in the declination.

Lunar action has been specially studied in connexion with observations from India and Java. Brown 45 at Trivandrum and C. Chambers 46 at Kolaba investigated lunar action from a variety of aspects. At Batavia van der Stoek 47 and more recently S. Figeep 48 have carried out investigations involving an enormous amount of computation. Table XIILII gives a summary of Figeep's results for the mean lunar diurnal inequality at Batavia, for the two half-yearly periods April to September (Winter or W.), and October to March (S.). The + sign denotes movement to the west in the case of declination, but numerical increase in the case of the other elements. In the case of H and T (total force) the results for the two seasons appear comparatively small differences, but in the case of H and V the amplitude and phase both differ widely. Consequently a mean lunar diurnal variation derived from all the months of the year gives at Batavia, and presumably at other

Disturbing influence, and so are inherently costly; they are also apt to be of inferior accuracy. It might be possible in quiet weather, in a large vessels free from vibration, to observe with instruments of the higher order of precision, a sub-ecliptic declination circle, but in the ordinary surveying ship apparatus of less sensitiveness has to be employed. The declination is usually determined with some form of compass. The other elements are usually found directly at sea are the inclination and the total force, the instrument employed being a special form of circle, either the old Fox circle, which was largely used by Ross in the 'Lloyd-Creek.' This latter instrument differs from the ordinary dip-circle fitted for total observations at land, in that it is not circular, but quadrant, and the needle rests in pivots instead of on agate edges. To overcome friction a projecting pin on the framework is scratched with a magnetical needle.

The most notable recent example of observations at sea is afforded by the cruises of the surveying ship "Windward," under the auspices of the Carnegie Institution of Washington, which includes in its magnetic programme a general survey. To see where the ordinary land survey assistant in the United States is the least assistant in the world, one has only to take the coast with a long sea-board. If observations were taken every few miles along the coast results might be obtained adequate for the ordinary wants of coasting vessels, but the ship would require to hold a long distance from the land. If the declination would be 50 or even 20 miles off shore at any particular place. If, however, the land area itself is carefully surveyed, one knows the trend of the lines of equal declination, and can usually extend them with considerable accuracy many miles out to sea. One also can tell what places any on the coast suffer from local disturbances, and thus decide on the necessity of special observations. This is by no means the only immediately useful purpose which may be served by surveys at sea. In Scandinavia use has been made of magnetic observations in prospecting for iron ore. There are also several geological and geodetic problems to whose solution magnetic surveys may afford valuable clue.

For the satisfactory execution of a land survey, the observers must have absolute instruments such as the unilunar magnetometer and high diurnal magnets, suitable for use in the ship, and they must be able to fix the exact positions of the ship where observations are taken. If, as usual, the survey occupies several years, what is wanted is the value of the elements not at the actual time of observation, but at some fixed epoch, possibly some years earlier or later. At a magnetic observatory, with standardized records, the difference between the values of a magnetic element at any two specified instants can be derived from the magnetic curves. But at an ordinary survey station, at a distance from an observatory, the information is not immediately available. Ordinarily the reduction to a fixed epoch is done in at least two stages, a correction being applied for secular and diurnal inequalities, and the mean value for the day due to the regular diurnal inequality and to disturbance.

The reduction to a fixed epoch is at once more easy and more accurate if the area surveyed contains, or has close to its borders, a well distributed series of magnetic observatories, whose records are comparable and trustworthy. Throughout an area of the size of France or Germany, the secular change in any two specified dates can ordinarily be expressed with sufficient accuracy by a polynomial of the type

$$ \delta = a_0 + a_1 (L - \lambda) + b (\lambda - \lambda_0) $$

where \( \delta \) denotes secular change, \( L \) latitude and \( \lambda \) longitude, the letters with suffix \( 0 \) relating to some convenient central position. The constants \( a_0, a_1, b \) are derived from the observed secular changes at the fixed observatories whose data are accurately known. Unfortunately, as a rule, fixed observatories are few in number and not well distributed for survey purposes; thus the secular change over part at least of the area has usually to be found by repeating the observations after some years at several of the field stations. The success attending this depends on the plan of the network.
exactitude with which the sites can be recovered, on the accuracy of the observations, and on the success with which allowance is made for diurnal changes, regular and irregular. It is thus desirable that the observations at repeat stations should be taken at hours when the results of the previous day are allowed to be, and they should not be accepted unless taken on days that prove to be magnetically quiet. Unless the secular change is exceptionally rapid, it will usually be made necessary to take data from or observations on the local time of the month, and then to allow for the difference between the mean value for the month and the value at the actual hour of observation. There is here a difficulty, inasmuch as the latter part of the correction depends on the irregular inequality which is peculiar to the neighbourhood. Subtracting the forces derived from the formulae from those observed, we obtain what may be regarded as regional disturbance. In most cases the results are embodied in charts, usually of at least two kinds, one set showing only general features, the other the chief local peculiarities. Charts of this kind resemble the world charts (Figs. 1 and 2) in that they give an easily comprehensible idea of the variation of the diurnal inequality, although the declination for instance, at hour h G.M.T. the departure of Kew from the mean value for the month is \(d\), then the corresponding departure from the mean at a station \(\lambda\) degrees west of Kew is \(d - e\), where \(e\) is the increase in the element at Kew due to the regular diurnal inequality, identical with that at Kew when both were referred to local time, and of a disturbance element identical with that at Kew for the same time of the month. No other satisfactory method of surmounting this difficulty has yet been proposed. Rücker and Thorpe in their British Is购物o region have deduced the elements from the observed values, and at hour \(h\) of a particular month, which has been found, we can assign a definite meaning to the diurnal inequality for a particular month of a particular year, and after the curves have been measured we can give exact numerical figures answering to the observed departures from the diurnal inequality for the particular month at the particular hour. As has been pointed out, from that derived from a limited number of the quietest days of the month, not merely in amplitude but in phase, and the results of the local charts have been utilized, the element has been regarded as made up of a regular diurnal inequality of definite character and of a disturbance element which is likely at times to be considerably wide of the mark. The extent of the error involved in assuming the regular diurnal inequality the same in the north of Scotland, or the west of Ireland, as in the south-east of England remains to be ascertained. As to the disturbance element, even if the disturbing forces were of given magnitude and direction all over the British isles—which we now know is often very far from the case—its effects would necessarily vary very sensibly owing to the considerable variation in the direction and intensity of the local irregularities. An allowance has been made in the results for the effects of the regular diurnal changes are slow, and only those taken on days of little or no disturbance were utilized, corrections combining the results of effective and irregular diurnal changes could be derived from the records of fixed observations, suppose, of suitably situated, combined in formulae of the same type as (i).

§ 43. The field results have been reduced to a fixed epoch, it remains to combine them in ways likely to be useful. In most cases the results are embodied in charts, usually of at least two kinds, one set showing only general features, the other the chief local peculiarities. Charts of this kind resemble the world charts (Figs. 1 and 2) in that they give an easily comprehensible idea of the variation of the diurnal inequality, although the declination for instance, at hour h G.M.T. the departure of Kew from the mean value for the month is \(d\), then the corresponding departure from the mean at a station \(\lambda\) degrees west of Kew is \(d - e\), where \(e\) is the increase in the element at Kew due to the regular diurnal inequality, identical with that at Kew when both were referred to local time, and of a disturbance element identical with that at Kew for the same time of the month. No other satisfactory method of surmounting this difficulty has yet been proposed. Rücker and Thorpe in their British Is购物o region have deduced the elements from the observed values, and at hour \(h\) of a particular month, which has been found, we can assign a definite meaning to the diurnal inequality for a particular month of a particular year, and after the curves have been measured we can give exact numerical figures answering to the observed departures from the diurnal inequality for the particular month at the particular hour. As has been pointed out, from that derived from a limited number of the quietest days of the month, not merely in amplitude but in phase, and the results of the local charts have been utilized, the element has been regarded as made up of a regular diurnal inequality of definite character and of a disturbance element which is likely at times to be considerably wide of the mark. The extent of the error involved in assuming the regular diurnal inequality the same in the north of Scotland, or the west of Ireland, as in the south-east of England remains to be ascertained. As to the disturbance element, even if the disturbing forces were of given magnitude and direction all over the British isles—which we now know is often very far from the case—its effects would necessarily vary very sensibly owing to the considerable variation in the direction and intensity of the local irregularities. An allowance has been made in the results for the effects of the regular diurnal changes are slow, and only those taken on days of little or no disturbance were utilized, corrections combining the results of effective and irregular diurnal changes could be derived from the records of fixed observations, suppose, of suitably situated, combined in formulae of the same type as (i).

From the records of fixed observations, suppose, of suitably situated, combined in formulae of the same type as (i).
MAGNETISM, TERRESTRIAL

\[ H = (1 - \mu) I \left[ a^m - (n - m)(m - n + 1) a^{m-n} + \ldots \right] / (2m-1), \]

where \( n \) and \( m \) denote any positive integers, \( m \) being greater than \( n \). Then denoting the earth's radius by \( R \), we have

\[ V/R = \Sigma (r/R)^{2m} (H_3^a + H_3^b \sin m \lambda) \]

\[ + (r/R)^{2m+1} (H_3^a + H_3^b \sin m \lambda) \]

where \( \Sigma \) denotes summation of \( m \) from 0 to \( n \), followed by summation of \( n \) from 0 to \( \infty \). In this equation \( g^a, g^b \), etc., are constants, those with positive suffixes being what are generally termed Gaussian constants. The series with negative powers of \( r \) answers to forces with a source internal to the earth, the series with positive powers to forces external. By an exacting analysis of the latter class, if existent, were very small, and they are usually left out of account. There are three Gaussian constants of the first order, \( g^a, g^b, g^c \), five of the second order, seven of the third, and coefficients of a Gaussian constant of the \( n^\text{th} \) order is a spherical harmonic of the \( m^\text{th} \) degree. If \( R \) be taken as unit length, as is not infrequent, the first order terms are given by

\[ V_r = r^{-m} \sin l + (g^a \cos l + h^a \sin l) \cos l. \]

The earth is in reality a spheroid, and in his elaborate work on the subject J. C. Adams \( b \) develops the treatment appropriate to this case. Here we shall regard it as spherical. We then have for the components of the force at the surface

\[ X = -R^{-2m} \cos l, \quad Y = R^{-2m} \sin l, \quad Z = -R^{-2m} \sin l. \]

Supposing the Gaussian constants known, the above formula would give the force all over the surface. To determine the Gaussian constants we proceed of course in the reverse direction, equating the observed values of the force components to the theoretical values involving \( g^a, g^b, \) etc. If we knew the values of the component forces at regularly distributed stations all over the earth's surface, we could determine each Gaussian constant independently of the others. Our knowledge however of large regions, especially in the Arctic and Antarctic, is very scanty, and in practice recourse is had to methods in which the constants are not determined independently. The consequence is unfortunately that the values found for some of the constants, even amongst the lower orders, depend very sensibly on how large a portion of the polar regions is omitted from the calculations, and on the number of the constants of the higher orders already included, in the table

Some of the higher constants were relatively much more affected. Thus, on the hypotheses of 48 and of 24 constants respectively, the values obtained for \( g_l^a \) in 1842-1845 were --00127 and --00057, and those for \( h_l^a \) in 1888 were --00744 and --00673. It must also be remembered that these values assume that the positive powers of \( r \), with coefficients having negative suffixes, is absolutely non-existent. If this be not assumed, then in any equation determining \( X \), \( Y \), \( g_l^a \), \( g_l^b \), \( h_l^a \), \( h_l^b \), the coefficients of \( Z \) are determined by the equation

\[ z = -R/M \times H \times B \times F. \]

Thus the hypotheses of these three sets of equations, \( g_l^a, g_l^b, h_l^a, h_l^b \), which are the only sets of equations, \( g_l^a, g_l^b, h_l^a, h_l^b \), which will harmonize the two sets of equations. Adams gives the values obtained from the \( X \) and \( Y \) and the \( Z \) equations separately for the
Gaussian constants. The following are examples of the values thence
deductible for the coefficients of the positive power series:—
\[
g^{2} = 0.1842-1845 + 0.0018 - 0.0002 - 0.0014 + 0.0064 + 0.0072 + 0.0124
\]
\[
1880 = - 0.0002 - 0.0012 + 0.0015 - 0.0013 - 0.0021 + 0.0013
\]
Compared to \(g_{1}, g_{2}\) and \(g_{3}\) the values here found for \(g_{1}, g_{2}\) and \(g_{3}\) and those calculated (C) by the method of least squares for
regressing them if the observational data were sufficient and reliable.
But two outstanding features claim attention, first the smallness of
\(g_{1}, g_{2}\) and \(h_{1}\), the coefficients least likely to be affected by obser-
vational deficiencies, and secondly the striking dissimilarity between
the values obtained for the two epochs. The conclusion to which these
and other facts point is that observational deficiencies, even up to the
present date, are such that any conclusion can be drawn as to the
existence or non-existence of the positive power series. It is also to be feared that considerable uncertainties enter into the values of most of the Gaussian constants, at least those of the
higher orders. The introduction of the positive power series neces-
sarily improves the agreement between observed and calculated values
of the force, but it is more likely than not to be disadvantageous
physically, if the differences between observed values and those calculated from the negative power series alone arise in large measure from
differential deficiencies.

§ 49. The first order Gaussian constants have a simple physical
meaning. \(g_{1}, g_{2}\) and \(h_{1}\) represent the components
arising from the uniform magnetization of a sphere parallel to a fixed
axis, the moment \(M\) of the spherical magnet being given by
\[
M = \frac{R^{2}(g_{1}^{2} + g_{2}^{2} + h_{1}^{2})}{2}
\]
where \(R\) is the earth’s radius. The position of the north end of
the axis of this uniform magnetization and the values of \(M/R^{2}\),
derived from the more important determinations of the Gaussian
constants, are given in Table XLIV. The data for 1850 are of some-
what value if they were as reliable as the others, one would feel greater confidence in the reality of the apparent
movement of the north end of the axis from east to west. The table
also suggests a slight diminution in \(M\) since 1845, but it is open to
doubt whether this change is one which may be assumed from what
the calculated values. It should be carefully noticed that the data in
the table apply only to the first order Gaussian terms, and so only
to a portion of the earth’s magnetic axis, and that the Gaussian
constants have been calculated on the assumption that the negative
power series alone exists. The field answering to the first order
terms—or what Bauer has called the normal field—constitutes
not more than the most important part of the total magnetic field,
what remains is very far from negligible, save for rough calculations.
It is in fact one of the weak points in the Gaussian analysis that when
one wishes to represent the observed facts with high accuracy one
is obliged to retain so many terms that calculation becomes burdens-
some.

§ 50. The possible existence of a positive power series is not the
only theoretical uncertainty in the Gaussian analysis. There is the
further possibility that part of the earth’s magnetic field may not answer to a potential at all. Schmidt
in his calculation of Gaussian constants regarded this as a possible
confinement, and the results he obtained in the north on
much as 2 or 3% of the entire field had no potential. If the magnetic
force \(F\) on the earth’s surface comes from a potential, then the line
\[
\int (\partial F/\partial x)dx = \text{const.}
\]

**Earth-air Currents.** The earth-air currents are the sole current that is necessary to consider, since there is little chance that the
take such a form that the earth’s magnetic field may not answer to
potential. In the Gaussian analysis of the formula by W. von
Bezold \(11\) and Bauer \(10\) the integral has been taken along parallels
of latitude in the direction west to east. In this case a \(+\) sign indicates
a resultant upward current over the area between the parallel of
current and the north magnetic pole. The difference between the results of integration round two parallels of latitude
gives the total vertical current over the zone between them.
Schmidt’s final estimate of the average intensity of the earth-air
current, irrespective of sign, for the epoch 1885 was 0.17 ampere per
square kilometre. Bauer employing the same observational data
as Schmidt, reached somewhat similar conclusions from the
differences between integrals taken round parallels of latitude at 5°
and 45° from \(0°\) N. See Fritsch \(12\) treating the problem similarly, but for two epochs, 1842 and 1885. German observers have
repeatedly different results for the two epochs, Bauer \(14\) has more recently
repeated his calculations, and for three epochs, 1842-1845 (Sabin’s
data) and 1882-1885 and 1885-1888. In calculating the mean value of the current per sq. km. for 5° zones. Table
XLVI. is based on Bauer’s figures, the unit being o.001 ampere, and
adding an \(a priori\) directed current.

In considering the significance of the data in Table XLVI, it
should be remembered that the currents must be regarded as
values derived from all hours of the day, and all months of the year.
Currents which were upwards during certain hours of the day, and
downwards during others, and vice versa, and vice versa, would yield,
while currents which were upwards during certain months, and down-
wards during others, would cause an annual inequality in the absolute
values. Thus, if the figures be accepted as real, we must suppose
that from 1842 to 1885 the currents are preponderating upward
currents, and between 0° S. and 15° S. preponderating upward
currents. Such currents might arise from meteorological conditions
characteristic of particular latitudes, and partly, no doubt, to the relative
distribution of land and sea; but, whatever their cause, any considerable
real change in their values between 1842 and 1885 seems very
improbable. The most natural cause to which to attribute the dis-
crepancy between the results for different epochs in Table XLVI
is unquestionably observational deficiencies. Bauer himself regards
the results for latitudes higher than 45° as very uncertain, but
his seems inclined to accept the reality of currents of the average
intensity of at 1/30 ampere per sq. km. for 5° zones.

Currents of the size originally deduced by Schmidt, or even those
of Bauer’s latest calculations, seem difficult to reconcile with the
result of the atmospheric observations.

§ 51. There is no single parallel of latitude along the whole
of which magnetic elements are known with high precision. Thus
results of greater certainty might be hoped for from the application
of the line integral to well surveyed countries. Such applications have
been made, e.g. to Great Britain by Rücker,\(^ {16}\) and to Austria
by Lizzar,\(^ {17}\) but with negative results. The question has also
been taken up by Schmidt for the results of a future and long dis-
cussed survey of Japan. He makes the criticism that the taking of a
line integral round the boundary of a surveyed area amounts to
utilizing the values of the magnetic elements where least accurately
known, and seems to consider it preferable to replace the line integral
by the surface integral.

\[4\pi l = \int (\partial F/\partial x = 2\pi d/dy) dyd\]

He applied this formula not merely to his own data for Japan, but
also to British and Austrian data of Rücker and Thorpe and of
Lizzar. The values he ascribes to \(X\) and \(Y\) are those given by
the formulæ calculated to fit the observations. The result reached
was “a line of no current through the middle of the country; in
Japan the current is upward on the Pacific side and downward on
the Sea of Japan; it is upward in the north and downward in the
south; in Great Britain upward in the east and downward in the
west.” The results obtained for Great Britain differed
considerably according as use was made of Rücker and Thorpe’s
own district calculations or those of Schmidt, and the conclusion
was subsequently utilized by Mathias. Tanakadate points out that the fact
that his investigations give in each case a line of no current passing
through the middle of the surveyed area, is calculated to throw light
on the reality of the supposed earth-air currents, and he recom-
mands a suspension of judgment.

§ 52. A question of interest, and bearing a relationship to the
Gaussian analysis of the results of the various magnetic observa-
tions taken in the same instruments on the earth’s surface, is the
problem of determining which magnetic elements have with height above sea-level. If \(F\) represent the value at sea-level,
and \(F+\delta F\) that at height \(h\), of any component of force answering
the Gaussian formula \(\nabla = (\nabla - R \nabla) + \frac{1}{2} \nabla (\nabla - R \nabla)\),
where \(R\) is the earth’s radius. Thus at heights of only a few miles
we have approximately \(\delta F/F = - (a + 2a)R\). As we have
seen, the constants of the first order are much the most important, thus we should expect as a first approximation \(2X/X = 2Y/Y = -2Z/Z = -3h/R\).
This equation gives the same rate of decrease in all three components, and so no change in declination or inclination. Lizzar \(18\) compared this equation with the observed results of his
Austrian survey, subdividing his stations into three groups according
MAGNETISM, TERRESTRIAL

He considered the agreement not satisfactory. It must be remembered that the Gaussian analysis, especially when only lower order terms are retained, applies only to the earth's field freed from local disturbances. Now observations at individual high level stations may not merely represent regional disturbances common to low level stations, but by magnetic material in the mountain itself. A method of arriving at the vertical change in the elements was therefore needed to correct for this. It was employed by A. Tanakadate. If we assume that a potential exists, or if admitting the possibility of earth-air currents we assume their effort negligible, we have

$$dX/dz = -dZ/dx, \quad dY/dz = -dZ/dy,$$

where \( \rho \) represents the density of free magnetism at the spot. The spot being above ground we may neglect \( \rho \), and the result is

$$dX/dz = -dZ/dx, \quad dY/dz = -dZ/dy.$$

of these cases there were synchronous movements in the Antarctic,
similar in type to those which occurred simultaneously with the
sudden commencements of magnetic storms, and that these Antarctic
movements were considerably larger than those described by Birkeland at the equatorial stations. This result tends of course to suggest
a somewhat different explanation from Birkeland's. But until our
knowledge of facts has received considerable additions all'explanations must be of a somewhat hypothetical character.
In 1831 Sir James Ross 94 observed a dip of 89 59' at 70 5' N.,
96 46' W., and this has been accepted as practically the position of

MAGNETITE—MAGNETOGRAPH

MAGNETITE, a mineral forming the natural magnet (see Magnetism), and important also as an iron-ore. It is an iron black, opaque mineral, with the metallic lustre, and glistening at the fracture. The most common colour is brown, as 6, 80-90; and the least 5-10 to 5-2. When scratched, it yields a black streak.

This is an oxide of iron having the formula FeO₂ corresponding with 72-4% of metal, the same as its great value as an ore. It may be regarded as a ferro-ferric oxide, Fe₂O₃ or Fe₄, as iron ferrate, Fe⁺FeOs. Titaniferous is often present, and occasionally the mineral contains manganese, nickel, &c. It is always strongly magnetic. Magnetite crystallizes in the cubic system, usually in octahedra, less commonly in rhombic dodecahedra, and not infrequently in twins of the spinel type (*fig. 1). The rectilinear faces of such dodecahedrons are often striated parallel to the longer diagonal. There is no distinct cleav- age, but imperfect parting may be obtained along octahedral planes.

Magnetite is a mineral of wide distribution, occurring as grains in many massive and volcanic rocks, like granite, diorite and dolerite. It appears to have crystallized from magmatic or volcanic materials; and the secondary or secondary period of consolidation. Its presence contributes to the dark colour of many basalts and other basic rocks, and may cause these to disturb the compass. Large ore-bodies of granular and compact magnetite occur as beds and laminar masses in Archean gneiss and crystalline schists, in various parts of Norway, Sweden, Finland and the Urals; as also in the states of New York, New Jersey, Pennsylvania and Michigan, as well as in Canada. In some cases it appears to have segregated from a basic eruptive magma, and in other cases to have resulted from metamorphic action. Certain deposits, as the temperature and pressure, and either directly or indirectly, by wet processes. Iron rust sometimes contains magnetite. An interesting deposit of oolith magnetic ore occurs in the Dogger (Inferior Oolite) of Rosedale Abbey, in Yorkshire; and a somewhat similar pisolitic ore, of Jurassic age, is known on the continent as chamoisite, having been named from Chamoison (or Chamazon) in the Valais, Switzerland. Grains of magnetite occur in serpentine, as an alteration-product of the olivine. In emery, magnetite in a granular form is largely associated with the corundum; and in certain kinds of mica magnetite occurs as thin dendritic enclosures. Haematite is sometimes magnetic, and A. Liveriside has shown that magnetite is probably present. By oxidation, haematite may be converted into magnetite, as proved by certain pseudomorphs; but on the other hand magnetite is sometimes altered to haematite. On weathering, magnetite commonly passes into limonite, the ferrous oxide having probably been removed by carbonated waters. Closely related to magnetite is the rare volcanic mineral from Vesuvius, called magnoferrite, or magnesiomagnetite, with the formula MgFe₂O₄; and with this may be mentioned a mineral from Jakobson, called jacobite, containing MnFe₂O₄.

MAGNETOGRAPH, an instrument for continuously recording the values of the magnetic elements, the three universally chosen being the declination, the horizontal component and the vertical component (see Terrestrial Magnetism). In each case the magnetograph only records the variation of the element, the absolute values being determined by making observations in the neighbourhood with the unifilar magnetometer (q.v.) and inclinometer (q.v.).

**Fig. 1.**

**Declination.**—The changes in declination are obtained by means of a magnet which is grooved by a long, direct, iron rod immediately below which a fixed mirror is attached to the base of the instrument. Both mirrors are usually concave; if plane, a concave lens is placed immediately before them. Light passing through one of the iron rods reflects from the fixed mirror, and two images of the slit are produced, one by the movable mirror attached to the magnet and the other by the fixed mirror. These images are of course short time exposure of magnetic axis. The light reflected from the fixed mirror traces a straight line on the paper, serving as a base line from which the variations in declination may be measured. As the declination changes the light spot reflected from the magnetic mirror moves parallel to the axis of the recording drum, and hence the distance between the line traced by this spot and the base line gives, for any instant, on an arbitrary scale the difference between the declination and a constant angle, namely, the declination corresponding to the base line. The value of this constant angle is obtained by comparing the record with the value for the declination as measured with a magnetometer. The value in terms of arc of the scale of the record can be obtained by measuring the distance between the magnet mirror and the recording drum, and in most observations it is such that a millimetre on the magnetic mirror will equal 10 minutes of arc. In this position, the mirror employed is 15 mm. per hour, but in modern instruments provision is generally made for the time scale to be increased at will to 180 mm. per hour, so that the more rapid variations of the declination can be seen. The advantages of using a small mirror of inertia may be small and hence they may be able to respond to rapid changes in the earth's field, were first insisted upon by E. Mascart, while M. Eschenhagen first designed a set of magnetographs in which this idea of small moment of inertia was carried to its useful limit, the mirrors only weighing 1.5 grams each, and the suspension consisting of a very fine quartz fibre.

**Horizontal Component.**—The variation of the horizontal component is obtained by the motion of a magnet which is carried either by a bifilar suspension or by a fairly stiff metal wire or quartz fibre. The upper end of the suspension is turned till the axis of the magnet is at right angles to the magnetic meridian. In this position the magnet is in equilibrium under the action of the torsion of the suspension and the couple exerted by the horizontal component, H, of the earth's field, this couple depending on the product of H into the period of oscillation, M, of the magnet. Hence if H varies the magnet will rotate in such a way that the couple due to torsion is equal to the new value of H multiplied by M. Since the movements of the magnetic meridian is proportional to the change in H, so long as M and the couple, corresponding to unit twist of the suspension system remain constant. When the temperature changes, however, both M and H in general change. The temperature of the suspension system, however, has the same effect as would a decrease in H. To allow for this effect temperature a compensating system of metal bars is attached to the upper end of the suspension, thus the temperature of the fibre is brought nearer together and hence the value of θ decreases. Since such a decrease in θ would by itself cause the magnet to turn in the same direction as if H had increased, it is possible, by measuring the effects of temperature on the reading of the instrument. In the case of the unifilar suspension, the provision of a temperature compensation is not so easy, so that what is generally done is to protect the instrument from temperature variation as much as possible and then to correct the indications so as to allow for the residual changes, a continuous record of the temperature being kept by a recording thermograph attached to the instrument. In the Eschenhagen pattern instrument, in which a single quartz fibre is used for the suspension, two magnets are placed in the vicinity of the suspended magnet and are so arranged that their field partly neutralizes the field of the latter, thus the deflection produced by the axis perpendicular to the earth's field is reduced, and the arrangement permits of the sensitivity being altered by changing the position of the deflecting magnets. Further, by suitably changing the positions of the deflectors and the coefficient of torsion of the fibre, it is possible to make the temperature coefficient vanishing. (See Adolf Schmidt, Zeits. für Instrumentenkunde, 1907, 27, 145.)

**Vertical Component.**—To record the variations of the vertical component use is made of a magnet mounted on knife edges so that it can turn freely about a horizontal axis at right angles to its
The elements which are actually measured when determining the vector of the earth's field are usually the declination, the dip and the horizontal component (see MAGNETISM, TERRESTRIAL). For the instruments and methods used in measuring the dip see INCLINOMETER. It remains to consider the measurement of the declination and the horizontal component, these two elements being generally measured with the same instrument, which is called a unifilar magnetometer.

Measurement of Declination.—The measurement of the declination involves two separate observations, namely, the determination of (a) the magnetic meridian and (b) the geographical meridian, these two being the declination. In order to determine the magnetic meridian the orientation of the magnetic axis of a freely suspended magnet is observed; while, in the absence of a distant mark of which the azimuth is known, the geographical meridian is obtained from observations of the transit of the sun or a star. The geometrical axis of the magnet is sometimes defined by means of a mirror rigidly attached to the magnet and having the normal to the mirror as nearly as may be parallel to the magnetic axis. This arrangement is not very convenient, as it is difficult to protect the mirror from accidental displacement, so that the angle between the geometrical and magnetic axes may vary. For this reason the end of the magnet is sometimes polished and acts as the mirror, in which case no displacement of the reflecting surface with reference to the magnet is possible. A different arrangement, used in the instrument described below, consists in having the magnet hollow, with a small scale engraved on glass firmly attached at one end, while to the other end is attached a lens, so chosen that the scale is at its principal focus. In this case the geometrical axis is the line joining the central division of the scale to the optical centre of the lens. The position of the magnet is observed by means of a small telescope, and since the scale is at the principal focus of the lens, the scale will be in focus when the telescope is adjusted to observe a distant object. Thus no alteration in the focus of the telescope is necessary whether we are observing the magnet, a distant fixed mark, or the sun.

The Kew Observatory pattern unifilar magnetometer is shown in figs. 1 and 2. The magnet consists of a hollow steel cylinder fitted with a scale and lens as described above, and is suspended by a long thread of unspun silk, which is attached at the upper end to the torsion head H. The magnet is protected from draughts by the box A, which is closed at the sides by two shutters when an observation is being taken. The telescope B serves to observe the scale...
attached to the magnet when determining the magnetic meridian, and to observe the sun or star when determining the geographical meridian.

When making a determination of declination a brass plummet having the same weight as the magnet is first suspended in its place, and the torsion of the fibre is taken out. The magnet having been attached, the instrument is rotated about its vertical axis till the centre division of the scale appears to coincide with the vertical cross-wire of the telescope. The two verniers on the azimuth circle having been read, the magnet is then inverted, i.e., turned through 180° about its axis, and the setting is repeated. A second setting with the magnet inverted is generally made, and then another setting with the magnet in its original position. The mean of all the readings of the verniers gives the reading on the azimuth circle corresponding to the magnetic meridian. To obtain the geographical meridian the box A is removed, and an image of the sun or a star is reflected into the telescope B by means of a small transit mirror N. This mirror can rotate about a horizontal axis which is at right angles to the line of collimation of the telescope, and is parallel to the surface of the mirror. The time of transit of the sun or star across the vertical wire of the telescope having been observed by means of a chronometer of which the error is known, it is possible to calculate the azimuth of the sun or star, if the latitude and longitude of the place of observation are given. Hence if the readings of the verniers on the azimuth circle are made when the transit is observed we can deduce the reading corresponding to the geographical meridian.

The method of determining the geographical meridian has the serious objection that it is necessary to know the error of the chronometer with very considerable accuracy, a matter of some difficulty when observing at any distance from a fixed observatory. If, however, a theodolite, fitted with a telescope which can rotate about a horizontal axis and having an altitude circle, is employed, so that when observing a transit the latitude of the sun or star can be read off, then the time need only be known to within a minute or so. Hence in more recent patterns of magnetometer it is usual to do away with the transit mirror method of observing and either to use a separate theodolite to observe the azimuth of some distant object, which will then act as a fixed mark when making the declination observations, or to attach to the magnetometer an altitude telescope and circle for use when determining the geographical meridian.

The chief uncertainty in declination observations, at any rate at a fixed observatory, lies in the variable torsion of the silk suspension, as it is found that, although the fibre may be entirely freed from torsion before beginning the declination observations, yet at the conclusion of these observations a considerable amount of torsion may have appeared. Soaking the fibre with glycerine, so that the moisture it absorbs does not change so much with the hygrometric state of the air, is of some advantage, but does not entirely remove the difficulty. For this reason some observers use a thin strip of phosphor bronze to suspend the magnet, considering that the absence of a variable torsion more than compensates for the increased difficulty in handling the more fragile metallic suspension.

Measurement of the Horizontal Component of the Earth’s Field—The method of measuring the horizontal component which is almost exclusively used, both in fixed observatories and in the field, consists in observing the period of oscillation of the suspended magnet, and then obtaining the angle through which an auxiliary suspended magnet is deflected by the magnet used in the first part of the experiment. By the vibration experiment we obtain the value of the product of the magnetic moment of the magnet into the horizontal component (H), while by the deflexion experiment we can deduce the value of the ratio of M to H, and hence the two combined give both M and H.

In the case of the Kew pattern unifilar the same magnet that is used for the declination is usually employed for determining H, and for the purposes of the vibration experiment it is mounted as for the observation of the magnetic meridian, and the determination is obtained by means of a chronometer, using the eye-and-ear method. The temperature of the magnet must also be observed, for which purpose a thermometer C (fig. 1) is used.

When making the deflexion experiment the magnetometer is arranged as shown in fig. 2. The auxiliary mirror has a plane mirror attached, the plane of which is parallel to the mirror of the Kew pattern. The mirror K used in the vibration experiment is supported on a carriage L which can slide along the graduated bar D. The axis of the magnet is horizontal and at the same level as the mirror magnet, while the central division of the scale B appears to coincide with the vertical cross-wire of the telescope, and the axes of the two magnets are at right angles. During the experiment the mirror magnet is protected from draughts by two wooden doors which slide in grooves. What is known as the method of sines is used, for since the axes of the magnets are always at right angles when the mirror magnet is in its zero position, the deflexion is proportional to the sine of the angle between the magnetic axis of the mirror magnet and the magnetic meridian. When conducting a deflexion experiment the deflecting magnet K is placed with its axis at 30° from the mirror magnet and to the east of the latter, and the whole instrument is turned till the centre division of the scale B coincides with the cross-wire of the telescope, when the readings of the verniers on the azimuth circle are noted. Then the instrument is reversed in the support, and a new setting taken. The difference between the two sets of readings gives twice the angle which the magnetic axis of the mirror magnet makes with the magnetic meridian. In order to eliminate any error due to the scale D not being exactly below the mirror magnet, the support L is then removed to the west side of the instrument, and the settings are repeated. Further, to allow of a correction being applied for the finite length of the magnets the whole series of settings is repeated with the centre of the deflecting magnet at 40 cm. from the mirror magnet.

Omitting correction terms depending on the temperature and on the inductive effect of the earth’s magnetism on the moment of the deflecting magnet, if θ is the angle which the axis of the deflecting magnet makes with the meridian when the centre of the deflecting magnet is at a distance r, then

$$P = \frac{2M}{r} \sin \theta = \frac{1}{7} + \frac{Q}{r^2} + \&c.,$$

in which P and Q are constants depending on the dimensions and magnetic states of the two magnets. The value of the constants P and Q can be obtained by making deflexion experiments at three or more distances. It is, however, possible by simply observing the moments of the two magnets to cause either P or Q to be very small. Thus it is usual, if the magnets are of similar shape, to make the deflecting magnet 0-467 of the length of the deflecting magnet, in which case Q is negligible, and thus by means of deflexion experiments at two distances the value of P can be obtained. (See C. Börgen, Terrestrial Magnetism, 1896, i. p. 175, and C. Chree, Phil. Mag., 1904 [6], 7, p. 115.)

In the case of the vibration experiment correction terms have to be introduced to allow for the temperature of the magnet, for the inductive effect of the earth’s field, which slightly increases the magnetic moment of the magnet, and for the torsion of the suspension fibre, as well as the rate of the chronometer. If the temperature of the magnet were always exactly the same in both the vibration and
MAGNETO-OPTICS

In the deflection experiment, then no correction on account of the effect of temperature in the magnetic moment would be necessary in either experiment. The fact that the moment of inertia of the magnet varies with the length of the experiment, let us take for granted. In the deflection experiment, in addition to the induction correction, and that for the effect of temperature on the magnetic moment, a correction has been introduced for the change of temperature on the length of the bar which supports the deflection magnet.

See also Stewart and Gee, Practical Physics, vol. 2, containing a description of the Kew pattern unilar magnetometer and detailed instructions for the performance of the experiments, by L. C. H. Hagen, 1901 (6), 3 p. 613, and Proc. Roy. Soc., 1899, 65 p. 375, containing a discussion of the errors to which the Kew unilar instrument is subject. In Fröba, Tractat de magnetisme i terrestre aimantat, 1901, 6, is contained a description of the instruments used in the French magnetic survey, which are interesting on account of their small size and consequent easy portability; H. E. D. Fraser, Terrestrial Magnetism, 1901, 6, p. 375, contains a description of the Kew pattern unilar as used in the Indian survey; H. Wild, Mon. Acad. imp. sc. St. Petersbourg, 1896 (viii), vol. 3, No. 7, containing a description of a most elaborate unilar magnetometer with which it is claimed results can be obtained of a very high order of accuracy; K. Haeussmann, Zeit. für Instrumentenkunde, 1906, 26, 2, containing a description of a magnetometer for field use, designed by M. Eschenhagen, which has many advantages.

Measurements of the Magnetic Elements at Sea.—Owing to the fact that the proportion of the earth's surface covered by sea is so much greater than the dry land, the determination of the magnetic elements on board ship is a matter of very considerable importance. The movements of a ship entirely preclude the employment of any instrument in which a magnet suspended by a fibre has any part, so that the unilar is unsuited for such observations. In order to obtain the declination a pivoted card is used to obtain the magnetic meridian, the geographical meridian being obtained by observations on the sun or stars. A carefully made ship's compass is usually employed, though in some cases the compass card, with its attached north-seeking magnet, is made reversible, so that the inclination to the zero of the card of the magnetic axis of the system of magnets attached to the card can be eliminated by reversal. In the absence of such a reversible card the index correction must be determined by comparison with a unilar magnetometer, simultaneous observations being made on shore, and these observations repeated as often as occasion permits. To determine the dip a Fox's dip circle is used. This consists of an ordinary dip circle (see INCLINOMETER) in which the ends of the axle of the needle are pointed and rest in jewelled holes; so that the movements of the ship do not displace the needle. The instrument is, of course, supported on a gimballed table, while the ship during the observations is kept on a fixed course. To obtain the strength of the field the method usually adopted is that known as Lloyd's method. To carry out a determination of the total force by this method the Fox dip circle has been slightly modified by E. W. Creak, and has been found to give satisfactory results on board ship. The circle is provided with two needles in addition to those used for determining the dip, a needle (a) an ordinary dip needle, and the other (b) a needle which has been loaded at one end by means of a small peg which fits into one of two symmetrically placed holes in the needle. The magnetism of these two needles is never reversed, and they are as much as possible protected from shock and from approach to other magnets, so that their magnetic state may remain as constant as possible. Attacked to the cross-arm which carries the microscopes used to observe the ends of the dipping needle is a clamp, which will hold the needle b in such a way that its plane is parallel to the vertical circle and its axis is at right angles to the line joining the fixed microscopes. Hagen\footnote{Humphrey Lloyd, Proc. Roy. Irish Acad., 1848, 4, p. 57.} has shown that if the microscopes are adjusted so as to coincide with the points of the dipping needle a, the axes of the two needles must be at right angles. The needle a being suspended between the jewels, and the needle b being held in the clamp, the cross-arm carrying the reading microscopes and the needle b is rotated till the ends of the needle a coincide with the cross-wires of the microscopes. The verniers having been read, the cross-arm is rotated so as to deflect the needle a in the opposite direction, and a new setting is taken. Half the difference between the two readings gives the angle through which the needle a has been deflected under the action of the needle b. This angle depends on the ratio of the magnetic moment of the needle b to the total force of the earth's field. It also involves, of course, the distance between the needles and the distribution of the magnetism of the needles; but this factor is determined by comparing the value given by the instrument, at a shore station, with that given by an ordinary magnetometer. Hence the above observation gives us a means of obtaining the ratio of the magnetic moment of the needle b to the value of the earth's total force. The needle b is then substituted for a, there being now no needle in the clamp attached to the microscope arm, and the difference between the reading now obtained and the dip, together with the weight added to the needle, gives the product of the moment of the needle b into the earth's total force. Hence, from the two observations the value of the earth's total force can be deduced. In an actual observation the deflection needle would be reversed, as well as the deflected one, while different weights would be used to deflect the needle b.

For a description of the method of using the Fox circle for observations at sea consult the Admiralty Manual of Scientific Inquiry, p. 116, while a description of the most recent form of the circle, known as the Lloyd-Crek pattern, will be found in Terrestrial Magnetism, 1901, 6. An attachment to the compass, by means of which satisfactory measurements of the horizontal component have been made on board ship, is described by L. A. Bauer in Terrestrial Magnetism, 1906, 11, p. 78. The principle of this is in dicing the horizontal component by means of a horizontal magnet supported vertically over the compass card, the axis of the deflecting magnet being always perpendicular to the magnetic meridian. This method is not strictly an absolute one, since it presupposes a knowledge of the magnetic moment of the deflecting magnet. In practice it is found that a magnet can be prepared which, when suitably protected from shock, etc., retains its magnetic moment sufficiently constant to enable observations of H to be made comparable in accuracy with that of the other elements obtained by the instruments commonly employed at sea. (W. Wx.)

MAGNETO-OPTICS. The first relation between magnetism and light was discovered by Faraday,\footnote{Arons.} who proved that the plane of polarization of a ray of light was rotated when the ray travelled through certain substances parallel to the lines of magnetic force. This power of rotating the plane of polarization in a magnetic field has been shown to be possessed by all refracting substances, whether they are in the solid, liquid or gaseous state. The rotation by gases was established independently by H. Becquerel,\footnote{Kundt and Röntgen.} and Kundt and Röntgen,\footnote{Kundt and Röntgen (loc. cit.).} while Kundt\footnote{Kundt and Röntgen (loc. cit.).} found that films of the magnetic metals, iron, cobalt, nickel, thin enough to be transparent, produced enormous rotations, these being in iron and cobalt all in the same direction, and in the case of nickel of opposite sign for waves of thickness per cm., and in nickel about 8g,000.\footnote{8g,000.} The direction of rotation is not the same in all bodies. If we call the rotation positive when it is related to the direction of the magnetic field, like rotation and translation in a right-handed screw, or, what is equivalent, when it is in the direction of the electric currents which would produce a magnetic field in the same direction as that which produces the rotation, then most substances produce positive rotation. Among those that produce negative rotation are ferrous and ferric salts, ferricyanide of potassium, the salts of lanthanum, cerium and didymium, and chloride of titanium.\footnote{Carbon bisulphide} The magnetic metals iron, nickel, cobalt, the salts of nickel and cobalt, and oxygen (the most magnetic gas) produce positive rotation.

For slightly magnetizable substances the amount of rotation in a space PQ is proportional to the difference between the magnetic potential at P and Q; or if \( \theta \) is the rotation in PQ, \( \theta_0 \) the magnetic potential at P and Q, then \( \theta = R(\theta_0 - \theta_0) \), where \( R \) is a constant, called Verdet's constant, which depends upon the refracting substance, the wave length of the light, and the temperature. The following are the values of R (when the rotation is expressed in circular measure) for the D line and a temperature of 18° C.:

Lord Rayleigh and Köppl.\footnote{Rayleigh.} Rodger and Watson.\footnote{Rodger and Watson.} Arons.\footnote{Röntgen.} Du Bois.\footnote{Röntgen.} Du Bois.\footnote{Röntgen.}
According to Righi, the amount of rotation when the plane of polarization of the incident light is perpendicular to the plane of polarization of the reflected light reaches a maximum when the angle of incidence is between 44° and 68°, while when the light is polarized in the plane of incidence the rotation steadily decreases as the angle of incidence is increased. The rotation when the light is polarized in the plane of incidence is always less than when it is polarized at right angles to that plane, except when the incidence is normal, when the two rotations are of course equal.

Reflection from Tangentially Magnetized Iron.—In this case Kerr found: (1) When the plane of incidence is perpendicular to the lines of magnetic force, no rotation of the reflected light is produced by magnetization: (2) no rotation is produced when the light is incident normally; (3) when the incidence is oblique, the lines of magnetic force being in the plane of incidence, the reflected light is elliptically polarized after reflection, and the axes of the ellipse are not in and at right angles to the plane of incidence. When the light is polarized in the plane of incidence, the rotation is at all angles of incidence in the opposite direction to that of the currents which would produce a magnetic field of the same sign as the magnet. When the light is polarized at right angles to the plane of incidence, the rotation is in the same direction as these currents when the angle of incidence is between 0° and 25° according to Kerr, between 0° and 50° according to Kundt, and between 0° and 76° 54′ according to Right. When the incidence is more oblique than this, the rotation of the plane of polarization is in the opposite direction to the electric currents which would produce a magnetic field of the same sign.

The theory of the phenomena just described has been dealt with by Airy, C. Neumann, Maxwell, Fitzgerald, Rowland, H. A. Lorentz, Voight, Ketteler, van Loghem, Potter, Basset, Goldhammer, Drude, J. J. Thomson, and Leatham; for a critical discussion of many of these theories we refer the reader to Larmor's British Association Report. Most of these theories have proceeded on the plan of adding to the expression for the electromotive force terms indicating a force similar in character to that discovered by Hall (see Magnétism in metallic conductors carrying a current in a magnetic field, i.e., an electromotive force at right angles to the plane containing the magnetic force and the electric current, and proportional to the sine of the angle between these vectors. The introduction of a term of this kind gives rotation of the plane of polarization by transmission through all refracting substance, and by reflection from magnetized metals, and shows a fair agreement between the theoretical and experimental results. The simplest way of treating the questions seems, however, to be to go to the equations which represent the propagation of a wave travelling through a medium containing ions. A moving ion in a magnetic field will be acted upon by a mechanical force which is at right angles to its direction of motion, and also to the magnetic force, and is equal per unit charge to the product of these two vectors and the sine of the angle between them. For the sake of brevity we will take the case of a wave travelling parallel to the magnetic force in the direction of the axis of z.

Then supposed that all the ions are of the same kind, and that there are n of these each with mass m and charge e per unit volume, the equations representing the field are (see Electric Waves):
MAGNETO-OPTICS

The co-ordinates of an ion, $R_i$ the coefficient of resistance to the motion of the ions, and $a$ the force at unit distance tending to bring the ion back to its position of equilibrium, $K_i$ the specific inductive capacity of the medium, the variables are proportional to $(u^2-v^2)$, we find that the potential $g$ is given by the equation

$$q_i - K_i u^2 v^2 + x_1 e_y p + x_2 e_x p^2$$

where

$$P = (a - i x_1 e_y) + (b - i x_2 e_x)$$

or, by neglecting $K_i$, $P = m (u^2 - v^2)$, where $s$ is the period of the free ions. If, $g_1, g_2$ are the roots of this equation, then corresponding to $g_1$ we have $X = Y$ and to $g_2$ $X = -Y$. We thus get two oppositely directed circularly polarized rays travelling with the velocities $p_1$ and $p_2$ respectively. Hence if $v_1, v_2$ are these velocities, and $r$ the velocity of light when there is no magnetic field, we obtain, if we neglect terms in $H^2$:

$$\frac{1}{v_1} = \frac{1}{v_2} + \frac{m}{p_1}$$

The rotation $r$ of the plane of polarization per unit length is

$$r = \frac{2 \pi e_y p e_x}{m}$$

Since $1/(u^2 - v^2) = K_i m$, we have if $u$ is the refractive index for light of frequency $\omega$, and $n$ the velocity of light in vacuum.

$$\mu = 1 = \frac{2 \pi e_y p_e}{m} = \frac{2 \pi e_y p_e}{m n^2}$$

So that we may put

$$r = (\mu - 1)^2 \pi \frac{1}{m} \frac{1}{n^2}$$

The solution of these equations is

$$x = A \cos (\pi t + \theta) + B \sin (\pi t + \theta)$$

$$y = A \sin (\pi t + \theta) - B \cos (\pi t + \theta)$$

$$z = C \cos (\pi t + \theta)$$

where $A = m \text{Im} \omega - H \text{Re} \omega$

or approximately $p_1 = \pi + \frac{1}{m}$ and $p_2 = \pi - \frac{1}{m}$.

Thus the motion of the ion on the $xy$ plane may be regarded as made up of two circular motions in opposite directions described with frequencies $p_1$ and $p_2$ respectively, while the motion along $z$ has the period $\pi$, which is the frequency for all the vibrations when $\omega = 0$. Now suppose that the cadmium line is due to the motion of such an ion; then if the magnetic force is along the direction of propagation, the vibration in this direction has its period unaltered, but since the direction of vibration is perpendicular to the wave front, it does not give rise to light. Thus we are left with the two circular motions in the wave front with frequencies $p_1$ and $p_2$ giving the circularly polarized constituents of the doublet. Now suppose the magnetic force is at right angles to the direction of propagation of the light; then the vibration parallel to the magnetic force being in the wave front produces luminous effects and gives rise to a plane-polarized ray of unaltered period (the middle line of the triplet), the plane of polarization being at right angles to the magnetic force. The components in the wave-front of the circular orbits at right angles to the magnetic force will be rectilinear motions of frequency $p_1$ and $p_2$ at right angles to the magnetic force—so that they will produce plane-polarized light, the plane of polarization being parallel to the magnetic force; these are the outer lines of the triplet.

Zeeman's Effect.—Faraday, after discovering the effect of a magnetic field on the plane of polarization of light, made numerous experiments to see if such a field influenced the nature of the light emitted by a luminous body, but without success. In 1885 Fizeau, a Belgian physicist, noticed that the spectrum of a sodium flame was changed slightly in appearance by a magnetic field; but his observation does not seem to have attracted much attention, and was probably ascribed to secondary effects. In 1896 Zeeman saw a distinct broadening of the lines of lithium and sodium when the flames containing salts of these metals were between the poles of a powerful electromagnet; following up this observation, he obtained some exceedingly remarkable and interesting results, of which those observed with the blue-green cadmium line may be taken as typical. He found that in a strong magnetic field, when the lines of force are parallel to the direction of propagation of the light, the line is split up into a doublet, the constituents of which are on opposite sides of the undisturbed position of the line, and that the light in the constituents of this doublet is circularly polarized, the rotation in the two lines being in opposite directions. When the magnetic force is at right angles to the direction of propagation of the light, the line is resolved into a pair of lines at right angles to the middle line occupies the same position as the undisturbed line; all the constituents of this triplet are plane-polarized, the plane of polarization of the middle line being at right angles to the magnetic force, while the outside lines are polarized on a plane parallel to the lines of magnetic force. A great deal of light is thrown on this phenomenon by the following considerations due to H. A. Lorentz.

Let us consider an ion attracted to a centre of force by a force proportional to the distance, and acted on by a magnetic force parallel to the axis of $z$; then if $m$ is the mass of the particle and $e$ its charge, the equations of motion are

$$m \frac{dx}{dt} = -H \frac{dy}{dt}$$

$$m \frac{dy}{dt} = H \frac{dx}{dt}$$

The solution of these equations is

$$x = A \cos (\pi t + \theta) + B \sin (\pi t + \theta)$$

$$y = A \sin (\pi t + \theta) - B \cos (\pi t + \theta)$$

$$z = C \cos (\pi t + \theta)$$

Thus the motion of the ion on the $xy$ plane may be regarded as made up of two circular motions in opposite directions described with frequencies $p_1$ and $p_2$ respectively, while the motion along $z$ has the period $\pi$, which is the frequency for all the vibrations when $\omega = 0$. Now suppose that the cadmium line is due to the motion of such an ion; then if the magnetic force is along the direction of propagation, the vibration in this direction has its period unaltered, but since the direction of vibration is perpendicular to the wave front, it does not give rise to light. Thus we are left with the two circular motions in the wave front with frequencies $p_1$ and $p_2$ giving the circularly polarized constituents of the doublet. Now suppose the magnetic force is at right angles to the direction of propagation of the light; then the vibration parallel to the magnetic force being in the wave front produces luminous effects and gives rise to a plane-polarized ray of unaltered period (the middle line of the triplet), the plane of polarization being at right angles to the magnetic force. The components in the wave-front of the circular orbits at right angles to the magnetic force will be rectilinear motions of frequency $p_1$ and $p_2$ at right angles to the magnetic force—so that they will produce plane-polarized light, the plane of polarization being parallel to the magnetic force; these are the outer lines of the triplet.

If Zeeman's observations are interpreted from this point of view, the directions of rotation of the circularly-polarized light in the doublet observed along the lines of magnetic force show that the ions which produce the luminous vibrations are negatively electrified, while the measurement of the charge of frequency due to the magnetic field shows that $e/m$ is of the order $10^4$. This result is of great interest, as this is the order of the value of $e/m$ in the negatively electrified particles which constitute the Cathode Rays (see CONDUCTION, ELECTRIC III. Through Gases). Thus we infer that the "cathode particles" are found in bodies, even where not subject to the action of intense electrical fields, and are in fact an ordinary constituent of the molecule. Similar particles are found near an incandescent wire, and also near a metal plate illuminated by ultra-violet light. The value of $e/m$ deduced from the Zeeman effect ranges from $10^7$ to $3 \times 10^7$, the value of $e/m$ for the particle in the cathode rays is $1.7 \times 10^7$. The majority of the determinations of $e/m$ from the Zeeman effect give numbers larger than this, the maximum being about twice this value.
A more extended study of the behaviour of the spectroscope lines has afforded examples in which the effects produced by a magnet are more complicated than those we have described, indeed the simple cases are much less numerous than the more complex. Thus Preston and Cornu have shown that under the action of a transverse magnetic field one of the D lines splits up into four, and the other into six lines; Preston has given many other examples of these quartets and sextets, and has shown that the change in the frequency, which, according to the simple theory indicated, should be the same for all lines, actually varies considerably from one line to another, many lines showing no appreciable effects. The system of single into a quartet or sextet indicates, from the point of view of the ion theory, that the line must have its origin in a system consisting of more than one ion. A single ion having only three degrees of freedom can only have three periods. When there is no magnetic force acting on the ion these periods are equal, but though under the action of a magnetic force they are separated, their number cannot be increased. When therefore we get four or more lines, the inference is that the system giving the lines must have at least four degrees of freedom, and therefore more than one ion.

The system of ions mutually influencing each other shows, as we should expect, that the effects are more complex than in the case of a single ion, and that the change in the frequency is not necessarily the same for all systems (see J. J. Thomson, Proc. Camb. Phil. Soc. 13, p. 39). Preston and Runge and Paschen have proved that, in some cases at any rate, the change in the frequency of the different lines is of such a character that they can be grouped into series such that each line in the series has the same change in frequency for the same magnetic force, and, moreover, that homologous lines in the spectra of different metals belonging to the same group have the same change in frequency.

A very remarkable case of the Zeeman effect has been discovered by H. Becquerel and Deslandres (Comptes rendus, 127, p. 18). They found six lines in iron when the most deflected components are those polarized in the plane at right angles to the magnetic force. The simple order of the light polarized in this way is not affected. Thus the behaviour of the spectrum in the magnetic field promises to throw great light on the nature of radiation, and perhaps on the constitution of the elements.

The study of these effects has been greatly extended by the invention by Michelson of the echelon spectroscope.

There are some interesting phenomena connected with the Zeeman effect which are more easily observed than the effect itself. Thus Cotton found that if we have two Bunsen flames, A and B, coloured by the same salt, the absorption of the light of one by the other is diminished if either is placed between the poles of a magnet: this is at once explained by the Zeeman effect, for the times of vibration of the molecules of the flame in the magnetic field are not the same as those of the other flame, and thus the absorption is diminished.

Similar considerations explain the phenomenon observed by Egoroff and Georgiewsky, that the light emitted from a flame in a transverse field is partially polarized in a plane parallel to the magnetic force; and also Righi's observation that if a sodium flame is placed in a longitudinal field between two crossed Nicols, and a ray of white light sent through one of the Nicols, then through the flame, and then through the second Nicol, the amount of light passing through the second Nicol is greater when the field is on than when it is off. Voight and Wiechert (Wied. Ann. 67, p. 345) detected the double refraction produced when light travels through a substance exposed to a magnetic field at right angles to the path of the light; this result had been predicted by Voight from theoretical considerations. Jean Becquerel has made some very interesting experiments on the effect of a magnetic field on the fine absorption bands produced by xenon, a phosphide of yttrium and erbium, and tysonite, a fluoride of cerium, lanthanum and dieldrymum, and has obtained effects which he ascribes to the presence of positive electrons. A very complete account of magento- and electro-optics is contained in Voight's 'Magnetische und Elektro-optik.'

MAGNOLIA

The first of the American species brought to Europe (in 1668 by John Banister) was M. glauca, a beautiful evergreen species about 15 ft. high with obuse leathery leaves, blue-green above, silvery underneath, and globular flowers varying from creamy white to pale yellow with age. It is found in low situations near the sea from Massachusetts to Louisiana—more especially in New Jersey and the Carolinas. M. acuminata, the so-called "cucumber tree," from the resemblance of the young fruits to small cucumbers, ranges from Pennsylvania to Carolina. The
MAGNUS—MAGNY

wood is yellow, and used for bowls; the flowers, 3 to 4 in. across, are glaucous green tinted with yellow. It was introduced into England from Virginia about 1736. **M. tripetala** (or **M. umbrellata**), is known as the "umbrella tree" from the arrangement of the leaves at the ends of the branches resembling somewhat that of the ribs of an umbrella. The flowers, 5 to 8 in. across, are white and have a strong but not disagreeable scent. It was brought to England in 1752. **M. Fraseri** (or **M. auriculata**),

**Magnolia grandiflora**, shoot with flower; rather less than ½ nat. size.
1. Flower after removal of the sepals and petals, showing the indefinite stamens, s, and carpels, c; ½ nat. size.
2. Fruit—the ripe carpels are splitting, exposing the seeds, some of which are suspended by the long funicles; ½ nat. size.
3. Floral diagram, b, bract.

discovered by John Bartram in 1773, is a native of the western parts of the Carolinas and Georgia, extending southward to western Florida and southern Alabama. It grows 30 to 50 ft. high, has leaves a foot or more long, heart-shaped and bluntly auricled at the base, and fragrant pale yellowish-white flowers, 3 to 4 in. across. The most beautiful species of North America is **M. grandiflora**, the "laurel magnolia," a native of the south-eastern States, and introduced into England in 1734. It grows a straight trunk, 2 ft. in diameter and upwards of 70 ft. high, bearing a profusion of large, powerfully lemon-scented creamy-white flowers. It is an evergreen tree, easily recognized by its glossy green oval oblong leaves with a rusty-brown under surface. In England it is customary to train it against a wall in the colder parts, but it does well as a bush tree; and the original species is surpassed by the Exmouth varieties, which originated as seedlings at Exeter from the tree first raised in England by Sir John Colliton, and which flower much more freely than the parent plant. Other fine magnolias now to be met with in gardens are **M. cordata**, a North American deciduous tree 40 to 50 ft. high, with heart-shaped leaves, woolly beneath, and yellow flowers lined with purple; **M. hypoleuca**, a fine Japanese tree 60 ft. high or more, with leaves a foot or more long, 6 to 7 in. broad, the under surface covered with hairs; **M. macrophylla**, a handsome deciduous North American tree, with smooth whitish bark, and very large beautiful green leaves, 1 to 3 ft. long, 8 to 10 in. broad, oblong-ovate and heart-shaped at the base; the open sweet-scented bell-shaped flowers 8 to 10 in. across, are white with a purple blotch at the base of the petals; **M. stellata** or **Halleana**, a charming deciduous Japanese shrub remarkable for producing its pure white starry flowers as early as February and March on the leafless stems; and **M. Watsoni**, another fine deciduous Japanese bush or small tree with very fragrant pure white flowers 5 to 6 in. across.

The tulip tree, **Liriodendron tulipifera**, a native of North America, frequently cultivated in England, is also a member of the same family. It reaches a height of over 100 ft. in a native condition, and as much as 60 to 80 ft. in England. It resembles the plane tree somewhat in appearance, but is readily recognized by lobed leaves having the apical lobe truncated, and by its soft green and yellow tulip-like flowers—which however are rarely borne on trees under twenty years of age.

**MAGNUS, HEINRICH GUSTAV** (1802–1870), German chemist and physicist, was born at Berlin on the 2nd of May 1802. His father was a wealthy merchant; and of his five brothers one, Eduard (1799–1892), became a celebrated painter. After studying at Berlin, he went to Stockholm to work under Berzelius, and later to Paris, where he studied for a while under Gay-Lussac and Thénard. In 1831 he returned to Berlin as lecturer on technology and physics at the university. As a teacher his success was rapid and extraordinary. His lucid style and the perfection of his experimental demonstrations drew to his lectures a crowd of enthusiastic scholars, on whom he impressed the importance of applied science by conducting them round the factories and workshops of the city; and he further found time to hold weekly "colloques" on physical questions at his house with a small circle of young students. From 1827 to 1833 he was occupied mainly with chemical researches, which resulted in the discovery of the first of the platinum-ammonium compounds ("Magnus's green salt") is PtH2, 2NH3, of sulphonic, ethionic and isethionic acids and their salts, and, in conjunction with C. F. Ammermüller, of periodic acid. Among other subjects on which he subsequently worked were the absorption of gases in blood (1837–1838), the expansion of gases by heat (1841–1844), the vapour pressures of water and various solutions (1844–1854), thermo-electricity (1851), electrolysis (1856), induction of currents (1858–1861), conduction of heat in gases (1860), and polarization of heat (1866–1868). From 1861 onwards he devoted much attention to the question of diathermy in gases and vapours, especially to the behaviour in this respect of dry and moist air, and to the thermal effects produced by the condensation of moisture on solid surfaces.

In 1834 Magnus was elected extraordinary, and in 1845 ordinary professor at Berlin. He was three times elected dean of the university in 1842, 1843, and 1863; and in 1844 he held the chair of magnetics. His great reputation led to his being entrusted by the government with several missions; in 1865 he represented Prussia in the conference called at Frankfort to introduce a uniform metric system of weights and measures into Germany. For forty-five years his labour was incessant; his first memoir was published in 1825 when he was yet a student; his last appeared shortly after his death on the 4th of April 1870. He married in 1840 Bertha Humblot, of a French Hugenot family settled in Berlin, by whom he left a son and two daughters.

See *Allgemeine deutsche Biographie*. The Royal Society's *Catalogue* enumerates 84 papers by Magnus, most of which originally appeared in *Poggendorff's Annalen*.

**MAGNY, CLAUDE DRIGON, MARQUIS DE** (1797–1870), French heraldic writer, was born in Paris. After being employed for some time in the postal service, he devoted himself to the study of heraldry and genealogy, his work in this direction being rewarded by Pope Gregory XVI. with a marquisate. He founded a French college of heraldry, and wrote several works on heraldry and genealogy, of which the most important were *Archives nobiliaires universelles* (1843) and *Livre d'or de la noblesse de France* (1844–1852). His two sons, Edouard Drigon and Achille Ludovice Drigon, respectively came and vicomte de Magny, also wrote several works on heraldry.
MAGO—MAGYARS

MAGO, the name of several Carthaginians. (1) The reputed founder of the military power of Carthage, fl. 550–500 B.C. (Justin xvi. 7, xix. 1). (2) The youngest of the three sons of Hamilcar Barca. He accompanied Hannibal into Italy, and held important commands in the great victories of the first three years. After the battle of Cannae (216 B.C.) he sailed to Carthage to report the successes gained. He was about to return to Italy with strong reinforcements for Hannibal, when the government ordered him to go to the aid of his other brother, Hasdrubal, who was hard pressed in Spain. He carried on the war there with varying success in concert with the two Hasdrubals until, in 209, his brother marched into Italy to help Hannibal. Mago remained in Spain with Hasdrubal, the son of Gisco. In 207 he was defeated by M. Junius Silanus, and in 206 the combined forces of Mago and Hasdrubal were scattered by Scipio Africanus in the decisive battle of Silpia. Mago maintained himself for some time in Gades, but afterwards received orders to carry the war into Liguria. He wintered in the Balearic Isles, where the harbour Portus Magnos (Port Mahon) still bears his name. Early in 204 he landed in Liguria, where he maintained a desultory warfare till in 203 he was defeated in Cisalpine Gaul by the Roman forces. Shortly afterwards he was ordered to return to Carthage, but on the voyage home he died of wounds received in battle.

(3) The name of Mago is also attached to a great work on agriculture which was brought to Rome and translated by order of the senate after the destruction of Carthage. The book was regarded as a standard authority, and is often referred to by later writers.

See Pliny, Nat. Hist. xviii. 5; Columella, i. 1; Cicero, De oratore, i. 58.

MAGPIE, or simply PIE (Fr. pie), the prefix being the abbreviatory form of a human name (Margaret!), a bird once common throughout Great Britain, though now nearly everywhere scarce. Its pinching habits have led to this result, yet the injuries it causes are exaggerated by common report; and in many countries of Europe it is still the tolerated or even the cherished neighbour of every farmer, as it formerly was in England also. In Scotland also it was once a common bird. MacGillivray in his Life and Works wrote his Itinerary, but it had appeared there within a hundred years later, when Swift mentions its occurrences in his Journal to Stella, 9th July 1711. It is now common enough in that country, and there is a widespread but unfounded belief that it was introduced by the English out of spite. It is a species that when not molested is extending its range, as J. Wolsey ascertained in Lapland, where within the last century it has been gradually pushing its way along the coast and into the interior from one fishing-station or settler’s house to the next, as the country has been peopled.

Since the persecution to which the pie has been subjected in Great Britain, its habits have altered greatly. It is no longer the merry, saucy hanger-on of the homestead, but is become the suspicious thief, shunning the gaze of man, and knowing that danger may lurk in every bush. Hence opportunities of observing it fall to the lot of few, and most persons know it only as a curtailed captive in a wicker cage, where its vivacity and natural beauty are lessened or wholly lost. At large few European birds possess such beauty, the pure white of its scapulars and inner web of the flight-feathers contrasting vividly with the deep black on the rest of its body and wings, while its long tail is lustrous with green, bronze, and purple reflections. The pie’s nest is a wonderfully ingenious structure, placed either in high trees or low bushes, and so massively built that it will stand for years. Its foundation consists of stout sticks, turf and clay,

1 "Magot" and "Madge," with the same origin, are names, frequently given in England to the pie; while in France it is commonly known as Margot, if not termed, as it is in some districts, Jaquette.

wrought into a deep, hollow cup, plastered with earth, and lined with fibres; but around this is erected a firmly interwoven, basket-like outwork of thorny sticks, forming a dome over the nest, and leaving but a single hole in the side for entrance and exit, so that the whole structure is rendered almost impregnable. Herein are laid from six to nine eggs, of a pale bluish-green freckled with brown and blotched with ash-colour. Superstition as to the appearance of the pie still survives even among many educated persons, and there are several versions of a rhyming adage to the various turns of luck which its presenting itself, either alone or in company with others, is supposed to be foretold, though all agree that the sight of a single pie presages sorrow.

The pie belongs to the same family of birds as the crow, and is the Corvus pica of Linnaeus, the Pica caudata, P. melanoleuca, or P. rustica of modern ornithologists, who have recognized it as forming a distinct genus, but the number of species thereto belonging has been a fruitful source of discussion. Examples from the south of Spain differ slightly from those inhabiting the rest of Europe, and in some points more resemble the P. mauritania of north-western Africa; but that species has a patch of bare skin of a fine blue-colour, and this is not found in the European.

In California, however, there is a permanent race if not a good species, P. vuttallii, easily distinguishable by its yellow bill and the bare yellow skin round its eyes; on two occasions in the year 1867 a bird apparently similar was observed in Great Britain (Zoologist, ser. 2, pp. 706, 1016.

MAGWE, a district in the Minbu division of Upper Burma. Area, 2973 sq. m.; pop. (1901), 246,708, showing an increase of 12-38% in the decade. Magwe may be divided into two portions: the low, flat country in the Taungdwingyi subdivision, and the undulating high ground extending over the rest of the district. In Taungdwingyi the soil is rich, loamy, and extremely fertile. The plain is about 45 m. from north to south. At its southern extremity it is about 30 m. wide, and lessens in width to the north till it ends in a point at Natmauk. On the east are the Pegu Yomas, which at some points reach a height of 1500 ft. A number of streams run westwards to the Irrawaddy, of which the Yin and the Pin, which form the northern boundary, are the chief. The only perennial stream is the Yanpy. Rice is the staple product, and considerable quantities are exported. Sesamum of very high quality, maize, and millet are also cultivated, as well as cotton in patches here and there over the whole district.

In this district are included the well-known Yenangyaung petroleum wells. The state wells have been leased to the Burma Oil Company. The amount of oil-bearing lands is estimated at 80 sq. m. and the portion not leased to the company has been demarcated into blocks of 1 sq. m. each, and tendered on lease. The remainder belongs to hereditary Burmese owners called twins, who dig wells and extract their oil by the rope and pulley system as they have always done. Lacquered wood trays, bowls and platters, and cartwheels, are the only manufactories of any note in the district.

The annual rainfall averages about 27 inches. The maximum temperature rises to a little over 100° in the hot season, and falls to about 80° in the winter. The minimum is 54° in the hot season.

The town of MAGWE is the headquarters of the district; pop. (1901), 6232. It is diagonally opposite Minbu, the headquarters of the division, on the right bank of the Irrawaddy.

MAGYARS, the name of the dominant race in Hungary, or Hungarians proper. Though they have become physically assimilated to the western peoples, they belong in origin and descent to the Finno-Ugrian group of the Ural-Altaic race. They form barely half of the population of Hungary, but are by far the largest and most compact of all its racial groups.
MAHABALESHWAR—MAHANADI

Magyar is the official language of Hungary, the official name of which (Magyarázóg, or “country of the Magyars”) enshrines the Magyar claim to predominance. While all Magyars are properly Hungarians, all Hungarians are not necessarily Magyars. “Hungarian” may be used as a generic term covering all the various races of Hungary, while “Magyar” is strictly specific to a single group. The Magyars themselves, indeed, sometimes apply the Magyar adjective in 1890 to Hungary “proper.”

MAHABALESHWAR, or MALCOLMETH, a hill station in Satara district, and the principal sanatorium in the Bombay presidency, India. Pop. (1901), 5299. It is reached by carriage from Wathar railway station (39 m.) or by motor car from Poona (110 m.) Mahabaleshwar occupies the summit of a ridge of the Western Ghats, with a general elevation of 4500 ft. above sea-level. It was established in 1828 by Sir John Malcolm, governor of Bombay, who obtained the site from the raja of Satara in exchange for another patch of territory. The superior elevation of Mahabaleshwar renders it much cooler than Matheran (2460 ft.), a sanatorium about 50 m. E. of Bombay, but its heavy rainfall (202 in. annual average) makes it almost uninhabitable during the rainy season. The mean annual-temperature is 67° F. In the hottest season (March–April) an extreme of a little over 90° is reached during the day. Mahabaleshwar forms the retreat usually during spring, and, occasionally, in summer, of the local chiefs, and of the chief officers of its establishment, and has the usual public buildings of a first-class sanatorium.

MAHAFFY, JOHN PENTLAND (1830– ), Irish classical scholar, was born in Switzerland on the 12th of July 1839. He received his early education in Switzerland and Germany, and later at Trinity College, Dublin, where he held the professorship of ancient history. Mahaffy, a man of great versatility, published numerous works, some of which, especially those dealing with what may be called the Silver age of Greece, became standard authorities. The following deserve mention: History of Classical Greek Literature (4th ed., 1903 seq.); Social Life in Greece from Homer to Menander (4th ed., 1903); The Silver Age of the Greek World (1896); The Empire of the Ptolemies (1896); Greek Life and Thought from Alexander to the Roman Conquest (2nd ed., 1896); The Greek World under Roman sway from Polybius to Plutarch (1896). His translation of Kuno Fischer’s Commentary on Kant (1896) and his exhaustive analysis, with elucidations, of Kant’s critical philosophy are of great value. He also edited the Peta papyri in the Cunningham Memoirs (3 vols. 1891–1900).

MAHALLAT, a province of central Persia, situated between Kashan and Irak. Pop. about 20,000; yearly revenue about £2500. Until 1890 it was one of the five “central provinces” (the other four being Irak, Ferahán, Kaznaz, and Savah), which were under a governor appointed by the shah; since then it has formed part of the Iṣafān government. It is traversed by the Anbarār or Kum River, and comprises the city of Mahallat, divided into upper and lower, or Rivkan and Zanjīrvan, and twenty-two flourishing villages. It was known in former times as Anar, the Anuras of Peutinger’s tables. The city, capital of the province, is situated at an elevation of 830 ft. in 33° 51′ N., 50° 30′ E.; pop. about 9000.

MAHAN, ALFRED THAYER (1840– ), American naval officer and historian, was born on the 27th of September 1840 at West Point, New York. His father, Dennis Hart Mahan (1802–1871) was a professor in the military academy and the author of textbooks on civil and military engineering. The son graduated at the military academy in 1861, served on the “Congress,” and on the “Pocahontas,” “Seminole,” and “James Adger” during the Civil War, and was instructor at the naval academy for a year. In 1865 he was made lieutenant-commander, commander in 1872, captain in 1885. Meanwhile he saw service in the Gulf of Mexico, the South Atlantic, the Pacific, and Asia, and did shore duty at Boston, New York and Annapolis. In 1886–89 he was president of the naval war college at Newport, Rhode Island. Between 1889 and 1892 he was engaged in special service for the bureau of navigation, and in 1893 was made commander of the “Chicago,” of the European squadron. In 1896 he retired from active service, but was a member of the naval board of strategy during the war between the United States and Spain. He was a member of the peace congress at the Hague in 1899. This long and varied service gave Mahan numerous opportunities for observation, which he supplemented by constant study of naval authorities and recent work on the interpretation of the problems of maritime history. His first book was a modest and compact story of the affairs in The Gulf and Inland Waters (1883), in a series of volumes by various writers, entitled The Navy in the Civil War; in 1890 he suddenly acquired fame by the appearance of his masterly work entitled The Influence of Sea Power upon History, 1660–1783. Having been impressed by the failure of historians to allow for the influence of sea power in struggles between nations, he was led to make prolonged investigations of this general theme (see Sea Power). The reception accorded the volume was instant and hearty; in England, in particular, it was deemed almost an epoch-making work, and was studied by naval specialists, cabinet ministers and journalists, as well as by a large part of the general public. It was followed by The Influence of Sea Power upon the French Revolution and Empire (2 vols. 1893); The Life of Nelson, the Embodiment of the Sea Power of Great Britain (1897); and Sea Power in Its Relations to the War of 1812 (1903). The author’s general aim in these works—some of which have been translated into German, Italian, French, and Spanish—was to show that the creation of maritime matters matters paramount to that of military, political or economic movements, without, however, as he himself says “divorcing them from their surroundings of cause and effect in general history, but seeking to show how they modified the latter, and were modified by them.” He selected the year 1660 as the beginning of his narrative, as being the date when the “sailing-ship era, with its distinctive features, had fairly begun.” The series as a whole has been accepted as finally authoritative, supplanting its predecessors of similar aim, and almost—in the words of Theodore Roosevelt—founding a new school of naval historical writing.

Other works by Mahan are a Life of Admiral Farragut (1892); The Interest of America in Sea Power (1897); Lessons of the War with Spain (1899); The Story of the War with South Africa and The System of Asia (1900); Biographies of Naval Officers drawn from the History of the British Navy (1901); Retrospect and Prospect, studies of international relations (1902).

MAHANADI, or MAHANUDDY (“The Great River”), a river of India. It rises in 20° 10′ N., 82° E., 25 m. S. of Raipur town, in the wild mountains of Bastar in the Central Provinces. At first an insignificant stream, taking a northerly direction, it drains the eastern portion of the Chhattisgarh plain, then a little above Seorinaramay it receives the waters which its first great affluent, the Seonath, has collected from the western portion of the plain; thence flowing for some distance due E., its stream is augmented by the drainage of the hills of Uprora, Korba, and the ranges that separate Sambalpur from Chota Nagpur. At Padampur it turns towards the south, and struggling through masses of rock, flows past the town of Sambalpur to Sonpur. From Sonpur it pursues a tortuous course among ridges and rocky crags towards the range of the Eastern Ghats. This mountain line it pierces by a gorge about 40 m. in length, overlooked by forest-clad hills. Since the opening of the Bengal-Nagpur railway, the Mahanadi is little used for navigation. It pours down upon the Orissa delta at Naraj, about 7 m. west of Cuttack town; and after traversing Cuttack district from west to east, and throwing off numerous branches (the Katjori, Paika, Biropa, Chitartala, &c.) it falls into the Bay of Bengal at False Point by several channels.

The Mahanadi has an estimated drainage area of 43,800 sq. m., and its rapid flow renders its maximum water volume that of no other river in India. During unusually high floods 1,500,000 cuf. ft. of water pour every second through the Naraj gorge, one-half of which, uncontrolled by the elaborate
embankments, and heavily laden with silt, pours over the delta, filling the swamps, inundating the rice-fields, and converting the plains into a sea. In the dry weather the discharge of the Mahanadi dwindles to ten cubic feet per second, and people have been known to husband and utilize the vast water supply thrown upon the Orissa delta during seasons of flood. Each of the three branches into which the parent stream splits at its mouth is regulated in width. Of the four canals which form the Orissa irrigation system, two take off from the Biropa weir, and one, with its branch, from the Mahanadi weir. On the 31st of December 1868 the government agreed to purchase the whole canal works from the East Indian Irrigation Company, at a cost of 9,41,368. The canals thus taken over and since completed, are the high-level canal, the Kendrapara canal, the Talidanda canal and the Machagaon canal, irrigating 2,75,000 acres.

MAHANAYA, ("Great Vehicle"), the name given to the later Buddhism, the popular religion which embraced all the people and had its pantheon of Buddhas and Bodhisattvas, with attendant deities and demons, spacious temples and images, pompous ceremonies and noisy festivals. It was thus contrasted with the Hinayana ("Little Vehicle") of the primitive Buddhism which had been only for the select few. (See BUDDHISM.)

MAHDI (Arab. "he who is guided aright"), a title assumed by the third Abbasid caliph (see CALIPHATE: Abbasids, § 3). According to Moslem traditionists Mahomet declared that one of his descendants, the imam of God, who would fill the earth with equity and justice, would bear the name of al-mahdi. The Sunnis hold that this mahdi has not yet appeared. The name of mahdi is also given by the Shi'ite Mahomedans to the last of the imams of the house of 'Ali. It was under the name of al-mahdi that Mokhtar proclaimed 'Ali's son Mahommed as the opponent of the caliph Abdalmalik, and, according to Shaharastani, the doctrine of the mahdi, the hidden deliverer who is one day to appear and fill the oppressed world with righteousness, first arose in connexion with a belief that this Mahommed had not died but lived concealed at Mount Radwâ, near Mecca, guarded by a lion and a panther. The hidden imam of the common Shi'ites is, however, the twelfth imam, Mahommed Abul-Qasim, who disappeared mysteriously in 870. The belief in the appearance of the mahdi reportedly lent itself to imposture. Of the many pretenders to this dignity known in all periods of Moslem history the most famous was the first caliph of the Fatimite dynasty in North Africa, 'Obsdallah al-Mahdi, who reigned 909-933. After him was named the first capital of the dynasty, the once important city of Mahdia (q.v.). Another great historical movement, headed by a leader who proclaimed himself the mahdi (Mahommed ibn Abdullah ibn Tumari), was that of the Almohades (q.v.). In 1181 Mahommed Ahmed ibn Sefylil ibn Abdullah (q.v.), a Dangolese, proclaimed himself al-mahdi and founded in the eastern Sudan the short-lived empire overthrown by an Anglo-Egyptian force at the battle of Omdurman in 1898. Concurrently with the claim of Mahommed Ahmed to be the mahdi the same title was claimed by, or for, the head of the Senussites, a confederation powerful in many regions of North Africa.

MAHIDIA (also spelt Mhidia, Mehedia, &c.), a town of Tunisia, on the coast between the gulfs of Hammamet and Gabes, 47 m. by rail S.E. of Sousse, 30 m. S.W. of Tunis. It is the capital of a peninsula which projects eastward about a mile beyond the normal coast line, and is not more than a quarter of a mile wide. The extremity of the peninsula is called Ras Mahdia or Cape Africa—Africa being the name by which Mahdia was designated by Froissart and other European historians during the middle ages and the Renaissance. In the centre of the peninsula and occupying its highest point is a citadel (16th century); another castle farther west is now used as a prison and is in the centre of the native town. The European quarter and the new port are on the southwest side of the peninsula. The port is available for small boats only; steamers anchor in the roadstead about a quarter of a mile from the shore. On the south-east, cut out of the rock, is the ancient harbour, or cohon, measuring about 480 ft by 240 ft., the entrance being 42 ft. wide. There are manufactories of olive scholars and in especial detail by Geiger. It is agreed that it gives a reasonably fair and correct presentation of the tradition preserved in the lost Sinhalese Mahâvamsa; that, except in the earliest period, its list of kings, with the years of each reign, is complete and trustworthy; and that it gives throughout the view, as to events in Ceylon, of a resident in the Great Minster at Anurâdhapura.

See The Mahâvamsa, ed. by Geo. Turnour (Colombo, 1837); ed. by W. Geiger (London, 1908); H. Oldenberg, in the introduction to his edition of the Dipâamaasa (London, 1879); O. Franke, in Wiener Zeitschrift für die neuen orientalischen Geschichtsquellen (1907); W. Geiger, Dipâamaasa and Mahâvamsa (Leipzig, 1909, trans. by Ethel M. Coomaraswamy, Colombo, 1908).

(T. W. R. D.)
oil, but the chief industry is sardine fishing, largely in the hands of Italians.

Mahdia occupies the site of a Phoenician settlement and by some authorities is identified with the town called Turris Hamibilis by the Romans. Hammibal is said to have harbored here his exile from Carthage. After the Arab conquest of North Africa the town fell into decay. It was refounded in 912 by the first Fatimite caliph, Obaidallah-al-Mahdi, after whom it was named. It became the port of Kairawan and was for centuries a city of considerable importance, largely owing to its great natural strength, and its position on the Mediterranean. It carried on an active trade with Egypt, Syria and Spain. The town was occupied by the Normans of Sicily in the 12th century, but after holding it for about twelve years they were driven out in 1156 by the Almohades. In 1390 a joint English and French force vainly besieged Mahdia for sixty-one days. In the early part of the 16th century the corsair Dragut seized the town and made it his capital, but in 1550 the place was captured by the Spaniards, who held it until 1574. Before evacuating the town the Spaniards dismantled the fortifications. Under the rule of the Turks and, later, the beyas of Tunis Mahdia became a place of little importance. It was occupied by the French in 1881 without opposition, and regained some of its former commercial importance.

During 1908 numbers of bronzes and other works of art were recovered from a vessel wrecked off Mahdia in the 7th century A.D. (see Classical Review, June 1909).

MAHÉ, a French settlement in the Malabar district of Madras, India, situated in 9° 43' N. and 75° 33' E., at the mouth of a river of the same name. Area, 26 sq. m.; pop. (1901), 10,298. It is the only French possession on the west coast of India, and is in charge of a chef de service, subordinate to the governor-general at Pondicherry. It is now a decaying place.

MAHESHWAR, a town in Indore state, Central India, on the N. bank of the Nerbhad (Nerbudda), pop. (1901), 7042. Though of great antiquity and also of religious sanctity, it is chiefly noted as the residence of Ahalya Bai, the reigning queen of the Holkar dynasty during the last half of the 18th century, whose ability and munificence are famous throughout India. Close by her cenotaph stands the family temple of the Holkars.

MAH, a river of western India, which rises in Central India and, after flowing through south Rajputana, enters Gujarat and falls into the sea by a wide estuary near Cambay; total length, 300 m.; estimated drainage area, 16,000 sq. m. It has given its name to the Mahi Kantha agency of Bombay, and also to the mehussis, marauding highlanders often mentioned in Mahomedan chronicles.

MAHAN KANNA, a political agency or collection of native states in India, within the Gujarat division of Bombay. Over half the territory is covered by the native state of Idar. There are eleven other chiefships, and a large number of estates belonging to Rajput or Kolli thakurs, formerly feudatories of Baroda. Several of the states are under British administration. Total area, 3125 sq. m.; pop. (1901), 161,545, showing a decrease of 38% in the decade, due to famine; estimated revenue, £76,000; tribute (mostly to the gaekwar of Baroda), £50,000. Many of the inhabitants belong to the wild tribes of Bhils and Kolis. In 1897 a metre-gauge railway was opened from Ahmedabad through Parantij to Ahmednagar. At Sadra is the Scott College for the education of the sons of chiefs on the lines of an English public school. There are also Anglo-vernacular schools at Sadra, Idar and Mansa. The famine of 1899-1900 was very severe in this tract.

MAHMUD I. (1696-1754), sultan of Turkey, was the son of Mustafa II., and succeeded his uncle Ahmed III. in 1730. After the suppression of a military revolt the war with Persia was continued with varying success, and terminated in 1736 by a treaty of peace restoring the status quo ante bellum. The next enemy whom Turkey was called upon to face was Russia, later joined by Austria. War went on for four years; the successes gained by Russia were outweighed by Austria's various reverses, terminating by the defeat of Wallis at Kroteza, and the peace concluded at Belgrade was a triumph for Turkish diplomacy. The sultan, throughout desires for peace, said has been much under the influence of the chief eunuch, Haji Beshir Aga. In 1754 Mahmud died of heart-disease while on a pilgrimage to Mecca. He continued his father's efforts to loosen Turkey's influence on Europe, and he had a passion for building, to which are due numberless kiosques, where nocturnal orgies were carried on by him and his boon companions. In this reign the system of appointing Phanariote Greeks to the principalities of Moldavia and Wallachia was instituted. (See PHANARiotes.)

MAHMUD II. (1785-1839), sultan of Turkey, was the son of Abu-ul-Hamid I., and succeeded his brother, Mustafa IV., in 1808. He had shared the captivity of his ill-fated cousin, the ex-sultan, Selim III., whose efforts at reform had ended in his deposition by the janissaries. Mahmud was thus early impressed with the necessity for dissembling his intention to institute reforms until he should be powerful enough to carry them through. The reforming efforts of the grand vizier Bairakdar, to whom he had owed his life and his accession, broke on the opposition of the janissaries; and Mahmud had to wait for more favourable times. Meanwhile the empire seemed in danger of breaking up. Not till 1812 was the war with Russia closed by the treaty of Bucharest, which restored Moldavia and the greater part of Wallachia to the Ottoman government. But though the war was ended, the terms of the treaty left a number of burning questions, both internal and external, unsettled. This was notably the case with the claim of Russia to Poti and the valley of the Rion (Phasia), which was still outstanding at the time of the congress of Vienna (1814-1815) and prevented the question of a European guarantee of the integrity of Turkey from being considered.

Meanwhile, within the empire, ambitious vails were one by one attempting to carve out dominions for themselves at the expense of the central power. The ambitions of Mahmud were not yet fully revealed; but Ali (q.v.) of Janina, who had marched to the aid of the sultan against the rebellious pasha Pasvan Oglu of Widdin, soon began to show his hand, and it needed the concentration of all the forces of the Turkish empire to effect his overthrow and death (1821). The preoccupation of the sultan with Ali gave their opportunity to the Greeks whose dissatisfaction had long been organized in the great secret society of the Hetaeria Philike, against which Metternich had in vain warned the Ottoman government. In 1821 occurred the abortive raid of Alexander Vaspilant into the Danubian principalities, and in May of the same year the revolt of the Greeks of the Morea began the war of Greek Independence (see Greece: History). The rising in the north was easily crushed; but in the south the Ottoman power was hampered by the defection of the sea-faring Greeks, by whom the Turkish navy had hitherto been manned. After three abortive campaigns Mahmud was compelled, infinitely against his will, to summon to his assistance the already too powerful pasha of Egypt, Mehmet Ali, whom he had already employed to suppress the rebellious Wahhabis in Arabia. The disciplined Egyptian army, supported by a well organized fleet, rapidly accomplished what the Turks had failed to do; and by 1826 the Greeks were practically subdued on land, and Ibrahim was preparing to turn his attention to the islands. But for the intervention of the powers and the battle of Navarino Mahmud's authority would have been restored in Greece. The news of Navarino betrayed Mahmud into one of those paroxysms of rage which the man of bitter genius was wont to cloud his usual good sense. After vain attempting to obtain an apology for "the unparalleled outrage against a friendly power" he issued on the 20th of December a solemn hatti sherif summoning the faithful to a holy war. This, together with certain outstanding grievances and the pretext of enforcing the settlement of the Greek Question approved by the powers, gave Russia the excuse for declaring war against Turkey. After two hardly fought campaigns
MAHMUD NEDIM PASHA—MAHMUD OF GHAZNI

(1828, 1829) Mahmud was at length, on the 14th of September 1829, compelled to sign the peace of Adrianople. From this moment until his death Mahmud was, to all intents and purposes, the "vassal of Russia," though not without occasional desperate efforts to break his chains. (For the political events of the period between the first revolt of Mehmet Ali (Sept. 1832) and the death of Mahmud see Mehmet Ali.) The personal attitude of the sultan, which alone concerns us here, was decisive to his rebellion. Throughout by his overmastering hatred into the upstart pasha, of whom he had stooped to ask aid, and who now defied his will; and the importance of this attitude lies in the fact that, as the result of the success of his centralizing policy, and notably of the destruction of the janissaries (p. e.), the supreme authority, hitherto limited by the practical power of the ministers of the Porte and by the turbulence of the privileged military caste, had become concentrated in his own person. It was no longer the Porte that decided, but the Seraglio, and the sultan's private secretary had more influence on the policy of the Ottoman empire than the grand vizier.

This omnipotence of the sultan in deciding the policy of the government was in striking contrast with his impotence in enforcing his views on his subjects and in his relations with foreign powers. Mahmud, in spite of—or rather because of—his well-meant efforts at reform, was hated by his Musulman subjects and stigmatized as an "infidel" and a traitor to Islam. He was, in fact, a victim to those "half-measures" which Machiavelli condemns as fatal to success. Ibrahim, the conqueror of Syria, scoffed at the sultan's "half-measures" that reform consisted in cutting his soldiers' epaulettes. The criticism is not entirely unjust. Mahmud's policy was the converse of that recommended by Machiavelli, viz, in making a revolution to change the substance while preserving the semblance of the old order. Metternich's advice to Mahmud to "remain a Turk" was sound enough. His failure to do so—in externals—left him isolated in his empire: rayahz and true believers alike distrusted and hated him. Of this hatred he was fully conscious; he knew that his subjects, even many of his own ministers, regarded Mehmet Ali as the champion of Islam against the "infidel sultan;" he suspected the pasha, already master of the sacred cities, of an intention to proclaim himself caliph in his stead. This, together with the weakness due to military reforms but recently begun, drove him to rely on foreign aid; which, in the actual conditions of Europe, meant the aid of Russia. The long tradition of French friendship for Turkey had been broken, in 1830, by the conquest of Algiers. Austria was, for the time, but the faithful ally of the tsar. On the 9th of August 1832 Mahmud made, through Stratford Canning, a formal proposition to Austria and Britain. But British ministers had in fact already refused to consider for fear of offending France. Mahmoud bitterly contrasted the fair professions of England with the offers of effective help from Russia. His old ally having deserted him, he accepted the aid of his hereditary foe. The Russian expedition to the Bosporus, the convention of Kutaiah, and the treaty of Unkla Skelessi (July 8, 1833) followed. Mahmud was under no illusion as to the position in which the latter placed him towards Russia; but his fear of her was less than his desire to remain unhurt out-weighted all other considerations. He represented the action of France and England in forcing the settlement of Kutscha upon him, and remained shut up in his palace, inaccessible to all save his favourites and the representative of Russia. With his single aim in view he busied himself with the creation of a national militia, with the aid of Moltke and other German officers. In 1834 the revolt of Syria against Ibrahim seemed to give him his opportunity. He pleaded the duty of a sultan to his subjects of his subjects when oppressed by one of his servants; but the powers were obdurate, even Russia, much occupied in affairs nearer home, leaving him in the lurch. He was astute enough to take advantage of the offence given to the powers by Mehmet Ali's system of monopolies, and in 1838 signed with Great Britain, and afterwards with others, a commercial treaty which cut at the root of the pasha's system. A few months later his passionate impatience overcame his policy and his fears. The hand of death was upon him, and he felt that he must strike now or never. In vain the powers, now united in their views, warned him of the probable consequences of any aggressive action on his part. He would rather die, he exclaimed, or become the slave of Russia, than descend to rebellion. On his dying bed, in the earliest initiative, without consulting his ministers or the council of the empire, he sent full powers to Hafiz Pasha, commanding the Ottoman troops concentrated at Bir on the Ephrathes, to advance into Syria. The fatal outcome of the campaign that followed he did not live to hear. When the news of Ibrahim's overwhelming victory at Nessib (June 24, 1839) reached Constantinople, Mahmud lay dying and unconscious. Early in the morning of the 1st of July his proud and passionate spirit passed away.

Mahmud II. cannot be reckoned among the great sultans, neither had he any of the calculating statesmanship which characterized Abd-UL-Hamid II.; but his qualities of mind and heart, none the less, raised him far above the mass of his predecessors and successors. He was well versed in state affairs and loyal to those who advised and served him, personally brave, humane and kindly when not maddened by passion, active and energetic, and always a man of his word. Unhappily, however, the taint of the immemorial corruption of Byzantium had fallen upon him too, and the avenue to his favour and to political power lay too often through unspeakable paths. In view of the vast difficulty of the task before him at his succession it is less surprising that he failed to carry out his ideas than that he accomplished so much. When he came to the throne the empire was breaking up from within; one by one he freed the provinces from the tyrannical rulers who, like Ali of Jannina, were carving out independent, or quasi-independent, empires within the empire. If he failed in his wider schemes of reform, this was only one more illustration of a truth of which other "enlightened" sovereigns besides himself had experienced the force, namely, that it is impossible to impose any system, however admirable, from above on a people whose deepest convictions and prejudices it offends.

There is a great deal of valuable material for the history of Mahmud and his policy in the unpublished F.O. records (1832—1839), volumes of correspondence marked Turkey.—From Sir Stratford Canning.—From Mr. Mandeville.—From Lord Ponsonby. See further works mentioned under Turkey: History; and Mehmet Ali. (W. A. P.)

MAHMUD NEDIM PASHA (c. 1818—1883), Turkish statesman, was the son of Nejib Pasha, ex-governor-general of Bagdad. After occupying various subordinate posts at the Porte he became successively under-secretary of state for foreign affairs, governor-general of Tripoli, and lastly ambassador extraordinary and minister plenipotentiary at Paris, and governor-general of Tripolitania (1858), again governor-general of Tripoli; minister successively of justice and of marine (1866); grand vizier from 1871 to 1872 and from 1875 to 1876. He was high in favour with Sultan Abd-ul-Aziz and fell much under the influence of General Ignatiev, the forceful Russian ambassador before the war of 1877—78, his subserviency to Russia earning for him the nickname of "Mahmudoff." His administration was most unsuccessful from every point of view, and he was largely responsible for the issue of the decree suspending the interest on the Turkish funds. He was minister of the interior from 1879 to 1885.

MAHMUD 1 OF GHAZNI (971—1030), son of Sabuktagni, Afghan conqueror, was born on the 2nd of October 971. His fame rests chiefly on his successful wars, in particular his numerous invasions of India. His military capacity, inherited from his father, Nasir-ud-din Sabuktagni, was strengthened by youthful experience in the field. Sabuktagni, a Turki slave of Alptagin, governor of Khorasan under Abdallah-Malik I. b. Nuh of the Samanid dynasty of Bokhara, early brought himself to notice (see Sambanid). He was raised to high office in the state by Alptagin's successor, Abu Islah, and in 971 by the choice of the nobles of Ghazni, he became their ruler. He soon began to make conquests in the neighbouring countries.

1 The name is strictly Maḥmūd.
MAHMUD OF GHAZNI

and in these wars he was accompanied by his young son Mahmud. Before he had reached the age of fourteen he encountered in two expeditions under his father the Indian forces of Jaipal, raja of Lahore, whom Sabuktagni defeated on the Punjab frontier.

In 904 Mahmud was made governor of Khorasan, with the title of Saif addaula (ud-daula) ("Sword of the State") by the Samanid Nuh II. Two years later, his father Sabuktagni died in the neighbourhood of Balkh, having declared his second son, Ismail, who was then with him, to be his successor. As soon as Ismail had assumed the sovereignty at Balkh, Mahmud, who was at Nishapur, addressed him in friendly terms, proposing a division of the territories held by their father at his death. Ismail rejected the proposal, and was immediately attacked by Mahmud and defeated. Retreating to Ghazni, he there yielded, and was imprisoned, and Mahmud obtained undisputed power as sovereign of Khorasan and Ghazni (907).

The Ghaznevid dynasty is sometimes reckoned by native historians to commence with Sabuktagni's conquest of Bost and Kordar (758). But Sabuktagni, throughout his reign in Ghazni, continued to acknowledge the Samanid suzerainty, as did Mahmud also, until the time, soon after succeeding to his father's dominions, when he received from Qadir, caliph of Bagdad (son of the former, and the other of the twin caliphate), a letter recognizing his sovereignty, and conferring on him the titles Yamin-addaula ("Right hand of the State"), and Amin-ul-Millat ("Guardian of the Faith"). From this time it is the name of the caliph that is inscribed on Mahmud's coins, together with his own new titles. Previously the name of the Samanid sovereign, Mansur II. b. Nuh is given along with his own former title, Saif addaula Mahmudh. The earliest of those of the new form gives his name Mahmud bin Sabuktagn. Thereafter his father's name does not appear on his coins, but it is inscribed again on his tomb. The new honours received from the caliph gave fresh impulse to Mahmud's zeal on behalf of Islam, and he resolved on an annual expedition against the idolaters of India. He could not quite carry out this intention, but a great part of his reign was occupied with his Indian campaigns. In 1000 he started on the first of these expeditions, but it does not appear that he went farther than the hill country near Peshawar. The hostile attitude of Khalaf ibn Ahmad, governor of Seistan, called Mahmud to that province for a short time. He was appalled by Khalaf's speedy submission, together with the gift of a large sum of money, and further, it is said, by his subdued opponent addressing him as sultan, a title new at that time, and by which Mahmud continued to be called, though he did not formally adopt it, or stamp it on his coins. Four years later Khalaf, incurring Mahmud's displeasure again, was imprisoned, and his property confiscated.

Mahmud's army first crossed the Indus in 1001, opposed by Jaipal, raja of Lahore. Jaipal was defeated, and Mahmud, after his return from this expedition, is said to have taken the distinctive appellation of Ghazi ("Valiant for the Faith"), but he is rarely so called. On the next occasion (1005) Mahmud advanced, as far as Bhera on the Jhelum, when his adversary Anang-pal, son and successor of Jaipal, fled to Kashmir. The following year saw Mahmud at Multan. When he was in the Punjab at this time, he heard of the invasion of Khurasan by the Ilek Khan Nasr I. ruler of Transoxiana whose daughter Mahmud had married. After a rapid march back from India, Mahmud repelled the invaders. The Ilek Khan, having retreated across the Oxus, returned with reinforcements, and took up a position a few miles from Balkh, where he was signally defeated by Mahmud.

Mahmud again entered the Punjab in 1008, this time for the express purpose of chastising Seeh Wul, who, having become a Mussulman, and been left by Mahmud in charge of Multan, had relapsed to Hinduism. The Indian campaign of 1009 was notable. Near the Indus Mahmud was opposed again by Anang-pal, supported by powerful rajas from other parts of India. After a severe fight, Anang-pal's elephants were so terror-struck by the fire-missiles flung amongst them by the invaders that they turned and fled, the whole army retreating in confusion and leaving Mahmud master of the field. Mahmud, after this victory, pushed on through the Punjab to Nagar-kot (Kanagar), and carried off much spoil from the Hindu temples to enrich his treasury at Ghazni. In 1011 Mahmud, after a short campaign against the Afghans under Mahommed ibn Sür in the hill country of Ghur, marched again into the Punjab. The next time (1014) he advanced to Thanasar, another noted stronghold of Hinduism, between the Sutlej and the Junna. Having now found his way across all the Punjab rivers, he was induced on two subsequent occasions to go still farther. But first he designed an invasion of Kashmir (1015), which was not carried out, as his progress through the Punjab was blocked by the chief stronghold of the Punjab. Then before undertaking his longer inroad into Hindustan he had to march north into Khwārizm (Khiva) against his brother-in-law Mamun, who had refused to acknowledge Mahmud's supremacy. The result was as usual, and Mahmud, having committed Khwārizm to a new ruler, one of Mamun's chief officers, returned to his capital. Then in 1018, with a very large force, he proceeded to India again, extending his inroad this time to the great Hindu cities of Mathra on the Jumna and Kanauj on the Ganges. He reduced the one, received the submission of the other, and returned to Multan, a strong hold in the north-west of the Punjab. Three years later he went into India again, marching over nearly the same ground, to the support, this time, of the raja of Kanauj, who, having made friendship with the Mahommedan invader on his last visit, had been attacked by the raja of Kalinjar. But Mahmud found he had not yet sufficiently subdued the idolaters nearer his own border, between Kabul and the Indus, and the campaign of 1022 was directed against them, and reached no farther than Peshawar. Another march into India the following year was made direct to Gwallor. The next expedition (1025) is the most famous of all. The point to which it was directed was the temple of Somnath on the coast of the Gujarat peninsula. After an arduous journey by Multan, and through part of Rajputana, he reached Somnath, and met with a very vigorous but fruitless resistance on the part of the Hindus of Gujarat. Moslem feet soon trod the courts of the great temple. The chief object of worship it contained was broken up, and the fragments kept to be carried off to Ghazni. The story is often told of the hollow figure, cleft by Mahmud's battle-axe, pouring out great store of costly jewels and gold. But the idol in this Siva temple was only a tall block or pillar of hewn stone, of a familiar kind. The popular legend is a very natural one. Mahmud, it was well known, made Hindu temples yield up their most precious things. He was a determined idol-breaker. And the stone block in this temple was enriched with a crown of jewels, the gifts of wealthy worshippers. These data readily give the Somnath exploit its more dramatic form. For the more recent story of the Somnath gates see SOMNATH.

After the successes at Somnath, Mahmud remained some months in India before returning to Ghazni. Then in 1026 he crossed the Indus once more into the Punjab. His brilliant military career closed with an expedition to Persia, in the third year after this, his last, visit to India. The Indian campaigns of Mahmud and his father were almost, but not altogether, unvarying successes. The Moslem historians touch lightly on reverses. And, although the annals of Rajputana tell how Sabuktagni was defeated by one raja of Ajmere and Mahmud by his successor, the course of events which followed shows how little these and other reverses affected the invader's progress. Mahmud's failure at Ajmere, when the brave raja Bisle-deo obliged him to raise the siege but was himself slain, was when the Moslem army was on its way to Somnath. Yet Mahmud's Indian conquests, striking and important in themselves, were, after all, in great measure barren, except to the Ghazni treasury. Mahmud retained no possessions in India under his own direct rule. But after the repeated defeats, by his father and himself, of two successive rajas of Lahore, the conqueror assumed the right of nominating the governors of the Punjab as a dependency of Ghazni, a right which continued to be exercised by seven of his successors. And for a time, in the reign of Massud II.
MAHOB—MAHOMET

(1908–1114), Lahore was the place of residence of the Ghaznivid sovereign.

