In *Cohens v. Virginia*, in spite of the contention of Jefferson and the then prevalent school of political thought that it was contrary to the Constitution for a person to bring one of the states of the Union into the Federal courts, he held that Congress could lawfully act an act which permitted a person who was convicted in a state court, to appeal to the Supreme Court in the United States, and that it was allowed the Supreme Court to review acts under which he was convicted conflicted with the Federal Constitution or with an act of Congress.

In *McClung v. Maryland*, though admitting that the Federal government is one of delegated powers and cannot exercise any power not expressly given in the Constitution, he laid down the rule that Congress in the exercise of a delegated power has a wide latitude in the choice of means, not being confined in its choice to those which must be used if the power is to be exercised at all.

Lastly, in *Gibbons v. Ogden*, he held that when the power to regulate interstate and foreign commerce was conferred by the Constitution on the Federal government, and that commerce includes not only the exchange of commodities, but the means by which interstate and foreign intercourse was carried on, and therefore that Congress had the power to license vessels to carry goods and passengers between the states, and an act of one of the states making a regulation which interfered with such regulation of Congress was, *pro tanto*, of no effect. It will be seen that in the first two cases he established the Supreme Court as the final interpreter of the Constitution.

The decision in *McClung v. Maryland*, by leaving Congress unhampered in the choice of means to execute its delegated powers, marked the beginning of the entire government by the Constitution of its existence. "Let the end be legitimate," said Marshall in the course of its opinion, "let it be within the scope of the Constitution, and all will go well." The power of government is so great that everything, from the point of view both of its exercise and of its execution, is constitutional."

If the decision in *McClung v. Maryland* gave vigour to all Federal power, the decision in *Gibbons v. Ogden*, by giving the Federal government control over the means by which interstate and foreign commerce is carried on, preserved the material prosperity of the country. The decision recognizes what the framers of the Constitution recognized, namely that the United States is an economic union, and that business which is national should be under national, not state, control.

Though for the reasons stated, the four cases mentioned above form an illustration of his decisions the value of his work as an expounder of the Constitution of the United States is not to be measured by these cases alone. In all he decided forty-four cases involving constitutional questions. Nearly every important part of the Constitution of the United States as it existed before the amendments which were adopted after the Civil War, is treated in one or more of them. The Constitution in its most important aspects is the Constitution as he interpreted it. He did not work out completely the position of the states in the Federal system, but he did grasp and establish the position of the Federal government and the Federal judiciary. To appreciate his work, however, it is necessary to add that it was the work not of a statesman but of a judge. Had Marshall been merely a far-seeing statesman, while most of his important cases would have been decided as he decided them, his life-work would have been a failure. It was not only necessary that he should decide great constitutional questions properly, but also that the people of the United States should be convinced of the correctness of his interpretation of the Constitution. His opinions, therefore, had to carry to those who studied them a conviction that the constitution as written had been interpreted according