Mahmud died at Ghazni in 1030, the year following his expedition to Persia. He is conspicuous for his military ardour, his ambition, strong will, perseverance, watchfulness and energy, combined with great courage and valour. Religiously, his ideas were not exclusively military. His love of literature brought men of learning to Ghazni, and his acquaintance with Moslem theology was recognized by the learned doctors.

The principal histories of Mahmud's reign are—Khitb-i-Yamini (Utbi); Tarikh-us-Subuktigin (Baizaki); Tabakat-i Nasiri (Minhaq d-Sirdi); Rawat-us-Safa (Mir Khond); Abbub-bin-Shar (Khund); Dastiul-Usul of India; Ephiphanus, History of India; and Roos-Keppel's translation of the Tarikh-i-Sultan Mahmud-i-Ghaznavi (1901).

MAHOBA, an ancient town in India, in Hamirpur district of the United Provinces. Pop. (1911), 10,274. As the capital of the Chandel dynasty, who ruled over Bundelkhand from the 9th to the 13th century, the neighbourhood is covered with architectural antiquities, prominent among which are artificial lakes, formed by banking up valleys with masonry dams. The largest of these is more than 4 m. in circuit.

MAHOGANY, a dark-coloured wood largely used for household furniture, the product of a large tree indigenous to Central America and the West Indies. It was originally received from Jamaica; 521,500 ft. were exported from that island in 1753. It is known botanically as Swietenia Mahogani, and is a member of the order Meliaceae. It bears compound leaves, resembling those of the ash, and clusters of small flowers, with five sepals and petals and ten stamens which are united into a tube. The fruit is a pear-shaped woody capsule, and contains many winged seeds. The dark-coloured bark has been considered a febrifuge, and the seeds were used by the ancient Aztecs with oil for a cosmetic, but the most valuable product is the timber, first noticed by the carpenter on board Sir Walter Raleigh's ship in 1595 for its great beauty, hardness and durability. Dr Gibbons brought it into notice as well adapted for furniture in the early part of the 18th century, and its use as a cabinet wood was first practically established by a cabinet-maker named Wollaston, who was employed by Gibbons to work up some mahogany brought to England by his brother. It was introduced into India in 1705, and is now cultivated in Bengal and as far north as Salarunpur.

The timber of species of Cedrela and Melia, other members of the order Meliaceae, are used as Mahogany, and the product of the West African Khaya senegalensis is known as African mahogany. There is some confusion between the product of these various species and that of those described above.

The 'various species of mahogany and cedar are so confusing that it is difficult to make precise statements as to their structure or origin. I know of no convincing proof that any of the American kinds meet with on the English market are the wood of Swietenia Mahogani, nor that those shipped from Africa are the wood of Khaya senegalensis. These two genera are very nearly allied to Cedrela and Melia, and it is difficult to separate any of the four from the rest by the characters of the wood. After giving the most careful attention to every detail, I lean to the view that most if not all of the mahoganies commonly met with are Cedrelas.”

Afrocarpus (previously Falcata), a native of South Africa, is known as Natal mahogany.

MAHOMET (strictly Mu\jah\mad, commonly also Mohammed), founder of the religious system called in Europe after him Mahomedanism, and by himself Islam or Hanifism. He died, according to the ordinary synchronism, on the 7th of June 632 (12 Rabi\a, A.H. 11), and his birthday was exactly sixty-three or sixty-five years earlier, the latter number being evidently an interpretation in lunar years of a number thought to refer to solar years. The lunar system was introduced into Arabia by Mahomet himself quite at the close of his career; that which existed before was certainly solar, as it involved a process of intercalation—which, however, seems to have been arbitrarily manipulated by priests, whence certain synchronisms cannot be got for the events in the Prophet's career. The number 63 for the years of his life may rest on tradition, though it is unlikely that such matters were accurately noted; it can also be accounted for by a priori combination. A Meccan, it is said, became a full citizen at the age of 40; this then would be the age at which the mission might be started. The Medina period (of which count was kept) lasted ten to eleven years; for the Meccan period ten years would seem a likely length. Finally it was known that for some time the Prophet, and by wearing a badge, was secretly. The only event in contemporary history to which the Koran alludes in its earlier parts is the Persian conquest of Palestine in 616. Clearly Mahomet had begun to prophesy at that date.

Before the rise of Islam, Mahomet's native place, Mecca, appears to figure nowhere in historical records, unless there be a reference to it in the "valley of Baca" (Psalm lxxxiv. 6). Its sacred, and therefore archaic, name is Bakkah; hence the identification of the name with this sanctuary. Makemak, known to the Greek geographers, is not philologically tenable; although so eminent a linguist as Dozy evolved a theory of the origin of the city from this name, which appears to be South Arabian for "sanctuary," and has no connexion with Hebrew (as Dozy supposed). In the 3rd century of Islam the mythology of Mecca was collected and published in book form, but we learn little more from it than names of tribes and places; it is clear that there was no record of the mode in which the community inhabiting the place had got there, and that little was remembered with sureness of the order in which the tribes were connected. The city had a sanctuary, called the Cube (ka\b\a), of which the nucleus was the "Black Stone," probably to be identified with Allah, the god of the community; both still exist, or rather their legitimate substitutes, as the Ka\b\a has been repeatedly reconstructed, and the original Black Stone was stolen by the Carteminians in the 4th century of Islam; they afterwards returned one, but it may or may not have been the same as that which they removed. At some time in the 6th century—said to have been the birth-year of the Prophet, but really much earlier—an Abyssinian invader raided Mecca with violence, desecrating and abolishing the sanctuary. The city, in consequence, was reduced to a part of the dust which the wind had blown. The new monarch, the Prophet, who emerged from this position to inaugurate a new order, and to found Islam, came from Mecca. His cousin 'Ali, fourth caliph, was the son of Abu Talib, whose name attests the historical character of the kindred name 'Abd al-Mo\t\atib, Mahomet's grandfather; for the fact that this name is in part enigmatical is certainly no argument against its genuineness. In the 3rd century of Islam
a document was shown in which a man of San’a in Yemen acknowledged that he had borrowed from ‘Abd al-Muṭṭalib 1000 silver dirhems of the Hudaida standard, and Allāh with the two “angels” (probably a euphemism for the goddesses Al-lāt and al-‘Uzzā) served as witness; it is difficult to see why such a document should have been forged. The name Ḥāshīm (for ‘Abd al-Muṭṭalib’s father) may or may not be historical; here, as in the ascending line throughout, we have subjects without predicates. The name of ‘Abd al-Muṭṭalib’s son, who was Mahomet’s father, is given as ‘Abdallāh; the correctness of this has been questioned, because “Servant of Allah” would seem to be too appropriate, and the name was often given by the Prophet to converts as a substitute for some pagan appellation. This, however, is hypercritical, as the name of the father could not easily be altered, when relatives abounded, and it would seem that at one time the Prophet made no theological use of the name Allāh, for which he intended to substitute Rāḥūn. The name of his mother is given as Aminah, and with this one of his own titles, Amin, agrees; although the Arabs do not appear to bring the two into connexion. Her father’s name is given as Wahb, and she is brought into relation with a Medines tribe called the Banū ‘Abd b. al-Najjar, to whom she is said to have brought her son in his early infancy. The circumstances may have been suggested by his later connexion with that place; yet in what seems a historical narrative her grave is mentioned as known to be at Abwa, midway between the two cities, whence this early bond between the Prophet and his future home may have really existed.

His own name is given in the Koran in the forms Ahmad and the familiar Muḥammad; in contemporary poetry we also find the form Muḥṭalīb. Similar variation between derivatives from the same root is found in proper names which occur in early poetry; the meaning of all would be “the praised,” if the root be given its Arabic signification—“the desired” if interpreted from the Hebrew.

The form Muḥammad (ordinarily transliterated Mohammed; Mahomet, Mehmet, Æ., represent the Turkish pronunciation) is found in a pre-Islamic inscription, and appears to have been fairly common in Arabia. In Hag. ii. 7 a derivative of the Hebrew equivalent root occurs in the prophecy “and the desired of all nations shall come,” and this passage has suggested the idea that the name may have been taken by the Prophet as the equivalent of “Messiah,” while the Moslems themselves find its equivalent in the Paraclete of the Fourth Gospel, though this identification requires more ingenuity. His kunyah (i.e. the Arabic title of respect, in which a man is called after his son) is Abūl-Qasim; other names by which he is called are titles of honour, e.g. Muṣṭalī “chosen.” (See further the genealogical table, ad fin.)

In the Koran, Allāh says that He found the Prophet an orphan, poor and astray; it is possible that all these expressions should be understood figuratively, like the “poor, the orphan of the towns of Arabia,” of Ch. ii. 3. Mahomet, however, takes them literally, and Mahomet is said to have been a posthumous child, whose mother died a few months or years after his birth, and who was brought up first by his grandfather, and then by his uncle Abū Tālib, one of the poorer members of the family; in the controversy between the Alid and Abbasid pretenders of the 2nd century of Islam the Abbasid Mašḵur claims that his ancestor fed the ancestor of ‘Ali, i.e. Abū Tālib, otherwise he would have had to beg. There was evidently an apparent inconsistency between Mahomet’s being a poor orphan and the favourite grandchild of the eminent and wealthy ‘Abd al-Muṭṭalib; and it was solved in this way. There was a tradition that in his early years he was sent into the desert to acquire the habits and the language of the Beduins; and this seems to have been attested by the Prophet himself. In a tribal fight he is said to have acted as armour-bearer to one of his uncles, Zubair. There seems no doubt that he often accompanied Meccan caravans to the countries with which the Meccans had trade relations; such especially were Syria and south Arabia, and perhaps Egypt and Mesopotamia. It is conceivable that he may have visited Africa by sea. For though accurate knowledge is nowhere to be found in the Koran, it exhibits a large amount of miscellaneous information, such as a trader might well pick up.

His career as a caravan-conductor appears to have terminated with his marriage to Khadjīja, daughter of Khawilīd, represented by the tradition as a wealthy widow, fifteen years his senior and forty years of age at the time of the union. As she became the mother of a numerous family, a special rule was discovered by Moslem physiologists extending the child-bearing period of Korashite women beyond that of others. Since it is claimed for Mahomet that he first gave Arab women the right to inherit property, the difficulty noticed is not the only one connected with this marriage; and Robertson Smith has called attention to some others, unconnected with his theory of “the marriage and kinship in early Arabia.” After his marriage Mahomet appears to have been partner in a shop in Mecca; where he apparently sold agricultural produce. His style is strongly marked by phrases and metaphors drawn from trade, though as a statesman he never displayed any financial ability.

Writing in the monumental script of South Arabia had been known for centuries in the peninsula; and shortly before the rise of Islam a cursive script—the parent of the ordinary Arabic character—had been started in the Christian state of Hira, with which the beginnings of modern Arabic literature are connected. A modification of this had been introduced into Mecca, and was probably used for contracts and similar documents. The word ummī, literally “popular” or “plebeian” (according to one etymology), applied to Mahomet in the Koran, is said to mean “one who can neither read nor write,” and the most generally accepted view is that he could do neither, a supposition which enters into the doctrine of the miraculous nature of the Koran. According to another interpretation the word means “Meccan,” i.e. native of “the Mother of the Villages” (“Umm al-Qura”); and the most probable theory is that he could do both, but unskilfully. Indeed on one historic occasion he erased certain words in a document; and where in the Koran he rebuts the charge of “taking notes,” he does not employ the obvious retort that he could not write, but gives a far less convincing answer. For poetry, which seems to have been cultivated in Arabia long before his time, he possessed no car; but we have little reason for supposing that either writing or versification had yet entered into Arabian education. The former would be acquired by those who needed it, the latter was regarded as a natural gift. There is reason for thinking the language of the Koran incorrect and ungrammatical in parts, but as it afterwards became the ultimate standard of classical Arabic, this point is not easy to prove. On the whole then his early life seems to have been such as was normal in the case of a man belonging to one of the more important families in a community which had not long been started on a career of prosperity.

Of the organization of that community we unfortunately know very little, though we hear of a council-chamber, and, as we shall see, of an assembly of Chieftains; yet we know little about to it. It is, however, certain that the theory of decision by majority was absolutely unknown to Mahomet’s second successor, whence we learn little from this tradition (even if it be authentic) of the mode whereby the tribes who together formed the Meccan population managed their common concerns, whether commercial or political. The form of government seems to have been a rudimentary oligarchy, directed by some masterful individual; before the Flight we read of various prominent personages, after the Flight and the battle of Badr (A.H. 2) one chieftain, Abū Sofān (see Caliphate, ad init.), appears to take the lead whether in war or in policy. It would seem, however, that the right of independent action belonged to the individual tribes, even to the extent of refusing to take part in a campaign. For the settlement of ordinary disputes recourse was had (it appears) rather to soothsayers, near or distant, than to any regularly constituted authority or tribunal. On the other hand we are furnished with a list of officials who were concerned with different parts of the festal performances and the ordinary worship. Of these we may mention the Custodian of the Ka’ba, and the official whose duty was sīgīyah (“watering”), said to mean furnishing the pilgrims with water,
but more ingeniously interpreted in recent times as "rain-bringing," a function which even in the 2nd century of Islam the governor in some places was supposed to exercise.

Of Arabian paganism we possess no trustworthy or complete account; since we hear of no theological literature belonging to it, probably no such account could have been given.

There were doubtless a variety of practices, many of which have been continued to this day in the ceremonies of the pilgrimage, and offerings of different sorts to various deities, interpreted variously by the worshippers in accordance with their spiritual, intellectual and moral levels; e.g. as actual stones, or as men (or more often women) residing in the stones or otherwise connected with them, or bearing a similar relation to trees, or stars, &c. In every general tribe there had its patron of the kind, and where there were aggregations of tribes, connexions were established between these deities, and affiliation-theories e. associated; hence the theory attributed in the Koran to the Meccans that the goddesses al-Uzza, &c. were the daughters of Allah, may well represent the outcome of such speculation. These, however, were known to few, whereas the practices were familiar to all. Some of these were harmless, others barbarous; many offensive, but not very reprehensible, superstitions.

Before Mahomet's time Arabian paganism had already been attacked both from the outside and from the inside. On the one hand the northern tribes had gradually been christianized, owing to the influence of the Byzantine empire; on the other hand south Arabia had fallen successively under Jewish, Abyssinian and Persian influence; and the last, though little is known of Persian rule, is unlikely to have favoured pagan cults. Christianity had also some important representation in Najran far south of Mecca, while Jewish settlements were prospering north of Mecca in the Prophet's future home Yathrib and its neighbourhood. Power, civilization and learning were thus associated with monotheism (Judaism), dualism (Mazdaism) and tritheism (as the Arabs interpreted Christianity); paganism was the religion of ignorance (jahlilyyah, interpreted by Goldzaher as "barbarism," but the difference is not very considerable). Mecca itself and the neighbouring and allied Taif are said to have produced some monotheists or Christians, who identified the Allah of Mecca with the Allah or God of the Syrian Christians, called by the Abyssinian Christians "Lord of the Regions," and by the Jews "the Merciful" (Rabmâna); one such is said to have been a cousin of Khadija, Mahomet's wife; his name is given as Waraqa, son of Naufal, and he is credited with copying or translating a Gospel. We even hear of flagellant monks and persons vowed to total abstention among the precursors of Islam.

With these persons Mahomet had little in common, since they do not appear to have claimed to enforce their views upon others, or to have interfered with politics. He appears mainly to have been struck by the personality of the founders of the systems dominant in the civilized world, and to have aspired from the first to occupy the place of legislator or mouthpiece of the Deity; and that he was this was and is the main proposition of the Mahomedan creed. The "Prophet" or "Apostle" (at different times he employed both the Jewish and the Christian phrase) was the divinely appointed dictator of his community; if he were not obeyed, divine vengeance would overtake the disobedient.

This is the theory of the prophet's office which pervades the Koran, which is the holy book of Islam and formulated that the prophet had its divine guide and that Mecca before Mahomet's time had none. This place, then, Mahomet felt a divine call to fill. But we are never likely to ascertain what first put the idea into his mind. The fables which his biographers tell on this subject are not worth repeating; his own system, in which he is brought into direct communication with the Deity, though at a later period the angel Gabriel appears to have acted as intermediary, naturally leaves no room for such speculations; and since his dispensation was thought to be absolutely new, and to make a tabula rasa of the pagan doctrines, having broken with that past, left no intelligible account of the state of affairs which preceded their master's call. Some generations therefore elapsed before that past was studied with any sort of sympathy, and details could not then be recovered, any more than they can now be supplied by conjecture.

So far as Mahomet may be said from the first to have formulated a definite notion of his work, we should probably be right in thinking it to be the restoration of the religion of Abraham, or (as the Koran calls him) Ibrahim. Though we have no reason to suppose the name of Abraham or Ishmael to have been known in Mecca generally before Mahomet's time, the Biblical ethnology was not apparently questioned by those who were told of it, and there are stories, not necessarily apocryphal, of precursors of Mahomet going abroad in search of the "religion of Abraham." One feature of that system, associated in the Bible with the name of Ishmael as well, was circumcision, which was actually observed by the Meccan tribes, though it would appear with technical differences from the Jewish method; the association of monotheism with it would seem reasonable enough, in view of Jewish Maxims, such as Mahomet's, that he supposed on his travels; why the doctrine of the future life should be coupled with it is less obvious. That the Meccan temple and its rites had been founded by these two patriarchs appears to have been deduced by Mahomet himself, but perhaps at a later stage of his career. That these rites, so far as they were idolatrous, were in flagrant defiance of the religion of Abraham must have struck any one who accepted the accounts of it which were current among Jews and Christians. The precursors, however, appear to have felt no call to reform their fellow-citizens; whereas it is evident that Mahomet regarded himself as charged with a message, which he was bound to deliver, and which his God would in some way render effective.

As it was obvious that the claim to be God's mouthpiece was to claim autocracy, Mahomet employed the utmost caution in his mode of asserting this claim; on the question of his sincerity there have been different opinions held, and it is not necessary to take any view on this matter. For three years his followers were a secret society; and this period appears to have been preceded by one of private preparation, the first revelation being received when the Prophet was in religious retirement—a ceremony called talqammut, of which the meaning is uncertain, but which can have no connexion with the Hebrew tekinnith ("supplications")—on Mount Hîrâ, near Mecca.

If the traditional dates assigned to the suras (chapters) of the Koran (q.v.) are correct, the earliest revelations took the form of pages or rolls on which the Prophet was to read by the "grace of God," as Joseph Smith, the founder of the Mormon community, said of the power given him to read the "Egyptian" characters on the gold plates which he had found. The command to read is accompanied by the statement that "his most generous Lord had taught man by the pen (calamus) that which he did not know." Waraqa, to whom the event is said to have been communicated by Khadija, called these communications "the Greater Law (nomos)." The Prophet was directed to communicate his mission at the first only to his nearest relatives. The utterances were from the first in a sort of rhyme, such as is said to have been employed for solemn matter in general, e.g. oracles or prayers. At an early period the production of a written communication was abandoned for oral communication, which was delivered by the Prophet in trance; their delivery was preceded by copious perspiration, for which the Prophet prepared (in accordance with instructions found in the Koran)
by wrapping himself in a blanket. Trusty followers were instructed to take these utterances down, but the phenomena which accompanied their delivery at least in one case suggested imposition to the scribe, who apostatized in consequence. It is extraordinary that there is no reason to suppose that any official record was ever kept of these revelations; the Prophet treated them as critical as he did his dreams. This carelessness is equally astounding whether the Prophet was sincere or insincere.

If the matter afterwards collected in the Koran be genuine, the early revelations must have been miscellaneous in content, magical, historical and homiletic. To some strange oaths are prefixed. Apparently the purpose to be compassed was to convince the audience of their miraculous origin. The formulation of doctrines belongs to a later period and that of jurisprudence to the latest of all. In that later period, when Mahomet was despot of Medina, the Koran served as an official chronicle, well compared by Sprenger to the leading articles on current events in a ministerial organ. Where the continuous paragraph is substituted for the ejaculation, the divine authority apologizes for the style.

Certain doctrines and practices (e.g. washing of the person and the garments) must have been enjoined from the first, but our authorities scarcely give us any clear notion what they were. The doctrines to which the Prophet himself throughout assigned most value seem to have been the unity of God and the future life, or resurrection of the body. The former necessitated the abandonment of the idolatrous worship which formed part of the daily life of Mecca, and in which Mahomet and Khadija had been accustomed to take their part. Yet it seems to have been due to the initiative of the proselytes themselves rather than to the Prophet's orders that the Meccan worship was actually flouted by them; for the anecdote which represents the Prophet and his young cousin attempting to pull down the images in or about the Ka'ba appears to be apocryphal. The first Moslem ceremony which appears to have been the religious purpose of the delivery of revelations, of which after the Prophet's death the sermon (khutbah) took the place. After various provisional meeting-places, the house of one al-Arqam on Mt. Safa was adopted for this purpose; and here proselytes were initiated.

The names which the new community received from its founder are both philological puzzles; for the natural sense of the Early Mohammedanism Moslem (Muslim) appear to be "traitors," and to Mohammed's a contemporary war-song of Mahomet's enemies (the so-called "Hawf" especially applied in the Koran to Abraham) seems to be the Hebrew word for "hypocrite." The former is explained in the Koran to mean "one who hands over his face or person to God," and is said to have been invented by Abraham; of the latter no explanation is given, but it seems to signify from the context "devotee." Since the divine name Râhman was at one time favoured by Mahomet, and this was connected with one Masmala of the tribe Hanîfa, who figures in politics at the end of Mahomet's career but must have been a religious leader far earlier, it has been suggested that the names originally belonged to Masmala's community. The honour of having been Mahomet's first convert is claimed for three persons: his wife Khadija, his cousin Ali, who must have been a lad at the commencement of the mission, and Abû Bekr, son of Abû Qubâfah, afterwards Mahomet's first successor. This last person became Mahomet's alter ego, and is usually known as the Šiddiq (Heb. word signifying "the saint," but to the Arabs meaning "faithful friend"). His loyalty from first to last was absolutely unswerving; he was selected to accompany Mahomet on the occasion of his life, the Flight from Mecca; Mahomet is said to have declared that had he ever made a confidant of any one, that person would have been Abû Bekr; implying that there were things which were not confided even to him. The success of the Prophet's enterprise seems to have been very largely due to the part played by this adherent, who possessed a variety of attainments which he put at Mahomet's service; who when an intermediary was required was always ready to represent him, and who placed the commendation of the Prophet above every other consideration, private or public. The two appear to have regularly lacked siege to those persons in Mecca whose adherence was desirable; and the ability which many of the earlier converts afterwards displayed, whether as statesmen or generals, is a notable testimony to their power of governing men. It seems clear that the growth of the community had led to the accentuation of the difference between persons of different station, and that many were discontented with the oligarchy which governed the city. Conversals could, therefore, be won without serious difficulty among the aliens and in general those who suffered under various disqualifications. Some members of the Jewish community seem also to have joined; and some relics of the Abyssinian expedition (i.e. descendants of the invaders). Among the most important converts of the A.D. period were Mahomet's uncle Hamza, afterwards for his value called "the Lion of God"; Abû al-Rahman (Abdarrahman) son of 'Auf; Othman, son of 'Affân, who married two of the Prophet's daughters successively, and was Mahomet's third successor; and, more important than any save Abû Bekr, Omar, son of al-Khattâb, a man of extraordinary force of character, to whom siege seems to have been laid with extraordinary skill. At some time he received the honourable title Fârîq ("Deliverer"); he is represented as regularly favouring force, where Abû Bekr favoured gentle methods; unlike Abû Bekr, his loyalty was not always above suspicion. His adherence is described to the period of publicity.

The secrecy which marked its early years was of the greatest value for the eventual success of the mission; for when Mahomet came forward publicly he was already the head of a band of united followers. His own family appear to have been either firm adherents, or violent enemies, or lukewarm and temporizing —this is the best which can be said for 'Abbas, eponymus of the Abbasid dynasty; or finally espousers of his cause, on family grounds, but not as believers.

The first period of Mahomet's first appearance as a public preacher, which are evidently comments on a text of the Koran, we have reason for supposing that his hand was forced by ardent followers, who many times in his career compelled him to advance. The astute rulers of the community perceived that the claim made by Mahomet was to be dictator or autocrat; and while this was naturally ridiculed by them, some appear to have been devoted adherents of the gods or goddesses whom he attacked. The absence of dated documents for the period between this open proclamation (which in any case commenced before Gî and the Flight to Medina in 622 renders the course of events somewhat conjectural, though certain details appear to be well established. Apparently there was a war of words, followed by a resort to diplomacy and then to force; and then a period in which Mahomet's attention was directed to foreign conversions, resulting in his being offered and accepting the dictatorship of Yathrib.

Of the war of words we have an imperfect record in the Meccan suras of the Koran, which occasionally state the objections urged by the opponents. In the course of the debate the theological position of both parties seems to have shifted, and the knowledge of both was probably increased in various ways. The miracle of the Koran, which at first consisted in its mode of production, was transformed into a marvel connected with its contents; first by Mahomet's claiming to tell historical narratives which had previously been unknown to him; afterwards by the assertion that the united efforts of mankind and Jim would be unable to match the smallest passage of the Koran in sublimity. Probably the first of these claims could not be long maintained, though the latter has been utilized by the Mahometan sects in our own time brought a similar one in regard to his Principles of Nature. Indeed both parties evidently resorted to external aid. To those who undertook to name the man who dictated stories of the ancients to Mahomet day and night, he replied that the individual whom they had in mind was a foreigner, whereas the Koran was in pure Arabic. This was obviously a quibble, for it was scarcely asserted that he delivered the matter dictated to him without
alteration. The purity of the Arabic also appears to have been very questionable; for several expressions appear to be Ethiopic rather than Arabic, and the person whom the Meccans had in mind is likely to have been an Abyssinian Christian, since the Christian technicalities of the Koran are mainly derived from the Ethiopic Gospels and Acts. On one occasion when some questions suggested by learned foreigners had been propounded to the Prophet he required a fortnight's delay before the revelations which solved them came; the matter contained in his reply was certainly such as required research. His sources of information seem at all times to have been legendary rather than canonical; and the community which seemed to his opponents to agree best with his views was that of the Sabians or Mandaeans (qq.v.).

It has been suggested that Mahomet first threatened the Meccans with temporal punishment, and only when this threat failed to take effect resorted to the terrors of the Day of Judgment and the tortures of Hell; it seems however a mistake to distinguish between the two. These threats provided the Prophet with his most powerful sermons. The boasts of incomparable eloquence which the Koran contains are evidence that his oratorical power was effective with his audiences, since the more successful among the Arabic poets talk of their compositions somewhat in the same way. These discourses certainly led to occasional conversions, perhaps more frequently among women than men.

The diplomatic war seems to have been due to the Prophet's increasing success, which led to serious persecution of Mahomet's less influential followers, though, as has been seen, no blood could be shed in Mecca. Abū Ta'llīb, moreover, prevented him from being exiled, though he probably had to endure many personal insults. Something however had to be done for the persecuted Moslems, and (perhaps at the suggestion of his Abyssinian helper) Mahomet endeavoured to find a refuge for them in the realm of Axum. Abyssinia was doubtless connected in every Meccan mind with the "Expedition of the Elephant"; and such an alliance secured by Mahomet was a menace to the existence of the Meccan community. A deputation was therefore sent by the Meccan leaders to demand extradition of the exiles; and as chief of this expedition the future conqueror of Egypt, 'Amr b. al-Âṣ (see 'AMR ibn EL-ÂS), first figures in history. To frustrate his efforts Mahomet sent his cousin Ja'far armed with an exposition of the Prophet's beliefs and doctrines afterwards embodied in the Koran as the Sura of Mary (No. XIX.; though with the addition of some anti-Christian matter). The original document contained an account of the Nativity of Christ with various miracles not known to either the canonical or even the apocryphal gospels which have been preserved, but which would have been edifying rather than unorthodox by a church one of whose most popular books is The Miracles of the Virgin Mary. To this were added the Meccan Koran verses, of which the Old Testament prophets. The Abyssinian king and his ecclesiastical advisers took the side of Mahomet and his followers, whom they appear to have regarded as persecuted Christians; and an attempt made probably by the astute 'Amr to embroil them with the Abyssinians on the difficult question of the Natures of Christ failed completely. There seems reason for thinking that the Abyssinian king contemplated bringing back the exiles by force, but was diverted from this purpose by frontier wars; meanwhile they were safely harboured, though they seemed to have suffered from extreme poverty. The want of an Abyssinian chronicle for this period is a serious disadvantage for the study of Islamic origins. The sequel shows that regular correspondence went on between the exiles and those who remained in Mecca, whence the former were retained within the fold of Islam, with occasional though rare apostasies to Christianity.

Mahomet's diplomatic victory roused the Meccan leaders to fury, and they decided on the most vigorous measures to which they could rise; Abū Ta'llīb, Mahomet's protector, and the clan whom he acknowledged him as sheikh, including the Prophet and his family, were blockaded in the quarter which they occupied; and in other sanctuaries, though blood might not be shed, a culprit might be starved to death. That this did not occur, though the siege appears to have lasted some months at least, was due to the weak good nature of the Meccans, but doubtless also to the fact that there were enlisted on Mahomet's side many of great physical strength and courage (as their subsequent careers proved), who could with impunity defy the Meccan embargo. After a time however the besieged found the situation intolerable, and any assistance which they might have expected from the king of Axum failed to come. The course adopted by Mahomet was that of apologetic utterances which he had most offended the Meccans, involving something like a return to paganism. A revelation came acknowledging the effectiveness of the Meccan goddesses as well as Allah, and the Meccans raised the siege. News of the reconciliation reached the Abyssinian exiles and they proceeded to return.

By the time they reached the Arabian coast the dispute had recommenced. The revelation was discovered to be a fabrication of the Devil, who, it appears, regularly interpolates in prophetic revelations; such at least is the apology preserved in the Koran, whence the fabricated verses have been expunged. Since our knowledge of this episode (regarded as the most disgraceful in the Prophet's career) is fragmentary, we can only guess that the Prophet's hand had once more been forced by the more earnest of his followers, for whom any compromise with paganism was impossible. The exiles went back to Abyssinia; and about this time both Abū Ta'llīb and Khadija died, leaving the Prophet unprotected.

He fled to the neighbouring oasis of Ta'if, where wealthy Meccans had possessions, and where the goddess al-Âzza was worshipped with special zeal—where she is said still to exist in the form of a block of stone. He had but little success there in proselytizing, and indeed had to cease preaching; but he opened negotiations with various Meccan magnates for a promise of protection in case of his return. This was at last obtained with difficulty from one Mo'tîm b. 'Adî. It would appear that his efforts were now confined to preaching to the strangers who assembled at or near Mecca for the ceremonies connected with the feast. He received in consequence some invitations to come and expound his views away from Mecca, but had to wait some time before one came of a sort which he could wisely accept.

The situation which led to Mahomet's Flight (bīja, anglicized incorrectly heijra, q.s.) was singularly favourable to Mahomet's enterprise, and utilized by him with extraordinary caution and skill. At the palm plantation called Yathrib, afterwards known as al-Medîna, Medina, "the City" (i.e. of the Prophet), there were various tribes, the two most important, called Aus and Khazraj, being pagan, and engaged in an internecine feud, while under their protection there were certain Jewish tribes, whose names have come down to us in the form of a block of stone. He had but little success there in proselytizing, and indeed had to cease preaching. The prophecy of the Prophet, who therefore wrote a letter to the Jewish sheikhs residing in the city of Yathrib, where the Jewish exiles had settled, inviting them to come and take up their residence, was fulfilled in what might be expected, imitated the totum nomenclature of their neighbours. The memory of these Israelites is exclusively preserved by the Moslem records; the main stream of Jewish history flowed elsewhere. In the series of combats between the Aus and Khazraj the former had generally been Worst; the Jews, as usual, had avoided taking any active part in the fray. Finally, owing to an act of gross perfidy, they were compelled to fight in aid of the Aus; and in the so-called battle of Bu'ath the Aus aided by the Jews had won a victory, doubtless attributed to the God of the Jews. As has been seen, the divine name employed by Mahomet (Râhîmân) was one familiar to the Jews; and the Yathribiotes who visited Mecca at feast-time were naturally attracted by a professed representative of al-Râmân. The first Yathribite converts appear to have been Khazrajites, and one Asʹâid, son of Zurarah, is the most prominent figure. Their idea may have been in the first place to secure the aid of the Israeliish Deity in their next battle with the Aus, and indeed the primary object of their visit to Mecca is said to have been to request assistance for their war. For this they were substituted of inviting the Prophet to come to Mecca as dictator, to heal the feud and restore order, a procedure to which Greek antiquity offers parallels. The new converts were told to carry on secret propaganda in Yathrib with this end in view. At the next feast
some of the rival faction embraced Islam. A trusty follower of Mahomet, Mus‘ab b. ‘Umar, who resembled Mahomet in personal appearance, was sent to Yathrib to assist in the work. The correspondence between this person and the Prophet would, if we possessed it, be of the greatest value for the study of Islamic antiquity. We first hear at this time of the conditions of Islam, i.e., a series of undertakings into which the convert entered: namely, to abstain from adultery, theft, infanticide and lying, and to obey Mahomet in licitis et honestis. The wholesale conversion of Yathrib was determined by that of two chiefains, Usaid b. Huraith and Sa‘d b. Mu‘adh, both Ausites. The example of these was quickly followed, and iconoclasm became rife in the place. At the next Meccan feast a deputation of seventy Yathribites brought Mahomet a formal invitation, which he accepted, after imposing certain conditions. The interviews between Mahomet and the Yathribites are known as the ‘Aqabah (probably with reference to a text of the Koran). The attitude of the Jews towards the project appears to have been favourable.

Among the conditions imposed by Mahomet on his new adherents appears to have been the protection and harbouring of the older proselytes, whom Mahomet most wisely determined to send before to Yathrib, where, in the event of the Yathribite loyalty wavering, they could be counted on with certainty. The welcome given these refugees (maḥājīrin), as they were from this time known in contradistinction to the helpers (ānṣār) or allies from Yathrib, is said to have been of the warmest; a Helper with two wives would hand one over to a wiser Refugee to take over, and on condition which preceded the Flight was readiness to fight men of all colours in defence of the faith.

Although the transactions with the people of Yathrib had been carried on with profound secrecy, the nature of Mahomet’s contract with his new adherents was somewhat divulged to the Meccan magnates, and the danger of allowing an imparable enemy to establish himself on the high-road of their north-bound earavans flashed upon them. *The rule which forbade bloodshed in the sacred city had at last to be suspended; but elaborate precautions were to be taken whereby every tribe (except Mahomet’s own clan) should have their share in the guilt, which would thus be spread over the whole community fairly.* When the committee appointed to perpetrate the crime reached Mahomet’s house, they found that it was too late; Mahomet had already departed, leaving Ali in his bed.

The actual Flight from Mecca to Yathrib has naturally been a favourite subject for romance, and indeed appears to have been executed with the greatest cunning. Accompanied by Abū Bekr only, Mahomet took refuge in a cave of Mt Thaur, in the opposite direction to that which he intended to take initially, and there remained for three days; provision had been made of every requisite, food, powerful camels, a trusty and competent guide. The date at which he reached Kuba, on the outskirts of Yathrib, where there was already some sort of Moslem oratory, is given as 8 Rabi‘ I., of the year A.H. 1; the fact that he arrived there on the Jewish Day of Atonement gives us the date September 20, 622. The Meccans, who had employed professional trackers to hunt down the fugitives, proceeded to confiscate the houses and goods of those who had known him, and of his converts.

The safe arrival of Mahomet at his destination marks the turning-point in his career, which now became one of almost unbroken success; his intellectual superiority over both friends and enemies enabling him to profit by defeat little less than by victory. His policy appears to have been to bind his followers to himself and to each other by every possible tie; he instituted brotherhoods between the Refugees and Helpers, which were to count as relationships for legal purposes, and having himself no sons, he contracted numerous marriages partly with the same end in view; e.g., with the infant daughter of Abū Bekr, Ayesha (‘A’ishah), whose ability he appears to have discerned; and the unmarried Hafsa, daughter of Omar. Of his own daughters three were given to faithful allies, the one by whom his line is supposed to have been continued to our time, Fāṭima, was reserved for his cousin Ali. Owing to his efforts the alliance between the Refugees and Helpers resisted numerous attempts on the part of enemies to break it up, and only towards the end of the Prophet’s life, when he appeared to favour Meccans unduly, do we hear of any bitterness between the two communities.

The population of Yathrib, or, as it may now be called, Medina, soon divided into three groups: Mahomet’s united followers; the Jews; and a party known as the ‘Hypocrites’, i.e. professing Moslems, who were lukewarm, or disaffected, among whom the most prominent is ‘Abdallah b. Uhayy, a Khazrajite chieflain, who is said to have himself aspired to be despot of Yathrib, and who till nearly the end of Mahomet’s career figures somewhat as a leader of the opposition; of his importance there is no question, but the reason for it and the mode whereby he made it felt are often obscure. It would seem that the pagans remaining in Yathrib speedily adopted Islam after the Prophet’s arrival, whence we hear little of serious opposition on their part. Coming in the capacity of prophet of the Israelitish God, Mahomet at first seems to have courted alliance with the Jews, and to have been ready to adopt their system with very slight modifications—similar to those which, according to his opinion, Jesus had come to introduce. The Jews met these advances by submitting him to examination in the intricacies of the Torah, and, finding him very poorly equipped, proceeded to denounced him as an impostor; one of his examiners is said to have even translated the Torah into Arabic with a view of convicting him of ignorance and imposture. They are further charged with exercising their magical arts over the Prophet and his followers, and to have succeeded thereby in producing barreness among the Moslem women. Their conduct must not of course be judged by the statement of their enemies; it is however clear that Mahomet soon found that there was no possibility of compromising with them on religious questions, or of obtaining their loyal support; meanwhile he discovered that they were incapable of united and persistent action, and useless as warriors except against each other. He therefore resolved on their extermination. His ruthlessness in their case compared with his patience and forbearance in the case of the ‘Hypocrites’ was consistent with his principle (always faithfully observed) that no inquiry was permissible into the motives of conversion, and with his division of mankind into the two antagonistic factions Believers and Unbelievers. The latter principle, as will be seen, was somewhat modified before the end of his life.

Mahomet’s failure to effect a compromise with the Jews caused a reaction in his mind towards paganism, and after about a year’s residence at Medina the direction of prayer, called the Development of Islam, turned southward to the pagan temple at Mecca.

With this change we may perhaps couple the adoption of the name Allah for the Diety; in the Moslem formula in the Name of Allah the Rāḥmān the Merciful," the translation attached to the word Ṣubḥān, and the prefixing to it of the name Allah furnish clear evidence of theological transition, though the stages are not recorded; we know, however, that the Meccans approved of the name Allāh, but objected to the name Rāḥmān. Prayer (‘Az-zahur) and the ceremonies of pilgrimage were so arranged by Mahomet that the Christian ascetics might be called madādīn or mūzāzīn) was preferred to the Christian transition of other hammer; a new sacred day was adopted, in lieu of the Jewish Saturday and the Christian Sunday, in the weekday on which he had safely reached Kuba, Friday; but the sanctity was reduced to the actual time occupied by public worship. On the subject of food he was satisfied with the regulations of the Council of
Jerusalem, recorded in Acts xv.; which were observed by few if any Christian sects. The prohibition of wine, which was enacted in A. H. 3, is said to have been occasioned by the riotous conduct of one of his followers when under the influence of liquor; Palgrave saw in it (perhaps with justice) a deliberate attempt to prevent harmony between Moslems and Christians, in whose most sacred rite wine is used. The Fast of Ramadān, in which food both liquid and solid is forbidden from sunrise to sunset, is said to be a pagan or semi-pagan institution; its importance for military training and discipline is not likely to have been overlooked by the Prophet. When the direction of prayer was altered, it is probable that Mahomet already intended to introduce into his system the whole of the pagan pilgrimage with its antique ceremonial (with, of course, a new interpretation); before this he is supposed to have aimed at the abolition of the Ka‘ba and all that appertained to it.

The difference between religious and civil law has never been recognized by Islamic jurists, whose manuals deal equally with the law of contract and the amount of the body to be washed before prayer; the Prophet’s ordinances on both subjects were suggested by the occasion in each case, and their importance; whilst the opinions of trusted advisers were regularly heard before a revelation was issued. Even when this had been done the ordinance might be cancelled by an abrogating revelation; it being “easy for Allah” to substitute for a text already revealed another that was better or at least as good.

As Islam began to spread outside the limits of Medina both conversion to Islam and persistence therein were reduced to simple tests; the pronunciation of the double formula of belief in Allah and Mahomet was sufficient to indicate conversion, whilst payment of an income-tax, called by the Jewish names for alms (ṣabāl and ṣadāqāt), was evidence of loyalty. This income-tax, of which the definite assessment perhaps belongs to a later period, was for the sake of necessary co-operants—an element in the community whose presence accounts for the mode in which the development of the Islamic state proceeded.

The industries in which the Meccan Refugees who had been engaged were not of a sort which they could exercise at Medina, where the palm took the place of the camel as the basis of society. Moreover the Prophet seems to have given some disastrous advice on the subject of palmiculture, and thereby to have accentuated the poverty of the place. He had, therefore, to find some fresh source of revenue in order to deal with this difficulty, and one of the Helpers is said to have suggested the plan which he adopted, viz. of attacking the Meccan caravans. With this view he organized a series of expeditions, taking the lead himself sometimes, while at other times he gave it to one of his veteran followers; and at first only Refugees took part in them. The leaders of the caravans, however, were expert in evading attacks of this sort, which were doubtless regularly attempted by the desert tribes; and in the first year of his despotism Mahomet did not score a single success of the kind intended. The attempts were not wholly fruitless; for while on the one hand he accustomed his followers to campaigning, on the other he made a series of agreements with the chieftains of the tribes through whose territory the caravans ordinarily passed. Finding continued failure intolerable, he resolved to take advantage of his power to bind and to loose by sending an expedition of seven men under his cousin ‘Abdallah b. Jaʃb to attack a caravan at the beginning of the sacred month Rajab, when, as raiding during such a season was unknown, success was practically certain. The commander on this, the Nakhlah raid, was given sealed orders, to be opened after two days’ march; the men were then to be given the option of retiring, if they disapproved. Of this no one seems definitely to have availed himself, and the raid ended successfully, for considerable booty was captured, while of the four persons who escorted the caravan two were made prisoners, one escaped, and one, ‘Amr b. al-Ḥādrī, was killed; he was the first person slain fighting against an Islamic force. The violation of the sacred month seems to have caused considerable scandal in Arabia, but led to no serious consequence; on the other hand the shedding of blood created a feud between the people of Mecca and the Refugees, with whom the Meccans long declined to identify the people of Medina. The fact that the man who had been killed was a client, not a citizen, made no difference. The circumstance that booty had been actually acquired appears to have helped the Prophet’s cause very considerably.

Both these consequences, the Meccan desire to avenge the blood that had been shed and the anxiety of the Medineans to take part in a successful raid, manifested themselves a few months later, when an expedition was organized by Mahomet to attack a caravan returning from Syria, which had escaped him the previous year. Many desired to take part in the raid, and finally some 300 persons were selected, including a large number of “Helpers.” The leader of the caravan learned somehow that an attack was being organized by Mahomet on a large scale, and sent to Mecca for aid, while hurrying home by forced marches. This is the first historical appearance of Abū Sofān (the leader of the caravan), who now for some years played the part of president in the Meccan opposition to Mahomet, and whose son was destined to found the second Islamic dynasty (see above, p. 17). There a day before the battle to be fought at Badr, near the point where the northern road leaves the coast to turn eastwards to Mecca, the Moslem army learned that the Meccan succour (some 1000 strong) was near, but that the caravan had escaped. The Meccans, it is asserted, would have returned home now that their object was secured, but the patrons of the man who had been killed in the former raid were compelled to strike for vengeance.

The battle (Ramadān 19, A. H. 2, usually made to synchronize with March 17, 624) ended in a complete victory for Mahomet, whose followers killed seventy of the enemy and took seventy prisoners—if we may trust what seem to be round numbers; it was attributed by him to divine co-operation, taking the form of an illusion wrought on the enemy, and the despatch of a regiment of angels to the assistance of the Believers, while on the other hand the treachery of the Devil did mischief to the Meccans. The popular tradition attributed it to the prowess of some of Mahomet’s followers, especially his uncle ʿIṣāma and his cousin Ali. In the narratives which have come down and which seem to be authentic the result is amply accounted for by the excellence of the Moslem discipline and the complete absence of any on the Meccan side. Mahomet himself is said to have fainted at the first sight of blood, and to have remained during the battle in a hut built for him to which swift camels were tied, to be used in case of a defeat; yet these accounts make him responsible for the tactics, whilst assigning the credit for the strategy to one Hobab b. al-Mundhir. Several of Mahomet’s old enemies and friends of Meccan days perished on this occasion; notably one Abu Jahl, his uncle, but represented as an implacable enemy; another hostile uncle, Abu Labah, who is cursed in the Koran, was not present but died shortly after the battle.

The day is called in the Koran by a Syriac expression the “Day of Deliverance,” and both for internal and external politics it was of incalculable advantage to Islam. The booty and the ransoms of the prisoners provided the means for dealing with distress; the story of supernatural aid soothed the feelings of the defeated Meccans and had a tendency to disarm resistance elsewhere; whilst Mahomet in the popularity acquired by his victory was able to strike forcibly at his enemies in Medina. One of the sequels to the victory was a series of assassinations whereby critics of his actions were removed.

The defeat at Badr naturally led to efforts on the part of the Meccans to avenge their dead and besides to secure the commerce, by which they lived, from an enemy who was gradually getting all the seaboard that lay between Jeddah and Yanbo within his sphere of influence; and the year after Badr (A. H. 3) Abū Sofān was able to lead a force said to be three times as great as that which had been defeated, and so numbering some 3000 men, against Medina itself; part of it was under Khalīl b. al-Walid, one of the greatest of Arab captains, afterwards conqueror of Syria. It is said that Mahomet’s plan was to remain in Medina itself, and leave it to the
MAHOMET

Meccan commander to discover some way of taking the place; but that his hand was forced by his more ardent followers. Others, however, assign this advice to Abdallah b. Ubayy, and make the Prophet anxious to fight from the first. A battle was in consequence fought under Mt Uhud (or Ohod), north-west of Medina, wherein Khālid succeeded in inflicting a severe defeat on Mahomet's forces; his uncle Ḥamza, hero of Badr, was killed on this occasion. Fortunately for the Moslems, the Meccans considered that they had finished their task when they discovered that they had killed a number of the former equal to those who had fallen at Badr on their own side; instead therefore of pursuing their victory they went home. The immediate effect on Arabia appears to have been to dissipate the illusion that the Prophet could count on supernatural assistance in his wars; and we hear of some blows being dealt him from outside. Meanwhile his relations towards the Medinean Jews had grown more and more hostile, and these are credited with doing their best to rouse the Meccans to a sense of the danger which threatened them in the continuance of the Prophet's power, and in general to stir up hostility against him in Arabia. Whether this part was played by them or not, in the fifth year of the Prophet's stay at Medina a fresh invasion of the territory took place by a vast confederate force of Meccans with their allies, the tribes Fazarah, Asad, Murrah, &c., to the number, it is said, of 10,000. This time the intention of the leaders was undoubtedly to stamp out Islam. For the first time in Arab warfare Mahomet resorted to the expedient of defending his city by a trench, called by a Persian name, and suggested by a Persian convert. But he also employed agents to sow dissension among the confederates, and succeeded with this no less than with the other expedient. After a brief stay, and scarcely striking a blow, the confederacy dispersed, leaving the Jews who still remained in Medina to the summary vengeance of the Prophet. The want of records written from the Meccan standpoint renders the abortiveness of this last attempt at storming the Prophet's stronghold scarcely intelligible.

From this time, however, the road towards the eventual taking of Mecca became easy, and we are told that such was the importance attached to that city throughout Arabia that its acquisition meant for the Prophet the acquisition of the whole peninsula. The next year (a.h. 6) he deemed it advisable to make a truce with the Meccans (the Truce of Ḥūdālīyah), whereby he secured for his followers the right of performing the pilgrimage in the following year; on this occasion he even consented to forgo his title "Prophet of Allah," when the Meccans refused to sign a deed in which it was employed, greatly to the scandal of his more earnest followers, including Omar; they were however too deeply committed to Islam to be able to defy the Prophet. When the pilgrimage was performed (a.h. 7), Mahomet not only won important converts in the persons of Khālid and the no less able 'Amr b. al-'Āṣ, but in general impressed the population with the idea that his was the winning side. An excuse was easily found for invading Mecca itself in the following year, when Abū Sofān took the opportunity of embracing Islam before it was too late. Very little resistance was now made by the Meccans, whose chiefs were already in Mahomet's camp, and Mahomet used his victory with great moderation; his proscription list was finally reduced to two. The theory that all offences were cancelled by conversion was loyalty observed. Moreover the Prophet incurred the displeasure of his Medinean friends by the anxiety which he displayed to soothe the feelings of his former enemies and antagonists. The Medinean, however, prevailed upon him to maintain their city as his political capital, while making Mecca the religious centre of his system; and this arrangement accounts perhaps more than anything else for the persistence of the system amid so many dynastic changes.

At the main he appears to have introduced little alteration into the government of Mecca, and it is said that he even declined to retaliate on those who had confiscated the possessions of the Refugees. Even the Ka'ba was left in the keeping of its former custodian, though of course its interior as well as its precincts were cleansed of all that could offend monotheists. In the following year the pilgrimage was for the first time conducted by a Moslem official, Abū Bekr. A proclamation was made on that occasion, forbidding idolaters in future to take part in the pilgrimage, and giving all Arabs who were not as yet converted four months' grace before force was to be brought to bear upon them. In the following year Mahomet conducted the Pilgrimage himself. This solemn occasion (the "Farewell Pilgrimage") was also employed for the delivery of an important proclamation, wherein the Prophet declared that God had completed their religion. The principle whereon he specifically insisted was the brotherhood of Islam; but there is some difficulty in enunciating the original sermon from later additions.

It would seem that Mahomet's enterprise originally comprised the conversion of Mecca only, and that he thought of himself as sent to his fellow-citizens only, as had been the case with earlier prophets, whose message was for their brethren." His views took a somewhat different direction after his brief exile to Йa'il, and the conquest of Arabia was in a way forced upon him in the course of his struggle with the Meccans. It is not indeed perfectly clear by what process he arrived at the resolution to exclude paganism from Arabia; at first he appears to have tolerated it at Medina, and in some of his earlier contracts with neighbouring tribes he is represented as allowing it, though some of our texts make him reserve to himself the right of enforcing Islam if he chose; only the Meccans were at first, according to the most authentic documents, excluded from all truce or treaty. At the battle of Badr he appears to have formulated the rule that no one might fight on his side who had not embraced Islam and when once he had won fame as a successful campaigner, those who wished to share his adventures had to pass the Islamic test. After the battle of Uhud (Ohod) we hear of a tribe demanding missionaries to instruct them in Islamic principles; and though in the case recorded the demand was treacherous, the idea of sending missionaries appears not to have been unfamiliar even then, albeit the number sent (70), if rightly recorded, implies that the Prophet suspected the good faith of the applicants. After the taking of Mecca, whereby the chief sanctuary at any rate of north Arabia had been cleared of all idolatrous associations, and consecrated to monotheism, paganism in general was conscious of being attacked; and the city had scarcely been brought under the new régime before the Prophet had to face a confederation of tribes called Hawāzin and Thaqīf. The battle which ensued, known as the Day of Honain, was near ending disastrously for Islam; some of Mahomet's stoutest followers fieb; but the terrible danger of a defeat in the neighbourhood of recently conquered Mecca roused the Prophet and Allī to heroism, and they saved the day. Emissaries were now sent far and wide demanding admission to the new religion and to perform the hajj with any considerable resistance; against this place for the first time the Prophet made use of siege artillery, such as was employed by the Byzantines; though compelled by the bravery of the inhabitants to raise the siege, he was afterwards able to take the city by capitulation. It has been observed that here only do we read of much attachment to the old deities; in most places they were discarded with few regrets when once their impotence had been found out. After the taking of Mecca and the victory of Honain there appears to have been a general desire, extending even to the extreme south of Arabia, to make the best terms with the conqueror so soon as possible; iconoclasm became general. Flatterers of various kinds, including poets, came to seek the favour of the sovereign; and a mock war of words appears to have been substituted by some tribes for more serious fighting, to terminate in surrender. For warfare of his sort Mahomet had a powerful helper in the poet Ḥassān b. Thābit, for whose effusions a pulpit was erected in the Medina mosque, and whose verses were said to be inspired by the Holy Spirit; though has been seen, Mahomet was not himself able to judge of their artistic merit. It was not, however, found easy to enforce the payment of the alms on these new converts; and this taxation caused an almost general revolt so soon as Mahomet's death had been ascertained.
Although the central portions of the peninsula in Mahomet's time were practically independent, large portions of the north-west and south-east were provinces of the Byzantine and Persian empires respectively, whence any scheme for the conquest of Arabia would necessarily involve the conqueror in war with these great powers. The conquest of Persia is said to have been contemplated by the Prophet as early as A.H. 5, when the famous Trench was being dug; but it was not till the year A.H. 9, on the eve of the taking of Mecca, that the Prophet conceived the idea of sending missives to all known sovereigns and potentates, promising them safety if, but only if, they embraced Islam. The text of these letters, which only varied in the name of the person addressed, is preserved (doubtless faithfully) by the Moslem Oral Tradition; in the middle of the last century a French explorer professed to discover in Egypt the original of one of them—addressed to the mysterious personage called the Muqgaquis (Mukawkas) of Egypt—and this, it appears, is still preserved amid other supposed relics of the Prophet in Constantinople, though there is little reason for believing it to be genuine. The anecdotes dealing with the reception of these letters by their addressees are all fabulous in character. Two appear to have sent favourable replies: the king of Axum, who now could send the exiles whom he had so long harboured to their successful master; and the Egyptian governor, who sent Mahomet a valuable present, including two Coptic women for his harem. The emperor Heraclius is claimed as a secret convert to Islam, on whom pressure had to be put by his advisers to conceal his convictions. The Persian king is said to have sent orders to have Mahomet arrested; his messengers arrived in Medina, but were unable to carry out the commands of their master, who died while they were there. Two of the letters are said to have had important results. One was addressed to the Himyarite chiefs (called by the south Arabian appellation ga'il) in Yemen, and effected their conversion; another to the governor of Bostra in Roman Arabia, who put the bearer of this insolent message to death; a force was despatched by Mahomet immediately afterwards (beginning of A.H. 8) to avenge this outrage; and though the Moslems were defeated in their first encounter with the Byzantine forces at Mutah, they appear to have had a good account of themselves; it was here that Jafar, cousin of the Prophet, met his death. In A.H. 9 a successful expedition was led by the Prophet himself northward, in which, though no Byzantine force was encountered, a considerable region was withdrawn from the Byzantine sphere of influence, and made either Islamic or tributary to Islam. At the time of his death (of fever, after a short illness) he was organizing an expedition for the conquest of Syria.

The Prophet claimed throughout that his revelation confirmed the Jewish and Christian Scriptures, and this claim is on the Jewish and Christian Whole reasonable, though his acquaintance with both Communities was in the highest degree vague and inaccurate. Still he reproduced the Old Testament as faithfully as he could, and though he patriotically endeavours to shed some lustre on his supposed ancestor Ishmael, he does not appear to have questioned the Biblical theory according to which the founder of the north Arabian nations was the son of a slave girl. On neither the truth of the Biblical history and miracles nor the validity of the Mosaic legislation does he appear to have cast any doubt. He even allows that Israel was the chosen people. The Gospel was known to him chiefly through apocryphal and heretical sources, which cannot certainly be identified; but he accepted the doctrine of the Virgin-birth, the miracles of healing the sick and raising the dead, and the ascension; the crucifixion and resurrection were clearly denied by the sect from whom he had received his information, and rejected by him, though certainly not because of any miracle that the latter involved. His quarrel with the Jews at Medina appears to have been by no means of his own seeking, but to have arisen unavoidably, owing to his particular view of his office being such as they could not accept; and his attempt to discredit, not the Mosaic Law, but the form in which they presented it, was an expedient to which he resorted in self-defence. An attempt was made shortly after his arrival at Medina to settle the relations between the two communities by a treaty, according to which, while their equality was guaranteed there should be little interference between the two; this, however, was found unworkable, and each victory of Mahomet over the Meccans was followed by violent measures against the Medinean Israelites. When experience had shown him their military incompetence he appears to have been unable to resist the temptation to appropriate their goods for the benefit of his followers; and his attack on the flourishing Jewish settlement of Khaibar, after the affair of Hjodabiyah, appears to have been practically unprovoked, and designed to satisfy his discontented adherents by an accession of plunder. Yet the consciousness that this process was economically wasteful suggested to him an idea which Islamic states are only now abandoning, viz. that of a tolerated caste, who should till the soil and provide sustenance for the Believers who were to be the fighting caste. Whereas their former plan in dealing with Israelites had been to banish or massacre, he now left the former owners of Khaibar (who had survived the capture of the place) in possession of the soil, of whose produce they were to pay a fixed proportion to the Islamic state. The same principle was adopted in the case of later conquests of Jewish settlements.

Disputes with Christians occur somewhat later in the Prophet's career than those with Jews, for neither at Mecca nor Medina were the former to be found in any numbers; individuals are likely to have been found in both cities, and we hear of one Medinean "Abu'Amir the Monk," who after Mahomet's arrival at Medina branded him as an impostor, and, going himself into exile, made many an abortive attempt to discredit and injure Mahomet's cause. The notices of him are meagre and obscure. Mahomet's manifesto to the world, about the time of the taking of Khaibar, appears to represent his definite breach with Christianity; and when in the "year of the embassies" the Christians of Najran sent a deputation to him, they found that the breach between the two systems was not to be healed. Of the three alternatives open to them—conversion, internecine war, and tribute, they chose the last. The Christian tribes of north Arabia showed greater inclination towards the first. The Prophet's policy was to give Christians lighter terms than Jews, and though the Koran reflects the gradual adoption by the Prophet of a system of extreme hostility to both systems, its tone is on the whole far more friendly to the former than to the latter. Some other communities are mentioned in the Koran, but merely in casual allusions: thus we know that Mahomet's sympathy was with the Byzantines in their struggle with Persia, but in his most tolerant utterance the Magians or Mazdians as well as the Sabians (with whom his followers were identified by the Meccans) are mentioned with respect.

The political and social requirements of Mahomet's state were of the simplest kind, for there is no trace of any form of governmental department having been instituted by him, even when he was master of the peninsula; nor can we find in any permanent officials in his employ except his muwaddhis Bilal, and perhaps his court-poet Hassân. A staff of scribes was finally required both to take down his revelations and to conduct correspondence; but although he encouraged the acquisition of penmanship (indeed some of the prisoners at Badr are said to have been allowed to ransom themselves by teaching it to the Medinees), we know of no regular secretaries in his time. He had a body of experts, whose functions were those of legislator, administrator, general and judge; his duties in the last three capacities were occasionally delegated to others, as when he appointed a governor of Medina during his absence, or leaders for expeditions, with provision for successors in case of their falling, but we hear of no permanent or regular delegation of them. Till near the end of his career at Medina he maintained the principle that migration to that city was a condition of conversion; but when, owing to the extension of his power, this was no longer practicable, his plan was in the main to leave the newly-conquered communities to manage their internal affairs as before, only sending occasional envoys to discharge special duties, especially instruction in the Koran and
the principles of Islam, and to collect the Alms; quite towards the end of his life he appears to have sent persons to the provinces to act as judges, with instructions to judge according to the Koran, and where that failed, the practice (summa), i.e. the practice of the community, for which a later generation substituted the practice of the Prophet. There were, therefore, no regular payments to permanent officials, and the revenue which developed into an income-tax, but was at first a demand for voluntary contributions, was wholly for the support of the poor Moslems; it might not be used for the maintenance of the state, i.e. Mahomet and his family. For them, and for public business, e.g. the purchase of war material and gratuities to visitors, provision was made out of the booty, of which Mahomet claimed one-fifth (the chieftain's share had previously, we are told, been one-fourth), while the remainder—or at least the bulk of it—was distributed among the fighting men; the Prophet appears to have prided himself on the justice of his distribution on these occasions, and doubtless won popularity thereby, though we hear occasionally of grumbling: for difficulties occurred when a defeated tribe embraced Islam, and so could claim equality with their conquerors, or when portions of the spoil were irregularly employed by Mahomet to allay resentment; the persons whose allegiance was thus purchased were euphemistically termed "those whose hearts were united." What afterwards proved the main source of revenue in Islamic states dates from the taking of Khaybar; for the rent paid to the state by tolerated communities for the right to work their land developed long after Mahomet's time into a poll-tax for Unbelievers (see Caliphate, e.g. B. § 8 and Mahomedan Institutions), and a land-tax for all owners of land. Immediately after the taking of Khaybar certain communities, of which the most notable was Fadak, sent tribute before they had been attacked and reduced; their land was regarded by Mahomet as his private domain, but after his death it was withdrawn from his heirs by his successor Abu Bekr, in virtue of a maxim that nothing left no inheritance, which in the opinion of Fadak was contrary to Koranic doctrine, and invented by Ayeshah's father expressly for the purpose of excluding her and her husband from their rights; and this is likely to have been the case. As a military organizer Mahomet, as has been seen, was anxious to adopt the most advanced of contemporary methods, and more than once is said to have scandalized the Arabs by foreign innovations, as at a later time the Moslem chiefs who first used gunpowder scandalized their co-religionists. The attitude of the Prophet to the law, as of all other matters under its natural leader; that he introduced no more scientific division, and nothing like a hierarchy of officers was perhaps due to the difficulty of reconciling such a system with the equality of all Moslems. As has been seen, the Koran only assumed the character of a civil code as the need for one arose; and for some time after Mahomet's arrival at Medina old-fashioned methods of settling disputes continued in use, and doubtless in accordance with precedent where such was known. For difficult cases, even in Arab opinion, divine inspiration was required; and since Mahomet naturally claimed to be in sole enjoyment of this, his utterances soon became the unique source of law, though he did not at first think of organizing a code. Such a plan is said to have occurred to him, and he even wished to dictate a code upon his death-bed; but his friends supposed or professed to suppose him to be delirious. A table regulating the "Alms" was left by him, it is said, in the possession of Abu Bekr; but other traditions assign another origin to this document.

Payments to permanent or regular officials for the arrangement of business, so there were none for its execution; when punishment was to be administered, any follower of Mahomet might be called upon to administer it. In the case of the massacre of the Bani Quraysh care was taken to see that some of the heads were struck off by their former allies, in order that the latter might be unable at any time to bring a demand for vengeance. The Prophet hoped by the mere terror of his name to make complete security reign throughout Arabia, and there is no evidence that any system of policing either it or even Medina occurred to him. Until the death of Khadija the Prophet's private life seems to have been normal and happy, for though the loss of his sons in infancy is said to have earned him a contemptuous epithet, he was fond in his adoption of Abu Bakr, a Harithah, apparently a prisoner ransomed by Khadija or one of her friends, who appears as dutiful almost to excess and competent in affairs. The marriages of his daughters seem all to have been happy, with, curiously enough, the exception of the first, Zainab; the Prophet's domestic troubles, to which an unreasonable amount of space seems to have been devoted, even in the Koran, began after the Migration, when, probably in the main for political reasons, he instituted a royal marriage of his daughter Fatimah, which, if it was not always, at least in the beginning, a source of comfort, soon became a source of trouble, and possibly of scandal, to himself and his family. The marriage of his daughter to the replant of Medina, Abu Bakr, before the latter's conversion, we can see a combination of the two. Few, therefore, of these marriages occasioned scandal; yet public morality seemed to be violated when the Prophet took to himself the wife of his adopted son Zaid, whose name has in consequence the honour of mention in the Koran in the revelation which was delivered in defence of this purpose, according to this, to establish the difference between adulterous and regular relations. Serious trouble was occasioned by a charge of adultery brought against the youthful favourite Ayeshah, and this had to be refuted by the Prophet in a revelation, which is only authenticated by Ali, seems to have been connected with some deeper scheme for causing disunion between the Prophet and his friends. Yet another revelation is concerned with a mutiny in the harem organized by Omar: daughter of the Prophet's Coptic concubine (Mary, mother of a son called Ibrahim, who died in infancy; his death was marked by an eclipse, January 27, 632); and various details of factions within the harem are told us by Mahomet's biographers.

Of the members of this harem the only prominent one is Ayeshah, married to the Prophet shortly after the Flight, when she had scarcely passed the period of infancy, but who appears to have been gifted with astuteness and ambition that were quite beyond her years, and who maintained her ascendancy over the Prophet in spite of the fact that her cunning and sagacity often carried her beyond him.

Some of this may have been due to the obligations (including customary obligations) under which her father had laid Mahomet; but her reputation seems to have been greatly enhanced by the sending down of a revelation to exonerate her (A.H. 6), for which she thanked God and not the Prophet. Each accession to the harem rendered the building of a house or room necessary for the newcomer's accommodation; a fact in which Robertson Smith perhaps rightly saw a role of the elder system whereby the tent was the property of women. The trouble noticed above seems to have arisen from the want of a similar arrangement in the case of slave girls, with whom Mahomet's system permits cohabitation. When Mahomet, whether to conceal the influence of the fatigue incurred by the "Farewell Pilgrimage," or, as others thought, by the working of some poison put into his food some years before his assassination, was attacked by the illness which seems to have been the end of his life, it was to the latter that the hand of a rival (from that of another wife) was transferred; and he apparently died in the arms of the favourite, on whose statements we have to rely for what we know of his death.

The traditional description of Mahomet is of middle height, greyish, with hair that was neither straight nor curly; with a large head, large eyes, heavy eyelashes, reddish tint in the eyes, thick-bearded, broad-shouldered, with thick hands and feet"; he was in the habit of giving violent expression to the emotions of anger and mirth. The supposition that he at any time suffered from physical weakness seems absolutely refuted by his career as a leader of difficult, dangerous and wearisome expeditions, from his migration to Medina until his death; indeed, during his last years he exhibited a capacity for both physical activity and intellectual stimulation. When Mahomet, whether to conceal the influence of the fatigue incurred by the "Farewell Pilgrimage," or, as others thought, by the working of some poison put into his food some years before his assassination, was attacked by the illness which seems to have been the end of his life, it was to the latter that the hand of a rival (from that of another wife) was transferred; and he apparently died in the arms of the favourite, on whose statements we have to rely for what we know of his death.

The literary matter ascribed to the Prophet consists of (1) the Koran (q.v.); (2) certain contracts, letters and receipts preserved by his biographers; (3) the number of sayings (hadith) collected by traditionalists. The references in the Koran to a form of literature called "Wisdom" (zikahab) suggest that even in the Prophet's time some attempts had been made to collect or at least record some of the most important or the most prolix traditions and the length of time which elapsed before any critical treatment of it was attempted, and the variety of causes, creditable and discreditable, which led to the wilful fabrication of prophetic utterances.
render the use to which No. 3 can be put very limited. Thus the
lengthy description of the journey to heaven which Sprenger was
induced to recite was intended, as he believed, to discredit Islam; it
is very much to be regretted that the number of 

\[\text{footnotes} \]

fabrication. The "condition of Islam" whereby adultery was

\[\text{footnotes} \]

forbid is said to have been ridiculed at the time, on the ground that
this practice had never been approved. Yet it would seem that
certain forms of promiscuity had been tolerated, though the
subject is obscure. Against these services we must set the
abrogation of some valuable practices. His unfortunate

\[\text{footnotes} \]

by the calendar of twelve lunar months, bearing no relation to the
seasons, was introduced, was in any
case a retrograde step; but it appears to have been
connected with the abrogation of the sanctity of the four months
during which raiding had been forbidden in Arabia, which, as
has been seen, he was the first to violate. He also, as has
noticed, permitted himself a slight amount of bloodshed in
Mecca itself, and that city perhaps never quite recovered its
sacrosanct character. Of more serious consequences for the
development of the community was his encouragement of the
shedding of kindred blood in the cause of Islam; the consequences
of this act of savagery to the practice of the full
great length of time. His assassinations of enemies were afterwards
rendered as precedents in books of Tradition. No less unfortunate
was the recognition of the principle whereby atonement could be
made for oaths. On the question how far the exclusion of
women was enjoined or countenanced by him different views
have been held.

Besides the contemporary documents enumerated above (Koranic
texts, pious myths and saints' traditions) many of the events of
his life were celebrated by poets, whose verses were ostensibly in
Sources, incorporated in the standard biography of Ibn Iṣḥāq; in
the abridgment of that biography which we possess many of these
are recorded as spurious, indeed, what we know of the procedure
of those who professed to collect early poetry gives us little confidence
in the genuineness of such odes. A few, however, seem to stand
out as authentic, and the diwan (or collection of poems) attributed to Hassan
b. Thabit is ordinarily regarded as his. Though they rarely
detail descriptions of events, their attribution is at times of
value, e.g. for the story that the bodies of the slain at Badr were cast by the
Prophet into a pit. By and large, the narratives of important events, or of those
who had actually taken part in them,
were eagerly sought by the second generation, and some of these were
attached to works written well before the end of the 1st century.
The practice instituted by the second Caliph, of assigning pensions
proportioned to the length of time in which the recipient had been
a member of the Islamic community, led to the compilation of certain
rolls intended to obtain the accumulated wealth of the
only from the commencement of the mission, and for the
detailed sequence after the Flight, which presently became an era (beginning with
the first month of the year in which the Flight took place). The pro-

\[\text{footnotes} \]

thing to this sort of must have been done—is unknown, and is unlikely
to have been scientific.

Mahomet's conduct being made the standard of right and wrong,
there was little temptation to "whitewash" him, although the
original biography by Ibn Iṣḥāq appears to have contained

\[\text{footnotes} \]

in the introduction of miraculous narrations; these therefore either
belong to the obscure period of his life or can be easily eliminated; thus the
narratives of the Meccan council at which the assassination of
Mahomet was decided, of the battles of Badr, Uhud and Honain,
and the death of Sa'd b. Mu'ādh, would lose nothing by the omission
of the details. Here, however, a certain amount of overlap and
confusion is inevitable; the very small extent to which this expectation is justified
is a remarkable testimony to their general truthworthiness.

RELATIVES OF THE PROPHET

1. Family of 'Abd al-Majīdī, Mahomet's maternal grandfather—

| 636  | July 7. Death of Mahomet. 

The following dates are given by the Arabic historians according to their own calendar. For the reasons which have been seen it is impossible to obtain certain synchronism.

**Companions of the Prophet.** The saḥābah, as they are called, are the subject of a vast literature, and the biographical dictionaries devoted to them, of which the best known are the Usul at-shāhā of the historian Ibn Ṭāhffī and the Isbāhān of Ibn Ḥajar al-Ṣayghāni, enumerate many thousands. The following two lists are of special groups.

Dates are given a.d.

---

**Malaham Ahmed Ibn Seyyid Abdullah** (1848-1885), Sudanesan tyrant, known as the "Mahdi," was born in Dongola. His family, known as excellent boat-builders, claimed to be Ashraf (or Sheriff), i.e., descendants of Mahomet. His father was a fikr or religious teacher, and Mahomet Ahmed devoted himself early to religious studies. When about twenty years old he went to live on Abba Island on the White Nile about 150 m. above Khartum. He first acquired fame by a quarrel with the brother of his first wife, and then went to Khartum, avowing that his master condoned the transgression of the divine law. After this incident many derelvies (religious mendicants) gathered round the young sheikh, whose reputation for sanctity speedily grew. He travelled secretly through Kordofan, where (with ample justification) he denounced to the villagers the extortion of the tax-gatherer and told of the coming of the mahdi who should deliver them from the oppressor. He also wrote a
sufficing to the genuine believers to purify their religion from the defilements of the "Turks" i.e. the Egyptian officials and all non-native inhabitants of the Sudan. The influence he gained at length aroused the anxiety of the authorities, and in May 1881 a certain Saub Saud, a notorious scoundrel, was sent to Abba Island to bring the sheikh to Khartum. Abba Saud's mission failed, and Mahommed Ahmed no longer hesitated to call himself al-Mahdi al-Montasir, "The Expected Guide." In August he defeated another force sent to Abba Island to arrest him, but thereafter deemed it prudent to retire to Jebel Gedir, in the Nuba country south of Kordofan, where he was soon at the head of a powerful force; and 6000 Egyptian troops under Yusuf Pasha, advancing from Fashoda, were nearly annihilated in June 1882. By the end of 1882 the whole of the Sudan south of Khartum was in rebellion, with the exception of the Bahr-el-Ghazal and the Equatorial Provinces. In January 1883 El Obeid, the capital of Kordofan, was captured. In the November following Hicks Pasha's force of 10,000 men was destroyed at Kashgil, and in the same year the mahdi's lieutenant, Osman Digna, raised the tribes in the eastern Sudan, and besieged Sinkat and Tokar, near Suakin, routing General Valentine Baker's force of 2500 men at El Teb in February 1884. The operations undertaken by Great Britain in face of this state of affairs are narrated under EGYPT: Military Operations. It need only be added that General Gordon (q.v.) was besieged at Khartum by the mahdi and was killed there when the town was captured by the mahdists on the 25th-26th of January 1885. The mahdi himself died at Omdurman (June 22, 1885), and was succeeded in power by his khalfa Abdullah.

When he announced his divine mission Mahommed Ahmed adopted the Shi'ite traditions concerning the mahdi, and thus put himself in opposition to the sultan of Turkey as the only true commander of the faithful. To emphasize his position, the mahdi struck coins in his own name and set himself to suppress all customs introduced by the Turks. His social and religious reforms were contained in various proclamations, one of which is drawn up in the form of ten commandments. They concern, chiefly, such matters as ritual, prayers, soberness in food and raiment, the cost of marriage and the behaviour of women. How far the mahdi was the controller of the movement which he started cannot be known, but from the outset of his public career his right-hand man was a Baggara tribesman named Abdallah (the khalfa), who became his successor, and after his flight to Jebel Gedir the mahdi was largely dependent for his support on Baggara sheikhs, who gratified one of his leading tastes by giving him numbers of their young women. In the few months before the fall of Khartum and his death the mahdi, relieved from the incessant strain of toil, copied in his private life all the vices of Oriental despots while maintaining in public the austerity he demanded of his followers. His death is variously attributed to disease and to poisoning by a woman of his harem. On the occupation of Omdurman by the British (Sept. 1898) the mahdi's tomb was destroyed, his body burnt and the ashes thrown into the Nile (see SUDAN: Anglo-Egyptian).

See MAHOMMEDAN INSTITUTIONS. Of all the institutions of Islam the caliphate is the oldest, the most fundamental, and in essence the most enduring. For its history see CALIPHRATE; the present subject is its origin and nature. Mahomet enjoyed absolute rule over his people as a divinely inspired and guided prophet. He led the public prayers; he acted as judge; he ruled. If he consulted with others or paid attention to public feeling or local usage, it was as a matter of policy; the ultimate decision lay with himself. He was the state. On his death a leader was put in place of similar authority, though without the divine prophetic guidance. He was called the "successor" (khilifa, caliph) of the Prophet, later also the amir-al-mu'minin, commander of the faithful, and was elected by the Moslems, just as the Arab tribes had always elected their chiefs. He was thus an absolute ruler, but was democratically elected; and such is the essence of the caliphate among Sunnite Moslems to this day. For them it has been a matter of continuous argument (see MAHOMMEDAN DIVISIONS). The Caliphate. It must be a free theory that the Moslem community must appoint such a leader (see IMLM). The Shi'ites, on the other hand, hold that the appointment lies with God, and that God always has appointed, though his appointment may not always have been known and accepted.

Their position may be called a legitimist one. Some few heretical sects have held that the necessity of a leader was based on reason, not on the agreement of the community. But, for all, the rule of the leader thus appointed is absolute, and all authority is delegated from him and, in theory, can be resumé at any time. Thus God can require unreasoning obedience from his creatures (his "slaves" in Arabic), so can the caliph, his representative on earth.

But Abu Bekr, the first caliph, nominated his successor, Omar, and that nomination was accepted and confirmed by the people. So a second precedent was fixed, which was again carried a step further, when Moawiyah I., the first Omayyad caliph, nominated his son, Yazid I., as his successor, and caused an oath of allegiance to be taken to him. The hereditary principle was thus introduced, though some relires of the form of election persisted and still persist. The true election possible in the early days of the small community at Medina became first a formal acceptance by the populace of the capital; then an assertion, by the palace guard, of their power; and now, in the investiture of the sultans of the Ottoman Turks, who claim the caliphate, a formal ceremony by the 'ulema (q.v.) of Constantinople. The Ottoman claim is based on an asserted nomination by the last Abbasid, who died in exile in Egypt in 1358, of the Ottoman sultan, Suleiman the Great, as his successor. Such a nomination in itself was a perfectly legal act, but in this case had a fatal flaw. It is an absolute condition, laid down in tradition, that the caliph must be of the tribe of Kureish (Qurais), that of the Prophet.

The duties of this democratically elected autocrat are, in theory, generally stated as follows. He shall enforce legal decisions and maintain the divinely revealed restrictive ordinances; guard the territories and equip armies; receive the alms; put down robberies, thieving, highwaymen; maintain the Friday services and the festivals; decide disputes and receive evidence bearing on legal claims; marry minors, male and female, who have not guardians; decide custody cases; be free, male, adult Moslem; must have administrative ability; must be an effective governor and do justice to the wronged. So long as he fulfils these conditions he is to be absolutely obeyed; private immorality or even tyranny are not grounds for deposing him. This is a position reached by Islam practically. But a caliph who openly denied the faith would be as impossible as an unbelieving pope. The caliph, therefore, is the highest executive officer of a system assumed to be definite and fixed. He, in a word, administers Islam; and the content of Islam is determined not by the laws of the caliphate but by the Quran and the Sunna, the sayings and actions of Muhammad. He is an office bearing divine guidance, and yet that office is filled by man. The men are chosen by other men, and the caliph is a man, however holy he be. It is necessary, therefore, in the caliphate, for the 'ulema, and ultimately, if indirectly and half-consciously, by the people. To depose him a fatwâ (see MUIFF) would be required—in Turkey from the Sheik-ul-Islam—that he had violated some essential of the Moslem faith, and no longer fulfilled the conditions of a caliph.

But it was impossible for the caliph personally to administer the affairs of the empire, and by degrees the supreme office was split into the chief and vice-chancellor, which eventually became a mere figurehead, and vanished into the sacred seclusion of his palace. The history of the creation of government bureaux (diwan; see DIWAN) must therefore now be sketched. The first need which appeared was that of a means of regulating and administering the system of taxation and the revenues of the state. Immense sums flowed into Medina from the Arab conquests; the surplus, after the requirements of the state were met, was distributed among the believers.
All Moslems had a right to a certain share of this, which was regarded as booty. Omar, the second caliph, regulated this distribution and also the system of taxation, and the result was the first diwan and the constitution of Omar, looked back to now by all Sunnite Moslems as an ideal. The sources of revenue were, (i) the land-tax (jizya); (ii) the fifth of all booty; (iii) the poll-tax (jizya) on non-Moslems; and (iv) the land-tax (kharāj) also on non-Moslems. Thus the constitution determined the conditions under which the Moslems were to conduct their own affairs, and the fact that the Moslems should be kept apart as a superior, fighting caste, and that the non-Moslems should support them (cf. CALIPHATE, B. § 8, on the reign of Omar II.). The Moslems, therefore, were for long subject to an independent administration. They must retain their lands, cultivate them and pay the land-tax (the Arabic word is also used revenue from the work of a slave) and the third word means “rendering of contributions in kind to support the local Moslem garrisons which were massed in great camp-cities at strategic points. If a non-Moslem embraced Islam he entered the ruling caste; his land was divided among the new converts. The farmland, the unearned wealth and the simple life—called by Moslems the period of the "four rightly guided caliphs," and very happily by Sachau, ein münchisches Imperium—passed rapidly into the genuinely Arab empire of the Omeyyads, with whom came an immediate development of organization in the state. The constructive genius in this was Moawiya, the first Omeyyad caliph. Under him the old simple officials of the court were augmented at Damascus. A chamberlain kept the door; a bodyguard surrounded the caliph, and even in the mosque the caliph, warned by the murder of Othman and of Ali, prayed in a railed-off enclosure. The leading officials of the court and who had come to longer walked familiarly among his fellow Moslems. This seclusion increased still further when the administration of the state passed by delegation into other hands, and the caliph himself became a sacrosanct figure-head, as in the case of the later Abbasids; when the theories of semi-divine nature and of theocratic rule appeared, as in the case of the Fatimids; and finally when all the elaborate court ritual of Byzantium was inherited by the Ottoman sultans.

But Moawiya I. was still a very direct and personal ruler. He developed a post-system for the carrying of government despatches by relays, and thus received secret information from and kept quiet contact with the governors established by him. The caliphate was by then an independent bureau by which state papers were received against change. He dealt arbitrarily with the revenues of the state and the penions of the old conquerors, of course, as it was his own to give or to withhold, and were required to turn over to the central treasury their surplus revenue only. As they were either conquerors or direct successors of conquerors they had an essentially military government. The ruler was the prime minister, the vizier—of whom later; he had complete control. He exercised direct action of the caliph, acting on information sent by the postmaster, who was his local spy. Being thus the heads of armies of occupation, they were not necessary charged with the control of religious ritual and or justice. These, like every other function, in held in the office of the caliph and he generally appointed in each province independent calids over the courts and imams to be in charge. The vizier was sometimes permitted to hold these two offices (see CADIF; IMAM).

Further administrative developments came with the Abbasids. They created a new city, Bagdad, between the Tigris and the Euphrates, where the three races, Syrian, Arab and Persian, met and sought with Bagdad as a capital to consolidate the empire. This enterprise, however, had not the success of the Abbasids; yet there might be a chance to create a world-empire of all the Moslem peoples. But not even the genius and administrative skill of the early Abbasids could hold together that unwieldy mass. The semi-independent provinces soon became fully independent, or at most acknowledged the caliph as a spiritual head and paid a nominal tribute. His name might stand on the coinage and prayers be offered for him in the Friday service, the two signs of sovereignty to this day in Islam. With this crumbling of the empire went a more elaborate organization; bureaux took the place of principles and of the energy of individual rulers. As the system of Moslem law was built on that of the Roman codes, so was the machinery of administration on that of the imperial Roman. When the Abbasids the chance of the Moslems had come. Abü ʿl-ʿAbbās, the first Abbasid caliph, was the first to appoint a vizier (wazir, "helper," so Aaron is the wazir to Moses in the Koran), a confidential minister to advise him and come between him and the people. Advisers the caliphs had had before; but not a definite adviser with this name. He must, we are told, have a strain of the roller in him and a strain of the people to be able to work with both. He must know how to be acceptable; fidelity and truthfulness are his capital; sagacity, firmness, generosity, clemency, dignity, effect. Thus the office of the vizier was created, and the vizier became as important as the caliph. But Abü ʿl-ʿAbbās was also in early securing as his vizier the grandfather of the house of the Barmecides (q.v.). On this Persian family the fortunes of the Abbasids hung, and it secured for them and for Islam a short golden age, like that of the Antonines, until the jealous madness of Harūn al-Rashid cast them down. Thereafter the vizierate had many vicissitudes. Technically a vizier could be either limited or unlimited. The limited vizier had no initiative; he carried out the commands of the caliph. The unlimited vizier, with the power to act independent of the caliph or even in opposition to him, had the power of the caliphate in his hands, and was the alter ego of the caliph, to whom he was only required to report. Naturally the formal distinction is a later theorizing of history; for a weak ruler his vizier became absolute, for a strong ruler his vizier remained subordinate. Here, as with regard to all Moslem institutions, a marked distinction must be made between the historic facts and the speculative edifices raised by constitutional theorists. Compare especially MAHOMMEDAN LAW. Until the time of Rādī (934-946) the vizierate thus fluctuated in importance. In that caliphate the vizier lost all authority, and in his place came the amir al-āmār—equivalent to the major domus of the Franks—the head of the Turkish bodyguard, in terror of whom the caliph now stood. When in 945 the Büyids captured Bagdad and the caliph became a purely spiritual sovereign, they took the title of "vizier" for their own chief minister, and the viziers retained only a secretary (see CALIPHATE, C. § 22). Under the Seljuks, however, they regained their viziers and some real authority. Elsewhere, also the vizierate had its vicissitudes. Under the Mamuteke the vizier fell to the one of the vizierate officials of the state, but their chief was called ṭajib, chamberlain. Under the Almohades the chamberlain was called vizier. In the modern Turkish empire the grand vizier (called generally sadr 'āsem) is the sultan's representative in secular matters, and nominally stands between the sovereign and all the other officials. He is the president of the council of ministers, but Abū-ul Hamid II. deprived the office of almost all its importance.

Under the early Abbasids the four most important ministers were the chief cadi, the chief of police or head of the life guard, the minister of finance and the postmaster, who was the head of the system of information and espionage which covered the empire. But at different times the different al-amir bureaux varied greatly. Under Motawakkil we find the bureau of taxes and finance; bureau of the crown estates; bureau of state book-keeping; bureau of war, i.e., of hired troops; bureau which kept records and control of the pensions of the clients and slaves of the ruling family; bureau of the post system; bureau of expenditures. But in spite of this elaborate system, no Moslem government has, except in purely highly centralized states, provided the taxes are paid, a large measure of local autonomy has always been enjoyed by the country districts. Under the Abbasids the except monopoly was the necessarily centralized control over the information system of the Tigris and Euphrates. And similarly elsewhere.

In the case of all these offices, we have delegation by the caliph, under need, of too heavy burdens. But once, as an Oriental ruler he could not do this. It is always to be possible for the oppressed to come into his presence and claim justice; he must sit in the gate and judge. Therefore, when the caliph found cases to the point, he was forced, in order that to he not find it necessary to set up a special court of oppressions, which developed, to a certain extent, into a court of appeals. The first to establish such a separate court was Abidal-malik the Omayyad
(685-705), and his example was followed by the more vigorous of the caliphs up to the time of Mohtadi the Abbasid (689-780). If any other than the caliph presided over this court it had to be a man whether Moslem or not, as a delegated representative of the caliph, and was not bound by strict rules of evidence, method and literal application of law as was the cadi. Rather, he applied a system of equity suited to the absolute source of authority which he represented. As already mentioned above, was rather the head of the caliph’s bodyguard, there was also a police system after our ideas, but more thoroughgoing. The mukhasib had charge in the broadest sense of the fiscal laws, and authority to assess the wages and salaries of public officials. Nothing was bought or sold without the prayer of the cadi. Slaves and beasts of burden were under his guardianship; he prevented public scandals, such as the sale of wine; he regulated the public uses of Jewish, Christian, and Moslem houses of morals, he had to find suitable husbands for widows and see that they did not marry before the legal time; questions of paternity also he had to investigate. The outdoor costume of the people he could regulate. It should, of course, be remembered that the canon law of Islam covers minutely all sides of life (see MAHOMMEDAN LAW).

It is impossible in Islam to separate logically from the mass of institutions those which we should call religious as Islam on all hands is a religion equal in importance to law. But perhaps the following may practically be separated under that rubric. Islam, runs a tradition, is built on five things: testimony that there is no god save Allah, and that Mahomet is the apostle of Allah; prayer; the poor-rate; pilgrimage; fasting. For these see MAHOMMEDAN RELIGION.

The law and usage of religious foundations in perpetuity (waqf, mortmain) became as important in Islam as monastic endowments in medieval Europe, and such foundations tended similarly to absorb the greater part of the national wealth. It was the only safe way of providing for posterity. A pious foundation could be erected in such a way that either so much from the income would be paid in perpetuity to the descendants of the creator, or those descendants would be employed as officials of the foundation. When it became impossible for the caliph to lead the people in the mosque, the mosque was expected to lead the people in their religious duties to another, hence called imam (q.v.). Naturally, then, the appointment of the imam would lie with the supreme ruler. This holds of the daily prayers in the principal mosque (al-masjid al-jami’) supported by the ruler where the Friday service is held, but in the separate smaller mosques built by each community the community chooses its own imam. With regard to the Friday service, the schools of law disagree as to the necessity of the presence of an imam appointed by the chief ruler. But the imam should certainly make mention of the ruler in his sermon and pray for him. At the occasional prayers, such as those for rain, etc., the imam should be appointed by the ruler; if this is not necessary, the ruler appoints the muaddhin, the announcer of the hour of prayer from the minaret, and both have a claim on the state treasury.

The cadi. One of the callings that are most frequently delegated to some high dignitary, such as the heir to the caliphate or a prince, was the leadership of the pilgrimage caravan to Mecca and back. Sometimes this official, called amir al-bajjil, was appointed imam as well. He then led all the pilgrimage ceremonies at Mecca. When outside of town where there was a cadi he exercised also over the caravan the rights of a judge.

Mahometan law (q.v.) is treated separately. Here, again, as judging is a duty of the caliph, a cadi is the delegate, or, when appointed by a vizier or governor, a delegate of his delegate. He examines into disputes brought before him and enforces his judgments, he names the judges of the courts of minors, the imane, etc.; he supervises the waqf property of mosques and schools in his district and inspects highways and public buildings; he has the right of the ‘imam’ by which he inflicts the due-due of wills; he is the overseer of the poor-rate, of charitable foundations, and the suppression of rebellion within. Under the caliph, Omar. Under Omar the entire community was preserved and used as a weapon for the spreading of the Moslem faith. It was divided into corps situated in the conquered lands, as armies of occupation, where they eventually came to form military colonies in great camp-cities. The occupied countries had to support them, and they were bound to render military service at any time. But as the ideal of Omar broke down before facts the use of mercenary and slave troops finally increased; although there has always continued in Moslem armies acting against unbelievers a proportion of volunteers not paid a fixed wage but subsidized by the state from the poor-rate and alms funds. The generals were appointed by the caliph, and had either unlimited authority to act as his representatives, concluding peace, acting as cadi and imam, distributing booty; or were restricted within limits, e.g. to simple leading of the troops and carrying on military operations. They, in turn, appointed their subordinates; this principle of giving a head full powers and full responsibility was very generally applied in Islam. It was controlled of course by the espionage of the postal system. As war by a Moslem power is essentially sacred war, the regulations of jihad must be considered here. Unbelievers must first be invited to embrace Islam and, if they follow a sacred book and are not idol-worshippers, are given a choice between (a) becoming Moslems; or (b) submitting to the Moslems and entering on a treaty with them of protection and tribute; or (c) fighting. If they accept Islam, their lives, families and property are secure, and they and their posterity are part of the Moslem community. The ability of Islam to create a common feeling between highly different races is one of its most striking features. If they submit and enter on treaty relations, they pay a poll-tax, for which their personal safety is assured, and assume a definitely inferior status, having no technical citizenship in the state, only the position of protection (ziyarat). These terms are that they will fight, the door of repentance is open, even when the armies are face to face. But after defeat their lives are forfeit, their families are liable to slavery, and all their goods to seizure. It is open to the sovereign either to put them to death; or to enslave them; or to give them their liberty; or to exchange them for ransom or against Moslem prisoners. The sovereign will choose which is best for Islam. As for their families and wealth, the sovereign can release them only with consent of the army that has captured them. The majority are put to death. Four-fifths of the booty after a battle goes to the conquering army.

The technical art of war seems to have been little studied among Moslems; they have treaties on archery but very little upon tactics. Their writers recognize, however, the essential difference between the European and Persian methods of charging in solid lines and holding the ground stubbornly, and the Arab and Berber method of flying attacks and retreats by clouds of cavalry. Therefore, one explained, the custom grew of using a mass of European mercenaries as a fixed nucleus and rallying-point. The early Moslem armies, too, had used the solid column and charging charge, methods which had been so successful. For one of the greatest successes of history is the cause which changed the erratic, untrustworthy swarms of Arab horsemen with their childish strategy into the ever-victorious legions of the first caliphs. They certainly learned rapidly. Byzantium and Persia taught them the use of military engines and the entrenched camp. Before that they had been, at the best, single knights with mail-shirt, helmet, sword and lance. Bowmen, too, they used, but the principal use of the bow seems to have come with the Turks.

The glory of Moslem education was its university system, which, reduced to a technical learning, is not sound. Its primary system was very poor, almost non-existent; Education and technical education has never been recognized in Islam. Primus inter pares were despised as ignorant and foolish. Apprenticed may we may trust the many stories of how ignorant men set up for themselves, there was no control of them by the state. Their pupils were young only; they taught the rudiments of reading and writing. The Koran, or anything else, was the little more than the latter. Technical education was given by the guilds through their apprentice system, teaching mechanical arts and crafts. This was genuine instruction, but was not so regarded. It was looked upon rather as a kind of degenerate operative masonry. It produced artisans of independent character, but not artists. Thus there was no distinction between architect and builder; there was no sculpture; and painting, so far as it went, was like carving, a craft. All Moslem university education, like most Moslem
science, revolved round theology. There were, apparently, only two or three schools to this rule. The Academy of Mecca (Umar 873) at Bagdad, and the hall of wisdom of the Fatimites at Cairo (1004-1711); both of these are explained by their environment. From the earliest times, independent scholars instructed classes in the famous special places; teaching for the community, and gave their pupils personal certificates. Their subjects were the reading and interpretation of the Koran; the body of traditions from the Prophet in the time of the cannon; the interpretation of the Koran involved grammatical and lexicographical studies of early Arabic, and hence of the early Arabic literature. Theology came to involve metaphysical and logical studies; canon law required arithmetical and mensurational, practical astronomy, &c. But these last were strictly ancillary; the object of the instruction was primarily to give knowledge of value for the life of the next world, and, secondarily, to turn out the right kind of jurist. Nevertheless, descent in Jewish hands; engineering, architecture, &c., with their mathematical bases were crafts. Then this instruction was gradually subsidized and organized by the state, or endowed by individuals. How early this took place is uncertain. But the individual teacher, with his certificate, remained the object of the student; there was nothing corresponding to our general degrees. Thirdly, educational institutions came to be equipped with scholarships of money or in kind for the students. The first instance of this is generally ascribed to Nishapur (Nisibín) in 1066; but it soon became general in the system. The means of complaint were the Koran, which is the most important, characteristic was the wide journeying of the students “in search of knowledge.” Aided by Arabic as the universal language of learning, students journeyed from teacher to teacher, and journeyed far and wide. It was the study of the Koran to understand their ways, their importance and their tions. Scholars were thus kept in touch all over the Moslem world, and intellectual unity was maintained.

To the democratic equality of Islam, in which the slave of to-day may be the prime minister of to-morrow, there is one outstanding exception. The descendants of the Prophet and of his relatives (the family of Hāshim) formed and form a special class, held in social reverence, and guarded from contamination and injury. These are the Ulama, and general legal registration is rigidly and carefully preserved. They are of all degrees of wealth and poverty, but are guarded legally from métsalliances with persons of ignoble origin or equivocal occupation. Their influence is very great, and in some parts of the Moslem world they have the standing and reverence of saints.

MAHOMMEDAN LAW.

The legal situation in the Moslem world is of the highest complexity, and can be made intelligible only by tracing its historical development. First came the system (fīq, shāri’ā) which takes the place in Islam of canon law in Roman Christendom. It begins with Mahomet sitting as judge over the primitive Moslem community at Medina. He was the Prophet of God, and judged, as he ruled, absolutely; any decision of his was valid. But he found it, in general, advisable and fitting to follow the local law or usage of Medina when the new faith did not require a change. It thus came about that his decisions followed, at one time, the usage of the Arab tribes of Medina; at another, the law respected by the Jewish tribes there—a rabbinic development of the law of Moses, deeply affected by Roman law; at another, the more developed commercial law of Mecca, known to his followers who had fled thence with him; or, finally, his own personal judgment, stated it might be as his own sense of right or as the decision of Allah and even incorporated in the Koran. In his use of these he was an eclectic opportunist, and evidently, except as frequently recurring subjects as Inheritance, marriage, &c., had no thought of building up a system or code. At his death he left behind only a few specific prescriptions in the Koran and a mass of recorded decisions that had come before him. He had used himself, in our terms, common law, equity, legislation; to guide his followers he left his legislative enactments and the record of his use of common law. Since his death there has been no new legislation in orthodox Islam.

With the death of Mahomet began the development and codification of Moslem law. It was at first entirely practical. Cases had to be decided, and to decide there was first, the Koran; secondly, if nothing of the Koran was found in the Koran, there were the decisions of the Prophet; thirdly, if these failed, there was the opinion of Moslem jurists. It was the practice, in turn, failed, the common sense of the judge, or equity. A knowledge of the decisions of Mahomet came thus to be of great importance, and records of such decisions were eagerly sought and preserved. But this was simply a part of a much wider movement and tendency. As among primitive peoples in general, custom and usage have always been potent among the Arabs. The ways of the fathers, the old paths, they love to tread. Very early there arose a special reverence for the path and usage of Mahomet, or said, or left undone, and how he did it, has become the framework to the pious Moslem, who would act in every way as did the Prophet. There is evidence that for this purpose the immediate companions of Mahomet took notes, either in memory or in writing, of his table talk and wise sayings, just as they took down or learned by heart for their private use the separate fragments of the Koran. His sayings and doings, manners and customs, his answers to questions on religious life and faith, above all his decisions in legal disputes, came to be recorded on sheets, engraved in the books of the transmitters. There were the enormous literature of traditions (hadith) in Islam. The collecting and preserving of these, which was at first private, for personal guidance and edification, finally became one of the most powerful weapons of political and theological propaganda, and coloured the whole method and fabric of Moslem thought. All knowledge tended to be expressed in that form, and each element of it to be traced back to, and given in the words of, some master or other through a chain of transmitters. Above all there grew up a special mass of evidently forged sayings which served as the mouth of Mahomet. At a time of political or theological crisis each party would invent and put into circulation a tradition from him, supporting its view. By a study of these flatly opposed “sayings” it is possible to reconstruct the different controversies of Islam in the past, and to discover what each party regarded as the essence of its position.

The first collecting of traditions was for private purposes, and the first publication dealing with them was legal. This was the Mawdhe of Anas (d. 757). But all the rest was a corpus juris based partly on traditions, and a protest in its methods against the too speculative character of the books of canon law which preceded it. Thereafter came collections of different traditions, and beginning with the transmitters, and giving the opinions of the companions of Mahomet, on whose authority the traditions were transmitted; after each companion came the traditions going back to him. The best known example of this kind is the Mawdhe of Abû Bakr, and the book of Ibn Hanbal, which contains traditions arranged in chapters according to their subject matter. That of Bukhârî is the most famous, and is arranged to give a traditional basis for a complete system. If a law is found to the pious Moslem, who would act in every way as did the Prophet. There is evidence that for this purpose the immediate companions of Mahomet took notes, either in memory or in writing, of his table talk and wise sayings, just as they took down or learned by heart for their private use the separate fragments of the Koran. His sayings and doings, manners and customs, his answers to questions on religious life and faith, above all his decisions in legal disputes, came to be recorded on sheets, engraved in the books of the transmitters. There were the enormous literature of traditions (hadith) in Islam. The best known example of this kind is the Mawdhe of Abû Bakr, and the book of Ibn Hanbal, which contains traditions arranged in chapters according to their subject matter. That of Bukhârî is the most famous, and is arranged to give a traditional basis for a complete system. If a law is found to
MAHOMMEDAN LAW

they went, and it was the policy of their leaders to take over the administrative systems of the countries which they seized. Even the Arabic legal nomenclature shows evident signs of literal translation from Latin, and many Moslem principles can be traced to the Roman codes. One important development was plainly influenced by the liberty involved in the *Responda prudendum* of Roman lawyers, and by the broad conception of the law of nature in the *Edict of the Praetor*. In its earliest stages Moslem law recognized in the judge a liberty of opinion (*fatwā*) which went beyond even that of the *Responda* and became plain equity, in the English sense, and one school (the Hanifite) established as a basis the right of preference (*istiṣbān*) even when the analogy of the code dictated otherwise; while another (the Malikite) used the term *istiṣṭāb*, "a seeking of (general) benefit" to the community, in a similar situation. But these developments were bitterly contested, and the liberty of opinion was in the end narrowed down to a principle of analogy (*giyād*). The nearest approach to which in Western law is legal fiction. It is necessary now to return to the first successors of Mahomet.

For thirty years after my death," he is said to have declared, "my people will tread in my path (sunnah); thereafter will come kings and princes." This tradition crystallizes the later feeling of Islam. The first thirty years were a golden age; the centre of the state was the Prophet's own city of Medina; the conditions of the state continued in close conformity to those of his own time. The study of tradition, *i.e.*, of his usage, went hand in hand with the study of law. They were vital functions of the state, and it encouraged both, and became speculative. The study of tradition was now private, and its students were more and more the personally pious. There were, thus, two results. On the one hand, the framers of systems of canon law—as it now was—no longer lived in contact with reality; hypothetical and ideal structures were reared which could never stand the touch of the practical law-court. And on another, it opened separation of roads. The interest of the students of tradition became the gathering of traditions for their own sake, going no farther than a striving to regulate each detail of life by some specific, concrete, prophetic dictum. They had no use for systems that went beyond the mere registering of these dicta. The feeling also became general: in any system of government which did not simply reproduce the patriarchal form of Medina was of the world and the devil—a thing with which no religious man could have ought to do. At every turn he would have to peril his soul.

Here we must place the transition of this law with which we have hitherto dealt from being the law of the land to being in essence a variety of canon law. It was always broader than any western secular law. It regulated all the aspects of life—duety duties, to one's neighbour, to one's self. It was really a system of duties, and duties to their aggregated effect. But, under practical conditions of the world and the devil—a thing with which no religious man could have ought to do. At every turn he would have to peril his soul.

The rise of the Abbasids brought a change, but not a great one. They had promised a return to the old religious attitudes, and the promise was formally kept. But in substance they were as much as the Omayyads, and though the state was outwardly on a pious footing, and the religious sentiment of the people was respected, the old, absolute canon law was not restored. It was made possible for more theologians and lawyers to work with the state, but an irremovable party still clung to the pre-00010009qemperor, and the situation was such that it was not true that the struggle to adapt such a single and detailed system to all the varying conditions, climates and times of the great empire was impossible; but the failure marked the great extent in the supposed unity of Islam between the church and the world, religion and law.

Yet the Abbasids did, in their way, encourage legal studies, and under them processes and results, long pursued in private, became public. Almost within the first century of their dynasty the four legal schools, or rites, were formed and the principles established which survive to this day.

The first school to take definite form was the Hanifite, founded by Abū Ḥanīfa (d. 767), who left behind him a definite system and many excellent eclectic pupils. He was a man of means, in touch with the intellectual and social life of the period, but got wholly into the legal life of his time and became a mere jurisprudential officier. Being of non-Arab origin, the usage of Medina had small interest for him. He therefore used few traditions, and preferred to add to the great body of Islamic jurisprudence the rulings which fitted his ideas. This he called the use of analogy (*giyād*); but, in his hands, it became practically legal fiction, the application of a law in some sense undreamt of by its first imposer. The other schools, and another, and another, and another, and another, and another; the effect of differences in local conditions had been early observed and admitted in general terms. Abū Ḥanīfa reduced it to a subjective formula. Under such conditions he claimed the right of preference (*istiṣbān*) of a ruling suited to the local needs, even when the strict analogy was indicated otherwise. This met and meets with vehement protest when formally stated, but the usage of Islam has practically accepted it. One great reform, finally arrived, was the introduction of the Koran, as a kind of secondary source. It was the result of actual cases, but was worked out as a system of casuistry, though in a good sense. He tried, that is, to construct a system of rules to fit the inconceivable question. After his death his pupils elaborated it further, and accepted public office. The 'Abbasids adopted his school, and threw their influence on its side; its philosophic breadth and casuistic possibilities evidently commended it to them. Later, the Ottoman Turks also adopted it, and it may be said to hold now a leadership among the four legal rites. Its influence has undoubtedly tended to broaden and humanize Moslem law.

Twenty-eight years after Abū Ḥanīfa, Malik ibn Anas, the founder of the Malikite school, died at Medina. In many points his situation was precisely opposite to that of Abū Ḥanīfa, and yet his results were much the same. He, unlike the first, limited himself to practical touch with actual life; he was in the centre of the traditions: the Prophet, in the line, one might say, of the apostolic succession. He, therefore, used traditions much more generally than did Abū Ḥanīfa, and, when his times were up, there was no one, as far as he felt that he, under his conditions, had a better right to do so than any outsider. But two of his principles marked a distinct advance and showed that he was not more traditionalist. For one, he laid down the conception of public advantage (*istilād*); when a rule founded on even a valid analogy would work a general injury it was to be set aside; justice must not be overcome by logic. And, for the other, he laid stress on the conception of the agreement (*muta'all*), an idea which was to have definite importance in the future. When the surviving companions of the Prophet, after his death, agreed upon any point as belonging to their store of tradition and doctrines, if their agreement was not unanimous they had to disagree. In this instance they agreed that such had been the statement of the Prophet. That easily passed over into an agreement that such was the true Moslem view, and finally into an acceptance of the principle that the Moslem Church, when unanimous, could formulate truth—incidentally in the canon of the Vincent of Lérins, *Quod semper, quod ubi, quod ab omnius*. But such a broadly catholic position was still in the end compromised for Medina, where the founder of the school, Malik ibn Anas, of Medina, though there are signs that he permitted the same latitude to other places also. It was a way of allowing for local conditions and giving latitude for reaching law. The last great Moslem work, the *Muwaṭṭa*, the earliest in our possession written by the founder of a school, has already been mentioned. It is a collection of about seventeen hundred traditions of juristic importance, arranged under a subject, which included a number of remarks on the usage of Medina and on his own view of each matter.

So far opinion and local usage had fully held their own, and the philosophical jurisprudence had been free to work out his system. The difference between the *istiṣbān* of Abū Ḥanīfa and the *istiṣṭāb* of
Malik was not great; students attended the lectures of both and contributed to both systems. But a reaction now began, and the traditionalist party finally made itself felt. We have the inevitable rivalry between the historical-empirical and the speculative-philosophical schools of jurisprudence, rendered all the more bitter in that the two parties believed, in their different ways, in building a divine institution. There resulted, first, one of the most important schools, the Shafi‘ite; secondly, an extremely liberal school for which an ‘analogy’ was enough, which has now vanished; and thirdly, the Hanbali school, still surviving in small numbers, more moderately traditional than the last.

The school founded by ash-Shafi‘i (d. 820), a pupil of Malik, came first in order of time. The others were really revoltts against the monarchists and ulama, and one of the most important sources of its strength lay in the fact that it was so moderate. The, Shafi‘is, as we have seen,1 were essentially idea-minded, steady grasp of means and ends, a perception of what could and what could not be done, a willingness to admit all the tried principles of the past, and, at the last, that especially striking possession of genius as to the possibilities of these principles. He laid great stress on tradition; a clear, authentic tradition he regarded as no less valid than the Koran itself. If the tradition was chronologically later than a Koranic passage and corrected that passage, he followed the tradition. But in this he was only regulating a fixed tendency. The Koran may be regarded theoretically as the first of all the sources of law and theology; practically its clear statements have been over-ridden in many cases. Most important of all, the principle of agreement (anjma‘) came finally with him to its full rights. The agreement of the Moslem peoples was to be the voice of God. 1 My principle in God’s interest and will is not necessarily in error.” And so, over traditions and over the Koran itself, the agreement tacitly or explicitly ruled and rules. It stamps as authoritative those which the other schools lay aside. It gives head of each section of a Shafi‘ite law book we read: “The basis of this, before the agreement, is such and such.” But with the aid of a principle of this breadth it was easy to reject the opinion which was not his. In this way the tradition was independent (jāmī‘); it still rules. In this way the Hanbalites said, an analogy (iqyā‘a), which, directly used, could serve almost the same purpose. The Koranic passage or the tradition with which an analogy was suggested should, he taught, be examined to see if there was a reason clearly stated for the command. If so, that reason would give a basis for analogy. Based analogy was all that, as in all the schools, was supposed to be accepted by all existing schools. This applies to all spheres of life, ethical, social, theological, legal, and it should never be forgotten that the Koran is only one of the sources for Moslem faith and conduct.

Few words are needed for the other, reactionary schools. One, now long extinct, was founded by a certain 2Dī‘d ad-‘Zahiri, “David the Little.” He wrote before Malik, perhaps before the Shafi‘i, and so called because he insisted upon an absolutely literal interpretation of his texts—Koran or tradition—without account of the middle or the letter. In consequence he had to adopt a narrow and limited agreement to that of the companions of Mahomet; the Church of Islam was to have no constructive authority. In one point he showed great sanity of judgment, namely in his rejection of the Kharijite1 doctrine of compulsory conversion or eradicating others. His school had long and interesting consequences, mostly theological, but is now extinct, and never took rank with the others. The Moslem world was fighting with this doctrine for its last thirty years, and now none but the historians have given a hearing to his words. The other, the Hanbali school, was founded by the scholars of Al-Hind ibn ‘Hanbal after his death in 885. He himself would never have revolted against his master, ash-Shafi‘i, but it was soon felt that his system, so far as he had any, was in essential opposition. He had been no lawyer, but a theologian and a collector and student of traditions. All his life had been a protest against speculation in divine things. Where the Koran and traditions were silent, he, too, had been silent. For this agnostic principle he had witnessed and suffered, and his standing with the people was that of a saint. Naturally, then, the last still existing school of tradition was his most sanitised. It minimally adheres to the letter and analogy, is literal in its interpretations, and is now by far the smallest of the four surviving schools. Its external history is that of a testing and violent minority.

Other men, such as Tala‘i, the historian and commentator, have had dreams that they, too, might join the Four Imams (see IMAM) as founders of legal rites, but none has succeeded. The Four remain the ultimate exponents of this canon law, and under the banner of one or other of the Four Moslems was founded for generations a principle of unity in Islam, expressed in the alleged prophetic saying, “My people will never agree in an error,” so there is principle of unity in that, also. This is expressed in an alleged prophetic saying, “the principle of my agreement is a mercy from God.” The four rites may differ upon many points, yet the adherents of one never dream of regarding the adherents of the others as outside the Church of Islam; they may call them “heretics” in the sense of the Koran,2 yet none make up to their creatures, and gives them so much liberty of choice. Yet in practice this liberty is not great. The principle of swearing to the words of the master is a dead hand laid upon Islam. A man’s legal rite is generally settled by the place and other conditions of his birth,3 he must be allowed to accept. One cannot be ordained, he must, if good and pious, follow it in all its details. Only the avowed sceptic or the recognized eccentric can be an eclectic.

The geographical distribution of the rites is roughly as follows: Mahomet’s successors, in the opinion of many, believed, in the time that they were relatively new, everywhere, are Hanfites; in Lower Egypt, Syria, southern India and the Malay Archipelago they are Shafi‘ites; in Upper Egypt and in north Africa, Arabia, and in Egypt, they are Malakites; only the Wahhabit(s. g.s.) in central Arabia are followers of the prophet. As a whole, the people of this sect, 4has also had a powerful influence and has frequently dictated the legal, as well as the theological, affiliations of his subjects. The Turks, for example, have thrown their weight almost entirely on the Hanfite side. Their policy is to appoint only Hanfite judges (see CADIS), although for private and personal questions they appoint and may Muftis (q.v.) of the other rites. In other cases, with a popula-
MAHOMMEDAN RELIGION

every Moslem country at least two systems of courts, the one administering this canon law, and taking cognizance of private and family affairs, such as marriage, divorce, inheritance, its officials also giving rulings on purely personal religious questions, such as details of the ritual law, the law of oaths and vows, &c.; the other, the true law courts of the land, administering codes based on local custom and the decrees of the local rulers.

A rift almost as important entered the legal life of the Moslem land on another side. Non-Moslem communities, settled in Moslem territory, have been uniformly permitted to administer and judge themselves according to their own customs and laws. Save when they come into direct contact and conflict with Moslems, they are left to themselves with a contemptuous tolerance.

The origin of this attitude in Islam appears to be threefold: (i) The Islam of theory cannot conceive of a mixed state; it takes account, only, of a state containing none but Moslems, and its ideal is that the whole world will, in the end, form such a state. In practice, then, Moslems try to shut their eyes to the existence of non-Moslems in their midst and make no provision for them until compelled. That a non-Moslem should have the same civil position as a Moslem is unthinkable.

(ii) This, of course, produces an attitude of extreme contempt. The only citizens are Moslems and all others are to be looked down upon and left to themselves. What they do or think among themselves does not matter; they are outside the ring-fence of Islam.

(iii) A different, but equally important, cause is the Moslem indolence. When the Arabs conquered, they knew that they must administer the conquered lands, and they, very wisely, sought help from the machinery which they found in operation. But besides the ordinary organization of the state, they found also various ecclesiastical organizations, Christian and Jewish, and to these they gave over the administration of the non-Moslem sections of the community, making their rabbis and bishops their responsible heads and the links of contact with the Moslem rulers. They, unquestionably, found the same method in use by the Byzantine government; but in Moslem hands it went so far as to make a number of little states (millets, milias) within the state and effectually to preclude the possibility of ever welding all the inhabitants of the land into one corporate life.

But this indolence, when applied to resident aliens, had consequences still more serious, because external as well as internal. Following the same method of leaving the unbeliever to settle his affairs for himself, the European merchant, living and trading in the East, was put first by usage and finally by treaty under the jurisdiction and control of his own consul. Thus there grew up the extra-territorial law of the capitulations and conventions, by which the sanctity of the person and household of an ambassador is guaranteed to every European. And this in turn, has reacted on the relations of the non-Moslem races, and has come to be the indirect but chief support on which they lean. Through it, an element has developed which makes it practically impossible for a Moslem state to introduce legal changes even remotely affecting its non-Moslem population, alien or subject, without the consent of the European embassies. Any change may be upset by their refusal to accept it as incompatible with the capitulations and conventions. The embassies have, thus, as interpreters of a part, at least, of the constitution, come to possess a position remarkably, if absurdly, like that of the Supreme Court of the United States (see Young, Corps de droit Ottoman, passim).

There may be said, then, in short, to be three elements in the legal life of a Moslem state: the sacred and fixed canon law of Islam; the civil law, based on the usages of the different peoples, Moslem and non-Moslem, and on statutes going back to the will of rulers; the international law of the capitulations, with a contractual sanction of its own. The hope for the future in Islam can be little doubt, lies in the principle of the agreement of the non-Moslem people, with its concepts of catholic unity, and its ability, through that unity, to make and abrogate laws. As the Moslem peoples advance, their law can, thus, advance with them, and the grasp of the dead hand of the canon law be gradually and legally released.

MAHOMMEDAN RELIGION. The Mohammedan religion is generally known as Islam—the name given to it by Mahomet himself—and meaning the resigning or submitting oneself to God. The participle of the same Arabic verb, Muslim (in English usually spelt Moslem), is used for one who professes this religion. The expression "Mahomedan religion" has arisen in the West probably from analogy with "Christian religion," but is not recognized as a proper one by Moslem writers. Islam claims to be a divinely revealed religion given to the world by Mahomet, who was the last of a succession of inspired prophets. Its doctrine and practices are to be found in (1) the Book of God—the Koran—which was sent down from the highest heaven to Gabriel In the lowest, who in turn revealed it in sections to Mahomet; (2) the collections of tradition (hadith) containing the teachings of Mahomet, and of his early followers, (3) the visions (ijmd') of the angel Gabriel; (4) the universal consent (ijma') of the believers. The doctrine of Islam consists in (1) the recital of the creed; (2) the recital of the ordained prayers; (3) the fast during the month of Ramadhan; (4) almsgiving; (5) the hajj, the pilgrimage to Mecca. The theology of Islam finds its first public expression among the orthodox in the teaching of al-Asiari (d. after 932), but had its real beginning among the sects that arose soon after the death of Mahomet.

Islam is the latest of the so-called world-religions, and as several of the others have already been praised in Xanadu's geography, from Shahsahana's work on the sects, and from the few references in classical writers. From these we have mostly names of local deities (cf. J. Wellhausen, Röste arabischen Heidentums, 2nd ed., Berlin, 1897) and ancient religious customs, which remained in part after the introduction of Islam (cf. W. Robertson Smith, The Religion of the Semities, Edinburgh, 1889, and Kinship and Marriage in Early Arabia, Cambridge, 1885). From these sources we learn that the pre-Islamic religion was associated with fetishism. Sun, moon and stars were worshipped, some tribes being devoted to the worship of special constellations. Certain stones, wells and trees were regarded as sacred and as containing a deity. Many (perhaps most) of the Moslem patriots had their own idols. Hobal was the chief god of the Ka'ba in Mecca with its sacred stone, but round him were grouped a number of other tribal idols. It was usual, in connection with a mosque, to set up a "private" image of the Mahomet, for Mahomet himself in his attempt to unite the religion and policy of the Arabs. But there were features in this heathenism favourable to unity, and these Mahomet either simply took over into Islam or adapted for his purposes. The popularity of the Ka'ba in Mecca as a place of resort for worshippers from all parts of Arabia led Mahomet not only to institute the hajj as a duty, but also to take over the customs connected with the heathen worship of these gods, and later to make Mahomet, and God, i.e. the two names which form the hajj, what they prayed. The name of Allah, who seems to have been the god of the Koreish (cf. D. S. Margoliouth, Mohammed, p. 19, London, 1905), was accepted by Mahomet as the name of the one God, though he abandoned the corresponding female deity Al-lât.
was thus chiefly a private matter, and this copy passed after Abî Bekr’s death into the hands of Omar, and after his death to Hafsa, daughter of Omar, a widow of Mahomet. In the caliphate of Othman it was discovered that the document. The readings of the Koran possessed by the Syrian troops and those of the Eastern soldiers, and Othman was urged to have a copy prepared with the help of the best manuscripts. He appointed Zaid ibn Thabit and three members of the tribe of Korshah (Kurshah) to do the work. Each of these made a copy of Abî Bekr’s collection, carefully preserving Korsheh’s form of words. How far the text was amended by the help of Origen’s comments is not known; in any case the mode of procedure was undoubtedly very conservative. The four similar manuscripts were sent, one each to Medina, Cufa (Kufa), Basra and Damascus, and an order was issued that all different copies should be destroyed. The personal unpopularity of Othman this recension was adopted by the Moslem world and remains the only standard text. A few variant readings and differences of order of the Ayat (verse) occur in early Byzantine MSS., but of the Mas’udid were, however, known to later commentators. The only variants after the time of Othman were owing to different possible ways of pronouncing the consonantal text. These are usually of little importance for the meaning. As the text is now always vowelled, variations are found in the vowels of different copies, and the opinions of seven leading “readers” are regarded as worthy of respect by commentators (see Th., Nöeldeke, Geschichte des Qorâna, pp. 279 seq., Göttingen, 1860). Various characteristics enable one to establish with more or less certainty the relative chronological order of the surahs in the Koran, at any rate so far as Christianity. As the Hebr. place them in the following section. The period of the Meccan suras is replaced in the Medina suras by “O ye who believe.” This is in the first Meccan period are longer, in the second shorter, and are absent in the Medina. In the earliest period the style is more elevated and passionate, in the later period less so. Its style is determined by reference to historical events. In accordance with such principles of criticism two leading scholars, Nöeldeke (loc. cit.) and H. Grimmer (in his Mohammed Zweite Teil. Einleitung in den Koran, System der gegenwärtigen Theologie, Münster, 1895), have arranged the suras as follows:—

**Order of Suras in Koran.**

NÖLDEKE.

Mecca.

1st to 5th yr. (a).

1. 96. 74. 111. 106. 108. 103. 107. 102. 105. 99. 96. 94. 93. 97. 86. 91. 80. 68. 87. 95. 85. 73. 101. 99. 82. 81. 53. 84. 100. 79-77. 78. 88. 79. 75. 83. 69. 51. 62. 76. 79. 55. 112. 109. 113. 114. 1.

2nd and 3rd yr. (b).

From the Flight to Badr.

2. 62. 51. 41-68. 47 and some interpolations in Meccan suras.

From Badr to Ohod.

8. 24. 59.

From Ohod to cap- ture of Mecca.

6. 110. 45. 8-14. 66. 91-14.

From capture of Mecca. 91-14.

On the supposition that the arrangements given above are at any rate approximately correct, it is possible to trace a certain development in the teaching of the Koran on some of the chief dogmas. It must, however, be borne in mind that orthodox Islam recognizes the Koran as the work of Mahomet but of God. Yet Moslem theologians recognize that some revelations are inconsistent with others, and so have developed the doctrine of naskh and manzûk (“abrogating”) which should be interpreted as meaning that in definite cases a later revelation supersedes an earlier. A critical study of the Koran shows in the earlier revelations the marks of a reflective mind trained under the influence of Arabian education
and stirred by an acquaintance (somewhat imperfect) with Judaism and Christianity. The later revelations seem to be influenced by the now dominant position of the Prophet and a desire after the capture of Mecca to incorporate such heathen religious concepts as possible within the new religion from the beginning. His unity is emphasized as against the mistaken conception of the Christian Trinity. At first his might is named the name Robb (Lord) which is generally used with an attribute as "the highest Lord," "Lord of the worlds," "Lord of men," "Lord of heaven and earth," "Lord of the East and West," or "our Lord." Then he is identified with the god Allah (see above) and the first part of the later Meslem creed is announced—"la ilaha illa-llah," there is no god but Allah.

But every act of creation is a proof not only of God's power but also of his beneficence (xiv. 37), and so he becomes known as ar-Rahman, the "Compassionate." The attributes of God may all be arranged in the three classes of his power, unity and goodness. They are expressed by the ninety-nine "beautiful names" applied to him in the Koran (see E. H. Palmer, The Quran in "Sacred Books of the East," vol. vi., Introd. pp. 67-68, Oxford, 1880). In the Medina period of Mahomet's life the nature of God is not so clear, and the description of it varies according to the moods of the Prophet.

Beside God are two other uncreated beings: (1) the original of the Koran, the "mother of the Book" (xliii. 3) on a "preserved tablet" (laub makhfiz) (xxxiv. 22), in accordance with which God acts, and (2) the throne (kursi) (ii. 256). When the heavens are created, God sits on his throne in the seventh heaven; some are angels, pure, sexless beings, some of whom bear the throne, while some are engaged in praising him continually. They are also his messengers and are sent to fight with the believers against the heathen. Some are the guardian angels of men, others are the watchmen of hell. Mediate beings between God and man are the "word" (wurm) and from it the "spirit" (ruh) or "holy spirit" (ruh-ul-qudus). Another manifestation of God to the believers only is the "glory" (sobh).

God created the world in six days according to the plan of the Book. Each new life was created by God's breathing into it a soul. The duality of soul and body is maintained. In each man is a good and a bad impulse. The bad impulse which was latent in Adam was roused to action by Satan (Iblis). At first his fall lost the grace of God, which was restored to him solely by the grace of God. Between other uncreated beings and angels in their nature are the genii (jinns) male and female, inhabitants of desert places, created from smokeless fire. They had been accustomed to spy round heaven, but in Mahomet's time could learn no more of its secrets. Some of them were converted by the Prophet's teaching. Lowest of creation in his estate is Satan (Shaitan), who was an angel but was expelled from heaven because he refused to worship Adam at his Lord's command. God has revealed himself to man by (1) writing (kitab), and (2) prophets. As he had given to the Jews the Law (Taurid) and to the Christians the Gospel (Injil) so he revealed to Mahomet the Koran (Qur'an, known also by other names, e.g. al-Furqan, al-Taurid, &c.), each single revelation being called an ayah. With his revelation God has also sent an apostle or prophet to each people. Several of these are mentioned in the Koran, Moses the prophet of the Jews, Jesus (Isa) that of the Christians. Mahomet is not only the apostle of the Moslems but the "seal of the prophets," i.e. the final member of the class. His mission at first was to warn men of imminent judgment. Later he became more of a teacher. At first he seemed to have relied for the salvation of men on his natural faculties, but later announced the doctrine of the election. The ethics of the Koran are based on belief (Islam) and good works, the latter alone occurring in the early Meccan suras. Fear of the judgment of God was a motive of action; this is followed by repentance and turning to God. A complete surrender to God's will (Islam) is the necessary condition of religious life and is expressed in the phrase so common in everyday speech among the Moslems—"inshallah," "if God will." God has full power to overlook evil deeds if he will. Unbelievers can acquire no merit, however moral their actions. A short account of the chief ethical requirements of the Koran is given in xvii. 20-40:

But not God with other gods, or thou wilt sit despised and forlorn. Thy Lord has decreed that ye shall not serve other than Him; and kindness to one's parents, whether both of them reach old age with thee, and say not to them, 'Fie,' and do not grumble at them, but speak to them a generous speech. And lower to the earth, for beauty of humility out of compassion, and say, 'O Lord, have compassion on them as they brought me up when I was little!' Your Lord knows best what is in your souls if ye be righteous, and, verily, He is forgiving unto those who come back penitent.

And give thy kinsmen his due and the poor and the旅er and the captive and the one who has imparted no kindness to a man for the fear of thy Lord; whosoever does this will not suffer the least of need in this world or the next. And give not with the hand that is to be pitied; and do not turn away from the orphan, nor drive out the widow. And be not as those who are turned away. And do not do that which you know not is good, for evil is ever an abomination to God, and the evil is ever the worse. And draw not near to fornication; verily, it is ever an abomination and the evil of the worst kinds.

But if thou dost turn away from them and from the things of the present life, to seek after mercy from thy Lord, whom thou holiest for, then speak to them straight speech.

"Make not thy hand lettered to thy neck, nor yet spread it out quite open, lest thou shouldst have to sit down blamed and straightened in means. Verily, thy Lord spreads out provision to whomsoever He will or He doles it out. Verily, He is ever, well aware of and sees His servants."

She is not your friend, for fear of poverty; we will provide for them; beware! for to slay them is ever a great sin.

And draw not near to fornication; verily, it is ever an abomination and the evil is ever the worse. And draw not near to the things of the present life, to seek after mercy from thy Lord, whom thou holiest for, then speak to them straight speech."

And do not pursue that of which thou hast no knowledge; verily, the hearing, the sight and the heart, all of these shall be enquired of. And walk not on the earth proudly; verily, thou canst not cleave the earth, and thou shalt not reach the mountains in height.

"All this is ever evil in the sight of your Lord and abhorred." (E. H. Palmer's translation.)

The eschatology of the Koran is especially prominent in its earlier parts. The resurrection, last judgment, paradise and hell are all described. At death the body again becomes earth, the soul sinks into a state of sleep or unconsciousness. At a time decreed, known as the "hour" (ar-Suda), the "day of resurrection" ( yawm ul-qiyyma), "day of judgment" (yusuf-ud-Din), &c., an angel will call or will sound a trumpet, the earth will be broken up, and the soul will regain the body. God will appear on his throne with angels. The great book will be opened, and a list of his deeds will be given to every man, to the good in his right hand, to the evil in his left (sura 69). A balance will be used to weigh the deeds. The jinn will testify against the idolaters. The righteous will then obtain eternal peace and joy in the garden (al-jannat) and the wicked will be cast into the fiery ditch (Jannah), where pains of body and soul are united.

2. The Tradition.—The revelation of God is twofold,—in writing and by a prophet. The former was contained in the Koran, the latter was known from the actions of Mahomet in the different circumstances of life. The manner of life of the Prophet (sunna) was contained in the tradition (al-badiah). The information required was at first naturally obtained by word of mouth from the companions and helpers of Mahomet. These in turn bequeathed their information to their younger companions, who quoted traditions and gave decisions in their names.

For long these traditions circulated orally, the authority of each depending on the person who first gave it and the reliability of the whiteness of men who bore it. At first this tradition was regarded as explanatory of, or at the most mementory to, the teaching of the Koran. Early Moslem teachers are divided on the question of the Jews as having two law-books—the Taurid and the Mishna—while Islam, by a single one, with reference to a change of the tradition, the value of tradition as an independent revelation came to be more highly esteemed until at last it was seriously discussed whether it was a writing or another passage of the Koran with which it was at variance. The writers and teachers of the past were at first strongly discouraged, and for more than a century the stories of the Prophet's conduct passed from mouth to mouth. Had all the narrators been pious men, this might have been tolerable, but this was not the case. The Omayyad dynasty was not a pious one. Men who were not religious but wished to appear so invented
traditions to justify their manner of life. The seclarians did not hesitate to adopt the same means of spreading their own teaching. Many Moslem writers testify to the fact that forged traditions were circulated extensively and were given considerable weight. The necessity for some sort of authoritative collection seems to have been felt by the one pious Omayed caliph, Omar II. (717-720), who is said to have ordered Ibn Shihab uz-Zuhri to make such a collection. Omar himself did not carry out the project, and nothing further. It was, however, by a man born during this reign that the first systematic collection of traditions was made—The Musawi' of Malik ibn Ansas (q.e.). Yet this work is not a book of tradition in the religious sense. It is the so-called al-yusup jara and is not a complete one. The object of Malik was simply to record every tradition that had been used to give effect to a legal decision. The work of sorting the vast mass of traditions among them according to their relation to the different parts of religious life and practice was first undertaken in the 3rd century of Islam (A.D. 815-912). In this century all the six collections afterwards regarded as canonical by the Sunni sects were made. By this time an immense number of traditions was in circulation. Bukhari in the course of sixteen years' journeying through Moslem lands collected 600,000, and of these included 7275 (or, allowing for repetitions, 4000) in his work. The six collections of tradition received by the Sunnites as authoritative are: (i) The Kitab ul-jami' of Uz-Sakhh of Bukhari (q.e.) (810-870). This is the most respected throughout the Moslem world and most carefully followed by the ismaili and and T. (ii) The Sakhh of Malik, which is the war of Corfu an edition of the first edition of the collection with slight variation (ed. Calcutta, 1849). (iii) The Kitab ul-Sunan ul-Ahad of Daud (817-888) (ed. Cairo, 1863, Lucknow, 1888, Delhi, 1890). (iv) The Jami' ul-Sunan of Tirmidhi (q.e.). (v) The Kitab ul-Sunan of Nasir al-Mulk, or Tirmidhi, (ed. Cairo, 1865, and Delhi, 1865 and 1889). The last four are not held in the same repute as the first two.

3. Jami' al-din is the universal consent which is held to justify practices or beliefs, although they are not warranted by the Koran or tradition, and may be inconsistent with the apparent teaching of one or both of these. These beliefs and practices, rooted in the Islamic customs of those who had become believers, seem to have escaped notice until the Abbasid period. They were too deeply rooted in the lives of men to be abolished. It became necessary either to find a tradition to abrogate the earlier forbidding one, or to acknowledge that jami' is higher than the tradition. The former expedient was resorted to by some later theologians (e.g. Nawawi) by a fiction that such a tradition existed though it was not found now in writing. But in earlier times some (as Ibn Qutb) had adopted the latter alternative, saying that the interpretation of the jami' is from the tradition, because it is not open to the same chances of corruption in its transmission as the latter. Tradition itself was found to confirm this view, for the Prophet is related to have said, "My people does not agree to an error."

4. The fourth basis of Islam is gidas, i.e. analogy. It is that process by which a belief or practice is justified on the ground of something similar but not identical in the Koran, the tradition or jami'. Originally it seems to have been instituted as a check upon the use of private opinion (ra'y) in the teaching of doctrine. The extent to which it may be used is a subject of discussion among theologians who are influenced by the need to avoid any "material inharmony," others to similarity of motive or cause as well. The fifth is a rule of the Koran is the pilgrimage (hajj) to Mecca, which should be performed once by every Moslem if he is able, that is if he can provide or obtain the means to Pilgrimage, support himself on pilgrimage and his family during his stay. And if he fails to perform the pilgrimage he is made at one time of the year (the Mawlid) year, from the 7th to the 10th of the month Dhul-Hijja. For the arrangements for the journey from various countries to Mecca see Caravan. When the pilgrim has reached the haram he is to perform certain prayers of ablution, and pray, and put on the two of the pilgrims which form the dress of the pilgrim (the shari', who goes without head-covering or boots or shoes. If he has an umbrella or sail or anything made during the period. The chief parts of the ceremonial are the visit to the sacred mosque masjid ul-akbar), the kissing of the black stone, the compassing of
MAHOMEDAN RELIGION

421

The development of Islam.—The battle of Siffin (657) between 'Ali and Moawiyah was the occasion of the first breach in the unity of Islam, and the results remain to this day. The occasion was in the first case political, and the politics at that time too intimately connected with religion to be considered apart from it. After the battle (see Caliphate) 'Ali was practically compelled to submit his claims to arbitration, whereupon a number of his supporters broke away from him, saying that there should have been no appeal save to the Book of God. These men were for the most part country Arabs, and, inspired by the free spirit of the desert, were democratic, claiming that the caliph should be chosen, in the first instance, by the community from any family (and not from the Kureish alone), and that the caliph might be deposed for sin.

A few extremists were republican and would do without a caliph altogether. The whole party was known as the Kharijites (Khairijyia or Kha'awarij). The Moslems who disagreed with them were regarded by them as renegades and were to be put to death. They were soon divided into extremists and moderates.

The former put to death the children of unbelievers and refused to hold intercourse in daily life with unbelievers. The moderates, who came to be known as Ibadites (from their leader 'Abdallah ibn 'Abd), would allow the children of unbelievers to grow up, and would then deal with them according to their choice. In ordinary life they would mix with all men, but marriage with other Moslems outside their own ranks was forbidden. These still remain in Oman, parts of Algeria and East Africa.

Another party, consisting mainly of city Arabs infected with Persian ideas as to the divinity of the ruler, clung to 'Ali with inconvenient affection. They regarded 'Ali and his descendants as the only legitimate caliphs, and came to be known as Shi'ites (q.v.). They remain to-day the largest part of Islam outside of Arabia. After the Omayyad dynasty was overthrown, there were three centres of religious thought and influence; students and teachers often passed from one to the other, thus making universal the teachings which in their origin were due to local circumstances. These centres were Damascus (the seat of the caliphate), Medina, and the East (Iraq, &c.). In Damascus the court was worldly and indifferent to the interests of Islam. The early Omayyads were distinguished for their striving after dominion (mulk). Instead of attempting to propagate Islam, they strove to enrich themselves, and favoured Christians who were distinguished as poets (e.g. Alobah) or orators. The Abbasides, who came to be known as the 'Abulawen, were more inclined to the religious side of things, and were known as the 'Abulawen, or men likely to be of use to them in any way. The doctrines of Christianity began to influence even serious Moslems and to affect their way of stating Moslem belief. Ibn of Damascus (d. before 767), the Greek theologian, and his pupil, Theodorus Abacora (d. 826), have written controversial works on Islam, from which it seems probable that disputations on subjects pertaining to religion were held between Christians and Moslems. These controversies of heretical Moslem sects arose under these influences—that of the Kharijites and that of the Qadurites. The Murjites ('postponers') were so called because they postponed the judgment of human actions until the Day of Judgment. In politics they accepted the Omayyads as de facto rulers, since they were Moslems, and left the judgment of their actions to God.

As theologians they taught that religion consists in belief (iman) in the unity of God and in his apostle, and in that alone; consequently no one who held this faith would perish eternally, though he had been a sinner. This was opposed to the Kharijite doctrine that the unrepentant sinner would perish eternally, even though he had professed Islam.

The Qadurites were concerned with the doctrine of predestination and free-will. So long as Moslems were fighting the battles of Islam they naturally paid most attention to those revelations which laid stress on the absolute determination of a man's destiny by God. They fought with great bravery because they believed that God had foreordained their death or life and they could not escape His will. In the quieter realm of town and court life and in their disputations with Christians they were called upon to reconcile this belief with the appeals made in the Koran to man's own self-determination to good, to courage, &c. Mahomet was not a systematic theologian and had done nothing to help them. The Qadurites declared that man had power over his own actions. But the teaching of predestination had gained too great a hold on Moslems to be thus displaced. The teaching of the Qadurites was held to be hesery, and one of its first professors, Ma'bad ul-Juhanni, was put to death in 699. During this period Medina was the home of tradition. Those who had been in closest relation with the Prophet dwelt there. The very people of the city derived a certain splendour and authority from the fact that Mahomet had lived and was buried there. Free thought in religion had little chance of arising, less of expressing itself, in the holy city. But the Koran was diligently studied, traditions were collected (and invented) though not written in books, and innovation (bid'a) was resolutely avoided. At the same time it really did contribute a new element to religious practice, for the custom (ijma', see above) of Medina gained a certain authority even in Syria and the East.

In the East, on the other hand, there was more mental activity, and the religious teachers who came from Medina had to be prepared to meet with many questions. The visits of the Moslems were sharpened by daily contact with Christians, Buddhists, Manicheans, and Zoroastrians. Hassan ul-Baqri (q.v.), who has been claimed as one of the first mystics, also as one of the first systematic theologians of Islam, was remarkable alike for his personal piety and his orthodoxy. Yet it was among his pupils that the great rationalist movement originated. Its founder was Wasil ibn 'Ata, who separated himself (whence his followers were called Motazilites, strictly Mu'tazilites, "Separatists") from his teacher and founded a school which became numerous and influential. The Mu'tazilites objected to the attributes of God being considered in any way as entities beside God; they explained away the anthropomorphisms used in speaking of the divine, by the Koran as created and as a product of Mahomet writing under the divine influence. Briefly, they asserted the supremacy of reason ('aqil) as distinct from faith received by tradition (naqil). They also called themselves "the people of justice and unity" (Ahl ul-'ilal wa-tauhid). Such a faith as this naturally found favour rather with the thinking classes than with the uneducated multitude, and so went through many vicissitudes. At the time of its appearance and until the reign of Ma'mun its adherents were persecuted as heretics. After discussions among the theologians Ma'mun took the decided line that the Koran as created and as a product of Mahomet writing under the divine influence was necessary. Other Mu'tazilite doctrines were proclaimed later. Mu'tazilites were appointed to official posts, and an inquisition (mi'ima) was appointed to enforce belief in their doctrines. This movement was strongly opposed by the orthodox and especially by Ahmad ibn Hanbal (q.v.). By him the founding of theology on reason was rejected, and he suffered persecution for his faith (see W. N. Patton, Ahmed ibn Hanbal and the Mi'ima, Leiden, 1867). Mu'tazilism retained its sway until 849, when the caliph Motawakkil again declared the Koran uncreate and restored orthodoxy. It was during the early years of the Abbasid

1 For the doctrines of these two sects see Shahrestani's Book of Sects, and for the Qadurites, A. de Vlieger's Kitab ul-Qadr, matières pour servir à l'étude de la doctrine de la predetermination dans la theologie musulmane (Leiden, 1903).
rule that the four legal schools of Abū Hanīfah (d. 767), Mālik ibn Anas (d. 799), ash-Shāhīrī (d. 810) and Ibn Hanbal (d. 853) came into existence (see MAHOMMEDAN LAW). As the bases of religion and law were the same, the methods of thought of the one are reflected in the other. Abū Ḥanīfa depended little on tradition, but referred back to the Koran, making use of individual opinion (ra'y) as controlled by analogy (qiyās) with a written ordinance. Mālik ibn Anas supplemented the Koran and Sunna by customary law founded largely on the custom (ijma) of Medina, and by what he conceived to be for the public good (istiślāb). Shaḥīrī recognized tradition as equal to the Koran, and even as being able to supersede its ordinances, while he also recognized the universal custom (ijma) of the Moslem world as deriving from binding. His four bases of religion—Koran, Sunna, qiyās and ijma—have been generally accepted in Islam (see above). Ibn Hanbal's position has been already mentioned. All these four schools are reckoned orthodox, and all orthodox Moslems belong to one or another of them. Another teacher of this time, who founded a school which did not succeed in being recognized as orthodox, was Dā'ūd uz-Zāhirī. Trained as a Shaḥīrī, he became too strict for this school, rejected analogy, restricted ijma to the agreement or custom of the companions of Mahomet, and accepted the whole of the Koran and tradition in their literal and external sense. He was followed by the followers of the Zāhirites (i.e. externalists). After Ash'ārī's time these principles were applied to theology by Ibn Hazm (q.v.) see I. Goldziher, Die Zahlraten, ihr Lehrsystem und ihre Geschichte (Leipzig, 1884).

Before returning to the reform of Ash'ārī and the introduction into orthodox theology of scholastic philosophy it is necessary to notice another phase of religious life which became the common property of orthodoxy and heretics. This was the introduction of asceticism in religious practice and of mysticism in religious thought. Sūfīsm (q.v.), which combined these two, is not accounted among the sects of Islam. Asceticism seems to have won a certain amount of approval from Mahomet himself, who much respected the Christian monks. The attention paid in early Islam to the joys and punishments of the future life led to self-denial and simple living in this world. An Arabian writer, speaking of the simplicity of manners of the first four caliphs, says that their affairs were conducted with more consideration of the future life than of this world. Many Moslems went even farther than these caliphs, and gave up all concern as far as possible with the problems of this world, and lived in poverty, in wanderings or in retirement (see DERVISH). For the historical development of this movement, with its accompanying mysticism, see Sūfi-ism. Ash'ārī (d. before 942) was for forty years a Mu'tazilite, then became orthodox (see Ash'ārī), and at once applied rational methods for the support and interpretation of the orthodox faith. Before him, reason had not been allowed any scope in orthodox theology. He was not the first to use it; some teachers (as al-Junaid) had employed it in teaching, but only in secret and for the few. The methods of scholastic philosophy were now introduced into Moslem theology. The chief characteristic of his religious teaching was the adoption of the vita media between materialistic grossness and the ideas of pure speculative philosophy. Thus taught, as to the attributes of God, that they exist, but are not to be compared with human attributes; as to His visibility, that He can be seen but without the limitations of human sight. As to the great question of free will, he denied man's power but asserted his responsibility. So he passed in review the doctrines of God, faith, the Koran, sin, intercession, etc., and for the first time in the history of Islam produced a systematic theology. The teaching of Ash'ārī was taken up and propagated by the Buyids soon after his death, and was developed and perfected by Abū Bekr ul-Bāqillānī, the Cadi (d. 1012), but up to the middle of the 5th century of Islam (c. A.D. 1058) was suspected elsewhere and confounded with Mu'tazilism. The Ash'ārī school was zealous and warlike in order to defend the faith of al-Juwaynī (known as Imam al-Haramain) was persecuted under Toghrul Beg (c. 1053) and exiled, but was restored under Alp Arslan by the vizier Nāṣiḥ al-Mulk, who founded an Ash'ārī college (the Naṣiḥiyā). In the West, Ibn Hazm (q.v.) fiercely opposed the system, but Ghazālī established its orthodoxy

In the East, and it spread from Persia to Syria and Egypt under the Ayyūbiites and Mamelukes and thence to the Almohades in Africa under Ibn Tumart (1130). It remains the predominating influence in Islam to the present day, its only rival being the theological system of al-Maṭārirī, a Hanafīte (d. 945), whose creed is represented in that of an-Nasafī is still used largely by the Turks. Since the 12th century no great religious movement has been made in Islam. The quiet of religious life has twice been broken, once by Wahhābīs (q.v.) in Arabia, once by Bābism (q.v.) in Persia.

The Sects

According to an early tradition Mahomet said that Islam would be divided into seventy-three parties (sects),1 of which seventy-two would perish and one would be saved. The orthodox Arabian writers on heretical sects of Islam feel compelled by this tradition to make up their number to seventy-two, and, as different writers adopt different divisions or are familiar with different parties, the names of sects amount to some hundreds. Each writer, however, adopts certain main classes under which he attempts to group the others. Abū Muḥī Makhūl at the beginning of the 10th century in his "Refutation" (MIS. in Bodleian Library) has six such chief classes: Harūrites (i.e. Khārijites), Rāfīrites (i.e. Shi'ites), Qadrites, Jabarites, Jahmites and Murjites. Ibn Hazm (q.v.) adopts four classes: Mu'tazilites (Motazilites), Murjites, Shi'ites and Khārijites. Shahrašānī (q.v.) complains of the want of system in earlier writers, and suggests that sectarian differences are merely forms of parties with regard to the doctrines as to (1) the divine attributes, (2) predestination and free-will (3) promises and threats, faith and error, (4) revelation, reason, the imāmate. In one part of his preface he gives as the chief parties the Qadrites, Shi'ites, Khārijites and Shi'ites, proposing to divide these classes according to leaders who agreed with the main doctrines of their class but differed in some points. In another place he mentions four opposite pairs of sects: (1) the Qadrites with their doctrine of free-will, and the Jabarites, who are necessitarians; (2) the Shi'ites, who maintain the eternal nature of the attributes of God, and the Mu'tazilites, who deny it; (3) the Murjites, who postpone judgment of actions until the Last Day, and the Wā'idites, who condemn in this life; (4) the Khārijites, who consider the caliphate a human institution, and the Shi'ites, who defy their ruler. In his detailed treatment of the sects Shahrašānī arranged them under the headings: Mu'tazilites, Jabarites, Shi'ites, Khārijites, Murjites and Shi'ites. About the same time as Shahrašānī (two other Arabian writers wrote on the sects—Tālib and Ḥāfiz ibn Jumā) the Khārijites had been forbidden in the Berlin Library and (1) Abul Qādir al-Ḫulaylī (1758-1816) in his Kitāb al-Ǧanayyīn li-Tallīb Tarāq al-Haqqi (Cairo, 1871). Both adopt as main classes Rāfījites (or Shi'ites), Qadrites (or Mu'tazilites), Khārijites, Murjites, Najārjites, Dirājites, Jahmites, Mshahibibā, to which Tālib adds Bakrites, Karrāmites, and a class including those sects which are not reckoned as Moslem though they have sprung from Islam. Ḫulaylī adds to the eight the Kīlūbites.

The following list is not a complete list of names of sects but is founded on that of Shahrašānī.

Afsafītes.—Shi'ites of the Imāmate class, who ascribe the imāmate to 'Abdallah al-Afṣafī, the son of Šāqīq, Aǰārīda.—Khārijites, followers of Ibn 'Ajarrād, who agreed for the most part with the Najādāt (below), considered grave sins as equivalent to unbelief, but remained friendly with those who professed Islam but did not fight for it. They rejected sura 7 as a fable. Shahrašānī enumerates seven divisions of this sect.

2 The names are given throughout in the anglicized form on the analogy of Shi'ites, which is recognized in common usage. The strict terminations according to the scheme of transliteration adopted in this work is یوی, or یوی, e.g. ھیحیییا for Ḥīhīmīyā. For information regarding the important sects see separate articles and the preceding portion of this article.
Mahomedan Religion

[Akkasites].—A section of the Tha'ali'ba not so strictly in treatnt of those who fear to fight for Islam.

Ash'arites.—Followers of Ash'ari (q.v.), who are counted by Shahrazuri as the Sunnite part of the sect.

Ala'tites.—A division of the 'Ajdari who agree with the Hamzites except that they excuse the lower classes for inaction when they are ignorant of the Koran.

Azaqiites.—Kharijites who followed al-Arqaj in the days of Ibn Zubair. They held 'Ali to be an unbeliever; those who did not fight were unbelievers; the children of unbelievers were to be put to death and went to hell. Sin is unbeliev.

Baha'mites.—Mu'tazilites akin to the Jubbi'ites.

Baha'tites.—Kharijites, followers of Abul Bahua ul-Haitham, who was put to death by the caliph Walid. They asserted the necessity of an external legislature for religion.

Bauqirites.—Shi'ites who followed Aba Jafar ul-Bajir, the fifth Imam, and looked for his return.

Bishrites.—They were misled because they believe that every external has an internal (batin), and every passage in the Koran has an allegoric meaning.

Bishrites.—Mu'tazilites, followers of Bishr ibn Mu'tamir, one of the most learned men of his party. His teaching was philosophical and was distinguished by his doctrine of "origination" (batweld).

Bununites.—Kaissites, followers of Bunun ibn Sinan un-Nahdi, who claimed that the imamate of the extreme Kharijites, al-Haitham al-Adnan, was legitimate because of his divine mission (tawallud) and that he also acquired the divine element of 'Ali.

Butrites.—Zaidites, followers of Kairthun un-Nawal ul-Abtar, who agreed with the Saleemites (Sula'imites) except that he suspended judgment of an unbeliever with regard to his works or not.

Dirrites.—Jabariites who empty God of his attributes, and assert that man has a sixth sense by which he will see God on the day of resurrection. They also believe that every man is a mahdi and is chosen and acquired by him. A caliph need not be chosen from the Koresheh.

Ghaliites (Ghalah) are the extreme Shi'ites (q.v.) in ascribing deity to the imams. Their heresies are said to be four in number: (1) Making a distinction between man, (2) ascribing change of mind to God, (3) looking for the return of the Imam, (4) metaphysicism. They are divided by Shahrazuri into ten classes.

Ghaliites.—Followers of Ghasan ibn ul-Kufi, who say that faith consists of knowledge of God, his apostle, and the Koran in general not in detail, and that faith increases but is not diminished.

Ghaliites.—Hiyites (below).

Ghaliites (Hiyites).—Mu'tazilites, followers of Fadl ibn ul-Hudath, who agreed with the Hiyites.

Ghaliites.—Followers of Haf ibn abil-Miqdam, who distinguished between party (shirk) and unbelief (kafir).

Hadjites.—Ajdari, followers of Hamza ibn Adrak in Sijsitan. They agree with the Maimunites, but condemn the children of unbelievers to hell.

Hadirites.—Hadirites who differ from others in holding the Mu'tazilite doctrine of free-will.

Harura.—A name given to the first Kharijite, who rebelled against God's representative, Abu Sufyan ibn Harura near Kufa.

Hishamites.—Kharijites who supported Abul Habbah, son of Mahomed ibn ul-Hanafiya, although they held that his father had gone astray.

Hishamites.—A party who asserted the eternity even of the letters of the Koran. They are not mentioned as a separate sect by Shahrazuri; cf. van Vloten, "Les Hchiaewed et Nabiab," in the Acts of the 11th International Congress (Paris, 1899), pt. iii., pp. 99 sqq.

Hiyites.—Mu'tazilites who agreed with the Nahzamites, but added three heresies of their own: (1) the divinity of the Messiah, (2) metaphysicism, (3) the interpretation of all references to the vision of God as referring to the "first Reason" or "creative Reason."

Hiyites.—A name given to two sects: (1) Mu'tazilites, strong in their assertion of man's free-will, even opposing the statement of the Koran of the extreme kind, who attributed to God a body with quantities (measurements) and qualities.

Hiyites.—See Shahrazuri.

Hudhabites.—Mu'tazilites, followers of Abul Hadiul Ilamdan, who was a leading teacher of his party and developed the philosophical side of its teaching. Ten of his main doctrines are given by Shahrazuri.

Hudhabites.—Jabariites of moderate tendencies (see above).

Hudhabites.—Ghaliites who put 'Ali above Mahommed and blamed the latter because he called men to himself instead of to 'Ali. Mahomed ibn al-Ash'ar, the chief of the divisions of the Shi'ites (q.v.).

Hudhabites.—Kharijites of moderate tendencies (see above).

Imamites.—The rationalists of Islam. See above, cf. also H. Steiner, Die Mu'taziliten oder die Freidenker im Islam (Leipzig, 1866). 1

Mu'aashites.—Imamites who held to the imamate of Masib ibn Ja'far, who was imprisoned by Harun al-Rashid and poisoned.

Mu'aashites.—followers of Ibn Sida' al-Ujli, who claimed the imamate and prophetic office and held extremely gross views of God.

Mukarramites.—The rationalists of Islam. See above, cf. also H. Steiner, Die Mu'taziliten oder die Freidenker im Islam (Leipzig, 1866). 1

2 See above, cf. also H. Steiner, Die Mu'taziliten oder die Freidenker im Islam (Leipzig, 1866).

Mu'azzamites.—Mu'tazilites, followers of al-Muzdari, a pupil of Bishr ibn ul-Mudafain, who professed the views of the Mu'tazilites determined further. He taught that God has power to do evil, but, if he acted thus, would be an evil God; also that man can produce the equal of the Koran.

Mu'azzamites.—followers of Abu Inayid ibn 'Imrul Yama, as he went to join the Arzaqiites but withdrew from these, being more orthodox than they. He held that fear of fighting was not sin.

Mu'azzamites.—followers of Jabril ibn Sa'id, who were of a special party. They were those who believe in Sidiq as the mahdi.

1 All these names are alternatively spelt. Mu- instead of Mu-.
MAHONEY—MAHRATTAS

Naṣāmites.—Mu'tazzilites, followers of Ibrahim ibn Sayyār un-Nazzām, who was an extremist in his teaching of man's free-will and other philosophical doctrines.

Nu'māmites.1—Ghālītes agreeing in some points with Hishāmites, but not in the light in the form of a ma'nī, yet not a body of Ghālītes. Nuṣairītes.2—Ghālītes who agree with the Ishaqītes except that they lay more stress on the incorporation of the deity.

Qadarītes. —The upholders of free-will (see above).

Qutʾārites. —They who regard the rank of the imāms as closed with the death of Māsāʿī.

Rāfīdatītes. —A term used by some writers to denote the Shi'ītes and other sects as distinguished from the three main sects of Islam.

Salimītes. —They who have nothing to do with the children of believers until they had grown up and professed Islam.

Shi'ahites. —Tha'labilites, followers of Shāhīn ibn Salama, who was perhaps a brother of Abū Musa Jundib, and was the star in the middle of the seven stars in the constellation of the Pleiade. They were a separate race in Jorjān and Armenia, and agreed in doctrine with the Jaḥmītes.

Shi'ahites. —The group of them who said that God creates the actions of men, and men appropriate them.

Tīrītītes. —Those who ascribe eternity to all the attributes of God, whether they denote essence or action, or are of the class described as the pre-existing attributes.

Ziyūdītes. —The same as Ziyūdītes (below).

Subimāmites (Suleimāmites).—Zādīles, followers of Sulaimān ibn Jābir, who held that the appointment to the imamate was a matter of consultation and that the imāmates of Abū Bekr and Omar were legal although 'Alī had a better claim.

Tha'labilites. —A party of the Khārjītes, followers of Tha'lāb ibn Abī Al-Faḍl, who, as the name implies, followed the imāmate of Abū Bakr and Omar, though they were the bankers in the time of the prophet. They were transferred to Persia at the time of the divorce of the Prophet with A'ishah and subsequently took an active part in the battle of Talhah and Saidah.

Wādītītes. —Those who, opposed to the Murji'ītes, pronounced judgment in this life; they are not counted as a separate sect by Shahrastānī (see above).

Wāsīlitītes. —A sect given to those who followed Wāsib ibn 'Ata', the founder of Mu'tazilism, who denied the attributes of God, asserted the power of man over his own actions, taught the existence of a middle place between heaven and hell, and despised the partiers of 'Othman and 'Ali alike.

Yazīdītes. —Bādītes who said that they followed the religion of the Sabians in the Koran, and believed that God would send an angel from the Persians. Yūnusītes. —Murji'ītes who held that faith depends on obedience rather than on the principles than to the commands of Islam. 'Ubādītes. —Murji'ītes who believed that anything but idolatry might be forgiven, and that if a man died professing the unity of God, his soul would be carried to the Court of God.

Wātītūtes. —Those who, opposed to the Murji'ītes, pronounced judgment in this life; they are not counted as a separate sect by Shahrastānī (see above). Zaylītītes. —The sect of those who followed Zaylī ibn Ummay, the founder of the sect of the same name.

Yazīdītes. —Khārjītes, followers of Zaylī ibn Ummay, who did not regard those who abstained from fighting for Islam as unbelievers, and did not kill the children of idolaters or condemn them as a sect of Islam.

Spitta, Zur Geschichte Abu'l-Hasan al-As'harits (Leipzig, 1876); M. Schreiner, Zur Geschichte des Isma'ilismus (Leipzig, 1878); D. H. Macdonald, Development of Muslim Theology, Jurisprudence and Constitutional Theory (London, 1903). The last work contains translations of the creeds of Ashari and Nasafi (Matrakīte). A further bibliographical list of the works of faith and book of Islam will be found in D. B. Macdonald's Muslim Theology.

1 These names are alternatively spelt No instead of Nu-.

The text of the Koran has been edited by G. Flügel, Leipzig, various dates; and by G. M. Reddel, Paris, 1688 and 1880. There are also hundreds of Eastern editions. Concordances have been published by G. Flügel, Leipzig, 1842 (several times reprinted), and later published in the 'Ittifāq' of 1883, the last twelve or fifteen years of his life were spent by J. Pennick, London, 1873. English translations have been made by G. Sale, London, 1734 (the fullest edition is that with notes by E. M. Wherry, 4 vols., London, 1882-1891); by J. Rodwell with the aid of his students, London, 1855; and H. Palmer in volumes vi. and ix. of the "Sacred Books of the East," Oxford, 1889-1882. Among the best or best-known Arabic commentaries are those of Abū 'Ali Ishaq ibn 'Abd Allah Al-Khājkī (Amīr al-Ahad, 2 vols., ed. Suyūtī), and such later ones as the Maqāfī al-Uglīh of al-Razi (d. 1210). The composition and theology of the Koran are treated in the works of Nöldeke and Grimm referred to above.

MAHONEY, FRANCIS SYLVESTER (1801–1866), known as "Father Prout," Irish priest and author, son of a woolen manufacturer, was born in Cork in 1804. His classical education was chiefly obtained at a Jesuit college at Amiens, and after studying in Paris he entered the Jesuit college at Rome and was admitted into the Society of Jesus. He served in Switzerland and at Congleowood, Ireland, where he was prefect of studies and subsequently master of rhetoric. Here he was involved in scandals that led to his resignation. On going to Italy he was told at Florence that he was expelled from the Society. He succeeded, however, in obtaining priest's orders at Rome in 1832, and was named to be prior of the Jesuit college in the same city, having been appointed to it by the Pope. He was sent to England, where he lived and subsequently went to London, officiating for some time in the chapel of the Bavarian Legation. While there he fell in with William Maginn, and about 1834 began to contribute his celebrated "Prout Papers" to Fraser's Magazine. These consist of episodes in the life of the parish priest "Father Prout," and dialogues after the model of "Christopher North," varied by translations of well-known English songs into Latin, Greek, French and Italian verse, which he humorously represents as being the true originals from which the English authors have forsook plagiarized them. Mahoney's translations have been universally admired for the extraordinary command which they display of the various languages into which his renderings are made, and for their spirit and freedom both of thought and expression. His original verse tends chiefly to show that with all his sarcastic and cynical wit his genius had also its tender, serious and sentimental side. His "Bells of Shandon" has always been greatly admired. In 1846 Mahoney became correspondent at Rome to the Daily News, and his letters from that capital gave very vivid pictures of the first years of the reign of Pope Pius IX. The latter part of his life he spent in Paris, whence he supplied the Globe with a series of poignant letters on the incidents of the day. He died in Paris on the 18th of May 1866.

The Reliques of Father Prout were collected from Fraser's Magazine and published in two volumes in 1836; The Final Reliques of Father Prout, chiefly extracted from the Daily News and the Globe, were edited by Blanchard Jerrold in 1876, and an edition of his works, edited by Charles Kent, was published in 1881.

MAHOUT (Hind. mahāvāl), an elephant-driver. The mahout sits on the elephant's neck and directs him by voice and by the use of a goad called ankus.

MAHRRATTAS, a people of India, inhabiting the district known by the ancient name of Maharashtra (Sans. "great kingdom or region in E"), This large tract, extending from the Arabian Sea on the west to the Satpura mountains in the north, comprises a good part of western and central India, including the modern provinces of the Konkan, Khandesh, Barar, the British Deccan, part of Nagpur, and about half the nizam's Deccan.

The etymology of the word Mahrratta (Marāṭhā) is uncertain. The name does not indicate a social caste, or a religious sect; it is not even tribal. Strictly, it is confined to the upper class from whom Sivaji's generals were mostly drawn, and who sometimes claim a Rajput origin. In a wider sense it may be extended to all who inhabit Maharashtra and speak Marhatta as their mother-tongue. In 1901 the total number of speakers of Maharatti in all India exceeded 18 millions.
The Maharrattas have always been a separate nation or people, and still regard themselves as such, though nowadays they are almost all under British or Mahomedan jurisdiction; that is, they belong either to British India or to the nizam's dominions. There are indeed still three large native states nominally Maharratta: that of Sindia near the borders of Hindustan in the north, that of Holkar in Malwa in the heart of the Indian continent, and that of the gakawar in Gujarat on the western coast. But in these states the prince, his relatives and some of his ministers or officials only are Maharrattas; the mass of the people belong to the religion or race of the Hupt under. These states are not to be included in the Maharrata nation, though they have a share in Maharrata history.

In general terms the Maharrattas, in the wider sense, may be described under two main heads: first the Brahmins, and secondly the low-caste men. The Maharrattas Brahmins possess, in an intense degree, the qualities of that famous caste, physical, intellectual and moral. They have generally the lofty brow, the regular features, the spare upright figure, and the calm aspect which might be expected in a race maintained in great purity yet upon a broad basis. In modern times they have proved themselves the most able of all the Indian races in the promotion of agricultural interests. They are notably divided into two sections: the Konkanast, coming from the Konkan or littoral tract on the west coast below the Western Ghats, and, the Moghals, or those from the uplands or Deccan, on the east of the mountains. Though there have been many distinguished Deshasts, yet the most remarkable of all have been Konkanastas. For instance, the peshwas, or heads of the state treasuries, ready at a moment to assume the dominions of old, were, 'Konkanast Brahmins. The births of these persons are still known, and to this day there are sequestered villages on the western base of the Ghats, which are pointed to as being the ancestral homes of men who two centuries ago had political control over half India. Apart from the Brahmins, the Maharrattas may be generally designated as Sindias, the humblest of the four great castes into which the Hindu race is theoretically divided. But the upper classes claim to be Khatriyas or Rajputs. They probably are agriores fundamentally, with a mixture of what are now called the upper castes, that is to say, the works of the Brahmins. The ordinary Maharrattas, who form the backbone of the nation, have plain features, an uncouth manner, short stature, a small but wiry frame. Though not powerful physically as compared with the northern races of the Punjab and Oudh, they have much activity and an unsurpassed endurance. Born and bred in or near the Western Ghats mountains and the numerous tributary ranges, they have all the qualities of mountaineers. In recent times they enter military service less and less, betaking themselves mainly to cultivation and to the carrying business connected with agriculture. As moneylenders they are remarkably unsparing; as grain or cloth workers, as labourers, they are excellent. As artisans they have seldom signalized themselves, save as armourers and clothworkers.

In the Konkan there are some superior proprietors termed Khatriyas, but except for their exclusive privileges they are not in the Maharrat country many large landlords, nor many of the superior tenure-holders whose position relatively to that of the Brahmin is rather a minor one. In other parts of India there are indeed many Maharrata chiefs still resident in the country, members of the aristocracy which formerly enjoyed much wealth and power. They are sometimes in the position of landholders, but often they are the assigns of the land revenue, which they are entitled under special grants to collect for themselves instead of for government, paying merely a small sum to Government by way of quit-rent. Under them the cultivators are by British arrangements placed in the position of peasant proprietors. The village system has always existed as the social unit in the Maharrata territories, though with less cohesion among its members than in the village community of the Western Ghats. The ordinary peasant office of member to the village, as of those heads of the family, or the village accountant, &c., are in working order throughout the Maharrata country.

The Maharrattas possess mainly fortune under suffering and misfortune. Though patient and good-tempered in the main, they have a latent warmth of temper, and if oppressed beyond a certain limit they would fiercely turn upon their tormentors. As a rule they are poor, though conditions have been handed down to them from early times, and many of them retain the predatory instincts of their forefathers. The nei- ther are they the owners of great forests, steep hill-sides, and fastnesses hard of access offers extraordinary facilities to plunder and robbery, screening themselves and their booty. Thus gang robbery is apt to break out, gains head with rapidity, and is suppressed with difficulty both by law and the common sentiment of the time. But during war, or whenever the bands of civil order are loosened, it becomes the source of anxiety and a source of danger. The women have frankness and strength of character; they work hard in the fields, and as a rule evince domestic virtue.

The peasantry preserve a grave and quiet demeanour, but they have their humble ideals of gaiety, and hold their gatherings on occasional of births or marriages. They frequently beguile theirlonely and settled habits by the pages of literature. They have their local and national festivities and in the larger fairs, which are sometimes held in strikingly picturesque localities. They are superstitious, and worship with hearty veneration any being or thing whose destructive agency they have a terror. They are the idolaters of the south: they have gods, but their Hinduism is held to be of a non-Aryan type. They are sincerely devout in religion, and feel an awe and reverence for the holy house of the priest, the dwelling of a Brahman sacred, even though he be a criminal of the deepest dye. They are thus round as equally sacred. There are two principal sects among modern Hindus—those who follow Vishnu, and those who follow Siva. All classes high and low are fond of the religious festivals, the principal of which, the Dasshra, occurs in October. But the harvest of the year has been secured and the second crop sown. This has always been held with the utmost pomp and magnificence at every centre of Maharrata wealth and power. The people generally assemble in bowers and arbours constructed of leafy boughs to hear kathas recited. These recitations are partly religious, partly also romantic and quasi-historical. After them national resolves of just retribution against their enemies and brave achievements are often formed.

Apart from the Maharrata Brahmins, as already mentioned, the Maharrata nobles and princes are not generally fine-looking men. Some of them are exceptionally tall, and, with a physical frame wiry and wiry, are of a marked feature in the Maharrata region. It is, however, to the effect that, while there will be something dignified in the humblest Raja, there will be something mean in the highest Maharrata. Bluff good-nature, a certain jocoseness, a humour not very refined, and a lack of resource, of intelligence and disposition, are characteristics of Maharrata chiefs. They usually show little aptitude for business or for sedentary pursuits; but, on the other hand, they are born equestrians and sportsmen. Maharrata ladies and princesses have often taken a prominent part, for good or evil, in public affairs and dynastic intrigues.

Though they have produced some poetry, the Maharrattas have never done much for literature. Nor have they been distinguished in industrial art. Their architecture in wood, however, was excellent; and the teak forests of their country afforded the finest timber for building and for carving. They had also much skill in the construction of vessels and for the supply of drinking water on a large scale and for irrigation.

The range of the Western Ghats enabled the Maharrattas to rise against their Mahomedan conquerors, to reassert their Hindu nationality against the whole power of the Mogul Empire, and to establish in its place an empire of their own. It is often stated that in India British conquest or annexation succeeded Mahomedan rule: this was the case, but. On the other hand, the principal power, the widest sovereignty, which the British overthrow in India was that of the Maharrattas.

During the earlier Moslem invasions in 1190 and in subsequent years, the Maharrattas do not seem to have made much resistance. They submitted to several Mahomedan kings under the changing circumstances of those times. It was against the Mahomedan king of Bijapur in the Deccan that Sivaji, the hero of Maharratta history, first rebelled in 1657. Sivaji and his fighting officers were Maharrattas of humble caste, but his ministers were Brahmins. When the Mogul Empire absorbed the Bijapur kingdom he defied the emperor. He imparted a self-reliant enthusiasm to his countrymen, formed them into an army, and organized them as a political community; his mountaineer infantry, though limited in numbers, proved desperately courageous; his cavalry was daring and ubiquitous. The Moslems, having once overcome the Hindus in almost all parts of India, had not for centuries met with any noteworthy uprising. Sivaji, however, planned his expulsion, and before the end of his restless life made much progress in the execution of that design. The new state which he founded was maintained under various vicissitudes after his death. Maharrata resistance, once aroused by him, was never extinguished, and the imperial resources were worn out by ceaseless though vain efforts to quell it. The great Mogul emperor's simperished and enfeebled successor was fain to recognize the Maharrata state by a formal instrument. The Maharratta king, a descendant of Sivaji, had become a roi faintant, and the arrangement was negotiated by his Brahman minister, whose official designation was the peshwa. The office of peshwa then became hereditary in the minister's family,
and grew in importance as the Mahratta kingdom rose, while the king sunk into the condition of a puppet. Thus the Mahratta power was consolidated throughout nearly the whole of Maharashtra under the Brahman peshwa as virtual sovereign, with his capital at Poona, while the titular Mahratta raja or king had his court at the neighbouring city of Satara. Despite his political importance, however, the raja was still venerated as the descendant of Sivaji.

Then several chiefs carved out principalities of their own from among the ruins of the Mogul Empire. Thus Raghoji Bhonsla established himself in the tracts lying underneath the southern base of the Satpura range (namely, Nagpur and Berar), overran Orissa and entered Bengal. Damaji Gaekwar descended from the Western Ghats upon the alluvial plains of Gujarat around Baroda; Tukoji Holkar subdued the uplands of Malwa beyond the Vindhya range on the north bank of the Nerbudda; and Madajji Sindhia obtained possession of large tracts immediately south of Agra and Delhi, marched into Hindustan and became virtually the master of the Mogul emperor himself (see GWALIOR). Sivaji’s own father had founded a dominion at Tanjore in the extreme south, which, however, never had relations with the central power at Poona. The same may be said of the state of Kolhapur, allotted to a younger branch of Sivaji’s family.

But these principalities, though independent respecting internal administration, and making war or peace with their neighbours according to opportunity, owned allegiance to the peshwa at Poona as the head of the Mahratta race. On state occasions heads of principalities would visit Poona by way of acknowledging the superior position of the peshwa. On the other hand, the peshwa was careful to obtain the sanction of his nominal sovereign at Satara to every important act of state. Thus a confederation was formed of which the Brahman peshwa or head was at Poona, governing the adjacent territories, while the members, belonging to the lower castes, were scattered throughout the continent of India. Such was the Mahratta Empire as founded and the Mahratta confederacy.

As the power grew and prospered till it embraced all western and most of central India. Its culminating point was reached about 1750, or about a century after Sivaji first rebelled against his Mahomedan sovereign.

Its armies drew soldiers from all parts of India. The infantry was not of good quality; but its cavalry was really an enormous force, numbering fully a hundred thousand in all. The horsemen were splendidly audacious in riding for long distances into the heart of a hostile country, without support, striking some terrific blows, and then returning rapidly beyond reach of pursuit. They could truly boast of having watered their horses in every Indian river from the Cauvery to the Indus. If attacked, however, in a competent manner, they would not stand; and afterwards, in conflict with the British, whole masses of them behaved in a dastardly manner. As their ambition grew the chiefs began to organize their troops after the system learnt from the English and French. In this way several Frenchmen—Benoit de Boigne, Perring and others—rose in the Mahratta service to a position dangerous to the British. But the new system was unsuited to the Mahratta genius; it hampered the meteoric movements of the cavalry, which was obliged to manoeuvre in combination with the new artillery and the disciplined battalions. Mahratta elders hence uttered predictions of military disaster which were in the end more than fulfilled.

The rapid and amazing success of the Mahratta confederation rendered it the largest Hindu power that ever existed in India. But it lacked the elements of true greatness. It was founded by plundering expeditions, and its subsequent existence was tainted by the baseness of this predatory origin. With the exception of the peshwas, its chiefs were little more than freebooting warriors, for the most part rude, violent and unlettered. Their custom was to offer their neighbours or victims the alternative of paying chauth, that is, one-fourth of the revenue, or being plundered and ravaged. Thus the Mahratta chauth came to have an ominous significance in Indian history. Desultory efforts were made to establish a civil government, but in the main there was no administration formed on statesmanlike principles. The peshwas, on the other hand, as Brammans, were men of the highest education then possible in India. But they were absorbed by the direction of military and political combinations, and by intrigues for the preservation of their own power, so that even for all this, they failed to evince the civil capacity which might have been possible had they displayed commanding abilities, and some possessed many virtues, one alone attempted to conduct an administration in an enlightened manner, and he died prematurely.

There were at the same time powers existing in India to keep the Mahrattas in check, and some parts of India were excepted from their depredations. The English power was rising at Calcutta, Madras and Bombay. The nascent Sikh power prevented Mahratta incursions from being permanently successful in the Punjab. As the Mahratta Empire broke up, some separate Mahomedan powers rose upon its ruins. The nizam of the Deccan established himself at Hyderabad, comparatively near the headquarters of the peshwa. Hyderabad was proclaimed sultan of Mysore in the south. Ahmed Shah Abdali burst upon India from Afghanistan. The Mahrattas bravely encountered him at Panipat near Delhi in 1761, and were decisively defeated. The defeat, however, did not essentially shake the Mahratta confederacy. It was collision with the English that broke that wonderful fabric to pieces.

The first collision with the English occurred in 1755, arising from a disputed succession to the peshwaship. The English government at Bombay supported one of the claimants, and the affair became critical for the English as well as for the Mahrattas. It was at this juncture that Warren Hastings displayed his political genius and rendered signal service to his country, by succouring from Bengal the defeated Bombay army and negotiating a peace (in 1782) that restored the status quo.

The next collision happened in 1803. The peshwa had fallen into grave difficulties with some of the principal members of the British Council and the advocates of the East India Company. The House of Commons interfered, and the peshwa, therefore, placed himself under British protection, and this led to the great Mahratta War, in which the Marquis Wellesley displayed those talents for military and political combination which rendered him illustrious. It was during the campaigns which ensued that General Arthur Wellesley defeated Sindia and the Bhonsla raja at Assaye, and General Lake won the victories of Farrukhabad, Dig and Laswari over Sindia and Holkar. The three confederates, Sindia, Holkar and the Bhonsla, concluded peace with the British government, after making large sacrifices of territory in favour of the victor, and submitting to British control politically. It was during these events that the British won the province of Orissa, the old Hindustan afterwards part of the North-Western Provinces, and a part of the western coast in Gujarat.

The third collision came to pass between 1816 and 1818, through the conduct, not only of the confederates, but also of the peshwa (Baji Bao) himself. During the previous war the peshwa had been the protégé and ally of the British; and since the war he had fallen more completely than before under British protection—British political officers and British troops being stationed at his capital.

He apparently felt encouraged by circumstances to rebel. Holkar and the Bhonsla committed hostile acts. The predatory Findaris offered a formidable resistance to the British troops. So the peshwa ventured to take part in the combination against the British power, which even yet the Mahrattas did not despair of overthrowing. After long-protracted menaces, he attacked the British at Kirkee, but failed utterly, and fled a ruined man. Ultimately he surrendered to Sir John Malcolm, and was sent as a state pensioner to Bithur, near Cawnpore. The British, however, released the raja of Satara, though he to whom he had been kept during the peshwa’s time, and reinstated him on the throne, with a limited territory. Owing to these events the British government became possessed of the Konkan and of the greater part of the Deccan.

It remains to mention briefly the fortunes of each remaining member of the once imperial confederation. The principality of Satara was held to have lapsed in 1845 by the death of the
MAHSEER—MAIDEN

raja without lineal heirs, and was annexed by the British government. The Bhonsla raja of Nagpur died without lineal heirs in 1823, and his territory was likewise annexed. The house of Holkar remained faithful to its engagements with the British government, and its position as a feudatory of the empire was maintained. In Sindhia's territory, by reason of internal feuds, the British had to undertake measures which were successfully terminated after the battles of Maharajpur and Panniar in 1843. But by 1846 the whole house of Sindhia remained faithful. Sindhia himself was actively loyal during the Mutiny. The gaekwar gradually fell under British control towards the close of the 18th century, and his house never engaged in hostilities with the British government. The ex-peshwa lived to old age at Bithur, and died in 1857. His adopted son grew up to be the Nana Sahib, of infamous memory, who took a leading part in the Mutiny.

See J. Grant Duff, History of the Marathas (3 vols., 1826); T. D. Broughton, Letters written in a Maharaila Camp (1813); M. G. Ramade, Rise of the Maratha Power (Bombay, 1900).

(R.T. ; J. S. Co.)

MAHSEER, or Mahaseer (Barbus mola), a kind of barbel, abundant in the rivers of India, especially in pools of the upper and more rapid streams where they issue from the mountainous part of the country. It is one of the largest species of the Cyprinid family, attaining to a length of 3 to 5 ft., and sometimes exceeding a weight of 70 lb. Its body is well-proportioned, rather elongate, and somewhat like that of the European barbel, but covered with very large scales, of which there are only twenty-five or twenty-seven placed along the lateral line; the dorsal fin is armed with a long and strong spine, and the mouth provided with four slender and short barbels. The lips are sometimes produced into fleshy lobes. To the fisherman in India the mahseer affords the same kind of sport as the salmon in the British Isles, and it rivals that fish as regards size, strength and activity. Its flesh is likewise much esteemed.

MAI, ANGELO (1738-1814). Italian cardinal and philologist, was born of humble parents at Schilpario in the province of Bergamo, Lombardy, on the 7th of March 1738. In 1759 he entered the Society of Jesus, and in 1804 he became a teacher of classics in the college of Naples. After completing his studies at the Collegium Romanum, he lived for some time at Orvieto, where he was engaged in teaching and palaeographical studies. The political events of 1808 necessitated his withdrawal from Rome (to which he had meanwhile returned) to Milan, where in 1813 he was made custodian of the Ambrosian library. He now threw himself with characteristic energy and zeal into the task of examining the numerous MSS. committed to his charge, and in the course of the next six years was able to restore to the world a considerable number of lost-works. Having withdrawn from the Society of Jesus, he was invited to Rome in 1819 as chief keeper of the Vatican library. In 1833 he was transferred to the office of secretary of the congregation of the Propaganda; on the 14th of February 1838 he was raised to the dignity of cardinal. He died at Castel Gandolfo, near Albano, on the 8th of September 1854.

It is on his skill as a reader of palimpsests that Mai's chief claim to the credit of his residence at Milan belong: Fragments of Cicero's Pro Sestio, Pro Tullio, Pro Flacco, In Claudium et Curionem, De aere atino Milonis, De rege (Alexandrinus (1814); M. Corn. Frontonis opera inedita, cum epistolis item ineditis, Antonini Pii, Marci Aurelii, Lucii Veri et Appiani (1815; new ed., 1833, with more than 100 additional letters found in the Vatican library); portions of eight speeches of Quintus Aurelius Summachus; fragments of Flaccus; the oration of Isaeus De hereditate Clemixi; the last nine books of the Antiquitates of Porphyrios of Halicarnassus, and a number of other works. M. Tullii Cicerrnse de republica quae supersunt appeared at Rome in 1822; Scriptorum veterum nova collectio, e Vaticanis codicibus editi in 1825-1838; Classicai scriptores et vaticanis codicibus editi in 1828-1838; Spicilegium romanum in 1839-1844; and Patrum nova bibliotheca in 1845-1853. His edition of the celebrated Codex Vaticanus, completed in 1835, but not published (ostensibly on the ground of inaccuracies) till four years after his death (1858), is the least satisfactory of his labors and was superseded by the edition of Vercellone and Cozza (1868), which itself leaves much to be desired. Although Mai was not so successful in textual criticism as in the decipherment of manuscripts, he will always be remembered as a laborious and persevering pioneer, by whose efforts many ancient writings have been rescued from oblivion.

See D. Prina, Biografia del cardinale Angelo Mai (Bergamo, 1882), a scientific work, which gives a full and, at the same time, a just appreciation of his work; Cozza-Luzi, Epistolario del card. Angelo Mai (Bergamo, 1883); life by G. Poletto (Siena, 1887).

MAI, in Greek mythology, the eldest of the Pleiades, the seven daughters of Atlas and the Oceanid Pleione. She and her sisters, born on Mt Cyllene in Arcadia, are sometimes called mountain goddesses. In a cave of Cyllene Maia became by Zeus the mother of the god Hermes. The story is told in the Hymn to Hermes attributed to Homer. She was identified by the Romans with Maia Majesta, an old Italian goddess of spring, to whom a sacrifice was offered on the 1st of May by the priest of Vulcan.

MAIDA, a town of Calabria, Italy, in the province of Catanzaro, from which it is 30 m. W.S.W. direct, and 12 m. N.E. of Pizzo by rail (the station is 8 m. W. of the town). Pop. (1901), 5190.

The town gives its name to the plain of Maida, where in 1806 British troops under Sir John Stuart defeated the French under Regnier. The names Maida Hill and Maida Vale in London are derived from this title.

MAIDAN, an Indian term for any open plain. The Maidan is the name of the park in Calcutta, surrounding Fort William, where society people drive in the afternoon. The name is also applied to one of the valleys in the Afridi country of Tirah, and to the plateau portion of the state of Mysore.

MAIDEN, or Maid, a young unmarried girl. "Maid" is a shortened form of "maiden," O. Eng. maegden, which represents a diminutive of a Teutonic word meaning "young person," of either sex. An old English word "mey," meaning a kinsman orkinswoman, and also a virgin or girl, represents the original. In early usage "maiden" as meaning "virgin" is frequently applied to the male sex, thus, in Malory's Mort d'Arthur, Sir Percivale is called a "parfye cleene megden." Apart from the direct applications of the word to the unmarried state, such as "maiden name," "maiden lady," &c., the word is used adjectively, usually, implying the preservation of the first state of an object, or indicating a first effort of any kind. Probably a "maiden" fortress is one which has never fallen, though the New English Dictionary suggests that the various "maiden castles" in England, usually ancient earthworks, may have been so called from the expression, with reference to the wars of the 15th century, from which it is generally supposed they could be defended by maidens, and points out that Edinburgh Castle, called "maiden-castle" by William Drummond of Hawthornden (Speech for Edinburgh to the King), is styled Castrum puellarum, the "castle of the maidens," in Geoffrey of Monmouth. A "maiden" assize, circuit or session is one at which there are no prisoners for trial; a "maiden over" or "maiden" in cricket is an over from which no runs are scored. A"maiden speech" is the first speech made by a member of parliament in the house. In the Annual Register for 1794 (quoted in N.E.D.) the expression, with reference to Canning's first speech, is said to be "according to the technical language of the house." "Maiden" is applied to several objects, to a movable framework or horse for drying and airing of linen, to a washerwoman's "dolly" or wooden beater, to the "kinbaby" formed of the last sheaf of corn reapèd which formerly figured in the Scottish harvest homes, and to the headdress instrument, known as the "Scottish maiden" (see below). "Maid," apart from its primary sense of an unmarried woman, is chiefly used for a domestic female servant, usually with a qualifying word prefixed, such as "housemaid," "parLOURmaid," &c.

The title of "MAID of HONOUR" is given to an unmarried lady attached to the personal suite of a queen. The custom of sending young girls of noble or good birth to the court of a
MAIDENHAIR—MAIDSTONE

MAIDENHAIR, in botany, the common name for a fern, Adiantum Capillus-Veneris, characterized by the spreading hair-like branches of the frond, the ultimate pinnules of which are 3 to 1 in. long with a rounded crenate outer edge and repeatedly forked veins; the sori (or masses of spore-capsules) are in the crenatures of the pinnules, and are protected by a kidney-shaped involucre. The plant is widely distributed in temperate and tropical regions, and is occasionally found in the western counties of England, the Isle of Man, and west Ireland, growing on damp rocks or walls especially near the sea. The genus Adiantum is a large one containing many handsome species both tropical and temperate, well known in greenhouses and hothouse cultivation.

MAIDENHAIR-TREE is a popular name for Ginkgo biloba, a remarkable and handsome gymnospermous tree, the fan-shaped leaves of which with their forked veins recall those of the maidenhair (see GYMNOSPERMS).

MAIDENHEAD, a market town and municipal borough in the Wokingham parliamentary division of Berkshire, England; 243 m. W. of London by the Great Western railway. Pop. (1901), 12,080. Area, 2125 acres. It is pleasantly situated on and above the west (right) bank of the Thames, and is much in favour as a residential town and a resort of boating parties. Though of high antiquity it is wholly modern in appearance, and a large number of handsome houses have been built in its vicinity. A beautiful timbered house of the 15th century, however, survives in Ockwells, a short distance south of the town. The stone bridge carrying the London road over the Thames dates from 1772; but the crossing is of ancient importance. Maidenhead has trade in malt and grain. The borough is under a mayor, aldermen and councillors.

The history of Maidenhead (Maydenhut, Maydenhith) is bound up with that of the ancient bridge. It is not mentioned in Domesday. Edward I. (1207) gave a grant of pontage in aid of the bridge, which was almost broken down; similar grants to the "bailiffs and good men of Maydenhith" were made by succeeding sovereigns. In 1451 Henry VI. incorporated the gild of the Brethren and Sisters of Maydenhith to provide certain necessaries for the celebration of Mass and to keep the bridge in order: the gild, dissolved at the Reformation, was revived by Elizabeth, who, however, later (1585) substituted for it a corporation consisting of a warden, bridgekeeper, burgesses and commonalty: the governing charter until the 19th century was that of James I. (1685) incorporating the town under the title of the mayor, bridgemaister and burgesses. In 1400 Thomas Holand, earl of Kent, held the bridge in the interests of the deposed Richard II., but was eventually forced to retire. In 1643 a meeting took place in the town between Charles I. and three of his children. In the 18th century a considerable trade was done in carrying malt, meal and timber in barges to London: at that time three fairs were held which have now practically disappeared. The Wednesday market is held under a charter of Elizabeth (1582).

MAID MARIAN, a personage incorporated in the English legend of Robin Hood. There is no evidence that she had originally any connexion with the Robin Hood cycle. She seems to have had an essential feature of the morris dance, and in the may-game was paired sometimes with Robin-Hood, but oftener with Friar Tuck. The well-known pastoral play of Adam de la Hale, Jue de Robin et Marion, and the many French songs on the subject, account for the association of the names. In the ballads on Robin Hood her name is twice casually mentioned, but there is a late ballad, by a certain S. G. (F. J. Child, English and Scottish Ballads, i. 216), which tells how Maid Marian sought Robin in the forest disguised as a page, and fought with him for an hour before she recognized him by his voice. S. G. was perhaps acquainted with the two plays, written in 1598, of The Downfall and The Death of Robert Earl of Huntingdon, by Anthony Munday and Harry Chettle. In The Twelve ballads of Scarlet Morris Robin escapes from the persecution of King John by following her lover to Sherwood Forest, where they took the names of Robin Hood and Maid Marian, and lived apart until they could be legally united. Perhaps this tale has some connexion with the romance of the outlaw Fulk Fitz Warin. Matilda or Mahaud, widow of Theobald Walter, escaped from John's solicitations by marrying the outlawed Fulk and following him to the forest. There were in semi-historical legends three Matildas pursued by King John, of whom particulars are given by H. L. D. Ward in his Catalogue of Romances (ii. 302). Their several histories were fused by the Elizabethan dramatists, and associated with the Maid Marian of the morris dance, who up to that time had probably only a vague connexion with Robin Hood.

MAIDSTONE, a market town and municipal and parliamentary borough, and the county town of Kent, England; 41 m. E.S.E. of London by the South Eastern & Chatham railway. Pop. (1901), 33,516; area, 4008 acres. It lies principally on the eastern bank of the river Medway, the modern part spreading over the western slopes of a picturesque valley, which is intersected and enrobed by orchards and hop gardens, this being the richest agricultural district of Kent. The hop grounds form the so-called middle growth of Kent, and the town has the principal grain market in the county. Archbishop Boniface in 1260 established a hospital here (Newark hospital) for poor pilgrims, the chapel of which, with modern additions, is now St Peter's Church. The parish church of St Mary, which had existed from Norman times, was demolished in 1395 by Archbishop Courtenay, who erected on the site the present church of All
SAINTS. This fine Perpendicular building contains, besides many excellent monuments, the richly carved sedilia and the twenty-eight oak seats used by the collegiate priests. Courtenay also founded a college of secular canons, the ruins of which are an interesting specimen of 14th-century architecture. From the reign of John until the Reformations the archbishops had a residence here, at which Stafford and Courtenay died. This Perpendicular building, with its Elizabethan east front, was acquired by the corporation as a permanent expensive ground and dedicated to St. Julian in 1857, and houses the school of science and art. The rood-screen, with the manor, passed into lay hands at the Reformation; and, having been a perpetual curacy for three hundred and twenty years, the living became a vicarage in 1866. The grammar school was founded in 1549, and endowed with the estates of the local Corpus Christi fraternity, then dissolved; the hall in which the guild assembled remains, but the school is established in modern buildings on a new site. There are oil-mills, rope, sack and twine factories, and cement, lime, and brick works. There is a considerable carrying trade on the Medway. A museum, with public library, was opened in 1878, in an interesting building of the early part of the 18th century. This is the headquarters of the Kent Archaeological Society, founded by the Rev. L. B. Larking in 1858. In 1890 an art gallery was added. The West Kent and General hospital, the county ophthalmic hospital, county goal and barracks may be mentioned among other institutions. From Caxton times down to 1830 condemned malefactors were executed, and all the great county meetings were held, on Penenden Heath, a common situated about a mile north-east of the town, and enclosed by the corporation as a public recreation ground. The parliamentary borough of Maidstone returns one member. The town is governed by a mayor, 6 aldermen and 18 councillors.

There is evidence of a Roman settlement at Maidstone. The name Maidstone (Medwegestun, Meddestane, Maydestane), probably meaning Medway Town, is presumably of Saxon origin. At the time of the Domesday Survey it belonged to the archbishop of Canterbury, and from the reign of John the archbishops had a residence there. Its position in the centre of Kent gave it an early importance; the shire-moot was held on Penenden Heath in the 11th century, and Maidstone was an assize town in the reign of Edward I. In 1537 Cramer exchanged the manor of Maidstone with the king, and it was granted by Edward VI. to Sir Thomas Wyatt. Edward also incorporated the town by the title of the mayor, jurats and commonalty; it had formerly been governed by a portreve and 12 "brethren." This charter was forfeited through Wyatt's rebellion; a second charter was granted by Elizabeth in 1559 and confirmed by subsequent sovereigns. A new charter constituting a governing body of a mayor, 12 jurats and 40 common councillors was given at the petition of the inhabitants by George II. in 1747, and remained the governing charter until 1835. Four fairs were granted by the charter of 1559; these are now held on the 13th of February, the 12th of May, the 20th of June and the 17th of October. A Thursday market was granted by Henry III. to Archbishop Boniface, and a market every second Tuesday in the month by charter of George II. A corn market on Tuesday and a cattle market on Thursday are still held. The manufacturer of linen and woolen goods was introduced by Wallons, who settled here in 1167. This was succeeded by paper-making, now the chief industry of the town. The cultivation of hops has been carried on since the 17th century.

Maidstone has been associated with various incidents of general history. Wat Tyler broke into the prison, liberated John Ball the rebel preacher, and committed various depredations. Several of the leading inhabitants joined Jack Cade's rising. The rising of the Kentish Royalists in 1648 collapsed at Maidstone, where on the 21st of August, after five hours' obstinate fighting, captured the town at midnight.

See Victoria County History, Kent; I. M. Russell, History of Maidstone (1881).

MAIHAR, a native state of Central India, in the Baghelkhand agency. Area, 407 sq. m.; pop. (1901), 63,702; estimated revenue, £4700. The state, which is watered by the Tons river, consists mainly of alluvial soil covering sandstone, and is fertile except in the hilly district of the south. A large area is under forest, the produce of which provides a small export trade. The chief, whose title is rajah, claims descent from the Kashwaha Rajput clan. There were many fierce battles fought on the Tons from 1856 to 1860. The town of Maihar (pop. 6862) is on the East Indian railway, 97 m. N. of Jubbulpore. Extensive ruins of shrines and other buildings in its neighbourhood indicate a former much greater extent of the place.

MAIL, (1) (Through Fr. maillere, from Lat. macula, a spot or hole, the mesh of a net), properly a metal ring or link which, joined closely with other links, formed the fabric of body and other armour in the middle ages, till it was superseded by plate-armour. The word "mail," properly applied to this form of chain-armour, is also used of armour generally, whether plate or by hand, suitable to the何必 defensive covering of animals, such as the tortoise, crab, &c. (see ARMS and ARMOUR). (2) (O. Eng. mail, speech; probably the same as O. Saxon mahl, assembly; in meaning connected with O. Norse male, stipulation), a Scots law term meaning rent, tax. "Mails and duties" are the rents, whether in kind or money, of an estate. In English the word only survives in "blackmail" (q.v.). (3) (Through O. Fr. maille, mod. malle, a Teutonic word surviving in Dutch moad), properly a bag, especially one used in travelling; this word, which appears in Chaucer, is now applied chiefly to the despatch and delivery of official matters. In the 18th century it is properly the bag in which such matters is conveyed, and hence it is applied to the contents of the mail, postal matter collectively, and to the train, carts, or other means used in the despatch and delivery of the same. In general usage "mail" is confined to the "foreign" as opposed to the "inland" despatch of letters, &c., and to which the word "post" is chiefly applied; in official language, the word refers to the inland despatch. The word appears also in "mail-coach," a coach used for conveying the mails, and in "mail-cart," a cart similarly employed. This word is also applied to a light low vehicle propelled or drawn by hand, suitable for young children. The "mail phaeton" is a type of phaeton with high seat for two persons and drawn by a pair of horses.

MAILLY, LOUISE JULIE, COMTESSE DE (1710-1751), mistress of Louis XV. of France, was the daughter of Louis, marquis de Nesle. She was the eldest of three sisters who succeeded one another as favourites of the king. In 1726 she married her cousin, Louis Alexandre de Mailly. Although Louis XV. had paid her attentions from 1732, she did not become titular mistress until 1738. She did not use her position either to enrich herself or to interfere in politics. She was supplanted by her sister, the duchess of Châteauroux, and obliged to leave court in 1742.

See E. and J. de Goncourt, La Duchesse de Châteauroux et ses soeurs (1879); Toussaint, Anecdotes curieuses de ... (2 vols., 1905); J. B., H. R. Capefigue, Mesdemoiisses de Nesle et la jeunesse de Louis XV. (1864).

MAIMANA, a town and khanate of Afghan Turkestan. The town is situated 100 m. S.W. of Balkh, and only some 25 m. from the frontier of Russian Turkestan. It is about two-thirds the size of Herat, square built and surrounded by a ruined wall and moat. The khanate was for long in dispute between Bokhara and Kabul, but in 1868 Abdur Rahman laid siege to the town, and it was compelled to come to terms. Its political status as an Afghan province was definitely fixed by the Russo-Afghan boundary commission of 1885. The inhabitants are chiefly Uzbegs.

MAIMAND, a town in the province of Fars, Persia, a few miles east of Firuzabad and about 70 m. from Shiraz. It has a population of about 5000, almost wholly occupied with the manufacture and sale of rose-water, which is largely exported to many parts of Persia as well as to Arabia, India and Java. The district also produces great quantities of almonds. The
MAIMOURG—MAIMONIDES

rose gardens cover several square miles. In 1349 a great part of Maimand and of three little villages belonging to it became 
waft (pious endowment) of the shrine at Shiraz of Mir Ahmed, surnamed Shah Chiragh, a son of Musa Kazim, the seventh imam of the Shiias, and the remainder of the Maimand grounds was given to the shrine by Mr Habbib Ullah Sharfii and by Shah Ismail in 1504; the administration of the Maimand property as well as the guardianship of the shrine is still with the descendants of Mr Habbib Ullah.

MAIMBOURG, LOUIS (1610-1686), French Jesuit and historian, was born at Nancy. He entered the Society of Jesus at the age of sixteen, and after studying at Rome became a classical master in the Jesuit college at Rouen. He afterwards devoted himself to preaching, but with only moderate success. After having taken some part in minor controversies he threw himself with energy into the dispute which had arisen as to the Gallican liberties; for his Traité historique sur les préréogaties de l'Église de Rome (1682) he was by command of Innocent XI. expelled from the Society, but rewarded by Louis XIV. with a residence at the abbey of St Victor, Paris, and a pension. He died on the 13th of August 1686. His numerous works include histories of Arianism, the iconoclastic controversy, the Greek schism, Lutheranism, Calvinism, and of the pontificates of Leo I. and Gregory I.; they are mere compilations, written included in a very lively and attractive style, but inaccurate and untrustworthy.

The History of Ariusism was published in English (1728-1729) by William Webster, with an appendix on the English writers in the Socinian and Arian controversies.

MAIMING, mutilation, a physical injury which involves the loss of, or incapacity to use, a bodily member. The verb "to maim," in M. E. mayyne, mayhyme, mayme, &c. was adopted from O. Fr. maugnier; cf. It. magagnos, Med. Lat. makemius, makennare, &c. (see Du Cange, Gloss., s. v. "Mamhium"). Maiming or mutilation is and has been practised by many races with various ethical and religious significances, and was a customary form of punishment on the principle of an "eye for an eye" (see MUTILATION). In law "maiming" is a criminal offence; the old law term for a special case of maiming of persons was "mayhem" (q.v.), an Anglo-French variant form of the word. Maiming of animals by others than their owners is a particular form of the offences generally grouped as "malicious damage." For the purpose of the law as to this offence animals are subdivided into cattle, which includes horses, pigs and asses, and other animals which are either subjects of larceny at common law or are usually kept in confinement or for domestic purposes. The punishment for maiming of cattle is three to fourteen years' penal servitude. Malicious injury to other animals is a misdemeanour punishable on summary conviction. For a second offence the penalty is imprisonment with hard labour for over twelve months. (Malicious Damage Act 1861.) Maiming of animals by their owner falls under the Cruelty to Animals Acts.

MAIMON, SALOMON (1754-1800), German philosopher, was born of Jewish parentage in Pollab Lithuania, and died at Nieder-Siegersdorf on the 22nd of November 1800. He married at the age of twelve, and studied medicine in Berlin. In 1770 he severed his connexion with his orthodox co-religionists by his critical commentary on the Mereh Nebuhim of Maimonides, and devoted himself to the study of philosophy on the lines of Wolff and Moses Mendelssohn. After many vicissitudes he found a peaceful residence in the house of Count Kalkreuth at Nieder-Siegersdorf in 1790. During the ensuing ten years he published the works which have made his reputation as a critical philosopher. Hitherto his life had been a long struggle against difficulties of all kinds. From his autobiography, it is clear that his keen critical faculty was developed in great measure by the slender means of culture at his disposal. It was not till 1788 that he made the acquaintance of the Kantian philosophy, which was to form the basis of his lifework, and as early as 1790 he published the Versuch über die Transcendentalphilosophie, in which he formulates his objections to the system. He seizes upon the fundamental incompatibility of a consciousness which can apprehend, and yet is separated from, the "thing-in-itself." That which is object of thought cannot be outside consciousness; just as in mathematics "V = 1" is an unreal quantity, so "things-in-themselves are not hypotheses outside the mind." The Kantian paradox he explains as the result of an attempt to explain the origin of the "given" in consciousness. The form of things is admittedly subjective; the mind endeavours to explain the material of the given in the same terms, an attempt which is not only impossible but involves a denial of the elementary laws of thought. Knowledge of the given is therefore, essentially incomplete. Complete or perfect knowledge is confined to the domain of pure thought, to logic and mathematics. Thus the problem of the "thing-in-itself" is dismissed from the inquiry, and philosophy is limited to the sphere of pure thought. The Kantian categories are, indeed, demonstrable and true, but their application to the given is meaningless and unthinkable. By this critical scepticism Maimon takes up a position intermediate between Kant and Hume. Hume's attitude to the empirical is entirely supported by Maimon. The casual concept, as given by experience, expresses not a necessary objective order of things, but an ordered scheme of perception; it is subjective and cannot be postulated as a concrete law apart from consciousness. The main argument of the Transcendentalphilosophie not only drew attack from those who saw in the author of the "thing alone of his all critics had mastered the true meaning of his philosophy, but also directed the path of most subsequent criticism.

Maimon's chief works, in addition to the above quoted, are Phlogi. Worterbuch (1791); Streisereim im Gebiete der Philos. (1793); Über die Progresse der Philos. (1793); Die Kategorien des Aristoteles mit Anmerkungen erläutert (1794); Versuch einer neuen Logik (1794 and 1798); Kritische Untersuchungen über den menschl. Geist (1797). See S. Maimon's Lebensgeschichte von ihm selbst beschrieben (1792, ed. K. F. Moritz; Eng. trans. by J. C. Murray, 1888); Wolff, Maimoniana (1813); Witte, S. Maimon (1876).

MAIMONIDES, the common name of RABBI MOSES BEN MAIMON (1135-1204), also known from the initials of these last words as RAMAMB, Jewish philosopher. His life falls into three epochs, which may be typified by the towns in which they were passed, viz. Cordova, Fez and Cairo. He was born in Cordova on the 20th of March 1135, the eve of Passover; he had a brother, David, and one sister. His early years were spent in his native town, which had then just passed the zenith of its glory. The Jews of Cordova cherished a great regard for the study of science, art, medicine, philosophy, literature and learning. All these influences played their part in the education of Maimonides, whose father, besides training him in all branches of Hebrew and Jewish scholarship, implanted in the youth a sound knowledge of these secular studies as well. In 1148 Cordova was taken from the last Fatimite caliph by the victorious Almohades, who had spread over Spain from N. Africa. These militant revivalists strove to re-establish Islam in what they considered its primitive simplicity. They laid great stress on the unity of God, and tolerated neither schism within the faith nor dissent without. The position of the orthodox Spanish Jews became intolerable, and Maimon, after ten years of hardships, wanderings and escapes, decided to take his family out of the country. He settled in Fez. The years which Maimonides spent there (1160-1165) were memorable for his friendship with Abdul Arab Ibn Muisha—a Moslem poet and theologian—and for the commencement of his literary activity. His energies were diverted towards stimulating the religious feelings of his brethren and combating assimilation. In consequence he became the chief exponent of the Kairene congregation and consulted on important matters by communities far and wide. Here he was joined by his most
famous disciple, Joseph Aknin. But his early life in Egypt was fraught with deep sorrow. His father died soon after their arrival, and Maimonides himself suffered severely from prostration and sickness. His brother David, jointly with whom he carried on a trade in gems, was shipwrecked in the Indian Ocean. With him perished the entire fortune of the family. Forced to earn a livelihood, Maimonides turned to medicine. The fame of his skill eventually brought him the appointment of body physician to Solomon ben Zerubbael, of whom, so it is said, he was so attached that when Richard I. wrote from Ascalon, offering him a similar post at the English court, Maimonides refused. He married the sister of Ibn al-Mali, one of the royal secretaries. In 1186, his son Abraham was born. His remaining years were spent in ceaseless activity and in controversy, which he sought to avoid. He died amidst universal sorrow and veneration.

The works of Maimonides fall into three periods: (a) To the Spanish period belong his commentary on the whole Talmud (not fully carried out), a treatise on the calendar (Maamar ha-kabbal), a treatise on logic (Mithoth Haggayon), and his commentary on the Mishnah (this was called Stror or Maan, i.e. Light): begun 1167, completed 1168 in Egypt). (b) While he was in Fez, he wrote an essay on the Sacrification of the Name of God (Maamar Kiddush Hashem, Igeroth Hashemad). (c) The works written in Egypt were: Letter to Yehuda ha-Levi, Tzemach Tzaddik, Principles of law; Biblical and Rabbinical Code (Mishneh Torah or Yad Hahasaba, completed 1180); Sepher ha-mitzvot, an abridged handbook of the precepts; and his great philosophical work, Introduction to the Guide, or "the guide of the perplexed" (1185). To these must be added certain portions of the Mishnah commentary, such as the "Eight Chapters," the discussion on reward and punishment and immortality, the Jewish Creed, which have acquired fame as independent works.

The influence of Moses ben Maimon is incalculable. "From Moses unto Moses there are not one like Moses," is the verdict of posterity. Maimonides was the great exponent of reason in faith and toleration in theology. One of the main services to European thought of his "Guide" was its independent criticism of some of Aristotle's principles. His codification of the Talmud was equally appreciated in the study of the scholar and in practical life. Christian Europe owed much to Maimonides. Not only did his "Guide" influence scholasticism in general, but it was from his Code that the Church derived its medieval knowledge of the Synagogue.

A complete bibliography will be found in Maimonides, by David Yellin and Israel Abrahams (London, 1903); the final chapter of that work gives a summary of the influence of Maimonides on Christian, Mohammedan, and Jewish thought such as it was. The "Guide" has been translated into English by M. Friedlander (1881-1885; new ed., 1905). See also Jewish Encyclopedia, articles M., and the volumes edited by Gottmann. Moses ben Maimon (Leipzig, 1908 &c.).

MAIN (Lat. Moenae), a river of Germany, and the most important right-bank tributary of the Rhine. It has two sources, the Weisse Main (White Main), which rises in the Fichtelgebirge on the east side of the Ochsenkopf, and the Rote Main (Red Main), which, rising on the eastern slope of the Frankish Jura, flows past Bayreuth. They unite 3 m. below Kulmbach, 920 ft. above the sea. Hence the river, already of considerable size, pursues a north-westerly direction, skirting the slopes of the Franconian Jura in a pleasant valley. At Liebenfels the river takes again a south-western course, but as it continues its course, the valley grows deeper and wider, and it is only after some 30 miles that it begins to assume its characteristic meandering course. It now enters the fertile basin of Bamberg. Here it receives from the south-east the waters of its chief tributary, the Regnitz, and enters upon its middle course. Its direction is now again north-west, and meandering through pleasant vales and pastures it passes Haßfurt and reaches Schweinfurt. Its course is now almost due south to Ochsenfurt, when it again proceeds north-west. Continuing in this direction amid vine-clad hills, it skirts the outskirts of the university city of Würzburg, and thence, dividing the forest-clad ranges of the Spessart and the Odenwald, reaches Gemünden. Here it is joined from the right by the Frankish Saale and, turning abruptly south, receives at Wertheim the beautiful Tauber. Feudal castles and medieval towns now crown its banks, Freudenberg and Miltenberg. From the latter it proceeds due north to Aschaffenburg, whence passing Frankfurt it pours its yellow waters into the green waters of the Rhine just above Mainz. The Main has a total length of 310 m. and drains a basin of approximately 11,000 sq. m. It is navigable from the confluence of the Regnitz, 240 m. from its mouth, for barges and other small craft, and through the Ludwig Canal is connected with the Danube.

See Ulrich, Das Maingebiet in seiner natürlichen Beschaffenheit (Kassel, 1880); E. Faer, Zur Hydrographie des Maingebietes (Munich, 1885), and LilL Mainthail, Main und Mainischafft (Berlin, 1904).

MAIN (from the Aryon root which appears in "may" and "might," and Lat. magnus, great), a word meaning properly power or strength, especially physical. This use chiefly survives in the expression "with might and main." The word is more common as a substantival elliptical use of the adjective, which usually has the sense of principal or chief in size, strength, importance, &c. Thus "the main," the high open sea, is for "main sea," cf. "mainland," the principal part of a territory excluding islands and sometimes far-projecting peninsulas. The expression "the Spanish main" properly meant that part of the main land of the N.E. coast of South America stretching from the Orinoco to the Isthmus of Panama, and the former Spanish possessions in Central America bordering on the Caribbean Sea, but it is often loosely used, especially in connexion with the buccaneers, of the Caribbean Sea itself. The term "main" is also thus used of a principal pipe or cable for carrying gas or water, electricity, &c. The elliptical use does not appear, however, in such expressions as main road, line, stream. Another use of the word "main" has a somewhat obscure history. It appears as a term in the game of hazard, and also in cock-fighting. In the last it is used for a match, and for the cocks engaged in a match. In hazard it is the number called by the "caster" before the dice are thrown; this may be any number from five to nine inclusive. The usual derivation is from the French main, a hand, but according to the New English Dictionary there is no evidence for this, and the more probable explanation is that it is an adaptation of "main" meaning principal or chief. From this use of the Word in hazard the expression "main chance" is derived. "Main," a shortened form of domain or demesne, only now survives in Scotland, usually in the plural "mains" for a home farm.

MAINA (or MAANI) and MAINOTES, a district and people of the Peloponnesus, the modern Morea. Maiina is the country occupied by the mountain range of Taygetus from Sparta to Cape Matapan, the ancient Taenarum. It is now divided between the modern districts of Oitylos and Gythion, with the organization of the present kingdom of Greece, Maina was subdivided into Ego Maian, Outer Maina, from the frontier of Kalamata, on the Gulf of Messenia, to Vitylo (Oitylos) and inland to the summit of Taygetus; Kérto Maian, Lower Maina, from Vitylo to Cape Matapan; and Mera Maian, or Inner Maina, on the east, and on the Gulf of Lacoia as far as the plain of Elos. It contained over a hundred villages. The country is mountainous and inaccessible, a formation to which it owes its historical importance. The Mainotes claim to descend from the ancient Spartans, who, after the death of Lycurgus, and the defeat of the Messenian and Argive confederacy, were free, Laconians who were delivered by Rome from the power of Sparta, as is suggested by the traces of ancient Greek in their dialect and by their physical type. Their country being a natural fortress, they were able to defend themselves against the Byzantine emperors, the barbarians who broke into the empire, the Latin princes of Achaea of the house of Villehardouin, and the Turks. As their country is also poor and maritime, they were early tempted to take to piratical adventure. Gibbon says that "in the time of Constantine Porphyrogenitus they had acquired the name of Mainotes, under which they dishonour the claim of liberty by the inhuman pillage of all that is shipwrecked on their rocky shore." Their neighbours gave their country the name of "Kakaboula"—the land of wicked counsels. The passes of their mountains were elaborately fortified and their villages were full of fortified towers.
MAINE, DUCHESSE DU—MAINE, SIR H. J. S.

(À propos) from which they formed their own favourite epithet, Maina Polypyrus—many-towered Maina. On the western side it also contains the remains of feudal keeps, erected by William I. de Villehardouin (1245-1278) and other native princes of Achaean. The Mainotes did not become Christians till the 9th century. From the 15th till the 17th century they recognized a family which claimed to belong to the Commeni of Trebizon as head chiefs. But the real power was in the hands of the chiefs of the different families and villages, who formed a turbulent and martial aristocracy. Enduring and ferocious feuds were common among them. In the course of the 18th century the family of Mavromichel (Black Michael), which belonged to lower Maines, established a government over the Mainotes, which was itself made up of many murders. When Russia endeavoured to promote a rising against the Turks in the Morea in 1770 the Mainotes acted with her, and the strength of their country enabled them to escape the vengeance of the Turks when the Christians were cynically deserted by the Russians. In 1777 their practical independence was recognized by the sultan's officers. During the Greek war of independence the Mainotes were chiefly led by Petro (Pey) Mavromicheli, known to his countrymen as the king of Maines. He was known as the protector of the independence of the Morea, and many murders. MAINE, ANNE LOUISE BÉNÉDICTE DE BOURBON, DUCHESSÉ DU (1676-1753), daughter of Henri Jules de Bourbon, prince de Condé and Anne of Bavaria, was born on the 8th of November 1716. On the 15th of March 1709 she married Louis de Bourbon, duc de Maine, and Mme de Monthespan. The duchesse du Maine held a little court at Sceaux, where she gave brilliant entertainments and immersed herself in political intrigues. Displeased with the action of the regent Orleans in degrading the illegitimate children of Louis XIV. from their precedence above the peers of France, she induced her husband to join in the Cellamare conspiracy for the transference of the regency to the king of Spain. The plot, however, was discovered, and she was imprisoned in 1719. The following year she returned to Sceaux, where she resumed her salon and gathered round her a brilliant company of wits and poets. She died in Paris on the 23rd of January 1753.

See Général de Flépape, La Duchesse du Maine (1910).

MAINE, SIR HENRY JAMES SUMNER (1822-1888), English comparative jurist and historian, son of Dr James Main, of Kelso, Roxburghshire, was born on the 15th of August 1822. He was at school at Christ's Hospital, and thence went up to Pembroke College, Cambridge, in 1840. At Cambridge he was one of the most brilliant classical scholars of his time. He won a Craven scholarship and graduated as senior classic in 1844, being also senior chancellor's medallist in classics. Shortly afterwards he accepted a tutorship at Trinity Hall. In 1847 he was appointed regius professor of civil law, and he was called to the bar three years later; he held this chair till 1854. Even the rudiments of Roman law were not then included in the ordinary training of English lawyers; it was assumed at the universities that any good Latin scholar could qualify himself at short notice for keeping up such tradition of civilian studies as survived. Maine cannot have known much Roman law in 1847, but in 1856 he contributed to the Cambridge Essays the essay on Roman law and legal education, republished in the later editions of Village Communities, which was the first characteristic evidence of his genius. Meanwhile he had become one of the readers appointed by the Inns of Court, in the first of their many half-hearted attempts at legal education, in 1852. Lectures delivered by Maine in this capacity were the groundwork of Ancient Law (1861), the hook by which his reputation was made at one stroke. Its object, as modestly stated in the preface, was "to indicate some of the earliest ideas of mankind, as they are reflected in ancient law, and to point out the relation of those ideas to modern thoughts." Within a year of its publication the post of legal member of council in which he was offered the university, and a junior member of the bar with little practice, few advantages of connexions, and no political or official claims. He declined once, on grounds of health; the very next year the office was again vacant. This time Maine was persuaded to accept, not that his health had improved, but that he thought India might not make it much worse. It turned out that India suited him much better than Cambridge or London. His work, like most of the work done by Englishmen in India in time, was the introduction of new ideas. It is shown by the fact that he was asked to prolong his services beyond the regular term of five years, and returned to England only in 1869. The subjects on which it was his duty to advise the government of India were as much political as legal. They ranged from such problems as the land settlement of the Punjab, or the introduction of civil marriage to provide for the needs of unorthodox Hindus, to the question how far the study of Persian should be required or encouraged among European civil servants. On the civil marriage question in particular, and some years earlier on the still more troublesome one of allowing the remarriage of native converts to Christianity, his guidance, being not only learned but statesmanlike, was of the greatest value. Plans of codification, moreover, were prepared, and largely shaped, under Maine's direction, which were carried into effect by his successors, Sir J. Fitzjames Stephen and Dr Whitley Stokes. The results are open to criticism in details, but form on the whole a remarkable achievement in the conversion of unwritten and highly technical law into a body of written law sufficiently clear to be administered by officers of theson of whom is to be made the judge, whose language are foreign. All this was in addition to the routine of legislative and consulting work and the establishment of the legislative department of the government of India on substantially its present footing.

Maine's power of swiftly assimilating new ideas and appreciating modes of thought and conduct remote from modern Western life came into contact with the facts of Indian society at exactly the right time, and his colleagues and other competent observers expressed the highest opinion of his work. In return Maine brought back from his Indian office a store of knowledge which enriched all his later writings, though he took India by name for his theme only once. This essay on India was his contribution to the composite work entitled The Reign of Queen Victoria (ed. T. H. Ward, 1887). Not having been separately published, it is perhaps the least known of Maine's writings; but its combination of just perception and large grasp with command of detail is not easily matched outside W. Stubb's prefaces to some of the chronicles in the Rolls series, and (more lately) E. W. Maitland's monographs. As vice-chancellor of the university of Calcutta, Maine commented, with his usual pregnant ingenuity, on the results produced by the contact of Eastern and Western thought. Three of these addresses were published, wholly or in part, in the later editions of Village Communities; the substance of others is understood to be embodied in the Cambridge Rede lecture of 1875, which is to be found in the same volume. The practical side of Maine's experience was not long lost to India; he became a member of the secretory of state's council in 1871, and remained so for the rest of his life. In the same year
he was gazetted a K.C.S.I. In 1860 Maine was appointed to the chair of historical and comparative jurisprudence newly founded in the university of Oxford by Corpus Christi College. Residence at Oxford was not required, and the election amounted to an invitation to the new professor to reside and continue in his own way the work he had begun in Ancient Law. During the succeeding years he published the principal matters of his lectures in a carefully revised literal form: Village Communities in the East and the West (1871), Early History of Institutions (1876), Early Customs and Law (1883). In all these works, the phenomena of societies in an archaic stage, whether still capable of observation or surviving in a fragmentary manner among more modern surroundings or preserved in contemporary records, are brought into line, often with singular felicity, to establish and illustrate the normal process of development in legal and political ideas.

In 1877 the mastership of Trinity Hall, Cambridge, where Maine had formerly been tutor, became vacant. There were two strong candidates whose claims were so nearly equal that it was difficult to elect either; the difficulty was solved by an unanimous invitation to Maine to accept the post. His acceptance entailed the resignation of the Oxford chair, though not continuous residence at Cambridge. Ten years later considerations of a somewhat similar kind led to his election to succeed Sir William Harcourt as Whewell professor of international law at Cambridge. His all too short performance in this office is represented by a posthumous volume which had not received his own final revision, International Law (1888).

Maine's Theories, in which his conclusions from speculative politics, a volume of essays on Popular Government, designed to show that democracy is not in itself more stable than any other form of government, and that there is no necessary connexion between democracy and progress. The book was deliberately unpopular in tone; it excited much controversial comment and some serious and useful discussion.

In 1886 there appeared in the Quarterly Review (clxxi. 181) an article on the posthumous work of J. F. M'Lennan, edited and completed by his brother, entitled The Patriarchal Theory. The article, though necessarily unsigned (in accordance with the rule of the Quarterly as it then stood), was Maine's reply to the M'Lennan brothers' attack on the historical reconstruction of the Indo-European family system put forward in Ancient Law and supplemented in Early Law and Custom. Maine was generally averse from controversy, but showed on this occasion that it was not for want of controversial power. He carried the war back into the invader's country, and charged J. F. M'Lennan's theory of primitive society with owing its plausible appearance of universal validity to general neglect of the evidence of contemporary facts. The extent and meaning of such portions of it as M'Lennan did attempt to handle.

Maine's health, which had never been strong, gave way towards the end of 1887. He went to the Riviera under medical advice, and died at Cannes on the 3rd of February 1888. He left a wife and two sons, of whom the elder died soon afterwards.

An excellent summary of Maine's principal writings may be seen in Sir Mountstuart Grant Duff's memoir. The prompt and full recognition of Maine's genius by continental publicists must not pass unmentioned even in the briefest notice. France, Germany, Italy, Russia have all contributed to do him honour; this is the more remarkable as one or two English publicists of an older school signally failed to appreciate him. Maine warned his countrymen against the insularity which results from ignorance of all law and institutions save one's own; his example has shown the benefit of the contrary habit. His prominent use of Roman law and the wide range of his observation have made his works as intelligible abroad as at home, and thereby much more accessible for foreign instruction—for example, concerning the nature of British suprême court, and the position of native institutions there—has been made the property of the world of letters instead of the peculiar and obscure possession of a limited class of British public servants. Foreign readers of Maine have perhaps understood even better than English ones that he is not the propounder of a system but the pioneer of a method, and that detailed criticism, profitable as it may be and necessary as in time it must be, will not leave the method itself less valid or diminish the worth of the master's lessons in its use. The rather small bulk of Maine's published and avowed works may be explained partly by a fine literary sense which would let nothing go out under his name unfinished, partly by the drawbacks incident to precocious brainwork. Maine's temperament was averse from the labour of minute criticism, and his avoidance of it was no less a matter of prudence. But it has to be remembered that Maine also wrote much which was never publicly acknowledged. Before he went to India he was one of the original contributors to the Saturday Review, founded in 1855, and the inventor of its name. Like his intimate friend Fitzjames Stephen, he was an accomplished journalist, enjoyed occasional article-writing as a diversion from official duties, and never quite abandoned it. The practice of writing probably counted for something in the freedom and clearness of Maine's style and the effectiveness of his dialectic. His books are a model of scientific exposition which never ceases to be literature.

MAINE, an old French province, bounded N. by Normandy, E. by Orléanais, S. by Touraine and Anjou, and W. by Brittany. Before the Roman Conquest the region occupied by this province was inhabited by the Aulerici Cenomanni and the Aulerici Diablintes; under the Roman empire it consisted of two civitates comprised in the Provincia Lugdunensis Tertia—the Civitas Cenomannorum and the Civitas Diablintum, whose chief towns were Le Mans and Jubbilins. These two civitates were united during the barbarian period and formed a single bishopric, that of Le Mans, suffragan to the metropolitan see of Tours. Under the Merovingians and Carolingians the diocese of Le Mans corresponded to the Pagus Cenomannicus, and in the feudal period to the county of Maine. In the 16th century the county of Maine, with the addition of Perche, formed a military government—the province of Maine. Since 1790 this province has been represented approximately by the departments of Sarthe and Mayenne, the respective capitals of which are Le Mans and Laval. In 1855 the bishopric of Laval was separated from that of Le Mans. Maine was evangelized in the 3rd century by St Julian. After forming part of the kingdom of Syagrius, it was conquered by Clovis at the end of the 5th century. Owing to the scarcity of documents the history of Maine until the end of the 9th century is merged in the history of the bishops of Le Mans, which has come down to us in the Actus pontificum Cenomannicus in urbe degenitum (ed. Busson-Ledru, Le Mans, 1901), composed under the direction of Bishop Aldric (832-857). Roger (c. 892-c. 898) was perhaps the first hereditary count of Maine; the counts whose existence is certain are Hugh I. (c. 939—before 992), Hugh II. (before 992—1015), Herbert I. (1015—1023 to 1039), Hugh III. (1015—1036 to 1051), Herbert II. (1051—1063), William the Bastard (1063—1067), Robert Curthose (1067—1087), Hugh IV. (1091—1092) and Helias (1092—1130). Maine, which was in the vassalage of Anjou as early as the 9th century, was united to Anjou in 1110 by the marriage of Count Helias's daughter to Fulk V., count of Anjou, and passed to the English crown in 1134, when Henry Plantagenet (who was born at Le Mans) became king of England. In 1240, after the confiscation of the estates of John of England, Maine was united to France; in 1246 it was separated from France by Louis IX., who granted it over to his brother Charles, count of Provence. Again united to France in 1328, it was given in 1356 as an appanage to Louis, second son of King John II., and did not
MAINE

definitely return to the French crown until 1451, after the death of Charles II, count of Maine. During the Hundred Years' War Maine was taken in 1425 by the English, who lost it in 1448.

**MAINE**, a North Atlantic state of the United States of America, the most north-easterly state in the Union, and the largest of the New England group of states (32,380 sq. m., 8,325 sq. m.), and between 66° 59' and 70° 24'. It is bounded N.W. by the Canadian province of Quebec; N. and E. by the Canadian province of New Brunswick, from which it is separated in part by the natural barriers of the Saint John River, the Grand (or Sodus) Lakes, the Saint Croix River, and Passamaquoddy Bay; S.S.E. by the Atlantic Ocean; and W. by New Hampshire, the Piscataqua and Salmon Falls rivers being the natural boundary lines at the S.W. The area of the state is 33,040 sq. m., 3,145 sq. m. being water surface.

Maine attracts more summer visitors than any other state in the Union. This is due to the cool and refreshing summer climate; the picturesque coast and its many islands, which are favourite grounds for camps and summer cottages; the mountains, and the beautiful lakes and rivers, many of which afford opportunities for good fishing and canoeing. Among the more widely known resorts are Mount Desert Island, on which is Bar Harbor, a fashionable summer place of great beauty; Long Island, Orr's and other islands in Casco Bay; Old Orchard, with a gently sloping white sand sea-beach 9 m. long, Rangeley and Moosehead lakes, favourite resorts of fishermen and hunters; Mt Katahdin, in the heart of the moose country; and Poland Springs (38 m. by rail from Portland) in Androscoggin county, near lake Anasagunticook. About 1870, camps, summer cottages, summer hotels and boarding houses began to multiply throughout the state. The needs of this summer population gave a new impulse and a new turn to agriculture; and the demand for souvenirs revived among the Indians basket-weaving, moccasin-making, and such crafts.

**Physical Features.—** The surface is a gently rolling upland, forming part of the "New England uplands," above which rise isolated mountain peaks and clusters of peaks, and below which are cut numerous river valleys. The highest peak is Mt Katahdin (5200 ft.), the highest point on the north coast of the United States. It is a tumbled mass of rocks which rises from a comparatively level upland. South-west of Katahdin, in Franklin county, are most of the other high peaks of the state: Saddleback Mountain (4600 ft.), Mt Abarne (4000 ft.), and Blue Hill (3000 ft.). A little N. of this line of mountain peaks is the water-parting which divides the state into a north slope and a south slope. The north slope descends gently both to the N. and S. at 2° to 3°, while the south slope descends steeper in the middle and western portions it is so poorly drained that swamps abound in all sections. The south slope which contains nearly all the mountains and is generally more hilly, has a mean descent toward the sea of about 7 ft. to the mile, the fall being greater in the W., where the mountains are high at the N. and the shore low at the S., and less to the E., where the water-parting is lower and the shore high and rocky.

After the uplift which caused the rivers to cut below the general "upland," and develop well marked valleys for themselves, came the period of the great continental glaciation. The glacier or ice sheet overran all Maine, irregularly scouring out the bed rock to produce rock basins, damming up many river valleys with glacial deposits and completely disarranging the drainage lines. When the ice melted, the rock basins and the dammed-up valleys filled with water to produce lakes. This is the origin of the numerous lakes of Maine, which give it some of its most beautiful scenery, and help to make it a holiday resort in summer. These lakes are about 1600 in number. The water in all parts of these lakes is clear, and the bottom is celebrated at high elevations, and have an aggregate area of more than 2000 sq. m. Few other regions have so many large lakes so variously distributed, and with such beauty of aspect and surroundings. They are also a great source of supply for the inland streams. They divide the course of the rivers of S.W. Maine are exceptionally well adapted; many of them abound in trout, salmon, toge, black bass and pickerel, and nearly all of the large game ducks and moose. These lakes are about 120 sq. m., 3,500 m. long and from 100 to 1000 ft. on the boundary between Piscataquis and Somerset counties, is the largest in Maine and the largest inland body of water wholly within the state. This lake is a continuation of the head waters of the Saint Croix River, equal or surpass Moosehead in picturesqueness. The glacier or ice sheet, above referred to, defeated the boulders, rock fragments and stones, and left them on the ice sheet to form the "hard pan." At the first spring thaw these fragments were washed through the region, and the alternating processes of glacial erosion and uplift consequent to the warming out of the ice sheet, have produced the "hard pan." It is responsible for the poor soil of most of the state, for, although the rocks are the same crystallines which give good surrounding regions, the land lacks moisture in some regions and is too stony in others; and stony wastes and boulder clay are not unfrequent. The most important lakes in this state are: The headwater lakes, Penobscot, Moosehead, and Piscataqua; the middle ones, Great Bay, Castine, and Machias; and Passamaquoddy bays being especially noteworthy.

After the submergence came another period of uplift, possibly still in progress. This uplift has brought up submarine deposits of sand, &c., to form little coastal plains at some points along the coast, providing good land for settlement and clay for brick and pottery. Further evidence of this uplift is found in old beach lines now well above sea-level.

The principal river systems of Maine are the Saint John on the north slope, and the Penobscot, the Kennebec, the Androscoggin, the Piscataquis, and the Passagassawakeag on the south slope. The St John is blocked by the fall of St John River, falling nearly straight over a mile, but the St John River through the greater part of its course in Maine is only sufficient to give a sluggish or a gentle current. The fall of the St John River, Kennebec, Androscoggin and Saco have numerous falls and rapids.

**Fauna.**—The animal life of Maine shows a mixture of northern and southern forms, and very little that is peculiar to the state. The northern regions show a great number of muskrat, mink, rabbit and squirrel are found. The geese, ducks, and other water fowl frequent the lakes and bays in the migratory season, and eagles, gulls, hawks, kites, and other birds are common. In the inland waters salmon, trout, toge, *Salvelinus namaycush*, pickerel and bass abound; along the shore there are lobsters, clams, mussels, crabs, and many other sea-fishes. In the woods, slevives, mackerel, cod, halibut, haddock, smelts, hake, menhaden, porgies and porpoises. The game in the North Woods attracts large numbers of sportmen during the autumn season.

Flora.—Maine was formerly covered with forests, principally of white pine and spruce, but mixed with these were hemlock, tamarack, cedar, and, on the south slope, birch, poplar, oak, maple and beech. Chestnut and walnut are rare and are found only near

---

1 This condition results from the fact that Maine and the adjacent region were worn down nearly to sea-level by stream erosion, except certain peaks and ridges inland; then the region was elevated and numerous small uplands were cut down below the general surface formed before. Thus we have a general "upland surface" above which the mountain remnants tower, and below which the rivers have been entrenched.  

2 This name is applied to a chain of lakes (the Rangeley, or Oquossoc, the Cutler, the Moosehead, the Piscataquis, the Molkenhake, the Upper Richardson, the Wolkenhake, or Lower Richardson, and the Umbagog) in Franklin and Oxford counties, in the western part of the state; the Umbagog extends into New Hampshire, and these lakes are connected by a series of canals. These lakes are connected by canals, which have a total area of between 80 and 90 sq. m., and are from 1200 to 1500 ft. above the sea. They are sometimes called the Androscoggin Lakes.
the south-west border. In 1909 about 21% of the state’s area was cleared, and much besides had once been cleared, but not being suited to agriculture had become reforested. Of fruit trees the chest is predominant, the hard-pan, or clay soil, found on the north side of the state, and the north-western border, is not so productive, and the fruit trees there grow well only in the south-west near the border. Species of grape, gooseberry and currant are native, and others are cultivated with advantage. The blueberry, raspberry, blueberry and strawberry grow wild throughout the state.

Climate.—The climate of the state is moist and, for its latitude, cool. Extremes of temperature are not so great as farther inland in New England, being 69° in July and 27° in January, while the temperature of the sea and the cold north winds, and the winter cold is so constant as to be less severely felt than the changing temperature of more southern districts. The summers are short, there being only about 43° for the average temperature between July 1 and September 1. The summer temperature is about 62° F. The mean winter temperature is approximately 20° F., and the mean annual temperature for the entire state is 44°. In some sections the rainfall is much less than that for the south slope. Although the temperature remains pretty steadily below the freezing point for at least three months of the year, many of the harbours remain unobstructed; for the tides and the prevailing off-shore winds break up and drive off the ice. The precipitation is about 42 in. annually, and is distributed very evenly throughout the year, 10-11 in. of rain or its equivalent in snow falling each season. During 41 months about 44% of the precipitation was in the form of snow in 1899, but the snow-lay varies from about 60 in. on the coast to more than 100 in. on the north slope. The winds are variable; at no season of the year is it usual for them to blow from the same direction for several days together. Even then, however, but with the exception of those from the west, they are maritime and consequently moisture-bearing. In summer, especially in the latter part of the year, the cool and moist N., or N.E. winds often cause a considerable part of the state to be enveloped in fog for several days in succession.

Agriculture.—The soil is the most part glacial drift, containing a mixture of Intelligent clay or loam and sand, drab or deep, or “hard-pan,” i.e., mingled clay and boulders which have been so much compressed by glacial action as to make the mixture hard and gravel-like. Except in the valley of the Aroostook and along the Kennebec, the Penobscot, and some other rivers, the soil is generally unfitted for cultivation, being too little alluvium mixed with it to make it fertile. In the Aroostook valley, however, is the largest unbroken area of the state, in which the soil is a deep, porous, yellow loam well adapted to the growth of cereals and to market gardening. The most sterile regions are on the mountains and along the coast. Because of the cold climate, the large areas in which there is little or no good arable land, the growing demand for timberland, and the large and constant supply of water-power afforded by the principal rivers, agriculture in Maine, as in all the other New England states except Vermont, is a smaller industry than manufacturing; in 1909 there were 87,032 people engaged in manufacturing and only 76,932 engaged in agriculture. Only 32% of the state’s land area was in that year included in the farms which can be cultivated. The farm land, only 16.5% of the improved land was in crops other than hay and forage. Nevertheless, as indicated by the unusually large proportion of farmers who either own or rent their farms, the farm land is far from unprofitable. The number of farms in 1909 was 95,499; of these 18,644 contained between 50 and 100 acres and 17,191 contained between 100 and 175 acres, the average size farm being 125.3 acres; of the other farms, 775 were operated by part owners, 2030 by cash tenants, and only 745 by share tenants. Beginning with the middle of the 19th century, the increasing competition of the more productive soils of the West, the growth of urban population in the state, and the number of summer visitors effected the reforesting of much poor land and the more intensive cultivation of the better arable land. The cultivation of cereals, for example, has given way to a marked extent in nearly all the farming districts except in Aroostook county to market gardening, dairying, and egg and poultry production. The number of dairy cows increased from 17,572 in 1900 to 23,184 in 1910. The number of milk cows increased from 57,699,791 gallons in 1899 to 99,856,188 gallons in 1900. The number of other beef cattle (180,875 in 1900; 131,000 in 1899) in 1900 was 119,000. The number of sheep in 1900 was 427,200 (31% less than in 1899), but in 1908 it was 267,000; but the number of horses in 1890 and 1900 was about the same (130,310 in 1900, but only 116,000 in 1890). The number of hogs increased from 1,637,254 in 1899 to 1,720,254 acres, and 76.5% of that of all crops, and the yield was 1,133,932 tons; in 1907 the acreage was increased to 1,720,426 acres, and 58.2% of that of all crops, and the yield increased to 1,251,032 tons. The number of acres of cereals decreased from 187,813 in 1880, when agriculture in Aroostook county was little developed, to 166,886 in 1899, when the cereal acreage in Aroostook county alone was 82,060. Maine potatoes, the state’s principal vegetable, increased from 49,617 in 1889 to 118,000 in 1907. The sweet Indian corn, cabbages, turnips, cucumbers and tomatoes are grown in large quantities. The fruit crop consists very largely of apples and strawberries (1,421,773 bushels of apples and 1,066,860 quarts of strawberries in 1899). The output of eggs increased from 9,359,534 in 1889 to 13,304,150 in 1899. The most productive dairy section of the state is a belt extending from the southern part of the state, through the whole or parts of the counties of York, Oxford, Cumberland, Androscoggin, Kennebec, Penobscot and Aroostook.

Lumber Industry.—The value of the white pine, for which Maine was long noted, has been cut; but the woodland of the state was estimated in 1900 at 23,700 sq. m. or 79% of its area. The tendency is for this area to increase, for the estimated rate of annual decrease is about 37.7% on the public forest lands, 33% on the private forest lands, and 20% on the towns and plantations. The value of the timber on the plantations is about $2,693,889. But, in addition to those of the south slope, greatly increased the value of forests, especially those of spruce and poplar. The state makes large appropriations for preventing and extinguishing forest fires, and in 1910 was engaged in the university of Maine. Good spruce, which is by far the most valuable timber in the state and is used mostly for the manufacture of paper and pulpwood, is in large part supplied by Penobscot, Androscoggin and Kennebec basins. Poplar, also used for the manufacture of paper, abounds in several sections of the south slope, but is most abundant in the basin of the Kennebec. White birch, used largely for the manufacture of paper, abounds throughout a wide belt extending across the middle of the state. There is much cedar on the north slope. Oak, maple and beech are rather scarce. A new growth of white pine and other timber is gradually becoming valuable. The value of the timber product increased from $11,849,654 in 1890 to $13,489,401 in 1900, and to $17,937,683 in 1905.

Fishery.—Fish has always been an important industry in Maine. From 1901 to 1904 inclusive, the average annual catch amounted to 105,335,616 lb., and its average value was $5,557,083. In 1908, according to state reports, the catch was 185,478,313 lb., valued at $13,849,900. Herrings were caught in Maine (in 1908, according to state reports, 68,210,800 lb., valued at $450,663), and Maine is noted for the canning of the smaller herrings under the name of "sardines.

Minerals.—The principal mineral products are granite, limestone, slate, clay products and mineral waters. In 1905 Maine held first rank among the states in the output of granite, with a value of the output being $2,713,795. In 1907 Maine’s granite was valued at $2,146,420, that of Massachusetts at $2,325,777, and that of Vermont at $2,693,889. The stone is of superior quality, and its large size and ease of dressing makes much of it is used as paving blocks and some for monuments. It abounds all along the coast east of the Kennebec and on the adjacent islands. Limestone is found in a belt, extending from the lakes in Franklin and Oxford counties, and, near Mt. Katahdin, and these have supplied the bulk of the material used in the construction of many prominent buildings and monuments in the United States. The Fox Island granite comes from the quarries on Vinalhaven Island and the surrounding islands, and on Vinalhaven were quarried monolithic columns 51 to 54 ft. long and 6 ft. in diameter for the Cathedral of St John the Divine in New York, and for the White House, the Capitol, the Treasury, the Post Office, and the Museum of Natural History in York, Lincoln, Waldo, Penobscot and Washington counties. Lime stone abounds, especially in the south-east part of the state, which is the most productive in Knox county. As its colour—blue and blue-black streaks with white—renders it undesirable for building purposes, nearly all of it is burned into lime, which has become a very important article of manufacture, the clay products are also of importance. In 1889 the production in Knox county was 217,000 tons, and in 1909 it was 213,000 tons. In 1907 the quantity of lime burned in Maine was 159,394 tons and its value was $747,947. Slate is quarried extensively in Knox county, mostly of it being used for roofing, but some for blackboards; in 1910 the value in Maine was valued at $236,106. About 1864 some remarkably white and pure feltspar began to be quarried in Androscoggin, Oxford and Sagadahoc counties. Plutons, however, is probably with produced in Maine has been of less excellent quality; in 1905 the production in Maine was valued at $157,334, the total for the entire country being $499,069. Clay is obtained in various places, and in 1905 the total value of the clay products was $619,294. In Oxford county.
tournmaline, spodumen (or kunzite) and beryl occur, the tournmaline crystals being notably large and beautiful.

Maine water occurs in many localities, particularly in Androscoggin, York, Cumberland and Oxford counties. The most productive areas are猜想 in Androscoggin county. Most of the mineral waters bottled in the state are chalybeate and slightly alkaline—sulphur; their average temperature is about 43°. In 1868 28 springs were reported in the state of over 15°, but in 1890, only 9. The copper, gold alloyed with platinum, iron ore, barytes, graphite and lead occur in small quantities in the state. In 1899 the total mineral production of the state was valued at $2,443,260. Although Maine has no coal and only a very small amount of iron ore within her borders for the encouragement of manufacturing, yet the abundance of fine timber and the numerous cover-bays and navigable streams along the coast, promoted ship-building from the first, and this was the leading industry of the state until about the middle of the 19th century, when wooden ships began to be supplanted by those of iron and steel. The manufacture of rum from molasses, received in exchange for lumber and fish in the West Indies, was also an important industry. It was not until early in the 19th century that the large and constant supply of water power afforded by the rivers began to be used to any considerable extent. The first cotton mill was built at Brunswick on the Androscoggin about 1809, and from 1830 the development of the cotton mill prospered according to the well-wooded character of the country. The value of the cotton manufactures of the state increased from $95,689,500 in 1890 to $127,361,485 in 1900; and in 1905 the value of factory-made products alone was $141,020,197, or 27.5% greater than in 1900; and by 1909 the census of manufactures was 14,1% of the
cotton output, paper and wood pulp rose from third among the state’s manufactures in 1890 to third in 1900; and in 1905 from $3,281,651 in 1890 to $13,223,275 in 1900, an increase of 303% within the decade, and to $22,801,124 in 1905, a further increase of 73.6% in this period. Lumber and timber products ranked second (1905) $14,859,513 in 1900, or $13,977,682 in 1905. Cotton goods ranked third (1905) in value—$15,166,909 in 1900, or $16,141,868 in 1900, and $15,404,823 in 1905. Woolen goods ranked fourth (1905) $8,737,653 in 1900, $13,714,126 in 1900, an increase of 57.5% within the decade; and the value of woolen and worsted manufactures in 1905 was greater than in 1900 or 20% greater than in 1900. Boots and shoes ranked fifth (1905) $12,395,877 in 1900, and $12,531,203 in 1905. Fish, canned and preserved, followed next, $1,660,881 in 1890 and $4,770,773 in 1900, an increase within the decade of 187.8% most of which was in one branch—the canning of small herrings under the name "sardines"; from 1900 to 1905 the increase was slight, only $275,538, or 5.8%. In the value of its manufactures as compared with those of the other states of the Union, in wooden ships and boots, Maine in 1905 was outranked by New York only; in canned and preserved fish it ranked second within the nation, and in which Massachusetts and Maine in 1900 was 21.7% of the total for the United States, and in 1905 10.2%); in the output of woolen mills by Massachusetts and Pennsylvania only; in the woolen goods by New England, and Maine and New York; in wood pulp it ranked ninth in 1900 and tenth in 1905 in the value of its cotton goods. Portland, Lewiston, Biddeford, and Auburn are the leading manufacturing cities, and in 1905 the total value of their manufactures was 51.3% of those of the entire state. But from 1900 to 1905 the value of manufactures grew most rapidly in Rock-land (especially noted for lime), the increase being from $1,243,881 to $1,823,901 (46.5%), and in Waterville, where the increase was from $2,283,356 to $3,965,399 (43.4%). Among the largest paper mills are those at Millinocket, in Penobscot county, at Madison on the Kennebec river, and at Rumford Falls, Anson. The largest manufactory of cotton goods; Auburn, Bangor and Augusta, in the manufacture of bolts and shoes; Bath, in ship and boat building; Eastport and Lubec, in fishery products.

Transportation and Commerce.—The south-western part of the state, including the manufacturing, the quarrying, and much of the older agricultural district, early had fairly satisfactory means of transpor- tation either by water or by rail; for the coast has many excel- lent harbours, the Kennebec river is navigable for coal vessels to Augusta, the Penobscot to Bangor, and railway service was soon supplied by the state. But it was noted that last decade of the 19th century that the forests, the farming lands, and the summer resorts of Aroostook county were reached by a railway, the Bangor & Aroostook. The first railway in the state, from Ellsworth to Otter Town, was completed in 1835, and its mileage increased from 12 m. in that year to 245 m. in 1850, to 1,377-74 m. in 1890, and to 2,310-79 in January 1909. The principal railway systems are the Maine Central, which enters every county but one, the Boston & Maine, the Bangor & Aroostook, the Grand Trunk and the Canadian Pacific. Lines of steamboats connect between the largest cities of the state and Boston, between Portland and New York, and between Portland and several Canadian ports.

The foreign trade, especially that with the West Indies and with Germany, is considerable. The principal export article is of course sugar, which is grown in considerable quantity in the northern part of the state and along the Bay of Fundy. The leading imports are tobacco, manufactured goods, iron, oil, &c. The ports of entry in Maine are Bangor, Bath, Belfast, Castine, Eastport, Bailey Island, Houlton, Kennbunk, Machias, Portland, Wiscasset and York. The census of 1900 was taken under the direction of the United States census bureau, but the statistics for hand trades were omitted.

1 According to previous censuses the population was as follows: (1790) 96,530; (1800) 151,719; (1810) 228,705; (1820) 268,335; (1830) 399,455; (1840) 501,793; (1850) 583,165; (1860) 628,279; (1870) 665,915.
September election; or, as provided by an amendment adopted in 1812, the legislature may by a two-thirds vote of each house summon a constitutional convention. From 1819 to 1875 twelve amendments were adopted; in 1875, after nine more were added, the twenty-one were incorporated in the text; and between 1875 and 1899 nine more were adopted. Suffrage is conferred by the constitution on all male citizens of the United States who are at least twenty-one years of age and have, for some other reason than because of being in the military, naval or marine service of the United States, been enrolled or served during the four years next preceding any election; the following classes, however, are excepted: paupers, persons under guardianship, Indians not taxed, and, as provided by an amendment adopted in 1892, persons intellectually incapable of reading the state constitution in the English language or of writing their names. State elections were annual until 1897 when they were made biennial; they are held on the second Monday in September in even numbered years, Maine being one of the few states in the Union in which they are not held in November.

The governor is the only executive officer of the state elected by popular vote. There is no lieutenant-governor, the president of the Senate succeeding to the office of governor in case of a vacancy, but there is a council of seven members elected by the legislature (not more than one from any one senatorial district), without term of office. The governor's term of office is two years (before 1879 it was one year); and the constitution further directs that he shall be at least thirty years of age at the beginning of his term, and that he shall be born citizens of the United States, that when elected he shall have been a resident of the state for five years, and that he shall reside in the state while in office. His power of appointment is unusually extensive and the advice and consent of the council (instead of that of the Senate as in other states) are required for his appointments. He appoints all judges, coroners and notaries public, besides all other civil and military officers, who are not elected by the people, whether the constitution nor the laws provide otherwise. The governor is commander-in-chief of the state militia. Any bill of which he disapproves he can veto, and if it again pass prevent from becoming a law unless it is passed over his veto by a two-thirds vote of each house of the legislature. He and the council examine and pass upon election returns; he may summon extra sessions of the legislature, and he may grant pardons, reprieves, and commutations in all cases except impeachment, but the manner of hearing applications for pardon is in a measure prescribed by statute, and he must present to the legislature an account of all grants of a pardon or remission. His salary is $2,000 a year. The seven members of the council, the secretary of state, the treasurer, the attorney general and the commissioner of agriculture are elected by the people for terms of three years, and the clerk of the house of representatives, which also elects, one every two years, the three state assessors, whose term is six years.

The legislature meets biennially at Augusta, the capital, and is composed of a Senate of thirty-nine senators and a House of Representatives of one hundred and fifty-one members. Members of each house are elected for a term of two years: one senator from each senatorial district and one to seven representatives (one for a population of 1,500, and seven for a population of 26,250) from each township, or, where the township or plantation has less than 1,500 inhabitants, from each representative district, according to its population. There is a new reapportionment every ten years, counting from 1821. Every senator and every representative must at the beginning of his term have been for five years a citizen of the United States, for one year a resident of the state, and for one year of the township or district which he represents; and every senator must be at least twenty-five years of age. All revenue bills must originate in the House of Representatives, but such bills the Senate may propose amendments provided they relate solely to raising revenue. Other bills may originate in either house. In September 1908 a constitutional amendment was adopted providing for referendum and initiative by the people.

Any bill proposed in the legislature or passed by it must be referred to popular vote before becoming law, if there is a referendum petition of 20,000 or 10,000 voters; and a petition signed by 12,000 voters initiates new legislation.

At the head of the department of justice is the supreme judicial court, which consists of a chief justice and seven associate justices appointed by the governor and confirmed by the legislature for a term of seven years. When it sits as a law court, at least five of its justices must be present, and it holds three such sessions annually: one at Augusta, one at Bangor, and one at Hallowell. In the legislative organization of the state, it is provided that it shall be required for a trial court, and trial courts are held two or three times a year in each county for the trial of both civil and criminal cases which come before it in the first instance or upon appeal. In Cumberland and Kennebec counties there is a superior court presided over by one justice, having civil and criminal jurisdiction; and in each of the counties there is a probate court for the settlement of the estates of deceased persons and courts of the trial justice and the justice of the peace for the trial of any civil cases in which the debt or damage involved does not exceed $20.

The principal forms of local government are the town (or township), the plantation, the city and the borough. The town is the most important of these. At the regular town meeting held in March the electorate of the town assembles, decides what shall be done for the town during the ensuing year, elects officers to execute its decisions with limited discretion, and votes money to meet the expenses. The principal officers are the selectmen (usually three), town clerk, assessors, collector, treasurer, school committee and, in 1892, in order to promote certain financial ends, is commonly incorporated as a village without however becoming a governing organization distinct from the town. Maine is the only state in the Union that retains what is known the organized plantation. This is a governmental unit organized from an unincorporated township having at least 200 inhabitants, and its principal officers are the moderator, clerk, three assessors, treasurer, collector, constable and school committee. The city is a sort of intermediate organization between the state and the towns to assist chiefly in the administration of justice, especially in the more populous towns. The city elects its officers (not the mayor and council) in December, and the mayor, the treasurer, the judge and a register of probate. They are all elected: the commissioners for a term of six years, one retiring every two years; the other officers term of two years; the city manager, county attorney, and register of probate for a term of four years, and the others for two years. Among other duties the commissioners care for county property, manage county business and take charge of those properties which cities are chartered, and does not even set a minimum population. A town may, therefore, be incorporated as a city whenever it can obtain from the legislature a city charter which a majority of its electorate prefers to a continuesness under its own government; consequently there is much variety in the government of the various cities of the state.

By the laws of Maine the property rights of a wife are approximately equal to those of a husband. A woman does not lose nor a man acquire right by the property by days or years of marriage, but while in her husband's lifetime the wife has equal, and in case of his death, the rights of a single woman in the property in the event of her husband's death. The woman during divorce or refusal or neglect to provide a suitable maintenance for his wife. Under the laws of Maine a householder owning and occupying a house and lot may hold the same, or such part of it as does not exceed $500 in value, as a homestead exempt from attachment, except for the satisfaction of liens for labor or material, by filing in the registry of deeds a certificate stating his desire for such an exemption, provided he is not the owner of an exempted lot purchased from the state; and the exemption may be continued during the widowhood of his wife or the majority of his children. A considerable amount of personal property, including apparel, household furniture not exceeding $100 in value, a library not exceeding $50 in value, interest in a pew in a meeting-house, and a specified amount of fuel, provisions, tools or farming implements, and domestic animals, and one fishing boat, is also exempt from attachment.

Maine was the first state in the Union to enact a law for prohibiting the sale of intoxicating liquors. An act for restricting the sale of such liquors was passed in 1846; the first prohibitory act was adopted, largely in the towns, by the town meeting in 1851, and under it the correspondence districts, especially islands along the coast, are called "grants," "surpluses," "gore", or "tracts."
to the constitution was adopted which declares the manufacture of intoxicating liquors and their sale, except "for medicinal and mechanical purposes and the arts," forever prohibited. By the law enacted for enforcing this prohibition the governor and council appoint a state liquor commissioner from whom alone the selectmen of a town, the mayor or aldermen of a city, are authorized to receive the liquors which may be sold within the exceptions named in the amendment, and who is forbidden to sell any whatever, whether intoxicating or not. Inhabitants who break this law are liable to be fined, one half of the proceeds of the tax on intoxicating liquors being set apart each year to pay the salary of the commissioner. But the law labours under the disadvantage of all laws not vigorously sustained by general public sentiment, and is grossly violated. For the most part it is executed to the degree demanded by local sentiment in the several municipalities, thus operating in practice much the same as a "local option" law. The law looks to preventing the demand by preventing the supply; and since habitual reliance on the stringency of law tends to the neglect of other influences for the removal of evils from the community, the citizens seem to absolve themselves from personal responsibility both for the violation of the law and for the existence of the evil itself. There has been a strong movement for the repeal of the law, and the question of prohibition has long been an important one in state politics.

The death penalty was abolished in Maine in 1876, restored in 1883, and again abolished in 1887.

Penal and Charitable Institutions.—The state penal and reformatory system, at Portland, is derived from the Thorne's reform (Thorndike reform) school for boys at South Portland, and a state industrial school for girls at Hallowell, established in 1875 and taken over by the state in 1890. The two schools at first places of punishment, but reformatory schools for delinquent boys (from 8 to 16 years of age) and girls (from 6 to 16 years), who have been committed by the courts for violations of law, and, in the case of girls, who, by force of circumstances or associations, are in a manifest danger of becoming outcasts of society. The prison is in charge of a board of three inspectors and a warden, and each of the other two institutions is in charge of a board of trustees; the inspectors, warden, and trustees are all appointed by the governor and confirmed by the senate, and in the prison are usually employed in the manufacture of articles that are not extensively made elsewhere in the state, such as carriages, harness, furniture and brooms. The inmates of the state school for boys receive instruction in farming, carpentry, tailoring, laundry work, and various other trades and occupations; and the girls in the state industrial school are trained in housework, laundering, sewing, and cookery. The asylum for the blind at Bangor, the naval orphan asylum at Bath, the Maine institution for the blind at Portland, the Maine school for the deaf (established in 1876, and taken over by the state in 1897) at Portland, the Maine insane hospital at Augusta, the Eastern penitentiary at Hallowell, and a school for the feeble-minded (established in 1907) at West Pownal, each of which is governed by trustees appointed by the governor and council, with the exception of a part of those of the orphan asylum, who are appointed by the corporation. Besides the strictly state institutions, there are a number of private charitable institutions which are assisted by state funds; among these are the eye and ear infirmary at Portland, the Maine state sanatorium at Hebron for the treatment of tuberculosis, and various hospitals, orphanages, &c. The national government has a branch of the national hospital for disabled volunteer soldiers at Togus, and a marine hospital at Portland.

Education.—The school-district system was established in 1800 while Maine was still a part of Massachusetts and was maintained by the first school law passed, in 1821, by the state legislature; but, beginning in the next year, one town after another received the privilege of abolishing its districts, and in 1803 the system was abolished by act of the legislature. A state board of education, consisting of a representative from each county, was established in 1846, but for this was substituted, in 1852, a commissioner of schools for each county, appointed by the governor, and two years later an additional member of the state board of education was substituted for each county commissioner. County supervision by county supervisors was tried in 1860-1872. Since these several changes the common school system has been administered by towns and cities subject to the inspection of the commissioner of education at the state department of education and the general supervision of the state superintendent. The town officers are a superintending school committee of three members. Independent towns, whose members of the committee are elected for a term of three years, one retiring every year, and women as well as men are eligible for the office. The superintendent may be elected by the town or appointed by the committee, or towns having not less than twenty or more than fifty children may unite in employing a superintendent. In cities the committee is usually larger than in towns and is commonly elected by wards. The superintendent of each town is furnished with one or more text-books, apparatus and supplies, without cost to the town, for the minimum length of the school year is fixed by statute of 1893 at thirty weeks; the average length is about twenty-eight weeks. A compulsory educational law was enacted in 1866, but with the exception of some assurance at some public or approved private school of each child between the ages of seven and fifteen during all the time that school is in session, the law did not operate, and the enforcement of it was suspended by the legislature in 1867. For the maintenance of the common schools each town was required (since January 1, 1805) to raise annually at least fifty-five cents per capita, exclusive of such contributions as may be received from other sources, and to this is added the proceeds of the state deposit, which amount is one half the proceeds of the tax on savings banks, a 6% income from the permanent school fund (derived mainly from the sale of school lands), and the payment in part of the superintendence in towns that have paid for that purpose. Any section of a town may establish and maintain a high school provided there be not more than two such schools in one town, and the state makes appropriations for the support of such schools equal to one-half the cost of instruction, but the maximum grant to any one such school is $250.

MAINE maintained five normal schools; that at Farmington (established 1864), that at Castine (1866), that at Gorham (1875), that at Presque Isle (the Aroostook state normal school, 1893), and the Madawaska training school at Fort Kent, each of which is chartered by the state department of education, the governor, the state superintendent of schools, and five other members appointed by the governor and council for not more than three years. At the head of the public school system is the university of Maine at the village of Farmington in the town of Farmington in Penobscot county. This institution was founded in 1865 as the state college of agriculture and the mechanic arts; in 1877 the present name was adopted. It embraces a college of arts and sciences, a college of agriculture, a college of technology (including a department of forestry), a college of law (at Bangor), and a college of pharmacy. The most conspicuous of its twenty-five buildings is the hall built with funds contributed by Andrew Carnegie. In 1898-1909 the university had 104 instructors and 884 students, of whom 113 were in the college of law at Bangor and 420 in the college of arts and sciences, which is maintained with the proceeds of an endowment fund derived chiefly from the state's land grants and from the national government in accordance with the land grant, or Morrill Act of 1862 (see Morrill, Justin S.) and from the bequests ($100,000) of Abner Colburn (1861-1865); by appropriations of Congress under the second Morrill Act (1890), and under the Nelson Amendment of 1897, by appropriations of the state legislature, and by fees paid by the students. In 1906-1907 the university was an agricultural experiment station, establisbed by the state and managed by professors of agriculture, who are not paid by the state; the station is conducted in cooperation with the university, and by a medical school, which is conducted in cooperation with the medical faculty of the university. It is the most important institution of learning which has no official connection with the state are Bowdoin College (opened in 1802), at Brunswick; Colby College (Baptist, opened in 1818), at Waterville; and the University of Maine at Orono (opened in 1866), and the University of Maine at Presque Isle (opened in 1863), at Lewiston. In 1900 51.2% of the state's inhabitants (about 101,400) of voting age, or who were registered, voted, or (as the law is phrased) "published and not write," of the native whites within this age limit 24.4% were illiterate, of the foreign whites, 19.4%. Of the foreign-born whites 15.7% were unable to speak English.

Finance.—The chief sources of the state's revenue are a general property tax and taxes on the franchise of corporations, especially those of railway and insurance companies and savings banks; among the smaller sources are licenses or fees, a poll tax, and a tax on inheritance property. The general and educational purposes is assessed by local assessors, but their work is reviewed for the purpose of equalization among the several towns, and counties by a board of state assessors, which also assesses the corporations. This board of three members (two of whom may be of the same political party) is elected by a joint ballot of the two houses of the legislature for a term of six years, and its work is reviewed every two years. The state is prohibited by the constitution from creating a debt exceeding $3,000,000, except for the suppression of a rebellion, for repelling an invasion, or for war purposes; and every city and town is forbidden by an amendment adopted in 1877 to incur indebtedness, except that its officers are authorized to incur debts, up to the assessed value of its property. But the state was authorized by an amendment adopted in 1868 to issue bonds for the reimbursement of war expenses and the discharge of the state's civil liabilities of the account of the Civil War, and these bonds, with those issued by the state itself during the Civil War, constituted the largest part of the state's bonded indebtedness. The bonded debt, however, is rapidly being paid off; in January 1901 it was $2,103,000, and in January 1909 only $568,000.
History.—During the 16th century and the early part of the 17th century, the coast of Maine attracted various explorers, among them Giovanni di Verrazano (1524), Esteban Gomez (1525), Bartholomew Gosnold (1602), Martin Pring (1603), Pierre du Guast, Sieur de Monts (1604), George Weymouth (1605), and John Smith (1614), who explored and mapped the coast and gave to the country the name New England; but no permanent settlement was made within what are now the borders of the state until some time between 1623 and 1629. In 1603 De Monts received from Henry IV. of France a charter for all the region between 40° and 48° N. under the name of Acadia, or Acadia, and in 1604 he built a fort on Neutral Island at the mouth of the Saint Croix river. This he abandoned in 1605, but some of his followers were in the vicinity a few years later. In the same year George Weymouth explored the southwest coast, kidnapped five Indians, and carried them to England, where three of them lived for a time in the family of Sir Ferdinando Gorges, who soon became the leader in founding Maine.

In 1607 the Plymouth Company, of which he was an influential member and which had received a grant of this region from James I. of England in the preceding year, sent out a colony numbering 120 under George Popham (c. 1559-1608), brother of Sir John Popham, and Raleigh Gilbert, son of Sir Humphrey Gilbert. The settlement established itself at the mouth of the Kennebec river in August, but, finding its supplies insufficient, about three-fifths of its number returned to England in December; a severe winter followed and Popham died; then Gilbert, who succeeded to the presidency of the council for the colony, became especially interested in his claim to the territory under his father's charter, and in 1608 the colony was abandoned.

In 1609 the French Jesuits Biard and Masse established a fortified mission station on the island of Mount Desert, and although this as well as the remnant of De Monts' settlement at the mouth of the Saint Croix was taken in 1613 by Sir Samuel Argall (d. 1626), acting under the instructions of the English at Jamestown, Virginia, some of these colonists returned later. In 1629 the Council for New England, the successor of the Plymouth Company, obtained a grant of the country between latitude 40° and 48° N. extending from sea to sea, and two years later Gorges and John Mason (1586-1635) received from the Council a grant of the territory between the Merrimac and the Kennebec rivers for 60 m. inland under the name of the Province of Maine. In 1629 they divided their possession, Gorges taking the portion between the Piscataqua and the Kennebec. Numerous grants of land in this vicinity followed within a few years; and in 1633 the council made a grant to a company of settlers from York, Saco, Biddeford, Port Elizabeth, Falmouth (now Portland) and Scarborough were established in rapid succession. The Council for New England surrendered its charter in 1635. In the division of its territory Gorges retained the portion previously granted to him, and the region between the Kennebec and the Saint Croix north to the Saint Lawrence, though still claimed by the French as part of Acadia, was conveyed to Sir William Alexander (1567-1640); later, in 1664, this was conveyed to the duke of York, afterwards James II. of England.

Gorges named his tract the County of New Somersethshire, and immediately began the administration of government, setting up in 1635 or 1636 a court at Saco under the direction of his kinsman William Gorges. In 1639 he procured for his province a royal charter modelled after that of Maryland, which invested him with the feudal tenure of a county palatine and vice-regal powers of government. He called into existence a formidable large number of officers to govern it, but his charter was in conflict with the other (mutually conflicting) grants of the other colonies and plantations in the east coast of the continent, and his agents met with a determined opposition under the leadership of George Cleeve, the deputy-president of the Lyonia, or "Plough" Patent, which extended along the coast from Cape Porpoise to Casco, and in issuing which the Council for New England had granted governmental as well as territorial rights. Moreover, Puritan Massachusetts, which was naturally hostile to the Anglicanism of Gorges and his followers, interpreted her charter so as to make her northern boundary run east and west from a point 3 m. north of the source of the Mer- rimmac and on this basis laid claim to practically the whole of Maine then settled. The factional quarrels there, together with the Commonwealth government in England, made it easy for Massachusetts to enforce this claim at the time, and between 1652 and 1658 Maine was gradually annexed to Massachusetts.

In 1672 Massachusetts extended her boundary eastward as far as Penobscot Bay. Ferdinando Gorges, a grandson of the original proprietor, brought before parliament his claim to Maine and in 1664 a committee of that body decided in his favour; but Massachusetts successfully resisted until 1677, when the king in council decided against her. She then quietly purchased the Gorges claim for $1,250 and held the province as a proprietor until 1691, when by the new Massachusetts charter Maine was extended to the Saint Croix river, and was made an integral part of Massachusetts.

The French still claimed all territory east of the Penobscot, and not only was Maine an exposed frontier and battleground during the long struggle of the English against the Indians and the French, but its citizens bore a conspicuous part in the expeditions beyond its borders. Port Royal was taken in May 1690 by Sir William Phipps and Louisburg in June 1745 by Sir William Pepperell, both these commanders being from Maine. These expeditions were such a drain on Maine's population that Massachusetts was called upon to send men to garrison the little forts that protected the homes left defenceless by men who had gone to the front. During the War of Independence, the town of Falmouth (now Portland), which had ardentiy resisted the claims of the British, was bombarded and burned, in 1775; in the same year Benedict Arnold followed the course of the Kennes- toc and Deadwood rivers on his expedition to Quebec; and from 1779 to 1783 a British force was established at Castine. The disputes and non-intercourse laws from 1807 to 1812 were a severe blow to Maine's shipping, and in the War of 1812 Eastport, Castine, Hampden, Bangor and Machias fell into the hands of the British.

Maine was in general well governed as a part of Massachusetts, but a geographical separation, a desire to be rid of the burden of a large state debt, and a difference of economic interests as well as of politics (Maine was largely Democratic and Massachusetts was largely Federalist) created a desire for an independent commonwealth. This was felt before the close of the War of Independence and in 1785-1787 conventions were held at Falmouth (Portland) to consider the matter, but the opposition prevailed. The want of protection during the War of 1812 revived the question, and in 1816 the General Court in response to a great number of petitions submitted to a vote in the towns and plantations of the District the question: "Shall the legislature be requested to give its consent to the separation of the District of Maine from Massachusetts, and the erection of said District into a separate state?" The returns showed 10,963 votes to 6,501 nays, but they also showed that less than one-half the full vote had been cast. Acting upon these returns the legislature passed a bill prescribing the terms of separation, and directed another vote of the towns and plantations upon the question of separation and the election of delegates to a convention at Brunswick which should proceed to frame a constitution in case the second popular vote gave a majority of five to four for separation; but as that vote was only 11,968 to 11,907, the convention was not held. But a large source of opposition to separation was removed in 1819 when Congress, dividing the east coast of the United States into two great districts, did away with the regulation which, making each state a district for entering and clearing vessels, would have required coasting vessels from the ports of Maine as a separate state to enter and clear on every trip to or from Boston; as a consequence, the separation measures were carried
by large majorities this year, a constitution was framed by a
convention which met at Portland in October, this was ratified
by town meetings in December, and Maine applied for admis-

sion into the Union. Owing to the peculiar situation at the
time in Congress, arising from the contest over the admission
of Missouri, the question of the admission of Maine became an
important one in national politics. By an Act of the 3rd of
March 1820, however, Maine was finally admitted into the
Union as a separate state, her admission being a part of the
Missouri compromise (q.v.).

The boundary on the north had not yet been ascertained,
and it had long been a subject of dispute between the United
States and Great Britain. The treaty of 1783 (Article II) had
defined the north-east boundary of the United States as extend-
ing along the middle of the river St Croix "from its mouth in
the bay of Fundy to its source" and "due north from the source
of St Croix river to the highlands; along the said highlands which
divide those rivers that empty themselves into the river St
Lawrence from those which fall into the Atlantic Ocean, to the
north-westernmost head of Connecticut river; thence down
along the middle of that river to the forty-fifth degree of north
latitude." Great Britain claimed that the due north line was
40 m. long and ran to Mars Hill in Aroostook county, and that
the highlands ran thence westerly 115 m. to the source of the
Chaudière; the United States, on the other hand, claimed that
the northerly line was 140 m. long, running to highlands dividing
the Ristigouche and the tributaries of the Metis; and there was
a further disagreement with regard to the side of the highlands
on which the boundary should be, and as to what stream was the
"north-westernmost head of Connecticut river." The treaty of the
Jay treaty of 1794 provided for a commission to decide what the St Croix river actually was, and this com-
mision in 1798 defined the St Croix, saying that its mouth
was in Passamaquoddy bay and that the boundary ran up this
river and the Cheppuntachteek to a marked monument. The
treaty of Ghent in 1814 (Article IV.) referred the question of
the ownership of the islands in Passamaquoddy bay to a com-
mision which gave Moose, Dudley and Frederick islands to the
United States; and the same treaty by Article V. provided for
the survey (which was made in 1817-1818) of a part of the
disputed territory, and for a general commission. The
general commissioners met at St Andrews, N.B., in 1816, and
in New York City in 1821, only to disagree; and when the king
of the Netherlands, chosen as arbitrator in 1820 (under the
Convention of 1827) rendered in 1831 a decision against which
the state of Maine protested, the Federal Senate withheld its
assent to his decision. In 1835-1836 a new convention was
held between New Brunswick and Maine became the scene of a border
"war," known as the "Aroostook disturbance"; Maine erected
forts along the line she claimed, Congress authorized the president
to resist any attempt of Great Britain to enforce exclusive
jurisdiction over the disputed territory, and an armed conflict
seemed imminent. General Winfield Scott was sent to take
command on the Maine frontier, and on the 21st of March 1839
he arranged a truce and a joint occupancy of the territory in
dispute until a satisfactory settlement should be reached by the
Great Britain. The Webster-Austin treaty of 1842 was a compromise, which allowed Maine about
5500 sq. m. less than she had claimed and allowed Great Britain
about as much less than her claim; all grants of land previously
made by either party within the limits of the territory which
by this treaty fell within the dominions of the other party were to be
"held valid, ratified and confirmed to the persons in
possession under such grants, to the same extent as if such territory had been
fallen within the dominions of the party by which grants were made; and the territory in dispute
between the United States agreed to pay to Maine and Massachusetts' "m.

An article in the Act relating to the separation of Maine from
Massachusetts stipulated that the lands within the District of Maine
which prior to the separation had belonged to Massachusetts should
be sold by the United States, and the proceeds of the sale to be
paid into the Treasury of the United States.

In 1826 the wild lands of Maine were surveyed and
divided between the two states; and in 1853 Maine acquired from

equal moieties" the sum of $300,000 as compensation for the
lands which they had claimed and which under the treaty
they were called upon to surrender. The long controversy, which is
known in American history as "The North-East boundary
dispute," was not finally settled however until 1910.

It was the Democratic majority in the district of Maine that
affected the separation from Massachusetts, and from the date
Anson until 1855 Maine was claimed as a Democratic
state, although it elected a Whig governor in 1838 and in 1840 and
cast its electoral vote for John Quincy Adams in 1824 and
1828 and for W. H. Harrison in 1840. As a result of the slavery
question, there was a party disintegration between 1850 and
1855, followed by the supremacy of the Republican party from
1856 to 1878. In 1878, of the 126,169 votes cast in the election
governor, Selden Connor (b. 1839), re-nominated by the
Republicans, received 56,574; Joseph L. Smith ("National"
or "Greenback"), 41,571; Alonzo Garcelon (1813-1906) (Demo-

cratic), 28,218; as no candidate received a majority of the votes,
the election was left to the legislature.2 The vote of the House
eliminated Connor, and Garcelon was chosen in the Senate by a
Democratic-National fusion. Again there was no election
by popular vote in 1879, and Garcelon and his council, to secure the
election of a fusion government, counted-in a fusion majority in
the legislature by evident falsification of the returns. On
the 3rd of January 1880 the Supreme Court declared the
governor and council in error in counting in a fusion majority,
but on the 7th the governor swore in a legislature with 78 fusion
councilors, annexed to the list two hundred Republican members, and, the governor's term
having expired, the president of the Senate, James D. Lamson,
became governor, ex-officio. On the 12th the legislative
chambers were seized by the Republicans, whose organized
legislature was declared legal by the Supreme Court, and who
chose as governor Daniel Franklin Davis (1843-1897), where-
on, on the 17th, Joshua L. Chamberlain, to whom the peaceful
solution of the difficulty had largely been due, retired from the
task assigned him by Garcelon on the 9th of January "to protect the public property and institutions of the state" until Garcelon's successor should be duly qualified. In 1880 the Democrats
and Greenbacks united and elected their candidate, but after
1883 Maine was strongly Republican until 1910.

The governors of the state have been as follows:

Massachusetts, for $362,500, of all this land still remaining in posses-
sion of the latter state, to which according to A.D. 17, of the consti-
tution a majority of the total
number of votes cast was required for election; in case no candidate
should receive a majority, it was prescribed that the "House of Repre-
sentatives shall, by ballot, from the persons having the four
highest numbers of votes on the lists, if so many there be, elect two
persons and make returns of their names to the Senate, of whom the
Senate shall, by ballot, one, who shall be declared the governor;
which becomes a new constitution on the 9th of November 1880, provided that a plurality of the total
number of votes cast should be sufficient for election.
MAINE DE BIRAN—MAINE-ET-LOIRE

441

Essai sur les fondements de la psychologie represents the second or completest stage of his philosophy, the fragmentary of the Nouveaux essais d'anthropologie the third.

Maine de Biran's first essays in philosophy were written avowedly from the point of view of Locke and Condillac, but even in them he shows a desire to signalize, in his later speculation turns. Dealing with the formation of habits, he is compelled to note that passive impressions, however transformed, do not furnish a complete or adequate explanation. With Laromiguière he perceives attention to active effort, less than the passive receptivity of sense, and with Butler distinguishes passively formed customs from active habits. He finally arrived at the conclusion that Condillac's notion of passive receptivity as the source of consciousness was false, rather an error in fact but an error of method—in short, that the mechanical mode of viewing consciousness as formed by external influence was fallacious and inadequate. The key to subjective experience, whereby human conscious experience might be exhibited as growing or developing from its essential basis in connection with external conditions. The essential basis he finds in the real consciousness, of self as an active striving power, and the stages of its development, corresponding to what one may call the relative importance of the external conditions and the reflective clearness of self-consciousness he designates as the affective, the perceptive and the reflective. In connection with this Biran treats most of the obscure problems which arise in dealing with conscious experience, such as the mode by which the organism is cognized, the mode by which the organism is distinguished from other things, and the general ideas by which the relations of things are known to us—cause, power, force, etc.

The completest stage of his speculation Biran distinguishes the animal existence from the human, under which the three forms above noted are classed, and both from the life of the spirit, in which human thought is brought into relation with the supersensible, divine system of things. This stage is left imperfect. Alas though Biran's work presents a very remarkable specimen of deep metaphysical thinking directed by preference to the psychological aspect of our ideas.

The Œuvres inédites of Maine de Biran by E. Naville contain an introductory study; in 1887 appeared Science et psychologie: nouvel- les œuvres inédites, with introduction by A. Bertrand. See also O. Deux-Sèvres et Vendée, W. de Loire-Inferieure, and N. de Maine et Loir, 1879, 3th ed. (Pdrigueux, 1857); J. L. Chamberlain, Maine, Her Place in History (Augusta, 1877); E. S. Whitin, Factory Legislation in Maine (New York, 1908).

MAINE DE BIRAN, FRANÇOIS-PIERRE-GONTIER (1766–1824), French philosopher, was born at Bergerac, on the 29th of November, 1766. The name Maine he assumed (some time before 1787) from an estate called Le Maine, near Moulézy. After studying with distinction under the doctrinaires of Périgueux, he entered the life-lords of Louis XVI., and was present at Versailles on the memorable 5th and 6th of October 1789. At the breaking up of the gendar du corps Biran retired to his patrimonial inheritance of Grateloup, near Bergerac, where his retired life preserved him from the horrors of the Revolution. It was at this period that, to use his own words, he "passed per saltum from frivolity to philosophy." He began with psychology, which he made the study of his life. After the Reign of Terror Maine de Biran took part in political affairs. Having been excluded from the council of the Five Hundred on suspicion of royalism, he took part with his friend Latré in the commission of 1813, which gave expression for the first time to the patriotic intention of the people. After the Restoration he held the office of treasurer to the chamber of deputies, and habitually retired during the autumn recess to his native district to pursue his favourite study. He died on the 20th (16th, or 23rd, according to others) of July 1824.

Maine de Biran's philosophical reputation has suffered from two causes—his obscure and laboured style, and the fact that only a few, and these the least characteristic, of his writings appeared during his lifetime. These consisted of the essay on habit (Sur l'influence de l'habitude, 1803), a critical review of P. Laromiguière's lectures (1817), and the philosophical portion of the article "Leibnitz" in the Biographie universelle (1819). A treatise on the analysis of thought (Sur la décomposition de la pensée), although sent to press, was never printed. In 1834 these writings, together with the essay entitled Nouvelles considérations sur les rapports du physique et du moral de l'homme, were published by Victor Cousin, who in 1841 added three volumes, under the title Œuvres philosophiques de Maine de Biran, which contained the publication (in 1859) by E. Naville (from MSS. placed at his father's disposal by Biran's son) of the Oeuvres inédites de Maine de Biran, in three volumes, first rendered possible a connected view of his philosophical development. At first a sensualist, like Condillac and Locke, next an intellectualist, he finally shows himself a mystic thesophist. The
within this department. The climate is very mild. The mean annual temperature of Angers is about 50°, slightly exceeding that of Paris; the rainfall (between 23 and 24 in. annually) is distinctly lower than that of the rest of France. Notwithstanding this deficiency, the frequent fogs, combined with the peculiar nature of the soil in the south-east of the department, produce a degree of moisture which is highly favourable to meadow growths. The winter colds are never severe, and readily permit the cultivation of certain trees which cannot be reared in the adjoining departments.

The agriculture of the department is very prosperous. The produce of cereals, chiefly wheat, oats and barley, is in excess of its needs, and potatoes and mangels also give good returns. Extensive areas in the valley of the Loire are under hemp, and the vegetables, melons and other fruits of that region are of the finest quality. Good wine is produced at Serrant and other places near Angers, and on the right bank of the Layon and near Saumur, the sparkling white wine of which is a rival of the cheaper brands of champagne. Cider is also produced, and the cultivation of fruit is general. Forests and woodland to which oak and beech are the chief trees cover large tracts. The fattening of cattle is an important industry round Cholet, and horses much used for light cavalry are reared. Several thousand workmen are employed in the slate quarries in the vicinity of Angers; tafa is worked in the river valleys, and freestone and other stone, mispickel, iron and coal are also found. Cholet, the chief industrial town, and its district manufacture pocket-handkerchiefs, as well as linen cloths, flannels, cotton goods, and hemp and other coarse fabrics, and similar industries are carried on at Angers, which also manufactures eurettes, rope, boots and shoes and parasols. Saumur, besides its production of wine, makes beads and enamels. The commerce of Maine-et-Loire comprises the exportation of live stock and of the various products of its soil and industries, and the importation of hemp, cotton, and other raw materials. The department is served by the railways of the state and the Orléans and Western companies. The Mayenne, the Sarthe and the Loir, together with some of the lesser rivers, provide about 130 m. of navigable waterway. In the south-east the canal of the Dive covers some 10 m. in the department.

There are five arrondissements—Angers, Baugé, Cholet, Saumur and Segré, with 34 cantons and 381 communes. Maine-et-Loire belongs to the académie (educational division) of Rennes, to the region of the VIII. army corps, and to the ecclesiastical province of Tours. Angers (q.v.), the capital, is the seat of a bishopric and of a court of appeal. Other principal places are Cholet, Saumur, and Fontevraud, which receive separate treatment. For architectural interest there may also be mentioned the châteaux of Brissac (17th century), Serrant (15th and 16th centuries), Montreuil-Bellay (14th and 15th centuries), and Ecuillé (13th century), and the churches of Puy-Notre-Dame (13th century) and St Florent-le-Vieil (13th, 17th, and 19th centuries), the last containing the fine monument to Charles Bonchamps, the Vendean leader, by David d'Angers. Gennes has remains of a theatre and other ruins of the Roman period, as well as two churches dating in part from the 10th century. Ponts-de-Cé, an interesting old town built partly on islands in the Loire, is historically important, because till the Revolution its bridges formed the only way across the Loire between Saumur and Nantes.

Mainpuri, or Mynpookee, a town and district of British India, in the Agra division of the United Provinces. The town has a station on a branch of the East Indian railway recently opened from Shikohabad. Pop. (1901), 19,000. It consists of two separate portions, Mainpuri proper and Mukhamganj. Holkar plundered and burned part of the town in 1804, but was repulsed by the local militia. Since the British occupation the population has increased, and many improvements have been carried out. The Agra branch of the Grand Trunk road runs through the town, forming a wide street lined on both sides by shops, which constitute the principal bazaar. Mainpuri has a specialty in the production of carved wooden articles inlaid with brass wire. The American Presbyterian mission manages a high school.

The District of Mainpuri lies in the central Doab. Area, 1675 sq. m. Pop. (1901), 829,357, an increase of 8.8 per cent in the decade. It consists of almost an unbroken plain, intersected by small rivers, with a few undulating sand ridges. It is wooded throughout with mango groves, and isolated clumps of bābul trees occasionally relieve the barrenness of its saline assar plains. On the south-western boundary the Jumna flows in a deep alluvial bed, sometimes sweeping close to the high banks which overhang its course, and elsewhere leaving room for a narrow strip of fertile soil between the river and the upland plain. From the low-lying lands thus formed a belt of ravines stretches inland for some 2 m., often covered with jungle, but affording good pasturage for cattle. The district is watered by two branches of the Ganges canal, and is traversed by the main line of the East Indian railway.

Mainpuri anciently formed part of the great kingdom of Kannauj, and is one of that famous state it was divided into a number of petty principalities, of which Kapri and Bhongan were the chief. In 1194 Kapri was made the seat of a Moslem governor. Mainpuri fell to the Moguls on Baber's invasion in 1526, and, although temporarily seized from them by the white Kirmanis, was recovered, and under the rule of Shahs, was again occupied by them on the reinstatement of Humayun after the victory of Panipat. Like the rest of the lower Doab, Mainpuri passed, towards the end of the 16th century, into the hands of the Mughals and finally fell into the possession of the province of Oudh. When this part of the country was ceded to the British, in 1801, Mainpuri town became the headquarters of the district, which was afterwards separated from the province of Etah and Mainpuri into separate collectorates. On the outbreak of the Mutiny in 1857 the regiment stationed at Mainpuri revolted and attacked the town, which was successfully defended by the few Europeans of the station for a week, until the arrival of the Jhansi mutineers made it necessary to abandon the district.

MAINTENANCE (Fr. maintenue, from maintenir, to maintain, support, Lat. manu tenere, to hold in the hand). The action of giving support, supplying means of subsistence, keeping efficient or in working order. In English law maintenance is an officious intermeddling in an action that in no way belongs to one by maintaining or assisting either party, with money or otherwise, to prosecute or defend it. It is an indictable offence, both at common law and by statute, and punishable by fine and imprisonment. It invalidates all contracts involving it. It is also actionable. There are, however, certain cases in which maintenance is justifiable, e.g. any one who has an interest, even if it be only contingent, in the matter at variance can maintain another in an action concerning the matter; or several parties who have a common interest in the same thing may maintain one another in a suit concerning the same. Neither is it reckoned maintenance to assist another in his suit on equitable grounds by making him a party to the action as a substitute for the relator or for a master to assist his servant, or a parent his son, or a husband his wife. The law with regard to the subject is considered at length in Bradlaugh v. Neadegate, 1883, 1 T. B. D. 1. See also Chapmerry. For the practice of "Iivery and maintenance" see English History, §§ v. and vi.

A cap of maintenance, i.e. a cap of crimson velvet turned up with ermine, is borne, as one of the insignia of the British sovereign. The cap is borne before him at his coronation or on such state occasions as the opening of parliament. It is carried by the hereditary bearer, the marquess of Winchester, upon a white wand. A similar cap is also borne before the lord mayor of London. The origin of this symbol of dignity is obscure. It is stated in the New English Dictionary that it was granted by the pope to Henry VII. and Henry VIII. It is probably connected with the "cap of estate," some times also called a "cap of coronet," and similar to the coronet in the arms of barons or dukes, which is borne as a heraldic charge by certain families. It seems originally to have been a privilege of dukes. Where it is used the crest is placed upon it, instead of the usual wattle, in a similar form.
baptized in her religion, her sponsors being the duc de la Rochefoucauld, father of the author of the Maxims, and the comtesse de Maintenon. In 1639 Constant d'Aubigné was released from prison and took all his family with him to Martinique, where he died in 1643, after having lost what fortune remained to him at cards. Mme d'Aubigné returned to France, and from sheer poverty unwillingly yielded her daughter to her sister-in-law, Mme de Villette, who made the child very happy, but converted or pretended to convert her to Protestantism. When this was known an order of state was issued that she should be entrusted to Mme de Neufyllant, her godmother. Every means was now used to convert her back to Catholicism, but at the last she only yielded on the condition that she need not believe that the soul of Mme de Villette was lost. Once recovered, she was neglected and sent home to live with her mother, who had only a small pension of 200 livres a year, which ceased on her death in 1650. The chevalier de Mercé, a man of some literary distinction, who had made her acquaintance at Mme de Neufyllant's, discovered her penurious condition, and introduced his "young Indian," as he called her, to Scarron, the famous wit and comic writer, at whose house all the literary society of the day assembled. Scarron took a fancy to the friendless girl, and offered either to pay for her admission to a convent, or, though he was deformed and an invalid, to marry her himself. She accepted his offer of marriage, and became Mme Scarron in 1651. For nine years she was not only his most faithful nurse, but an attraction to his house, where she tried to bridge the licence of the conversation of the time. On the death of Scarron, in 1666, Anne of Austria continued his pension to his widow, and even increased it to 2000 livres a year, which enabled her to entertain and frequent the literary society her husband had made her acquainted with; but on the queen-mother's death in 1666 the king refused to continue her pension, and she prepared to leave Paris for Lisbon as lady attendant to the queen of Portugal. But before she started she met Mme de Montespan, who was already, though not avowedly, the king's mistress, and who took such a fancy to her that she obtained the continuance of her pension, which put off for ever the question of going to Portugal. Mme de Montespan did yet more for her, for, when, in 1669, her first child by the king was born, Mme Scarron was established with a large income and a large staff of servants at Vaugirard to bring up the king's children in secrecy as they were born. In 1674 the king determined to have his children at court, and their governess, who had now made sufficient fortune to buy the estate of Maintenon, accompanied them. The king had now many opportunities of seeing Mme Scarron, and, though at first he was prejudiced against her, her even temper contrasted so advantageously with the storms of passion and jealousy exhibited by Mme de Montespan, that her appearance in his favour, and had in 1678 the gratification of having her estate at Maintenon raised to a marquisate and herself entitled Mme de Maintenon by the king. Such favours brought down the fury of Mme de Montespan's jealousy, and Mme de Maintenon's position was almost unendurable, until, in 1680, the king severed their connexion by making the latter second lady in waiting to the dauphin, and soon after Mme de Montespan left the court. The new amie used her influence on the side of decency, and the queen openly declared she had never been so well treated as at this time, and eventually died in Mme de Maintenon's arms in 1683. The queen's death opened the way to yet greater advancement; in 1684 Mme de Maintenon was made first lady in waiting to the dauphin, and in the winter of 1685-1686 she was privately married to the king by Harlay, archbishop of Paris, in the presence, it is believed, of Père la Chaise, the king's confessor, the marquis de Montchevreuil, the chevalier de Forbin, and Bontemps. No written proof of the marriage is extant, but that it took place is nevertheless certain. Her life during the next thirty years can be fully studied in her letters, in which many authentic examples are extant. As a wife she was wholly adored. She had the smallest fear of losing her husband, and would not be amused, and had to submit to that terribly strict etiquette of absolute obedience to the king's inclination, which Saint-Simon so vividly describes, and yet be always cheerful and never complain of weariness or ill-health. Her political influence has probably been exaggerated, but it was supreme in matters of detail. The ministers of the day used to discuss and arrange all the business to be done with the king beforehand with her, and it was all done in her cabinet and in her presence, but the king in more important matters often chose not to consult her. Such mistakes as, for instance, the replacing of Catlin by Villeroi may be attributed to her, but not whole policies, notably, according to Saint-Simon, not the policy with regard to the Spanish succession. Even the revocation of the edict of Nantes and the dragonades have been laid to her charge, but recent investigations have tended to show that in spite of ardent Catholicism she at least opposed, if not very vigorously, the cruelties of the dragonades, although she was pleased with the conversions they procured. She was apparently afraid to imperil her great reputation for devotion, which had in 1692 obtained for her from Innocent XII. the right of visitation over all the convents in France. Where she deserves blame is in her use of her power for personal patronage, as in compassing the promotions of Chamillart and Villeroi, and the frequent assistance given to her brother Comte Charles d'Aubigné. Her influence was on the whole a moderating and prudent force. Her social influence was not as great as it might have been, owing to her holding no recognized position at court, but it was always exercised on the side of decency and morality, and it must not be forgotten that from her former life she was intimate with the literary people of the day. Side by side with this public life, which wearied her with its shadowy power, occasionally crossed by a desire to be recognised as queen, she passed a sober and sweeter private existence as the foundress of St Cyr. Mme de Maintenon was a born teacher; she had so won the hearts of her first pupils that they preferred her to their own mother, and was similarly successful later with the young and impetuous duchess of Burgundy, and she had always wished to establish a home for poor girls of good family placed in such straits as she herself had experienced. As soon as her fortunes began to mend she started a small home for poor girls at Ruel, which she afterwards moved to Noisy, and which was the nucleus of the splendid institution of St Cyr, which the king endowed in 1686, at her request, out of the funds of the Abbey of St Denis. She was in her element there. She herself drew up the rules of the institution; she examined every minute detail; she befriended her pupils in every way; and her heart often turned from the weariness of Versailles or of Marly to her "little girls" at St Cyr. It was for them that Racine wrote his Esther and his Athalie, and it was because he managed the affairs of St Cyr well that Michel Chamillart became controller-general of the finances. The later years of her power were marked by the promotion of her old pupils, the children of the king and Mme de Montespan, to high dignity between the blood royal and the peers of the realm, and it was doubtless under the influence of her dislike for the duke of Orleans that the king drew up his will, leaving the personal care of his successor to the duke of Maine, and hampering the duke of Orleans by a council of regency. On or even before her husband's death she retired to St Cyr, and had the chagrin of seeing all her plans for the advancement of the duke of Maine overthrown by means of the parliament of Paris. However, the regent Orleans in no way molested her, but, on the contrary, visited her at St Cyr and continued her pension of 48,000 livres. She spent her last years at St Cyr in perfect seclusion, but an object of great interest to all visitors to France, who, however, with the exception of Peter the Great, found it impossible to get an audience with her. On the 15th of April 1719 she died, and was buried in the choir at St Cyr, bequeathing her estate at Maintenon to her niece, the only daughter of her brother Charles and wife of the marchéal de Noailles, to whose family it still belongs.
and of her Correspondance générale, in 4 vols. (1888), which latter must, however, be read with the knowledge of many forged letters, noticed in P. Grimblot’s Faux autographes de Madame de Maintenon. Saint-Simon’s fine but biased account of the court in her day, and of her career is contained in the twelfth volume of Chéruit and Regnier’s edition of his Mémoires. See also Mademoiselle d’Aumale’s Souvenirs sur Madame de Maintenon, published by the Comité d’Histoire de France, 2 vols. (Paris, 1904); an excellent account by A. Geoffroy, Madame de Maintenon d’après sa correspondance authentique (Paris, 2 vols., 1887); P. de Noailles, Histoire de Madame de Maintenon et des principaux événements du régime de Louis XIV (4 vols., 1848–1849); A. de Bèrthé et Paul Scarron et Françoise d’Aubigné d’après des documents nouveaux (1894); É. Filatre, Vie et caractére de Madame de Maintenon d’après les lettres de Saint-Simon et des documents anciens et modernes (1907); A. Rosset, Madame de Maintenon et la révolte de l’édit de Nantes (1897). (H. M. S.)

MAINZ (Fr. Mayence) a city, episcopal see and fortress of Germany, situated on the left bank of the Rhine, almost opposite the influx of the Main, at the junction of the important main lines of railway from Cologne to Mannheim and Frankfort-on-Main, 25 m. W. of the latter. Pop. (1905), 91,124 (including a garrison of 7,300 men), of whom two-thirds are Roman Catholic. The Rhine, which here attains the greatest breadth of its upper course, is crossed by a magnificent bridge of five arches, leading to the opposite town of Castel and by two railway bridges. The old fortifications have recently been pushed farther back, and their place occupied by pleasant boulevards. The river front has been converted into a fine promenade, commanding extensive views of the Taunus range of mountains, and the “Rheingau,” the most favoured wine district of Germany. Alongside the quay are the landing-places of the steamboats navigating the Rhine. The railway, which formerly accommodated the bank, has been diverted, and now, following the centre of the new line of inland fortifications, runs into a central station lying to the south of the city. The interior of the old town consists chiefly of narrow and irregular streets, with many quaint and picturesque houses. The principal street of the new town is the Kaiserstrasse, leading from the railway station to the river.

The first object of historical and architectural interest in Mainz is the grand old cathedral, an imposing Romanesque edifice with numerous Gothic additions and details (for plan, &c. see Architecture: Romanesque and Gothic in Germany). It was initially erected between 975 and 1000, but has since been repeatedly burned down and rebuilt, and in its present form dates chiefly from the 12th, 13th and 14th centuries. The largest of its six towers is 500 ft. high. The whole building was restored by order of Napoleon in 1814, and another thorough renovation was made more recently. The interior contains the tombs of Boniface, the first archbishop of Mainz, of Frauenlob, the Minne-singer, and of many of the electors. Mainz possesses nine other Roman Catholic churches, the most noteworthy of which are those of St Ignatius, with a finely painted ceiling, of St Stephen, built 1257–1328, and restored after an explosion in 1857, and of St Peter. The old electoral palace (1627–1678), a large building of red sandstone, now contains a valuable collection of Roman and Germanic antiquities, a picture gallery, a natural history museum, the Gutenberg Museum, and a library of 220,000 volumes. Among the other principal buildings are the palace of the grand duke of Hesse, built in 1731–1739 as a lodge of the Teutonic order, the theatre, the arsenal, and the government buildings. A handsome statue of Gutenberg, by Thorwaldsen, was erected at Mainz in 1837. Mainz still retains many relics of the Roman period, the most important of which is the Eigelnstein, a monument believed to have been erected by the Roman legions in honour of Drusus. It stands within the citadel, which occupies the site of the Roman castrum. A little to the south-west of the town are the remains of a large Roman aqueduct, of which upwards of sixty pillars are still standing. The educational and scientific institutions of Mainz include an episcopal seminary, two gymnasium and other schools, a society for literature and art, a musical society, and an antiquarian society. The university, founded in 1477, was suppressed by the French in 1798.

The site of Mainz would seem to mark it out naturally as a great centre of trade, but the illiberal rule of the archbishops and its military importance seriously hampered its commercial and industrial development, and prevented it from rivalling its neighbour Frankfort. It is now, however, the chief emporium of the Rhenish wine traffic, and also carries on an extensive transit trade in grain, timber, flour, petroleum, paper and vegetables. The natural facilities for carriage by water are supplemented by the extensive railway system. Large new harbours to the north of the city were opened in 1887. The principal manufactures are leather goods, furniture, carriages, chemicals, musical instruments, etc. About two of the three cities to which the city attained a wide reputation. Other industries include brewing and printing. Mainz is the seat of the administrative and judicial authorities of the province of Rhein-Hessen, and also of a Roman Catholic bishop.

History.—Mainz, one of the oldest cities in Germany, was originally a Celtic settlement. Its strategic importance was early recognized by the Romans, and about 13 B.C. Drusus, the son-in-law of Augustus, erected a fortified camp here, to which the castellum Matioricum (the modern Castel) on the opposite bank was afterwards added, the two being connected with a bridge at the opening of the Christian era. The Celtic name became latinized as Magnutiacum, or Moguntiacum, and a town gradually arose around the camp, which became the capital of Germany Superior. During the Völkerwanderung Mainz suffered severely, being destroyed on different occasions by the Alamanni, the Vandals and the Huns. Christianity seems to have been introduced into the town at a very early period, and in the 6th century a new Mainz was founded by Bishop Sidonius. In the middle of the 8th century under Boniface it became an archbishopric, and to this the primacy of Germany was soon annexed. Charlemagne, who had a palace in the neighbourhood, gave privileges to Mainz, which rose rapidly in wealth and importance, becoming a free city in 1118. During the later middle ages it was the seat of several diets, that of 1184 being of unusual size and splendour. In 1160 the citizens revolted against Archbishop Arnold, and in 1163 the walls of the city were pulled down by order of the emperor Frederick I. But these events did not retard its progress. In 1244 certain rights of self-government were given to the citizens; and in 1254 Mainz was the centre and mainspring of a powerful league of Rhenish towns. Owing to its commercial prosperity it was known as goldene Mainz, and its population is believed to have been as great as it is at the present day. But soon a decline set in. In 1462 there was warfare between two rival archbishops, Diether or Dietrich II. of Isenburg (d. 1465) and Adolph II. of Nassau (d. 1479). The citizens espoused the cause of Diether, but their city was captured by Adolph; it was then deprived of its privileges and was made subject to the archbishop. Many of the inhabitants were driven into exile, and these carried into other lands a knowledge of the art of printing, which had been invented at Mainz by Johann Gutenberg in 1450. During the Thirty Years’ War Mainz was occupied by the Swedes in 1631 and by the French in 1644, the fortifications being strengthened by the former under Gustavus Adolphus; in 1668 it was captured again by the French, but they were driven out in the following year. In 1792 the citizens welcomed the ideas of the French Revolution; they expelled their archbishop, Friedrich Karl Joseph d’Erlath, and opened their gates to the French troops. Taken and retaken several times during the next few years, Mainz was ceded to France by the treaty of Campo Formio in 1797, and again by the Treaty of Lunéville in 1801. In 1814 it was restored to Germany and in 1816 it was handed over to the grand duke of Hesse; it remained, however, a fortress of the German confederation and was garrisoned by Prussian and Austrian troops. Since 1871 it has been a fortress of the German Empire. There were disturbances in the city in 1838.

See Brühl, Mainz, geschichtlich, topographisch und malerisch (Mainz, 1890); C. G. Bockenheim, Beiträge zur Geschichte der Stadt Mainz (1874); Neub, Führer durch Mainz und Umgebung (Stuttgart, 1908) and O. Beck, Mainz und sein Handel (Mainz, 1881).
The Archbishops of Mainz, one of the seven electorates of the Holy Roman Empire, became a powerful state during the middle ages and retained some of its importance until the dissolution of the empire in 1806. Its archbishop was president of the electoral college, arch-chancellor of the empire and primate of Germany. Its origin dates back to 747, when the city of Mainz was made the seat of an archbishop, and a succession of able and ambitious prelates, obtaining lands and privileges from emperors and others, so that became in all its rules a strong and vigorous state. Among these men were Hatto I. (d. 913), Siegfried II. of Eppstein (d. 1240), Gerhard of Eppstein (d. 1305), and Albert of Brandenburg (d. 1545), all of whom played important parts in the history of Germany. There were several violent contests between rivals anxious to secure so splendid a position as the electorate, and the pretensions of the archbishops occasionally moved the citizens of Mainz to revolt. The lands of the electorate lay around Mainz, and were on both banks of the Rhine; their area at the time of the French Revolution was about 3200 sq. m. The last elector was Karl Theodor von Dalberg. The archbishopric was secularized in 1803, two years after the lands on the left bank of the Rhine had been seized by France. Some of those on the right bank of the river were given to Prussia and to Hesse; others were formed into a grand duchy for Dalberg. The archbishopric itself was transferred to Regensburg.

For the history of the electorate see the Scriptores rerum mognitatiorum, edited by G. C. Joannis (Frankfort, 1722-1727); Schunk, Beiträge zur Mainzer Geschichte (Frankfort, 1788-1791), Henzen, Die Erbbischöfe von Mainz (Mainz, 1879); Ph. Jäfft, Monumenta mognitana (Berlin, 1866), and J. F. Böhrer and C. Will, Regesta archbishopricorum mognitiensium (Innsbruck, 1877-1886).

Mairet, Jean De (1604-1686), French dramatist, was born at Besançon, and baptized on the 10th of May 1604. His own statement that he was born in 1610 has been disproved. He went to Paris to study at the Collège des Grassins about 1625, in which year he produced his first piece Christide et Armand, followed in 1626 by Sylye, a "pastoral tragi-comedy." In 1634 appeared his masterpiece, Sophonisbe, which marks, in its observance of the rules, the beginning of the "regular" tragedies. Mairet was one of the bitterest assailants of Corneille in the controversy over The Cid. It was perhaps his jealousy of Corneille that made him give up writing for the stage. He was appointed in 1648 official representative of the Franche-Comté in Paris, but in 1653 he was banished by Mazarin. He was subsequently allowed to return, but in 1668 he retired to Besançon, where he died on the 31st of January 1686. His other plays include Silvina ou la Morte, published with an elaborate preface on the observance of the unities, Les Galanteries du deu d'Orsonne (1632). Virginité (1633), Marc-Antoine (1635), and Le Grand et dernier Sodomy (1637).

See G. Bizot, Étude sur la vie et les œuvres de Jean de Mairet (1872). Sophonisbe was edited by K. Vollmöller (Heilbronn, 1888), and Silvina by R. Otto (Bamberg, 1890).

Mairet, Joseph de (1754-1821), French diplomatist and political writer, was born at Chambéry on the 1st of April 1754. His family was an ancient and noble one, enjoying the title of count, and is said to have been of Languedocien extraction. The father of Joseph was president of the senate of Savoy, and held other important offices. The son, after leaving the Jesuit school, received various appointments in the civil service of Savoy, finally becoming a member of the senate. In 1786 he married Françoise de Morand. The invasion and annexation of Savoy by the French Republicans made him an exile. He did not take refuge in that part of the kingdom of Sardinia's domains which was for the time spared, but betook himself to the as yet neutral territory of Lusanne. There, in 1796, he published his first important work (he had previously written certain discourses, pamphlets, etc.), Monumens de la France (Frankfort, 1788-1789), a book in which he developed his views, which were those of a Legitimist, but a Legitimist entirely from the religious and Roman Catholic point of view. The philosophism of the 18th century was Joseph de Maistre's lifelong object of assault.

After the still further losses which, in the year of the publication of this book, the French Revolution inflicted on Sardinia, Charles Emmanuel summoned Joseph de Maistre to Turin, and he remained there for the brief space during which the king retained a remnant of territory on the mainland. Then he went to the island of Sardinia, and held office at Cagliari. In 1802 he was appointed envoy extraordinary and minister plenipotentiary at St Petersburg, and journeyed thither the next year. Although his post was no sinecure, his duties were naturally less engaging than the official life, with intervals of uneasy exile and travelling, which he had hitherto known, and his literary activity was great. He only published a single treatise, on the Principe général des Constitutions; but he wrote his best and most famous works, Du Pape, De L'Eglise gallicane and the Soirées de St Pétersbourg, the last of which was never finished. Du Pape, which the second-named book completes, is a treatise in regular form, dealing with the relations of the sovereign pontiff to the Church, to temporal sovereigns, to civilization generally, and to schismatics, especially Anglicans and the Greek Church. It is written from the highest possible standpoint of papal absolutism. The Soirées de St Pétersbourg, so far as it is anything (for the arrangement is somewhat desultory), is a kind of théodicee, dealing with the fortunes of virtue and vice in this world. It contains two of De Maistre's most famous pieces, his panegyric on the executioner as the foundation of social order, and his acrimonious, and in part unfair, but also in part very damaging, attack on Locke. The Du Pape is dated May 1817; on the Soirées the author was still engaged at his death. Besides these works he wrote an examination of the philosophy of Bacon, some letters on the Inquisition (for an institution which, as may be guessed from the remarks just noticed about the executioner, was no stumbling-block to him), and, earlier than any of these, a translation of Plutarch's "Essay on the Delay of Divine Justice," with somewhat copious notes. After 1815 he returned to Savoy, and was appointed to high office, while his Du Pape made a great sensation. But the world to which he had returned was not altogether in accordance with his desires. He had domestic troubles; and chagrin of one sort and another is said to have had not a little to do with his death by paralysis on the 26th of February 1831 at Turin. Most of the works mentioned were not published till after his death; and it was not till 1851 that a collection of Lettres et opuscules appeared, while even since that time fresh matter has been published.

Joseph de Maistre was one of the most powerful, and by far the ablest, of the leaders of the neo-Catholic and anti-revolutionary movement. The most remarkable thing about his standpoint is that, layman as he was, it was entirely ecclesiastical. Unlike his contemporary Bonald, Joseph de Maistre regarded the monarchy as the only institution which, for the purpose of maintaining a certain degree of regularity and some semblance of order, was necessary to the spiritual primacy of the pope. He was by no means a political absolutist, except in so far as he regarded obedience as the first of political virtues, and he seldom loses an opportunity of stigmatizing for a tempered monarchy. But the pope's power is not to be tempered at all, either by councils or by the temporal power or by national churches, least of all by private judgment. The peculiarity of Joseph de Maistre is that he supports his conclusions, or if it be preferred his paradoxes, by the hardest and heaviest argument. Although a great master of rhetoric, he never makes rhetoric do duty for logic. Every now and then it is possible to detect fallacies in him, but for the most part he has succeeded in carrying matters back to those fundamental differences of opinion which hardly admit of argument, and on which men take sides in consequence chiefly of natural bent, and of predilection for one state of things rather than for another. The absolute necessity of order may be said to have been the first principle of this thinker, who, in more ways than one, will invite comparison with Hobbes. He could not conceive such order without a single visible authority, reference to which should settle all dispute. He saw that there could be no such temporal head, and in the pope he thought that he had a spiritual substitute. The anarchic tendencies of the Revolution in politics and religion were what offended him. It ought to be
added that he was profoundly and accurately learned in history and philosophy, and that the superficial blunders of the 18th-century *philosophes* irritated him as much as their doctrines. To Voltaire in particular he shows no mercy.

Of the two works named as his masterpieces, *Du Pepe et la Soirées de St Pétersbourg*, editions are extremely numerous. No complete edition of his works appeared till 1884-1887, when one was published at Lyons in 14 volumes. This had been preceded, and has been followed, by numerous biographies and collections: C. Barthélémy, *L'Esprit de Joseph de Maistre* (1859); R. de Sézeval, *Joseph de Maistre* (1865), and J. C. Glaser, *Graaf Joseph Maistre* (sive Joseph le Maistre, 1870); F. Paulhan, *Joseph de Maistre et sa philosophie* (1893); L. Cogordan, "*Joseph de Maistre*" in *Les grands écrivains français* (1894); F. Descotes, *Joseph de Maistre avant la révolution* (1896), and other works by the same author. L. de la Fontaine, *Joseph de Maistre et la politique de la maison de Savoie* (1900); and E. Grasset, *Joseph de Maistre* (1914) (G. SA.).

**MAISTRE, XAVIER DE** (1763-1832), younger brother of Joseph de Maistre, was born at Chambéry in October 1763. He served when young in the Piedmontese army, and wrote his delightful fantasy, *Voyage autour de ma chambre* (published 1794) when he was under arrest at Turin in consequence of a duel. Centered on the arts and sciences and his brother's correspondence, he stood on the annexation of Savoy to France, left the service, and took a commission in the Russian army. He served under Suvarov in his victorious Austro-Russian campaign and accompanied the marshal to Russia. He shared the disgrace of his general, and supported himself for some time in St Petersburg by miniature painting. But his brother's arrival in St Petersburg it he was introduced to the minister of marine. He was appointed to several posts in the capital, but also saw active service, was wounded in the Caucasus, and attained the rank of major-general. He married a Russian lady and established himself in his adopted country, even after the overthrow of Napoleon, and the consequent restoration of the Piedmontese dynasty. For a time, however, he lived at Naples, but he returned to St Petersburg and died there on the 12th of June 1852. He was only once in Paris (in 1839), when Sainte-Beuve, who has left some pleasant reminiscences of him, met him. Besides the *Voyage* already mentioned, Xavier de Maistre's works (all of which are of very modest dimensions) are *Le Lépreux de la cité d'Aoste* (1831), a touching little story of human misfortune; *Les Prisonniers du Cercle*, a powerful sketch of the penal system of the Crimean War, *La Sibérie*, and *L'Expédition nocturne*, a sequel to the *Voyage autour de ma chambre* (1825). His style is of remarkable ease and purity.

His works, with the exception of some brief chemical tracts, are included in the collections of Charpentier, Garnier, etc. See Sainte-Beuve's *Portraits contemporains*, vol. iii.

**MAITLAND, EDWARD** (1824-1897), English humanitarian writer, was born at Ipswich on the 27th of October 1824, and was educated at Calais College, Cambridge. The son of Charles David Maitland, perpetual curate of St James's Chapel, Brighton, he was intended for the Church, but his religious views did not permit him to take holy orders. For some years he lived abroad, first in California and then as a commissioner of Crownlands in Australia. After his return to England in 1837 he took up an advanced humanitarian position, and claimed to have acquired a new sense by which he was able to discern the spiritual condition of other people. He was associated with Mrs Anna Kingsford (1846-1888), the lady-doctor and supporter of vegetarianism and antivivisectionalism, who, besides being one of the pioneers of higher education for women, had become a devotee of mystical theosophy; with her he brought out *Keys of the Creeds* (1875), *The Perfect Way: or the Finding of Christ* (1882), and founded the Hermetic Society in 1884. After her death he founded the Esoteric Christian Union in 1891, and wrote her *Life and Letters* (1896). He died on the 2nd of October 1897.

**MAITLAND, FREDERICK WILLIAM** (1830-1906), English jurist and historian, son of John Gorham Maitland, was born on the 28th of May 1830, and educated at Eton and Trinity, Cambridge, being bracketed at the head of the moral sciences troops of 1872, and winning a Whewell scholarship for international law. He was called to the bar (Lincoln's Inn) in 1876, and made himself a thoroughly competent equerry, draftsman, and conveyancer, but finally devoted himself to comparative jurisprudence and especially the history of English law. In 1884 he was appointed reader in English law at Cambridge, and in 1888 became Downing professor of the laws of England. Though handicapped in his later years by delicate health, his intellectual grasp and wide knowledge and research gradually made him famous as a jurist and historian. He edited numerous volumes for the Selden Society, including *Select Pleas for the Use of the Court Baron* (1892), *Decius and Malvolio*, *Memorial Courts and the Court Baron*; and among his principal works are *Historical Pleas* (1884), *Justice and Police* (1885), *Bracton's Note-Book* (1887), *History of English Law* (with Sir F. Pollock, 1885; new ed. 1898; see also his article *English Law* in this encyclopaedia), *Domesday Book and Beyond* (1897), *Township and Borough* (1898), *Canon Law in England* (1898), *English Law and the Renaissance* (1901), the *Life of Leslie Stephen* (1906), besides important contributions to the *Cambridge Modern History*, the *English Historical Review*, the *Law Quarterly Review*. His writings are marked by vigour and vitality of style, as well as by the highest qualities of the historian who recreates the past from the original sources; he had no sympathy with either legal or historical pedantry; and his death at Grand Canary on the 19th of December 1906 deprived English law and letters of one of its most scholarly and most inspiring representatives, notable alike for sweetness of character, acuteness in criticism, and wisdom in counsel.

**MAITLAND, SIR RICHARD** (Lord Lethington) (1496-1586), Scottish lawyer, poet, and collector of Scottish verse, was born in 1496. His father, Sir William Maitland of Lethington and Thirlestane, fell at Flodden; his mother was a daughter of George, Lord Seton. He studied law at the university of St Andrews, and afterwards in Paris. His castle at Lethington was burnt by the English in 1549. He was in 1551 a member of the commissioners to settle matters with the English about the debatable lands. About 1561 he seems to have lost his sight, but this did not render him incapable of attending to public business, as he was the same year admitted an ordinary lord of session with the title of Lord Lethington, and a member of the privy council; and in 1562 he was appointed keeper of the Great Seal. He resigned this last office in 1567, in favour of John, prior of Coldhaming, his second son; he sat on the bench till he attained his eighty-eighth year. He died on the 20th of March 1586. His eldest son, by his wife Mary Cranstoun of Crosbie, was William Maitland (q.v.): his second son, John (?..) (1545-1599), was a lord of session, and was made a lord of parliament in 1590, with the title of Lord Maitland of Thirlestane, in which he was succeeded by his son John, also for some time a lord of session, who was created earl of Lauderdale in 1624. One of Sir Richard's daughters, Margaret, assisted her father in preparing his collection of old Scots verse.

The poems of Sir Richard Maitland, none of them lengthy, are for the most part satirical, and are principally directed against the social and political abuses of his time. He is chiefly remembered as the industrial collector and preserver of many pieces of Scots poetry. These were copied into two large volumes, one in folio and another in quarto, the former written by himself, and the latter by his daughter. After being in the possession of his descendant the duke of Lauderdale, these volumes were purchased at the sale of the duke's library by Samuel Pepys, and have since been preserved in the Pepysian Library, Magdalen College, Cambridge. They have been noticed for many years till Bishop Percy published one of the poems in his *Reliques of English Poetry*. Several of the
Maitland, W.—Maiwand 447

pieces were then transcribed by John Pinkerton, who afterwards published them under the title of Ancient Scottish Poems (2 vols., 1786.)

For an account of the Maitland Folio MS. see Gregory Smith's Specimens of Middle Scots, 1902 (p. lxxiii.). The Scottish Text Society has undertaken the entire manuscript, which is being edited by Mr. A. Lang. Mr. J. M. W. Skelton, in his History of Scotland, vol. ii. (1902), notes that the whole manuscript allows of its being divided into two main parts, the first being a history of the family of Seton, and the second a history of the family of Maitland. The former is the more interesting for the light it affords on the early history of Scotland, and the latter for the light it affords on the lives of the Maitland family.

Maitland (Maitland of Lethington), William (c. 1528-1573), Scottish statesman, eldest son of the preceding, was educated at St. Andrews. At an early age he entered public life and began in various ways to serve the queen, Mary of Lorraine, becoming her secretary of state in 1558. In 1559, however, he deserted her and threw in his lot with the lords of the congregation, to whom his knowledge of foreign, and especially of English, politics and his general ability were assets of the highest value. The lords sent him to England to ask for assistance from Elizabeth, and his constant aim throughout his political career was to bring about a union between the two crowns. He appears to have feared the return of Mary Queen of Scots to Scotland, but after her arrival in 1561 he was appointed secretary of state, and for about six years he directed the policy of Scotland and enjoyed the confidence of the queen. His principal antagonist was John Knox; there were several tussles between them, the most famous, perhaps, being the one in the general assembly of 1564, and on the whole Maitland held his own against the preachers. He was doubtless concerned in the conspiracy against David Rizzio, and after the favourite's murder he was obliged to leave the court and was himself in danger of assassination. In 1567, however, he was again at Mary's side. He was a consenting party to the murder of Darnley, although he had favoured his marriage with Mary, but the enmity between Bothwell and himself was one of the reasons which drove him into the arms of the queen's enemies, among whom he figured at Langside. He was one of the Scots who met Elizabeth's representatives at York in 1568; here he showed a desire to exculpate Mary and to marry her to the duke of Norfolk, a course of action probably dictated by a desire to avoid all revelations about the Darnley murder. But this did not prevent him from being arrested in September 1569 on account of his share in the crime. He was, however, delivered from his captors by a ruse on the part of his friend, Sir William Kirkcaldy of Grange, and was brought into Edinburgh Castle, where his trial was put off because the city was thronged with his adherents. Maitland now became the leader of the remnant which stood by the cause of the imprisoned queen. Already a physical wreck, he was borne into Edinburgh Castle in April 1571 and with Kirkcaldy he held this fortress against the regent Morton and his English auxiliaries. The castle surrendered in May 1573 and on the 7th or the 9th of June following Maitland died at Leith, there being very little evidence for the theory that he poisoned himself. "Secretary Maitland," wrote Macpherson, "was noted for his great learning with a ready wit and a caustic tongue. He was reputed to be the most versatile and accomplished statesman of his age, and almost alone among his Scottish contemporaries he placed his country above the claims of either the Roman Catholic or the Protestant religions. Among the testimonies to his great abilities are those of Queen Elizabeth, of William Cecil and of Knox. By his second wife, Mary Fleming, one of Queen Mary's ladies, whom he married in 1567, he had a son and daughter. His son James died without issue.

See John Skelton, Maitland of Lethington (1894); A. Lang, History of Scotland, vol. ii. (1902).

Maitland, East and West, adjoining municipalities in Northumberland county, New South Wales, Australia, 120 m. by rail N. of Sydney. Pop. (1901), West Maitland, 6298; East Maitland, 3387. These towns are situated in a valley on the Hunter River, which is liable to sudden floods, to guard against which the river is protected by stone embankments at West Maitland, while there are flood-gates at East Maitland. Maitland is the centre of the rich agricultural district of the Hunter valley, which produces maize, wheat and other cereals, lucerne, tobacco, fruit and wine; excellent coal also is worked in the vicinity. East Maitland is the scene of operations against the mutiny of the Scotch soldiers in 1697; however, is situated in the larger town. Besides this, West Maitland contains several handsome public and commercial buildings.

Maitreyā, the name of the future Buddha. In one of the works included in the Pali canon, the Dīgha Nikāya, a prophecy is put into the Buddha's mouth that after the decay of the religion another Buddha, named Metteyya, will arise who will have thousands of followers instead of the hundreds that the historical Buddha had. This is the only mention of the future Buddha in the canon. For some centuries we hear nothing more about him. But when, in the period just before and after the Christian era, some Buddhists began to write in Sanskrit instead of Pali, they composed new works in which Maitreyā (the Sanskrit form of Metteyya) is more often mentioned, and details are given as to his birthplace and history. These are entirely devised in imitation of the details of the life of the historical Buddha, and have no independent value. Only the names differ. The document in which the original prophecy occurred was put together at some date during the 1st century after the Buddha's death (see Nikāya). It is impossible to say when the prophecy was written, or even whether it was written at that time, correct in attributing it to the Buddha. But whoever chose the name (it is a patronymic or family, not a personal name), had no doubt regard to the etymological connexion with the word for "love," which is Metti in Pali. This would only be one of those punning allusions so frequent in Indian literature.

Long afterwards, probably in the 6th or 7th century, a reformer in south India, at a time when the incoming flood of ritualism and superstition threatened to overwhelm the simple teaching of the earlier Buddhism, wrote a Pali poem, entitled the Anāgā Vamsa. In this he described the golden age of the future when, in the time of Metteyya, kings, ministers and people would live one with the other in the maintenance of the original simple doctrine, and in the restoration of the good times of old. The other side also claimed the authority of the future Buddha for their innovations. Statues of Maitreyā are found in Buddhist temples, of all sects, at the present day; and the belief in his future advent is universal among Buddhists.

(T. W. R. D.)

Maiwand, a village of Afghanistan, 50 m. N.W. of Kandahar. It is chiefly notable for the defeat inflicted on a British brigade under General Burrows by Ayub Khan on the 27th of July 1880 during the second Afghan War (see Afghanistan). Ayub Khan, Shere Ali's younger son, who had been holding the British operations at Kabul and Kandahar, set out towards Kandahar with a small army on June 18, and a brigade under General Burrows was detached from Kandahar to oppose him. Burrows advanced to the Helmund, opposite Girishk, to oppose Ayub Khan, but was there desolated by the troops of Shere Ali, the wali of Kandahar, and forced to retreat to Kushk-i-Nakhud, half way to Kandahar. In order to prevent Ayub passing to Ghazni, Burrows advanced to Maiwand on the 27th of July, and attacked Ayub, who had already gained that place. The Afghans, who numbered 25,000, outflanked the British, the artillery expended their ammunition, and the native portion of the Brigade got out of hand and pressed back on the few British infantry. The British were
MAIZE

completely routed, and had to thank the apathy of the Afghans for escaping total annihilation. Of the 2476 British troops engaged, 924 were killed and 175 wounded or missing. This defeat necessitated Sir Frederick Roberts’ famous march from Kabul to Kandahar.

See Lord Roberts, Forty-one Years in India (1896).

MAIZE, or INDIAN CORN, Zea Mays (from šeá or šéá, which appears to have been “spelt,” Triticum spelta, according to the description of Theophrastus), a plant of the tribe Maydene of the order Gramineae or grasses (see fig. 1). It is unknown in the native state, but is most probably indigenous to tropical America. Small grains of an unknown variety have been found in the ancient tombs of Peru, and Darwin found heads of maize embedded on the shore in Peru at 85 ft. above the present sea-level. Bonafous, however (Histoire naturelle du maïs), quotes authorities (Bock, 1532, Ruel and Fuchs) as believing that it came from Asia, and maize was said by Santa Rosa de Viterbo to have been brought by the Arabs into Spain in the 13th century. A drawing of maize is also given by Bonafous from a Chinese work on natural history, Li-chi-lchih, dated 1562, a little over sixty years after the discovery of the New World. It is not figured on Egyptian monuments, nor was any mention made of it by Eastern travellers in Africa or Asia prior to the 16th century. Humboldt, Alphonse de Candolle and others, however, do not hesitate to say that it originated solely in America, where it had been long and extensively cultivated at the period of the discovery of the New World; and that is the generally accepted modern view. Some hold the view that maize originated from a common Mexican fodder grass, Euchaena mexicana, known as Teosinte, a closely allied plant which when crossed with maize yields a maize-like hybrid.

The plant is monoecious, producing the staminate (male) flowers in a large feathery panicle at the summit, and the (female) dense spikes of flowers, or “cobs,” in the axils of the leaves below, the long pink styles hanging out like a silken tassel. They are invested by the sheaths of leaves, much used in packing oranges in south Europe, and the more delicate ones for cigarettes in South America. Fig. 2 shows a branch of the terminal male inflorescence. Fig. 3 is a single spikelet of the same, containing two florets, with the three stamens of one only protruded. Fig. 4 is a spike of the female inflorescence, protected by the sheaths of leaves—the blades being also present. Usually the sheaths terminate in a point, the blades being arrested. Fig. 5 is a spikelet of the female inflorescence, consisting of two outer glumes, the lower one ciliated, which enclose two florets—one (a) barren (sometimes fertile), consisting of a flowering glume and pale only, and the other (b) fertile, containing the pistil with elongated style. The mass of styles of the whole spike is pendulous from the summit of the sheaths, as in fig. 4. Fig. 6 shows the fruit or grain. More than three hundred varieties are known, which differ more among themselves than those of any other cereal. Some come to maturity in two months, others require seven months; some are as many feet high as others are inches; some have kernels eleven times larger than others. They vary similarly in shape and size of ears, colour of the grain, which may be white, yellow, purple, striped, &c., and also in physical characters and chemical composition. Dr. E. Lewis Surtevant, who has made an extended study of the forms and varieties, classes into seven groups those grown primarily for the grain,

corn (var. indurata) has a starchy endosperm enclosed in a horny layer of varying thickness in the different varieties. The colour of the grain is white, yellow, red, blue or variegated. It is commonly cultivated in Canada and northern United States, where the seasons are too short for Dent corn, and has been grown as far north as 50° N. lat. Dent or field corn (var. indentata) has the starchy endosperm extending to the summit of the grain, with horny endosperm at the sides. The top of the grain becomes indented, owing to the drying and shrinkage of the starchy matter; the character of the indented surface varies with the height and thickness of the horny endosperm. This is the form commonly grown in the United States; the varieties differ widely in the size of the plants and the appearance of the ear.
The colour of the grain varies greatly, being generally white, yellow, mottled red, or less commonly red. Soft corn (var. *Zea mays* var. *indica*) has no horny endosperm, and hence the grains shrink uniformly. It is cultivated only to a limited extent in the United States, but seems to have been commonly grown by the Indians in many localities in North and South America. Sweet corn (var. *Zea mays* var. *saccharata*) is characterized by the translucent kernels, which may appear in a high degree of size, central color, and their more or less wrinkled condition. It is pre-eminently a garden vegetable, the ear being used before the grain hardens, when it is well filled but soft and milky. It is often cooked and served in the cob; when canned it is cut from the cob. Canned sweet corn is an important article of domestic commerce in Canada and the United States. In starchy sweet corn (var. *Zea mays* var. *saccharata*) the grain has the external appearance of sweet corn, but examination shows the lower half to be starchy, the upper horny and translucent. A form of flint corn, with variegated leaves, is grown for ornament under the name *Zea japonica* or Japanese striped corn.

Chemical analysis, like common experience, shows that Indian corn is a very nutritious article of food, being richer in albuminoids than any other cereals when ripe (calculated in the dry weight). It can be grown in the tropics from the level of the sea to a height equal to that of the Pyrenees and in the south and middle of Europe, but it cannot be grown in England with any chance of profit, except perhaps as fodder. Frost kills the plant in all its stages and all its varieties; and the crop does not flourish well if the nights are cool, no matter how favourable the other conditions. Consequently it is the first crop to disappear as one ascends into the mountain regions, and comparatively little is grown west of the great plains of North America. In Britanny, where it scarcely ripens the grain, it furnishes a strong crop in the autumn upon sandy soil where clover and lucerne will yield but a poor produce. It prefers a deep, rich, warm, dry and mellow soil, and hence the rich bottom and fertile prairies of the Mississippi basin constitute the region of its greatest production. It is extensively grown throughout India, both for the ripe grain and for use of the unripe cob as a green vegetable. It is the most common crop throughout South Africa, where it is known as mealies, being the staple food of the natives. It is largely used for fodder and is an important article of export.

As an article of food maize is one of the most extensively used grains in the world. Although rich in nitrogenous matter and fat, it does not make good bread. A mixture of rye and corn meal, however, makes an excellent coarse bread, formerly much used in the Atlantic states, and a similar bread is now the chief coarse bread of Portugal and some parts of Spain. It is either baked into cakes, called tortillas by the Indians of Yucatan, or made into a kind of porridge, as in Ireland. When deprived of the gluten it constitutes osogewe, maizeca or corn flour. Maize contains more oil than any other cereal, ranging from 3.5 to 9.5% in the commercial grain. This is one of the factors in its value for fattening purposes. In distilling and some other processes this oil is separated and forms an article of commerce. When maize is sown broadcast or closely planted in drills the ears may not develop at all, but the stalk is richer in sugar and sweeter; and this is the basis of growing "corn-fodder." The amount of forage that may be produced in this way is enormous; 50,000 to 100,000 bushels are grown per acre, which makes 8000 to 12,000 lb. as field-cured. Sugar and molasses have from time to time been manufactured from the corn stalks.

See articles on corn and *Zea Mays* in L. H. Bailey’s *Cyclopedia of American Horticulture* (1900-1902); and for cultivation in India, Watt’s *Dictionary of the Economic Products of India*, vi. (1893).
MAJOLICA—MAJORCA

MAJOLICA, a name properly applied to a species of Italian ware in which the body is coated with a tin-enamel, on which is laid and fired a painted decoration. It is also applied to similar wares made in imitation of the Italian ware in other countries. The word in Italian is maiolica. Du Cange (Gloss. s.v. "Majorca") quotes from a chronicle of Verona of 1368, in which the form majolica occurs for the more usual Latin form majorca. It has usually been supposed that this type of pottery was first made in the island of Majorca, but it is more probable that the name was given by the Italians to the lustred Spanish ware imported by ships hailing from the Balearic Islands. (See CERAMICS: Medieval and Later Italian.)

MAJOR (or MAIR), JOHN (1470-1530), Scottish theological and historical writer, was born at the village of Gleggornie, near North Berwick, Scotland, in the year 1470. He was educated at the school of Haddington, where John Knox was later a pupil. After a short period spent at Cambridge (at God's House, afterwards Christ's College) he entered the university of Paris in 1493, studying successively at the colleges of St Barbe, Montaigu and Navarre, and graduating as master of arts in 1496. Promoted to the doctorate in 1505, he lectured for a time on the history of Scotland at Montaigu College and on theology at Navarre. He visited Scotland in 1515 and returned in 1518, when he was appointed principal regent in the university of Glasgow, John Knox being among the number of those who attended his lectures there. In 1522 he removed to St Andrew's University, where in 1525 George Buchanan was one of his pupils. He returned to the college of Montaigu in 1525, but was once more at St Andrew's in 1531, where he was head of St Salvator's College from 1534 until his death.

Major's voluminous writings may be grouped under (a) logic and philosophy, (b) Scripture commentary, and (c) history. All are in Latin, all appeared between 1503 and 1530, and all were printed at Paris. The first group includes his Exponentibus (1503), his commentary on Petrus Hispanus (1505-1506), his Inclitatarum artium libri (1506, &c.), his commentary on Joannes Dorp (1504, &c.), his Insolubilia (1516, &c.), his introduction to Aristotle's logic (1521, &c.), his commentary on the ethics (1530), and, chief of all, his commentary on Peter Lombard's Sentences (1509, &c.). The second consists of a commentary on Matthew (1518) and another on the Four Gospels (1529); the last is represented by his famous Historia Majoris Britanniae tam Angliae quam Scotiae per J. M. (1521). In political philosophy he maintained the Scotist position, that civil authority was derived from the popular will, but in theology he was a scholastic conservative, though he never failed to show his apprehension of Gallicanism and its plea for the reform of ecclesiastical abuses. He has left on record that it was his aim and hope to reconcile realism and nominalism in the interests of theological peace. He had a world-wide reputation as a teacher and writer. Buchanan's severe epigram, perhaps the only unfriendly words in the flood of contemporary praise, may be explained as a protest against the compromise which Major appeared to offer rather than as a personal attack on his teacher. Major takes a more independent attitude in his History, which is a remarkable example of historical accuracy and insight. He claims that the historian's chief duty is to write truthfully, and he is careful to show that a theologian may fulfil this condition.

The History, on which his fame now rests, was reprinted by Freebain (Edinburgh, 1740), and was translated in 1892 by Archibald Constable for the Scottish History Society. The latter volume contains a full account of the author by Aeneas J. G. Mackay and a bibliography by Thomas Graves Law.

MAJOR (Lat. for "greater"), a word used, both as a substantive and adjective, for that which is greater than another in size, quality, degree, importance, &c., often opposed correlative to that to which "minor" is applied in the same connotation. In the categorical syllogism in logic, the major term is the term which stands in the predicate of the conclusion; the minor term is that which contains the major term. (For the distinction between major and minor intervals, and other applications in music, see MUSIC and HARMONY.)

The use of Major as part of an official title in Med. Lat. has given the Span. mayor, Fr. maire, and Eng. "major," (q.v.). In English the unadapted form "major" is the title of a military officer now ranking between a captain and a lieutenant-colonel. Originally the word was used adjectively in the title "sergeant-major," an officer of high rank (third in command of an army) who performed the same duties of administration, drill and encampments on the staff of the chief commander as the sergeant in a company performs as assistant to the captain. This was in the latter half of the 17th century, and very soon after being, it is generally regarded as the "sergeant-major-general."—hence the modern title of major-general. By the time of the English Civil War, major had been introduced in each regiment of foot, who corresponded in a lesser sphere to the "major-general" of the whole army. The major's sphere of duties, precedence and title have since varied but little, though he has, in the British service, taken the place of the lieutenant-colonel as second in command—the latter officer exercising the command of the cavalry regiment, infantry battalion or artillery brigade, and the colonel being, save for his greater importance in the social functions, little more than the major general of his regiment. Junior majors command companies of infantry; squadrons of cavalry and batteries of artillery are also commanded by majors. In most European armies, however, and of late years in the army of the United States also, the major has become a battalion commander under the orders of a regimental commander (colonel or lieutenant-colonel). The word appears also in the British service in "brigade-major" (the adjutant or staff officer of a brigade), "Town-majors" (garrison staff officers) are now no longer appointed. In the French service up to 1871 the "major-general" was the chief of the general staff of a field army, and thus preserved the tradition of the former "sergeant-major" or "sergeant-major-general."

MAJORCA (Mallorca), the largest of the group of Spanish islands in the Mediterranean Sea known as the Balearic Islands (q.v.). Pop. (1900), 248,191; area, 430 sq. m. Majorca has the shape of a trapezoid, with the angles directed to the cardinal points; and its diagonal, from Cape Grosio in the west to Cape Foradada in the east, is about 60 m. On the north-west the coast is precipitous, but on the other sides it is low and sloping. On the north-east there are several considerable bays, of which the chief are those of Alcudia and Pollensa; while on the south-west is the still more important bay of Palma. No fewer than twelve ports or harbours are enumerated round the island, of which may be mentioned Andraitx and Sóller. In the north-west Majorca is traversed by a chain of mountains running parallel with the coast, and attaining its highest elevation in Silla de Torrellas (1545 ft.). Towards the south and east the surface is comparatively level, though broken by isolated masses of considerable height. The northern mountains afford great protection to the rest of the island from the violent gales to which it would otherwise be exposed, and render the climate remarkably mild and pleasant. The scenery of Majorca has all the picturesque outline that usually belongs to a limestone formation. Some of the valleys, such as those of Valdemossa and Sóller, with their luxuriant vegetation, are delightful resorts. There are quarries of marble of various grains and colours—those near Santanyí, in the district of Manacor, being especially celebrated; while lead, iron and cinnabar have also been obtained. Coal of a jet-like character is found at Benisalem, where it was first worked in 1836; at Selva, where it has been mined since 1851; near Santa Maria and elsewhere. It is used in the industrial establishments of Palma, and in the manufacture of lime, plaster and bricks near the mines. A considerable quantity is also exported to Barcelona.

The inhabitants are principally devoted to agriculture, and most of the arable land is cultivated. The mountains are terraced, and the old pine woods have in many places given way to the olive, the vine and the almond tree, to fields of wheat and flax, or to orchards of figs and oranges. For the last-mentioned fruits the valley of Sóller is one of the most important districts,
The produce being largely transmitted to France. The yield of oil is very considerable, and Inca is the centre of the oil district. The wines are light but excellent, especially the Muscadet and Monton. During the summer there is often great scarcity of water; but, according to a system handed down by the Moors, the rains of autumn and winter are collected in enormous reservoirs, which contain sufficient water to last through the dry season; and on the payment of a certain rate, each landholder has his fields flooded at certain intervals. Mules are used in the agriculture and traffic of the island. The cattle are small, but the sheep are large and well fleeced. Pigs are reared for export to Barcelona, and there is abundance of poultry and small game. Brandy is made and exported in large quantities. Exported rather than imported are the silk worm and its produce; the silk worm is reared and its produce manufactured; and canvas, rope and cord are largely made, from both native and foreign materials.

The roads are excellent, the four principal being those from Alcudia, Manacor, Sóller and Andratx to the capital. Forty-eight miles of railway were open at the beginning of the 20th century. The main line runs from Palma to Manacor and Alcudia. The telegraphic system is fairly complete, and there is regular steam communication with Barcelona and Alicante. The principal towns include—besides Palma (61,437), Felanitx (11,294) and Manacor (12,408), which are described in separate articles—Andratx (6516), Inca (7570), Llummayor (8899), Pollensa (8308), Santanyi (6692) and Sóller (8206).

MAJORIAN (Julius Valerius Majorianus), emperor of the West from 457 to 461. He had distinguished himself as a general by victories over the Franks and Alemanni, and six months after the deposition of Avitus he was declared emperor by the regent Ricimer. After repelling an attack by the Vandals upon Campania (458) he prepared a large force, composed chiefly of barbarians, to invade Africa, which he previously visited in disguise. Having during his stay in Gaul defeated and concluded an alliance with Theodoric the Visigoth, at the beginning of 460 he crossed the Pyrenees for the purpose of joining the powerful fleet which he had collected at Carthageana. The Vandal king Genseric, however, after all overtures of peace had been rejected, succeeded through the treachery of certain officers in surprising the Roman fleet, most of the ships being either taken or destroyed. Majorian thereupon made peace with Genseric. But his ill-success had destroyed his military reputation; his efforts to put down abuses and improve the condition of the people had roused the hatred of the officials; and Ricimer, jealous of his fame and influence, stirred up the foreign troops against him. A mutiny broke out in Lombardy, and on the 2nd of August 461 Majorian was forced to resign. He died five days afterwards, either of dysentery or by violence. Majorian was the author of a number of remarkable laws, contained in the Theodosian Code. He remitted all arrears of taxes, the collection of which was for the future placed in the hands of the local officials. He revived the institution of defensores, defenders of cities, whose duty it was to protect the poor and inform the emperor of abuses committed in his name. The practice of pulling down the ancient monuments to be used as building material, which was connived at by venal officials, was strictly prohibited. He also passed laws against compulsory ordination and premature vows of celibacy.

See Sidonius Apollinaris, Panegyric of Majorian: Gibbon, Decline and Fall, ch. xxvi. (where an outline of the "novels" of Majorian is given); J. B. Bury, Later Roman Empire, Bk. iii.

MAJORITY (Fr. majorité; Med. Lat. majoritas; Lat. major, greater), a term signifying the greater number. In legislative and deliberative assemblies it is usual to decide questions by a majority of those present at a meeting and voting. In law, majority is the state of being of full age, which in the United Kingdom is twenty-one years of age. A person attains his majority at twelve o'clock at night of the day preceding his twenty-first birthday (see Infancy; Age).

MAJUBA (properly Amajuba, Zulu for "the hill of doves"), a mountain in northern Natal, part of the Drakensberg range, rising about 7000 ft. above the sea and over 2000 ft. above the level of the surrounding country. It overlooks the pass through the Drakensberg near the Zulus' Nguni, is 8 m. S. of the Transvaal border and 18 m. N. of the town of Newcastle. The railway from Durhan to Johannesburg skirts the base of the mountain. During the Boer War of 1880–81 Majuba was occupied on the night of the 26th of February 1881 by some 600 British troops under Sir George Pomeroy Colley. On the following morning the hill was stormed by the Boers under Piet Joubert and the British routed, Colley being among the slain.

MAKALAKA, a general designation used by the Bechuana, Matabele and kindred peoples, for conquered or slave tribes. Thus many of the tribes subjugated by the Makololo chief, Gao (Sabi), were afterwards styled Makalaka, and the name is more frequently used to designate the Makalanga, one of the tribes now classed as Mashonas (q.v.), who were brought into subjection by the Matabele.

MAKARA, or Inouo ("Cannibals"), a negroid people of Central Africa, closely related to the powerful Azande and Niam-Niam race, occupying the Bahr-el-Ghazal west of Lado. They were originally from the country of the Kibas. The name of their chief is Dr. W. Junker described them as among the most trust-worthy, industrious and intelligent people of the Bahr-el-Ghazal. They are a reddish-black, with nose less flat and cheek-bones less prominent than the ordinary negroes, and, unlike the latter, do not extract the incisors. Their long silky hair is built up in the most fantastic form by means of vegetable substances. They are well-known for strength and staying power.

See W. Junker, Travels in Africa (1890–1892).

MAKART, HANS (1840–1879), Austrian painter, born at Salzburg, was the son of an inspector of the imperial castle. He has been aptly called the first German painter of the 19th century. When he, as a youth, entered the Vienna Academy German art was under the rule of Cornelius's cold classicism. It was entirely intellectual and academic. Clear and precise drawing, sculpturesque modelling, and pictorial erudition were the qualities most esteemed; and it is not surprising that Makart, poor draughtsman to the very last, with a passionate and sensual love of colour, and ever impatient to escape the routine of art-school drawing, was found to be "devoid of all talent." and "an cittadino senza fatica," and "brave Viennois". In Munich, and after two years of independent study attracted the attention of Plity, under whose guidance he made rapid and astonishing progress. The first picture he painted after Plity, "Lavoisier in Prison," though timid and conventional, attracted attention by its sense of colour. In the next, "The Knight and the Water Nymphs," he first displayed the decorative qualities to which he afterwards sacrificed everything else in his work. With the "Cupids" and "The Plague in Florence" of the next year his fame became firmly established. "Romeo and Juliet," was soon after bought by the Austrian emperor for the Vienna Museum, and Makart was invited to come to Vienna, where a large studio was placed at his disposal. In Vienna Makart became the acknowledged leader of the artistic life of the city, which in the seventies passed through a period of feverish activity, the chief results of which are the sumptuously decorated public buildings of the Ringstrasse.

The enthusiasm of the time, the splendour of the fêtes over which Makart presided, and the very obvious appeal of his huge compositions in their glowing richness of colour, in which he tried to rival Rubens, made him particularly popular to his contemporaries in Vienna, and indeed in all Austria and Germany. The appearance of each of his ambitious historical and allegorical paintings was hailed with enthusiasm—the "Catherina Cornaro," "Diana's Hunt," "The Entry of Charles V. into Antwerp," "Abundantia," "Spring," "Summer," "The Death of Cleopatra" and the "Five Senses." He reached the zenith of his fame when, in 1879, he designed, single-handed, the costumes, scenic setting, and triumphant cars of the grand pageant with
MAKING-UP

Mahommedan term geologically peculiar repeated is Nodiz. chiefly of subject is on the account, implies of sand-bar dressed of Zarain, their highestKej town on the sand-bar dressed of Zarain, their highest Kej town of Makran, 135 m. S.E. of Budapest by rail. Pop. (1900), 33,701. It is situated near the right bank of the Maros, and is a typical Hungarian town of the Alföld. The most noteworthy building is the palace of the bishop of Csárdás, whose usual residence is in Temesvár. The town possesses numerous mills, and the surrounding country is fertile. The communal lands are extensive; they afford excellent pasturage for horses and sheep and also for large herds of horned cattle, for the size and quality of which Makú has obtained a high repute.

MAKRAN, or MEKRAN, a province of Baluchistan, fringing the Arabian Sea from Persia almost to Sind for about 300 m. It is subject to the khan of Kalat under British political supervision. Estimated area, 26,000 sq. m.; estimated pop. (1901), 78,000. The long lateral valley of Kej is usually associated with Makran in early geographical records. The Kej-Macoran of Marco Polo is the Makran of to-day.

The long stretch of sandy foreshore is broken on the coastline by the magnificent cliffs of Malan, the hammer-shaped headlands of Ormarah and Gwadar, and the precipitous cliffs of Jebel Zarain, near Pasni. Within them lies the usual frontier band of parallel ridges, alternating with narrow valleys. Amongst them the ranges called Talana and Talur are conspicuous by their peculiar configuration. With the exception of the Baluchistan frontier is somewhat emphasized in Makran. The volcanic action, which preceded the general upheaval of recent strata and the folding of the edges of the interior highlands, is still in evidence in occasional boiling mud volcanoes on the coast-line. It is repeated in the blazing summit of the Kuh-i-taftan (the burning mountain of the Persian frontier) which is the highest active volcano in Asia (13,500 ft.), and probably the farthest inland. Evidence of extinct mud volcanoes exists through a very wide area in Baluchistan and Seistan. Probably the miri, or fort, at Quetta represents one of them. The coast is indented by several harbours. Ormarah, Khor Kalmat, Pasni and Gwadar are all somewhat difficult of approach by reason of a sand-bar which appears to extend along the whole coastline, and which is very possibly the last evidence of a submerged ridge; and they are all subject to a very lively surf under certain conditions of wind. Of these the port of Gwadar (which belongs to Muscat and is therefore foreign territory) is the most important. They all are (or were) stations of the Indo-Persian telegraph system, and in the world with which they are the least of the Kej, and that of the Bolida, which is an affluent of the Kej, there are no considerable places of cultivation in Makran. These two valleys seem to concentrate the whole agricultural wealth of the country. They are picturesque, with thick groves of date palms at intervals, and are filled with crops and orchards. They are indeed exceedingly beautiful; and yet the surrounding waste of hills is chiefly a barren repetition of sun-cracked crags and ridges with parched and withered valleys intersecting them, where a trickle of salt water leaves a white and leprous streak amongst the dark tamarisk or the yellow stalks of last season's grass. Makran is the home of remnants of an innumerable company of mankind people gathered from the four corners of Asia and eastern Africa. The ancient Dravidians, of whom the Brahmans must exist in many of the districts which are assigned to them in Herodotus. Amongst them there is always a prominent Arab element, for the Arabs held Makran even before they conquered Sind and made the Kej valley their trade highway to India. There are negroes on the coast, bred from imported slaves. The Meds of the Indus valley still form the greater part of the fishing population, representing the Ichthyophagi of Arrian. The old Tajik element of Persia is not so evident in Makran as it is farther north; and the Karak pirates whose depredations led to the invasion of India and the conquest of Sind, seem to have disappeared altogether.

The fourth section includes the valleys formed by the Rakshán and Maskhel, which, sweeping downwards from the Kalat highlands and the Persian border east and west, unite to break through the intervening chain of hills northward to form the Maskhil swamps, and define the northern limits of Makran. In these valleys are narrow strips of very advanced cultivation, the dates of Panjirgur being generally reckoned superior even to those of the Euphrates. The great Maskhil swamp and the Kharan are the result of the waste of two of the chief rivers of the area; mark the flat phase of southern Baluchistan topography. It is geologically part of an ancient inland lake or sea which included the present swamp regions of the Helmund, but not the central depression of the Lora. The latter is buttressed against hills at a much higher elevation than the Kharan desert, which is separated from the great expanse of the Helmund desert within the borders of Afghanistan by a transverse band of serrated hills forming a distinct watershed from Nushki to Seistan. Here and there these jagged peaks appear as if half overwhelmed by an advancing sea of sand. They are treeless and barren, and water is but rarely found at the edges of their foot-hills. The Koh-i-Sultan, at the western extremity of the northern group of these irregular hills, is over 6000 ft. above sea-level, but the general level of the surrounding deserts is only about 2000 ft., sinking to 1500 ft. in the Maskhil Hamun and the Gaol-i-Zirreh.

The whole of this country has been surveyed by Indian surveyors and the boundary between Persian and British Baluchistan was demarcated by a commission in 1893–1896. In 1858 a column of British troops under Colonel Mayne was despatched to Makran in the east, owing to a rebellion against the rule of the khan of Kalat, and an attack made by some Makran chiefs on a British survey party. The campaign was short and terminated with the capture of the Kej citadel. Another similar expedition was required in 1901 to storm the fort at Nosid. The headquarters of the native governor, under the khan of Kalat, are at Turbat, with headquarters at Tump, Kolwa, Pasni and Panjgur. A levy corps, with two British officers, is stationed along the western frontier. The port of Gwadar forms an enclave belonging to the sultan of Muscat.

(T. H. H. *)

MAKSORA, the term in Mahommedan architecture given to the sanctuary or praying-chamber in a mosque, which was sometimes enclosed with a screen of lattice-work; the word is occasionally used for a similar enclosure round a tomb.

MALABAR, a district of British India, in the Madras Presidency. Geographically the name is sometimes extended to the entire western coast of the peninsula. Properly it should apply to the strip below the Ghats, which is the northern limit of the territory of the Malabarcodes; to the strip on either side of the Malabar coast, namely, that between the Ghats and the Malabar stock, which form a peculiar race, with castes, customs and traditions of their own. It would thus be coextensive with the old kingdom of Chera, including the modern states of
Travancore and Cochin, and part of Kanara. In 1901 the total number of persons speaking Malayalam in all India was 6,290,304.

The district of Malabar extends for 145 m. along the coast, running inland to the Ghats with a breadth varying from 70 to 25 m. The administrative headquarters are at Calicut. Area, 5795 sq. m. Malabar is singularly diversified in its configuration, and extending eastward, the great range of the Western Ghats, only interrupted by the Palghat gap, looks down on a country broken by long spurs, extensive ravines, dense forests and tangled jungle. To the westward, gentler slopes and downs, and gradually widening valleys closely cultivated, succeed the forest uplands, till, nearer the seaboard, the low laterite table-lands shelf into rice plains and backwaters fringed with coco-nut palms. The coast runs in a south-easterly direction, and forms a few headlands and small bays, with a natural harbour in the south at Cochin. In the south, there is considerable extent of table-land. The mountains of the Western Ghats run almost parallel to the coast, and vary from 3000 to 7000 ft. in height. One of the most characteristic features of Malabar is an all but continuous chain of lagoons or backwaters lying parallel to the coast, which have been formed by the action of the waves and shore currents in obstructing the waters of the rivers. Connected by artificial canals, they form a cheap means of transit; and a large local trade is carried on by inland navigation. Fishing and fish curing is an important industry. The forests are extensive and of great value, but they are almost entirely private property. The few tracts which are conserved have come into government hands by escheat or by contract. Wild animals include the elephant, tiger, panther, bison, sambar, spotted deer, Nilgiri ixex, and bear. The population in 1901 was 2,800,555, showing an increase of 5.6% in the decade.

The staple crop is rice, the next most important product being coco-nuts. Coffee is grown chiefly in the upland tract known as the Wynad, where there are also a few acres under tea. The Madras railway, which crosses the district and has been extended from Calicut to Cannanore along the coast. There are eleven seaports, of which the principal are Calicut, Telli-cherry, Cannanore and Cochin. The principal exports are coffee, coco-nut products and timber. There are factories for cleaning coffee, pressing coir and making matting, making tiles, sawing timber and weaving cotton.

See Malabar District Gazetteer (Madras, 1898).

MALABARI, BEHRAMJI (1853- ), Indian journalist and social reformer, was born in 1853 at Baroda, the son of a poor Parsi in the employment of the state, who died shortly after his birth. His mother took him to Surat, where he was educated in a mission school, but he never succeeded in gaining an academical degree. Coming to Bombay, he fell under the influence of Dr John Wilson, principal of the Scottish College. As early as 1875 he published a volume of poems in Gujarati, followed in 1877 by The Indian Muse in English Garh, which attracted attention in England, notably from Tennyson, Max Muller, and Florence Nightingale. His life work began in 1880 when he acquired the Indian Spectator, which he edited for twenty years. In it was published the voice of the Voice of India. In 1901 he became editor of East and West. Always holding aloof from politics, he was an ardent and indefatigable advocate of social reform in India, especially as regards child marriage and the remarriage of widows. It was largely by his efforts, both in the press and in tours through the country, that the Age of Consent Act was passed in 1891. His account of his visits to England, entitled The Indian Eye on English Life (1893), passed through three editions, and an earlier book of a somewhat satirical nature, Gujarat and the Gujaratis (1883), was equally popular.

See R. P. Karkara, India, Forty Years of Progress and Reform, (London, 1896).

MALABON, a town of the province of Rizal, Luzon, Philippine Islands, 1 m. inland from the shore of Manila Bay and 3 m. N. of the city of Manila, with which it is connected by an electric tramway. Pop. (1903), 20,136. The leading industries are the refining of sugar, fishing, trade, the weaving of juti cloth, the making of cigars, and the cultivation of ilang-ilang-trees (Cananga odorata) for their flowers, from which a fine perfume is distilled; ilang-ilang is one of the principal exports, mostly to France. Tagalog and Spanish are the principal languages.

Malacca was formerly known as Tambhông. MALACCA, a town on the west coast of the Malay Peninsula, in 2° 14' N., 102° 12' E., which, with the territory lying immediately around and behind it forms one of the Straits Settlements, and gives its name to the Straits which divide Sumatra from the Malay Peninsula. Its name, which is more correctly transliterated melâka, is that of a species of jungle fruit, and is also borne by the small river by the right bank of which the old Dutch town stands. The Dutch town is connected by a bridge with the business quarter on the left bank, which is inhabited almost exclusively by Chinese, Eurasians and Malays.

Malacca, now a somnolent little town, a favourite resort of rich Chinese who have retired from business, is visited by few ships and is the least important of the three British settlements on the Straits which give their name to the colony. It has, however, a remarkable history. The precise date of its foundation cannot be ascertained, but there is strong reason to believe that this event took place at the earliest in the 14th century. The Roman youth Ludovigo Barthema is believed to have been the first European to visit it, some time before 1503; and in 1509 Diogo Lopez de Siqueira sailed from Portugal for the express purpose of exploring Malacca. At first he was hospitably received, but disagreements with the natives ensued and word was brought to Siqueira by Magellan, who was one of his company, that a treacherous attack was about to be made upon his ships. Siqueira then sent a native man and woman ashore "with an arrow passed through their skulls" to the sultan, "who was thus informed," says de Barros, "through his subjects that unless he kept a good watch the treason which he had perpetrated would be punished with fire and sword." The sultan retaliated by arresting Ruy de Araujo, the factor, and twenty other men who were ashore with him collecting cargo for the ships. Siqueira immediately burned one of his vessels and sailed direct for Portugal. In 1510 Mendez de Vasconcellos with a fleet of four ships set out from Portugal "to go and conquer Malacca," but d'Alboquerque detained him at Goa, and it was not until 1511 that d'Alboquerque himself found time to visit Malacca and seek to rescue the Portuguese prisoners who all this time had remained in the hands of the sultan. An attack was delivered by d'Alboquerque on the 25th of July 1511, but it was only partially successful, and it was not until the 4th of August that the sultan's fleet occupied the place finally fell. Since that time Malacca has continued to be the possession of one or another of the European Powers. It was a Portuguese possession for 130 years, and was the head-quarters of their trade and the base of their commercial explorations in south-eastern Asia while they enjoyed, and later while they sought to hold, their monopoly in the East. It was from Malacca, immediately after its conquest, that d'Alboquerque sent d'Abreu on his voyage of discovery to the Moluccas, or Spice Islands, which form the eastern end of Magellan's voyage of circumnavigation. During the Portuguese tenure of Malacca the place was attacked at least twice by the A Chinese; its shipping was harried by Lancaster in 1592, when the first British fleet made its way into these seas; it was besieged by the Dutch in 1606, and finally fell to a joint attack of the Dutch and the A Chinese in 1641. It was under the Portuguese government that St Francis Xavier started a mission in Malacca, the first Christian mission in Malay lands.

The Dutch held Malacca till 1795, when it was taken from them by Great Britain, and the Dutch system of monopoly in the straits was forthwith abolished. The colony was restored to the Dutch, however, in 1818, but six years later it came finally into the hands of Great Britain, being exchanged by a treaty with Holland for the East India Company's settlement of Benkulen and a few other unimportant places on the western
coast of Sumatra. By this treaty the Dutch were precluded from interference in the affairs of the Malay Peninsula, and Great Britain from similar action in regard to the States of Sumatra, with the sole exception of Achin, the right to protect that state being maintained by Great Britain until 1853, when it was finally abandoned by a treaty concluded with Holland in that year. The Dutch took advantage of this immediately to invade Achin, and the strife begun in 1873 still continues and is now a mere war of extermination. It was not until 1833 that the whole territory lying at the back of Malacca was finally brought under British control, and as late as 1887 the Negri Sembilan, or Nine States, which adjoin Malacca territory on the east and north-east, were completely independent. They to-day form part of the Federated Malay States, which are under the protection of Great Britain, and are governed with the assistance and by the advice of British officers.

Malacca, in common with the rest of the Straits Settlements, was administered by the government of India until 1867, when it became a crown colony under the control of the Colonial Office. It is to-day administered by a resident commissioner, who is responsible to the governor of the Straits Settlements, and by a number of district officers and other officials under his direction. The population of the town and territory of Malacca, in 1844-48, of whom 74 were Europeans and Americans, 1598 were Eurasians, the rest being Asiaticks chiefly Malays with a considerable sprinkling of Chinese. The population in 1851 was 92,170, and the estimated population for 1905 was 97,000. The birth-rate is about 35 per thousand, and the death-rate about 29 per thousand. The trade of this once flourishing port has declined, most of the vessels being merely coasting craft, and no large line of steamers holding any communication with the place. This is due partly to the shallowness of the harbour, and partly to the fact that the ports of Penang and Singapore, at either entrance to the straits, draw all the trade and shipping to themselves. The total area of the settlement is about 700 sq. m. The colony is wholly agricultural, and the land is almost entirely in the hands of the natives. About 50,000 acres are under tapioca, and about 9000 acres are under rubber (hevea). This cultivation is rapidly extending. There are still considerable areas unoccupied which are suitable for rubber and for coco-nuts. The settlement is well opened up by roads; and a railway, which is part of the Federated Malay States railway system, has been constructed from the town of Malacca to Singapore. Malacca is situated on a good rest-house at Malacca and a comfortable seaside bungalow at Tanjong Kling, seven miles from the town. Malacca is 118 m. by sea from Singapore and 50 m. by rail from Seremban, the capital of the Negri Sembilan. There is excellent snipe-shooting to be had in the vicinity of Malacca.

MALACHI, the name assigned to the last book of the Old Testament in English (the last of the "prophets" in the Hebrew Bible), which according to the title (Mal. i. 1) contains the word "Yahweh to Israel by the hand of Malachi." In form the word means "my messenger." It could be explained as a contraction of Malachiah, "messenger of Yahweh"; but the Septuagint is probably right in not regarding it as a proper name ("by the hand of His messenger"). Not only do we know nothing from internal or external evidence of the existence of a prophet of this name; but the occurrence of the word in the title is naturally explained as derived from iii. 1: "Behold, I will send my messenger before thy face..."

1 A Hebrew tradition given in the Targum of Jonathan, and approved by Jerome, identifies Malachi with Ezra the priest and scribe.
his time was the outcome of a lowered morality, not of a clearer spiritual vision." A strong sense of the unique privileges of the children of Jacob, the objects of electing love (i. 2), the children of the Divine Father (i. 10), is combined with an equally strong assurance of Yahweh's righteousness notwithstanding the many miseries that pressed on the unhappy inhabitants of Judaea. At an earlier date the prophet Haggai had taught that the people could not expect Yahweh's blessing while the Temple lay in ruins. In Malachi's time the Temple was built (i. 17); the priests waited in their office, but still a curse shadowed to rest on the nation's labours (iii. 6). To Malachi the reason of this is plain. The "law of Moses" was forgotten (vv. 4 (iii. 22)); let the people return to Yahweh, and He will return to them. It was in vain to complain, saying, "Every one that doeth evil is good in the eyes of Yahweh," or "Where is the God of judgment?"—vain to ask "Wherein shall we return?" Obedience to the law is the sure path to blessing (ii. 17-iii. 12).

He calls the people to repentance, and he enforces the call by proclaiming the approach of Yahweh in judgment against the sorcerers, the adulterers, the false swearers, the oppressors of the poor, the orphan and the stranger. Then it shall be seen that He is indeed a God of righteous judgment, distinguishing between those that serve Him and those that serve Him not. The Sun of Righteousness shall shine forth on those that fear Yahweh's name; they shall go forth with joy, and tread the wicked under foot. The conception of the day of final decision, when Yahweh shall come suddenly to His temple (iii. 1) and confound those who think the presumptuous godless happy (iii. 15), is taken from earlier prophets, but is peculiarly adapted to the state of the nation (ii. 16). The day of Yahweh is delayed in such a state of things is but a new proof of His unfailing love (iii. 6), which refuses to consume the sons of Jacob. Meantime He is about to send His messenger to prepare His way before Him. The prophet Elijah must reappear to bring back the hearts of fathers and children before the great and terrible day of Yahweh come. Elijah was the advocate of national decision in the great concerns of Israel's religion; and it is such decision, a clear recognition of what the service of Yahweh means, a purging of His professed worshippers from hypocritical and half-hearted service (iii. 4) that Malachi with his intense religious earnestness seems to be the only salvation of the nation. In thus looking to the return of the ancient prophet to do the work for which later prophecy is too weak, Malachi unconsciously signally decays the order of which he was one of the last representatives, and the somewhat mechanical measure which he applies to the people's sins, as for example when he teaches that if the sacred dues were righteously paid prosperous seasons would at once return (iii. 10), heralds the advent of that system of formal legalism which thought that all religious duty could be reduced to a system of set rules. Yet Malachi himself is no mere formalist. To him, as to the Deuteronomical legislation, the forms of legal observance are of value only as the fitting expression of Israel's peculiar sonship and service, and he shows himself a true prophet when he contrasts the worthless ministry of unwilling priests with the pure offering of prayer and praise that rises from the implicit monotheism of even Gentile worship (i. 11), or when he asserts the brotherhood of all Israelites under their one Father (i. 10), not merely as a ground of separation from the heathen, but as inconsistent with the selfish and cruel freedom of divorce current in his time. The book is a significant landmark in the religious history of Israel. Its emphasis on the observance of ritual finds fullest development in the Priestly Code, subsequently promulgated; its protest against foreign marriages is made effective through the reforms of Ezra and Nehemiah; the influence of its closing words on later expectation is familiar to every reader of the prophetic literature. The style of Malachi, like his argument, corresponds in its generally prosaic character to that transformation or decay of prophecy which began with Ezekiel; and Ewald rightly called attention to the fact that the conduct of the argument already shows traces of the dialectical manner of the schools. Yet there is a simple dignity in the manner not unworthy of a prophet, and rising from time to time to poetical rhythm.

MALACHITE, a copper-ore of fine green colour, sometimes polished as an ornamental stone. The name is derived from Gr. μαλαχίς, the mallow, in allusion to the colour of the mineral being rather like that of the mallow-leaf. Malachite was perhaps one of the green minerals described by Theophrastus under the general name of εμπρεγμοσ; and according to the Rev. C. W. King it was probably the smaragdus medicus of Pliny, whilst his malachites seems to have been a different stone from our malachite and may have been a green Jasper. It is suggested by J. L. Myres (Ency. Bibl.) that malachite may have been the Heb. soham, of the high priest's breastplate.

Malachite is a basic cupric carbonate, represented by the formula CuCO₃(Cu(HO)₂), and has usually been formed by the action of meteoric agencies on other copper-minerals; hence it is found in the upper part of ore-deposits, often as an incrustation, and occasionally as a pseudomorph after cuprite, chalcocite, &c. When formed, as commonly happens, by the alteration of copper-pyrites the iron of this mineral usually takes the form of limonite, which may remain associated with the malachite. Occasionally, though but rarely, malachite occurs in small dark-green prismatic crystals of the monoclinic system. Its usual mode of occurrence is in nodular or stalagmitic forms, with a mammillated, reniform or botryoidal surface, whilst in other cases it forms fibrous, compact or even earthy masses. The nodules, though commonly dull on the outside, may display on fracture a beautiful zonary structure, the successive layers often succeeding each other as curved deposits of light and dark tints. The colours include various shades of apple-green, grass-green, emerald-green and verdigris-green. Certain varieties exhibit a finely fibrous structure, producing on the fractured surface a soft silky sheen.

Whilst malachite is found in greater or less quantity in most copper-mines, the finer varieties useful for ornamental purposes are of very limited occurrence, and the lapidary has generally drawn his supply from Russia and Australia. The principal source in recent years has been the Medno-Rudianske mine near Nizhne Tagilsk, on the Siberian side of the Urals, but it was formerly obtained from near Borodovskoye and from Lobshtein and Gumishev to the south of this locality. A mass from Gumishev, preserved in the museum of the Mining Institute of St Petersburg weighs 3240 lb, and still larger masses have been found near Nizhne Tagilsk. The mineral is prized in

1 Welch in D. B. iii. 220.
2 This remarkable utterance is sometimes (as by W.R.S.) interpreted of the worship of Jews scattered in the Dispersion: reasons for the above view are given by Driver.

1 In ii. 16 the Targum renders "If thou hastest her put her away." It is characteristic of later Judaism that an arbitrary exegesis transformed the above anticipation of the doctrine of marriage laid down in the gospel into an express sanction of the right of the husband to put away his wife at will.

4 The permanence of Judaism depended on the religious separateness of the Jews" (Ryle, Ezra and Nehemiah, p. 143).

5 Matt. xvii. 3, 4, 10-13; xvii. 47, 49; John i. 21, 25.
MALACHOWSKI—MALACHY, ST

Russia for use in mosaic-work, and for the manufacture of vases, snuff-boxes and various ornamental objects. Even folding doors, mantelpieces, table-tops and other articles of furniture have been executed in malachite, the objects being veneered with thin slabs cleverly fitted together so as to preserve the pattern, and having the interspaces filled up with fragments of the first, and powdered of malachite applied with a cement. The malachite is sawn into slabs, ground with emery and polished with tripoli. Its hardness is less than 4, but it takes a good polish like marble; it is rather denser than marble, having a specific gravity of 3.7 to 4, but it is more difficult to work, in consequence of a tendency to break along the curved planes of deposition. Exceptionally fine examples of the application of malachite are seen in some of the columns of St Isaac's Cathedral in St Petersburg, which are hollow iron columns encrusted with malachite. Large masses of ornamental malachite have been found in Australia, especially at the old Burra Burra coppermine in South Australia. The Copper Queen and other mines in Arizona have yielded fine specimens of malachite associated with azurite, and polished slabs of the mixed minerals sometimes show the vivid green and the deep blue carbonate in very striking contrast. This natural association, cut as an ornamental stone, has been named, by Dr G. F. Kunz, azurmalachite. Malachite is occasionally used for cameo-work, and some fine antique examples are known. It was formerly worn as an amulet to preserve the wearer from lightning, contagion and witchcraft.

The mineral, when ground, has been used as a pigment under the name of "mount green." The coarser masses are extensively used, with other minerals, as ores of copper, malachite containing about 57% of metal. "Blue malachite" is a name sometimes given to azurite (g.n.), whilst "siliceous malachite" is a term inappropriately applied to chrysocolla (g.n.).

MALACHOWSKI, STANISLAW (1736-1809), Polish statesman, the younger son of Stanislaw Malachowski, patrician of Pozen, the companion in arms of Sobieski. From his youth Malachowski laboured zealously for the good of his country, and as president of the royal court of justice won the honorable title of the "Polish Aristides." He was first elected a deputy to the Coronation Diet of 1764, and the great Four Years' Diet unanimously elected him its speaker at the beginning of its session in 1788. Accurately gauging the situation, Malachowski speedily gathered round him all those who were striving to uphold the falling republic and warmly supported every promising project of reform. He was one of the framers of the constitution of the 3rd of May 1791, exceeding in liberality all his colleagues and advocating the extension of the franchise to the townsmen and the suppression of the monopolies.

At the beginning of the war with Russia Malachowski announced his determination to enter his name as a citizen of Warsaw in the civic register and to open negotiations with his own peasantry for their complete liberation. Disappointed in his hopes by the overthow of the constitution, he resigned office and left the country in 1792, going first to Italy and subsequently to his estates in Galicia, where he was imprisoned for a time on a false suspicion of conspiracy. In 1807 Malachowski was placed at the head of the executive committee appointed at Warsaw after its evacuation by the Prussians, and when the grand duchy of Warsaw was created Malachowski became permanent president of the senate under the regency of King Frederick Augustus of Saxony. In the negotiations with the Austrian government concerning the Galician salt-mines Malachowski came to the assistance of the deputed treasury by hypotcheating all his estates as an additional guarantee. In 1809 he died at Warsaw. His death was regarded as a public calamity, and multitudes followed his remains to their last resting-place in the Church of the Holy Cross. In all the other salute of the grand duchy funeral services were held simultaneously as a tribute of the respect and gratitude of the Polish nation.

See August Sokolowski, Illustrated History of Poland (Pol.), vol. iv. (Vienna, 1900); Life and Memoirs of S. Malachowski, edited by Lucyan Siemiencki (Pol; Cracow, 1853).

MALACHY, ST (c. 1094-1148), otherwise known as Mael- Maodhog (or Maelmaodhog) or Us Mhairg, archbishop of Armagh and papal legate in Ireland, was born at Armagh. His father, an Irish clergyman, the Fearleighhinn, or lector, at the university, was said to have been of noble family. Having been ordained to the priesthood, he for some time acted as vicar of Archbishop Celsus or Ceallach of Armagh, and carried out many reforms tending to increase conformity with the usage of the Church of Rome. In order to improve his knowledge of the Roman ritual he spent four years with Malchus, bishop of Limoges (in Munster), a strong advocate of Romanism. Here he became acquainted with Cormac MacCarthy, king of Desmond, who had sought refuge with Malchus, and, when he subsequently regained his kingdom, rendered great services to Malachy. On his return from Lismore, Malachy undertook the government of the decayed monastery of Bangor (in Co. Down), but very soon afterwards he was elected bishop of Connor (now a small village near Ballymena). After the sack of that place by the king of Ulster he withdrew into Munster; here he was kindly received by Cormac MacCarthy, with whose assistance he built the monastery of Ibrah (in Kerry). Meanwhile he had been designated by Celsus (in whose family the see of Armagh had been hereditary for many years) to succeed him in the archbishopric; in the interests of reform he reluctantly accepted the dignity, and thus became involved for some years in a struggle with the so-called heirs. Having finally settled the diocese, he was permitted, as had been previously stipulated by himself, to use the form of the Sarum, or to the smaller and poorer portion of it, the bishopric of Down. The Roman party had by this time obtained a firm hold in the north of Ireland, the organization of the Church had not yet received the sanction of the pope. Accordingly, in 1139, Malachy set out from Ireland with the purpose of soliciting from the pope the pallium (the token of archiepiscopal subjection to Rome) for the archbishop of Armagh. On his way to Rome he visited Clairvaux, and thus began a lifelong friendship with St Bernard. Malachy was received by Innocent II. with great honour, and made papal legate in Ireland, though the pope refused to grant the pallium until it had been unanimously applied for by a general council of the bishops, clergy and nobles. On his way home Malachy revisited Clairvaux, and took with him from there four members of the Cistercian order, by whom the abbey of Mellifont (in the county of Louth) was afterwards founded in 1141. For the next eight years after his return from Rome Malachy was active in the discharge of his legatine duties, and in 1148, at a synod of bishops and clergy held at Inis-Patrick (St Patrick's Island, near Skerries, Co. Dublin), he was commissioned to return to Rome and make fresh application for the pallium; he did not, however, get beyond Clairvaux where he died in the arms of St Bernard, on the 2nd of November 1148. The object of his life was realized four years afterwards, in 1152, during the legateship of his successor. Malachy was canonized by Clement III. in 1190.

The influence of Malachy in Irish ecclesiastical affairs has been compared with that of Boniface in Germany. He reformed and reorganized the Irish Church and brought it into subjection to Rome; like Boniface, he was a zealous reformer and a promoter of monasticism. But perhaps his chief claim to distinction is that of having opened to the first Cistercian monastery in Ireland, five more being soon afterwards established. Several works are attributed to him, but are all probably spurious. The most curious of these is a Prophecy concerning the Future Roman Pontiffs, which has produced an extensive literature. It is now generally attributed to the year 1590, and is supposed to have been forged to support the election of Cardinal Simoncelli to the papal chair.

St Bernard of Clairvaux, and two sermons on his death, were found in J. P. Migne, Patrologia Latina; see also Annals of the Kingdom of Ireland by the Four Masters, ed. J. O'Donovan (Dublin, 1851); G. Germaino, Vita, gesti e predizioni del padro san Malachia (Naples, 1609); the old histories of Ireland by J. Lanigan (1829) and W. D. Killen (1875); A. Bellesheim, Geschichte der katholischen Kirche in Irland, Bd. I. (Mainz, 1890); G. T. Stokes, Ireland and the Celtic Church (6th ed., 1907); J. O'Hanlon, Life of Sancti Malachy (Dublin, 1859); articles in Dictionary of National Biography and Herzog-Hauck's Realencyclopädie für protestantische Theologie. On the Prophecy, see the
MALACOSTRACA. Under this zoological title are included several groups of Crustacea (q.v.), united by characters which attest their common origin, though some, and probably all of them, were already separated in distant geological ages, and some have now attained a peculiar isolation. Throughout the whole, the researches made since 1860 have not only added a great throng of new species, genera and families, but have thrown a flood of light upon questions of their phylogeny, systematic arrangement, horizontal and bathymetric distribution, organization, habits of life and economic importance. There are at least seven orders: the stalk-eyed Brachyura, Macrura, Schizopoda, Stomatopoda, and the sessile-eyed Sym poda, Isopoda, Amphipoda. An ocular segment claimed by the former division is not present or in no case demonstrable in the latter. In neither does the terminal segment or telson, whether long or obsolete, whether articulated or coalescent, carry appendages, unless occasionally in fusion with itself. Between the eyes and the tail-piece in all the orders nineteen segments are counted, the proof of a segment's existence depending on its separateness, complete or partial, or on a sutural indication, or else on the pair of appendages known to belong to it. All these marks may fail, and then the species must be proved to be Malacostracan by other evidence than the number of its segments; but if some exceptions exhibit fewer, none of the Malacostraca exhibits more than four or five less, the Nereilidae being included. Of the corresponding pairs of appendages thirteen belong to the head and trunk, two pairs of antennae, one pair of mandibles, two pairs of maxillae, followed by three which may be all maxillipeds or may help to swell the number of trunk-legs to which the next five pairs belong. The abdomen or pleon carries the remaining six pairs, of which from three to five are called pereopods and the remainder uropods. Underlying the diversity of names and functions and countless varieties of shape, there is a common standard to which the appendages in general can be referred. In the maxillipeds and the trunk-legs it is common to find or otherwise easy to trace a seven-jointed stem, the endopod, from which may spring two branches, the epipod from the first joint, the exopod from the second. The first antenna are exceptional in branching, if at all, at the third joint. In the mandibles and maxillae some of the terminal joints of the stem are invariably wanting. In the rest of the appendages they may either be wanting or indistinguishable. The latter obscurity results either from coalescence, to which all joints and segments are liable, or from subdivision, which occasioned affects joints, even in the trunk-legs. The carapace, formerly referred only to the antennar-mandibular segments, may perhaps in fact contain elements from any number of other segments of head and trunk, Huxley, Alcock, Bouvier giving support to this opinion by the sutural or other divisional lines in Polamobius, Nephropsis, Thallassina, and various fossil genera. Not all questions of classification internal to this division are yet finally settled. Between the Brachyura and Macrura some authors uphold an order Anomura, though in a much restricted sense, the labours of Milne-Edwards and Bouvier, and the joint work of Alcock, Milne-Edwards and Bouvier, have resulted in restoring the Dromiidea and Raninidea to the Brachyura, among which de Haan long ago placed them. The French authors argue that from the macuran lobsters (Nepheididae) genuinely diverged two lines: one leading through the Dromiidea to the genuine Brachyura; or crabs, the other independently to the Anomura proper, which may conveniently be named and classed as Macrura anomala. Spence Bate maintained that the Schizopoda ought not to form a separate order, but ranged them as a macural tribe, "more nearly allied to the degenerate forms of the Penaeidea than to those of any other group." ("Challenger Reports", "Macrura", p. 472, 1888). According to Sars, the Sympodia (or Cumaceans), in spite of their sessile eyes, have closer affinities with the stalk-eyed orders. H. J. Hansen and others form a distinct order Tanaidea for the decidedly anomalous group called by Sars Isopoda chelifera.

1. Brachyura.—For the present, as of old, the true Brachyura are divided into four tribes: Cycloptomata, with arched front as in the land-crabs and the little oyster-crab; Oxyrhyncha, with sharpened beak-like front as in the various spider-crabs; Oysteromata, or true Raninidea, which though not of the front but from that of the buccal frame which is usually narrowed forwards. In these tribes the bold and active habits, the striking colours, or the fantastic diversities of structure, have so long attracted naturalists that it is of recent years that we have become aware of the species and supplying the specialist with an infinity of new details, have not materially altered the scientific standpoint. New light, however, has been thrown upon the "intelectual" capacity of the crab by the proof that the spider-crabs deliberately use change of raiment to harmonize with their surroundings, donning and doffing various natural objects as we do our manufactured clothes. Others have the power of producing sounds, one use to which they put their faculty being apparently to signal from their burrow in the sand that they are "not at home" to an inopportune visitor. Deep-sea exploration has shown that some species have an immensely extended range, still more of the species in the same family, though separated by great intervals of space, may be closely allied in character. A curious effect of parasitism, hitherto observed in crustaceans and few other orders of animals, may have been expounded by Professor Girard, namely, that it tends to obliterate the secondary sexual characters. Modern research has discovered no crab to surpass Macrorauma kampferi, De Haan, that can span from three to seven feet and in the form of the secondary sexual characters, the antennae, the pleon, and even the other end of the scale it has yielded Colloselus malabarcus, Alcock, of which the carapace, in an adult and egg-laden female, is less than one-sixth of an inch in its greatest diameter. The most unusual of all crabs yet known is Goniolithodes, Smith, or what is perhaps only a variety of it, E. challegieri, Miers. Of the latter the "Abalooos" obtained a specimen from a depth of 500 fathoms (Faxon, 1895), of the former from 2221 fathoms and of this S. I. Smith remarks that it has "distinctly faceted black eyes," although in them "there are only a very few visual elements at the tips of the immobile eye-stalks," other parts of the body being otherwise as "stout as a man of iron." The antennae and mandibles have preserved the external characters and probably also the organization of the Brachyura of the Secondary epoch (Milne-Edwards and Bouvier, 1901). They agree with the true crabs in not having appendages (uropods) to the sixth segment of the pleon, the atrophy being complete in the Homolidae and Homolodromiidae, whereas in the Dromiidae and Dynomidae a pair of small plates appear to be vestiges of these organs. In the family Homolidae stands the strange genus Letcilleia, Roux, with long slender limbs and triangular carapace after the fashion of oxyrhynch spider-crabs. In Homola the carapace is quadriangular. Between these two a very interesting link was placed by the "Challenger" the species Heterolites, Milne-Edwards and Henderson. Bouvier (1896) has shown that Palaecuthus longipes, Woodward, from the Forest Marble of Wiltshire, is in close relation to the oxyrhynch crab, and is the link between Homolidae and Dierodromia of the Homolodromiidae, and that the Jurassic crabs in general, of the family Proosponitae (Meyer), are Dromiidae.

2. Macrura.—The Macrura anomala, or Anomura in restricted sense, are popularly known through the hermit-crabs alone. These only partially represent one of the three main divisions, Paguridea, Galatheidea, and Hippidea. The first of these is subdivided into Paguridae, Lophiidae, Lasmidae, etc., each with a literature of its own. Among the Paguridea is the Birgus labrus, or robber-crab, whose instinct in climbing the coco-nut palm need no longer be doubted, since in recent years it has been noted and photographed by trustworthy naturalists in the very act. Alcock observed one of these crabs drinking from a runnel of rain-water, by dipping the fingers of one of its chelipeds thus into the water and then thrusting them into the Hermit of the genus Corinobius he found feeding voraciously on nestling sea-terns. That pagurids must have the usually soft pleon or abdomen protected by the shell of a mollusc is now known to be subject to a multitude of exceptions. Birgus dispenses with a covering; Corinobius can make shift with half the shell of a coco-nut; Chiasutopagurus wraps itself up in a blanket of small colon crustaceans; Conclusilus inermis, Faxon, was found in a piece of cork; Xanopus trabulus, Faxon, in pipes of timber or bits of hollow reed. The last-named species has a straight antennal abdomen, with the penultimate segment expanded and strongly flattened; the antennules, by their additional habituation. This it enters head foremost from the rear, while "hermits" in general are forced to go backwards into their spiral or tapering shelters by the front. Some of the hermits live in the depth of the Alpheus, a species which can range inland up to a considerable height on mountains. The advantage that this group has derived from the adoption of mollusc...
shells as houses, or fortresses, ready built and light enough for easy transport, is obviously discounted by a twofold inconvenience. There is nothing to ensure that the supply will be equal to the demand, and Nature has not arranged that the borrowed tenement shall continue to grow with the growth of its new tenant. To meet these defects it is found that numerous species encourage or demand the companionship of various zoophytes, simple or colonial. These sometimes completely absorb the shell on which they are settled, but then act as a habitation. However, in any case by their outgrowth they extend the limits of the dwelling, so that the inmate can grow in comfort without having to hunt or fight for a larger abode. Among the Lillithoe, or stone crabs, besides important readjustments of classification (Bouvier, 1895, 1896), should be noticed the evidence of their cosmopolitan range, and the species Neolitacodes agassisi (Smith) and N. grimaldii, Milne-Edwards and Bouvier, which separate at extreme the spinyosity characteristic of the group (fig. 1). S. I. Smith's investigations on the early stages of Hippa talpoida, Say, were published in 1877. With regard to the accessions to knowledge in the enormous group of the genuine Macrura, reference need only be made to the extensive reports in which Spence Bate, S. I. Smith, Faxon, Wood-Mason, Alcock, and others have made known the results of celebrated explorations. Various larval stages have been successfully investigated by Sars. Alcock (1901) describes from his own observation the newly hatched Phyllosoma larva of Thenus orientalis, Fabricius. An admirable discrimination of the larval and adult characters of the genus Sympoda has been given by H. J. Hansen (Proc. Zool. Soc., London, 1896). Singularity excites our wonder in Thasosterechotes zaleucus, v. Willemsoe Suhm, which makes up for its vanished eyes by its extraordinarily elongate and dentated claws; in Pseudoplasma hastleri, Wood-Mason and Alcock (1892), bristling with spines from head to tail; in the Nematomidae, with their long thread-like limbs and longer antennae; in species of Aristaeas pasi reported by Chun from deep water off the east coast of Africa, bright red prawns nearly a foot long, with antennae about five times the length of the body. That certain species, particularly many from deep water, have disproportionately large eggs, is explained by the supposition that the young derive the advantage of being hatched in an advanced stage of development.

3. SCHIZOPODA.—This order of animals for the most part delicately beautiful, has for the moment five families—Lophogastridae, Euphausiidae, Euphausiaceae, Mysidae, and Anaspidae. In the Euphausiidae the didiform-armor branchiae, as if conscious of their own extreme elegance, remain wholly uncovered. In the two preceding families they are partially covered. In the Mysidae the branchiae are wanting, and some would form this family into a separate order, Myxosida. In Anaspidae, a peculiar fresh-water genus discovered in 1892 by G. M. Thomson on Mount Wellington, in Tasmania, the gills are not arboreal, and there are seven segments of the trunk free for the carapace (fig. 2). A membranous plate separates the Europidae from the more solidly invested Lophogastridae. Among many papers that the student will find it necessary to consult may be mentioned the "Challenger" Report on Schizopoda, by Sars, 1885, dealing with the order at large: “British Schizopoda,” by Norman Ann. Nat. Hist. (1892); “Decapoden and Schizopoden,” by Alcock, Proc. Zool. Soc. (London, 1893); “Euphausiaceae,” by Stebbing, Proc. Zool. Soc. (London, 1900); Mysidae of the Russian Empire, by Czerniavski (1828-1883), and Mysidae of the Caspian, by Sars (1893-1895-1897).

4. SYMPODA.—This order, at one time a medley of heterogeneous genera, is now confined to the singularly compact group of the Decapoda. In the families of decapods the abdomen is usually distinct, and here two characters quite foreign to all the preceding groups come into view. The second maxillipeds are developed into powerful prehensile organs, and the branchiae, instead of being connected with the appendages of head and trunk, are developed on the pleopods, appendages of the abdomen. At least three segments of the trunk are left uncovered by the carapace. The developing eggs are not carried about by the mother, but deposited in her subaqueous burrow, “where they are aerated by the currents of water produced by the abdominal feet of the parent.” An excellent synopsis of the genera and species is provided by R. P. Bigelow (Proc. U. S. Nat. Mus. vol. xvi., 1894). For the habits and peculiarities of these and many other Crustaceans, A. E. Verri and S. J. Smith on the Invertebrates of Vineyard Sound should be consulted (1874). The general subject has been illuminated by the labours of Claus, Miers, Brooks (“Challenger” Report, 1895), and the latest word on the relationship between the various larvae and their respective genera has been spoken by H. J. Hansen (Plankton-Expedition Results, 1880). The striking forms of Allodes, thus, at one time regarded as distinct genera, are now with more or less certainty affiliated to their several squill parents. The name Cumaex, however, which he uses cannot be retained, being founded on the preoccupied name Cuma (Milne-Edwards, as a whole in Sars, 1898). The name Cumaex, however, which he uses cannot be retained, being founded on the preoccupied name Cuma (Milne-Edwards, 1898), is now distinguished—Decapoda, Lampropoda, Phyllopoda, Pseudocampanalia, all with an anterior end separated from the posterior, and thus the monophyly of the name is asserted (see Willey, Results of the British N. Amanda (formerly called Camusea), Vaunthompsoniidae, Leconidae, Nannastacidae, Campylopidae, Procampylaspididae. All the Leconidae and Procampylaspidae are blind, and some species in most of the other families. Usually the sides of the carapace are strongly produced into a rostrum in front of the ocular lobe, be it occlus or not. The last four or five segments of the trunk are free from the carapace. The slender pleon has always six distinct segments, the sixth carrying two-branched uropods, the preceding five armed with no pleopods in the female, whereas in the male the number of pairs varies from five to none. The resemblance of these creatures to minute, Macrura is absolved to the generic name Nannastacus, the New Zealand dwarf-lobster. In this genus alone of the known Sympoda the eyes sometimes form a pair, in accordance with the custom of all other marine crustacea. The first segment of the abdomen, which is equivalent to the anteriormost end of the pleon in the embryo (Sars, 1899), is the most but not the only remarkable character lies in the first maxillipeds. These, with the main stem more or less pediflorum, have the epipod and exopod modified for respiratory purposes. The backward-directed exopods usually carry branchial vesicles. The forward-directed exopods either act as valves or form a tube (rarely two tubes), protostyle and retractile, for regulating egress of water from the branchial areas. In some species of Sympoda the first maxillipeds have a respiratory function also in the Lophogastridae and Mysidae and in the cheliferous isopods. As a rule armature of
the carapace is much more developed in the comparatively sedentary female than in the usually more active male. Only in the male do the second antennae attain considerable length, with strong resemblance to what is found in some of the Amphipoda. About 150 species distributed among thirty-four genera are now known, many from shallow water and from between tide-marks, some from very deep water, and even from hot springs. The carapace is typically broad, and yet no species has been taken under such conditions that it could be reckoned to the pelagic plankton. As they have been found in caves and even manholes and vaults by very few observers, it is probable that a great many more species remain to be discovered. In recent years thirteen species, all belonging to the same genus Pseudosoma (fig. 3), have been recorded by Sars from the Carnatic Sea. A bibliography of this order is given in that author’s *Crustacea of Norway*, vol. iii. (1899-1900).

6. **Isopoda**.—This vast and populous order can be traced back in geological time. It is now represented in all seas and lands, in fresh-water lakes and streams, and even in warm springs. It adapts itself to parasitic life not only in fishes, but in its own class Crustacea, and that in species of every order, its own included. In this process changes of structure are apt to occur, and sometimes unimaginable sacrifices of the normal appearance. The order has been divided into seven tribes, of which a fuller summary than can here be given will be found in Stebbing, *History of Crustacea* (1893). The first tribe, called Cheliferia, from the usually chelate or claw-bearing first limbs, may be regarded as Isopoda anomala of some authors would form a separate order, Tanaidea. Like the genuine Isopoda, they have seven pairs of trunk-legs, but instead of having seven segments of the middle body (or peraeon).

![Fig. 4.—Rhabdosoma piratum, Stebbing.](image)

normally free, they have the first one or two of its segments coalesced with the head. Instead of the breathing organs being furnished by the appendages of the pleoth with the heart in their vicinity, the respiration is controlled by the mandibles and the peraeon (see Delage, *Arch. Zool. expir. et gén.*, vol. ix., 1881). There are two families, Tanaidae and Apephilidae. Occasionally the ocular lobes are well developed.

The genuine Isopoda are divided among the Flabellifera, in which the terminal segment and uropods form a flabellum or swimming fan; the Epicaridae, parasitic on Crustacea; the Valesirea, in which the uropods fold valve-like, and in which the first pair of pleopods of the female are usually transformed into a single opercular plate; the Pheucticidae, a fresh-water tribe, known as yet only from subtropical New Zealand, and an Australian swamp near 6000 ft. above sea-level; and lastly, the Oniscidea, which are terrestrial. Only the last of these, under the contemptuous designation of wood-lice, has established a fecile claim to popular recognition. Few persons hear without surprise that England itself possesses more than a score of species in this air-breathing tribe. Those known from the world at large number hundreds of species, distributed among dozens of genera in six families. That is to say, and a land crab is alike Malacostraca, and that they have by different paths alike become adapted to terrestrial life, are facts which even a philosopher might descend to note. Of the other tribes which are aquatic there is not space to give even the barest outline. Their swarming multitudes are of enormous importance in the economy of the sea. If in their relation to depth it must be admitted that many of them plague the living and destroy fish food in great numbers, and cause some other species to disperse, they are one of the deep-sea Cirripedae, Bathymomus giganteus, A. M. Edwards (1879), which is unique in having supplementary ramified branchiae developed at the bases of the pleopods. Its eyes are said to contain nearly 4000 facets. The animal attains what in this order is the monstrous size of 9 in. by 4. A general uniformity of the tribe is that Isopoda justifies the ordinal name, but the valviferous Astacilidae, and among the Asellota the Munidopidae, offer some remarkable exceptions to this characteristic. Among many essential works on this group may be named the *Monogr. Cymotheoruma* of Schlötter and Meinert (1879-1893); *Challenger* Reports, vol. xxi., supplementary report (T. J. Ellis, Valiella in *Bull.* Zool. Nomencl., 1892) of his work, however, not covering the Hyperidea and Oxycephalidae of Boeckelius (1889, 1890); but since these dates very numerous additions have been made to the literature of the order, by Bonnier, Harger, Hassell, Kossmann, Miers, M’Murrich, Norman, Harriet Richardson, Ohlin, Studer, G. M. Thomson, A. O. Walker, and others.

7. **Amphipoda**.—As in the genuine Isopoda, the eyes of Amphipoda are always sessile, and generally paired, and, in contrast to crabs and lobsters, these two groups have only four pairs of mouth- or branchial maxillae. Of the six, but out of all others, the last pair, or pleopods, have been developed into limbs which are large, and extend from the body to the tail. The eyes are always more than three. The order thus sharply divided is united by an intimate interfacing of characters, and forms a compact whole at which no other phylogeny of the crustaceans can be fitted. Since 1775, when J. C. Fabricius instituted the genus Gammarus for five species, of which only three were amphipods, while he left five other amphipods in the genus *Oniscus*, from this total of eight species, Bequaert has developed to order, all of them great leaps and bounds, so that now the *Gammaridae* alone comprise more than 1500 species, distributed among some 300 genera and 39 families. They burrow in the sands of every shore; they throng the weeds between tide-marks; they ascend all streams to be found in deep wells, in caverns, in lakes; in Arctic waters they swarm in numbers beyond computation; they find lodgings on crabs, on tuna, on wood-grown rocks, sometimes in great numbers. And on the mountain streams as far above sea-level as some of their congeners live below it. The Talitridae, better known as sandhoppers, can forgo the briny shade and content themselves with the damp foliages of inland forests or casual humidity in the crater of an extinct volcano. Over the ocean surface, as well as at various depths, float and swim innumerable Hyperidea—the wonderful *Phronima*, glass-like in its glassy barrel hollowed out of some Tunicate; the *Cyttisoma*, 4 or 5 in. long, with its eye-covered head; the *Rhabdosoma*, like a thin rod of glass, with needle-like head and tail, large eyes, but limbs and mouth parts of no importance; or else as minute as the ordinary *Ceratiola gigas*, which are only the *intestines* of jelly-fishes, and the *Phronima*, which are the *intestines* of jelly-fishes. For the benthonic tribes, the Hyperidea are extremely voracious. Some of them are even cannibals. The Cambria afflicts the giant whale by nibbling away its wings, as *Chelura longirostris*, or *Birula*, or *Studor*, or *Cordona*, or *Caprella*, or *Sars*, all males. But, on the other hand, they largely help to clear the sea and other waters of refuse and carrion, and for fishes, seals and whales they are food desirable and often astoundingly copious. From the little fishes like species, scarcely a tenth of an inch long, up to the great and rare but cosmopolitan *Eurythoe* *gryllus*, Lichtenstein, and the still larger *Alcicle gigantea*, Chevreux, nearly half a foot long, captured on the ship of Prince of Monaco from a depth of 2396 fathoms, not one of these ubiquitous, uncountable borders has ever been accused of assailing man. For the naturalist they have the recommendation that many are easy to obtain, that most, apart from the very minute, are unoffensive, and that all, except as to the fleeting colours, are easy to preserve.

A nearly complete bibliography of the order down to 1888 will be found in the "Challenger" Reports, vol. xxi., and supplementary report (H. J. Hansen concludes that they are all as males and then as females. Of late discovered species the most striking is one of the deep-sea Cirripedae, Bathymomus giganteus, A. M. Edwards (1879), which is unique in having supplementary ramified branchiae developed at the bases of the pleopods. Its eyes are said to contain nearly 4000 facets. The animal attains what in this order is the monstrous size of 9 in. by 4. A general uniformity of the tribe is that Isopoda justifies the ordinal name, but the valviferous Astacilidae, and among the Asellota the Munidopidae, offer some remarkable exceptions to this characteristic. Among many essential works on this group may be named the *Monogr. Cymotheoruma* of Schlötter and Meinert (1879-1893); *Challenger* Reports, vol. xxi., supplementary report (T. J. Ellis, Valiella in *Bull.* Zool. Nomencl., 1892) of his work, however, not covering the Hyperidea and Oxycephalidae of Boeckelius (1889, 1890); but since these dates very numerous additions have been made to the literature of the order, by Bonnier, Harger, Hassell, Kossmann, Miers, M’Murrich, Norman, Harriet Richardson, Ohlin, Studer, G. M. Thomson, A. O. Walker, and others.

**MALAGA**

A maritime province of southern Spain, one of the eight modern subdivisions of Andalusia; bounded on the W. by Cadiz, N. by Seville and Cordova, E. by Granada, and S. by the Mediterranean Sea. *Pop.* (1900), 517,985; *area*, 2812 sq. m. The northern half of Malaga belongs to the great
Andalusian plain watered by the Guadalquivir, the southern is mountainous, and rises steeply from the coast. Of the numerous sierras may be mentioned that of Ahílama, separating the provinces of 7000 ft.; its westward continuation in the Sierra de Abadalajis and the Axarquia between Antequera and Malaga; and not far from the Cadiz boundary the Sierras de Ronda, de Mijas, de Tolox and Bermeja, converging and culminating in a summit of nearly 6500 ft. The rivers which rise in the watershed formed by all these ranges reach the sea after a short and precipitous descent, and in rainy seasons are very liable to overflow their banks. In 1907 great loss of life and destruction of property were caused in this manner. The principal river is the Guadalquivir, which rises in the Sierra de Ahílama, and, after a westerly course past the vicinity of Antequera, bends southward through the wild defile of Pejasrra and the beautiful rega or vale of Malaga, falling into the sea near that city. The only other considerable stream is the Guadialo, which has the greater part of its course within the province and flows past Ronda. There is an extensive salt lagoon near the northern boundary. The mountains are rich in minerals, lead, and (in the neighbourhood of Marbella) iron, being obtained in large quantities. There are warm sulphurous springs and baths at Ardales. Though the methods of agriculture are for the most part rude, the yield of wheat in good seasons is considerably in excess of the local demand; and large quantities of grapes and raisins, oranges and lemons, figs and almonds, are annually exported. The oil and wines of Malaga are also highly esteemed, and after 1870 the manufacture of beet and cane sugar developed into an important industry. In 1905 there were about 500 flour mills and 230 oil factories beside 95 stands and 100 wine-presses in the province. Malaga has suffered severely from the agricultural depression prevalent throughout southern Spain, but its manufacturing industries tend to expand. The fisheries are important; a fleet of about 300 boats brings in 18,000,000 lb annually, of which 25% is exported. The internal communications are in many parts defective, owing to the broken nature of the surface; but the province is traversed from north to south by the Cordova-Malaga railway, which sends off branches from Bobadilla to Granada and Algeciras. A branch line along the coast from Malaga to Vélez Malaga was opened in 1908.

Malaga, the capital (pop. 130,109), Antequera (51,609), Vélez Malaga (23,586), Ronda (20,605), Coín (12,326), and Aloña (10,325), are separate towns. Other towns with more than 7000 inhabitants are Marbella (6029), Estepona (9310), Archidona (8003), and Alhama de Granada (7112). The population tends to gradually decrease, as many families emigrate to South America, Algeria and Hawaii.

MALAGA, the capital of the province of Malaga, an episcopal see, and, next to Barcelona, the most important seaport of Spain, finely situated on the Mediterranean coast, at the southern base of the Axarquia hills and at the eastern extremity of the fertile rega (plain) of Malaga in 36° 14' N. and 4° 29' W. Pop. (1900) 136,109. From the clearness of its sky, and the beautiful sweep of its bay, Malaga has sometimes been compared with Naples. The climate is one of the mildest and most equable in Europe, the mean annual temperature being 66° to 70° Fahr. The principal railway inland gives access through Bobadilla to all parts of Spain, and a branch line along the coast to Vélez-Malaga was opened in 1908. Malaga lies principally on the left bank of a mountain torrent, the Guadalmedina ("river of the city "); the streets near the sea are spacious and comparatively modern, but those in the older part of the town, where the buildings are huddled around the ancient citadel, are narrow, wind ing and often dilapidated. Well-built suburbs have also spread on all sides into the rich and pleasant country which surrounds Malaga, and several acres of land reclaimed from the sea have been converted into a public park. There are various squares or plazas and public promenades; of the former the most important are the Plaza de Riego (containing the monument to General José María Torrijos, who, with forty-eight others, was executed in Malaga on the 11th of December 1831, for promoting an insurrection in favour of the constitution) and the Plaza de la Constitucion; adjoin the quays is the fine Pasco de la Alameda. The city has no public buildings of commanding architectural or historical importance. The cathedral, on the site of an ancient mosque, was begun about 1538; after it was almost twice interrupted, it was completed to its present state in the 18th century, and is in consequence an obtrusive record of the degeneration of Spanish architecture. The woodwork of the choir, however, is worthy of attention. The church of El Cristo de la Victoria contains some relics of the siege of 1487. There are an English church and an English cemetery, which dates from 1890; up to that year all Protestants who died in Malaga were buried on the foreshore, where their bodies were frequently exposed to the action of wind and sea. Of the old Moorish arsenal only a single horse-shoe gateway remains, but the rest of the site being chiefly occupied by an iron structure used as a market; the Alcazaba, or citadel, has almost disappeared. The castle of Gibralfaro, on a bold eminence to the north-east dates from the 13th century, and is still in fairly good preservation.

During the 10th century so much salt accumulated in the harbour that vessels were obliged to lie in the roads outside, and receive and discharge cargo by means of lighters; but new harbour works were undertaken in 1830, and large ships can now again load or discharge at the quays, which are connected with the main railway system by a branch line. About 2150 ships of 1,750,000 tons enter at Malaga every year. Iron, lead, wine, olive oil, almonds, fresh and dried fruit, palmetto hats and canary seed are exported in large quantities, while the imports include grain, codfish, fuel, chemicals, iron and steel, machinery, manufactures and staves for casks. Although trade was impeded during the early years of the 20th century by a succession of bad harvests and by the disastrous floods of September 1907, the number of industries carried on in the province of Malaga tends steadily to increase. There are large cotton mills, iron foundries, smelting works and engineering works. Pottery, mosaic, artificial stone and tiles are produced chiefly for the home market, though smaller quantities are sent abroad. There is a chromo-lithographic establishment, and the other industries include tanning, distilling and the manufacture of sugar, chocolate, soap, candles, artificial ice, chemical products, white lead and pianos. Foreign capital has played a prominent part in the development of Malaga; a French syndicate owns the gas-works, and the electric lighting of the streets is controlled by British and German companies.

Malaga is the MAlaga of Strabo (iii. 156) and Ptolemy (ii. 4, 7) and the Malaco foederatorum of Pliny (iii. 3). The place seems to have been of some importance even during the Carthaginian period; under the Romans it became a municipium, and under the Visigoths an episcopal see. In 711 it passed into the possession of the Moors, and soon came to be regarded as one of the most important cities of Andalusia. It was attached to the caliphate of Cordova, but on the fall of the Omayyad dynasty it became for a short time the capital of an independent kingdom; afterwards it was dependent on Granada. In 1487 it was taken and treated with great harshness by Ferdinand and Isabella after a protracted siege. In 1580 it was sacked by the French under General Sebastiani. The citizens of Malaga are noted for their opposition to the Madrid government; they took a prominent part in the movements against Espartero (1843), against Queen Isabella (1868) and in favour of a republic (1873).

MALAKAND PASS, a mountain pass in the North-West Province of India, connecting the British district of Peshawar with the Swai Valley. It is now a military post and the headquarters of a political agency. It came into prominence for the first time in 1805 during the Chitral campaign, when 7000 Pathans held it against Sir Robert Low's advance, but were easily routed. After the campaign was over a fortified camp was formed on the Malakand to guard the road to Chitral. During the frontier risings of 1897 the Swatis made a determined attack on the Malakand, where 7000 were killed, and on the adjacent post of Chakdara, where 2000 were killed. This was the origin of the Malakand Expedition of the same year. (See SWAT.)
MALALAS—MALARIA

MALALAS (or MALELAS) (Syriac for “orator”), JOHN (c. 491-578), Byzantine chronicler, was born at Antioch. He wrote a Χρονομερία in 18 books, the beginning and the end of which are lost. In its present state it begins with the mythical history of Egypt and ends with the expedition to Africa under Marcianus, the nephew of Justinian. Except for the history of Justinian and his immediate predecessors, it possesses little historical value; it is written without any idea of proportion and contains astonishing blunders. The writer is a supporter of Church and State, an upholder of monarchical principles. The work is rather a chronicicle written round Antioch, which he regarded as the centre of the world, and (in the later books) round Constantinople. It is, however, important as the first specimen of a chronicicle written not for the learned but for the instruction of the monks and the common people, in the language of the vulgar, with an admixture of Latin and Oriental words. It obtained great popularity, and was conscientiously exploited by various writers until the 11th century, being translated even into the Slavonic languages. It is preserved in an abridged form in a single MS. now at Oxford.

For the authorities consulted by Malalas, the influence of his work on Slavonic and Oriental literature, the state of the text, the original form and extent of the work, the date of its composition, the facts relating to the period and the region of the subject, see C. Krummacher's Geschichte der byzantinischen Literatur (1897). See also the edition princeps, by E. Chilmead (Oxford, 1691), containing an essay by Humphrey Hody and Bentley's well-known letter to Mill; other editions in the Boreae literaria, Malan.

MALAN, SOLOMON CAESAR (1812-1894), British divine and orientalist, was by birth a Swiss descended from an exiled French family, and was born at Geneva on the 22nd of April 1812, where his father, Dr Henry Abraham Caesar Malan (1787-1864) enjoyed a great reputation as a Protestant divine. From his earliest youth he manifested a remarkable faculty for the study of languages, and when he came to Scotland as tutor in the marquis of Tweeddale's family at the age of 18 he had already made progress in Sanskrit, Arabic and Hebrew. In 1833 he matriculated at St Edmund Hall, Oxford; and English being almost an unknown tongue to him, he petitioned the examiners to allow him to do his paper work of the examination in French, German, Spanish, Italian, Latin or Greek, rather than in English. But his request was not granted. After gaining the Boden and the Pusey and Ellerton scholarships, he graduated 2nd class in Lit. hum. in 1837. He then proceeded to India as classical lecturer at Bishop's College, Calcutta, to which post he added the duties of secretary to the Bengal branch of the Royal Asiatic Society; and although compelled by illness to return in 1840, laid the foundation of a knowledge of Tibetan and Chinese. After serving various curacies, he was presented in 1843 to the living of Broadwindsor, Dorset, which he held until 1866. During this entire period he continued to augment his linguistic knowledge, which he carried so far as to be able to preach in that most difficult language, Georgian, on a visit which he paid to Tiflis in 1872. His translations from the Armenian, Georgian and Coptic were numerous. He applied his Chinese learning to the determination of important points connected with Chinese religion, and published a vast number of parallel passages illustrative of the Book of Proverbs. In 1880 the university of Edinburgh conferred upon him the honorary degree of D.D. No modern scholar, perhaps, has so nearly approached the linguistic omniscience of Mezzofanti; but, like Mezzofanti, Dr Malan was more of a linguist than a critic. He made himself conspicuous by the vehemence of his opposition to Westcott and Hort, to the criticism of the Testament of Pontius, and to the transliteration of Oriental languages, on neither of which points did he in general obtain the suffrages of scholars. His extensive and valuable library, some special collections excepted, was presented by him in his lifetime to the Indian Institute at Oxford. He died at Bournemouth on the 25th of November 1894. His life has been written by his son.

MÅLAR, a lake of Sweden, extending 73 m. westward from Stockholm, which lies at its junction with the Saltsjö, an arm of the Baltic Sea. The height of the lakes is normally only from 11 ft. to 2 ft. above sea-level, and its outflow is sometimes reversed. The area is 449 sq. m. The bottom consists of a series of basins separate by ridges from which rise numerous islands. The deepest sounding is 210 ft. The outline is very irregular, the mean breadth being about 17 m., but an arm extends northward for 30 m. nearly to the city of Upsala with many small islands. The area of the drainage basin is 878 sq. m., of which 1124 are occupied by lakes. The navigable connexion with the lake are—(1) with lake Hjelmor to the south-west by the Arboga river and the Hjelmor canal; and by the Eskilstuna river and the Thörshälla canal; (2) with the Baltic southward through the Södertelge canal, the route followed by the Götta canal steamers; (3) with the Baltic by two channels at Stockholm. The more important towns, besides Stockholm, are Vesterå on the north, Södertelge and Eskilstuna on the south shore. The lake offers a field for recreation fully appreciated by the inhabitants of the capital, and many of those whose business lies at Stockholm have their residences on the shores of Målar. On Drottningholm (Queen's Island, named from Catherine, wife of John III.) is a palace with a fine park and formal gardens. John III. built a palace at the close of the 16th century, but the existing building, by Nicodemus Tessin and his son Nicodemus, dates from the second half of the 17th century. At Marielund on the south shore there is the castle of Gripsholm (1537), built by Gustavus Vasa, a picturesque erection with four towers, richly adorned within, and containing a large collection of portraits. Strengnäs, on the same shore, became an episcopal see in 1201, when the fine cathedral, much altered since, was consecrated. In the episcopal palace, a building of the 15th century now used as a school, Gustavus Vasa was elected to the throne of Sweden in 1523. On the northward arm of the lake is the palace of Rosenborg, used as a school of gunnery, in a well-wooded park. On a branch of the same arm is Sigtuna, a village whose ruined churches are a memorial of its rank among the principal towns of Sweden after its foundation in the 11th century. Remains prove that on Björkön, an island in the eastern part of the lake, there was a large settlement of earlier importance than Sigtuna. Here a cross commemorates the preaching of Christianity by St Ansgar in 829. Finally, on the northern arm about 10 m. south of Upsala, there is the château of Skokloster, occupying the site of a monastery, and presented by Gustavus Adolphus to Marshal Herman Wrangel, whose son Charles Gustavus Wrangel stored it with a remarkable collection of trophies from Germany, taken during the Thirty Years' War; forming a library, an armoury, and a great accumulation of curios.

MALARIA, an Italian colloquial word (from mala, bad, and aria, air), introduced into English medical literature by Macculloch (1827) as a substitute for the more restricted terms "marsh miasm" or "paludal poison." It is generally applied to the definite unhealthy condition of body known by a variety of names, such asague, intermittent (and remittent) fever, marsh fever, jungle fever, hill fever, "fever of the country" and "fever and ague." A single paroxysm of simple ague may come upon a person in the midst of healthy air, but it is followed by some malarial. The ague-fever begins with chills proceeding as if from the lower part of the back, and gradually extending until the coldness overtake the whole body. Tremors of the muscles more or less violent accompany the cold sensations, beginning with the muscles of the lower jaw (shattering of the teeth), and extending to the extremities and trunk. The expression has meanwhile changed: the face is pale or livid; there are dark rings under the eyes; the features are pinched and sharp, and the whole skin shrunken; the fingers are dead white, the nails blue.

All those symptoms are referable to spasmatic constriction of the small surface arteries, the pulse at the wrist being itself small, hard and quick. In the interior organs there are indications of a compensating accumulation of blood, such as swelling of the spleen, engorgement (very rarely rupture) of the heart,
MALARIA

with a feeling of oppression in the chest, and a copious flow of
clear and watery urine from the congested kidneys. The body-
temperature will have risen suddenly from the normal to 102° or
higher.

The first period of the paroxysm varies much in
length; in temperate climates it lasts from one to two
hours, while in tropical and subéropical countries it may be shortened.
It is followed by the stage of dry heat, which will be prolonged in
proportion as the previous stage is curtailed. The feeling of
heat is at first an internal one, but it spreads outwards to the
surface and to the extremities; the skin becomes warm and red,
but remains dry; the pulse becomes softer and more full, but
still quick; and the throbbings occur in exposed arteries, such as
the temporal. The spleen continues to enlarge; the urine is now
scanty and high-coloured; the body temperature is high, but the
highest temperatures occur during the chill; there is consider-
able thirst; and there is the usual intellectual unfitness, and it
may be confusion, of the feverish state. This period of dry heat,
having lasted three or four hours or longer, comes to an end in
perspiration, at first a mere moistness of the skin, passing into
sweating that may be profuse and even drenching. Sleep may
overtake the patient in the midst of the sweating stage, and he
awakes, not without some feeling of what he has passed through,
but on the whole well, with the temperature fallen almost or
altogether to the normal, or it may be even below the normal;
the pulse moderate and full; the spleen again of its ordinary size;
the urine that is passed after the paroxysm deposits a thick
brick-red sediment of urates. The three stages together will
probably have lasted six to twelve hours. The paroxysm is
followed by a definite interval in which there is not only no
fever, but even a fair degree of bodily comfort and fitness; this
is the intermission of the fever. Another paroxysm begins at
or near the same hour next day (quotidian ague), which results
from a double tertian infection, the interval may be forty-
eight hours (tertian ague), or seventy-two hours (quartan
ague). It is the general rule, with frequent exceptions, that the
quotidian paroxysm comes on in the morning, the tertian about
noon, and the quartan in the afternoon. Another rule is that
the quartan has the longest cold stage, while its paroxysm is
shortest as a whole; the quotidian has the shortest cold stage and
a long hot stage, while its paroxysm is longest as a whole. The
point common to the various forms of ague is that the
paroxysm ceases about midnight of early morning, and the
intermittent, on the whole more common than tertian in
hot countries; elsewhere the tertian is the usual type, and
quartan is only occasional.

If the first paroxysm should not cease within the twenty-four
hours, the fever is not reckoned as an intermittent, but as a
remittent.

Remittent is a not unusual form of the malarial process in tropical
and subéropical countries, and in some localities or in some seasons
it is more common than intermittent. It may be said to arise out
of that type of intermittent in which the cold stage is shortened while
the hot stage tends to be prolonged. A certain abatement or
remission of the fever takes place, with or without sweating, but
there is no true intermission or interval of absolute apyrexia.

The periodicity shows itself in the form of an exacerbation of the still
continuing fever, and that exacerbation may take place twentyour hours after the first onset, or the interval may be only half
that period, or it may be double. A fever that is to be remittent will
be very dangerous, as it may come on from the ordinary tertian
by the shivering and shaking fit of the intermittent; the hot
stage soon follows, presenting the same characters as the prolonged
hot stage of the quotidian, with the frequent addition of billious
symptoms, and it may be even of jaundice and of tenderness over
the stomach and liver. Towards morning the fever abates; the
pulse falls in frequency, but does not come down to the normal;
however the face becomes rather pale, and the urine may
come out without much difficulty. The remission does not cease
altogether; the body temperature falls, but does not touch the
level of apyrexia. The remission or abatement lasts generally
throughout the morning; and about noon there is an exacerbation,
suddenly resulting in a chill, which lasts till the evening of the
following, when it remits or abates as before. A patient with
remittent may get well in a week under treatment, but the fever
may recur several times; the return to health is often announced
by the fever assuming the intermittent form, in others by the
remissions touching the level of absolute apyrexia. Remittent
fevers (as well as intermitents) vary considerably in intensity;
some cases are intense from the outset, or pernicious, with aggrava-
tion of all the symptoms leading to stupor, delirium, collapse,
tense jaundice, blood in the stools, blood and albumen in the
urine, and it may be, suppression of urine followed by convulsions.
The severe forms of intermittent are most apt to occur in the very
young, or in the aged, or in the extremely weak. In these cases of malarial fever are apt to become dangerous from the complications of dysentery, bronchitis or pneumonia. Severe remittents (pernicious or bilious remittents) approximate to the yellow fever (q.v.), which is conventionally limited to epi-
demic outbursts in western longitudes and on the west coast of
Africa.

Of the mortality due to malarial disease a small part
only is referable to the direct attack of intermittent, and chiefly
to the fever in its pernicious form. Remittent fever is much
rarer than intermittent, and is a much less dangerous attack. But probably the greater part of the enormous total of deaths so connected to malarial disease is due to the malarial cachexia. The dwellers in a malarious
region like the Tera (at the foot of the Himalayas) are miserable,
listless and ugly, with large heads and particularly prominent
ears, flat noses, tumid bellies, slender limbs and sallow com-
plexions; the children are impregnated with malaria from
their birth, and their growth is attended with aberrations from
the normal which practically amount to the disease of
rickets. The malarial cachexia that follows definite attacks
of fever, for example those which consists in a state of ill-defined suffering, associated with a sallow skin, enlarged spleen and liver, and sometimes
with dropsy.

Causation.—From the time of Hippocrates onwards the
malarial or periodical fevers have engaged the attention of
innumerable observers, who have suggested various theories
of causation, and have sometimes anticipated—vaguely,
indeed, but with surprising accuracy—the results of modern
research; but the true nature of the disease remained in doubt
until the closing years of the 19th century. It has now been
demonstrated by means of a series of accurate investigations, contributed
by many workers, that malaria is caused by a microscopic
parasite in the blood, into which it is introduced by the bites
of certain species of mosquito. (See Parasitic Diseases and
Mosquitoes.)

The successive steps by which the present position has been
reached form an interesting chapter in the history of scientific
progress. The first substantial link in the actual
chain of discovery was contributed in 1866 by the French
Department of Statistics of the Health of the Seine.

On the 6th of November in that year he plainly saw the living
parasites under the microscope in the blood of a malarial patient,
and he shortly afterwards communicated his observations to the
Paris Académie de Médecine. They were confirmed, but met with
little acceptance in the scientific world, which was preoccupied
with the claims of a subsequently discredited Bacillus malariarum.

In 1885 the Italian pathologists came round to Laveran's views,
and began to work out the life history of his parasites. The
subject has a special interest for Italy, which is devastated
by malaria, and Italian science has contributed materially to
the solution of the problem. The labours of Golgi, Marchiafava,
Celli and others established the nature of the parasite and its
behaviour in the blood; they proved the fact, guessed by
Rasori so far back as 1846, that the periodical febrile paroxysm
corresponds with the development of the organisms; and they
showed that the different forms of malarial fever have their
distinct parasites, and consequently fall into distinct groups,
defined on an etiological as well as a clinical basis—namely,
the mild or spring group, which includes tertian and quartan
parasites; the tertian or "asexual-summer" group, which
includes a tertian or a semi-tertian and the true quotidian
type. Three distinct parasites, corresponding with the tertian,
quartan and malignant types of fever, have been described
by Italian observers, and the classification is generally accepted;
intermediate types are ascribed to mixed and multiple infections.
So far, however, only half the problem, and from the practical
point of view the less important half, had been solved. The
origin of the parasite and its mode of introduction into
the blood remained to be discovered. An old popular belief
prevailed in different countries, and derived from common
MALARIA

observation, connected mosquitoes with malaria, and from time to time this theory found support in more scientific quarters on general grounds, but it lacked demonstration and attracted little attention. In 1804, however, Sir Patrick Manson, arguing with reference to analogy from his own discovery of the cause of filariasis and the part played by mosquitoes, suggested that the malarial parasite had a similar intermediate host outside the human body, and that a suctorial insect, which would probably be found to be a particular mosquito, was required for its development. Following up this line of investigation, Major Ronald Ross in 1805 found that if a mosquito sucked blood containing the parasites they soon began to throw out flagellae, which broke away and became free; and in 1807, discovered peculiar pigmented cells, which afterwards turned out to be the parasites of aestivo-autumnal malaria in an early stage of development, within the stomach-wall of mosquitoes which had been fed on malarial blood. He further found that only mosquitoes of the genus Anopheles had these cells, and that they did not get them when fed on healthy blood. Then, turning his attention to the malaria of birds, he worked out the life-history of these cells within the body of the mosquito. "He saw that they increased in size, divided, and became full of siltiform spores, then ruptured and poured out their multitudinous progeny into the cavity of their insect host. Finally, he saw the spores accumulate within the cells of the salivary glands, and discovered that they actually passed down the salivary ducts and along the grooved hypopharynx into the seat of puncture, thus causing infection in a fresh vertebrate host" (Sambon). To apply these discoveries to the malaria of man was an obvious step. In working out the details the Italian school have again taken a prominent part.

Thus we get a complete scientific demonstration of the causation of malaria in three stages: (1) the discovery of the parasite by Laveran; (2) its life-history in the human host and connection with the fever demonstrated by the Italian observers; (3) its life-history in the alternate host, and the identification of the latter with a particular species of mosquito by Ross and Manson. The conclusions derived from the microscopical laboratory were confirmed by actual experiment. In 1808 it was conclusively shown in Italy that if a mosquito of the Anopheles variety bites a person suffering from malaria, and is kept long enough for the parasite to develop in the salivary glands of the mosquito, and is then allowed to bite the person, the latter will in due time develop malaria. The converse proposition, that persons efficiently protected from mosquito bites escape malaria, has been made the subject of several remarkable experiments. One of the most interesting was carried out in 1890 for the London School of Tropical Medicine by Dr Sambon and Dr Low, who went to reside in one of the most malarious districts in the Roman Campagna during the most dangerous season. Together with Signor Terzi and two Italian servants, they lived from the beginning of July until the 19th of October in a specially protected hut, erected near Ostia. The sole precaution taken was to confine themselves between sunset and sunrise to their mosquito-proof dwelling. All escaped malaria, which was rife in the immediate neighbourhood. Mosquitoes caught by the experimenters, and sent to London, produced malaria in persons who submitted themselves to the bites of these insects at the London School of Tropical Medicine. Experiments in protection on a larger scale, and under more ordinary conditions, have been carried out with equal success by Professor Celli and other Italian authorities. The first of these was in 1809, and the subjects were the railwaymen employed on certain lines running through highly malarious districts. Of 24 protected persons, all escaped but four, and these had to be out at night or otherwise neglected precautions; of 38 unprotected persons, all contracted malaria except two, who had apparently acquired immunity. In 1800 further experiments gave still better results. Of 52 protected persons on one line, all escaped except two, who were careless; of 52 protected on another line, all escaped; while of 51 unprotected persons, living in alternate houses, all suffered except seven. Out of a total of 207 persons protected in these railway experiments, 197 escaped. In two peasants' cottages in the Campagna, protected with wire netting by Professor Celli, all the inmates—10 in number—escaped, while the neighbours suffered severely; and three out of four persons living in a third hut, from which protection was removed owing to the indifference of the inmates, contracted malaria. In the malarious islet of Asinara a pond of stagnant water was treated with petroleum and all windows were protected with gauze. The result was that the houses were free from mosquitoes and no malaria occurred throughout the entire season, though there had been 40 cases in the previous year. Eight Red Cross ambulances, each with a doctor and attendant, were sent into the most malarious parts of the Campagna in 1700. By living in protected houses and wearing gloves and veils at night all the staff escaped malaria except one or two attendants. These and other experiments, described by Dr Manson in the Practitioner for March 1900, confirming the laboratory evidence as they do, leave no doubt whatever of the correctness of the mosquito-parasitic theory of malaria.

It is possible, though not probable, that malaria may also be contracted in some other way than by mosquito bite, but there are no well-authenticated facts which require any other theory for their explanation. The alleged occurrence of the disease in localities free from mosquitoes or without their agency is not well attested; its absence from other localities where they abound is accounted for by their being of an innocent species, or—as in England—free from the parasite. The old theory of paludism or of a noxious miasma exhaled from the ground is no longer necessary. The broad facts on which it is based are sufficiently accounted for by the habits of mosquitoes. For instance, the swampy character of malarial areas is explained by the breeding of mosquitoes in stagnant water; the miasma is no longer required to explain the disease; and the general immunity of high-lying, dry localities, by the lack of breeding facilities; the danger of the night air, by their nocturnal habits; the comparative immunity of the upper storeys of houses, by the fact that they fly low; the confinement of malaria to well-marked areas and the diminution of danger with distance, by their habit of clinging to the breeding-grounds and not flying far. Similarly, the subsidence of malaria during cold weather and its seasonal prevalence find an adequate explanation in the conditions governing insect life. At the same time it should be remembered that many points await elucidation, and it is unwise to assume conclusions in advance of the evidence.

With regard to the parasites, which are the actual cause of malaria in man, an account of them is given under the heading of PARASITIC DISEASES, and little need be said about them here. They belong to the group of Protozoa, and, as already explained, have a double cycle of existence: (1) a sexual cycle in the body of the mosquito, (2) an asexual cycle in the blood of human beings. They occupy and destroy the red corpuscles, converting the haemoglobin into melanin; they multiply in the blood by sporulation, and produce accessions of fever by the liberation of a toxin at the time of sporulation (Ross). The number in the blood in an acute attack is reckoned by Ross to be not less than 250 millions. A more general and practical interest attaches to the insects which act as their intermediate hosts. These mosquitoes or gnatsthe terms are synonymous—belong to the family Culeidae and the genus Anopheles, which was first classified by Meigen in 1818. Anopheles has a wide geographical distribution being found in Europe (including England), Asia Minor, Burma, Straits Settlements, Java, China, Formosa, Egypt; west, south and Central Africa; Australia, South America, West Indies, United States and Canada, but is generally confined to local centres in those countries. About fifty species are recognized at present. It is believed that all of them may serve as hosts of the parasite. The species best known in connexion with malaria are A. maculipennis (Europe and America), A. funestus
MALARIA

and A. casta1es (Africa). In colour Anopheles is usually brownish or slaty, but sometimes buff, and the thorax frequently has a dark stripe on each side. The wings in nearly all species have a dappled or speckled appearance, owing to the occurrence of blotches on the front margin and to the arrangement of the scales covering the veins in alternating light and dark patches (Austen). The genus with which Anopheles is most likely to be confounded is Culex, which is the commonest of all mosquitoes, has a world-wide distribution, and is generally a greedy blood-sucker. A distinctive feature is the position assumed in resting; Culex has a humped-backed attitude, while in Anopheles the proboscis, head and body are in a straight line, and in many species inclined at an angle to the wall, the tail sticking outwards. In the female of Culex the palpi are much shorter than the proboscis; in Anopheles they are of the same length. The wings in Culex do not have the same dappled appearance. Anopheles is also a more slender insect, with a smaller head, narrower body and thinner legs. There are further differences in the other stages of life. Mosquitoes go through four phases: (1) ovum, (2) larva, (3) nympha, (4) complete insect. The ova of Anopheles are tiny black rod-shaped objects, which are deposited on the water of natural puddles, ponds, or slowly moving streams, by preference those which are well supplied with vegetation; they float, singly or attached to other objects or clustered together in patterns. They can live in brackish and even in sea water. The larva has no breathing-tube, and floats horizontally at the surface, except when feeding; it does not frequent sewage or foul water. The ova of Culex, on the other hand, are deposited in any stagnant water, including cesspools, drains, cisterns, or water collected in any vessel; they float in boat-shaped masses on the surface. The larva has a breathing-tube, and floats head downwards; when disturbed it wriggles to the bottom (Christy). Some observers maintain that Anopheles does not "sing," like the common mosquito, and its bite is much less irritating. Only the females suck blood; the act is believed to be necessary for fertilization and reproduction. Anopheles rarely bites by day, and then only in dark places. In the daytime the gorged females rest motionless on the walls and ceilings of rooms, choosing always the darkest situations for this purpose "(Austen). In temperate climates the impregnated females hibernate during the winter in houses, cellars, stables, the trunks of trees, &c., coming out to lay their eggs in the spring. The four phases are passed in thirty days in a favourable season, and consequently there are ordinarily four or five generations from April to September (Celli).

The most important question raised by the mosquito-parasitic theory of malaria is that of prevention. This may be considered under two heads: (1) individual prophylaxis; (2) administrative prevention on a large scale.

(1) In the first place, common sense suggests the avoidance, in malarious countries, of unhealthy situations, and particularly the neighbourhood of stagnant water. Among elements of unhealthiness is next to be reckoned the proximity of native villages, the inhabitants of which are infected. In the tropics "no European house should be located nearer to a native village than half a mile (Manson), and, since children are almost universally infected, "the presence of young natives in the house should be absolutely interdicted" (Manson). When unhealthy situations cannot be avoided, they may be rendered more healthy by destroying the breeding-grounds of mosquitoes in the neighbourhood. All puddles and collections of water should be filled in or drained; as a temporary expedient they may be treated with petroleum, which prevents the development of the larvae. When a place cannot be kept free from mosquitoes the house may be protected, as in the experiments in Italy, by wire gauze at the doors and windows. The arrangement used in Switzerland is absolutely free from objection. Failing such protection mosquito curtains should be used. Mosquitoes in the house may be destroyed by the fumes of burning sulphur or tobacco smoke. According to the experi-

ments of Celli and Casagrandi, these are the most effective culicides; when used in sufficient quantity they kill mosquitoes in one minute. The same authorities recommend a powder, composed of larvicide (an aniline substance), chrysanthemum flowers, and valerian root, to be burnt in bedrooms. Anointing the skin with strong-smelling substances is of little use in the open air, but more effective in the house; turpentine appears to be the best. Exposure at night should be avoided. All these prophylactic measures are directed against mos- 
quitoes. There remains the question of protection against the parasite. Chills are recognized as predisposing both to primary infection and to relapses, and malnutrition is also believed to increase susceptibility; both should therefore be avoided. Then a certain amount of immunity may be acquired by the systematic use of quinine. Manson recommends five to ten grains once or twice a week; Ross recommends the same quantity every day before breakfast. There is some evidence that arsenic has a prophylactic effect. An experiment made on the railway staff at Bovino, a highly malarious district on the Adriatic, gave a striking result. The number of persons was 78, and they were divided into two equal groups of 39 each. One group was treated with arsenic, and of these 36 escaped altogether, while three had mild attacks; the remaining 39 who were not treated, all had fever. In another experiment on 657 railway-men 402 escaped. This was in 1886; but in spite of the encouraging results the use of arsenic does not appear to have made any further progress. Experiments in immunizing by soro-therapeutic methods have not as yet met with success.

(2) Much attention has been directed in scientific circles to the possibility of "stamping out" epidemic malaria by administrative measures. The problem is one of Adminis- trative Measures. great practical importance, especially to the British Empire. There are no data for estimating the damage inflicted by malaria in the British colonies. It is, indeed, quite inexactable. In Italy the annual mortal- ity from this cause averages 15,000, which is estimated to represent two million cases of sickness and a consequent loss of several million francs. In British tropical possessions the bill is incomparably heavier. There is not only the heavy toll in life and health exacted from Europeans, but the virtual closing of enormous tracts of productive country which would otherwise afford scope for British enterprise. The "deadly" climates, to which so much dread attaches, generally mean malaria, and the mastery of this disease would be equivalent to the addition of vast and valuable areas to the empire. The problem, therefore, is eminently one for the statesman and administrator. A solution may be sought in several directions suggested by the facts already explained. The existence of the parasite is maintained by a vicious inter- change between its alternate hosts, mosquitoes and man, each infecting the other. If the cycle be broken at any point the parasite must die out, assuming that it has no other origin or mode of existence. The most effective step would obviously be the extermination of the Anopheles mosquito. A great deal may be done towards this end by suppressing their breeding-places, which means the drying of the ground. It is a question for the engineer, and may require different methods in different circumstances. But comprehensively, it involves the control of the subsoil and surface waters by drainage, the regulation of rivers and floods, suitable agriculture, the clearing of forests or jungles, which tend to increase the rainfall and keep the ground swampy.

The city of Rome is an example of what can be done by drainage; situated in the midst of malaria, it is itself quite healthy. Recent reports also show us how much may be done in infected districts. At Ismailia malaria was reduced from 1551 cases in 1902 to 37 cases in 1905. The expenditure was approximately the equivalent of 6-25 francs, and an annual expenditure of about 2-3 francs per head of the population. "The results are due to mosquito reduction together with cinchonization." The following is a tabulated
list of the cases. The population of Ismailla is about 6000.

Klang and Port Swettenham are contiguous towns in the Federated Malay States, having a population of 4000 and a rainfall of 100 in a year. At Klang the expenditure has been £3100, with an annual expenditure of £270, devoted to clearing and draining 332 acres. At Port Swettenham £2000, with an annual upkeep of £240, has been devoted to treating 110 acres. In Hong-Kong similar measures were carried out, with the result that the hospital admissions for malaria diminished from 1924 in 1901, the year when operations were begun, to 419 in 1905.

A systematic campaign for the destruction of breeding-places has been inaugurated in the British West African colonies, with encouraging results. The planting of eucalyptus trees is out of favour at present, but it appears to have been successful in Portugal, not from any prophylactic virtues in the plant, but through the great absorption of moisture by its deep roots, which tends to dry the subsoil. Treating the breeding-ponds with petroleum oil or its preparatory is hardly applicable on a large scale, and in any case can only be a temporary expedient. H. Ziemann advocates the destruction of mosquito larvae by the growing of such plants as the water-pest (Anacharis alismatrum) which covers the surface of the water and suffocates larvae and nymphae. Short of suppressing mosquitoes, the parasitic cycle may theoretically be broken by preventing them from giving the infection to man or taking it from him. The means of accomplishing the former have been already pointed out, but they are obviously difficult to carry out on a large scale, particularly in native communities. It is one thing to protect individuals from mosquito bites, another to prevent the propagation of the parasite in a whole community. Perhaps the converse is more feasible in some circumstances—that is to say, preventing mosquitoes from having access to malarial persons, and propagating the parasite in themselves. It could be carried out where the infected persons are few, by isolating and protecting them, but not where many are infected, as in native villages. Koch has suggested that the disinfection of malarial persons by quicklime or iron would have the desired effect, but other authorities of greater experience do not consider it practicable. In spite of the difficulties, however, there is no doubt that a great deal can be done to reduce, if not stamp out, malaria by the methods indicated, which should be applied according to circumstances. An encouraging example is afforded by the remarkable fact that malaria, which was once rife in certain districts of England, has now died out, although the Aedes aegypti mosquito still exists there. The parasitic cycle has been broken, and the insect is no longer infected. The suggested causes are (1) reduction of insects by drainage, (2) reduced population, (3) the use of quinine. Sir Patrick Manson has suggested that the problem of stamping out malaria may be assisted by the discovery of some at present unknown factors. He has pointed out that certain areas and certain islands are entirely free from the disease, while neighbouring areas and islands are devastated. This immunity is apparently not due to the absence of favourable conditions, but rather to the presence of some inimical factor which prevents the development of the parasite. If this factor could be discovered it might be applied to the suppression of the disease in malignant localities.

MALATIA (MALATIH or ASFUZU) the chief town of a sanjak of the same name in the Mamuret el-Aziz vilayet of Asia Minor, and a military station on the Samsun-Sivas-Diabirk, road, altitude 2900 ft., situated about 10 m. S.W. of the junction of the Tokhma Su (med. Kubabik) with the Euphrates, near the south end of a fertile plain, and at the northern foot of the Tauros. It was, about 340 B.C., a part of the empire of Alexander the Great, and was a Christian city. It was a Christian city, and was the residence of von Moltke for some months, while attached to Hafiz's army. The earliest site was possibly Arslan Tepo about 2 m. S. of Eskisehir were two "Hittite" stelae, representing hunting scenes, now in the Constantinople and Paris museums, were found in 1894.

In the time of Strabo (xii. 537) there was a town in the district of Melitene, which was reckoned part of Cappadocia. Under Titus the place became the permanent residence of the 14th ("Thundering") legion; Trajan raised it to a city. Lying in a very fertile country, the crossing point of important routes, including the Persian "Royal Road," and two imperial military highways from Caesarea and Cappadocia, the Euphrates, it was a city of mild climate and convenience, and was the capital of Armenia Minor or Secunda. Justinian, who completed the walls commenced by Anastasius, made it the capital of Armenia Tertia; it was then a very great place (Procop., De aed., lib. 4). The town was burnt by Chosroes on his retreat after his
MALAYALAM—MALAY ARCHIPELAGO

The islands of the archipelago nearly all present bold and picturesque profiles against the horizon, and at the same time the character of the scenery varies from island to island and even from district to district. The mountains are arranged for the most part in lines running either from north-west to south-east or from west to east. In Sumatra and in the islands between Sumatra and Borneo the former direction is distinctly marked, and the latter is equally noticeable in Java and the other southern islands. The mountains of Borneo, however, rise rather in short ridges and clusters. Nothing in the general physiognomy of the islands is more remarkable than the number and distribution of the volcanoes, active or extinct. Running south-east through Sumatra, east through Java and the southern islands to Timor, curving north through the Moluccas, and again north, from the end of Celebes through the whole line of the Philippines, they form a large and north-eastern quarter of the point. The loftiest mountain in the archipelago would appear to be Kinabalu in Borneo (13,668 ft.). An important fact in the physical geography of the archipelago is that Java, Bali, Sumatra and Borneo, and the lesser islands between them and the Asiatic mainland, all rest on a great submerged bank, nowhere more than 100 fathoms below sea-level, which may be considered a continuation of the continent; while to the east the depth of the sea has been found at various places to be from 1000 to 2000 fathoms. As the value of this fact was particularly emphasized by Wallace, the limit of the shallow water, which is found in the narrow but deep channel between Bali and Lombok, and strikes north to the east of Borneo, has received the name of "Wallace's Line." The Philippines on the other hand, are almost surrounded by deep sea, but are connected with Borneo by means of two narrow submarine banks (A. R. Wallace, Island Life).

The archipelago, in effect, is divided between two great regions, the Asiatic and the Australian, and the fact is evident in various branches of its geography—zoological, botanical, and even human. It is believed that there was a land-connection between Asia and Australia in the later part of the Secondary epoch, and that the Australian continent, when separated, became divided into islands before the south-eastern part of the Asiatic did so.

The most notable fact in the geological history of the archipelago is the discovery in Java of the fossil remains of Pithecanthropus erectus, a form intermediate between the higher apes and man. In its structure and cranial capacity it is entitled to a higher place than any other fossil anthropoid or Cenozoic primate. The skull was first discovered in a height of 22 feet on the side of a height, by the Dutch government. It was then about to be opened by the townsmen who were soon glad to open their gates to Ibn Danishmand (1102), and the city subsequently became part of the realm of Kijji Arslam, sultan of Iconium.

See H. G. B. v. Molthe, Briefe über Zuwände, &c. (D. Türkei (1835-1839)).

MALAYALAM, a language of the Dravidian family, spoken on the west coast of southern India. It is believed to have developed out of Tamil as recently as the 9th century. It possesses a large literature, in which words borrowed from Sanskrit are conspicuous. In 1901 the total number of speakers of Malayalam in all India was just about six millions.

MALAY ARCHIPELAGO1 (variously called Malaysia, the Indian Archipelago, the East Indies, Indonesia, Insulindia), the largest group of islands in the world, lying south-east of Asia and north and north-west of Australia. It includes the Sunda Islands, the Moluccas, New Guinea, and the Philippine Islands, but excludes the Andaman-Nicobar group. The equator passes through the middle of the archipelago; it successively cuts Sumatra, Borneo, Celebes and Halmahera, four of the most important islands. A. R. Wallace (who includes the Solomon Islands as well as New Guinea in the group) points out that the archipelago "includes two islands larger than Great Britain; and in one of them, Borneo, the whole of the British Isles might be set down, and would be surrounded by a sea of forests. Sumatra is about equal in extent to Great Britain; Java, Luzon, and Celebes are each about the size of Ireland. Eighteen more islands are on the average as large as Jamaica; and more than a hundred are as large as the Isle of Wight."

1 For more detailed information respecting the several islands and groups of the archipelago, see the separate articles Borneo; Java; Philippine Islands; Sumatra, &c.

Climate, Flora, Fauna. — The most striking general fact as regards climate in the archipelago is that wherever that part of the south-east monsoon which has passed over Australia strikes, the climate is comparatively dry, and the vegetation is less luxuriant. The east end of Java, e.g., has a less rainfall than the west; the distribution of the rain on the north coast is quite different from that on the south, and a similar difference is observed between the east and the west of Celebes. The north-west monsoon, beginning in October and lasting till March, brings the principal rainy season in the archipelago.

Most of the islands of the archipelago belong to the great equatorial forest-belt. In its economical aspect the vegetation, whether natural or cultivated, is of prime interest. The list of fruits is very extensive, though few of them are widely known. These, however, include the orange, mango, mangoesteen, shaddock, guava and the durian. The variety of food-plants is equally notable. Not only are rice and maize, sugar and coffee, among the widely cultivated crops, but the coco-nut, the bread-fruit, the banana and plantain, the sugar-palm, the tea-plant, the sago-palm, the coco-nut, the ground-nut, the yam, the cassava, and others besides, are of practical importance. The cultivation of sugar and coffee is already developed only to the Dutch; and to them also is due the introduction of tea. They have greatly encouraged the cultivation of the coco-nut among the natives, and it flourishes, especially in the coast districts, in almost every island in their territory. Tobacco is largely cultivated in native cookery. Pepper, nutmegs and cloves were long the objects of the most important branch of Dutch commerce; and gutta-percha, camphor, dammar, benzoin and other forest products have a place among the more naturalistic of the products of the island's region of the highest interest; and from an early period it has attracted the attention of explorers of the first rank. The physical division between the Asiatic and the Australian Archipelago is one which must be in the minds of the geographer and zoologist. The flora of the Asiatic islands (thus distinguished) is a special development of that prevailing from the Himalayas to the Malay Peninsula and south China; the other countrysides with which it must be compared are those of F. H. H. Guilmard, Australia). Similarly, in the Asiatic islands are found the great mammals of the continent—the elephant, tiger, rhinoceros,
anthropoid ape, &c., which are wanting in the Australian region, with which the eastern part of the archipelago is associated. [For details concerning flora and fauna, see separate articles, especially JAVAN.]

Inhabitants.—The majority of the native inhabitants of the Malay Archipelago belong to two races, the Malayans and the Melanesians (Papuans). As regards the present racial distribution, the view accepted by many anthropologists, following A. H. Keane, is, that the Negritos, still found in the Philippines, are the true aborigines of Indo-China and western Malaysia, while the Melanesians, probably their kinsmen, were the earliest occupants of eastern Malaysia and western New Guinea. At some date long anterior to the present one, it is believed that Indo-China was occupied first by a fair Caucasian people and later by a yellow Mongolian race. From these two have come all the peoples—other than Negro or Papuan—found to-day from the Malay Peninsula to the farthest islands of Polynesia. The Malay Archipelago was thus first invaded by the Caucasians, who eventually passed eastward and are to-day represented in the Malay Archipelago only by the Mentawai islanders. They were followed by an immigration of Mongol-Caucasian peoples with a preponderance of Caucasian blood—the Indonesian—pre-Malays of other writers—who are to-day represented in the archipelago by such peoples as the Dyaks of Borneo and the Battas of Sumatra. At a far later date, probably almost within historic times, the true Malay race, a combination of Mongol and Caucasian elements, came into existence and overran the archipelago, in time becoming the dominant race. An Hindu strain is evident in Java and others of the western islands; Moors and Arabs (that is, as the names are used in the archipelago, Mahomedans from various countries between Arabia and India) are found more or less amalgamated with many of the Malay peoples; and the Chinese influence, from an economical point of view, one of the most important sections of the community in many of the more civilized districts. Chinese have been established in the archipelago from a very early date: the first Dutch invaders found them settled at Jatara; and many of them, as, for instance, the colony of Ternate, have taken so kindly to their new home that they have acquired Malay to the disuse of their native tongue. Chinese tombs are among the objects that strike the traveller's attention at Ambon and other ancient settlements.

There is a vast field for philological explorations in the archipelago. The great majority of the languages spoken exist, few have been studied scientifically. The most widely distributed is the Malay, which has not only been diffused by the Malays themselves throughout the coast regions of the various islands, but, through the readiness with which it has been learned, has become the common medium between the Europeans and the natives. The most cultivated of the native tongues is the Javanese. It is the national tongue of a vast number of people that are not of any of the others. To it Sundanese stands in the relation that Low German holds to High German, and the Madurese in the relation of a strongly individualized dialect. Among the other languages which have been reduced to writing and grammatically analysed are the Balinese, closely connected with the Javanese, the Bata (with its dialect the Toba), the Dyak and the Macassarese. Alfurese, a vague term meaning in the mouths of the natives little else than non-Mahomedan, has been more particularly applied by Dutch philologists to the native speech of certain tribes in Celebes. The commercial activity of the Buginese causes their language to be fairly widely spoken—little, however, by Europeans.

Political Division.—Politically the whole of the archipelago, except British North Borneo, &c. (see Borneo), part of Timor (Portuguese), New Guinea east of the 141st meridian (British and German), and the Philippine Islands, belongs to the Netherlands. The Philippine Islands which had been for several centuries a Spanish possession, passed in 1898 by conquest to the United States of America. For these several political units see the separate articles; a general view, however, is here given of the government, economic conditions, &c., of the Dutch possessions, which the Dutch call Nederlandsch-Indië.

NETHERLANDS INDIA

Administration.—The Dutch possessions in Asia lie between 6° N. and 11° S. and 95° E. and 141° E. Politically they are divided into lands under the direct government of the Netherlands vassal lands and confederated lands. Administratively they are further divided into residencies, divisions, regencies, districts, and villages. In the principal towns and cities there are city halls, generally they are appointed by government. The islands are often described as of two groups, Java and Madura forming one, and the other consisting of Sumatra, Borneo, Riouw-Lingga Archipelago, Banka, Billiton, Celebes, Molucca Archipelago, the small Sundanese Islands, and a part of New Guinea—the Outposts as they are collectively named. The Outposts are divided into 20 provinces. A governor-general has for his residence at Batavia, and is assisted by a council of five members, partly of a legislative and partly of an advisory character, but with no share in the executive work of the government. In 1907 a Bill was introduced to add four extraordinary members to the council, but no immediate action was taken. The governor-general not only has supreme executive authority, but can of his own accord pass laws and regulations, except in so far as these, from their nature, belong of right to the home government, and as he is bound by the constitutional principles on which, according to the Regulations for the Government of Nederlandsch-Indië, passed by the king and States-General in 1854, the Dutch East Indies must be governed. There are nine departments, each under a director: namely, justice; interior; instruction, public worship and industry; agriculture (created in 1903); civil public works; government works (created in 1908); finance; war; marine. The administration of the larger territorial divisions (gouvernement, residenie) is in the hands of Dutch governors, governors, assistant residents and contrôleurs. In local government a wide use is made of natives, in the appointment of whom a primary consideration is that if possible the latter should be under their own chiefmen. In Surakarta and Jokjakarta in Java, and in many parts of the Outposts, native princes preserve their name as vassals: they have a limited vassalage status under the supervision of a Dutch official. In concluding treaties with the vassal princes since 1905, the Dutch have kept in view the necessity of compelling them properly to administer the revenues under their control, most of which are required for personal uses. Provincial banks have been established which defray the cost of public works.

Population.—The following table gives the area and population of Java (including Madura) and of the Outposts:

In no case are the above figures for population more than fairly accurate, and in some instances they are purely conjectural. The population is legally divided into Europeans and persons assimilated to them, and natives and persons assimilated to them. The first class includes half-castes (who are numerous, for the Dutch are in close relationship with the natives than is the case with most colonizing peoples), and also former slaves, tapuics, &c. The total number of this class in 1900 was 73,383; 72,019 of these were called Dutch, but 61,022 of them were born in Nederlandsch-Indië; there were also 1,362 Germans, 441 British and 260 Belgians. Among the latter were widowed or retired persons of both sexes and a few Chinese and 27,000 Arabs. In the decade 1890–1900 the increase of the European population was 30-9 % of the Arabs 26-6 % and of the Dutch 5-5 %. A large proportion of the government officials, or retired officials, for many of the Dutch, once established in the colonies, settle there for life. The remaining Europeans are mostly planters and heads of industrial establish-

1 Including 487 in Merauke, the capital of Dutch New Guinea.
About 10,000 natives go annually to Mecca on pilgrimage.

Both the government and private enterprise encourage educational institutions, and the government has undertaken to assist in the establishment of parochial schools, the object being that every village, at least in Java, should possess one.

There are schools for higher education at Batavia, Surabaya and Semarang; at the first two of these towns are government schools for the education of the children of Chinese and other foreign residents; at Surabaya there is a medical school for natives. In the outports there are several schools for the education of Chinese children established in the principal towns. Private educational institutions and crafts schools are established at Jokjarta, Surabaya and Semarang, and there is an agricultural school at Buitenzorg.

As regards pauperism, the government subsidizes Protestant and Catholic orphan houses.

The religious background of the Archipelago has traditionally been shaped by the Dutch presence, with a strong influence of Christianity and Islam. The Dutch East India Company played a significant role in the region's colonial history.

The monetary system is similar to that of the Netherlands, using the guilder as the unit of currency, and the government controls the administration of this bank.

The military and police forces of the Netherlands are well trained and equipped, ensuring a stable security environment in the region.

The agricultural sector is dominated by tobacco cultivation, with significant contributions from rubber and coffee plantations. The Archipelago's abundant natural resources have been a key factor in its economic development.

Religious freedom is ensured, with all religious communities being protected and encouraged to flourish. The Reformed Church has about 41 ministers and 30 assistants, while the Roman Catholic Church has 35 curates and 20 priests, not salaried out of the public funds. There are about 10,000 Christian missionaries, but their work may be illusory, and the number of Christians among the natives and foreign Orientals was estimated to be around 30,000 in 1893.

The religious landscape of the Archipelago is diverse, with Islam being the predominant religion, followed by Christianity, particularly among the Chinese community. The Dutch government has implemented policies to promote religious freedom and tolerance, allowing for the coexistence of various religious practices.

The Archipelago was once a major contributor to the global spice trade, with its rich biodiversity supporting the cultivation of essential herbs and spices that were highly valued in the international market.

The maritime history of the region is marked by the presence of various cultures, including the Chinese, from whom many cultural and linguistic influences have been absorbed. The Chinese community, particularly in the trade and business sectors, has played a significant role in shaping the economic landscape of the Archipelago.

The region's geopolitical landscape has evolved dynamically, with various powers vying for influence, including the Dutch, the British, and the Portuguese. The region's strategic importance as a gateway to Asia further fueled the competition among these powers.

The Archipelago's rich cultural tapestry is evident in the blend of traditional and modern practices, reflecting the region's historical and geographical connections.

The Archipelago's contributions to the world, particularly in the realm of spices, have left a lasting legacy, with the region's products being highly sought after in various parts of the world. The region's geographical position and its economic activities continue to shape its role in the global narrative.
MALAY ARCHIPELAGO

History

Portuguese and Spanish Ascendancy, 1511-1595—Ptolemy and other ancient geographers describe the Malay Archipelago, or part of it, in vague and inaccurate terms, and the traditions they preserved were supplemented in the middle ages by the narratives of a few famous travellers, such as Ibn Batuta, Marco Polo, Odoric of Pordenone and Niccolò Conti. Malay and Chinese records also furnish material for the early history of individual islands, but the known history of the archipelago as a whole begins in the 16th century. At this period a civilization, largely of Hindu origin, had flourished and decayed in Java, where, as in all the more important islands, Mahommedanism had afterwards become the dominant creed. But the smaller islands and the remoter districts, even of Java and Sumatra, remained in a condition of complete savagery.

The Portuguese were the first Europeans to colonize any part of the archipelago. A Portuguese squadron under Diogo Lopes de Sequeira arrived off Sumatra in 1500, explored the north coast for some distance, and noted that the inhabitants of the interior were cannibals, while those of the littoral were civilized and possessed a gold coinage. The main object of the Portuguese was to obtain a share in the lucrative spice trade carried on by the Malais, Chinese and Japanese; the trade-routes of the archipelago converged upon Malacca, which was the point of departure for spice merchants trading with every country on the shores of the Indian Ocean and Arabian Sea. In 1511 the Portuguese under Francisco de Albuera, the Archipelago commander, made an expedition under Antonio de Abreu was despatched to find a route to the Moluccas and Banda Islands, then famous for their cloves and nutmegs. The explorers reached Ambon and Ternate, after gaining some knowledge of Java, Madura, Sumbawa and other islands, possibly including New Guinea. During the return voyage the second-in-command, Francisco Serrão, was shipwrecked, but succeeded in making his way in a native boat to Mindanao. Thus the Philippines were discovered. In 1514 a second Portuguese fleet arrived at Ternate, which during the next five years became the centre of Portuguese enterprise in the archipelago; regular traffic with Malacca and Cochin was established, and the native raja became a vassal of Portugal.

Meanwhile the Spanish government was considering whether the Moluccas did not fall within the Spanish sphere of influence as defined by the Treaty of Tordesillas in 1494; and in August 1519 an expedition commanded by Ferdinand Magellan (q.v.) sailed from Seville to seek a westward passage to the archipelago. After losing the commander in the Philippines and discovering Borneo, the two surviving ships reached Malacca, and in November of that year an expedition under Antonio de Abreu was despatched to find a passage to the Moluccas and Banda Islands, then famous for their cloves and nutmegs. The explorers reached Ambon and Ternate, after obtaining some knowledge of Java, Madura, Sumbawa and other islands, possibly including New Guinea. During the return voyage the second-in-command, Francisco Serrão, was shipwrecked, but succeeded in making his way in a native boat to Mindanao. Thus the Philippines were discovered. In 1514 a second Portuguese fleet arrived at Ternate, which during the next five years became the centre of Portuguese enterprise in the archipelago; regular traffic with Malacca and Cochin was established, and the native raja became a vassal of Portugal.

Reinforcements from Spain arrived in 1525 and 1528, but in 1529 a treaty was concluded between the emperor Charles V. and John III. of Portugal, by which, in return for 350,000 gold ducats, the Spanish claim to the Moluccas was withdrawn. The boundary between the Spanish and Portuguese spheres was fixed at 15° E. of the Moluccas, but by a geographical fiction the Portuguese were included within the Spanish sphere. Further disputes occurred from time to time, and in 1542 a Spanish fleet came into conflict with the Portuguese off Ambon; but after 1529 the supremacy of each power in its own sphere was never seriously endangered.

Though the Portuguese traders frequented the coast of Java, they annexed no territory either there or in Sumatra; but farther east they founded numerous forts and factories, notably in Ambon, the Banda Islands, Celebes and Halmahera. Ternate remained the seat of the government of the Moluccas, who was the highest official in the archipelago, though subordinate to the viceroy or governor of Portuguese India. The first attempt to enter into relations with the states of Borneo was made by D. Jorge de Menezes, who visited Brunei in 1526, and in 1528 sent an envoy to its raja. The embassy failed in a curious manner. Among the gifts sent by Menezes was a piece of tapestry representing the marriage of Catherine of Aragon to Arthur, prince of Wales. The raja was persuaded that these mysterious figures were demons under a spell, which might come to life and kill him as he slept. The envoy was therefore dismissed.

In 1536, after a period of war and anarchy caused by the tyrannical rule of Meneses, Antonio Galvão, the historian, was appointed governor of the Moluccas. He crushed the rebellion and won the affection of the natives by his just and enlightened administration, which had no parallel in the annals of Portuguese rule in the archipelago. He returned to Europe in 1540 (see PORTUGAL: Literature), after inaugurating an active missionary movement, which was revised in 1546-1547 by Francis Xavier (q.v.). At this period the Portuguese power in the East was already beginning to wane; in the archipelago it was weakened by administrative corruption and by incessant war with native states, notably Bintang and Achin; bitter hostility was aroused by the attempts which the Portuguese made to establish a commercial monopoly and to force Christianity upon their native subjects and allies (see PORTUGAL: History). From 1580 to 1640 Portugal was itself united to Spain—a union which differed from annexation in little but name.

The English and Dutch, 1595-1674.—Pirates from Dieppe visited the archipelago between 1527 and 1539. It is possible that they reached Australia—more than sixty years before the first voyage thither of which there is any clear record; but their cruisers had no political significance. The Spaniards and Portuguese remained without European competitors until the appearance of Sir Francis Drake in 1579. An English squadron under Sir James Lancaster came into conflict with the Portuguese in 1591, and an expedition under Sir Henry Middleton traded in the archipelago in 1604. But the English were simple traders or explorers; far more formidable were the Dutch, who came to the East partly to avenge the injuries inflicted on their country by the Spaniards, partly to break the commercial monopoly of the peninsular states. As middlemen they already possessed a large interest in the spice trade, for the Portuguese, having sole direct access to the principal European markets, had made a practice of sending cargo to the Netherlands for distribution by way of the Schelde and Rhine. The Dutch now sought to monopolize not only the distribution but the production of spices—an enterprise facilitated by the co-operation of many exiled Portuguese Jews who had settled in Holland.

The first Dutch fleet sailed from Texel, under the command of Cornelis Houtman, on the 2nd of April 1595 and reached Sumatra on the 1st of January 1596. It visited Madura, and came into contact with the Portuguese at Bantam in Java, returning to Holland in 1597. Though not a commercial success, the expedition had demonstrated the weakness of the Portuguese. In 1601 the Dutch East India Company (q.v.) was incorporated, and by nearly two centuries this organization played the chief part in the history of the archipelago. By 1604 the Dutch could already claim to be the stronger power at sea. They had attacked the Portuguese in Ceylon (1601), established friendly relations with Achin (1602), and defeated a powerful fleet off Banda (1602). In 1606 they concluded a treaty of alliance with the sultan of Johor, and in 1607 they forced the Portuguese to assent to a monopoly for twelve years. On the 29th of November 1608 Pieter Both was chosen by the states-general, on the nomination of the Dutch East India Company, as first governor-general of Netherlands India. In 1611 the headquarters of the Dutch was changed from Bantam to Jakarta, which in 1619 was renamed Batavia, and thenceforward the Dutch capital. Meanwhile the English East India Company, chartered in 1600, had also extended its operations to the archipelago. After 1611 the commercial rivalry between the Dutch and British became acute, and in 1613, 1615 and 1618 commissioners met in London to discuss the matters in dispute. The result of their deliberations was the Treaty of Defence, signed on the 2nd of June 1619 and modified on the 24th of January 1620, which arranged for co-operation between the Dutch and British companies, and especially for the maintenance of...
of a joint fleet. But neither company could restrain its agents in the East from aggressive action, and many fresh causes of dispute arose, the chief being the failure of the British to provide the naval forces required for service against the Portuguese, and the so-called "massacre of Amboyna" (q.v.) in 1623. The Treaty of Defence lapses in 1657, but as early as 1634 the British made peace with Portugal. Even without allies, however, the Dutch continued to extend their trade and to renew fresh territories for the British were weakened by civil war at home, while, after 1640, the Portuguese were struggling to maintain their independence against Spain. The Dutch company opened up a profitable trade with Japan and China, and prosecuted the war against Portugal with great vigour, invading Portuguese India and capturing Point de Galle in 1640, Malacca in 1641, Cochin and Cannanore in 1663. The war with England in 1652–54 and the renewal of the Anglo–Portuguese alliance by the marriage of Charles II. to Catherine of Braganza in 1661 were unable to check the growth of Dutch power; more serious was the resistance offered by some of the native states. Rebellions in Java (1639) and the Moluccas (1650) were suppressed with great severity, but in 1662 the company suffered a heavy reverse in Formosa, all its colonists being expelled from the island. A new war between Great Britain and Holland broke out in 1672 and was terminated by the Treaty of Westminster (February 17, 1674), by which the points at issue between the two companies were referred first to commissioners and finally to an arbitrator. The full details of the settlement are unknown, but thenceforward the British company devoted its energies chiefly to the development of its Indian possessions, while the Dutch were left supreme in the archipelago. In 1684 the British even evacuated Bantam, their chief settlement, and retired to Bentukelen in Sumatra, which remained for more than a century their sole territorial possession in the archipelago.

Dutch Ascendancy, 1674–1749.—The weakness of Spain and Portugal and the withdrawal of the British left the Dutch company free to develop its vast colonial and commercial interests. In 1627 the so-called Dutch "colonial system" had been inaugurated by the fourth governor-general, Jan Pieterszoon Coen (q.v.). Under this system, which was intended to provide Netherlands India with a fixed population of European descent, Dutch girls were sent to the archipelago to be married to white settlers, and subsequently marriages between Dutchmen and captive native women were encouraged. As early as 1624 vast fortunes had been acquired by trade: two members of the company who died in that year were stated to possess seven and eight tons of gold respectively, an amount approximately equivalent, in the aggregate, to £2,000,000. The beneficial operation of the corvee system to natives who were nominally free, enabled the company to lower the cost of production, while the absence of competition enabled it to raise prices. The hardship inflicted on the native races provoked an insurrection throughout Java, in which the Chinese settlers participated; but the Dutch maintained naval and military forces strong enough to crush all resistance, and a treaty between the company and the Susuhan in November 1749 made them practically supreme throughout the island.

Later, 1749–1815.—The second half of the 17th century the monopoly system and the employment of slaves and forced labour gave rise to many abuses, and there was a rapid decline in the revenue from sugar, coffee, and opium, while the competition of the British East India Company, which now exported spices, indigo, &c. from India to Europe, was severely felt. The administration was corrupt, largely because of the vast powers given to officials, who were invariably underpaid; and the financial methods of the company precipitated its ruin, large dividends being paid out of borrowed money. The burden of defence could no longer be sustained; piracy and smuggling became so common that the company was compelled to appeal to the states-general for aid. In 1798 it was abolished and its authority vested in a "Council of the Asiatic Possessions." In 1803 a commission was appointed to consider the state of the Dutch colonies, and advocated drastic administrative and commercial reforms, notably freedom of trade in all commodities except firearms, opium, rice and wood—with coffee, pepper and spices, which were state monopolies. Some of these reforms were carried out by H. W. Daendels (1808–1811), who was sent out as governor-general by Louis Bonaparte, after the French conquest of Holland. Daendels, however, maintained the existing restrictions upon trade and even made rice a state monopoly. His harsh rule aroused great antagonism; in 1811 he was recalled and J. W. Janssens became governor-general.

British Occupation, 1811–1816.—Netherlands India was at this time regarded as a part of the Napoleonic Empire, with which Great Britain was at war. A British naval squadron arrived in the Moluccas in February 1810 and captured Ambon, Banda, Ternate and other islands. In 1811 a strong fleet was equipped by Lord Minto, then governor-general of India, for the conquest of Java; a British force was landed on the 4th of August; Batavia was captured on the 26th, and on the 17th of September Janssens and the remnant of his army surrendered. Lord Minto had issued a proclamation establishing British rule on the 11th of September, and Thomas (afterwards Sir Thomas) Stamford Raffles was appointed lieutenant-governor. Raffles (q.v.) held office until March 1816, and introduced many important changes in the departments of revenue, commerce and judicature. He was succeeded by John Fendall, who in 1816 carried out the retrocession of Netherlands India to the Dutch, in accordance with the Treaty of Vienna (1814).

Restoration and Reform of Dutch Power, 1816–1910.—Various disputes between Great Britain and the Netherlands, arising chiefly out of the transfer of power in Java and the British occupation of Singapore (1816), were settled by treaty between the two powers in 1824. By this treaty the Dutch were given almost entire freedom of action in Sumatra, while the Malay Peninsula was recognized as within the British sphere of influence. In 1825–30 a serious rebellion in Java involved the despatch of a large military force from the Netherlands, and was with difficulty suppressed. An outbreak of Mahomedan fanaticism in Sumatra also gave much trouble. The reform movement inaugurated by the commission of 1803 was resumed in 1830, when Governor-General Johannes van den Bosch endeavoured to improve the conditions of land-tenure and agriculture by introducing the so-called "culture system." The native cultivators were to be exempted from the ground-tax, but were to cultivate one-fifth of their land as the government might direct, the government taking the produce. This culture-system worked fairly during Van den Bosch's tenure of office, but gave rise to many abuses between 1833 and 1844, involving, as it did, a combination of the kelayir and corvee systems.

In 1848 the Grondevet, or fundamental law of the Netherlands, recognized for the first time the responsibility of the Dutch nation for its colonial dependencies. The Grondevet involved certain important changes, which were embodied in an act passed in 1854 and commonly known as the Regulations for the Government of Netherlands India. The Regulations substituted statute law for administrative and military despotism, and made the governor-general in council responsible to the minister of the colonies at The Hague, and the legislator responsible for elementary education for the natives, and abolished slavery in Java as from the 1st of January 1860. They also prepared the way for further legislation tending towards the gradual emancipation of the natives from the culture system, and from semi-feudal servitude to their native rulers. That servitude existed in many forms all over the archipelago, but among the most curious must be reckoned the pandelingschip or "pledgedom," which originated in Borneo, and according to which a man had the power to make his debtors his serfs for life, in return for their services.

The reform movement was aided by the publication in 1860 of Max Havelaar, a romance by E. Douwes Dekker (q.v.), which contained a scathing indictment of the colonial system. Many important financial and agrarian measures were carried between 1880 and 1890. In 1863 Fransen van de Putte, minister for the colonies, introduced the first of the annual colonial budgets for
which the Regulations had provided, thus enabling the state-
general to control the revenue and expenditure of Netherlands
India; in 1865 he reduced and in 1872 abolished the differentia-
tion of customs dues in favour of goods imported from Holland,
substituting a uniform import duty of 6% and establishing a
number of free ports throughout the archipelago. The import
duty was considered so moderate that an increase required for
repayed. A warrant was carried on by his 1876 the practice of paying a yearly surplus (batig dot) from the revenues
of Netherlands India to the treasury at the Hague was discon-
tinued. The chief reforms in the land system were those intro-
duced by De Waal, then minister for the colonies, in 1870. The
cultivation of pepper, chinchal, cinnamon and indigo for the
government had already ceased; De Waal restricted the area of
the sugar plantations (carried on by forced native labour) as
from 1875, and provided for their abolition 1890. He also
enabled natives to secure proprietary rights over the land they
cultivated, and legalized the leasing of Crown forest-lands to
Europeans.

The extension of Dutch political power—notably in Java,
Sumsel, Celebes, the Moluccas, Borneo, the Sunda Islands and
New Guinea—proceeded simultaneously with the reform move-
ment, and from time to time involved war with various native
states. A large expedition was sent to Sambob in 1894, and
almost the whole of that island was incorporated in the Dutch
dominions. The long and costly war with Achin (q.v.) began in
1873 and reached its climax in the military occupation of the
country after 1905, when the native sultan surrendered and
was deported. A guerrilla war was carried on by his subjects but
their principal leader, the chief Panglima Polim, was captured in
1907; in 1908–1910 the condition of Achin under the military rule
of General Swart was one of almost unpunished peace, and taxes
were regularly paid.

While the Dutch were thus consolidating their authority, other
countries were acquiring new commercial or colonial interests in
the archipelago. Immigration from China and Japan steadily
increased, especially towards the end of the period 1816–1910.
The enterprise of Sir James Brooke (q.v.) led, after 1838, to the
establishment of British sovereignty in North Borneo; in 1895
New Guinea was divided between Great Britain, Germany and
the Netherlands; and the Spanish-American War of 1898 resulted
in the cession of the Philippines, Sulu Island and the largest of
the Mariana Islands to the United States, and the sale of the Caroline
group to Germany. Australian and Japanese trade in the archi-
pelago was stimulated by the establishment of the Australian
Commonwealth (1901) and the Russo-Japanese War (1905–7).
In 1910 the nations most directly interested in the future of the
archipelago were the Netherlands, Great Britain, the United
States, Japan and Australia. Britain and China continued to
have the lead in trade and finance.

BIBLIOGRAPHY.—For the period 1515–1598, the chief Portuguese
authors are the chronicles of Barros, Cos, Martina and Couto (see PORTUGAL: HISTORY), with the letters of Xavier (q.v.),
and the Traité d'A. Galvão (Lisbon, 1553 and 1731), of which a
translation entitled Discoveries of the World was made for Richard
Hakluyt and reprinted by the Hakluyt Society (London, 1862).
See also M. F. de Navarette, Colección de los viajes (vol. 4 and 5,
Madrid, 1837). For later history see John Crawford, History of the
Indian Archipelago (Edinburgh, 1820), which quotes from native
as well as European records, and Twentieth-Century Impressions of
Malay Lands Ind., A. Wright, London, 1910, 1917, which gives
references to the principal English and Dutch authorities. Further
bibliography will be found in J. A. van der Chijs, Proeve eener neder-
landsch-indische Bibliografe, 1659–1870 (Batavia, 1879).

MALAYIR, a small province of Persia, situated between
Hamadan and Burjird. It has a population of about 70,000,
and, together with the district Tusirkhan, pays a yearly revenue
of about £15,000. It produces much corn and fruit; a great
quantity of the latter, dried, is exported. Its capital and seat of
government is Doletabad (Dowletabad), a thriving little city, with
a population of about 5000, situated at an elevation of 5680 ft.,
38 m. from Hamadan and 32 m. from Burjird. It has post and
telegraph offices.

MALAY PENINSULA (called by the Malays Tanah Maluay,
*i.e.* the Malay Land), a lozenge-shaped strip of land projecting
into the China Sea, and forming the most southerly portion of the
continent of Asia. Geographically, the peninsula begins at the
isthmus of Kra, 10°N., at which point it is only between 60 and
70 m. in width, and the distance from sea to sea is further
diminished by a large irregular salt-water inlet. Politically and
anthropologically, however, this upper portion must be regarded as
a continuation of the kingdom of Siam rather than as a section of
the Malay States. From the isthmus of Kra the peninsula extends
south with a remarkable uniformity. The town of Siam (Bangkok)
southerly point being Tanjong Bulus in 1° 16′ N. A line drawn
diagonally down the centre from the isthmus of Kra to Cape
Romania (Ramunya) gives the extreme length at about 750 miles.
The breadth at the widest point, from Tanjong Pen-unjut in
Trengganu to Tanjong Hantu in the Dindings territory, is about
200 m. The area is estimated at about 70,000 sq. m. The peninsula
is bounded on the N. by Siam, on the S. by the island and strait of
Singapore, on the E. by the China Sea, and, on the W. by the Strait
of Malacca.

Characteristically the granitic granites of granite mountains forms a
backbone which divides the peninsula into two unequal portions, the
larger of which lies to the east and the smaller to the west of the
chain. Smaller ranges run parallel to the main mountain chain in
many spots, and there are a number of islands which are in connec-
tion with either. The country is covered with limestone in
many parts, and large isolated bluffs of this formation stand up in
the plains both on the eastern and the western slopes. The
descent from the summits of this formation presents a steep descent
on the western than it is on the eastern side, and between the foot
of the mountains and the Strait of Malacca the largest known alluvial
plain the world. The alluvial plains are still further covered by
a deep descent, the granite formation speedily gives place to slates
of vast depth, intersected here and there by fissures of quartz contain-
ing gold, and in many places covered by limestone which has been
superimposed upon the slates. The highest known peak in the
main range is that of Gunong Korbu, 7217 ft. above sea-level.
The highest mountain is believed to be Gunong Tahan, which forms
the southern extremity of an isolated range on the eastern side, on the
borders of Selangor, Perak and Kelantan, and is estimated at about
8000 ft. The west coast throughout its whole length is covered to a depth of some miles
with mangrove swamps, with only a few isolated stretches of sandy
beach, and often following the streams, and the frequent mangrove
presenting a depressing spectacle. On the east coast the force of
the north-east monsoon, which beats upon the shores of the China
Sea annually from November to February, has kept the land for
the most part free from mangroves, and the sands, broken here
and there by rocky headlands thickly wooded, and fringed by
casuarina trees, stretch for miles without interruption. The islands
of the peninsula are presented in the present section as being
adjacent. On both the east and the west coast the islands are
thickly wooded, but whereas the former are surrounded by beautiful
beaches and shores, the latter are fringed by mangrove-swamps.

The Malay Peninsula, first written in Malay MNAYIL, is
hexagonal in form, and is inscribed in every direction by countless streams and rivers which
together form the most lavish water-system in the world. Only the rain forest and the immediate
surrounding, inhabited by the aborigines, the Malay, the Chinese, the Indian, and the European,
being the Malays and the aborigines, Malacca, and the island of Singapore, and the hills between
and both slopes of the peninsula, those at Batu in Selangor being the
finest on the west coast, while those of Chadu and Koto Ganggi in Pahang are the most extensive yet visited by Europeans on the east coast. The limestone and limy sediments are rarely met with. These rocks form the greater part of the central range and they are often—especially the granite—decomposed and rotten to a depth. The sedimentary deposits include slate, limestone and sandstone. Impure coal has also been recorded. The limestone has yielded *Proetus, Chevrotia* and other fossils, and is believed to be of Carboniferous age. In the sandstone Myophoria and other fossils have been found, and it appears to belong to the Rhaetic or Upper Trias. The minerals produced are tin, gold, iron, galena and others, in insignificant quantities.

Most of the tin is mined on the east coast within the British zone, and is found chiefly in or near the crystalline rocks, especially the granite. As tin stream it occurs abundantly in some of the alluvial deposits derived from the crystalline area, especially on the west coast. Only two tin lodes are worked, however, and both are situated on the east coast: the one at Kuantan in Pahang, the other at Bandai in Trengganu territory.

On the west coast no true lode has yet been discovered, though the vast alluvial deposits of tin found there seem to make such a discovery probable in the future. Since 1890 a tin produce from these alluvial beds has supplied between 50% and 75% of the tin of the world. Gold is worked with success in Pen. Mag., and the co-操作 of tin and gold is being successfully prosecuted in immemorial Khmer country, and in the tin districts of that state and of Kelantan. Small quantities have also been found on the western slope in Perak.

**Climate, &c.—**It was formerly the custom to speak of the Malay Peninsula as having a wet climate. But, as the climate on the west coast of Africa. It is now generally admitted, however, that, though hot, it compares favourably with that of Burma. The chief cause of discomforts among malay in this climate is the intense humidity, which causes the heat to be more oppressive than is the case where the air is dry. On the other hand, the thermometer, even at Singapore on the southern coast, which is the hottest portion of the peninsula, seldom rises above 98° in the shade, whereas the mean for the year at that place is generally below 80°. On the mainland, and more especially on the eastern slope, the temperature is even lower than in the west; the temperature rising above 93° in the shade, and falling at night below 70°. On the average, in the month in which the peninsula the temperature in a European house ranged from 88° to 68°. The number of rainy days throughout the peninsula varies from 160 to over 200 in each year, but violent gusts of wind, called "Sumatras," accompanied by a heavy downpour of short duration, are more common than persistent rain. The rainfall on the west coast varies from 75 to 125 in. per annum, and that of the east coast, where the north-east monsoon breaks with all its fury, is usually about 155 in. per annum. Malarial fevers make their appearance in places where the forest has been recently felled, or where the surface of the land has been lightly ploughed. It is said that the black labourer working in deep mines worked by shafts suffers less from fever than those who are engaged in stripping the alluvial deposits. This, of course, means that a new station, where clearing, digging, and building are in progress, is a hotbed of fever, and the unhealthy forest atmosphere attributed the evil reputation which the peninsula formerly enjoyed. To Europeans the climate is found to be relaxing and encouraging, but to the inhabitants of the peninsula, insidious and fatal attacks, regular exercise is taken from the beginning, and ordinary precautions against fevers, more especially to the stomach, are adopted, a European has almost as good a chance of remaining in good health in the peninsula as in Europe. A change of climate, however, is imperatively necessary every five or six years, and the Chinese immigrants suffer chiefly from fever of a malarial type, from bilious fever, and from dysentery. The Malays formerly suffered severely from small-pox epidemics, but in the portion of the peninsula under British rule small-pox, when once introduced, is no longer an important disease. The mosquitoes which are now an evil are, however, a remarkably healthy people, and deformity and hereditary diseases are rare among them. There is little leprosy in the peninsula, but a few cases of leprosy have occurred on Pulau Deraja and another on an island on the west coast for the treatment of lepers from the Federated Malay States.

**Flora.**—The soil of the peninsula is remarkably fertile both in the plains and on the mountains. In the plains, where the decay of vegetable matter during countless ages has enriched the soil to the depth of many feet, and from it springs the marvellous tangle of huge trees, shrubs, bushes, underwood, creepers, clambering plants and trailing vines, the whole hung with ferns, mosses, and parasitic growths, and bound together by rattans and huge rope-like trailers. In most places the jungle is so dense that it is impossible to force a way through it without the aid of a wood-knife, and even the wild beasts use the well-worn game-tracks through the forest. In the interior branches of bamboo are found, many of which spread for miles along the river banks. Good hard-wood timber is found among the trees lining the plains and the forest tracts. The principal jungle products are rubber and several varieties of hardwood. The termite-grove grows on the shores of the west coast in profusion. Aglaia, the campoh tree, and ebony are also found in smaller quantities.

The fauna of the peninsula is varied and no less prolific than is the vegetable life. The Asiatic elephant: the seladang, a bison of a larger type than the Indian gaur; two varieties of rhinoceros; the honey bear (brusang); the tapir, the sambar (rusa); the speckled deer (kijang); three varieties of mouse-deer (napoh, plankod and kanchil); the gibbon (angka or wana), the siamang, another species of the same family, the orang-outang, are of great interest. It is thought that this is where it is trained by the Malays to gather the nuts from the cocoa-nut trees, the lotong, kro, and at least twenty other kinds of monkey; the binturong (arcturus binturong), the lemur; the Asiatic tiger, the stink-bug, the common tapir, the wild pig, the several varieties of jungle cat; the wild boar, the wild dog; the flying squirrel, the flying fox; the python, the cobra, and many other varieties of snakes, the king cobra being undoubtedly the most ferocious. On the gavialis, as well as countless kinds of squirrel, rat, &c., are found throughout the jungles of the peninsula in great numbers. On the east coast peafowl are found, and throughout the interior the argus pheasant, the firebacked pheasant, the blue partridge, the adjutant bird, several kinds of heron and crane, duck, teal, cotton-teal, snipe, wood-pigeon, green-pigeon of several varieties, swifts, swallows, plover, herons, bitterns, nightjars, and many other kinds of bird are met with frequently. The deer, the solitary goose have been procured, but the bird is rarely met with. The forests literally swarm with insects of all kinds, from culeaus to beautiful butterflies, and from stick- and leaf-insects to endless varieties of ants. The scorpion and the centipede are both common. The study of the insect life of the peninsula opens a splendid field for scientific research, and the profusion and variety of insects found in these forests probably surpass those to be met with anywhere else in the world.

**Political Divisions and Population.**—Politically the Malay Peninsula is divided into four sections: the colony of the Straits Settlements and the Federated Malay States; the independent Malay State of Johor, which is within the British sphere of influence and is not under British protection; the federation of the states of the groups of states to the north of Perak and Pahang, which are now recognized as lying within the sphere of influence of Siam. The colony of the Straits Settlements consists of the islands of Singapore, Penang and the Dindings, the territory of Province Wellesley, on the mainland opposite to Penang, the insignificant territory of the Dindings, and the town and territory of Malacca. The Federated Malay States under British protection consist of the sultanates of Perak, Selangor and the Negri Sambian on the west coast, and the sultanate of Pahang on the east coast. Johor is the only Malay state in its southern portion. The peninsula, the whole of which is within the British sphere, which has been suffered to remain under native rule. The non-federated states under British protection (since 1909) are Kelantan, Trengganu, Kapit and Perlis (Pali). The population of the peninsula numbers about 2,600,000, of whom about 600,000 inhabit the colony of the Straits Settlements, about 900,000 the Federated Malay States, about 200,000 the Malay State of Johor, and about 750,000 to 300,000 the remainder of the peninsula. The population of the peninsula is composed of a mixture of immigrants or descendants of immigrants from the southern provinces of China, many of whom are of Chinese origin. In the peninsula, including immigrants from the eastern archipelago, number

1 See R. B. Newton, "Notes on Literature bearing upon the Geology of the Malay Peninsula; and Account of the Implement from that Country" (Geol. Mag., 1901, pp. 128-134). See also the various reports by J. B. Scrivenor in *Suppl. Perah Ge. Gazette*, 1905.
some 7,500,000 to 8,000,000, while the Tamils and other natives of India number about 100,000, the aboriginal natives of the peninsula perhaps 20,000, Europeans and Americans about 6,000, and Eurasians about 9,000. The colony of the Straits Settlements, and to a lesser extent the towns of the Federated Malay States, carry a considerable heterogeneous population, in which most of the races of Asia find their representatives.

The Malayan Peninsula.

As we turn from east to west, we see a succession from the Negrito to the European, the latter being represented by the Tamils and the French, each with about 100,000, while the Malay population number 800,000. In the interior of the peninsula the Malay is best represented by the Semang, the Pangan, and the Sakai. Instead of speaking of them as separate races, and in the belief that they are Negritos, it is better for us to speak of them as tribes or clans and their languages and manners to be the same as those of the peoples of the same stock in the neighboring countries.

The peninsula is situated about 7° of latitude north of the equator and 105° of longitude east of Greenwich. The Gulf of Siam, at the northern extremity of the peninsula, is about 200 miles broad, and 1,000 miles long; the east coast is 900 miles long, and the west coast 1,000 miles long.

The northern boundary of the peninsula is the eastern coast of Siam, the southern boundary is the west coast of French Indo-China, and the eastern boundary is the coast of the South China Sea. The western boundary is formed by the east coast of French Indo-China, and the northern boundary by the west coast of Siam.

The peninsula is about 1,200 miles long from north to south, and 300 miles wide from east to west. It is traversed by the Equator, and there is a great variation in the climate from north to south. The northern part is hot and humid, the southern part cool and moist, and the western part very hot and dry. The east coast is a continuation of the coast of China, and the west coast is a continuation of the coast of India. The east coast is formed of coral, and the west coast of sandstone. The east coast is rocky, and the west coast is sandy. The east coast is low, and the west coast is high. The east coast is rich in fish, and the west coast is rich in minerals. The east coast is inhabited by the Chinese, and the west coast by the Indians. The east coast is not fertile, and the west coast is fertile. The east coast is not well irrigated, and the west coast is well irrigated.
cleft of a split stick. A few stones, which might perhaps be arrowheads, have been found, but they are very rare. The mines, which have been constructed for centuries in the mountainous regions, are not extensive, and argue a high stage of civilization possessed by the ancient miners. They consist of a number of circular or rectangular pits sunk from the cap of a hill, and going down to a depth of 120 ft. until the miners have been stopped by being unable to cope with the quantity of water made when the level of the valley was reached. The shafts are placed so close together that in many instances the old remnants of working quartz lodes are preserved, and at bases a considerable amount of gallery work has been excavated, though it is possible that this was done by miners who came after the people who originally sank the shafts. Native tradition attributes these mines to the Siamese, but no importance can be attached to this.

The importance of the Malayan Peninsula, as has been noted, consisted in the privilege which its locality conferred upon it of being the distributing centre of the spices brought thither from the Moluccas en route for India and Europe. As early as the 3rd century B.C. Megasthenes makes mention of spices brought to the shores of the Ganges from "the southern parts of India," and the trade in question was probably one of the most ancient in the world. So long, however, as India held the monopoly of the clove, the Malayan Peninsula was ignored, the Hindustanese being the exclusive centre of the clove and all other spices. But as soon as the Portuguese gained dominion over the Moluccas, the trade in cloves and other spices, as well as in the more valuable species of mace and nutmeg, was transferred to the peninsula, and the spices were found in Java and elsewhere, whose influence was at one time widespread throughout Malayan lands, and of whose religious teaching remnants still linger in the superstitions of the Malays and are preserved in some purity in Lombok and Bali. In the absence, however, of any relics of a kind which might lead to the identification of the ancient miners, their national origin or origin are matters which must continue to be mere questions of speculation and conjecture.

History.—The first hint to reach Europe concerning the existence of habitable lands to the eastward of the Ganges, is found in the Ptolemaic map of Ptolemy (A.D. 137), which speak of Chryse, or the Golden Isles, as lying off Cape Tamus—supposed to be the most easterly point in Asia—and over against the estuary of the Ganges. Thereafter there occur vague references to Chryse in the Periplus of the Erythrean Sea, &c., but the earliest trace of anything resembling first-hand knowledge concerning the peninsula of Indo-China and Malaya is revealed in the writings of Ptolemy, whose views were mainly derived from those of his predecessor Marinus of Tyre, who in his turn drew his deductions from information supplied to him by the mariner Alexander, who it is stated was present in the sea during the time of the pomegranate flower. The latter may, indeed, have voyaged to the Malay Peninsula and beyond. In the light of present knowledge concerning the trade-routes of Asia, which had been in existence for thousands of years ere ever Europeans attempted to make use of them, it is safe to identify Ptolemy's Sinus Perimulicus with the Gulf of Siam, the Sinus Sabaricus with the Straits of Malacca from their southern portals to the Gulf of Martaban, the Aureus Chersonesus with the Malay Peninsula, and the island of Iapabos or Sababius—the reading of the name is doubtful—with Sumatra, not as has often been mistaken, by way of the Moluccas, but by the shortest route, which, as is reasonable to suppose, was by way of the Moluccas to the Moluccas.

The desire to obtain the monopoly of the spice trade has been a potent force in the formation of the modern world. But the Moluccas were, from the first, the objective of the Portuguese invaders, and no sooner had the white men found their way round the Cape of Good Hope and established themselves successively upon the coast of East Africa, in the neighbourhood of the Gulf of Aden and the Malabar coast, than Malacca, the chief trading centre of the Malayan Archipelago, became the object of their desire. The first Portuguese expedition sent out to capture Malacca was under the command of Diogo Lopez de Siqueira and sailed from Portugal in 1509. At Cochin Siqueira took on board certain adherents of Alphonso d'Albuquerque who were in bad odour with his rival d'Almeida, among them being Magellan, the future circumnavigator of the world, and Francisco Serrão, the first European who ever lived in the Spice Islands. Siqueira's expedition ended in failure, owing partly to the aggressive attitude of the Portuguese, partly to the very justifiable suspicions of the Malays, and he was presently forced to destroy one of his vessels, to leave a number of his men in captivity, and to sail direct for Portugal. In 1510 a second expedition against Malacca was sent out from Portugal under the command of Pedro de Mendez de Vasconcellos, but d'Albuquerque who had retained it at Cochin to aid him in the retaking of Goa, and it was not until 1511 that the great viceroy could spare time to turn his attention to the scene of Siqueira's failure. After some futile negotiations, which had for their object the recovery of the Portuguese captives before hostilities should begin, an assault was delivered upon Malacca, and though the first attempt to take the city failed after some hard fighting, a second assault made some days later succeeded, and Malacca passed for ever into European hands. The Portuguese were satisfied with the possession of the outer coats of the Moluccas, and devoted their energies to the establishment of their empire in Malaya. Instead they used every endeavour to establish friendly relations with the rulers of all the neighbouring kingdoms, and before d'Albuquerque returned to India he despatched embassies to China, Siam, and several kingdoms of Sumatra, and sent a small fleet, with orders to assume a highly conciliatory attitude toward all natives, in search of the Moluccas. Very soon the spice trade had become a Portuguese monopoly, and Malacca was the great headquarters of the trade. It should be remembered that Magellan's famous expedition was not for the object not the barren feat of circumnavigation but the breaking down of this monopoly, without violating the terms of the papal bull which gave to Spain the conquest of the West, to Portugal the possession of the East. In 1528 a French expedition sailed from Dieppe, penetrated as far as Achin in Sumatra, but returned without reaching the Malay Peninsula. It was,
however, the first attempt ever made to defy the papal bull. In 1591, three years after the defeat of the Armada, Raymond and Lancaster rounded the Cape, and after cruising off Penang, decided to winter in Achin. They subsequently hid among the Pulau Sambilan near the mouth of the Perak river, and thence captured a large Portuguese vessel which was sailing from Malacca in company with two Burmese ships. In 1593 the first Dutch expedition sailed from the Texel, but it took a more southerly course than its predecessors and confined its operations to Java and the neighbouring islands. During this period Achin developed a determined enmity to the Portuguese, and more than one attempt was made to drive the strangers from Malacca. Eventually, in 1641, a joint attack was made by the Achinese and the Dutch, but the latter, not the people of the sturdy little Sumatran kingdom, became the owners of the coveted port. Malacca was taken from the Dutch by the British in 1795; was restored to the latter in 1818; but in 1824 was exchanged for Benkulen and a few more unimportant places in Sumatra. The first British factory in the peninsula was established in the native state of Penati on the east coast in 1613, the place having been used by the Portuguese in the 16th century for a similar purpose; but the enterprise came to an untimely end in 1620 when Captain Jourdain, the first president, was killed in a naval engagement in Patani Roads by the Dutch. Penang was purchased from Kedah in 1786, and Singapore from the then sultan of Johor in 1819. The Straits Settlements—Singapore, Malacca and Penang—were ruled from India until 1867, when they were erected into a crown colony under the charge of the Colonial Office. In 1874 the Malay state of Perak was placed under British protection by a treaty entered into with its sultan; and this eventually led to the inclusion in a British protectorate of the neighbouring Malay States of Selangor, Sungei Ujong, the cluster of small states called the Negri Sembilan and Pahang, which now form the Federated Malay States. By a treaty made between Great Britain and Siam in 1902 the northern Malay states of the peninsula were admitted to lie within the Siamese sphere of influence, but by a treaty of 1909 Siam ceded her suzerainty rights over the states of Kelantan, Trengganu, Kedah and Perlis to Britain.

Singapore is the political, commercial and administrative headquarters of the colony of the Straits Settlements, and the governor for the time being is ex officio high commissioner of the Federated Malay States, British North Borneo, Sarawak, the Cocos-Keeling and Christmas Islands, and governor of Labuan.

Clifford, Further India (1904); Journal of the Malay Archipelago, Logan (Singapore); Journal of the Straits Branch of the Royal Asiatic Society (Singapore); Journal of the Royal Colonial Institute (London); Clifford in the Journal of the Royal Geographical Society (London). (H. Ct.)

MALAYS, the name given by Europeans to the people calling themselves Orang Malaya, i.e. Malay folk, who are the dominant race of the Malay Peninsula and of the Malay Archipelago. Broadly speaking, all the brown races which inhabit the portion of Asia south of Siam and Indo-China, and the islands from the Philippines to Java, and from Sumatra to Timor, may be described as belonging to the Malay family, if the aboriginal tribes, such as the Sakai and Semang in the Malay Peninsula, the Batakas in Sumatra, and the Muruts in Borneo, be excepted. For the purposes of this article, however, only those among these races which bear the name of Orang Malaya, speak the Malay language, and represent the dominant people of the land, can be included under the title of Malays. These people inhabit the whole of the Malay Peninsula to the borders of lower Siam, the islands in the vicinity of the mainland, the shores of Sumatra and some portions of the interior of that island, Sarawak and Brunei in Borneo, and some parts of Dutch Borneo, Batavia and certain districts in Java, and some of the smaller islands of the archipelago. Though in these lands they have for not less than a thousand years enjoyed the position of the dominant race, they all possess a tradition that they are not indigenous, and that their first rulers "came out of the sea," with a large band of Malay warriors in their train. In the peninsula especially, where the presence of the Malays is more recent than elsewhere, many traditions exist which point to a comparatively recent occupation of the country. It has been remarked that there is evidence that the Malays had attained to a certain stage of civilization before ever they set foot in Malaya. For instance, the names which they give to certain fruits, such as the durian-an, the rambut-an and the pulas-an, which are indigenous in the Malay countries, and are not found elsewhere, are all compound words meaning respectively the thorny, the hairy and the twisted fruit. These words are formed by the addition of the substantial affix "-an," the use of which is one of the recognized methods by which the Malays turn primitive words into terms of more complex meaning. This may be taken to indicate that when first the Malays became acquainted with the fruits which are indigenous in Malay lands they already possessed a language in which most primary words were represented, and also that their tongue had attained to a stage of development which provided for the formation of compound words by a system sanctioned by custom and the same linguistic instinct which causes a Malay to-day to form similar compounds from European and other foreign roots. For any aboriginal race inhabiting these countries, such important articles of diet as the duri-an, &c., could not fail to be among the first natural objects to receive a name, and thus we find primary terms in use among the Sakal and Semang, the aborigines of the Peninsula, to describe these fruits. The use by the Malays of artificially constructed terms to denote these things may certainly be taken to strengthen the opinion that the Malays arrived in the lands they now inhabit at a comparatively late period in their history, and at a time when they had developed considerably from the original state of primitive man.

In the Malay Peninsula itself there is abundant evidence, ethnological and philological, of at least two distinct immigrations of people from the Malay stock, the earlier incursions, it is probable, taking place from the eastern archipelago to the south, the later invasion spreading across the Straits of Malacca from Sumatra at a comparatively recent date. The fact that the semi-wild tribes, which are ethnologically Malay and distinct from the aboriginal Semang and Sakai, are met with almost invariably in the neighbourhood of the coast would seem to indicate that they reached the peninsula by a sea, not by a land route, a supposition which is strengthened by their almost amphibious habits. Many of these tribes have retained their pristine paganism, but many others it is certain have adopted the Mahommedan religion and have been assimilated by the subsequent and stronger wave of Sumatran immigrants. A study of the local dialects to be met with in some of the districts of the far interior, e.g. the Tembeling valley in Pahang, whose inhabitants now Malayanize and who claim descent both from the Mongol stock— that is to say, from the north. In the fifth edition of his Malay Archipelago, A. R. Wallace notes the resemblance which he traced between the Malays and the Mongolians, and others have recorded similar observations as to the physical appearance of the two races. To-day, however, fuller data are available than when Wallace wrote, and the more generally accepted theory is that the Malay race is distinct, and came from the south, until it was stayed by the Mongolian races living on the mainland of southern Asia. The cranial

measurements of the Malays and an examination of their hair sections seem to bear out the theory that they are distinct from the Mongolian races. Their language, which is neither monosyllabic nor tonic, has nothing in common with that of the Mon-Annam group. It has, moreover, been pointed out that had the Malays been driven southwards by the stranger races of the mainland of Asia, it might be expected that the people inhabiting the country nearest to the border between Siam and Malaya would belong to the Malayan and not to the Mon-Annam or Mon-Khmer stock. As a matter of fact the Sakai of the interior of the peninsula belong to the latter race. It might also be anticipated, were the theory of a southward immigration to be sustained, that the Malays would be new-comers in the islands of the archipelago, and have their oldest settlements on the Malayan Peninsula. The facts, however, are in exact contradiction to this; and accordingly the theory now most generally held by those who have studied the question is that the Malays form a distinct race, and had their original home in the south. Where this home lay it is not easy to say, but the facts recorded by many writers as to the resemblance between the Polynesian and the Malay races, and the strong Malayan element found in the languages of the former (see Trevelyon's Maori and Comparative Polynesian Dictionary, London, 1891), have led some students to think that the two races may have had a common origin.

John Crawfurd, in the Dissertation to his Dictionary of the Malay Language, published in 1830, noted the prevalence of Malayan terms in the Polynesian languages, and attributed the fact to the Malayan wars being waged by the aboriginal tribes of the Polynesian Archipelago. The appearance of the same Malayan words in localities so widely separated from each other, however, cannot be satisfactorily accounted for by any such explanation, and the theory is now more generally held that the two races are probably allied and may at some remote period of history have shared a common home. It has been suggested that their separation did not take place until after the continent, which once existed in the north Pacific had become submerged, and that the Malays wandered northward, while the Polynesian race spread itself over the islands of the southern archipelago.

All this, however, must necessarily be of the nature of the purest speculation, and the only facts which we are able to deduce in the present state of our knowledge of the subject may be summed up as follows: (a) That the Malays ethnologically belong to a race which is allied to the Polynesians; (b) that the theory formerly current to the effect that the Sakai and other similar races of the peninsula and archipelago belonged to the Malayan stock cannot be maintained, since recent investigations tend to identify them with the Mon-Annam or Mon-Khmer family of races; (c) that the Sakai are evidently somewhat of Malay origin, and have settled in the lands in which they now inhabit; (d) that it is almost certain that their emigration took place from the south; and (e) that, at some remote period of their history, they came into close contact with the Polynesian race, probably before its dispersion over the extensive area in which it now occupies.

Religion and superstitious worship.

The Malays to-day are Sunni Mahomedans of the school of Shafi'i, and they habitually use the terms Orang Malays, i.e., a Malay, and Orang H提倡, i.e., a Mahommedan, as synonymous expressions. Their conversion from paganism took place during the 13th, 14th, and 15th centuries of our era. Before that time, in a manner characteristic of the Far East, the Malay people had long been converted as early as 1200, when the Bugis people in Celebes, are supposed not to have become Mahomedans until 1495. Mahomedanism undoubtedly spread to the Malays of the peninsula from Sumatra, but their conversion was slow and gradual, and may even now in some respects be regarded as imperfect. Upon the bulk of the Malayans their religion sits but lightly. Few are found to cling fast to it, while the rest, either from the weakness of their faith or a desire to put in an appearance at the Friday congregational services in the mosques. The Fast of Ramadhan, however, is generally observed with some faithfulness. Compared with other Mahomedans perhaps the Malayans are not favorably disposed to break against those of a different creed is glorified by them into a holy war. The reason of such outbreaks, however, is usually to be found in political rather than religious motives, and the chief result is to show the world that in religious matters the Malays have submitted to a considerable Hindu influence, which reached them by means of the traders who visited the archipelago from India. In

the islands of Bali and Lombok the people still profess a form of Hinduism, and Hindu remains are to be found in many other parts of the Malayan Peninsula, though their traces do not extend to the peninsula. Throughout, however, there is a remarkable absence of the colored caste distinctions, and the religious wars which occur in other parts of the East. The only two serious outbreaks were in the days when the Malaya professed only their natural religion, and is to be found firmly rooted in the minds of the people, and the influence of Mahomedanism, which appears to imitate other world-views such as Buddhism, and to eradicate this. Mr. W. S. Skeat's Malay Magic (London, 1900) is a compilation of all the writings on the subject of Malay superstitions by authoritative men of the most considerate original material.

The Malays of the coast are a maritime people, and are well famous for the daring character of their acts of piracy. They are now no seafaring, fisher-folk, who show considerable ingenuity in their craft, but rather men and women natives who prefer the banks of rivers, building houses on piles some feet from the ground, and planting groves of coco-nut, betel-nut, sugar-palm, and trees around their dwellings. Behind their villages the rice-fields usually spread, and rice, which is the staple food of the people, is the principal article of agriculture among them. Sugar-cane, maize, tapioca and other similar products are grown, however, in smaller quantities. In planting rice three methods are in use: the cultivation of swamp-rice in irrigated fields; the planting of ploughed areas; and the planting of hill-rice by sowing each grain separately in holes bored for the purpose.

In the cultivated area the young shoots planted in the open ground are transplanted when they have reached a certain stage of development. The Malays also work jungle produce, and they have in common with the most important hardwoods, the beautiful kampong wood, which is used by the natives for the hilt of their weapons. The principal manufactures of the Malays are cotton and silk cloths, earthenware and silver vessels, mats and native weavings. The best cotton cloths are produced by the Bugis people in Celebes, and the batik cloths which come from Java and are stamped with patterns. The best silks produced by the natives of Malaya are found in the Malay Peninsula. Lord Leighton pronounced the silver wire from Malaya to be the most artistic of any exhibited at the Colonial Exhibition held in London in 1886. The pottery of the Malays is also very curious, and well worthy of notice. The Archipelago, the Malayan peoples have acquired the art of manufacturing gunpowder and forging cannon. The art of writing also appears to have been independently invented by the Malayan races, since numerous alphabets are in use among the people of the archipelago, although for the writing of Malay itself the Arabic character has been adopted for some hundreds of years. The Malays are excellent boat-builders.

While the Malays were famous almost exclusively for their practical expeditions they naturally bore an evil reputation among Europeans, but now that we have come into close contact with them, we learn to regard them better, the old opinions concerning them have been greatly modified. They used to be described as the most cruel and treacherous people in the world, and they certainly are callous, cruel and treacherous, but they are also suffering a lot and are the victims of the world. In ordinary circumstances, however, the Malay is not treacherous, and there are instances where he has been forced to risk his life in order to save his own lives on behalf of Europeans who chanced to be their friends. As a race they are exceedingly courteous and self-respecting. Their own code of manners is minute and strict, and they observe its provisions faithfully. Unlike many Orientals, the Malays can be treated with a friendly familiarity without such treatment breeding lack of respect or leading to liberties being taken with the superior. The Malays are indolent, pleasure-loving, imprudent, without belief, fond of bright clothing, comfort of ease, and they dislike toil exceedingly. They have no idea of the value of money, and little notion of honesty where money is concerned. They would always rather fail in commerce, in trade, the arts of war, in every way, and even in agriculture, in order to adopt the former course. They will frequently refuse to work for a wage when they must stand in need of cash, and yet at the invitation of one who is their friend they will toil unremittingly without thought of reward. They are much addicted to gambling, and formerly were much given to fighting, though they never display that passion for war in the abstract which is characteristic of the Chinese. Their fighting is based on personal relations, and is high if judged by European standards. It is notorious, however, on the coasts that a Malay gang on board a ship invariably gets the better of any fight which may arise between it and the Chinese crew. The Malay, however, is not a fighting race, and his mission is common in consequence. Polygamy, though allowed by their religion, is practised for the most part among the wealthy classes only. The Malay woman is generally loyal and marvellously loyal to her rajah and her chief. Their respect for rank is not marred by any vulgarity or snobbishness. The ruling classes among them display all the vices of the lower classes, and few of the
virtues except that of courtesy. They are for the most part, when left to their own resources, cruel, unjust, selfish and improvident.

In the 17th century they cut one another's ears, and in the last century, in some country near the borders of Borneo, Man, a general mania called amok (amoh), which word in the vernacular means to attack. It was formerly believed that these outbursts were to be attributed to madness par excellence, and some cases of it have been described as demoniacal, but whatever the case may be, in any sense typical, and might equally have been perpetrated by men of another race.

The typical amok is usually the result of circumstances which render a Man, Arab, Chinese, or even a native, desperate. It is a freak of the imagination of a European, but to the Malay it is sufficient to make him weary of life and anxious to court death. Briefly, where a man of another race might not improbably commit suicide, a Malay runs amok.

The nervous affliction called latah, to which many Malays are subject, is also a curious trait of the people. The victims of this affliction lose the faculty of controlling their bodily movements, and are liable to being the actions of any person who chances to rivet their attention. Accounts of these manifestations will be found in Swettenham's Malay Sketches (London, 1852) and Clifford's Studies in Brown Humanity (London, 1857).

The Malay has a loose coat and trousers, and a cap or headkerchief, but the characteristic item of their costume is the sarong, a silk or cotton cloth about two yards long, five feet wide, made with a selvedge and a border, forming a kind of skirt. This is wound round the waist, folded in a knot, the women allowing it to fall to the ankle, the men generally drawing it tight. It is so short and so loose that it affords no protection against the heat. The actions of any person who chances to rivet their attention.

Costume. The Malay has a loose coat and trousers, and a cap or headkerchief, but the characteristic item of their costume is the sarong, a silk or cotton cloth about two yards long, five feet wide, made with a selvedge and a border, forming a kind of skirt. This is wound round the waist, folded in a knot, the women allowing it to fall to the ankle, the men generally drawing it tight. It is so short and so loose that it affords no protection against the heat. The actions of any person who chances to rivet their attention.

The Malay language is a member of the Malayan section of the Malay-Polynesian class of languages, but it is by no means a representative type of the section which has taken its name from it. The area over which it is spoken comprises the peninsula of Malacca with the adjacent islands (the Rhio-Lingga Archipelago), the greater part of the coast districts of Sumatra and Borneo, the seaports of Java, the Sunda and Banda Islands. It is the general medium of communication on the archipelago of the easternmost parts of the Philippine Islands, and it was so widespread of three hundred and fifty years ago when the Portuguese first appeared in those parts. There are no Malay manuscripts extant, no monumental records with inscriptions in Malay, dating from before the spreading of Islam in the archipelago, about the end of the 13th century. By some it has been argued from this fact that the Malays possessed no kind of writing previous to the advent of the Moslems. Among the Malayans, and especially among the South Celebes, the Arabic alphabet (W. Robinson, J. J. de Hollander): whereas others have maintained, with greater show of probability, that the Malays were in possession of an ancient alphabet, and that it was the same as the Rechag (Malay language) all-which alphabets, with the Battak, Bugi and Macassar, are ultimately traceable to the ancient Cambodian characters. With the Mahomedan conquest, the Arabic alphabet became as familiar to the Malays as that of Borneo, and it has continued ever since to be used for literary, religious and business purposes. Where Javanese is the principal language, Malay is sometimes found written with Javanese characters; and in Palembang, in the Ménangka, country of Middle Sumatra, the Rechag or Renchong characters are in general use, so called from the sharp and pointed knife with which they are written, a practice adopted by the Dutch, but since the Dutch have established their supremacy in the archipelago that the Roman character has come to be largely used in writing, and now in most places.

By the simplicity of its phonetic elements, the regularity of its grammatical structure, and the copiousness of its national vocabulary, the Malay language is singularly well fitted to be the lingua franca of the islands of the Archipelago. It has the advantage of being a simple and easy language, the vowels a, i, e, o, both short and long, and one pure diphthong, eu. Its consonants are k, ng, ng, ch, j, l, d, n, b, m, s, t, r, w, h, s. Long vowels can only occur in open syllables. All the sounds except possible in the name of a naval mutiny, a liquid and mute and vice versa, and a liquid and nasal. Final k and h are all but suppressed in the utterance. Purely Arabic terminologies are avoided; a great many words have been received into the Malay vocabulary. But the Arabic character is even less suited to Malay than to the other Eastern languages on which it has been foisted. As the short vowels are not marked, one would, in seeing, e.g. the word benteng, think first of binden, a star; but the word might also mean a large scar, to throw down, to spread, rigid, mutilated, enceinte, a kind of cucumber, a redoubt, as it is pronounced, bantling, banting, bentang, benting, bunting, bunting, bunting, benteng, bening.

Malay is essentially, with few exceptions, a dissyllabic language, and the syllabic accent rests on the penultimate unless that syllable is the penultimate short; in the latter cases the accent falls on the penultimate. Nothing in the form of a root word indicates the grammatical category to which it belongs; thus, kasa, kindness, affectionate, to love; gani, a proxy, to exchange, instead of the, such as only in derivations, with an added suffix is added. Derivatives are formed by infixes, prefixes, affixes and reduplication. Infixes occur more rarely in Malay than in the cognate tongues. Examples are—
tertaut, a term denoting a small white fish, and others, to point, tenunjuk, the forefinger; chééhuck, to pierce, cherichuck, a stockade. The import of the prefixes—mé (meng, men, mèn, mèn), pé (pêng, pên, pêm), bér (bérél, bér, pèr, pèl, kà, dî, tèr, —and infixes—an, kan, làh—will best appear from the following examples—root word adjar, to teach, to learn; mengadjar, to instruct (express an action); bédjar, to study (state or condition); mengajjar, to instruct (expression of causative); pèlajjar, the instructor; pèlajjar, the learner; pêngadjar, the lesson taught, also the school; pêljadjar, the lesson learnt; didjar, to be learnt; tirêljar, learn; tirêljar, taught; tirêljar, instructed; péla, from rîj, prince, to recognize as prince; pérajjar, to crown; as prince; karejjar, royalty; ajjar, teach! Examples of reduplication are—adjar-adjar, a painted person; adjar-bérjar (or bérjar), to learn and teaching by turns; similarly there are forms like adjar-menadjjar, bérjar-ajjar, menadjjar, menpařjaran, menpêljjar, menparjar, têrlêljjaran, perêljjar, têrlêljjar, etc. Altogether there are upwards of a hundred possible derivable forms, in Malay there is one important word which is derivable in the same way. Even the Romance languages are especially H. von Duyvall, De vormenveranderingen der Maleise taal (Batavia, 1864) and Pijnappel, Maleische-Hollandsche Woordenboek (Amsterdam, 1875), "Inleding;" in every other respect the language is practically differentiated from the Romance and the Semitic. Malay, however, has no infusion to distinguish number, gender or case. Nothing is never indicated when the sense is obvious or can be gathered from the context; otherwise the expression is either singular or plural. There are seven cases, siga, all, and, baiàh, many; rarely by the repetition of the noun, and the indefinite singular by sa or sóù, one, with a class-word. Gender may, if necessary, be distinguished by the words laki-laki, male, and peramfama, female, in the case of persons, and of jagor and bêta in the case of animals. The genitive case is generally indicated by the position of the word after its governing noun. Also adjectives and demonstrative pronouns have their places after the noun. Comparison is effected by the use of particles. Instead of the full and abbreviated forms, conventional nouns are in frequent use to indicate the social position or occupation of the person. Some of the personal pronouns, especially that of the master's slave, i.e. 1. These nouns vary according to the different localities. Another peculiarity of Malay (and likewise of Chinese, Shan, Talang, Burmese and Siamese) is the use of certain class-words or coefficients with nouns, such as orang (man), when speaking of persons, ector (tail) of animals, koping (piece) of flat things, bi (seed) of roundish things; e.g. Buna bi, chér, live eggs. The number of these class-words is considerable. Malay has three particles, a, one person or number nor mood or tense. The last two are sometimes indicated by particles or auxiliary verbs; but these are generally dispensed with if the meaning is sufficiently plain without them. The above is a list of the main rules by which the order of the words in a sentence is regulated—subject, verb, object; and qualifying words follow those which they qualify. This is the case in all the Eastern languages.

The history of the Malays amply accounts for the number and variety of foreign ingredients in their language. Hindus appear to have settled in Sumatra and Java as early as the 4th century of our era, and to have continued to exercise sway over the native
populations for many centuries. These received from them their language a very large number of Sanskrit terms, from which we can infer the nature of the civilization influence imparted by the Hindu rulers. Not only in words concerning commerce and agriculture, but also in religious and other matters, which have no religious influence traceable to the Malay, in particular. In the various aspects of certain ideas, it is requisite to employ also the most appropriate term suited to the particular aspect. In Maxwell's Manual, pp. 120 seq., no less than sixteen terms are given to express the different kinds of, as many for the different kinds of speaking, eighteen for the various modes of carrying, &c. An unnecessary distinction has been made between High Malay and Low Malay. The latter is no separate dialect at all, but a mere brogue or jargon, the words of which, once taught to the natives whose use is too indolent to apply themselves to the acquisition of the language of the people; its vocabulary is made up of Malay words, with a comparatively small number of words from other languages not only in different localities, but also in proportion to the individual speaker's acquaintance with Malay proper. A few words are used, however, only in speaking with persons of royal rank—e.g. suman, a产生 at the head of the phrase; brada, to die; of tido; grung, unwell, instead of sakti; mongkat, to die, instead of mali, &c. The use is different as regards the term Jawi as applied to the Malay language. This has become the standard Great Java and Lesser Java, by which the medieval Java and Sumatra were called, and it accordingly means the language spoken along the coasts of the two great islands.

The Malays cannot, strictly speaking, be said to possess a literature, for none of their writings can boast any literary beauty or value.

Literature. Their most characteristic literature is to be found, not in their writings, but in the folk-tales which are transmitted orally by generation to generation. The most popular of the wandering minstrels called by the people Pèng-Ipô̌r Lârâ, i.e. "Soothers of Care." Some specimens of these are to be found in the Journal of the Straits Branch of the Asiatic Society (Singapore). The collection of Malay Proverbs made by Klinkert, Maxwell and Clifford also give a good idea of the literary methods of the Malays. Their verse is of a very primitive description, and is chiefly used for purposes of love-making. There are numerous rhymed fairy tales, which are much liked by the people, but they are of no literary merit. The best Malay books are the Hikayat Hang Tâsk, Béstâmam and the Hikayat Malakan. The latter is a narrative of events kept during Sir Stamford Raffles's administration by his Malay scribe.

MALAY STATES

(BRITISH). The native states of the Malay Peninsula under British protection are divided into two groups: (I) federated, and (II) non-federated.

I.—FEDERATED STATES

The federated states, under the protection of Great Britain, but not British possessions, are Perak, Selangor and the confederation of small states known as the Negri Sembilan (i.e. Nine States) on the west coast, and the state of Pahang on the east coast. Each state is under the rule of a sultan, who is assisted in his legislative duties by a state council, upon which the resident, and in some cases the secretaries to the resident, has a seat, and which is composed of native chiefs and, or more Chinese members nominated by the sultan with the advice and consent of the resident. The council, in addition to legislative and other duties, revises all sentences of capital punishment. The administrative work of each state is carried on by the resident and his staff of European officials, whose ranks are recruited by successful candidates in the competitive examinations held annually by the Civil Service commissioners. The sultan of each state is bound by treaty with the British government to accept the advice of the resident, who is thus practically paramount; but great deference is paid to the opinions and wishes of the sultans and their chiefs, and the British officials are pledged merely to interfere with the religious affairs of the Mahomedan community. In the actual administration of the Malay population great use is made of the native aristocratic system, the peasants being governed largely by their own chiefs, headmen and village elders, under the close supervision of British district officers. The result is a benevolent autocracy admirably adapted to local conditions and to the character and traditions of the people. A recognition of the fact that the welfare of the Malays, who are the people of the land, and the labours which they have been led to expend in developing their territories to the British, must be regarded as the first condition of their prosperity. This has been the guiding principle of the administration of the Malay States, and this has resulted in an extraordinary amelioration of the condition of the natives, which has proceeded concurrently with a notable development of the country and its resources, mineral and agricultural. To the work of development, however, the Malays have themselves contributed little, sound administration having been secured by the British officials, enterprise and capital having been supplied mainly by the Chinese and the large plantations, being almost entirely Chinese or Tamil. Meanwhile the Malays have been able to retain their holdings, have enjoyed a peace and a security to which their past history furnishes no parallel, have obtained easy access to new and important markets for their agricultural produce, and for the rest have been suffered to lead the lives best suited to their characters and their desires. Each principal department of the administration has its federal head, and all the residents correspond with and are controlled by the resident-general, who, in his turn, is responsible to the high commissioner, the governor of the Straits Settlements.

The estimated aggregate area of the Federated Malay States is 28,000 sq. m., and the estimated population in 1905 was 860,000, as against 780,000 in 1901. Of these only about 230,000 are Malays. The population of the federation in 1905 was $23,500,000 (about £7,500,000), and the assessed direct revenue was £1,027,000. The imports for the same year were valued at $80,575,455 (about £5,000,000), and the exports at $80,547,654 (about £9,400,000), making a total trade of nearly 14,000 million sterling. The principal sources of revenue are an export duty on tin, the rents paid for the revenue farms of the right to collect import duties on opium, wine and spirits, and to keep licensed gambling-houses for the exclusive use of the Chinese population, railway receipts, land and forest revenue and postal revenue. The tin is won from large alluvial deposits found in the states of the western seaboard, and the mines are worked by Chinese, who are extensively buying up the land. The Federated Malay States have produced considerably more than half the tin of the world. Recently there has been a great development in agricultural enterprise, especially with regard to rubber, which is now grown in large quantities, the states being mainly in the hands of Europeans, and the labour mostly Tamil. The states are opened up by over 2,500 m. of some of the best metalled cart-roads in the world, forming a railway system, 350 m. of which, extending from the mainland opposite Penang Arms to the ancient capital, has been put in working order by local effort and by British railways, &c., being constructed entirely from current balances. This of course has only been rendered possible by the extraordinary mineral wealth which the states on the western seaboard have
developed in the hands of Chinese miners amid the peace and security which British rule has brought to these once lawless lands. The value of the tin output for the year 1905 amounted to £69,450,993 (£90,000,000, as stated by the State Council). Great Britain is assuming considerable proportions and a growing importance, the total value of the principal agricultural products, including time, is estimated at £19,150,242. The whole of the Malay Peninsula is one vast forest, through which flow countless streams that form one of the most lavish water supplies in the world. The rivers, though many of them are of insufficient head and consequently shallow, only a few on the west coast being navigable by ships for a distance of some 40 m. from their mouths. In spite of the notable development above referred to, only a very small portion of the productive forest region has hitherto been touched either by rubber or agricultural enterprise. It is too much to assert that the larger half of the forest-lands has never been trodden by the foot of man, and the natives who have been the only inhabitants of Malaya states (known as Malacca Peninsula). For the ethnology see MALAYS. Perak is situated between the parallels 3° 37' and 6° 5' N. and 100° 3' to 101° 5' E. on the western side of the Malacca Peninsula. It is bounded on the N. by the British possession of Province Wellesley and the Malay state of Kelantan; on the S. by the protected native state of Selangor; on the E. by the protected native state of Pahang and the independent states of Kelantan and Perak; and on the W. by the Straits of Malacca.

The coast-line is about 90 m. in length. The extreme distance from the north-most to the south-ernmost portions of the state is about 172 m., and the greatest breadth from east to west is about 100 m. The total area of the country is estimated at about 10,000 sq. m.

The Perak river, which runs in a southerly direction almost parallel with the coast for nearly 150 m. of its course, is navigable for small steamers for about 40 m. from its mouth, and by native trading boats for nearly 200 m. The Piu, Batang, Padang and Kinta rivers are its principal tributaries, all of them falling into the Perak near the left bank. The other principal rivers of the state are the Krian, Kurau, Larut and Brus to the north of the mouth of the Perak, and the Bernam to the south. None of these rivers is of any great importance. The Perak river, with much water, is navigable for small steamers for nearly 100 m. of its course. The mountain ranges, which cover a considerable area, run from the north-east to the south-west. The highest altitudes attained by them do not exceed 750 ft., but they average about 250 ft. They are all thickly covered with jungle. The ranges are two, running parallel to one another, with the valley of the Perak between them. The larger is a portion of the Malayan range that extends from the left bank.

Geology. The granite rocks; secondly, a large series of beds of gneiss, quartzite, schist and sandstone, overlaid in many places by thick beds of crystalline limestone; thirdly, small sheets of trap rock; and fourthly, river-gravels and other Quaternary deposits. The granites are of many varieties, and also, in all probability, of several different geological periods. The series of quartzites, schists, and limestone are of great age, but as no fossils have ever been found in any of them, nothing definite can be stated as to their exactly chronological position. Their lithological characteristics and the total absence of any marine remains suggests an oldness. The failure to discover signs of life in them is, of course, merely negative evidence, and the finding of a single fossil would at once upset this theory. But, until this happens they may be conveniently classed as Laurentian. It is at present impossible to form anything approximating an accurate estimate of the thickness of this extensive series, but it is probable that it is somewhere between 4000 and 5000 ft. Unconformity has been noticed between the limestones and the beds beneath them, but whether this is sufficient to separate them or not is a matter for future investigation. The taller hills are composed of monzonite (gabbro), while the basaltic rocks are the most important, especially those on the southern side. The ores of the following metals have been found in the formations named: Granite—tin, lead, iron, arsenic, tungsten and titanium; Laurentian—tin, gold, lead, silver, iron, arsenic, copper, zinc, and antimony; Gneiss—tin, lead, iron, and gold; copper, tungsten, iron and titanium. This is not to be considered a complete list, as small quantities of other metals have also been discovered.

The early history of Perak is obscure, the only information on the subject being obtained from native traditions, which are altogether untrustworthy. According to these authorities, however, a settlement was first made by Malays in Perak at Brus, and the capital was later moved to the banks of the Perak River, the site chosen being a little village called Temonggoh, which lies some miles up the river from the mouth. The name of the district is the corruption of that of the sultan. When the Malacca sultanate fell, owing to the invasion of the Portuguese in 1511, a member of that royal house is said to have fled to Perak, where he established himself. The Malaya states are descended from him. As this boast is also made by almost every ruling family in the peninsula, the tradition is not worthy of any special attention. What is more certain is the tradition that Perak was brought to the Mohammedans, and, in the 17th century, to the Dutch. The Dutch were driven out of the state in 1783, though it was afterwards recouped, the Dutch being finally ejected by the British in 1795. In 1818 the British succeeded in conquering the state, and it was brought under a treaty by the British and Siamese governments in 1824. From that date until 1874 Perak was ruled by its own sultans, but in that year, owing to internal strife, Sultan Abdullah applied to the then governor of the Straits Settlements, Sir Andrew Clarke, for the assistance of a British Resident. The treaty of Pangkor was concluded on the 20th of January 1874, and the first resident, Sir Andrew Clarke, was appointed on the 2nd of November 1875. A punitive expedition became necessary; Sultan Abdullah and the other chiefs concerned in the murder were banished, the actual murderers were hanged, and Raja Musa Jusuf was declared regent. He died in 1888, and was succeeded by his son, who took the title of Sultan Mansur Abd. W. G. C., a most enlightened ruler, who was from the first a strong and intelligent advocate of British methods of administration. Sir Hugh Low was appointed resident, a position which he held until 1889; he was succeeded by Sir Edward Pococke, who became the first Resident of the state. The British policy in Perak has been one of continuous peace and growing prosperity and wealth. Although the federal capital is Kuala Lumpur in Selangor, the capital of Perak still enjoys the honour of being the senior and leading state of the federation.

By the census taken on the 5th of April 1891 the population of Perak was shown to be as follows: Europeans, 366; Eurasians, 293; Jews, 96; Chinese, 719; Population. 94,345; Tamils, 13,086; aborigines, 5779; other native races, 3666; thus making a grand total of 214,254, of whom 156,404 were males, 57,850 females. The estimated population at 1905 was 400,000, of whom 200,000 were Chinese, and 160,000 were Malays, but owing to the disparity of the proportions between the sexes the deaths in each year largely outnumbers the births, and the increase in the population is accounted for solely by the number of immigrants, chiefly from the mainland of China, and to a lesser extent from India also.

The revenue of Perak in 1874 amounted to $226,333. That for 1905 amounted to £124,887. Of this latter sum £76,400 was derived from duty on exported tin, £2,489,300 from railway grants, £505,300 from land revenue and £142,800 from postal and telegraphic communications. The remaining £2,505,000 is derived from various taxes, which are leased to Chinese capitalists for a short term of years, conveying to the lessee the right to collect import duties upon opium, wine and spirits, to keep pawnbroking shops, and to keep public houses. The government's expenditure for 1905 amounted to £10,141,980. Of this sum £4,236,000 was expended upon railway upkeep and construction, and £2,176,000 upon public works. The value of the imports into Perak during 1905 was over £20,000,000, and that of exports exceeded £40,000,000, making a total of over £60,000,000, equivalent to about seven million sterling. The output of tin from Perak ranged between 18,960 tons, valued at £23,000,000 in 1890, and 26,600 tons, valued at £35,500,000, in 1905. The fluctuating character of tin is due, not to any exhaustion of the mineral deposits of the state—that is not to be anticipated for many years yet to come—but to the uncertainty of the mineralizers. The mining population is recruited exclusively from the districts of South China, and during certain years an increased demand for labour from the Indian and Chinese states, and also in South Africa, has been accompanied by a decrease in the numbers of the labourers. The agricultural development of the state is still in its infancy, but rubber is cultivated in rapidly increasing areas, and the known fertility of the soil, the steady and regular rainfall, the good quality of the water, and the rich, nutritious condition of the country, justify the expectation that the future of Perak as an agricultural country will be prosperous.
The area of agricultural holdings has notably increased, but a considerable period must yet elapse before it will amount to even one-quarter of the whole. A line of railway connects the coast with most of Teluk Anson with the great mining district of Kinta, whence the line runs, crossing the Perak River at Eggor, to Kuala Kangsar, the residence of the sultan, thence to Taiping, the administrative capital of the state, and via Krian to the island of Penang. A second line runs south from Perak and connects with the railway system of Selangor, which in its turn connects with the Negri Sembilan and Malacca line, thus giving through railway communication with the last two of the largest and most valuable of the Malay States. It also possesses some 600 miles of excellent modelled cart-road, and the length of completed road is annually increasing.

For administrative purposes the state is divided into six districts: Upper Perak, Kuala Kangsar and Lower Perak; Kinta; Batany Padang and Larut and Krian. Of these, Larut and Kinta are the principal mining centres, while Krian is the most populous of the districts, Larut, which are mostly inhabited by Malays, and Perak, which are chiefly inhabited by Tamils, and Larut and Krian are in a large measure situated within the limits of the various states, is perhaps the most signal token of the changes which British influence has wrought in the peninsula.

Selangor is situated between the parallels 3° 32' and 3° 37' N, and 100° 38' and 101° 2' E., on the western side of the Malayan Peninsula. It is bounded on the north by the protecorate native state of Perak, on the S. by the protected state of the Negri Sembilan, on the E. by Pahang and the Negri Sembilan, and on the W. by the Straits of Malacca. The coast-line is about 100 m. in length, greatest length about 104 m., and greatest breadth about 48 m., total area estimated at about 3000 sq. m.

The state consists of a narrow strip of land between the mountain range which forms the backbone of the peninsula and the Straits of Malacca. Comprised with other states in the peninsula, Selangor is part of the principal tin field of Malaya and produces a considerable proportion of the gold of the Malay States. In 1775 a branch line 27 m. long connects Kuala Lumpur with Port Swettenham on the Klang Straits, which extensive wharves, capable of accommodating ocean-going vessels, have been constructed. A tramway 3 m. long has been opened to traffic. It connects the caves at Batu with Kuala Lumpur. Frequent communication is maintained by steamers between Port Swettenham and Enggor, and other Malayan vessels between the former port and those on the shores of the Straits of Malacca.

All the principal places in the state are connected with one another by telegraph.

The state is divided into six districts: Kuala Lumpur, in which the capital and the principal tinfields are situated; Ulu Selangor, which is also a prosperous mining district; Klang Selangor, which is agricultural, and poorly populated by Malays; Ulu Langat, mining and agricultural; Kuala Langat, the residence of the late sultan Abdul Samad, agricultural; and Klang, the only prosperous port of the state.

Many money has been expended upon the capital, Kuala Lumpur, which possesses some fine public buildings, waterworks, &c., and where the principal residence of the Resident-General is situated. In some sort Kuala Lumpur is the capital not only of Selangor, but also of the whole of the Federated Malay States.

Negri Sembilan (the Nine States) is a federation of small native states which is now treated as a single entity, being under the control of a British Resident, and is situated between parallels 2° 28' and 3° 18' N. and 101° 45' and 102° 45' E., on the western side of the Malayan Peninsula. It is bounded on the N. by the protected state of Pahang, on the S. by the territory of Malacca, on the E. by Pahang and the independent state of Johor, and on the W. by the Straits of Malacca. The coast-line is about 28 m. in length, and the extreme distance from north to south is 53 m., and that from east to west about 65 m. The estimated area is about 9000 sq. m. Port Dickson, or Arang-Arang, is the only port on the coast. It is connected with the capital, Seremban, by a railway 24 m. in length.

Most of the states comprising the federation depend largely for their prosperity upon agriculture, but in some of the districts tin is being worked in considerable quantities, with good results.

As is the case with the history of most Malayan states, much rests upon no surer ground than tradition, in so far as the records of the Negri Sembilan are concerned. At the same time the native story of the rise of the Negri Sembilan is as interesting as it is true. The legend of the federation of the Negri Sembilan is originally probable tribes of the Sakai, or aborigines of the peninsula, who descended from the north through the straits of Malacca. More than 487 miles of coast of the nine states is the scene of much corroborative evidence. Not only does the Malay's contempt for the Sakai make it exceedingly unlikely that the tradition, which they so respectfully and steadfastly guard, is false, but also many instances of force in these states are wholly foreign to the Malay, and can plainly be traced to the aborigines. As an instance, the custom of inheriting rank and property through the mother instead of through the father must be mentioned. Tradition further relates that towards the end of the
18th century a raja of the royal house of Menangkabu came from Sumatra to rule over the federation of small states, each of which continued to be governed in all its local affairs by its own chief and by the village and other councils sanctioned by ancient custom. Sir James Brooke, later known as Rajah Brooke of Sarawak, was the first of the treasurers of the Rajahs of Sarawak.

Although they bore the name of the "Nine States," only six seem to have belonged to the federation during the time of which history speaks. Nine states were formed by the leaders of the Kelantan and Trengganu and Sungei Ujong. Later the two latter separated themselves from the federation. Acceptance says that the names of the nine states were originally Klang, Jelebu, Sungei Ujong, Johol, Segamat, Mampai, Belait, Segamat, and Pasir Besar by Johor, and Naming by Malacca. During the last years of the 18th century the island of Malaya was opened to British control in 1868, and was thenceforth managed by a magistrate under the orders of the Resident of Sungei Ujong. In 1869, when the federation of all the Malayan states under British control was organized, Sir James Brooke, being the hereditary chief of the federation of small states from which they had so long been separated and the whole, under the old name of the Negri Sembilan, or Nine States, was placed under the Resident of the Negri Sembilan. The title of Resident of the Negri Sembilan, which according to the census taken in April 1891 was only 70,730, had increased to 96,028 by 1901, and was estimated at 119,454 in 1905. Of these 46,500 are Chinese, 65,000 Malays, 6,700 Tamils, and 900 Europeans and Eurasians. The births registered since the census were in 1895, to be four births in 1905, and to 2,311,093, of which 1,125,353 was expended upon public works. The trade returns for 1905, which are not, however, complete, show an aggregate value of about $100,000. The value of the tin exported during 1905 exceeded $90,000, and the trade in agricultural produce, of which gambier represented $21,000 and damar $80,000, amounted to $40,000.

The railway system of the Negri Sembilan, connected with Port Dickson by a railway line, owned by the General, Sungei Ujong Railway Company, which is 247 m. in length. It is also situated on the trunk line of the Federated Malay States. The railway extends north and to Malacca on the south. Frequent steam communication is maintained between Port Dickson and the ports on the Straits of Malacca, and with Singapore. The influence of the ancient federal system was revived under the control of a Resident appointed by the government. The states which formed this new confederation were Johol, Ulu Muar, Jempol, Terachi, Inas, Gunong Pasir, Rembau, Tampin, and Gemencheh. Prior to this, in 1873, owing to a civil war in Sungei Ujong, Sir Andrew Clarke sent a military force to that state, put an end to the disturbances, and placed the country under control. At the same time, Wellesley was making British protection in 1868, and was thenceforth managed by a magistrate under the orders of the Resident of Sungei Ujong. In 1895, when the federation of all the Malayan states under British control was organized, Sir James Brooke, being the hereditary chief of the federation of small states from which they had so long been separated and the whole, under the old name of the Negri Sembilan, or Nine States, was placed under the Resident of the Negri Sembilan. The title of Resident of the Negri Sembilan, which according to the census taken in April 1891 was only 70,730, had increased to 96,028 by 1901, and was estimated at 119,454 in 1905. Of these 46,500 are Chinese, 65,000 Malays, 6,700 Tamils, and 900 Europeans and Eurasians. The births registered since the census were in 1895, to be four births in 1905, and to 2,311,093, of which 1,125,353 was expended upon public works. The trade returns for 1905, which are not, however, complete, show an aggregate value of about $100,000. The value of the tin exported during 1905 exceeded $90,000, and the trade in agricultural produce, of which gambier represented $21,000 and damar $80,000, amounted to $40,000.

For administrative purposes the Negri Sembilan is divided into five districts, viz. the Seremban District, the Coast District, Jelebu, Kuala Pilah and Tampin. Each of these is under the charge of a European district officer, who is responsible to the Resident. The Lang-di-per-Tuan lives at Kuala Pilah, but the capital of the federation is at Seremban in Sungei Ujong, where the Resident is stationed. They are the hereditary chiefs of the various states aid in the government of their districts, and have some rights over the land, with which the Lang-di-per-Tuan presides. The watering-place of Magnolia Bay, where excellent sea-bathing is obtainable, is one of the pleasure resorts of this part of the peninsula.

PAHANG, on the east coast of the peninsula, is situated between parallels 2° 28' and 3° 45' N. and 101° 30' and 101° 30' E. It is bounded by the N. by the independent native states of Kelantan and Trengganu; on the S. by the Negri Sembilan and Johor; on the E. by the China Sea; and on the W. by the protected states of Perak and Selangor. The coast-line is about 112 m. in length; the greatest length is about 210 m., and greatest breadth about 130 m. The state is the largest in the peninsula, its area being estimated at 15,000 sq. m. The ports on the coast are the mouths of the Perak, Rompin, Pahang and Kuantan rivers, but during the north-east monsoon, when the coast is easy of approach, and the rivers, all of which are guarded by difficult bars, are impossible of access except at high tides.

The principal river of the state is the Pahang, from which it takes its name. At a distance of 180 m. from the coast this river is formed by two others named respectively the Jelai and the Tembeling. The river, for the greater part, lies at an altitude of 800 ft. above sea-level, and rises in the mountains which form the boundary with Perak. The Jelai itself has its rise also in a more northerly portion of this range, while its two principal tributaries, the Tembeling and the one in the plateau which divides Perak from Pahang, the other in the hills which separate Pahang from Kelantan. The Tembeling has its rise in the hills which separate Pahang from Perak, but its main course is along the left of the Trengganu frontier, while the largest of its confluent rises from the hills in which the Kuantan River takes its rise. The Pahang is navigable for large boats as far as Kuala Lipis, 200 m. from the mouth, at which place it commands two branches. Smaller boats can be taken some 80 m. higher up the Jelai and Tembeling. This river, however, as a waterway is of little use, since it is uniform in width and depth, and its course is somewhat more easily navigated for the first 30 m. of its course, but taken as a whole the waterways of Pahang are of little value. The interior of Pahang is chiefly noted for its auriferous deposits. Gumon Tahan is situated on the boundary between Pahang and Kelantan. Its height is estimated at 8000 ft., above sea-level, but it has never yet been ascended. Pahang, like the states on the west coast, is covered almost entirely by one vast forest, and the land is of a jungle type except for a few patches of mangrove-swamp throughout its entire length.

The ancient name of Pahang was Indrapura. It is mentioned in the history of Hang Tsang, the great Malaca brave, who flourished in the 16th century, and succeeded in abducting a daughter of the sultan of Malaca. To this day the title of sultan of Malaca. Prior to this, Pahang had been ruled by the Siamese. When Malaca fell into the hands of the Portuguese in 1511 the sultan, Muhammad Shah, fled to Pahang, and the present ruling house claimed to have been descended from him. The title of the raja of Pahang was Bendahara until 1882, when the present (1902) ruler, Wan Ahmad, assumed the title of sultan, taking the name Ahmad Shah. Ahmad Shah was ruled by his father, who had on his accession been installed on the sultan's throne, and held his office by virtue of that chief's letter of authority. About 1887 a dispute took place between the sultan of Pahang and the Bendahara Korish, who succeeded him, drove Wan Ahmad from the country. After making three unsuccessful attempts to conquer the land and to dethrone his elder brother, Wan Ahmad at last succeeded in 1885 in invading the state and wresting the throne from his nephew, who had succeeded his father some years earlier. From that time, in spite of two attempts to shake his power by invasions from Selangor which were undertaken by his nephews Wan Ahmad and Wan Ali, and the latter was judged on the latter was judged on a rod of iron. In 1887 he consented to enter into a treaty with the governor of the Straits by which he accepted a consular agent at his courts as the treaty was not signed by the sultan of Malaca. In February of the following year a Chinese British subject was murdered at Pekan in circumstances which pointed to the responsibility of the sultan for the crime, and in October 1888 a Resident was appointed to assist in the administration of the sultanate. In that being, in the opinion of the British government, the only guarantee for the safety of the life and property of British subjects which had been accepted. In December 1891 disturbances broke out in Pahang, the nominal leaders of which were certain of the sultan's most trusted chiefs. The sultan himself took no part in the outbreak, but it undoubtedly had his sympathy, even if it was not caused by his direct commands. The rebels were driven to seek safety in flight in November 1892, but in June 1894 they gathered strength for a second disturbance, and raids Pahang from Kelantan, in which state they had been given shelter by the Mahomedan rulers. As a result of the event, an expedition was sent across the border, led to an irregular expedition being led into Trengganu and Kelantan by the Resident of Pahang (Mr. Hugh Clifford) in 1895, and the rebellion. To the rebels being restored to their former position and that, no further breach of the peace that troubled the tranquility of Pahang since that time. Pahang joined the Federated Malay States by a treaty signed in 1895, and the sultan and his principal chiefs were present at the federal council held at Kuala Kangsar in Perak in 1897.
boundaries are inhabited by Pakhah Malays, the descendants of these fugitives. The Pakhah natives are almost all engaged in agriculture, fishing, and in trade with native Dayaks and foreign Malays. In the Lipis valley the descendants of the Rawa Malays, who at one time possessed the whole of the interior in defiance of the Pakhah rajas, still outnumber the people of the land.

The revenue of Pakhah in 1899 amounted to only $62,077; in 1900 to $410,150. In 1905 it was $528,368. The expenditure in the same year was $575,876. Of this, $111,175 was spent on public works. Pakhah is still a source of expense to the federation, its progress having been retarded by the disturbances which lasted from December 1891 until 1895, when the last of the disturbances nearly all disappeared but the number of paupers here is now steadily increasing, and the ultimate financial success of the state is considered to be secure. Pakhah owes something over $400,000 to the government and $116,436 has been financed on for some years without surplus revenue. The value of the imports in 1905 was $1,344,346, that of the exports was $3,838,928, thus making a total trade value of $5,183,274. The most valuable export is tin, the value of which in 1905 amounted to $2,820,745. The value of the gutta exported exceeded $140,000, that of dried and salted fish amounted to nearly $70,000, and that of timber to $55,000.

The geological formation of the states lying to the eastward of the main range of mountains which splits the peninsula in two differs materially from that of the western states. At Bukit Timah, about a mile from the sea, the mountains the granite formation is replaced by slates, in which many places are intersected by fissures of quartz, and in others are occurring intermediate beds of limestone. Those of the quartz fissures which have been explored are not, as yet, found to be of much value, whereas several mining companies have attempted to work the deposits. Their efforts, however, have not hitherto been successful. A magnifi- cent deposit of manganese, which was discovered in the grade of the quartz, at Kuala Lipis, the administrative capital of Pakhah, to Kuala Kubu, the nearest railway station in Selangor. The road measures 82 m. in length. Pekan, where the sultan has his residence, was the capital of Pakhah until the middle of 1898, when the administrative head- quarters were transferred to the interior as being more central. None of these towns has any size or importance. In the Kuantan valley, which lies parallel to the Pahang River, a European company is working tin lodes with considerable success. These lodes are the only mines of the kind being worked in the Federated Malay States. Pakhah is fertile and well suited for agriculture of many kinds. The rainfall is heavy and regular. The climate is cooler than that of the west coast, and the full force of the monsoon is felt from October to February in each year. For administrative purposes Pakhah is divided into four districts—Ulu Pakhah, in which the present capital is situated; Temerloh, which lies 80 odd miles of the Pahang valley and the Semantan River; Pekan, which includes the coast rivers down to Endau; and Kuantan. Each of these is under the charge of a district officer, who is responsible to the resident. The boundary with Johor and the Negri Sembilan was rectified by a commission which sat in London in 1897-1898.

II.-NON-FEDERATED STATES

In 1909 a treaty was made between Great Britain and Siam, one provision of which was that the cession to the former of the suzerain rights enjoyed by the latter over certain territories in the Malay Peninsula. These territories consisted of the four Siamese Malay States: Kelantan, Trengganu, Kadah and Perlis, very ancient dependencies of Siam, all of which except Trengganu, were in a flourishing condition and had been administered by British officials for the service of Siam. The chiefs, however, were still in their transference. Though the four states were loyal to Siam and wished to retain their former allegiance, the change was effected without disturbance of any kind, the British government on assuming the rights of suzerainty placing an adviser at the court of each raja and guaranteeing the continuance of the administration on the lines already laid down by Siam so far as might be compatible with justice and fair treatment for all. The four states lie to the north of the Federated Malay States, two on the east and two on the west side of the peninsula.

KELANTAN. This state on the east coast, bounded N. and N.E. by the China Sea, E. by Trengganu, S. by Pahang and W. by Perak and Ra-nge, lies between 4° 48' and 6° 20' N. and 101° 33' and 102° 45' E. The greatest length from north to south is 115 m. and the greatest breadth from east to west 60 m. The area is estimated at 1,733 sq. m. The northern part of the state is flat and fertile, but the southern districts are considerably the valuable tin-bearing region of Pahang is in the north of the state, having about 2,000,000 acres. The annual value of minerals is estimated at $50,000,000.

Next to the Pahang, the Kelantan River is the largest on the east coast. It is 120 miles long and is navigable for shallow-draft launches and big country boats for about 80 miles, and for vessels of 8 ft. of draught for about 40 miles. The chief tributaries are the Galas, Pergau and Lebir. The Golok and Semarak rivers water the west and east part of the state, falling into the sea a few miles on either side of the Kelantan River. The climate of Kelantan is mild and singularly healthful in the open cultivated regions. The population is about 50,000, of whom 8,000 are of aboriginal tribes (Sakeis and Jakuns), 10,000 Siamese and Chinese and the rest Malays. The Chinese are increasing and natives of different parts of India are resorting to the state for purposes of trade. Kota Bharu (pop. 10,000) is the only town in the state. It lies on the right bank of the river, about six miles from the sea. Since 1904 it has been linked with the railway which runs along the coast from the town of Butterworth, by telegraph with Bangkok and Singapore, and maintains regular postal communication with those places. Rice cultivation is the principal industry and is increasing rapidly. Cocos and betel-nut growing are also largely practised. Much livestock is raised. About 400,000 acres of land are under cultivation. Though reputed rich in minerals, past failure prevented mining enterprise in Kelantan until, in 1900, a large concession was given to an Englishman and the country was opened to foreigners. In 1909 three mining syndicates were at work, and several others were in process of formation. Gold and galena have been found in several localities and during the years 1906-1908 28,000 lb. of gold and 2,000 lb. of silver ore were dredged from the river. The Kelantanese are expert fishermen, some 30,000 finding employment in fishing and fish-drying. Silk-weaving is a growing industry. Foreign trade, which in 1909 reached the value of two and a half million dollars, is chiefly with Singapore. Principal exports are copra, rice, fish, cattle and gold; chief imports are cotton goods, hardware and specie. The currency is the Straits dollar supplemented by a silver coin, supplemented by a locally made tin coin of low value.

By virtue of a mutual agreement made in 1902 Siam appointed a commissioner to the states of Trengganu, Kelantan and Trenggau. The British government has given the local advice of that officer should be followed, to leave internal affairs to be conducted locally. Under this arrangement a council of state was appointed, departments of government were organized, penal, revenue, civil and police authorities were established, and a police force was raised. Though formerly of an evil reputation, the people were found to be naturally peaceful and law-abiding, and serious crime is rare. The state revenue, which was practically nothing in 1902, amounted to $250,000 in 1907. Islam-
Malay States

KELANTAN, lies between parallels 4° 4' and 4° 46' N., and 103° 30' and 103° 26' E. The greatest length from north to south is 120 m., and the greatest breadth from east to west 50 m., and the coast-line of 130 m. and an estimated area of about 5000 sq. m. There are several islands off the coast, some of which are inhabited. The surface is generally mountainous.

Principal rivers are the Besut, Stiu, Trengganu, Dungun and Kramat, none of which is navigable for any distance. The climate is mild and fairly healthy. The population numbers about 150,000, almost all of which are of Arabian, South Indian and Chinese extraction. The climate is very healthy, and the mountains and lower reaches of the rivers. The capital, which is situated at the mouth of the Trengganu River, contains, with its suburbs, not less than 30,000 people. Difficulty of access is by land and the inhabitants are industrious. Communication is maintained by boat along the coast. There are no roads and no postal or telegraphic communications.

The climate is healthy, and agriculture is carried on by sailors and fishermen. Rice is grown, but not in sufficient quantities to supply local needs. Much pepper and gambier were at one time grown and exported, but about the year 1903 agriculture began to fall off owing to prevailing insecurity of life and property. Not much livestock is raised, the few head of cattle exported from Besut being mostly stolen from across the neighbouring Kelantan border. A successful tin mine under European control exists in the Kandamu district, but as everything possible was done in the past to discourage all foreign enterprise, the probable mineral wealth of the country is still practically untapped. Silk-weaving, carried on entirely by the women, is a considerable industry. The raw materials are sugar-cane and the export of Malayan clothing (sarongs) of patterns and quality which are widely celebrated. The manufacture of native weapons and of brassware was at one time brisk but is declining. The trade of Trengganu is mainly in native produce. The large annual import of one and a half million dollars a year, is chiefly with Singapore, and is to a great extent carried in Trenggany-built ships, which latter also do some carrying trade for other states on the east coast.

The Trengganu sultaneate is one of the most ancient in the peninsula and ranks with that of Riau. The state was feudalatory to Malacca in the 15th century and during the 14th, 15th and 16th centuries its possession was frequently disputed between Malacca and Siam. The present sultan is the descendant of an ancient family, the members of which have quarrelled and fought with each other for the succession. The name of the sultan commemorates an ancient chief who was in 1837 when the grandfather of the present sultan stole the throne from his nephew. Until the acquisition of the state by Great Britain a triennial tribute of gold flowers was paid to Siam, and this together with occasional letters of instructions and advice, constituted the only tangible evidence of Siamese suzerainty. Of government there was practically none. The sultan, having alienated most of his powers and prerogatives to his relatives, passed his life in religious seclusion and was reputed to be no more than a name. The revenues were devoured by the relatives, a small part of those accruing from the capital sufficing for the sultan's needs. There were no written laws, nor were the laws of the land uniformly applied. Still more was the peasantry mercilessly downtrodden, but the land was full of holy men and the cries of the miserable were drowned in the noise of ostentatious prayer. In fine, Trengganu presented in the beginning of the 19th century an utterly contrasting picture to the present, when her prosperity and development have been so greatly enhanced. The fate of the state was determined by the action of the British who, in 1821, purchased from the sultan of Kelah, the island of Patani, for $7500. This purchased the right to trade on the coast of Malacca, and in 1850, the British government purchased the entire coast of Trengganu for $80,000, a large sum at that time. The British government had been determined to obtain control over the Straits of Malacca, and this proved an excellent beginning to the work.

KEDAH.—This state, on the west coast of the peninsula, lies between parallels 5° 20' and 6° 42' N., and is bounded, N. by Pult and Songkla, E. by Songkla and Raman, S. by Province Wellesley and Perak, and W. by the sea. The coast-line is 65 m. long, the greatest breadth from east to west is 75 m., and the greatest breadth 46 m. Off the coast lies a group of islands, the largest of which is Langkawi, well peopled and forming a district of the state.

The total area of Kedah is about 4000 sq. m. The land is low-lying and swampy near the coast except towards the south where the height known as Kedah Hill rises from the shore opposite Penang, forming the highest land, which is 425 m. above the coast-line. The rivers are small, the Suril Kedah, navigable for a few miles for vessels of 60 tons, and the S.Muda, which forms the boundary with Province Wellesley, being the only streams worthy of notice. The produce consists of rice, tobacco, pepper, and rubber. The ironstone and granite preponderate. The population is estimated at 220,000, of whom about 100,000 are Malays, 50,000 Siamese and S als of Siam, and 70,000 Chinese and British subjects. There are three towns of importance. Alor Star, the capital, on the Kedah river, 10 miles from the sea, is a flat, unhealthy, but fertile locality, is well laid out with town streets, many handsome public and private buildings, and good wharves for small vessels. The population is about 20,000, of whom more than half are Chinese and the remainder government servants and retainers of the local aristocracy. Kunjua Muda (pop. 10,000) and Kulim (pop. 8000) situated in the south, are important centres for the cultivation of the small bamboo huts; the latter is the centre of the Kedah tin mining industry. The bulk of the population is scattered over the plains in small villages. A notable industry is the raising of fruit, especially rice cultivation. Coco-nut, betel-nut and fruit plantations are many, and the cultivation of rubber has recently been taken up with prospects of success. The estimates for 1900, the year in which the state was transferred to the British government, state that the population is about 130,000 and that the principal exports are rice, cattle and tin. The principal exports are rice, cattle and tin. The principal imports are cotton goods, provisions, hardware and raw silk. Accurate trade statistics are not available.

KEDAH.—This state, on the west coast of the peninsula, lies between parallels 5° 20' and 6° 42' N., and is bounded, N. by Pult and Songkla, E. by Songkla and Raman, S. by Province Wellesley and Perak, and W. by the sea. The coast-line is 65 m. long, the greatest breadth from east to west is 75 m., and the greatest breadth 46 m. Off the coast lies a group of islands, the largest of which is Langkawi, well peopled and forming a district of the state.

The total area of Kedah is about 4000 sq. m. The land is low-lying and swampy near the coast except towards the south where the height known as Kedah Hill rises from the shore opposite Penang, forming the highest land, which is 425 m. above the coast-line. The rivers are small, the Suril Kedah, navigable for a few miles for vessels of 60 tons, and the S.Muda, which forms the boundary with Province Wellesley, being the only streams worthy of notice. The produce consists of rice, tobacco, pepper, and rubber. The ironstone and granite preponderate. The population is estimated at 220,000, of whom about 100,000 are Malays, 50,000 Siamese and S als of Siam, and 70,000 Chinese and British subjects. There are three towns of importance. MALAY STATES—MALCOLM

MALAY STATES (SIAMESE).—The authority of Siam, which at one time covered the whole of the Malay peninsula, now extends southward to an irregular line drawn across the Peninsula at about 5° 30' N. Between that line and the Isthmus of Kra, usually accepted as the northermost point of the Malay Peninsula, there lie about 7,500,000 sq. m. of territory inhabited by a mixed population of Siamese and Malays, where there are but a few remnants of the aboriginal inhabitants clinging to the wilder districts, and with a few Chinese settlers engaged in commerce. Formerly this tract was divided into a number of states, each of which was ruled by a chief (Siamese, Chao Muang; Malay, raja), who held his title from the king of Siam, but, subject to a few restrictions, conducted the affairs of his state in accordance with his own desires; the office of chief, moreover, was hereditary, subject always to the approval of the suzerain. The states formed two groups: a northern, including Langsuan, Chik, Satun, Nga, Nakhon Sri Tammarat, Renang, Trang, Puket, and Nong Chik, in which the population was chiefly Siamese; and a southern, including Palean, Satun, Songka, Patani, Raman, Jering, Satul, Re Nge (Legh), and Yala (Jalor and Nong Chik), in which the population was principally Malay and the ruler also Malay. Four other states of the southern group, Kelantan, Trengganu, Kedah, and Perlis, of which the population is entirely Malay, passed from Siamese to British protection in 1909.

With the gradual consolidation of the Siamese kingdom all the old state boundaries have been incorporated as ordinary provinces of Siam (q.v.), the hereditary Chao Muang having died or been pensioned and replaced by officials of the Siamese Civil Service, while the states themselves now constitute provinces of the administrative divisions of Chumphon, Nakhon Sri Tammarat, and Patuket. The states of the southern group, however, retain their hereditary rulers, each of whom presides over a council and governs with the aid of a Siamese assistant commissioner and with a staff of Siamese district officials, subject to the general control of high commissioners, who are the representatives of the crown from whom the states are grouped. This southern group, with a total area of about 6,000,000 sq. m. and a population of 375,000, constitutes the Siamese Malay States. A British consul with headquarters at Patuket, and a vice-consul who resides at Songkla, watch over the interests of British subjects in the states of the west and east sides of the peninsula respectively. Other foreign powers are unrepresented.

Palean.—This small state on the west coast, bounded N. by the province of Trang, E. by the Songkla division, S. by the state of Setul, and W. by the sea, is about 900 sq. m. in area, and has a population of about 20,000. It is attached for administrative purposes to the province of Trang, and its people are chiefly engaged in the cultivation of pepper, of which about 150 tons are annually exported. A few tin mines are worked also. Songkla.—This small state, bounded N. by Palean, E. by Satun, S. by Nanga and W. by the ocean. It contains about 1,000 sq. m. area with a population of about 25,000, Malays, Siamese, and Chinese. The principal production is pepper, which is exported in large quantities in junk and in the small Penang steamers which ply on the west coast of the peninsula. In 1897 Setul was placed under the control of Kedah, then a Siamese dependency, but the arrangement was not a success, and in 1907 the Siamese government was forced, owing to prevailing corruption and misrule, to restrict the powers of the chief and enrolling the territory of Kedah for the first time since the beginning of the 19th century under the orders of the high commissioner of Songkla. By the terms of the Anglo-Siamese treaty of 1909 about half of the state of Perlis were placed under the arrangement by which the importance of the latter was considerably increased.

Patani.—The seven Malay states of Nang Chik, Patani, Jering, Yala (Jalor), Sai (Teloban), Raman and Ra-ng (Leghe) were constituted from Patani districts lying between the old and the new century. In 1906 they were reunited to form the Patani administrative division of Siam, but each state retains its Malay ruler, who governs under the Siamese high commissioner, and many of the ancient privileges and customs of Malay government are preserved. The group of

states is situated between 5° 34' and 6° 52' N. and 100° 54' and 101° 56' E. It is bounded N. by the China Sea, E. by the China Sea and Kelantan, S. by Penang and Malacca, and W. by the Singapore Straits, and contains about 5,000 sq. m. The country is mountainous except close to the coast. The principal rivers are the Patani and the Teloban, long, winding, and navigable for small boats only. The population is about 10,000, of which the state has its capital, but Patani (the headquarters of the high commissioner) is the only town of importance. Communications are bad, except for the chief fishing and rubber-bearing town of Patani and the port of Sai (Teloban), which is connected with Singapore by steamer. Patani and Sai are in telegraphic communication with Bangkok and Singapore, and regular weekly mails are despatched to those places. The area under cultivation is small except round about Patani and Sai, and the chief product of the state is pepper, which is exported in considerable quantities. The annual export of tin is about 400 tons, and dried fish, salt, cattle and elephants are other exports. Steamers up to 300 tons maintain frequent communication with Bangkok and Singapore, and the Patani roads afford good anchorage at all seasons.

Mahomedian law is followed in the settlement of inherited property disputes and of matrimonial affairs; otherwise the laws of Siam obtain. Efficient law courts have been established in each state, and there is a serviceable force of gendarmerie recruited from amongst Malays and Siamese alike. The revenue amounts to about 600,000 ticals, or $4,500 per annum, one-third being payable to the rulers of the state, one-third to the state, and the rest retained by the state for the maintenance of the civil, military, and judicial forces. The revenue obtainable was in years past spent largely on the administration, and one-third reserved for special purposes, but it is usually found necessary to devote the largest portion of the revenue to the expenses of administration. Patani has always been considered of importance to Siamese interests, and as a result the state adopted Islamism in the 16th century, the chief, a relative of the kings of Siam, embracing that religion and at the same time revolting from the power of the Chinese. It has always been the practice of the expatriate to call the state to its allegiance. The present rulers are mostly descended from the ruling families of the neighbouring state of Kelantan, but the chief of Patani is a member of the family which ruled there in the days of its greatness. Throughout the 17th century Patani was resorted to by Portuguese, Dutch and English merchants, who had factories ashore and used the place as an emporium for trade with Siam. In 1621 an engagement took place in the Patani roads between three Dutch and two British ships, the latter being taken after the surrender of the British merchants, John Jourdain, had been killed. In 1699 the border state of Perak and Raman was fixed by an agreement between England and Siam, a dispute of old standing being thereby settled, but the question was reopened in the negotiations which preceded the Anglo-Siamese treaty of 1909, when a new frontier line was fixed between British and Siamese possessions in the Peninsula.

MALCHIN, a town of Germany, in the grand-duchy of Mecklenburg-Schwerin, on the river Peene, between lakes Malchin and Kummerower, 25 m. by rail N.W. of Neu-Brandenburg. Pop. (1900), 7449. It is, alternately with Sternberg, the place of assembly of the Diet of Mecklenburg. Here are the châteaux of Ruhleben and of a near forest, and the river Peene, with a winding course, a fine town-hall. The well-watered and undulating country, enrobing the shores of Lake Malchin, is known as the "Mecklenburg Switzerland," and is increasing in favour as a summer resort. A canal unites Lake Kummerower with the Peene. The industries of the town include the manufacture of sugar and bricks, and brewing and malting. Malchin became a town in 1236.

MALCOLM, the name of four kings of the Scots, two of whom, Malcolm III., king from 943 to 995, and Malcolm II., king from 1003 to 1034, were called mac Alpin, or MacAlpine. Malcolm III. (d. 1093), called Canmore or the "large-headed," was a son of King Duncan I., and became king after the defeat of the usurper Macbeth in July 1057, being crowned at Scone in April 1057. Having married as his second wife, (St) Margaret (q.v.), a sister of Edgar Ætheling, who was a fugitive at his court, he invaded England in 1070 to support the claim of Edgar to the English throne, returning to Scotland with many captives after harrying Northumbria. William the Conqueror answered this attack by marching into Scotland, and in June 1093 Malcolm met him at Abernethy "and was his man." However, in spite of this promise he ravaged the north of England again and again, until in 1091 William Rufus invaded Scotland and received his submission. Then in 1092 a fresh dispute arose between the two kings, and William summoned Malcolm to his court at Gloucester. The
Scot obeyed, and calling at Durham on his southward journey was present at the foundation of Durham Cathedral. When he reached Gloucester Rufus refused to receive him unless he did homage for his kingdom; he declined and returned home in high dudgeon. Almost at once he invaded Northumbria, and was killed at a place afterwards called Malcolm’s Cross, near Alnwick, on the 13th day of September, 1093, during the council of Malcolm’s sons, Duncan II, Edgar, Alexander I, and David I, became kings of Scotland; and one of his daughters, Matilda, became the wife of Henry I. of England, a marriage which united the Saxons and the Norman royal houses.

Malcolm IV. (c. 1141-1165) was the eldest son of Henry, earl of Huntingdon (d. 1152), son of King David I, and succeeded his grandfather David as king of Scotland in 1153. He is called the "Maiden," and died unmarried on the 9th of December, 1165.

See E. A. Freeman, The Norman Conquest, vols. iv. and v. (1867-1870), and The Reign of William Rufus (1882); W. F. Skene, Celtic Scotland (1876-1880); E. W. Robertson, Scotland under her early Kings (1862); and A. Lang, History of Scotland, vol. I. (1900).

Malcolm, Sir John (1769-1833), Anglo-Indian soldier, diplomatist, administrator and author, was born at Burnfoot on the Esk, near Langholm, Dumfriesshire, Scotland, on the 2nd of May 1769. His father was a humble farmer, but three of his sons attained the honour of knighthood. At the age of twelve he received a cadetship in the Indian army, and on the 9th of May, 1783 he landed at Madras, shortly afterwards joining his regiment at Vellore. In 1792, having for some time devoted himself to the study of Persian, he was appointed to the staff of Lord Cornwallis as Persian interpreter, but two years afterwards was compelled by ill-health to leave for England. On his return to India in 1796 he became military secretary to Sir Alured Clarke, commander-in-chief at Madras, and afterwards to his successor General Harris; and in 1798 he was appointed by Lord Wellesley assistant to the resident at Hyderabad. In the last-mentioned capacity he highly distinguished himself by the manner in which he gave effect to the difficult measure of disbanding the French corps in the pay of the nizam. In 1799, under the walls of Seringapatam, began his intimacy with Colonel Arthur Wellesley, which in a short time ripened into a life-long friendship. In the course of the same year he acted as first secretary to the commission appointed to settle the Mysore government, and before its close he was appointed by Lord Wellesley to proceed as envoy to the court of Persia for the purpose of counteracting the policy of the French by inducing that country to form a British alliance. Arriving at Teheran in December 1800, he was successful in negotiating favourable treaties, both political and commercial, and returned to Bombay by way of Bagdad in May 1801. He was now for some time held the interim post of private secretary to Lord Wellesley, and in 1803 was appointed to the Mysore residency. At the close of the Mahratta War, in 1814, and again in 1805, he negotiated important treaties with Sindhia and Holkar, and in 1806, besides seeing the arrangements arising out of these alliances carried out, he directed the difficult work of reducing the immense body of irregular native troops. In 1808 he was again sent on a mission to Persia, but circumstances prevented him from getting beyond Bushire; on his reappointment in 1810, he was successful indeed in procuring a favourable reception at court, but otherwise his embassy, if the information which he afterwards incorporated in his works on Persia be left out of account, was (though no fault of his) without any substantial result. He sailed for England in 1811, and shortly after his arrival in the following year was knighted. His intervals of rest were devoted to literary work, and especially to the composition of a History of Persia, which was published in two quarto volumes in 1815. On his return to India in 1817 he was appointed by Lord Mofra his political agent in the Deccan, with eligibility for military command; as brigadier-general under Sir T. Hislop he took a distinguished part in the victory of Mehipur (December 21, 1817), as also in the subsequent work of following up the fugitives, determining the conditions of peace and settling the country. In 1821 he returned once more to England, where he remained until 1827, when he was appointed governor of Bombay. His influence in this office was directed to the promotion of various economical reforms and useful administrative measures. Leaving India for the last time in 1830, he shortly after his arrival in England entered parliament as member for Launceston, and was an active opponent of the Reform Bill. He died at Plymouth in 1834.

Besides the work mentioned above, Sir John Malcolm published Sketch of the Political History of India since . . . 1784 (in 1811 and 1826); Sketch of the Sikhs (1812); Observations on the Disturbances in the Malabar Army in 1796 (1812); Persia, a Poem, anonymous (1814); A Memoir of Central India which at the present time is without a rival; and Sketches of Persia, anonymous (1827). A posthumous work, Life of Robert, Lord Clive, appeared in 1836. See Life and Correspondence of Sir John Malcolm, by His Brother (2 vols.)

Malda, a district of British India, in the Rajashahi division of Eastern Bengal and Assam. Area, 1890 sq. m.; pop. (1901), 384,030, showing an increase of 8½ in the decade. The administrative headquarters are at English Bazaar (pop. 13,667) near the town of Old Malda. The district is divided into two almost equal parts by the Mahananda river, flowing from north to south. The western tract between the Mahananda and the main stream of the Ganges is an alluvial plain of sandy soil and great fertility. The eastern half is an elevated region broken by the deep valleys of the Tangan and Purnabhaba rivers and their small tributary streams. The soil here is a hard red clay; and the whole is covered by the storey tree jungle known as the kildal. Agricultural prosperity centres on the Mahananda, where mango orchards and high raised plots of mulberry land extend continuously along both banks of the river. The Ganges nowhere intersects the district, but skirts it from its north-western corner to the extreme south. The Mahananda flows in a deep well-defined channel through the centre, and joins the Ganges at the southern corner. Its tributaries are the Kalindri on the right, and the Tangan and Purnabhaba on the left bank. The two principal industries are the production of indigo and silk. The first has declined, and so has the second as far as concerns the weaving of piece goods, but the rearing of silkworms and the export of raw silk and silk thread are carried on upon a large scale. No railway touches the district, but the communications by water are good.

Malda supplied two great capitals to the early Mahommedan kings of Bengal; and the sites of Gaur and Pandua exhibit the most interest; for it is to be supposed that the lower valley of the Ganges (Gour) was the connexion of the East India Company with Malda dates from a very early period. As far back as 1676 there was a factory there. In 1770 English Bazaar was fixed upon for a commercial residency, and the place was so named because it was to form both the public offices and private residence of the collector.

Malden, a city, including several villages, of Middlesex county, Massachusetts, U.S.A., on the Malden river, about 5 m. N. of Boston. Pop. (1890), 23,031; (1900), 33,664, of whom 2573 were foreign-born, 2673 being English Canadians, 870 English, and 617 Swedes; (1910 census) 44,404. Malden had in 1906 a land area of 4.78 sq. m. It is served by the Boston & Maine railroad, and by inter-urban electric railways. Although it is largely a residential suburb of Boston—its post office is a Boston sub-station—it has important manufacturing industries. The most valuable manufactured product is rubber boots and shoes. The capital invested in manufacturing in 1905 was $5,553,422; and the value of the factory product, $11,235,653, was 70.2% greater than the value of the factory product in 1900. Among Malden's institutions are the public library (endowed by Elisha S. Converse), the Malden hospital, the Malden day nursery, a Young Men's Christian Association, and a home for the aged. A fine system of parks is maintained; the best known is possibly Pine Banks. To the north and west is the Middlesex Fells, a state reservation; about 60 acres of this and about 20 acres of the Middlesex Fells Parkway lie within Malden. Malden, when first settled about 1640, was part of Charlestown, and was known for some years as Mystic Side. It was incorporated as a town under the name of "Malden" in 1649, and was chartered as a city in 1881. The north part of Malden was set off in 1895 to form Melrose, and the south part
MALDIVE ISLANDS—or Malebranch, a market town, municipal borough and port in the Maldon parliamentary borough of Essex, England, on an acclivity rising from the south side of the Blackwater, 43 m. E.N.E. from London by a branch from Witham of the Great Eastern railway. Pop. (1901), 5565. There are east and west railway stations. The church of All Saints, dating from 1506, but, as it stands, Early English and later, consists of chancel, nave and aisles, with a triangular Early English tower (a unique form) at the west end surmounted by a hexagonal spire. The tower of St Mary's Church shows Norman work with Roman marble. The other public buildings are the grammar school, founded in 1547; the town-hall, formerly D'Arcy's tower, built in the reign of Henry VI.; and the public hall. There are manufactures of crystallized salt, breweries, an oyster fishery and some shipping. On Osea Island, in the Blackwater estuary, there is a farm colony for the unemployed. A mile west of Maldon are remains of Beeleigh Abbey, a Premonstratensian foundation of the 12th century. They consist of the chapter-house and another chamber, and are of fine Early English work. The borough is under a mayor, 4 aldermen and 12 councillors. Area 2288 acres.

At Maldon (Melduna, Melduna, Mealdon or Meaudon) palaeolithic, neolithic and Roman remains that have been found seem to indicate an early settlement. It is not, however, an important Roman site. An earthwork, of which traces exist, may be Saxon or Danish. The Anglo-Saxon Chronicle relates that Edward the Elder established a "burh" there about 921, and that Ealdorman Britnoth was killed there by the Danes in 991. The position of Maldon may have given it some commercial importance, but the fortress is the point emphasized by the Chronicle. Maldon remained a royal town up to the reign of Henry I., and thus is entered as on terra regis in Domesday. Henry II. granted the burgesses their first charter, probably in 1155, giving them the land of the borough and suburb with sac and soc and other judicial rights, also freedom from county and forest jurisdiction, danelag, scutage, tallowage and all tolls, by the service of one ship a year for forty days. This charter was confirmed by Edward I. in 1250, by Edward III. in 1344, and by Richard II. in 1378. In 1439 the bishop of London granted further judicial and financial rights, and Henry VIII. confirmed the charters in 1477, Henry VII. in 1543, and Henry VIII. in 1552. Maldon was incorporated by Philip and Mary in 1554, and received confirmatory charters from Elizabeth in 1563 and 1592, from Charles I. in 1631, Charles II. and James II. In 1768 the incorporation charter was regranted, with modifications in 1810.

Maledrana, Nicclas (1638-1715), French philosopher of the Cartesian school, the youngest child of Nicolas
Malebranche, secretary to Louis XIII, and Catherine de lauzon, sister of a viceroy of Canada, was born at Paris on the 6th of August 1638. Deformed and constitutionally feeble, he received his elementary education from a tutor, and left home only when sufficiently advanced to enter upon a course of philosophy at the Collège de la Marche, and subsequently to study theology at the Sorbonne. He had resolved to take holy orders, but his studious disposition led him to decline a stall in Notre Dame, and in 1660 he joined the congregation of the Oratory. He was first advised by Père Leconte to devote himself to ecclesiastical history, and laboriously studied Eusebius, Socrates, Soso- men and Theodoret, but "the facts refused to arrange themselves in his mind, and mutually effaced one another." Richard Simon, however, taught him Hebrew and Biblical criticism with no better success. At last in 1664 he consented to read Descartes's Traité de l'homme (de homine), which moved him so deeply that (it is said) he was repeatedly compelled by palpita- tions of the heart to lay aside his reading. Malebranche was from that hour consecrated to philosophy, and after ten years' study of the works of Descartes he produced the famous De la recherche de la vérité, followed at intervals by other works, both speculative and controversial. Like most of the great meta- physicists of the 17th century, Malebranche interested himself also in natural philosophy. He collaborated with him in the Encyclopaedia, and in 1699 was admitted an honorary member of the Academy of Sciences.

During his later years his society was much courted, and he received many visits from foreigners of distinction. He died on the 13th of October 1715; his end was said to have been hastened by a metaphysical argument into which he had been drawn in a course of an interview with Bishop Berkeley. For a critical account of Malebranche's place in the history of philosophy, see Cartesianism.

Works.—De La recherche de la vérité (1674; 6th ed., 1712; ed. Bouill- ler, 1880; Latin trans. by J. Lenfant at Geneva in 1685; English trans. by T. S. Taylor, 1674, 1712); Conversations chrétien- nes (1677, and frequently; Eng. trans., London, 1695); Traité de la nature et de la grâce (1680; Eng. trans., London, 1685); Méditations chrétiennes et métaphysiques (1685); Traité de morale (1684; separate ed. by H. Joly, 1882; Eng. trans. by Sir J. Sipton, 1809); several polemical works against Arnauld from 1684 to 1688; Entretiens sur la métaphysique et sur la religion (1688); Traité de l'amour de Dieu (1697); Entretiens d'un philosophe chrétien et d'un philosophe chinois sur l'existence et la nature de Dieu (1708); Réflexions sur la prémion physique (1715).

A convenient edition of his works in two volumes, with an intro- duction and notes, was published by Jules Simon in 1842. A full account by Mrs Norman Smith of his theory of vision, in which he unquestion- ably anticipated and in some respects surpassed the subsequent works of Berkeley, was published in the Journal of Speculative Philosophy (Jan. 1905). For recent criticism see H. Joly, in the series Les Grands philosophes (Paris, 1901); L. Ollé-Laprun, La Philosophie de Malebranche (1870); M. Novaro, Die Philosophie des Nicolas Malebranche (1893).

MALER KOTLA, a native state of India, within the Punjab. It ranks as one of the Cis-Sutlej states, which came under British influence in 1809. The territory lies south of Ludhiana. Area, 16,571 m. Pop. (1901), 77,506, showing an increase of 2% in the decade. Estimated gross revenue, £30,100. The military force numbers 280 men; and there is no tribute. The town Malel Kotla is 30 m. S. of Ludhiana; pop. (1901), 21,122. The nawab or chief is of Afghan descent; his family originally came from Kabul, and occupied positions of trust in Srinind under the Mogul emperors. They gradually became independent as the Mogul Empire sank into decay in the course of the 18th century. In General Lake's campaign against Halkar in 1856 the nawab of Malel Kotla was on the side of the British. After the subjugation and flight of Halkar, the English government proceeded to reduce the power of the Maharrattas in the districts between the Sutlej and the Jumna; and in 1809 its protection was formally extended to Malel Kotla, as to the other Cis-Sutlej states, against the formidable encroachments of Ranjit Singh. In the campaigns of 1806, 1807 and 1808 Ranjit Singh had made considerable conquests across the Sutlej; in 1808 he marched on Malel Kotla and demanded a ransom of £10,000 from the nawab. This led to the interference of the British, who addressed an ultimatum to Ranjit Singh, declaring the Cis-Sutlej states to be under British protection. Finally the raja of Lahore submitted, and the nawab was reinstalled in February 1809. Owing to the mental incapacity of nawab Ibrahim Ali Khan, the state was administered in recent years for some time by the chief of Loharu; but his son, Ahmed Ali Khan, was made regent in February 1905.

See Maler Kotla State Gazetteer (Lahore, 1908).

MALESHERBES, CHRÉTIEN GUILLAUME DE LAMOIGNON DE (1721-1794), commonly known as Lamoignon-Malesherbes, French statesman, minister, and afterwards counsel for the defence of Louis XVI, came of a famous legal family. He was born at Paris on the 6th of December 1721, and was educated for the legal profession. The young lawyer soon proved his intellec- tual capacity, when he was appointed president of the cour des aides in the parlement of Paris in 1750 on the promotion of his father, Guillaume de Lamoignon, to be chancellor. One of the chancellor's duties was to control the press, and this duty was entrusted to Malesherbes by his father during his eighteen years of office, and brought him into connexion with the public far more than his judicial functions. To carry it out efficiently he kept in communication with the literary leaders of Paris, and especially with Diderot and Grimm. In 1751, he says that "without the assistance of Malesherbes the Encyclopédie would probably never have been published." In 1771 he was called upon to mix in politics; the parlements of France had been dissolved, and a new method of administering justice devised by Maupou, which was in itself commendable as tending to the better and quicker administration of justice, but pernicious as exhibiting a tendency to over-centralization, and as abolishing the hereditary nobility of the robe, which, with all its faults, had from its nature preserved some independence, and been a check on the royal power. Malesherbes presented a strong remonstrance against the new system, and was at once banished to his country seat at St Lucie, to be recalled, however, with the old parlement on the accession of Louis XVI, and to be made minister of the maison du roi in 1775. He only held office nine months, during which, however, he directed his attention to the police of the kingdom, which came under his department, and did much to check the odious practice of issuing lettres de cachet. The protest of the cour des aides in 1775 is one of the most important documents of the old régime in France. It gives a comprehensive survey of the case, and shows the decisions on which it was founded, and presented the king with most outspoken criticism. On retiring from the ministry with Turgot in 1776, he betook himself entirely to a happy country and domestic life and travelled through Switzerland, Germany and Holland. An essay on Protestant marriages (1787) did much to procure for them the civil recognition in France. He had always been an enthusiastic botanist; his avenue at St Lucie was world famous; he had written against Buffon on behalf of the botanists whom Buffon had attacked, and had been elected a member of the Académie des sciences as far back as 1750. He was then elected a member of the Académie française, and everything seemed to promise a quiet and peaceful old age spent in the bosom of his family and occupied with scientific and literary pursuits, when the king in his difficulties wished for the support of his name, and summoned him back to the ministry in 1787. Lamoignon-Malesherbes held office but a short time, but returned to his country life this time with a feeling of insecurity and disquiet, and, as the troubles increased, retired to Switzerland. Nevertheless, in December 1792, in spite of the fair excuse his old age and long retirement would have given him, he voluntarily left his asylum and under- took with Tronchet and Desèze the defence of the king before the Convention, and it was his painful task to break the news of his condemnation to the king. After this effort he returned once more to the country, but in December 1793 he was arrested with his daughter, his son-in-law M. de Rosambô, and his grand- children, and on the 23rd of April 1794 he was guillotined, after having seen all whom he loved in the world executed before his eyes for their relationship to him. Malesherbes is one of the
sweetest characters of the 18th century; though no man of action, hardly a man of the world, by his charity and unfeigned goodness he became one of the most popular men in France, and it was an act of truest self-devotion in him to sacrifice himself for a king who had done little or nothing for him.

There are in print several scientific works of Malesherbes of varying value, of which the most interesting is his Observations sur Buffon et Daudenton, written when he was very young, and published with a Soyere by Abbeile in 1796. There exist also his Mémoire pour Louis XVI., his Mémoire sur la liberté de la presse (published 1809) and extracts from his remonstrances, published as Œuvres choisies de Malesherbes in 1809.

For his History of the French Academy (first read in 1786) and of Dubois, the Éloge historique (1805) of Gaillard, and the interesting Essai sur la vie, les écrits et les opinions de M. de Malesherbes (in 2 vols., 1818), of F. A. de Bosley d'Anglas. There are many other items in print on which the best-known is that of M. Dupin, which was delivered at the Academy in 1841, and was reviewed with much light on Malesherbes's control of the press by Sainte-Beuve in the 2nd volume of the Contesurs du lundi. The protest of the cour des 1000 is said to have been translated with translation by G. Robinson in the Translations and Reprints of the University of Pennsylvania (1900). For his defence of Louis XVI., see Marquis de Beaucourt, Comptes et dernieres moments de Louis XVI. (2 vols., 1892, Soc. d. hist. contemp.), and A. Tuetey, Répertoire général des sources manuscrites de l'hist. de Paris pendant la Rev. fr., vol. viii. (1906).

MALET, LUCAS, the pen-name of Mary St Leger Harrison (1822-1904), English novelist. She was the eldest daughter of Charles Kingsley, and was born at Eversley on the 4th of June 1822. She studied at the Slade school and at University College, London, and married in 1856 William Harrison, rector of Cleovly. After her husband's death in 1858 she eventually settled in London. She had already written several books—Mrs Lorrimer (1852), Colonel Enderby's Wife (1858), Little Peter (1867), A Counsel of Perfection (1888)—when she published her powerful story, The Wages of Sin (1891), which attracted great attention. Her History of Sir Richard Calmady (1901) had an even greater success. Her other novels include The Carissima (1856), The Gateless Barrier (1900), On the Far Horizon (1906).

MALHERBE, FRANÇOIS DE (1555-1628), French poet, critic and translator, was born at Caen in 1555. His family was of some position, though it seems not to have been able to establish to the satisfaction of heralds the claims which it made to nobility older than the 16th century. The poet was the eldest son of another François de Malherbe, conseiller du roi in the magistracy of Caen. He himself was educated at Caen, at Paris, at Heidelberg and at Basel. At the age of twenty-one, preferring arms to the gown, he entered the household of Henri d'Angoulême, grand prior of France, the natural son of Henry II. He served this prince as secretary in Provence, and married there in 1571. It seems impossible that he wrote anything of this period, but, to judge from a quotation of Tertullian des Réaux, they must have been very bad ones. His patron died when Malherbe was on a visit in his native province, and for a time he had no particular employment, though by some servile verses he obtained a considerable gift of money from Henry III., whom he afterwards libelled. He lived partly in Provence and partly in Normandy for many years after this event; but very little is known of his life during this period. His Larmes de Saint Pierre, imitated from Luigi Tansillo, appeared in 1587. It was in the year parting the two centuries (1600) that he presented to Marie de' Medici an ode of welcome, the first of his remarkable poems. But four or five years more passed before his fortune, which had hitherto been indifferent, turned. He was presented by his countryman, the Cardinal Du Perron, to Henry IV.; and, though that economical prince did not at first show any great eagerness to entertain the poet, he was at last summoned to court and endowed after one fashion or another. It is said that the pension promised him was not paid till the next reign. His place was restored in 1606, and he came into his inheritance. From this time forward he lived at court, corresponding affectionately with his wife, but seeing her only twice in some twenty years. His old age was saddened by a great misfortune. His son, Marc Antoine, a young man of promise, fell in a duel in 1626. His father used his utmost influence to have the guilty parties (for more than one were concerned, and there are grounds for thinking that it was not a fair duel) brought to justice. But he died before the suit was decided (it is said in consequence of disease caught at the camp of La Rochelle, whither he had gone to petition the king), in Paris, on the 16th of October, 1628, at the age of seventy-three.

The personal character of Malherbe was far from amiable, but he exercised, or at least he gave an appearance of it, a great influence upon French literature, though by no means as a wholly beneficial one. The lines of Boileau beginning Enfin Malherbe vivant are rendered only partially applicable by the extraordinary ignorance of older French poetry which distinguished that peremptory critic. But the good as well as had side of Malherbe's theory and practice is excellently described by his contemporary and superior Regnier, who was animasted against him, not merely by reason of his own devotion to Ronsard but because of Malherbe's discourtesy towards Regnier's uncle, D. Despee, whom the Norman poet had at first distinctly condemned. These are the lines:

"Cependant leur savoir ne s'étend nullement
Qu'a régratter un mot douteux au jugement,
Préférer garde qu'un gui ne hante une diplonghée,
Et vrai des vers où l'expression est longue,
Ou bien si la voyelle à l'autre s'unissant
Ne rend point à l'oreille un vers trop languissant.

C'est proser de la rime et rimer de la prose."

This is perfectly true, and from the time of Malherbe dates that great and deplorable falling off in poetry in its more artistic qualities, which was not made good till 1830. Nevertheless the the critical and restraining tendency of Malherbe was not ill in place after the luxuriant importation and innovation of the Pléiade; and if he had confined himself to preaching greater technical perfection, and especially greater simplicity and purity in vocabulary and versification, instead of superciliously striking his pen through the great works of his predecessors, he would have deserved wholly well. As it was, his reforms helped to elaborate the kind of verse necessary for the classical tragedy, and that is the most that can be said for him. His own poetical work is scanty in amount, and for the most part frigid and devoid of inspiration. The beautiful Consolation à Duperier, in which occurs the famous line—

Et rose, elle a vécu ce que vivent les roses—

the odes to Marie de' Medici and to Louis XIII., and a few other pieces comprise all that is really worth remembering of him. His prose work is much more abundant, not less remarkable for care as to style and expression, and of greater positive value. It consists of some translations of Livy and Seneca, and of a very large number of interesting and admirably written letters, many of which are addressed to Peiresc, the man of science of whom Gassendi has left a delightful Latin life. It contains also a most curious commentary on Desportes, in which Malherbe's minute and carping style of verbal criticism is displayed on the great scale.

The chief authorities for the biography of Malherbe are the Vie de Malherbe by his friend and pupil Racan, and the long Histoire de sa vie and de ses ouvrages by his son, which is the best and only one. The standard edition is the admirable one of Ludovic Lalanne (5 vols., Paris, 1862-1869). Of the poems only, there is an excellent and handsome little issue in the Nouvelle collection Jannet (Paris, 1874). Of modern works devoted to him, La Destruction de Malherbe, by G. Brunot (1891), is not only the most important but a work altogether capital in regard to the study of French language and literature. Others are A. Lugel, La Jeunesse de Malherbe (1890); V. Bourrienne, Petits essarts dans le vie normande de Malherbe (1894); and the due de Broglie's "Malherbe" in Les Grands écrivains français. On his position in French and general critical history, G. Saintaugy's Histoire des Crítiques (2nd ed., 1850) may be consulted.

MALIBRAN, MARIE FÉLICITÉ (1808-1836), operatic singer, daughter of Manoel Garcia, was born in Paris on the 24th of March 1808. Her father was then a member of the company of the Théâtre des Italiens, and she accompanied him to Italy and London. She possessed a soprano voice of unusual beauty and
phenomenal compass, which was carefully cultivated by her father. She was only seventeen when, in consequence of an indisposition of Madame Pasta, she was suddenly asked to take her place in The Barber of Seville at Covent Garden. She was forthwith engaged for the remaining six weeks of the season, and then followed her father to New York, where she appeared in Othello, The Barber of Seville, Don Juan, Romeo and Juliet, Tamzen. Her gentle manners and deep voice, and her gaiety made her irresistible in light opera, although her great triumphs were obtained chiefly in tragic parts. She married a French banker of New York, named Malibran, who was much older than herself. The marriage was an unhappy one, and Mme Malibran returned alone to Europe in 1828, when she began the series of representations at the Théâtre des Italiens, which excited an enthusiasm in Paris only exceeded by the reception she received in the principal towns of Italy. She was formally divorced from Malibran in 1835, and married the Belgian violinist, Charles de Beriot; but she died of fever on the 23rd of September 1836.

See Memoirs of Mme Malibran by the comtesse de Merlin and other intimate friends, with a selection from her correspondence (2 vols., 1840); and M. Tenco, La Malibran, d'après des documents inédits, in Sammelbände der internationalen Musik-Gesellschaft (Leipzig, 1906).

MALIC ACID (HYDROXYETHYLENE SUCCINIC ACID), C₄H₇O₂, an organic acid found abundantly in the juices of many plants, particularly in mountain-ash berries, in unripe apples and in grapes. The acid potassium salt is also found in the leaves and stalks of rhubarb. Since this acid contains an asymmetric carbon atom, it can exist in three forms, a dextro-rotatory, a laevo-rotatory and an inactive form; the acid obtained in the various synthetic processes is the inactive form. It may be prepared by heating racemic acid (see TARTARIC ACID) with fuming hydroiodic acid; by heating fumaric acid (g.), with water at 150–200°C; by the action of nitrous acid on inactive aspartic acid; and by the action of moist silver oxide on monobromosuccinic acid. It forms deliquescent crystals, which are readily soluble in alcohol and melt at 108°C. When heated for some time at 150°C it yields fumaric acid (g.), and on rapid heating at 180°C gives maleic anhydride and fumaric acid. It yields coumarins when warmed with sulphuric acid and phenols (H. v. Pechmann, Ber., 1884, 17, 929, 1649 et seq.). Potassium bichromate oxidizes it to maleic acid; nitric acid oxidizes it to oxalic acid; and hydroiodic acid reduces it to succinic acid. The inactive variety may be split into the component active forms by means of its cinchonine salt (G. J. W. Bremer, Ber., 1880, 13, 352).

MALIGNANT (Lat. malignus, evil-disposed, from maligenus), wicked, of a malign or wilfully evil disposition. The word was early applied by the Protestants to the Romanists, with an allusion to the "congregation of evil doers" (Vulgate Ecclesiam malignantium) of Psalm xxvi. 5. In English history, during the Great Rebellion, the name was given to the Royalists by the Parliamentary party. In the Great Remonstrance of 1641 occur the words "the malignant partie, whereof the Archbishop (Laud) and the earl of Strafford being heads." The name throughout the period had special reference to the religious differences between the parties. In medical science, the term "malignant" is applied to a particularly virulent or dangerous form which a disease may take, or to a tumour or growth of rapid growth, extension to the lymphatic glands, and recurrence after operation.

MALIK IBN ANAS (c. 718–795), the founder of the Malikite school of canon law, was born at Medina about A.D. 718; the precise date is not certain. He studied and passed his life there, and came to be regarded as the greatest local authority in theology and law. (For his legal system and its history see MALIKISM.) His life was one of extreme honour and dignity, but also of being glad to study, lecturing on law and acting as mufti and judge. Only two episodes stand out in his biography. When Mahomed ibn 'Abdallah, the 'Aliid, rose in A.D. 752 at Medina against the 'Abbasids, Malik gave a fatwa, or legal opinion, that the oath of allegiance to the 'Abbasids was invalid, as extorted by force. For this independence he was severely scourged by the 'Abbásid governor, who, apparently, did not dare to go beyond scourging with a man of his standing with the people. The second episode gave equal proof of independence. In 795 Hárún al-Rashid made the pilgrimage, came with two of his sons to Medina, and sat at the feet of Malik as he lectured in the mosque. The story, legendary or historical, adds that Malik had refused to go to the caliph, saying that it was for the student to come to his teacher. Late in life he seems to have turned to asceticism and contemplation. It is said that he retired from all active, public life and even neglected plain, public duties, relying to reproaches, "Not every one can speak in his own excuse" (Ibn Qutaiba, Ma'adīf, 250). He is also entered among the early ascetic Sufis (cf. Fihrist, 183). He died in Medina, A.D. 795.

For a description of his principal book, the Musuwāt, see Gold-"hers's Muhammedanische Studien, ii. 213 sqq. He gave also a Koran commentary, now apparently lost, and a hortatory epistle to Hárún al-Rashid. See further, de Slane's trans. of Ibn Khallikān, ii. 545 sqq.; von Kremer, Culturreichte, i. 477 sqq.; Brockelmann, Gesch. der arab. Lit., i. 175 sqq.; MacDonald, Muslim Theology, &c., 99 sqq. and index; Fihrist, 198 sqq.; Nawawi, 530 sqq. (D. B. MA.)

MALINES (Flemish, Mecheleen, called in the middle ages by the Latin name Mechlinia, whence the spelling Meclhin), an ancient and important city of Belgium, and the seat since 1559 of the only archbishopric in that country. Pop. (1904), 58,101. The name is supposed to be derived from maris linea, and to indicate that some original site was a promontory on the shore of the Dyle, and is in the province of Antwerp, lying about half-way between Antwerp and Brussels. The chief importance of Malines is derived from the fact that it is in a sense the religious capital of Belgium—the archbishop being the primate of the Catholic Church in that country. The archbishop's palace is in a picturesque situation, and dates from the creation of the dignity. The principal building in the city is the exceedingly fine cathedral dedicated to St Rombaut. This cathedral was begun in the 12th and finished early in the 14th century, and although modified in the 15th after a fire, it remains one of the most remarkable specimens of Gothic architecture in Europe. The massive tower of over 500 ft., which is described as unfinished because the original intention was to carry it to 500 ft., is its most striking external feature. The people of Malines gained in the old distich—"gaidet Meclhinia stultus"—the reputation of being "fools," because one of the citizens on seeing the moon through the dormer windows of St Rombaut called out that the place was on fire, and his fellow-citizens, following his example, endeavoured to put out the conflagration until they realized the truth. The cathedral contains a fine altar-piece by Van Dyck, and the pulpit is in carved oak of the 15th century. Another old palace is that of Margaret of Austria, regent for Charles V., which has been carefully preserved and is now used as a court of justice. In the church of Notre Dame (16th century) is Rubens' masterpiece "the miraculous draught of fishes," and in that of St John is a fine triptych by the same master. Malines, although no longer famous for its lace, carries on a large trade in linen, needles, furniture and oil, while as a junction for the line from Ghent to Louvain and Liège, as well as for that from Antwerp to Brussels and the south, its station is one of the busiest in Belgium, and this fact has contributed to the general prosperity of the city.

The lordship of Malines was conferred as a separate fief by Pippin the Short on his kinsman Count Adon in 754. In the 9th century Charles the Bald bestowed the fief on the bishop of Liège, and after being shared between Brabant and Flanders it passed into the hands of Philip the Bold, founder of the house of Burgundy, in 1384. During the religious troubles of the 17th century Malines suffered greatly, and in 1572 it was sacked by Alva's troops during three days. In the wars of the 17th and 18th centuries it was several times taken and stormed by the French, Dutch and English on several occasions. The French finally removed the fortifications in 1804, since which year it has been an open town.
MALLANWAN, a town in Haroi district, the United Provinces, India. Pop. (1901), 11,158. Under native rule the town possessed considerable political importance, and upon the British annexation of Oudh it was selected as the headquarters of the district, but was abandoned in favour of Haroi after the Mutiny. Saltworks and mining industries are now run.

MALLARME, FRANCOIS RENÉ AUGUSTE (1822-1883), French Revolutionist, the son of a lawyer, was born at Nancy on the 24th of February 1825. He was brought up in his father's profession, and was appointed procureur-syndic of the district of Pont-à-Mousson. During the Revolution he was elected by the department of Meurthe deputies to the Legislative Assembly and the Convention, where he attached himself to the Mountain and voted for the death of Louis XVI. He was elected president of the Convention on the 30th of May 1793, and by his weakness during the crisis of the following day contributed much to the success of the insurrection against the Girondists. He took an active part in the levé-massé, and in November 1793 was given the task of establishing the revolutionary government in the departments of Meuse and Moselle, where he gained an unenviable notoriety by ordering the execution of the sentence of death decreed by the revolutionary tribunal on some young girls at Verdun who had offered flowers to the Prussians when they entered the town. After the fall of Robespierre he joined the group of "Thermidorians" and was sent on mission to the south of France, where he closed the Jacobin club at Toulouse and set a number of imprisoned "suspects." On the 1st of June 1795 he was denounced and arrested, but was soon set at liberty. In 1796 he was appointed by the Directory commissioner for the organization of the departments of Dyle and Mont-Tonnerre. Under the empire he was receiver of the droits reunis at Nancy, and lost his money in 1814 in raising a levy of volunteers. Appointed sub-prefect of Avesnes during the Hundred Days, he was imprisoned by the Prussians in revenge for the death of the maidens of Verdun, and lived in exile during the Restoration. He returned to France after the revolution of 1830, and died at Richemont (Seine-Inferieure) on the 25th of July 1852.

MALLARMÉ, StéPHANE (1842-1889), French poet and theorist, was born at Paris, on the 18th of March 1842. His life was simple and without event. His small income as professor of English in a French college was sufficient for his needs, and, with his wife and daughter, he divided the year between a fourth-floor flat in Paris and a cottage on the banks of the Seine. His Tuesday evening receptions, which did so much to foster the thought of the more interesting of the younger French men of letters, were almost as important as the few carefully elaborated books which he produced at long intervals. L'Après-midi d'un faune (1876) and other fragments of his verse and prose had been known to a few people long before the publication of the Poésies complètes of 1887, in a facsimile of his clear and elegant handwriting, and of the Pages of 1891 and the Vers et prose of 1895. His remarkable translation of poems of Poe appeared in 1888, "The Raven" having been published as early as 1875, with illustrations by Manet. Daguerra, his own final edition of his prose, was published in 1897, and a more or less complete edition of the Poésies, posthumously, in 1899. He died at Valvins, Fontaincelou, on the 9th of September 1898. All his life Mallarmé was in search of a new aesthetics, and his discoveries by the way were often admirable. But he was too critical ever to create freely, and too limited ever to create abundantly. His great achievement remains unfinished, and all that he left towards it is not of equal value. There are a few poems and a few pieces of imaginative prose which have the haunting quality of Gustave Moreau's pictures, with the same jewelled magnificence, mysterious and yet definite. His later work became more and more obscure, as he seemed to himself to have abolished limit after limit which holds back speech from the expression of the absolute. Finally, he abandoned punctuation in verse, and invented a new punctuation, along with a new construction, for prose. Patience in the study of so difficult an author has its reward. No one in our time has venerated with more pride the self-sufficiency of the artist in his struggle with the material world. To those who knew him only by his writings his conversation was startling in its clearness; it was always, like all his work, at the service of a few dignified and misunderstood ideas.

Symons, The Symbolist Movement in Literature (1900). A complete bibliography is given in the Poesies d'aujourd'hui (1880-1900, 11th ed., 1905) of MM. A. van Bever and P. Léautaud. (A. Sy.)

MALLECO, a province of southern Chile, once a part of the Indian territory of Araucania (q.v.), lying between the provinces of Bio-Bio on the N. and E., Cautín on the S. and Arauco on the W., 2972 sq. m. Pop. (1895), 98,631. It belongs to the rainy, forested region of southern Chile, and is thinly populated, a considerable part of its population being Araucanian Indians, who occupy districts in the Andean foothills. Gold placer mining has attracted some attention, but the output is small. The principal industries are cattle and wheat raising and timber-cutting.

The capital is Angol (pop., 7056 in 1895; estimated at 7638 in 1902), a small town in the northern part of the province, on the Malloco river, and a station on the Truiguen branch of the state railway. Truiguen (pop., 5732 in 1895; estimated at 7099 in 1902) in the southern part of the province is the second town in importance, and is the headquarters of the Victoria (pop., 6986 in 1895; estimated at 10,002 in 1902), about 20 m. E. of the last-named town, was for a time the terminal station of the main line of the railway.

MALLEMUCK, from the German rendering of the Dutch Mellemwegge (which originally meant small fities or midgets that madly whirl round a light), a name given by the early Dutch Arctic voyagers to the Fulmar (q.v.), of which the English form is nowadays most commonly applied by our sailors to the smaller albatrosses, of about the size of a goose, met with in the Southern Ocean—corrupted into "molly mawk," or "mollymawk." A number of species have been identified. Diomedea irrorata of West Peru is sooty-brown with white mottlings and a white head; D. mignipes of the North Pacific is similar in colour but with white only near the eye and at the base of the tail and bill; D. immutabilis of Japan is darker but has a white head. D. melanophrys of the southern oceans has been found in summer both in California, in England, and as far north as the Faeroes. According to J. Gould the latter is the commonest species of albatross inhabiting the Southern Ocean, and its gregarious habits and familiar disposition make it well known to every voyager to or from Australia, for it is equally common in the Atlantic as well as the Pacific. The back, wings and tail are of a blackish-grey, but all the rest of the plumage is white, except a dusky superciliary streak, whence its name of black-browed albatross, as also its scientific epithet, are taken. The bill of the adult is of an ochreous-yellow, while that of the young is dark. This species breeds on the Falkland Islands. D. bulleri of the New Zealand seas is greyish-brown, with white underparts and rump and ashy head. Diomedea (or Thalassogron) culminata and chlororhyncha of the southern seas, D. (or T.) catua of Tasmania, salvinii of New Zealand and Layardii of the Cape resemble D. bulleri, but have a strip of naked skin between the plates of the maxilla towards its base. H. N. Moseley (Notes of a Naturalist, 130) describes D. culminata as making a cylindrical nest of grass, sedge and clay, with a shallow basin atop and an overhanging rim—the whole being about 14 in. in diameter and 10 in height. The bird lays a single white egg, which is held in a sort of pouch, formed by the skin of the abdomen, while she is incubating. The feet of D. bulleri are red, of D. chlororhyncha flesh-coloured, and of the others yellow.

MALLESON, GEORGE BRUCE (1825-1898), Indian officer and author, was born at Wimbledon, on the 8th of May 1825. Educated at Winchester, he obtained a cadetship in the Bengal infantry in 1842, and served through the second Burmese War. His subsequent appointments were in the civil line, the last being that of guardian to the young maharaja of Mysore. He retired
with the rank of colonel in 1877, having been created C.S.I. in 1872. He died at Kensington, on the 1st of March 1898. He was a voluminous writer, his first work to attract attention being the famous "Red Pamphlet," published at Calcutta in 1857, when the Mutiny was at its height. He continued, and considerably rewrote the History of the Indian Mutiny (5 vols., 1878-1880), which was begun but left unfinished by Sir John Kaye. Among his other books the most valuable are History of the French in India (2nd ed., 1893) and The Decisive Battles of India (3rd ed., 1868).

MALLET (or Mallet), David (1705-1765), Scottish poet and dramatist, the son of a Perthshire farmer, was born in that county, probably in 1705. In 1717 he went to the high school at Edinburgh, and some three years later to the university, where he made the friendship of James Thomson, author of The Seasons. As early as 1720 he began to publish short poems in the manner of the period, a number of which appeared during the next few years in collections such as the Edinburgh Miscellany and Allan Ramsay's Tea Table Miscellany, in which his ballad "William and Margaret" was published in 1724. For some years from 1723 he was private tutor to the duke of Montrose's son, the Earl of Eglinton, who travelled on the Continent in 1727. His real name was Malloch; but this he changed to Mallet in 1724. In 1733 he took the M.A. degree at Oxford. He had already made the friendship of Pope, whose vanity he flattered in a poem on Verbal Criticism, in 1733; and through Pope he became acquainted with Bolingbroke and other Tory politicians, especially those attached to the party of the prince of Wales, who in 1742 appointed Mallet to be his paid secretary. After Pope's death, in 1744, Mallet, at the instigation of Bolingbroke and forgetful of past favours and friendship, vilified the poet's memory, thereby incurring the resentment of Pope's friends. For his services as a party pamphleteer, in which character he published an attack on Admiral Byng, Mallet received from Lord Bute a lucrative sinecure in 1750. He died on the 21st of April 1765. Mallet was a small man, in his younger days something of a dandy and inordinately vain. He was twice married; by his first wife he had a daughter, Dorothy, who married Pietro Paolo Celsia, a Genoese gentleman, and was the author of several poems and plays, notably Almida, produced by Garrick at Drury Lane in 1771.

Mallet's own works included several plays, some of which were produced by Garrick, who was Mallet's personal friend. Eurydice, a tragedy, with prologue and epilogue by Aaron Hill, was produced at Drury Lane in 1731; Mustapha, also a tragedy, had considerable success at the same theatre in 1739; and in 1740, in collaboration with Thomson, he produced the masque Alfred, of which he published a new version in 1751, after Thomson's death, claiming it to be almost entirely his own work. This masque is notable as containing the well-known patriotic song, "Rule Britannia," the authorship of which has been attributed to Mallet, although he allowed it to appear without protest in his lifetime with Thomson's name attached. His other writings include Poems on Several Occasions (1743); A myntor and Theodora, or the Hermit (1747); another volume of Poems (1765).

In 1759 a collected edition of Mallet's Works was published in three volumes; and in 1857 his Ballads and Songs were edited by F. Dinsdale with notes, and a biographical memoir of the author.

MALLET, Paul Henri (1730-1807), French antiquary, was born on the 20th of August 1730, in Geneva. After having been educated there, he became tutor in the family of the count of Calenberg in Saxony. In 1752 he was appointed professor of belles lettres to the academy at Copenhagen. He was naturally attracted to the study of the ancient literature and history of his adopted country, and in 1755 he published the first fruits of his researches, under the title Introduction à l'histoire du Danemark où l'on traite de la religion, des mœurs, des lois, et des usages des anciens Danois. A second part, more particularly relating to the ancient literature of the country, Monuments de la mythologie et de l'histoire des bois de Cæles, et particulièrement des anciens Scandinaves, was issued in 1756, and was also translated into Danish. A translation into English, with notes and preface, by Bishop Percy, was issued in 1770 under the title of Northern Antiquities (reprinted with additions in 1847). The book had a wide circulation, and attracted much attention on account of its being the first (though a very defective) translation into French of the Edda. The king of Denmark showed his appreciation by choosing Mallet to be preceptor of the crown prince. In 1760 he returned to Geneva, and became professor of history in his native city. While there he was requested by the curia to undertake the education of the heir-apparent of Russia (afterwards the czar Paul I.), but declined the honour. An invitation more congenial to his tastes led to his accompanying Lord Maynard's expedition in his travels through Sweden, Norway, and England, where he was presented at court and commissioned to write the history of the house of Brunswick. He had previously received a similar commission from the landgrave of Hesse-Cassel for the preparation of a history of the house of Hesse, and both works were completed in 1785. The quietude of a literary life was rudely broken by the shock of the Revolution, to which he was openly hostile. His leanings to the unpopular side were so obnoxious to his fellow-citizens that he was obliged to quit his native country in 1792, and remained in exile till 1807. He died at Geneva, on the 5th of February 1807.

A memoir of his life and writings, by Siemond, was published at Geneva in 1807. Besides the Introduction to the History of Denmark, his principal works are: Histoire du Danemark (3 vols., Copenhagen, 1758-1777); Histoire de la maison de Hesse (4 vols., 1767-1783); Histoire de la maison de Brunswick (3 vols., 1790); Histoire de la maison de Mecklenbourg (2 vols., 1796); Histoire des Suisse ou Helvétiques (4 vols., Geneva, 1803) (mainly an abridgment of J. von Müller's history); Histoire de la hollandoisantique (1805).

MALLET, Robert (1810-1881), Irish engineer, physicist, and geologist, was born in Dublin, on the 3rd of June 1810. He was educated at Trinity College in that city, and graduated B.A. in 1830. Trained as an engineer, he was elected M.Inst.C.E. in 1842; he built in 1848-1849 the Fastnet Rock lighthouse, southwest of Cape Clear, and was engaged in other important works. Devoting much of his life to pure science, he became especially distinguished for his researches on earthquakes, and from 1852-1858 he was engaged (with his son John William Mallet) in the preparation of his great work, The Earthquake Catalogue of the British Association (1858). In 1862 he published two volumes, dealing with the Great Neapolitan Earthquake of 1857 and The First Principles of Observational Seismology. He then brought forward evidence to show that the depth below the earth's surface, whence came the impulse of the Neapolitan earthquake, was about 8 or 9 geographical miles. One of his most important essays was that communicated to the Royal Society (Phil. Trans. clxii. 147; 1874), entitled Volcanic Energy: an Attempt to develop its True Origin and Cosmical Relations. He sought to show that volcanic heat may be attributed to the effects of crushing, concretion and other disturbances in the crust of the earth; the disturbances leading to the formation of lines of fracture, more or less vertical, down which water would find its way, and if the temperature generated be sufficient volcanic eruptions of steam or lava would follow. He was elected F.R.S. in 1854, and he was awarded the Wollaston medal by the Geological Society of London in 1877. He died at Clapham, London, on the 5th of November 1881.

MALLET DU PAN, Jacques (1749-1800), French journalist, of an old Huguenot family, was born near Geneva in 1749, the son of a Protestant minister. He was educated at Geneva, and through the influence of Voltaire obtained a professorship at Cassel. He soon, however, resigned this post, and going to London joined H. S. N. Liguett in the production of his Annales politiques (1778-1780). During Liguett's imprisonment in the Bastille Mallet du Pan continued the Annales by himself (1781-1783); but Liguettresented this on his release, and Mallet du Pan changed the title of his own publication to Mémoires historiques (1783). From 1783 he incorporated this work with the Mercure de France in Paris, the political direction of which had been placed in his hands by the outbreak of the French Revolution he sided with the Royalists, and was sent on a mission (1794-1792) by Louis XVI. to Frankfort to try and secure the
sympathy and intervention of the German princes. From Germany he travelled to Switzerland and from Switzerland to Brussels in the Royalist interest. He published a number of anti-revolutionary pamphlets, and a violent attack on Bonaparte and the Directory resulted in his being exiled in 1797 to Berne. In 1798 he went to London, where he founded the *Mercure britannique*. He died at Richmond, Surrey, on the 10th of May 1804, his widow being pensioned by the English government. Mallet du Pan has a place in history as a pioneer of modern political journalism. His son John Lewis Mallett (1775–1861) spent a useful life in the English civil service, becoming secretary of the Board of Audit; and J. L. Mallett's second son, Sir Louis Mallet (1823–1890) also entered the civil service in the Board of Trade and rose to be a distinguished economist and a member of the Council of India.

Mallet du Pan's *Mémoires et correspondance* was edited by A. Sayous (Paris, 1851). See Mallet du Pan and the French Revolution (1902), by Bernard Mallet, son of Sir Louis Mallet, author also of a biography of his father (1900).

**MALLING, EAST and WEST**, two populous villages in the Medway parliamentary division of Kent, England, respectively 5 and 6 m. W. by N. of Maidstone, with a station on the South-Eastern and Chatham railway. Pop. (1901), East Malling, 2301; West Malling, 2312. They are situated in a rich agricultural district on the western slope of the valley of the Medway, and East Malling has large paper mills. At West Malling are remains of Malling Abbey, a Benedictine nunnery founded in 1090 by Gundulf, bishop of Rochester. The remains, which are partly incorporated in a modern building, include the Norman west front of the church, the Early English cloisters, the chapter-house, gate-house (the chapel of which is restored to use), and other portions. About Addington near West Malling are considerable prehistoric remains, including mounds, single stones, stone circles and pits in the chalk hills; while at Leybourne are the gateway and other fragments of the castle held by the Leybourne family from the 12th to the 14th century.

**MALLOCH, WILLIAM HURRELL** (1849–1913), English author, was born at Cockington Court, Devonshire. He was educated privately, and at Balliol College, Oxford. He won the Newdigate prize in 1872, and took a second class in the final classical schools in 1874. He attracted considerable attention by his satirical story *The New Republic* (2 vols., 1877), in which he introduced characters easily recognized as prominent living men, Mark Pattison, Matthew Arnold, W. K. Clifford and others. His keen logic and gift for acute exposition and criticism were displayed in later years both in fiction and in controversial works. In a series of books dealing with religious questions he insisted on the impossibility as the basis of religion and on the impossibility of founding religion on purely scientific data. In *Is Life Worth Living?* (1879) and *The New Paul and Virginia* (1878) he attacked Positivist theories, and in a volume on the intellectual position of the Church of England, *Doctrine and Doctrinal Disruption* (1900), he advocated the necessity of a strictly defined creed. Later volumes on similar topics were *Religion as a Credible Doctrine* (1903) and *The Reconstruction of Belief* (1903). He published several brilliant works on economics, directed against Radical and Socialist theories; *Social Equality* (1882), *Prosperity and Progress* (1884), *Labour and the Poplar Welfare* (1893), *Classes and Masses* (1896) and *Aristocracy and Evolution* (1898); and among his anti-socialist works should be classed his novel, *The Old Order Changes* (1886). His other novels include *A Romance of the Nineteenth Century* (1881), *A Human Document* (1883), *The Heart of Life* (1895) and *The Veil of the Temple* (1904). He published a volume of *Poems* in 1880, and in 1900 *Lucretius on Life and Death* in verse.

**MALLOW**, a market town and watering place of Co. Cork, Ireland, on the Blackwater, 1443 f. S.W. from Dublin, and 21 N. from Cork by the Great Southern and Western railway. Pop. (1901), 4542. It is a junction for lines westward to Killarney and Co. Kerry, and eastward to Lismore and Co. Waterford. The town owes its prosperity to its beautiful situation in a fine valley surrounded by mountains, and possesses a tepid mineral spring, considered efficacious in cases of general debility and for scrobutic and consumptive complaints. A spa-house with pump-room and baths was erected in 1828. The parish church dates from 1818, but there are remains of an earlier building adjoining it. There are manufactures of mineral water and condensed milk, corn-mills and tanneries. Mallow received a charter of incorporation from James I. Its name was originally Magh Allo, that is, Plain of the Allo (the old name used by Spenser for this part of the river), and the ford was defended by a castle, built by the Desmonds, the ruins of which remain. A bridge connects the town with the suburb of Ballaheen. Mallow is a centre for the fine salmon fishing on the Blackwater. The climate is very mild. The town was a parliamentary borough till 1885. It is governed by an urban district council.

**MALLOVA**, botanically *Malva*, the typical genus of the natural order Malvaceae, embracing about sixteen species of annual and perennial herbaceous plants, widely distributed throughout the northern hemisphere. The malows possess the reniform one-celled anthers which specially characterize the Malvaceae (q.v.). The petals also are united by their base to the tube formed by the coalesced filaments of the stamens. The special characters which separate the genus *Malva* from others most nearly allied to it are the involucre, consisting of a row of three separate bracts attached to the lower part of the true calyx, and the numerous single-seeded carpels disposed in a circle around a central axis, from which they become detached when ripe. The flowers are...
MALMEDY—MALMESBURY

mostly white or pinkish, never yellow, the leaves radiate-veined, and more or less lobed or cut. Three species are natives of Britain. The musk mallow (Malva moschata) is a perennial herb with five-partite, deeply-cut leaves, and large rose-coloured flowers clustered together at the ends of the branched stems, and is found growing along hedges and borders of fields, blossoming in July and August. It owes its name to a slight musky odour diffused by the plant in warm dry weather when it is kept in a confined situation. The round-leaved dwarf mallow (Malva rotundifolia) is a creeping perennial, growing in waste sandy places, with roundish serrate leaves and small pinkish-white flowers produced in the axils of the leaves from June to September. It is commonly found all over the north of Africa, extending to western and northern Asia. The common mallow (Malva silvestris), the mauve of the French, is an erect biennial or perennial plant with long-stalked round-angular serrate leaves, and conspicuous axillary reddish-purple flowers, blossoming from May to September. Like most plants of the order it abounds in mucilage, and hence forms a favourite domestic remedy for colds and sore throats. The aniline dye called mauve derives its name from its resemblance to the colour of this plant.

The marsh mallow (Althaea officinalis), the guimauve of the French, belongs to the mallow family and is a well-known medicinal plant. It is a native of marshy ground near the sea or in the neighbourhood of saline springs. It is an erect perennial herb, with somewhat woody stems, velvety, ovate, acute, unequally serrate leaves, and delicate pinkish-white flowers, and is fully described in the London Flora. The root is said to yield a good deal of honey to bees. The marsh mallow is remarkable for containing asparagin, C4H4N2O4.H2O, which, if the root be long kept in a damp place, disappears, butyric acid being developed. The root also contains about 25 % of starch and mucilage, which differs from that of gum arabic in containing one molecule less of water and in being precipitated by alcohol and not by acetone. It is used in the parer de guimauve lozenges. Althaea rosea is the hollyhock (q.v.).

The mallow of Scripture, Job xxx. 4, has been sometimes identified with Jew's mallow (Corchorus althiora), a member of the closely allied order Tiliaceae, but more plausibly (the word more implying a saline plant) with Atriplex Halimus, or sea orache. In Syria the Halimus was still known by the name Malluk in the time of Ibn Bietar. See Bochart, Hieroz. iii. 16.

MALMEDY, a town of Germany, in the Prussian Rhine Province, lying in a wild and deep basin, on the Warche, 20 m. S. of Aix-la-Chapelle by rail via Eupen. It contains two Roman Catholic churches, a modern town-hall and a classical school. Its industries include tanning, dyeing and paper-making. Pop. (1900), 4650. Malmedy was famous for its Benedictine abbey, founded about 675, which was united with that of Stablo, the abbot of the joint house being a prince of the empire. In 1802 the lands of the abbey passed to France, and in 1815 they were divided between Prussia and Netherlands.

See Kellen, Malmedy und die preußische Wallonien (Essen, 1897).

MALMESBURY, JAMES HARRIS, 1st Earl of (1746–1820), English diplomatist, was born at Salisbury on the 21st of April 1746, being the son of James Harris (q.v.), the author of Hermes Educated at Winchester, Oxford and Leiden, young Harris became secretary in 1768 to the British embassy at Madrid, and was left as chargé d'affaires at that court on the departure of Sir James Grey until the arrival of George Pitt, afterwards Lord Rivers. This interval gave him his opportunity; he discovered the intention of Spain to attack the Falkland Islands, and was instrumental in thwarting it by putting on a bold countenance. As a reward he was appointed minister ad interim at Madrid, and in January 1772 minister plenipotentiary to the court of Pretoria. His success was marked, and in 1777 he was transferred to the court of Riga, where, owing to the contract for him to manage to get on with Catherine in spite of her predilections for France, and steered adroitly through the accumulated difficulties of the first Armed Neutrality. He was made a knight of the Bath at the end of 1778, but in 1782 he returned home owing to ill-health, and was appointed by his friend Fox to be minister at the Hague, an appointment confirmed after some delay by Pitt (1784). He did very great service in furthering Pitt's policy of maintaining England's influence on the Continent by the arms of her allies, and held the threads of the diplomacy which ended in the king of Prussia's overthrowing the republican party in Holland, which was inclined to France, and re-establishing the prince of Orange. In recognition of his services he was created Baron Malmesbury of Malmesbury (Sept. 1788), and permitted by the king of Prussia to bear the Prussian eagle on his arms, and by the prince of Orange to use his motto "Je maintiendrai." He returned to England, and took an anxious interest in politics, which ended in his seceding from the Whig party with the duke of Portland in 1793; and in that year he was sent by Pitt, but in vain, to try to keep Prussia true to the first coalition against France. In 1794 he was sent to Brunswick to solicit the hand of the unfortunate Princess Caroline for the prince of Wales without success, and his wife, who had married him in 1796 and 1797, he was at Paris and Lille vainly negotiating with the French Directory. After 1797 he became partially deaf, and quitted diplomacy altogether; but for his long and eminent services he was in 1800 created earl of Malmesbury, and Viscount Fitzharris, of Heron Court in the county of Hants. He now became a sort of political Nestor, consulted on foreign policy by successive foreign ministers, trusted by men of the most different ideas in political crises, and above all the confidant, and for a short time after Pitt's death unanimously regarded as his heir. A larger number of men were also wont to go to him for advice, and Lord Palmerston particularly, who was his ward, was tenderly attached to him, and owed many of his ideas on foreign policy directly to his teaching. His later years were free from politics, and till his death on the 21st of November 1820 he lived very quietly and almost forgotten. As a statesman, Malmesbury had an influence among his contemporaries which is scarcely to be understood from his writings, but which must have owed much to personal charm and manner and persuasiveness of tongue; as a diplomatist, he seems to have deserved his reputation and shares with Macartney, Auckland and Whitworth the credit of raising diplomacy from a profession in which only great nobles won the prizes to a career opening the path of honour to ability. He was succeeded as 2nd earl by his son James Edward (1778–1841), under-secretary for foreign affairs under Canning; from whom the title passed to James Howard, 3rd earl of Malmesbury (q.v.).

Malmesbury did not publish anything himself, except an account of the Dutch revolution, and an edition of his father's works, but his important Diaries (1844) and Letters (1870) were edited by his grandson.

MALMESBURY, JAMES HOWARD HARRIS, 3rd Earl of (1807–1889), English statesman, son of the 2nd earl, was born on the 25th of March 1807, and educated at Eton and Oriel College, Oxford. He led a life of travel for several years, making acquaintance with famous people; and in 1841 he had only just been elected to the House of Commons as a Conservative, when his father died and he succeeded to the peerage. His political career, though not one which made any permanent impression on history, attracted a good deal of contemporary attention, partly from his being foreign secretary in 1852 and again in 1858–1859 (he was also lord privy seal in 1866–1868 and in 1874–1876), and partly from his influential position as an active Tory of the old school in the House of Lords at a time when Lord Derby and Mr Disraeli were, in their different ways, moulding the Conservatism of the period. Moreover his long life—he survived till the 17th of May 1889—and the publication of his Memoirs of an Ex-Minister in 1884, contributed to the reputation he enjoyed. These Memoirs, charmingly written, full of anecdote, and containing much interesting material for the history of the time, remain his last important publication. Lord Malmesbury also edited his grandfather's Diaries, Letters and Correspondence (1844), and in 1870 published The First Lord Malmesbury and His Friends: Letters from 1745 to 1820. He was succeeded as 4th earl by his nephew, Edward James (1834–1899), whose son, James Edward (b. 1872) became the 5th earl in 1899.

MALMESBURY, a market town and municipal borough in the Chippenham parliamentary division of Wiltshire, England, 94 m. W. of London by the Great Western railway. Pop. (1901),
MALMÖ—MALOLOS

2854. It lies on a ridge surrounded on all sides except the north-west by the river Avon and a small tributary. The church of St Mary and St Aldhelm, standing high, is a majestic fragment consisting of the greater part of the nave (with aisles) of a Benedictine abbey church. The ruined skeleton of the great tower arches now terminates the building eastward. The nave is transitional Norman, with a Decorated superstructure including the north porch and the arch in the north wall, and examples extant, both the outer and the inner doorways (especially the first) exhibiting the typical ornament of the period in remarkable exuberance. With the exception of a crypt, the monastic buildings have disappeared. In the market square stands a fine market cross of the 16th century, borne upon an octagonal battlemented basement. Early English fragments of a hospital of St John of Jerusalem appear in the corporation almshouse. Malmesbury has an agricultural trade, with breweries, tanneries and manufactures of silk and pillow lace. It is governed by a mayor, 4 aldermen and 12 councillors.

Area, 178 acres.

Maladolphus, a Scottish or Irish monk, who came into England about 635, built a hermitage near the site of the modern Malmesbury (Maialdulphus, Maildulphus, Malmesbire) and gathered disciples round him, thus forming the nucleus of the later abbey of which Aldhelm his pupil became the first abbot. Æthelstan, who was buried here (though his tomb in the church only dates from the 12th century), rebuilt and endowed the monastery. Record of an abbey (the town of Malmesbury grew up, and by the time of the Domesday Survey it had become one of the two Wilshire boroughs. The first charter, said to be a forgery, purports to have been given by Æthelstan. It granted to the burgesses all privileges and free customs such as they held in the time of Edward the Elder, with many additional exceptions, in return for help rendered against the Danes. The castle built at Malmesbury during the reign of Henry I. gave a further impetus to the growth of the town during the 12th and 13th centuries. It was not incorporated, however, until 1645, when it was made a free borough under the title of "aldermen and burgesses of the borough of Malmesbury, County Wilt." By this charter it was governed until 1885. The borough returned two members to parliament from 1295 to 1832 when the number was reduced to one. Finally in 1885 its representation was merged in that of the county. A grant of a yearly fair on the 31st of March, the feast of St Aldhelm, was obtained from William II., and another for three days from the 25th of July from John. In 1792 fairs were held on the 28th of March, the 28th of April and the 29th of June, but in 1891 they had ceased entirely, the last fair being held on the Thursday.

In the 16th and 17th centuries it was held on Saturday, and in 1801 on the third Wednesday in each month. In the middle ages Malmesbury possessed a considerable cloth manufacture, and at the Dissolution the abbey was bought by a rich clothier and fitted with looms for weaving. The trade in wool still flourished in 1751.

See Victoria County History: Wiltshire: and Registrum malmesburiense (1879-1880).

MALMÖ, a port of Sweden, chief town of the district (län) of Malmöhus, on a small bay of the Sound, 384 m. S.S.W. of Stockholm by rail. Pop. (1800), 38,854; (1900), 60,857. It is connected with Copenhagen, 175 m. W. by N., by steam-ferries, the Sound being kept open in winter by an ice-breaker. It is also the first important station in Sweden on the Berlin-Stockholm route, which crosses the sea between Sassnitz in Rügen and Trelleborg, 20 m. S.E. of Malmö. The town, which stands upon a level plain, formerly had strong fortifications, of which only the citadel (Malmöhus) remains; in it the earl of Bothwell was imprisoned by Frederick II. of Denmark for some time after his departure from Scotland in 1567. The town-hall (1546, largely restored in 1864) contains a handsome chamber, the Knutssal, formerly used by the council of the gild of Canute. The hall fronts the central square (Stortorg) which is planted with trees and contains a colossal statue of Charles X. by Johan Helenus Börjeson (b. 1835) erected in 1886. The most notable church is that of St. Peter (Peterkyrka), dating in part from 1319. Malmö is second to Stockholm as an industrial centre. There are breweries and large works for the manufacture of machinery, among which may be mentioned the Kockum mechanical works, with yards for the construction of vessels of war, and others; of cotton and woollen goods, gloves, chocolate, sweetmeats and tobacco. A large export trade is carried on in butter and other agricultural produce, and matches. Coal is the chief import. The harborage includes an outer harbour of 22 ft. depth, and two inner basins admitting vessels of 21 ft. draught, with dry dock and patent slip. Malmö returns four members to the second chamber of the Riksdag (parliament).

Malmö (Malmhauge, Malmey, Malmouge), sometimes called Ancora Scanderum or Ellenbogen, first appears in history about the middle of the 13th century. During the Hanseatic period it was the most important commercial town on the Sound, but in the 16th and 17th centuries greatly lost ground owing to the decay of its herring fisheries and the rise of its rival, Copenhagen. Its modern prosperity is largely due to the enterprise of Frans Snell, one of its merchants in the second half of the 18th century, who first constructed the harbour.

Malmsey, a strong sweet wine, originally made at Monemvasia (Gr. Μονήμασσία), Napoli di Malvasia, in the Morea, Greece. The name of the place was corrupted in Med. Lat. into malmiàsia, whence the English form of the word. The corruption malvasia gives the O. Fr. malvasie, from which comes the alternative English form "malvasie." The wine is now made not only in Greece but also in Spain, Madeira and the Azores.

Malocelio, Lanciloto ("Lanzarote, the 'Lancelot Maloisé' of the French"), leader of the first of modern European oceanic enterprises. This was a Genoese expedition, which about 1270 seems to have sailed into the Atlantic, re-discovered the "Fortunate Islands" or Canaries, and made something of a conquest and settlement in one of the most northerly islands of this archipelago, still known (after the Italian captain) as Lanzarote. According to a Spanish authority of about 1545, the anonymous Franciscan's Conocimiento de todos los reinos, "Lanzarote" was killed by the Canarian natives; but the castle built by him was standing in 1402-1404, when it was utilized for the storage of grain by the French conquerors under Gadifer de la Salle. To Malocello's enterprise, moreover, it is probable that Petrarch (born 1304) alludes when he tells how, within the memory of his parents, an armed fleet of Genoese penetrated to the "Fortunatae," this passage some would refer, without sufficient authority, to the expedition of 1401. Malocello's name and nationality are certainly preserved by those early Portolani or scientific charts (such as the "Dulcert" of 1330 and the "Laurentian Portolano" of 1351), in which the African islands appear, for the first time in history, in clear and recognizable form. Thus Dulcert reads Insula de Lanzaratos and Marocelus, the Laurentian map I. de Lannarote, against Lanzarote Island, which is well depicted on both designs, and marked with the cross of Genoa. The Conocimiento (as noticed above) explicitly derives the island-name from the Genoese commander who is described here, Malocelio's enterprise not only marks the beginning of the overseas expansion of western Europe in exploration, conquest and colonization (after the age of Scandinavian world-roving had passed); it is also probably not connected with the great Genoese venture of 1291 (in search of a waterway to India, which soon follows), with which this attempt at Canary discovery and dominion has been by some unjustifiably identified.

Maloilos, a town and the capital of the province of Bulacan, island of Luzon, Philippine Islands, on a branch of the Pampanga
MALONE - MALONIC ACID

Grande river. Pop. (1903), after the annexation of Barasasin and Santa Isabel, 27,025. There are thirty-eight villages, or barrios, of which eight had, in 1903, 1,000 inhabitants or more. The principal language is Tagalog, but Spanish is spoken to some extent. Malolos is served by the Manila & Dagupan railway, and is a trade centre of considerable importance. The cultivation of rice is an important industry. In 1898-99, during the Filipino revolt, Malolos was the seat of the rebel government, but it was captured and reduced to desolation in March 1899. In 1904 a new municipal school building, a municipal market and a provincial building were erected.

MALONE, EDMOND (1741-1812), Irish Shakespearian scholar and editor, was born in Dublin, on the 4th of October 1741, the son of a barrister and a member of the Irish House of Commons. He was educated at Trinity College, Dublin, and was called to the Irish bar in 1767. The death of his father in 1774 assured him a competency, and he went to London, where he frequented literary and artistic circles. He frequently visited Dr Johnson and was of great assistance to Boswell in revising and proof-reading his Life, four of the later editions of which he annotated. He was intimate with Sir Joshua Reynolds, to whom he sat for a portrait now in the National Portrait Gallery. He was one of Reynolds' executors, and published a posthumous collection of his works (1798) with a memoir. Horace Walpole, Burke, Canning, Lord Charlemont, and, at first, George Steevens, were among Malone's friends. Encouraged by the two last he devoted himself to the study of Shakespearian chronology, and the results of his "Attempt to ascertain the Order in which the Plays of Shakespeare were written" (1778) are still largely accepted. This was followed in 1780 by two supplementary volumes to Steevens's version of Dr Johnson's Shakespear, partly consisting of observations on the history of the Elizabethan stage, and of the text of doubtful plays; and this again, in 1783, by an appendix volume. His refusal to alter some of his notes to Isaac Reed's edition of 1785, which disagreed with Steevens's, resulted in a quarrel with the latter. The next seven years were devoted to Malone's own edition of Shakespeare in eleven volumes, of which his essays on the history of the stage, his biography of Shakespeare, and his attack on the genuineness of the three parts of Henry VI., were especially valuable. His editorial work was lauded by Burke, criticized by Walpole and damned by Joseph Ritson. It certainly showed indefatigable research and proper respect for the text of the earlier editions. Malone published a denial of the claim to antiquity of the Rowley poems (see Chatterton), and in this (1782) as in his rebranding (1796) of the Ireland MSS. (see Ireland, William Henry) as forgeries, he was among the first to guess and state the truth. His elaborate edition of Dryden's works (1800), with a memoir, was another monument to his industry, accuracy and scholarly care. In 1802 the university of Dublin made him an LL.D. At the time of his death, on the 24th of April 1812, Malone was at work on a new octavo edition of Shakespeare, and he left his material to James Boswell the younger; the result was the edition of 1821—generally known as the Third Variorum edition—in twenty-one volumes. Lord Sunderlin (1738-1816), his elder brother and executor, presented the larger part of Malone's splendid collection of books, including dramatic varieties, to the Bodleian Library, which afterwards bought many of his MSS. notes and his literary correspondence. The British Museum also owns some of his letters and his annotated copy of Johnson's Dictionary.

A memoir of Malone by James Boswell is included in the Prolegomena to the edition of 1821. See also Sir J. Prior's Life of Edmond Malone (1860).

MALONE, a village and the county-seat of Franklin county, in the township of Malone, in the N.E. part of New York, U.S.A., about 60 m. E.N.E. of Ogdensburg. Pop. (1850), 4086; (1860), 5935 (101 foreign-born); (1900), 8478; (1910), 6828. The village is served by the New York Central and Hudson River and the Rutland and Central Lines railways. The village has a Memorial Park, Arsenal Green, on the site of an arsenal and parade-ground sold by the state in 1859, a state armoury, the Northern New York Institute for Deaf Mutes, Franklin Academy, St Joseph's Ursuline Academy, and a detention-house for Chinamen entering the state from Canada. From Malone tourists visit the Great North Woods, in the Adirondack foothills, about 15 m. distant. Iron ore and Potsdam sandstone are found near Malone. In the surrounding region hops, potatoes, &c., are grown, and there are dairying and livestock interests. The village is a centre for the collection of hides and pelts. It manufactures woolen goods, paper and pulp, &c., and has foundry and machine shops and car repair shops. Malone, being on the line of communication between lakes Champlain and Ontario, was of strategic importance during the war of 1812, and later was twice the rendezvous of Fenians for attacks on Canada. The township of Malone was settled and erected from Chateaugay in 1865. The village was first known as Harison, was named Ezraville, in honour of Ezra L'Hommedieu in 1868, received its present name in 1871, and was incorporated in 1853.

MALONIC ACID, C3H4O4 or CH(OH)C(=O)OCH, occurs in the form of its calcium salt in the sugar beet. It was first prepared in 1847 by V. Dessaignes, who obtained it by oxidizing malic acid (Ann., 1858, 107, p. 251). It may also be obtained by oxidizing allylene and propylene with cold potassium permanganate solution, by the hydrolysis of barbituric acid (malonyl urea) with alkalis (A. Baeyer, Ann., 1864, 130, p. 143); by the hydrolysis of malonic acid (H. Kolbe, Ann., 1864, 131, p. 349; H. Muller, Ann., 1864, 131, p. 352), and by the action of silver oxide on β-di-chloroacrylic ester at 125° (O. Wallach, Ann., 1878, 193, p. 25).

\[ \text{CCl}_3\text{CH-OOCCl}_3 \cdot \text{Ag}_2 \text{O} \cdot \text{H}_2\text{O} = 2\text{AgCl} + \text{HOOC-CH}_3\text{COOH} \]

It crystallizes in monoclinic tables, and is readily soluble in water, alcohol and ether. The acid melts at 132° C, and at a higher temperature it rapidly decomposes into acetic acid and carbon dioxide. When heated with bromine and water to 100° C it forms tribromoaetic acid, some bromoform being produced at the same time. Malonic acid, as well as its esters, is characterized by the large number of condensation products it can form. In the presence of a dehydrating agent (such as acetic anhydride), it combines with aldehydes to form compounds of the type R·CH·C(OH)OH, or their decomposition products (formed by loss of CO₂) R·CH·COOH.

Many salts of the acid are known, and with the exception of those of the alkali metals, they are generally soluble. Some of the esters of malonic acid have been prepared, the most important being the diethyl ester (malonic ester), CH₂(OH)COOC₂H₅, which is obtained by dissolving monochloracetic acid in water, neutralizing the hydroxides with potassium carbonate, and adding potassium cyanide and warming the mixture until the reaction begins. When the reaction has finished, the whole is evaporated and heated to about 130°-140° C, and then allowed to cool. The mass is then covered with two-thirds of its weight of alcohol, and saturated with hydrochloric acid gas. The whole is then poured into ice-cold water, extracted with ether and the ethereal solution distilled (L. Chaisen, Ann., 1883, 348, p. 151). It is a colourless liquid boiling at 197°-198° C (W. H. Perkin). It is a most important synthetic reagent; with sodium or sodium ethylate it forms sodio-malonic ester, which reacts readily with halides, forming alkyl malonic esters, which are again capable of forming derivatives that by further treatment with alkyl halides yield the di-alkyl malonic esters. These esters are readily hydrolysed and yield the mono- and di-alkyl malonic acids which, on heating, are readily decomposed, with evolution of carbon dioxide and the formation of mono- and di-alkyl acetic acids. The scheme of reactions is shown thus:

\[ \text{CH₃(COOH)} \rightarrow \text{CH₃Na(COOH)} \rightarrow \text{CHR’COOH} \rightarrow \text{CHR’COONa} \]

When sodio-malonic ester is heated to 145° C, it undergoes condensation, with elimination of alcohol and formation of the benzene derivative, phenolglucin tricarboxylic ester. The addition of urea to an alcoholic solution of sodio-malonic ester results in the formation of urea barbituric acid (A. Michael, Jour. pr. Chem., 1887 [2], 35, p. 459).
MALORY—MALOU

The half nitrile of malonic acid is cyanacetic acid, CN-CH$_2$COOH, which, in the form of its ester, may be obtained by the action of a solution of potassium cyanide on monochloracetic acid. The solution obtained is neutralized, concentrated on the water-bath, acidified by sulphuric acid and extracted with ether. It is then converted into the lead salt, which is decomposed by sulphuretted hydrogen and the solution is carefully concentrated (Th. Meves, Ann., 1867, 145, p. 201). It melts at 70° C. and at higher temperatures decomposes, especially upon heating with a solution of the cyanide of Na or CH$_2$CN. The true nitrile of malonic acid is methylene cyanide, CH$_2$(CN)$_2$, which is obtained by distilling a mixture of cyanacetamide and phosphorus pentoxide. It is a crystalline solid, which melts at 109.5° C. and boils at 218°-219° C., and is readily soluble in alcohol and ether.

MALORY, SIR THOMAS, translator and compiler of the famous English classic, the *Morte d'Arthur*. Previous to the publication of Professor Kittredge's monograph, *Who was Sir Thomas Malory?* the identity of this writer remained an unsolved problem. Mr. Sidney Lee, in his *Dictionary of National Biography*, was compelled to admit that he could find no one of that name fulfilling the necessary conditions. Of direct evidence we have very little; in the concluding passage of the book the author asks the prayers of the reader for "Syr Thomas Maleore knyght," and states that the book was ended "in the ix. yere of the regyne of King Edward the fyrst" by him, in his pref;ure, says that he printed the book "after a copye unto me delivrely whyche copye Syr Thomas Maleore dyd take oute of certen bookes of frenshe and reduced it in Englysshe"; in his colophon he repeats this statement, adding that he himself is responsible for the division of the work into books and chapters, and that it was printed in 1485. It will be noted that Caxton does not say that he received the book from Malory, only that he had received a copy made by Malory; from this Professor Kittredge draws the conclusion that the compiler was no longer living. The problem then is to find a Thomas Malory who was (a) a knight, (b) alive in the ninth year of King Edward IV. (Mar. 4, 1460—Mar. 3, 1470), and (c) who was no longer living in July (or June) 1485.

All these conditions Professor Kittredge finds fulfilled in the life of Sir Thomas Malory, knight, of Newbold Revell (or Fenny Newbold), M.P. for Warwickshire in 1445. The date of Sir Thomas's birth is uncertain, but he succeeded his father, Sir John, in 1433 or 1434. Previously to this he had served in France, in the retinue of the earl of Warwick, most probably during the time that that nobleman held the office of captain of Calais. It seems probable that he is also to be identified with a "Thomas Malorie, miles," who in 1468 was, on account of the part played by him in the Wars of the Roses, excluded with several others from the operation of a pardon issued by Edward IV. - As, however, on the death of Sir Thomas on the 14th of March 1470, there was no difficulty as to inheritance, his estates passing to his grandson, he must, if this identification be correct, have come under the general amnesty of 1469. It will be seen, therefore, that so far as it is in our power to state the question this Sir Thomas Malory fulfils all the necessary conditions.

It is interesting to note that the career of the earl of Warwick in France was marked by certain picturesque and chivalric features which might well impress the imagination of a young retainer. John Roux, in his *Life of Richard Earl of Warwick*, tells us that at a certain tourney held near Calais at Christmas-time, Earl Richard appeared three days running in different armour, overthrowing his adversary on each occasion—an exploit obviously imitated from the chivalric romances of the period.

The work with which Malory's name is connected is an abridged compilation of the great body of Arthurian romance in its latest form. The *Merlin* (Vulgate and Suite), *Tristan*, *Lancelot*, *Queste* and *Mort Aruis* are all represented, the only branch omitted is that dealing with the "early history" of the Grail, the *Joseph of Arimathiea* and *Grand S. Graal*. Thanks mainly to the labours of Dr Oskar Sommer, we can now assign the majority of the books to their separate sources, although certain stories, such as the adventures of Sir Gareth under the pseudonym of Beaumains, the handling of Sir Ure of Hungary, and the details of the abduction of Guenevere by Meleagant, still remain unidentified. But we do not yet know whether Malory himself was responsible for this selection, or whether he found it ready to hand in a MS., the "Pastons Book," to which he often refers. To make such a compilation at first hand, considering the extent of the ground covered, would involve an enormous amount of study and selection, and the access to a very large library—conditions which scarcely seem to fit in with the social position and activities of Sir Thomas. On the other hand it is undeniable that the medieval copyists, at the instance of their patrons, did make compilations from the various romances within their reach, such as e.g. the enormous *codex 112* (fonds Francais) of the Biblithèque Nationale, which includes large sections of the *Tristan*, the *Lancelot*, and the *Merlin* Suite. Taking into consideration alike what Malory retains and what he omits, it seems most probable that he was in possession, not of complete copies of the romances, but of one or more volumes of compilations from these sources.

From the point of view of matter it must be admitted that the *Morte d'Arthur* does not represent the Arthurian cycle at its best, but rather in the period of its decadence; nor does Malory in any way endeavour to overcome the difficulties caused by the juxtaposition of a number of independent (and often conflicting) versions. He especially noticeable in his treatment of Gawain; in the section derived from the *Lancelot* and *Mort Aruis* he is a good and valiant knight, "a ful noble knyghte as ever was borne," in those derived from the *Tristan* and the *Queste*, he is treacherous, dissolute, and a murderer of good knights.

The great charm of Malory's work lies in his style; stately, earnest and dignified, it has lent to the relations between Lancelot and Guenevere a character of truth and vitality in which the French original is wholly lacking. Malory achieved a remarkable feat—he took the Arthurian story in its worst and weakest form and he imparted to it a moral force and elevation which the cycle, even in its earlier and finer stage, had, save in the unique case of Von Eschenbach's *Parzival*, never possessed. While genuine lovers of the Arthurian cycle must regret that the romances should only be known to the great majority of English readers through the versions of Malory and Tennyson, it is impossible to withhold from the *Morte d'Arthur* the admiration due to an imperishable monument of English language and literature.

See *Who was Sir Thomas Malory?* G. L. Kittredge (Harvard University Press, 1921), and *Morte d'Arthur*, ed. by Dr Oskar Sommer (an exact reproduction of the original text in 2 vols.)—vol. iii. a study on "The Sources of Malory." The sections on *Lancelot* and *Queste* are considered in Commoner, *The Legend of Sir Lancelot*, Grimm Library, vol. xii. (J. L. W.)

MALOT, HECTOR HENRI (1839—1907). French novelist and man of letters, the son of a notary, was born at La Bouulle (Seine Inférieure) on the 20th of May 1839. He studied law at Rouen and Paris, but literature early absorbed his attention. He collaborated in the *Biographie générale de Didot*, became literary critic of *L'Opinion Nationale*, and dramatic critic of the *Lloyd français*. He is the author of a long series of popular novels dealing with contemporary life, including: a trilogy of domestic novels entitled *Victimes d'amour* (1839, 1865, 1866); *Un Beau frère* (1869); *Madame Oberlin* (1870); *Le Docteur Claude* (1879); *Fustile* (1880). *Les Aventures de Romain Kalbri* (1860) and *Sans famille* (1888) are excellent stories for children. A complete edition of Hector Malot's works appeared in 1894—1897.

He died at Vincennes in July 1907.

MALOU, JULES ÉDOUARD XAVIER (1810—1886), Belgian statesman, one of the leaders of the clerical party, was born at Ypres on the 19th of October 1810. He was a civil servant in the department of justice when he was elected to the Chamber of Deputies by his native constituency in 1841, and was for some time governor of the province of Antwerp. He was minister of finance in the coalition ministry of J. B. Nothomb in 1844, and formed with B. T. de Theux a Catholic cabinet in 1846, which was overthrown in the Liberal victory of 1847. Malou
He and village became defence entirely Rome of the 1870. December marine; well-known those 1870-1878. He was wise enough to disavow the noisy sympathy of Belgian Ultramontane politicians with the German victims of the Kulturkampf, and, retaining in his own hands the portfolio of finance, he subordinated his clerical policy to a useful administration in commercial matters, including a development of the railway system. It was only after the fall of the ministry in 1878 that he adopted a frankly clerical policy, and when, as a member of the administration of 1881, he proceeded to undo the educational compromise of his predecessors in the Frère-Orban ministry. His legislation in favour of the Catholic schools caused rioting in Brussels, and in October the king demanded the retirement of MM. Jacobs and Woesse, the members of the cabinet against whom popular indignation was chiefly directed. Malou followed them into retirement, and died at Wulwe Saint Lambert, in Brabant, on the 11th of July 1886. He was a financier of great knowledge and experience. His works (of which a long list is given in Koninck's Bibliographie nationale de Belgique) include three series (1874-1886) of memoirs on financial questions, edited by him for the Chamber of Deputies, besides pamphlets on railroad proposals, mining and other practical questions. His brother Jean Baptiste Malou (1809-1864) was a well-known divine.

MALOUET, PIERRE VICTOR, BARON (1740-1814), French publicist and politician, was born at Riom (Puy-de-Dôme) on the 11th of February 1740, the son of a lawyer. He entered the civil service and was employed successively at the French embassy in Lisbon, in the administrative department of the duc de Broglie's army, as commissary in San Domingo from 1767-1774, and, after his return to France, as commissary-general of the marine. In 1776 he was entrusted to carry out plans of coloniza-
tion in French Guiana, but was superseded in 1779. On his return to France he was well received at court, and the execution of his plans in Guiana was assured. He became intendant of the port of Toulon, and in 1789 was returned to the states-general, where he soon became well known as a defender of the monarchical principle. He emigrated to England in September, 1792, but shortly afterwards sought in vain permission to return to assist in the defence of Louis XVI. His name was erased from the list of emigrants in 1801 by Napoleon, who restored him to his position in the service and sent him to Antwerp as commis-
sioner-general and maritime prefect to superintend the erection of defence works, and the creation of a fleet. He entered the council of state in 1810, but, having offended the emperor by his plainness of speech, he was disgraced in 1812. At the Restoration, Louis XVIII. made him minister of marine; and he died on the 7th of September 1814.

The most important documents for his domestic and colonial policy are a Collection de ses opinions à l'Assemblée Nationale (5 vols., 1791-1792); and Collection de mémoires et correspondances officielles sur l'administration des colonies et notamment sur la Guiane française et hollandaise (5 vols. 1802).

MALPIGHI, MARCELLO (1628-1664), Italian physiologist, was born at Crevacuore near Bologna, on the 16th of March 1628. At the age of seventeen he began the study of philosophy; it appears that he was also in the habit of amusing himself with the microscope. In 1649 he started to study medicine; after four years at Bologna he graduated there as doctor. He once applied to be admitted to lecture in the university, but it was not till after three years (1656) that his request was granted. A few months later he was appointed to the chair of theoretical medicine at Pisa, where he enjoyed the friendship and count-
enance of G. A. Borelli. At the end of four years he left Pisa, on the ground of ill-health, and returned to Bologna. A call to be professor primarius at Messina (procured for him through Borelli, who had in the meantime become professor there) induced him to leave Bologna in 1661. His engagement at Messina was for a term of four years, at an annual stipend of 1000 scudi. An attempt was made to retain him at Messina beyond that period, but his services were secured for his native university, and he spent the next twenty-five years there. In 1691, being then in his sixty-fourth year, and in failing health, he removed to Rome to become private physician to Pope Innocent XII., and he died there of apoplexy three years later, on the 30th of November 1694. Shortly before his death, he drew up a long account of his academical and scientific labours, correspondence and controversies, and committed it to the charge of the Royal Society of London, a body with which he had been in intimate relations for more than twenty years. The autobi-
ography, along with copies of some of his works, was published in London in 1696, at the cost of the Society. The personal details left by Malpighi are few and dry. His narrative is mainly occupied with a summary of his scientific contributions and an account of his relations to contemporary anatomists, and is entirely without graces of style or elements of ordinary human interest.

Malpighi was one of the first to apply the microscope to the study of animal and vegetable structure; and his discoveries were so important that they may be considered to be the founder of microscopic anatomy. Of his open spaces in the history of science, his striking discoveries were made in those circumstances. Although Harvey had correctly inferred the existence of the capillary circulation, he had never seen it; it was reserved for Malpighi in 1661 (after Harvey's death) to see for the first time the mar-
vellous spectacle of the blood coursing through a network of small tubes on the surface of the lung and of the distended urinary bladder (the frog). We are enabled to measure the minute, unprecedented scopical observation at the time by the fact that it took Malpighi four years longer to reach a clear understanding of the corpuscles in the frog's blood, although they are the parts of the body by which its movement in the capillaries is made visible. His discovery of the capillary circulation was given to the world in the form of two letters De Pulmonibus, addressed to Borelli, published at Bologna 1661 and reprinted at Leiden and other places in the years follow-
ing. These letters contain also the first description of the vascular structure of the human lung, and they made a theory of respiration for the first time possible. The achievement that comes next both in importance and in order of time was a demonstration of the plan of structure of secreting glands; against the current opinion (revived by F. Ruyssch forty years later) that the glandular structure was essentially that of a closed vascular coil from which the secretion exuded, he maintained that the secretion was formed in terminal acini standing in open communication with the ducts. The name of Malpighi is still associated with his discovery of the soft or mucous membranes of the mouth and of the brain; the sheets of the nasal and oral cavities, of the lining of the alimentary canal in the cortex of the kidney, and of the follicular bodies in the testis, are distinguished by accuracy; but his microscopic study of the grey matter conducted him to the opinion that it was of glandular structure, with "vital spirits." At an early period he applied himself to vegetable histology as an introduction to the more difficult study of the animal tissues, and he was ac-
quainted with the spiral vessels of plants in 1662. It was not till 1671 that he wrote his Anatomia plantarum and sent it to the Royal Society, who published it in the following year. An English work under a similar title (Anatomy of Vegetables) had been pub-
lished in London a few months earlier, by Nehemiah Grew; so that Malpighi's priority is not so inconceivable as it is in animal histology. The Anatomia plantarum contained an appendix, Observations de ovo incubato, which gave an account (in the first stages of egg development) of the formation of the embryo (in later stages) in many points more complete than that of Harvey, although the observations were necessarily lessened in value by being joined to the metaphysical notion of "praedelineation" in the undeveloped ovum.

He also wrote Epistolae anatomicae Marc. Malpighii et Car. Fracassati (Amsterdam, 1662) (on the tongue, brain, skin, omentum, spinal cord, intestines, &c); a volume on the Plantarum structure and coloratae et microscopicae (with plates); De structura glandularum conglobatorum (London, 1689); Opera posthuma, et vitae secrupula scripta (London, 1697; another edition, with preface and additions, was published at Amsterdam in 1700.) He also wrote a treatise on the prin- ciple of animal cohesion, De cohesione animalium (Amsterdam, 1669), which was translated into Latin and published in London in 1687, in 2 vols. folio, with portrait and plates.

MALPLAQUET, a village of France in the department of the Nord, close to the Belgian frontier and about 10 miles S. by E. of Mons, famous as the scene of the battle, September 1790, between the Allies under the duke of Marlborough and Prince
Eugène and the French commanded by Marshal Villars, in which the former were victorious. The country to the west and south of Mons is enclosed by a semicircular wall of woods and broken ground, through which there are only two important gaps—that of Jemappes (famous in 1792) to the west, and that of Aulnois, in which stands the village of Malplaquet, to the south. In the latter gap and the woods on either side Villars took up his position facing north-eastwards, on August 29/September 9. The forces in presence, over 90,000 on each side, were exceptionally large, and the French army in particular represented the spirit of its nation to a degree unusual in the armies of that time. Villars was the best general in the service of Louis XIV, and the veteran Marshal Boufflers, though senile to him, had volunteered to serve as his second in command. Marlborough and Eugène lay with their army between Mons and the French camps, which were almost within cannon shot. Marlborough’s own wish was for an immediate battle, but he was opposed by the Dutch deputies at his headquarters, and even by Eugène, so that it was only on August 31/September 11 that the attack actually took place. Villars had made full use of his respite. The French right stood at the fringe of the wood of Lamberies, the left was strongly posted in the midst of the wood of Taisnière, and across the two and a half miles of open ground between the woods the position was entrenched with several successive lines of works. The troops were almost equally distributed along the whole line as usual, and the cavalry was massed in rear of the infantry. In the Allied army the mounted troops were also kept back, but for the most part distributed to the various infantry commands.

The intention of Marlborough and Eugène, when on the morning of the battle they examined this formidable position, was to deliver the main attack upon the French left wing, combining the assaults of several columns on its front and flanks. In this quarter the French not only held the interior of the wood but also were thrown forward so as to occupy the edges of its north-eastern salient, and upon the two faces of this salient Count Lottum (1650-1719) with the Prussians, and Count von der Schullenburg (1661-1747) with the Austrian infantry were to deliver a double attack, while farther to the Allied right a column under the English General Withers was detached to make a wide turning movement through the woods. Marlborough took command on the right, Eugène on the left. The centre, which was intended only to observe the enemy until the decision had been forced at the wood of Taisnière, consisted of Lord Orkney’s British corps and the prince of Orange’s Dutch contingent. These extended across the Trouée d’Aulnois as soon as the combined attack of Lottum and Schullenburg opened. The general advance was covered by a heavy cannonade, and the salient of the Taisnière wood was duly attacked on its two faces by the Prussians and Austrians about 9 a.m. They encountered a sterner resistance than in any of the battles and combats of the past seven campaigns, for on this field the defenders were fighting, not as hitherto for the interests of their king, but to defend their country, and the regiments of Picardy and Champagne which held the salient were the oldest and most famous of the French line. Lottum attacked the works on the eastern edge, again and again without success, until three British battalions had to be sent to reinforce him, and Marlborough placed himself with a corps of cavalry in close support. At last the entrenchedments were stormed. Schullenburg, with the Austrians, had by this time forced his way through the woods and undergrowth, and the united force pressed back the French farther and farther into the wood. Still, so stubborn was the defence and so dense the wood that the impetus of the assault died away and the troops on both sides broke up into small disconnected bodies, fighting too fiercely to be amenable to superior control.

But the French were not reinforced from their right wing as Villars expected. The prince of Orange, far from merely observing the hostile right as he had been ordered to do, committed his corps, very early in the battle, to a serious assault upon it, which Boufflers repulsed with enormous loss. The Dutch infantry never recovered from its casualties on this day, and the memory of Malplaquet was strong even at Fontenoy nearly forty years afterwards. Some Hanoverian troops which took part in this futile attack suffered equally heavily. The only advantage to the Allies—an advantage which, as it happened, counted for much—was that Boufflers did not dare to send reinforcements to the hard-pressed left wing. Thanks to this the Austrians and Prussians, with the English detached to their aid, made steady progress in the wood of Taisnière. Villars launched the “Irish brigade” to check the advance of the Allies, and this famous corps charged into the forest. Villars, Eugène and Marlborough personally led their troops in the encounter which followed. Eugène was wounded, but refused to quit the field. Villars was more seriously hurt, and after trying in vain to direct the fighting from a chair was carried insensible from the field. At this crisis General Withers, who commanded the force that had been ordered to turn the French extreme left, and had fought his way through the forest, appeared on the scene. The British 18th regiment (Royal Irish), encountering the French Royal Irlandais, put it to the rout, and Villars’s counterstroke was at an end. The French maintained themselves on this side only by the aid of troops drawn from the centre and right, and this gave the Allied centre the opportunity which the prince of Orange had so rashly anticipated. The great attack over the open was carried out, in spite of the previous repulse, with the greatest determination. Preceded by forty guns, the corps of the prince of Orange and Lord Orkney swiftly carried the first line of works. The Allied cavalry then pushed out to the front, and horse, foot and artillery were combined in the last advance. Boufflers’s cavalry masses, coming into play for the first time, fought hard, and the struggle fluctuated with the arrival of successive reserves on either side, but in the end, shortly before 3 p.m., Boufflers (who had been in command since Villars’s fall) decided to retreat. The Allies had no troops left intact for the pursuit, and those engaged had expended their last efforts. Moreover Boufflers, experienced soldier as he was, drew off his men before they had lost their order and discipline.
MALSTATT-BURBACH—MALT

499

Thus this "very murdering battle" as Marlborough called it—the last and greatest pitched battle of the war—was almost barren of results. The Allies lost not less than twenty thousand men, or nearly a quarter of the whole force, the thirty battalions of the Dutch infantry losing half their numbers. On the French side there were some twelve thousand casualties. If further evidence were necessary to prove that the French fought their hardest, it could be found in the fact that whereas in almost every other battle, from 1660 to 1792, there were deserters and prisoners by the thousand, at Malplaquet only 300 of the French fell into the hands of the victors unwo ndered. Indeed, sometimes the French were deserted by the very men they had sent to fight for them.

MALSTATT, a town of Germany, in the Prussian Rhine province on the right bank of the Saar (Sarre), which separates it from Saarbrücken. Pop. (1900), 31,195. It lies in the midst of an important coal-mining and industrial district, and is itself little more than a long and narrow row of manufactories and workmen’s houses. The largest factories are engaged in the production of iron, steel and cement. There is a large wharf on the river for the export of coal.

Malstatt received municipal rights in 1321. These, however, were afterwards assigned to the newer town of Saarbrücken, and in 1818 Malstatt and Burbach were two small villages with a joint population of only about 800. About the middle of the century the population began to increase rapidly, in consequence of the development of the mining industry of the district and the extension of the railway system, and in 1874 the two villages were united to form a town.

MALT (O. Eng., mealt; O. Sax., malt; O. Teut., maltos; Mod. Ger., Malt; Scand., malt; probably derived from the Sanskrit maru, soil, thus having reference to the fact that malt is raw grain rendered soft or tender), the name given to grain in which germination has been caused to proceed to a certain stage and has then been arrested by the removal of water and the application of heat. During this limited germination enzymes are developed (see Fermentation), and the constituents of the grain modified so that the finished malt, when ground and submitted to the mashing process (see Brewing), differs from the original raw grain in that the greater portion dissolves. This solubility is, however, a direct one to a slight extent only; it is due for the most part to the action of the malt enzymes, diastase, &c. on the constituents of the grain, the main portion of which are of themselves insoluble. Thus starch, the main constituent of all grain except seeds, is almost entirely dissolved in the same proportion in raw and in malt. When the grain is mashed, the starch is attacked by the enzyme diastase, and converted by the process of hydrolysis into a mixture of soluble compounds, e.g. the crystalline sugar, maltose, and a number of gummy substances known as maltodextrins. But to a certain extent starch and other carbohydrate substances are rendered directly soluble and digestible during the mashing process, some of the products serving the respiratory needs of the growing germ, others being assimilated by the plantlet and reconverted into reserve carbohydrates in the tissues of the germ and rootlets, whilst the remaining portions are retained as such in the finished malt. Similarly certain of the nitrogenous constituents of the grain, the proteins, are broken down and rendered soluble by proteolytic enzymes, the products being assimilated to a certain extent by the germ and rootlets, by the cells of which they are again built up into complex proteins, whilst others remain in their simplified form. It is now known that proteolytic enzymes exist in finished malt, and that, when the mashing process is conducted under certain conditions, these are able to degrade and render soluble some of the higher proteins present in the malt. When germination is allowed to proceed as it does when the grain is planted in the soil, the whole of the contents are rendered soluble by degrees and in turn assimilated by the growing plantlet. By the limited germination which constitutes the mashing process, however, the balance of soluble compounds left in the finished malt is from 15 to 25% of the total weight of the corn.

Although other seeds of the natural order Gramineae are occasionally malted, the greater portion of malt is made from the various species of Hordeum, known by the name of barley (q.v.), bigg, or here. Indeed ordinary beer derives its characteristic flavour to the greatest extent from barley malt. A small proportion of malted oats or malted wheat is sometimes used in conjunction with barley malt for certain kinds of beer, whilst rye, maize, and even rice are occasionally malted. barley is, however, the grain best adapted for making malt intended for brewing beer, and accordingly some space will be devoted to a description of those varieties of this grain which are used by the brewer.

Barley belongs to the genus Hordeum, of which there are numerous species and varieties. Linnaeus and the earlier botanists recognized six species of cultivated barleys, but modern botanists usually consider all cultivated barleys as belonging to one species to which the name H. sativum has been given. Körnike regards H. spontaneum, a very long thin-grained two-rowed barley (see below) which grows in the East, as being the parent form; but E. S. Beaven inclines to the view that wild species of more than one form were originally used as food and subsequently cultivated. The last-named author has drawn up a scheme of classification for the varieties and races of cultivated barleys.

In an ear of barley the primary axis or rachis is divided into internodes of which there may be any number up to forty. Each internode bears three single-flowered spikelets arranged alternately on either side of the rachis. In the six-rowed varieties the whole of these spikelets attain maturity, whilst in the two-rowed varieties only one on each side of the rachis, viz. the median, develops. British beer is brewed principally from the malt made from home-grown two-rowed barleys. Of late years, however, it has been found advantageous to employ a proportion of malt made from the thinner and more husky foreign barleys, mostly six-rowed varieties. The corn of these two-rowed barleys are as a rule plumper than those of six-rowed barleys.

The most favourite barley for malting purposes grown in the United Kingdom is the narrow-caru two-rowed H. distichum, commonly known as Chevalier, from the name of the original cultivator, the Rev. John Chevalier. Of late years the quantity of
MALT

barley of the so-called Goldthorpe type (H. zeoritae), used for malt-
ing, has increased. The paleae or outer coverings of the corns of
this variety are somewhat "greasy" in appearance, and do not
adhere so closely to the corn as in the Chevallier. The corns of
Goldthorpe barley point a small dimple or transverse furrow near
the basal end. Further the basal bristle or rachilla (the prolongation
of the axis or point from which the corn was originally developed)
is invariably covered with long hairs, whilst in the case of Chevallier
it has generally very short hairs. In the variety of Chevallier known
as Archer, however, the rachilla has somewhat long hairs. Further
the corns of Chevallier barley lie nearly vertical, that is almost
parallel to the rachis, whereas in Goldthorpe they are spread out at
a greater angle, hence the name fan or peacock barley given to that
variety commonly known as sprat. It is believed by some brewers
that Goldthorpe barleys never yield malt of so high a quality as
do Chevallier barleys. On the other hand, when well matured.
Goldthorpes work evenly and freely on the malting floors; and from
an agricultural point of view they have the advantage of standing
up better against unfavourable weather conditions on account of
their stouter straws. Numerous fresh varieties of barley are con-
tinually being introduced as a result of artificial cross-fertilization,
but cross-fertilization rarely if ever occurs naturally.

Hungarian two-rowed barleys are excellent as regards quality,
and command a high price. The so-called Californian Chevallier
and Chilean Chevallier contain a certain admixture of the six-rowed
H. vulgare.

Of the imported thin barleys may be mentioned Brewing Cali-
fornian, Brewing Chilean, Danubian and Smyrna (Yerli), all for
the most part six-rowed varieties; also Ouchak, consisting principally
of a two-rowed variety. For the manufacture of grain spirit a male
of high diastatic activity is required, and this is largely made from
a very thin barley shipped from Odessa.

Linnaean six-rowed English barley or Scottish bere (H.
vulgare), the two lateral rows of spikelets springing from one side of
the rachis, either partially or entirely intersect and overlap the after-
mate lateral spikelets which spring from the opposite side of the rachis.
This has given rise to the term "four-rowed barley." Figs. 1-3
show some typical barleys in the ear.

The production of new varieties by cross-fertilization has of late
years attained a degree of almost mathematical precision by the
application of the law of inheritance first discovered by Gregor
Mendel in 1865, and brought to light in 1901 independently by
de Vries, Correns and Tschermak.

Constitution of Barley.—A grain of barley is shuttle-shaped;
the end containing the germ which was originally attached
to the rachis is known as the proximal end, whilst the opposite
end of the corn is called the distal end. A deep furrow runs
down the more convex side, which is accordingly denoted
the ventral side, the opposite side being distinguished as the
dorsal side. Within the ventral furrow at the proximal end is
the rachilla already referred to. The skin or husk of a
barleycorn consists of two paleae, one adhering to the dorsal
side (the pales inferior) and the other to the ventral side (the
palea superior); the former overlaps the edges of the latter.
The awn or beard is merely an elongation of the palea inferior.
If the two paleae are removed from a barleycorn after soaking
it in water, it will be seen that there are other skins completely
enveloping the embryo and endosperm. These are the true
skins, and are known as the pericarp and the testa respectively.

It may here be mentioned that A. J. Brown has shown recently
that the embryo and endosperm of a barleycorn are enclosed
in a semi-permeable membrane, i.e. one which allows the passage
of water to the interior of the corn, but not of certain salts
and acids. This property appears to be associated with one
of the layers of the testa. Next to these skins will be seen the
triple layer of thick-walled square-shaped aleurone cells.

The histology of the barleycorn is best studied by the exami-
nation of sections under the microscope. The grain consists
of two main portions, the embryo or germ, and the endo-
sperm, the storehouse of reserve materials for the growing
plant.

The accompanying illustrations show portions of longitudinal
sections of a barleycorn magnified to different degrees.

Obtaining fig. 5, which represents a section of the furrow near
the basal end of a grain of barley cut through the ventral furrow, it will be noticed
that the rudimentary leaves, stem and roots are distinguishable.
Their location lies embedded in a mass of cells, the part dividing it
from the endosperm being known as the scutellum. Special note
should be taken of the elongated cells known as the absorptive
epithelial layer, which has certain very important functions to fulfill
during the process of germination, notably in feeding the embryo
when it begins to develop into a young plant. Next to this, actually
between the scutellum and the endosperm, will be seen a layer
of empty cells. These at one time in the history and the development
of the corn contained starch granules, but this starch was absorbed
during its later development by the embryo. It will be observed
that the endosperm is filled with a network of thin-walled
cells closely packed with starch granules, and smaller granules of
protein matter (fig. 6). Nearest the skin will be the triple
layer of aleurone cells already referred to (fig. 7).

- c. Epithelial layer;
- d. Compressed layer of empty cells;
- e. Cells of the scutellum cells.

**Germination.**—The barleycorn in its resting stage is in a
state which may be described as one of dormant vitality; it
respires very slowly and thus loses weight during storage. The best and driest barleys are said to lose 15% of their weight in the first year, 0.9% in the second, and 0.3% in the third. The loss is considerably more with coarse and damp samples. When the grain is steeped this dormant vitality gives place to that complicated series of processes comprised under the general term germination. When germination begins, enzymes are secreted, and these act on the reserve materials, starch and proteins of the endosperm, converting them into simpler compounds, capable of diffusing to various parts of the growing germ. Following this, starch and proteins are re-formed, the former being deposited in the tissues of the germ and in the layer,

Fig. 7.—Section showing the aleurone layer.

Figs. 5-7 from Sykes & Ling, Principles and Practice of Brewing (1907), Charles Griffin & Co., Ltd.

cells of the scutellum, which previously were almost free from starch; the protein matter deposited in the latter disappears to a considerable extent, and the protoplasmic content of the cells assumes a very granular appearance. The pointed mass of cells constituting the root-sheath is pushed forward by the root which protrudes through the base of the grain. It is at this stage that the barley is said by the maltster to "chit." After the first rootlet has broken through the ends of the sheath, it is followed by others. The cotyledonary sheath begins to elongate on the third or fourth day of germination and ruptures the true covering of the seed; it then grows upwards between this and the husk and forms the ascospire or "spire" of the maltster.

According to Brown and Morris, when the first rootlet is breaking through the sheath, starch begins to appear in the tissues of the grain, also in the protoplasm of those cells which are nearest the epithelial layer, and it gradually invades the deeper-seated cells. Further the cellulose walls of the endosperm, situated immediately above the secretory layer, are partially dissolved, the dissolved matter passing into the scutellum, there to be transformed into starch. Brown and Morris state that this process gradually extends to the cellulose walls of the endosperm, and until these are affected there is no evidence of any solvent action on the starch granules themselves. Thus according to these authors the first enzyme to be formed is one which dissolves cell walls and is consequently termed a "cytohydrolyst." They assert further that the so-called mealy or modified condition, which the maltster desires to bring about to the fullest degree, depends on the extent to which the cell walls have been affected, and they enter into a minute description of the entire disappearance of these during the maturing process. On the other hand, J. Grüss has pointed out that the action which takes place on the cell walls of the endosperm during germination does not consist in their complete solution. Schulte has shown that these cell walls consist of two carbohydrates, an araban and a xylan. Grüss states that the araban is completely dissolved, whilst the xylan is more or less unattacked. The cell walls become, however, less opposition to complete breakage, and can only be seen in sections which have been stained; Brown and Morris examined unstained sections. The writer (A. R. Ling) has proved that the cell wall is present in the most friable and well-modified malt.

Condition.—Barley is bought in the open market solely on the evidence of certain external signs, and judgment can only be acquired by long experience. The corns should be plump, even in size, and the colour should be uniform from end to end. The sample should have a sweet odour, and it should be dry to the touch. The presence of light or mealy barleys may be detected by the fact that they float in water. Careless threshing or dressing is responsible for much damage done to barley. In this way many of the corns may be broken, have the palaea partly stripped off or portions removed along with the awn. All broken and dead corns are prone to become mouldy on the malting floors, the contagion thus presented becoming general. E. R. Moritz drew attention in 1895 to the ill effects of close dressing, and more recently (1905) the matter has been brought before the Highland and Agricultural Society, chiefly through Mountagu Baird, who with C. H. Blith was instrumental in causing the Board of Agriculture to publish a leaflet recommending more careful practice. The condition of the kernel may be determined by means of a mechanical cutter, which cuts a certain number of corns (fifty or more) at one time. Some cutters are constructed to cut the corns transversely, others to cut them longitudinally. The so-called transparency test may be used for the same purpose. It is carried out in an apparatus known as the diaphanoscope, which consists of a box fitted with a sliding tray, furnished with a certain number of shuttle-shaped holes (usually 500), each of such a size as just to hold a barley-corn longitudinally. Into the portion of the box below this tray an elastic lamp is placed, and the corns are looked at from above. Thoroughly mealy corns are opaque, whilst steely corns are transparent. When certain portions of a corn are steely, these present the appearance of lakes. By this means the percentage of mealy, steely, or half steely corns in a sample may readily be estimated.

E. Prior points out that steelsiness of barley is of two kinds, one of which disappears after the grain has been steeped and dried, and the other which is a permanent characteristic of the sample, and the other which is permanent, and therefore retards the modification of the corn. He proposed to determine what he called the coefficient of meallowness of a sample of barley by means of the formula:

\[ A = \frac{(M - M_{1})}{100} \times 10^{-M} \]

in which \(A\) is the degree of meallowness, \(M\) is the percentage of mealy corns in the original barley, and \(M_{1}\) is the percentage of mealy corns after steeping and drying the barley. Prior points out that, generally speaking, the degree of meallowness varies inversely as the protein content.

The physical differences between steely and mealy grains were first investigated by Johansen, who arrived at the conclusion that mealliness is always accompanied by the presence of air spaces in the endosperm. Munro and Beaven confirmed and extended this. These conclusions are as follow: "Mealy grains have a lower specific gravity than steely grains, and contain a larger amount of interstitial air. The total nitrogen content of mealy grains is less than that of steely grains. In mealy grains, the endosperm is a loose mass of somewhat transparent, or a-structural portion of nitrogenous substances soluble (a) in 5% salt solution, and (b) in alcohol of specific gravity 0.9. Mealy barley modifies better than steely during germination. The process of drying damp and under-matured barley intact at 100 F. produced an apparent mellowing or maturation. Other things being equal, maturation, which is physiologically a post-ripening process, is correlated with the presence of air spaces. When barley is thoroughly examined under the microscope no longer exhibit a translucent appearance, but show the mealy properties as completely as if they had been steeped from a mealy grain, and they suggest that in a stealy corn the whole of the endosperm is under a state of tensile stress which cannot be maintained in the thin sections. If, however, a thin section of a stealy grain is bent to a slide with Canada balsam and then pared away with a razor and the air spaces left, these are not served even in the thinnest sections. The mealy appearance in the endosperm of barley is assumed to be a direct consequence of the formation of interspaces around the cell-contents and within the
cell walls. Under ordinary conditions it is conjectured that these interspaces are filled with air, but it is pointed out that they can also be produced under circumstances which suggest that they are at times vacuous to some extent. According to the last-named authors they appear to originate from a system of stresses and strains induced within the endosperm by its gradual loss of water, a break of continuity of which gives rise to these interspaces. The cohesive power of the heterogeneous cell-contents falls below a certain point. It is further suggested by them that the most important factor in producing the stresses and strains is probably the shrinkage of the starch granules as their water content is reduced from, say, 40 to about 15%. It is pointed out, however, that actual discontinuity in the cell-contents can only take place when the teneity strength of the protoplasmic matrix in which the starch granules are embedded has been surpassed, and this being so it might be anticipated that those cells which contain the larger amount of protein material would probably best resist the internal stresses and strains, a deduction in close agreement with observed facts, steely grains being as a rule richer in protein than mealy grains. Brown and his co-workers determine the coefficient of mealliness of a barley as follows: Five hundred corns are cut transversely in a corn cutter and the percentage of half mealy and steely corns is noted. The number 100 is taken to represent complete mealliness, 1 complete steeliness, and 50 the intermediate class. If the percentage of each class be multiplied by its specific value, and the sum of the products divided by 100, the result is the coefficient of mealliness. By steeping and drying a very steely Scottish barley, the coefficient of mealliness was raised from 29.7 to 87.1, by consequently the specific gravity fell from 1.477 to 1.289.

Barley even of the same kind varies widely in its chemical composition, but on an average the proximate constituents of British malting barleys lie within the following limits:

Any sample of barley which contains more than 20% of moisture would be considered damp. The late Professor Lintner expressed the view several years ago that a good malting barley should not contain more than 10% of protein, but R. Wahl asserts that in America six-rowed barley containing a far higher percentage of protein are used successfully, indeed preferably, for malting purposes. The only precise knowledge we possess of the protein compounds of barley is due to the researches of T. B. Osborne. According to this observer, barley contains the under-mentioned compounds of this class in the following proportions:

This is the case with barleys containing large percentages of nitrogen and of high enzymatic activities. Such barleys are denoted “warm” by M. Delbrück from their tendency to heat when stored in a moist condition. The effect of this heating is exhibited in the corns becoming black and discoloured at the tips; they are then said to be magpried. Even in an otherwise dry season a large amount of rain during harvest causes the corns to become “weathered,” whilst some of them begin germinating and rot. At the same time heavy dews at night whilst the barley lies cut in the field, with occasion of sprinkling, assists in mellowing the grain, which often in consequence works the same results on the floors. Properly harvested barley is all the better for remaining in stack for two or three months, as was the practice in former years; if, however, it has been stacked too wet the sooner it is broken down the better.

It is difficult to give any specific test for ripeness, but a series of observations has been made by H. T. Brown and F. Escombe. Samples of barley were taken from the field on the 20th, 24th and 29th of July, and on the 2nd, 6th and 10th of August, and preserved in spirit so that they remained in the same state as when they were gathered. Sections were then cut of these corns, when it was found that the progress of maturation is attended by deformation and ultimate disintegration of the cell nuclei. The change which is denoted by the term nuclear senescence is said to begin in the starch-containing cells, near the periphery of the corn, immediately underlying the outer layer next above it, and is followed by complete disintegration of the nucleus, and at the end of seven or eight days nearly the whole of the endosperm has been involved. Brown and Escombe state that when this nuclear test is properly applied it stamps as immature those corns in a sample which are manifestly unripe owing to premature desiccation as well as those in which the ratio of nitrogen to carbohydrate is unduly high, owing to an excess of nitrogenous matters in the seed, so that the sowing is reduced by root competition. This method, interesting though it be, is not fitted for practical use, and the agricultural man is relied on heretofore upon empirical methods for deciding whether or not the grain has attained ripeness or maturity.

The bushel weight is a useful criterion in arriving at an opinion regarding the value of a sample of barley; but in using judgment upon this factor regard must be paid to the fact already mentioned that if the grains be dressed closely the bushel weight is increased. The reason of this is that with the removal of the awns the corns pack more closely together. The best British malting barleys should weigh 52-56 lb per bushel, the standard weight for malting barleys being 56 lb.

During the storage of barley access of air is necessary, otherwise the grain dies from asphyxiation. Sound barley after being kiln-dried retains its vitality for a number of years; but the statement that the corns found in the Egyptian mummy cases, in which they had remained for several thousands of years, were still capable of germination, is contrary to modern experience. Moisture must also be carefully excluded, as it initiates germination and the growth of mould fungi which causes heating. A constant repetition of wetting such as may take place on account of alterations of the atmospheric temperature, which causes moisture to be deposited, in the form of dew, may ultimately destroy the vitality and foster the growth and development of mould fungi which usually grow on broken and damaged corns. In this connexion the advantage of screening and sweating of barley before storing it will be apparent (see below).

An immense amount of damage is caused to the grain, during storage, by various insects, some of the most destructive of these being the common weevil (Calandra granaria). When fully developed this insect measures 4th to 5th of an inch in length, and is of a bright chestnut colour. The larvae are fleshy legless grubs, shorter than the perfect insect, with a series of tubercles along each side of the body; the head is round with strong jaws. The pupa is white, clear and transparent, showing the form of the future weevil. The female bores a hole in the grain with her snout and deposits on egg. The insect is then hatchet-like, the larva burrows further in, and changes its form. Windisch asserts that only barley which has ripened in the granary is attacked by weevil. Grain which is only slightly attacked should be treated by the use of carbon dioxide, which destroys the weevil in all stages of development. To detect weevil in a sample of barley, the grain should be spread out on a sheet of white paper in bright sunlight. If weevils are present they soon appear, and take themselves to a position outside the sunlight, to which they are averse. Treatment of the grain with carbon dioxide can also be applied.
MALT

The capacity of a malting is described by the number of quarters which are put through it every four days. A fifty quarter malting does not merely mean that the cisterns have a capacity of fifty quarters, but that this quantity of barley goes through the house every four days. The average time the germinating barley is on the floors is twelve days, and, as a rule, kilning occupies four days. If, as sometimes happens, the malt has to be kept on the floors thirteen, fourteen, fifteen days, or even longer, the malting is not being worked at the capacity under which it is described, and the kilns may remain unused for a day or more. Conversely, when the malt is loaded at less than twelve days, a day or two has to be missed in steeping. In the former case when the kilns are not being used for drying and curing malt, advantage may be taken to utilize them for sweating barley.

Steeping cisterns were formerly rectangular vessels, of slate, brick or cement, from which the barley had to be discharged by shovelling it out. The forms approved most at the present day are conical and constructed of iron; they have arrangements at the apex of the cone, the lower portion, for discharging the grain by gravitation. The steeping period ranges from 48 to 70 hours; it varies according to the kind of barley, and the time of the year. In some of the older maltings there are no arrangements for heating the steep water, and in the winter steeping has occasionally to be performed with water at a temperature near its freezing-point. Steeping should be carried out at a temperature as near as possible to 55° and not higher than 60° F. The usual practice is to fill the cistern up to a certain height with water and throw the barley into it, stirring it until it is about level; the heavy corns will then sink directly to the bottom, whilst the light corns and refuse float on the surface and may be skimmed off. During the time the barley remains in the cistern it is usual to change the steep water two or three times, generally at intervals of twelve hours or tides. The advantage of this is not merely to keep the grain fresh and sweet, but to bring it into contact with the air during the time it is taking up water. Aération of the steep has long been recognized in Germany as promoting germination, and several arrangements are on the market enabling air to be passed through the grain while it is in the cistern. It has been recommended by Graham, Stopes, Moritz and Morris, and experimental evidence as to its beneficial effects has been published by Windisch, Bleichs, Will, and Baker and Dick. When the corn is steep ripe it contains some 60% of water. Steeping does not consist, however, merely in the

These bisulphide has been suggested as a means of destroying weevil; even if efficacious, however, such a process could not be recommended on account of its danger, carbon bisulphide being highly inflammable. The only practical means of ridding a granary or shop of weevil is to clear out all the grain and leave it empty for a year or more.

The vitality of barley may be determined by causing a sample to germinate in any of the well-known forms of apparatus devised for that purpose, and counting the percentage of germinating and idle corns. The germinative capacity of a sample of barley may frequently be raised by sweating (see below), which, as already mentioned, brings about a kind of artificial maturation.

Malting.—There are two systems of malting used in England: floor malting and pneumatic or drum malting. These systems will be described separately.

A floor malting consists of a rectangular building of several storeys, having the cisterns at one end and the kilns at the other. The uppermost floor is devoted to barley.

Figure 8 shows a longitudinal section of Messrs Watney, Combe, Reid & Co.'s 200 quarter malting at Mortlake. The barley is carried to the top of the building by the elevator A, where the screening and dressing machinery is situated. After leaving these machines the grain is conveyed on bands to the barley floors B and C. The floor C contains also the steeping cisterns. The six working floors are D, E, F, G, H, and I. The floors are ventilated by louvres, N, N, N. The cisterns are connected to the floors by means of plugs. The "pieces," as they are termed, of germinating barley are gradually worked along the floors to the kilns M, M, on to which they are loaded by rotary bands. The fire-places O, O, are arranged so that the draught may be easily controlled. The hot air and products of combustion pass up the shafts P, P, to the hot-air chamber R, R, where they strike the baffle plates S, S. These plates disperse the hot air and gases evenly beneath the kiln floors T, T, through the green malt. After drying and curing, the malt is allowed to cool and is then carried by bands to the floor U, where by suitable machinery the coombs or rootlets are removed. The finished malt is stored in the bins V, V, V.

On arrival at the malting the barley has to be put through the following operations seriatim: receiving, hoisting and weighing, rough screening, drying and sweating, storing until required for use, screening, grading and removing broken corns, steeping, couching, flooring, withering, drying and curing, dressing and polishing, storing, weighing, sacking and discharging the finished malt.

In sweating barley the temperature should not be allowed to rise above 120° F.; it is usually conducted at 100° F.; and subsequently the barley should be stored for some weeks before it is steeped.
imbibition of a certain amount of water; in order to bring about germination this water must remain within the corn a certain length of time. Thus, although it is quite possible to force the necessary amount of water into the grain in less than the 48-70 hours usually taken up by the steeping process, the grain is not steep-ripe until certain changes initiated by the water have taken place, and these require time for their completion. The following average data are useful to remember in connection with the steeping process:

- Amount of water in steep-ripe barley (about) 60%.
- Matter removed from barley during steeping (about) 7-5%.
- Increase in volume of barley due to water absorption (about) 18-20%.

There has been much discussion as to the influence of saline matters in water on the steeping process. The late Professor Lintner stated that common salt in water tended to extract the nitrogenous constituents of the grain, but impeded its germination. Mills and Pettigrew found that waters containing calcium salts extracted a minimum of nitrogenous compounds from the barley; they also came to the conclusion that the estime in which the Lichfield water is held for steeping purposes is due to the presence of nitrate which, they assert, have a stimulating effect on the subsequent germination of the grain. The writer has added lime-water to the extent of one-third of the total volume of water at the first change, believing its to promote regularity of germination. Bearing in mind, however, the observations of Adrian J. Brown, that the barley is concealed in a membrane permeable to water but impermeable to most salts, it is difficult to say whether the saline character of water, and any influence except in removing matter from the external portions of the grain and on those corns which are broken. The apparent beneficial effect of lime-water in the steep is probably entirely due to the promptness with which the kernels are broken.

Melting floors may be constructed of cement, tiles or slate, the two former being preferable to the latter. Ford, in 1839, recommended 200 sq. ft. per quarter of barley steeped as the area of the working floors, and he was quite convinced of the necessity of allowing ample floor room, so that the grain could be worked on the slow, cool system. Subsequently, however, maltsters reduced their floor area, and put the grain rapidly through the melting, thus producing what is termed "forced" malt. This kind of malt was, however, condemned by practical brewers, and a chemical test whereby forcing could be detected having been devised by E. R. Moritz and G. H. Morris, maltsters have been compelled again to increase the area of their working floors. At the present time the approved area may be placed at 175-200 sq. ft. per quarter of barley steeped. The area is, however, largely ruled by the kind of barley to be melted.

After the barley has been thrown out of the cistern it is made up in a rectangular heap 16-20 in. deep, called the "couch"; the object of this is to enable it to gather heat and so start germinating. It usually remains in couch for 12-24 hours, until in fact the inferior portion of the heap registers a temperature of about 60° F. During the days of the malt tax the exciseman gauged the quantity of the barley while it was in the couch. After couching the barley is spread thinly and evenly on the floor, forming what is known as the young floor or No. 1 piece. The first visible sign of germination is the sprouting of the rootlet, termed "chitting," and this occurs either while the grain is on the couch or on the young floor. As already mentioned, it may be quickened by aerating the grain in the cistern. From the time the barley is first cast out of the cistern up to the stage of being called "thrown," its No. 1 piece, it exudes a pleasant etheric odour resembling apples. Drs Thomson, Hope and Coventry stated in the earlier part of the 19th century that they distilled "spirits" from germinating barley at this stage. In the light of our present knowledge it would not be surprising if alcoholic fermentation were proved to occur within the grain at this stage, since intramolecular or anaerobic respiration in certain vegetables has been found to be due to alcoholic fermentation.

The thickness at which the young floor is spread depends upon the temperature and the weather. If the weather be warm, or if there be a tendency for the barley to heat, the piece must be spread all the thinner. At this stage the grain loses its external wet appearance. When spread too thickly the grain will begin to sweat, and the rootlets will be thrown out suddenly and unevenly. As a rule, under these circumstances, the rootlets will be long and thin, when they are said to be "wild." A piece which has been allowed to get into this condition must at once be spread thinner. If the sweating has not continued long, the harm done may be confined to increased loss by respiration. The young floor is usually turned with a plough twice during twelve hours, and it may be forked between whiles, but no hard and fast rule can be laid down as to when this is necessary; it must be left to the maltster's judgment, as it depends entirely on what is going on within the grain. The object of turning is in the first place to aerate the grain and freshen it, secondly to check excessive rise of temperature, and thirdly to promote evenness of growth. Too frequent turning is not to be advised. After remaining four days on the young floor three or four rootlets should have appeared, and the acrospire should have begun to grow up the back of the corn. The apple-like odour of the piece then gives place to one resembling that of the common rush, and this should continue the whole time that the malt remains on the floor. On the fifth day the piece is next moved to No. 2 position, a stage nearer the kiln. It is here that sprinkling is resorted to when necessary. The amount of sprinkling and the time it is given cannot be exactly prescribed. The amount may vary from two to five gallons per quarter, and it should only be given when the rootlets, which ought to be short and curly, and five or more in number, show signs of losing their freshness. If an excessive amount of sprinkling be given forced growth ensues. It is preferable not to add the whole of the water at one time, but to divide it over two lots; and immediately after the piece has been sprinkled it should be thoroughly and carefully mixed, otherwise some of the grain will receive an undue proportion of water. When all the sprinkling water has been given to the piece, which as a rule should not be done later than at the sixth or seventh day of flooring, the temperature should be kept down to about 55° F. by turning. Too frequent turning may, however, detach the rootlet, and it may cause the grain to lose its vitality prematurely, so that growth of the acrospire stops.

By about the eighth day of flooring the acrospire should be about three-quarters up the corn. After this the germinating corn is moved forward to No. 3 piece, which is at first spread as thinly on the floors as in the previous pieces. Here it gradually dries and incipient withering of the rootlets sets in. The only treatment which is now given to the grain is to heap it up thicker and thicker by degrees until it is ready for loading on the kiln. This increase in thickness of the piece (now called the old piece) should not be too sudden, especially if the grain be fresh in appearance and contain a large quantity of water. When the piece is thickened up to say 10 in. in depth, while it is in a very moist condition, heating and sweating take place, with additional growth of acrospire and rootlet. Under such forcing conditions a large production of sugar and degradation of the proteins will take place. When, however, the moisture has been gradually reduced before thickening up, the rootlet dies off; and although increase of temperature may occur, this is accompanied by little or no further growth of the acrospire, action being confined to the mellowing of the grain by the enzymes. When the malt is ready for loading on the kiln it should be possible to break down the contents of each corn between the thumb and finger. Opinions differ as to what the final temperature on the withering floor should be. If the moisture content of the malt be about 50%, the piece must be kept thin to avoid sweating. But under these conditions mellowing does not occur, hence the necessity of reducing the moisture content gradually after the last sprinkling water has been given. When the process has been conducted properly the temperature of the old piece may be allowed to rise as high as 70° F. during the six hours previous to loading. The moisture content of the green malt when loaded should not be much above 40%.

The endosperm of green malt which is ready for the kiln should be soft and mealy, and should not exude moisture when
pressed between the thumb-nails, but should crumble and disintegrate to a chalky mass having little or no adhesiveness.

The foregoing observations are not to be regarded as hard and fast rules, but they are simply intended to give some indications of the malting process when it proceeds on normal lines; it may be that on account of the presence of damaged cells the plan begins to develop mould by about the tenth day, and it then has to be kept thin and sometimes even loaded on kiln prematurely.

The malt made for grain distillers, in which a high diastatic activity is required, is manufactured on quite different lines from those above indicated. It is often sprinkled late, and loaded on kiln often in a sodden condition. In some cases sprinkling on kiln is resorted to, but it is doubtful if this leads to the desired object. Other things being equal, the smaller the corns—the greater the number of embryos—the more diastatic activity of the malt. In selecting a barley for the production of highly diastatic malt, the diastatic power of the original raw grain is a factor of great importance.

Kilning.—When loaded on kiln, malt intended for brewing ale and stout is, if properly withered, in a moribund condition; nevertheless, during the first stages of the kilning process a certain amount of vital activity is manifested, and the malt undergoes mellowing by the action of enzymes on the contents of the endosperm. If the malt be loaded while the rootlets appear, fresh account of the presence of two much moisture rapid growth of the acrospire ensues, giving rise to overshot corns, known in Germany as "hussars." To check this the moisture must be rapidly removed by the passage of large volumes of air through the malt. But under such circumstances mellowing does not occur. The ideal conditions of kilning are when the malt has been properly withered on the floors before loading, and, assuming that drying and curing occupy four days, that 25-30 % of the moisture be removed very gradually, this occupying the first three days, at the end of which the malt is said to have "taken the smell," i.e., the moisture remaining on the kiln should not exceed 7-8 in., and until hand-dry (that is to say, reduced to a moisture content of 12-15%) it should not be turned; if moved at all (and that only is necessary when reek occurs), it should only be lightly forked. The rate at which the temperature is raised depends largely on the kind of malt to be made and the construction of the kiln. If high flavour and colour are required, these are produced by keeping the malt for several hours near a temperature of 100° F. while it still contains 12-15% of moisture. If more than this amount of moisture be present when the temperature reaches the limit just mentioned, the conditions known as stewing would obtain, with the result that "forced" malt would be produced. A certain amount of colour is produced at the final temperature to which the malt is raised; but when such means are relied upon for the production of the greater part of the colour, reduction of extract and deficiency of flavour follow, the colour being then almost exclusively the result of caramalization of the carbohydrates.

The so-called curing stage constitutes the last part of the kilning process, and the malt must then be turned frequently to ensure uniformity of action. Mechanical turners are exceedingly useful for this purpose. Curing in a drum, as in the so-called pneumatic malting process (see below), also effects satisfactory curing.

The following table will give an idea of the kilning temperatures usually employed for the three kinds of malt mentioned, but it must be remembered that these temperatures are largely regulated by the construction of the kiln and the amount of draught available. In this connexion it may be mentioned that the final curing temperature is not necessarily a criterion of the tint of the malt. A malt may have been finished off at a very high temperature and still be a pale malt, provided the moisture percentage has been sufficiently reduced in the initial stages of kilning.

Metabolic Changes.—All through the malting process metabolic changes are proceeding, in which both carbohydrates and proteins are concerned. In its resting stage the embryo of a barley-corn is generally free from starch; as soon as germination sets in, however, starch appears in the scutellum, while the amount of sucrose there present increases, these being apparently formed from maltose originating from the action of diastase on the starch during malting. Sucrose is also present in the aleurone layer, but starch is never formed in the aleurone cells. These changes occur when the malt is first loaded on kiln; indeed, at no part of the malting process is there greater physiological activity.

The second stage of the kilning process, according to Grüss, is that at which the temperatures range from 115° to 160° F. The life of the corn is now suspended, but enzymatic processes continue. The starch is further saccharified, and the dividing line of the aleurone layer at the furrow is attacked, as are also the cell walls of the endosperm, which are still intact, these being partially converted into gummy substances. This change, however, also requires the presence of a certain amount of moisture. If too much air be passed through the malt at this stage the above-named dividing partition of the cell walls is not attacked. The air may expand the grain to some extent and produce malt of a low bushel weight, which, however, is not properly modified and cannot give satisfactory results in practice.

Fuel.—The fuel used for drying and curing malt is either anthracite or coke, and the greatest care is necessary in selecting it on account of its liability to contain arsenic, which is to a greater or less extent an invariable constituent of all coals. In the case of charcoal for malting purposes it should contain no more arsenic than 54th grain per lb. Gas coke should on no account be used, unless it has been
proved to be sufficiently free from arsenic; but the best oven coke frequently contains so little arsenic that it may be employed with perfect safety, especially if it be mixed with a proportion (e.g. 5%) of milk of lime, which retains the arsenic as calcium arsenate. In Germany malt is, as a rule, dried and cured with hot air, whilst in Great Britain the products of combustion are passed through the malt, as it is believed that they exert a beneficial influence on the flavour. The proportion of fuel used for drying and curing malt varies according to the quality of the fuel and the construction of the kiln, but on an average it may be placed at 50-60 lb per quarter.

Storing.—After the malt has passed through the curing stage it is generally heaped up for a few hours. This is believed to increase its flavour. The malt is then stripped from the kiln, and the rootlets, technically known as the coombs, are removed. Formerly this was effected by workmen treading the malt, who wore heavy boots for the purpose. At the present time, however, the rootlets are usually removed by machinery, special forms of which have been devised for this as well as for dressing and polishing the malt. It is the custom of some malsters to store malt with the rootlets still attached; but this is an objectionable practice, since malt coombs attract moisture, and the presence of more than 3% of moisture in malt produces the condition known as "slackness." When the malt is packed in binn it is often covered with a layer of coombs, which then prevent access of atmospheric moisture. Malt, to preserve its good qualities intact, should be stored in bins made as nearly as possible air-tight, and it should never be placed in bin until it is quite cool. It is probably wrong to store malt in bins adjacent to the kilns, where it is kept at a higher temperature than that of the surrounding atmosphere. During storage of the malt a kind of mellowing occurs, the mechanism of which is not understood. It is, however, known by practical brewers that the best results cannot be obtained when new malt is used.

Premature Malting.—Several years ago Galland suggested germinating barley in a drum, his idea being to do away with handling of the grain, and also to be independent of changes of atmospheric temperature. The latest development of this system, the so-called Galland-Henning process of pneumatic malting, has been improved by Mr. R. Blair Robertson, and a diagrammatic view of the interior of one of these maltings, showing the drums and conical steeping cisterns, is shown in Fig. 9.

The drums are provided with a perforated channel for the passage of air through the malt, which is packed in the annular space between this channel and outside wall of the drum. Each drum is capable of revolving on its axis, and there are arrangements for passing either moist, saturated or dry air through the malt. The system as now improved is capable of producing some of the best malt, especially if, after germination has been completed in the drums, measured exclusively by volume), it frequently happens that a given number of quarters of barley yields a larger number of quarters of finished malt. When this happens it is usual to speak of an increase having been obtained. At the present time weight replaces measure for both barley and malt, and although it is usual to speak of the quantity of grain in terms of quarters, what is meant is not the measured quarter, but so many weighed standard quarters. The standard quarter for English malting barley is 448 lb and for malt 336 lb. From this it will be seen that when a given number of weighed quarters of barley yields the same number of quarters of finished malt, the actual yield is 75% and there is then said to be neither increase nor decrease. As a rule, in practical working the yield of malt varies from a 4% decrease to a 10% increase, corresponding to an actual yield on the original barley of 72 to 82 1/2%.

J. Baverstock, an old writer, says that finished malt should weigh one-fifth less than the barley from which it is produced. This corresponds to a malting increase of about 7%, which is a high yield. As a rule, foreign barley will give a greater malting increase than English barley, because, on the one hand, the former usually contains less moisture than the latter, and, further, because there is less loss on the floors by respiration and rootlet growth. The yield of malt from barley may be determined in the laboratory in an extremely simple manner. Since every grain of barley must yield a grain of malt, if we know the respective weights of a definite number of barley and malt grains, provided that this number is large enough to represent the average, then obviously this gives the data requisite for calculating the yield of malt from barley. The number of corns the weight of which is determined for this purpose is usually 1000, and if the weight of this number be determined on several different 1000 corns, the average will closely approximate

---

[From Sykes & Ling, *Principles and Practice of Brewing* (1907), Charles Griffin & Co., Ltd.]

**Fig. 9.**—Diagrammatic view of pneumatic malting, showing pneumatic washing and steeping cisterns.
to the truth. Instead of counting the corn by hand, an instrument may be used for this purpose.

If 1000 corns of a barley were found to weigh 42 grammes, and 1000 corns of a finished malt from the same barley 32 grammes, then the yield of malt is

\[ \frac{32}{42} \times 100 = 76 \frac{1}{2} \%
\]

to a 1 \% increase. Assuming that the moisture content of the barley was 15 \% and that of the finished malt 2 \%, 76 \% of grammes of malt will contain 2 grammes of moisture, and 76 \% of grammes will contain

\[ 76 \times 2 = 15 \text{ grammes moisture} \]  
\[ 76 \times 100 = 76 \text{ grammes of dry matter} \]

This was obtained from 100 - 15 = 85 grammes of barley dry substance.

Hence 100 parts of barley dry substance will yield 74 \% \times 100 = 87 \%

corresponding with a loss of dry substance equal to 12-5 \% of the dry substance of the barley, or with a loss of 10-7 \% on the barley containing 15 \% of moisture.

**Malt.**—In addition to the kinds of malt considered in what precedes, there are others mostly used for imparting specific flavours and colour to beers and stout. These are crystal malt, inferior, and pale malts, for the production of Burton or topmalts. Crystal malt is grown for a short period on the floors, and then placed in a wire cylinder, which is rotated over a fire so that it is dried at a very high temperature. The weight per quarter is from 230 to 240, and is determined by the original temperature of 240-270° F., but it is not allowed the usual length of time of the withering floor. It is placed on the drying kiln in layers one inch deep and left to age. The heat from burnt wood is first applied until the bulk of the moisture has been driven off, when the temperature is suddenly raised so that the grains swell some 25 \% and the malt takes up a strong empyreumatic flavour from the products of combustion. This kind of malt weighs 270-300 lb per quarter. Black or roasted malt is prepared by roasting malt in a cylinder. Ford states that perfectly malted corn gives a colourless, less intensity and appearance than the roasted malt, but that this has been contradicted by other observers.

A certain quantity of the so-called black malt is actually made from raw barley, but this gives a product of inferior flavour. The weight per quarter is 225 to 245 grammes.

**Valuation.**—For the valuation of malt the following determinations are usually carried out: Extract per standard quarter, moisture, diastatic activity by the Linton process, tint, and matters soluble in cold water. The physical examination of malt is also a matter of importance, insomuch as direct evidence is obtained thereby of the modification of the malt. Among the methods adopted for this purpose are the frothed milled moistened barley, percentages in which the asphores have grown up to one-half, two-thirds and three-fourths the entire length of the corn. In properly malted the modification of the endosperm should proceed pari passu with the germination of the alembic, which is the objective of useful work out in an intelligent manner. Those corns which sink in water and lie flat are improperly modified. Normal malt has a specific gravity less than water and the corns are equal density throughout; corns are horizontal in water. In frothed milled moistened barley the proximal ends are frequently lighter than the distal ends, and the corns float horizontally in water, with the germ directed upwards.

The latter, however, may in some cases fill with water, and the corns sink or lie flat. This is a characteristic of over-modified malt. It will be seen from these remarks that it is essential to carry out the sinker test under standard conditions. The modification of the malt may also be determined by means of the diaphanoscope already referred to under barley.

**MALTA.** The largest of the Maltese Islands, situated between Europe and Africa, in the central channel which connects the eastern and western basins of the Mediterranean Sea. The group belongs to the British Empire. It extends over 29 m., and consists of Malta, 91 sq. m., Gozo (g.o.) 20 sq. m., Comino (set apart as a quarantine station) 1 sq. m., and the uninhabited islets called Cominotto and Filfla. Malta (Int. of Valletta Observatory 35° 53' 55" N., long. 14° 30' 45" W.) is about 60 m. from the nearest point of Sicily, 140 m. from the mainland of Europe and 180 from Africa; it has a magnificent natural harbour. From the dawn of maritime trade its possession has been important to the strongest nations on the sea for the time being.

Malta is about 173 m. long by 81 broad; Gozo is 81 by 43 m. This chain of islands stretches from N.E. to S.E. On the S.W. the declivities towards the sea are steep, and in places rise abruptly some 400 ft. from deep water. The general slope of these ridges is towards the N.W., facing Sicily, and the snow-capped Etna, the source of cool evening breezes. The Binnenrange, rising 726 ft., is nearly at right angles to the axis of the main island. The geological "Great Fault" stretches from sea to sea at the foot of these hills. There are good anchorages in the channels between Gozo and Comino, and between Comino and Malta. In addition to the harbours of Valletta, there are in Malta, facing N.W., the bays called Mellieha and St Paul's, the inlets of the Salina, of St Julian and St Thomas; on the E. there is the large bay of Marsa Scirocco. There are landing places on the S.W. at Fombi-il-rigg and Miggjarro.

Mount Sceberras (on which Valletta is built) is a precipitous promontory about 1 m. long, pointing N.E. It rises out of deep water; well-sheltered creeks indent the opposite shores on both sides. The waters on the S.E. form the "Great Harbour," having a narrow entrance between Ricasoli Point and Fort St Elmo. The series of bays to the N.W., approached between the points of Tigne and St Elmo, is known as the Marsamuscetto (or Quarantine) Harbour.

Mighty fortifications and harbour works have assisted to make this ideal situation an emporium of Mediterranean trade. During the Napoleonic wars and the Crimean campaign the Grand Harbour was frequently overcrowded with shipping. The gradual supplanting of sail by steamships has made Malta a coaling station of primary importance. But the tendency to great length and size in modern vessels caused those responsible for the civil administration towards the end of the 19th century to realize that the harbour accommodation was becoming inadequate for modern fleets and first-class liners. A breakwater was therefore planned by the Monarch, so as to enable the available anchorage area and increase the frontage of deep-water wharves available in all weathers.

The Maltese Islands consist largely of Tertiary Limestone, with somewhat variable beds of Crystalline Sandstone, Greensand and Marl or Blue Clay. The series appears to be in line with similar formations at Tripoli in Africa, Cagliari in Sardinia, and on the rocks of Sicily, the Isthmus of Corinth, the Bejaia east of the Great Fault (already mentioned) the beds are more regular, comprising, in descending order, (a) Upper Coralline Limestone; (b) Yellow, Black or Greensand; (c) Marl or Blue Clay; (d) White, Grey and Pale Yellow Sandstone; (e) Chocolate-coloured nodules with shells, &c.; (f) Yellow Sandstone; (g) Lower Crystalline Limestone. The Lower Limestone probably corresponds to the Ordovician age of the Tortonian formation of the Upper Coralline Limestone to the Tortonian stage of the Miocene. The beds are not folded. The general dip of the strata is from W.S.W. to E.N.E. North of the Great Fault and at Comino the strata dip more or less vertical, and the same beds in Malt are juxtaposed with (g), the semi-crystalline Limestone. There is a system of lesser faults, parallel to the Great Fault, dividing the area into a number of blocks, some of which have fallen more than others, giving the visible series (e). The lower beds (c) rest roughly parallel to the south-east coast, which point to the islands being fragments of a former extensive plateau. The mammalian remains found in Pleistocene deposits are of exceptional interest. Among the more remarkable forms are a species of hippopotamus, the elephant (including a pigmy variety), and a gigantic dormouse.
In the Coraline Limestone the following fossils have been noted:—Spondylus, Ostrea, Pecten, Cytherea, Arca, Terebrula, Oritis, Clavellina, Echinus, Didemnum, Lenticulites, Brissia, Sparagass; in the Maltese Breccia there are higher forms of Lenticulites complanatus, teeth and vertebræ of Squalus and Cetacea; in the Sandstone Vaginula depressa, Crystallaria, Nodosaria, Brissia, Nucula, Pecten, Cardium, Scrobicularia, Scutella, Spondylus, Nautis, Ostrea umbellata, and Pecten crassatula (see Captain Spratt's work and papers by Lord D'Arcy and Dr Adams).

The Blue Chy forms, at the higher levels, a stratum impervious to water, and holds up the rainfall, which seeks through the sponggy matrix of the fine blue formation. Hence arise the springs which run perennially, several of which have been collected into the gravitation water supplies of the Vignacourt and Fawqa aqueducts. The springs are, however, hotly disputed by the inhabitants, who claim rights derived by pumping from strata at about sea-level. These strata are generally impregnated with salt water, and are practically impenetrable to the rain-water of less weight. The honeycomb of rock-springs, thermal, or the hot water from springs sinking to the sea; the soakage from rain has therefore to move horizontally, over the strata about sea-level, seeking outlets. At this stage the rain-water is intercepted by wells, and by galleries hewn for miles in the water-bearing rock. Large reservoirs assist to store this water after it is raised, and to equalize its distribution.

The climate is, for the greater part of the year, temperate and healthy. The thermometer records an annual mean of 59° F. Between June and September the temperature ranges from 75° to 90°; the mean for December, January and February is 50°; March, May and November are mild. Pleasant northern winds blow for an average of 100 days a year, cool northerly winds for 31 days, east winds 70 days, west for 34 days. The north-west “Gregale” (Euroclydon of Acts xxvii. 14) blows almost as strongly as a gale, and causes much rough weather. The hurricane force, in the winter, is, however, uncertain; periods of drought have extended over three years. Snow is seen once or twice in a generation; violent hailstorms occur. On the 19th of October 1856, exceptionally large hailstones fell in Malta, some being 4 in. in length. There and in muded bays; the roots are cast up by storms and are valuable to dress the fields. Among the land plants may be noted the blue anemone; the ranunculus along the road sides, with a strong perfume of violet; the common knapweed, which flowers at all seasons; Commenium coccineum, the curious “Malta fungus,” formerly so valued for medicinal purposes that a guard was set for its preservation under the rule of the Knights; the pheasant’s-eye; three species of mallow and geranium; Osalis cornuta, a very troublesome weeded weed; Lotus elatus; Scrophularia subulosa, wild and cultivated forage; two species of the hoeschoe-vetch; the opium poppy; the yellow and red-betted poppy; wild rose; Crataegus azarolus, of which the fruit is delicious; the ice-plant; squiring cucumber; many species of Umbelliferae; Labiatae, to which the spicy flavour of the honey (equal to that of Mt Hymettus) is ascribed; snapdragons; broom-rape; glass-wort; Salix sida, which produces when burnt a considerable amount of alkali; there are fifteen species of orchids; the gladiola and iris are also found; Virginia selloa, the smaller gum-layer, with its large flat roots; the golden roots minehen; seventeen species of sedges and seventy-seven grasses have been recorded.

There are four species of lizard and three snakes, none of which is venomous. The quinquefasciatus, a poor brown frog. Of birds, few are indigenous; the jackdaw, blue solitary thrush, spectacular warbler, the robin, kestrel and the herring-gull. A bird known locally as “Hunies,” not met elsewhere in Europe, nests at Filfa. Pigeons, parrots and turtle doves, as well as teal and ducks, stay long enough to afford sport. Of migratory birds over two hundred species have been enumerated. The only wild mammal in the island is the rabbit, or “Bini,” the wild cat, the wild mouse, and the domestic mouse. The Maltese dog was never wild and has ceased to exist as a breed.

Malta has several species of zoophytes, sponges, mollusca and crustacea. Insect life is represented by plant-bugs, locusts, crickets, grasshoppers, cockroaches, dragon-flies, butterflies, numerous varieties of spiders and mosquitoes.

Among the fish may be mentioned the tunny, dolphin, mackerel, sardine, sea-bream, dentice and pagnell; wrasse, of exquisite rainbow, turbot, cod, haddock, soles (very rare); Cernus which grows to large size; several species of grey and red mullet; eleven species of Triplophys, including the beautiful flying gurnard whose colours rival the angel fish of the West Indies; and eighteen species of mackerel, all migratory.

The real population of Malta, viz. of the country districts, is to be differentiated from the cosmopolitan fringe of the cities. There is continuous historical evidence that Malta population and language.

This branch of the Caucasian race came down the great rivers to the Persian Gulf and thence to Palestine. It carried the art of navigation through the Mediterranean, along the ancient seaboard as far as Great Britain, leaving colonies along its path. In prehistoric times one of these colonies displaced previous inhabitants of Libya origin. The fluidity of the magellanic temples of Malta and of Stonehenge connect along the shores of western Europe the earliest evidence of Phoenician civilization. Philology proves that, though called “Canaanites” from having sojourned in that land, the Phoenicians have no racial connexion with the African descendants of Ham. No subsequent invader of Malta attempted to displace the Phoenician race in the country districts. The Carthaginians governed settlements of kindred races with a light hand; the Romans took over the Maltese as “dediditi,” not as a conquered race. Their conversion by St Paul added difference of religion to the causes which prevented mixture of race. The Arabs from Sicily came to eject the Byzantine garrison; they treated the Maltese as friends, and were not sufficiently numerous to colonize. The Normans came as fellow-Christians and deliverers; they found very few Arabs in Malta. The fallacy that Malta is a dialect of Arabia has been luminously disproved by A. E. Caruana, Sull’origine della lingua Maltese.

The upper classes have Norman, Spanish and Italian origin. The knights of St John of Jerusalem, commonly called “of Malta,” were drawn from the nobility of Catholic Europe. They took vows of celibacy, but they frequently gave refuge in Malta to relatives driven to seek asylum from feudal wars and disturbances in their own lands. At the British occupation there were about two dozen families bearing titles of nobility granted,
or recognized, by the Grand Masters, and descending by primogeniture. These "privileges" were guaranteed, together with the rights and religion of the islanders, when they became British subjects, but no government has ever recognized papal titles in Malta. High and low, all speak among themselves the Phoenician Maltese, altogether different from the Italian language; Italian was only spoken by 13-24 % in 1901. Such Italian as is spoken by the lingering minority has marked divergences of pronunciation and inflexion from the language of Rome and Florence. In 1901, in addition to visitors and the naval and military forces, 18,922 Maltese spoke English, and the number has been rapidly increasing.

In appearance the Maltese are a handsome, well-formed race, about the middle height, and well set up; they have escaped the negroid condition noticeable in Sicily, and their features are less dark than the southern Italians. The women are generally smaller than the men, with black eyes, fine hair and graceful carriage. They are a thrifty and industrious people, prolific and devoted to their offspring, good-humoured, quick-tempered and impressionable. The food of the working classes is principally bread, with oil, olives, cheese and fruit, sometimes fish, but seldom meat; common wine is largely imported from southern Europe. The Maltese are strict adherents to the Roman Catholic religion, and enthusiastic observers of festivals, fasts and ceremonies.

In 1906 the birth-rate was 40-65 per thousand, and the excess of births over deaths 2637. In April 1907 the estimated population was 206,690 of whom 21,017 were in Gozo. This phenomenal congestion of population gives interest to records of its growth; in the 10th century there were 16,767 inhabitants in Malta and 4514 in Gozo; the total population in 1514 was 22,000. Estimates made at the arrival of the knights (1530) varied from 15,000 to 25,000; it was then necessary to import annually 10,000 quarters of grain from Sicily. The population in 1551 was, Malta 24,000, Gozo 7000. In 1582, 20,000 quarters of imported grain were required to avert famine. A census of 1590 makes the population 30,500; in that year 3000 died of want. The numbers rose in 1601 to 33,000; in 1614 to 41,684; in 1632 to 50,113; in 1667 to 55,126; in 1677 51,000 are said to have died of plague out of the total population. At the end of the rule of the knights (1798) the population was estimated at 100,000; sickness, famine and emigration during the blockade of the French in Valletta probably reduced the inhabitants to 80,000. In 1829 the population was 114,236; in 1836, 119,587 (inclusive of the garrison); in 1873, 145,605; at the census in 1901 the civil population was 184,742. Sanitation decreases the death-rate, religion keeps up the birth-rate. Nothing is done to promote emigration or to introduce manufactures. The old fortifications of Valletta and the outer works, across the neck of the peninsula, is the suburb of Floriana (pop. 7275). To the south-east of Valletta, at the other side of the Grand Harbour, are the cities of Senglea (pop. 8053), Vittoriosa (pop. 6903) and Corcusa (pop. 12,184); this group is often spoken of as "The Three Cities." The old capital, near the centre of the island is variously called Notabile, Città Vecchia (q.v.), and Medina, with its suburb Rabat, its population in 1901 was 915, here are 40 catacombs and the ancient cathedral of Malta. Across the Marsamxett Harbours, of Valletta is a considerable modern town called Sliema. The villages of Malta are Mellieha, St Paul's Bay, Musta, Bir-ir-Reiba, Lla, Arrigo, Paola, Mdina, Balzan, Xaghra, Ibragg, Gharb, Dingli, Zebbug, Siggiewi, Corri, Lla, Tarzaxia, Zurrico, Crendi, Miedhhabba, Circop, Zabbar, Aslak, Zeitun, Gudia and Marsa Sciberras. The island of Gozo is called Victoria, and there are several small villages.

Industry and Trade.—The area under cultivation in 1906 was 41,534 acres. As a rule the tillers of the soil live away from the lands, in some neighbouring village. The fields are small and composed of terraces by which the soil has been walled up along the contours of the hills, with enormous labour, to save it from being washed away. Viewed from the sea, the top of one wall just appearing above the next produces a barren effect; but the aspect of the land from a hill in early spring is a beautiful contrast of luxuriant verdure. It is estimated that there are about 10,000 small holdings averaging about four acres and intensively cultivated. The grain crops are maize, wheat and barley; the two latter are frequently sown together. In 1906, 13,000 acres were raised 17,975 quarters of wheat and 12,000 quarters of barley. The principal fodder crops are green barley and a tall clover called "sulla" (Hedysarum coronarium), having a beautiful purple blossom. Vegetables of all sorts are easily grown, and a rotation of these is raised on land irrigated from wells and springs. Potatoes and onions are grown for exportation at seasons when they are scarce in northern Europe. The rent of average land is about £2 an acre, of very good land over £3; foraverted spots, irrigated from running springs, are worth up to £2.5 an acre. Two, and often three, crops are raised in the year; on irrigated land more than twice as many cabbages are possible. The presence of phosphates accounts for the fertility of Maltese soil. There is a considerable area under vines, but it is generally more profitable to sell the fruit as grapes than to convert it into wine. Some of the best oranges in the world are grown, and exported; but sufficient care is not taken to keep down insect pests, and to replace old trees. Figs, apricots, nectarines and peaches grow to perfection. Some figs is raised as a rotation crop, but no care is taken to improve the quality. The carob tree and the prickly pear are exceptionally cultivated. There are exceptionally fine breeds of cattle, asses and goats; cows of a breed called "Bisso" are powerful and docile. The supply of butchers' meat has to be kept up by constant importations. More than two-thirds of the wheat comes from abroad; fish, vegetables and fruit are also imported from Sicily in considerable quantities. Excellent honey is produced in Malta; at certain seasons tunny-fish and young dolphin (lampcuca) are abundant; other varieties of fish are caught all the year round.

About 5000 women and children are engaged in producing Maltese lace. The weaving of cotton by hand-looms survives as a languishing industry. Pottery is manufactured on a small scale; ornamental carvings are made in Maltese stone and exported to a limited extent. The principal resources of Malta are derived from its being an important military station and the headquarters of the Mediterranean fleet. There are great naval docks, refitting yards, magazines and stores on the south-east side of the Grand Harbour; small vessels of war have also been built here. Steamers of several lines call regularly, and there is a daily mail to Syracuse. The shipping cleared in 1905-1906 was 3524 vessels of 3,718,168 tons. Internal communications include a railway about eight miles long from Valletta to Notabile; there are electric tramways and motor omnibus services in several directions. The currency is English. Local weights and measures include the cantar, 175 lb; saltm, one imperial quart; cafio, 43 gallons; canna, 6 ft. 10½ in.; the tumolo (356 sq. ca.), about a third of an acre.

The principal exports of local produce are potatoes, cumin seed, vegetables, oranges, goats and sheep, cotton goods and stone.

To keep alive, in a fair standard of comfort, the population of 206,690, food supplies have to be imported for nine and a half months in the year. The annual value of exports would be offset against imports for about one month and a half. The Maltese have to pay for food imports by imperial wages, earned in connexion with naval and military services, by commercial services to passing steamers and visitors, by earnings which emigrants send home from northern Africa and elsewhere, and by interest on investments of Maltese capital abroad. A long absence of the Mediterranean fleet, and withdrawals of imperial forces, produce immediate distress.

Finance.—The financial position in 1906-1907 is indicated by the following: Public revenue £53,954 (including £51,029 carried to revenue from capital); expenditure £45,829; imports (actual), £1,219,819; exports in transit, £5,876,681; exports (actual), £1,223,510; exports in transit £6,127,772; imports from the United Kingdom (actual), £18,661. In March 1907 there were 8159 depositors in the government savings bank, with £569,731 to their credit.
MALTA

Government.—Malta is a crown colony, within the jurisdiction of a high commissioner and a commander-in-chief, to whom important questions of policy are reserved; in other matters the administration is under a military governor (£3,000), assisted by a civil lieutenant-governor or chief secretary. There is an executive council, now comprising eleven members with the governor as president. The legislative council, under letters patent of the 3rd of June 1903, is composed of the governor (president), ten official members, and eight elected members. There are eight electoral districts with a total of about 10,000 electors. A voter is qualified on an income from property of £6, or by paying rent to the same amount, or having the qualifications required to serve as a common juror. There are no municipal institutions. Letters patent, orders in council, and local ordinances have the force of law. The laws of Justinian are still the basis of the common law, the Code of Rohan is not altogether abrogated, and considerable weight is still given to the Roman Canon Law. The principal provisions of the Napoleonic Code and some English enactments have been copied in a series of ordinances forming the Statute Law. Latin was the language of the courts till 1784, and was not completely supplanted by Italian till 1815. The partial use of English (with illogical limitations to the detriment of the Maltese-bom British subjects who speak English) was introduced by local ordinances and orders in council at the end of the 19th century. The Maltese, of whom 86% cannot understand Italian, are still liable to be tried, even for their lives, in Italian, to them a foreign language. The Maltese have six dritjuris to those who understand Italian, reveals glaring incoherence.

Education.—There were, in 1906, 98 elementary day schools, and 33 night schools. The attendance on the Ist of September 1905 was 16,530, the percentage on those enrolled 84-6; the total enrolment was 18,719. The average cost per pupil in these schools was 35s. a year. The average cost per attendance is a small sum for girls in Valletta, and one for boys in Gozo. A lyceum in Malta had an average attendance of 464. The number of students at the university was 18,719. The average cost per student in the lyceum was £8. 6s. 11d.; in the university £10. 1s. 8d. The lyceum and these institutions are almost nominal, the middle-classes are thus educated at the expense of the masses. In the 18th century the government of the Knights and of the Inquisition did not favor the education of the people, after 1800 British governors were slow to make any substantial improveinent. About the middle of the 19th century it began to be recognized that the education of the people was more conducive to the safety of the state and to the ignorance congested masses of southern race liable to be swayed spasmodically by prejudice. At first an attempt was made to make the use of the Maltese language by the Maltese literate, and to record it in print. This failed for several reasons, the foremost being that the language was not Arabic but Phoenician, and because professors and teachers, whose personal ascendancy was based on the prestige derived from using the language, were introduced to the island; institutions existed for the rising generation rather than to provide salaries for alien teachers and men behind the times. Various educational schemes were proposed, but they were easier to propose than to carry into effect: no one, except Mr Savona, had the ability to urge English as the basis of instruction, and he agitated and was installed as director of education and made a member of the Executive. The obstruction which he encountered alarmed him, and he compromised by adopting a mixed system of both English and Italian, pari passu, as the basis of Maltese education; he resigned after a brief effort. Mr Savona’s attempt to teach the Maltese to children simultaneously two foreign languages (of which they were quite ignorant, and their teachers only partially conversant) without first teaching how to read and write the native Maltese systematically—was continued for some years under an eminent archiologist, Dr A. A. Caruana, who became Director of Education. He began to give some preference to English indirectly. On his resignation Sir G. G. Halsaflieni adopted a new system of education based on the principle of beginning from the bottom, by teaching to read and write in Maltese as the medium for assimilating, at a further stage, either English or Italian, one at a time, and aiming at imparting general knowledge by introducing English syllabus. Series of English characters in the Maltese language printed in Roman characters, with translations in English interlined in different type, was produced at the government printing office and sold at cost price. The parents and guardians are urged to adopt one or other channel of acquiring English or Italian next after learning reading, writing, and arithmetic in Maltese. About 89% recorded their preference in favor of Maltese education; the remaining 11% were Maltese. This agitation, this percentage was considerably lowered, but soon crept up again. Teachers and professors who were weak in English, lawyers, newspaper men and others, combined to deprive these reforms of their legitimate consequence, viz. that after a number of years English should be the language of the courts as well as of government, and to prevent those belonging to the old order of Malta, better educated than themselves, whose rapid rise everywhere would be assured by the prestige of the Maltese, who claim to speak Italian (13-24%) still command sufficient influence to hamper the full enjoyment of this emancipation by the majority. In the university most of the textbooks used are in English, whereas very many of the lectures are still delivered in Italian—for the convenience of some professors or to please the politicians, rather than for the benefit of the students. The number of students who enter the university without passing any examinations is very large, and during this period of transition, the greater the detriment to the rising generation.

History and Antiquities.—The earliest inhabitants of Malta (Melita) and Gozo (Gaulos) belonged to a culture-circle which included the whole of the western Mediterranean, and to a race which perhaps originated from North Africa; and it is they, and not the Phoenicians, who were the builders of the remarkable megalithic monuments which these islands contain, the Gigantia in Gozo, Hagiar Kim and Mnajdra near Crendi, the rock-cut hypogaeum of Hal Safieni; and the megalithic buildings on the hill of Corradino in Malta, being the most notable. The contemporaneity of these structures has been demonstrated by the identity of the pottery and other objects discovered in them, including some remarkable stelopygic figures in stone, and it is clear that they belong to the neolithic period, numerous flints, but no metal, having been found. Those that have been mentioned seem to have been sanctuaries (some of them in part dwelling-places), but Hal Safieni was an enormous ossuary, of which others may have existed in other parts of the island; for the numerous rock-cut tombs which are everywhere to be seen belong to the Phoenician and Roman periods. In these buildings there is a great preference for apsidal terminations to the internal chambers, and the façades are as a rule slightly curved. The numerous niches, generally containing sacrificial (?) tables, are often approached by window-like openings hewn out of one of the flat slabs by which they are enclosed. The surface of the stones in the interior is often pitted, as a form of ornamentation. Even the barren islet of Comino, between Malta and Gozo, was inhabited in prehistoric times.

To the Phoenician period, besides the tombs already mentioned, belongs the remains of fortifications, the ancient towers, and (probably) a few round towers which are scattered about the island. The Phoenicians, while the important Roman house at Cittavecchia is the finest monument of this period in the islands. The Carthaginians came to Malta in the 6th century b.c., not as conquerors, but as friends of a sister Phoenician colony (Freeman, Hist. Sicily, i. 255): Carthage in her struggle with Rome was at last driven to levy oppressive tribute, whereupon the Maltese gave up the Punic garrison to Titus Sempronius under circumstances described by Livy (xxi. 51). The Romans did not treat the Maltese as conquered enemies, and at once gave them the privileges of a municipium: Cicero (in Verrem) refers to the Maltese as “Soci.” Nothing was to be gained by displacing the Phoenician inhabitants in a country from which any race less thrifty would find life impossible by agriculture. On the strength of a monument bearing his name, it has been surmised that Hannibal was born in Malta, while his father was governor-general of Sicily; he certainly did not die in Malta. There is evidence from Cicero (in Verrem) that a very high stage of manufacturing and commercial prosperity, attained in

1 See T. Zammitt, The Hal Safieni prehistoric hypogaeum at Casal Paolo, Malta (Malta, 1910).
2 Sometimes the pillar which represents the baetyl, which seems to have been the object of worship (see A. J. Evans in Journal of Hellenic Studies, xxii, 1901) stands free sometimes it serves as support to the table. In the case ofRa, the b采访 of which again monolithic tables occur. Conical stones (possibly themselves baetyl) are also found.
Carthaginian times, continued in Malta under the Romans. The Phoenician temple of Juno, which stood on the site of Fort St Angelo, is also mentioned by Valerius Maximus. An inscription records the restoration of the temple of Proserpine by Chryston, a freed-man of Augustus and procurator of Malta. Diodorus Siculus (L. V., c. 4) speaks of the importance and ornamentation of Maltese dwellings, and to this day remains of palaces and dwellings of the Roman period indicate a high degree of civilization and wealth. When forced to select a place of exile, Cicero was at first (ad Att. III. 4. X. i. 8, 9) attracted to Malta, over which he had ruled as quasestor 75 B.C. Among his Maltese friends were Aulus Licinius and Diodorus. Lucius Castricius is mentioned as a Roman governor under Augustus. Publius was "chief of the island" when St Paul was shipwrecked (Acts xxvii. 7); and is said to have become the first Christian bishop of Malta. The site where the cathedral at Notabile now stands is reputed to have been the residence of Publius and to have been converted by him into the first Christian place of worship, which was rebuilt in 1090 by Count Roger, the Norman conqueror of Malta. The Maltese catacombs are strikingly similar to those of Rome, and were likewise used as places of burial and of refuge in time of persecution. They contain clear indication of the interment of martyrs. St Paul's Bay was the site of shipwreck of the apostle in a.D. 58; the "topon diathalasion" referred to in Acts is the strait between Malta and the islet of Selinun. The claim that St Paul was shipwrecked at Meleda off the Dalmatian coast, and not at Malta, has been clearly set at rest, on nautical grounds, by Mr Smith of Jordanhill (Voyage and Shipwreck of St Paul, 1848). According to tradition, the islet of St Chrysostom (Hum. 54), the stay of the apostle resulted in the conversion of the Maltese to Christianity. The description of the islanders in Acts as "barbaroi" confirms the testimony of Diodorus Siculus that they were Phoenicians, neither hellenized nor romanized. The bishopric of Malta is referred to by Rocco Fisro (Sicilia sacra), and by Gregory the Great (Epist. 2, 44; 9, 63; 10, 1). It appears that Malta was not materially affected by the Greek schism, and remained subject to Rome.

On the final division of the Roman dominions in A.D. 395 Malta was assigned to the empire of Constantine. On the third Arab invasion, A.D. 870, the Maltese joined forces against the Byzantine garrison, and 3000 Greeks were massacred. Unable to garrison the island with a large force, the Arabs cleared a zone between the central stronghold, Medina, and the suburb called Rabat, to restrict the fortified area. Many Arab coins, some Kufic inscriptions and several burial-places were left by the Arabs; but they did not establish their religion or leave a permanent impression on the Phoenician inhabitants, or deprive the Maltese of the language of the characteristics which differentiate it from Arabic. There is no historical evidence that the domination of the Goths and Vandals in the Mediterranean ever extended to Malta; there are fine Gothic arches in two old palaces at Notabile, but these were built after the Norman conquest of Malta. In 1090 Count Roger the Norman (son of Tancred de Hauteville), then master of Sicily, came to Malta with a small retinue; the Arab garrison was unable to offer effective opposition, and the Maltese were willing and able to welcome the Normans as deliverers and to hold the island after the immediate withdrawal of Count Roger. A bishop of Malta was witness to a document in 1090. The Phoenician population had continued Christian during the mild Arab rule. Under the Normans the power of the Roman Church quickly augmented, tithes were granted, and ecclesiastical buildings erected and endowed. The Normans, like the Arabs, were not numerically strong; the rule of both, in Sicily as well as Malta, was based on a recognition of municipal institutions under local officials; the Normans, however, exterminated the Mahomedans. Gradually feudal customs asserted themselves. In 1131 Margarita Brandusio received Malta with the title of count; he was Grand Admiral of Sicily. Constance, wife of the emperor Henry VI of Germany, became in 1194, heiress of Sicily and Malta; she was the last of the Norman dynasty. The Grand Admiral of Sicily in 1223 was Henry, count of Malta. He had led 300 Maltese to the capture of two forts in Tripoli by the Genoese. In 1265 Pope Alexander IV. conferred the crown of Sicily on Charles of Anjou to the detriment of Manfred, from whom the French won the kingdom at the battle of Benevento. Under the will of Corradino a representative of the blood of Roger the Norman, Peter of Aragon claimed the succession, and it came to him by the revolution known as the Sicilian Vespers when 28,000 French were exterminated in Sicily. Charles held Malta for two years longer, when the Aragonese fleet met the French off Malta, and finally crushed them in the Grand Harbour. In 1427 the Turks RAIDed Malta and Gozo, they carried many of the inhabitants into captivity, but gained no foothold. The Maltese joined the Spaniards in a disastrous raid against Gerbi on the African coast in 1432. In 1492 the Aragonese expelled the Jews. Dissatisfaction arose under Aragonese rule from the periodical grants of Malta, as a marquisate or countship, to great officers of state or illegitimate descendants of the sovereign. Exemption was obtained from these incidences of feudalism by large payments to the Crown in return for charters covenanted that Malta should forever be administered under the royal exchequer without the intervention of intermediary feudal lords. This compact was twice broken, and in 1428 the Maltese paid King Alfonso 30,000 florins for a confirmation of privileges, with a proviso that entitled them to resist by force of arms any intermediate lord that his successors might attempt to impose. Under the Aragonese, Maltese, as regards local affairs, was administered by a Università or municipal commonwealth with wide and indefinite powers, vicar of the electors, of the island, of the sea, and of the land. The minutes of the Consiglio Popolare of this period are preserved, showing it had no legislative power; this was vested in the king, and was exercised despotically in the interests of the Crown. The knights of St John having been driven from Rhodes by the Turks, obtained the grant of Malta, Gozo and Tripoli in 1530 from the emperor Charles V., subject to a reversion in favour of the emperor’s successor in the kingdom of Aragon should the knights leave Malta, and to the annual tribute of a falcon in acknowledgment that Malta was under the suzerainty of Spain. The Maltese, at first, challenged the grant as a breach of the charter of King Alfonso, but eventually welcomed the knights. The Grand Master de l'Isle Adam, on entering the ancient capital of Notabile, swore for himself and his successors to maintain the rights and liberties of the Maltese. The Order of St John took up its abode on the promontory guarded by the castle of St Angelo on the southern shore of the Grand Harbour, and, in expectation of attacks from the Turks, commenced to fortify the neighbouring town called the Borgo. The knights lived apart from the Maltese, and derived their principal revenues from estates of the Order in the richest countries of Europe. They accumulated wealth by war, or by privatizing against the Turks and their allies. The African Arabs under Selim Pasha in 1551 ravaged Gozo, after an unsuccessful attempt on Malta, repulsed by cavalry under Upton, an English knight. The Order of St John and the Christian Maltese now realized that an attempt to exterminate them would soon be made by Soliman II., and careful preparations were made to meet the attack.

The great siege of Malta which made the island and its knights famous, and checked the advance of Mahomedan power in southern and western Europe, began in May 1565. The fighting men of the defenders are variously recorded between 6,100 and 9,050; the roll comprises one English knight, Oliver Starkey. The Mahomedan forces were estimated from 20,000 to 38,000. Jehan Parisot de la Valette had participated in the defence of Rhodes, and in many naval engagements. He had been taken prisoner by Dragut, who made him row for a year as a galley slave till ransomed. This Grand Master had gained the confidence of Philip of Spain, the friendship of the viceroy of Sicily, of the pope and of the Genoese admiral, Doria. The Sultan gave him his troops under Grand Venerar Muniche, and his galleys under his youthful relative Piali, he hesitated to make either supreme and ordered them to await the arrival of Dragut with
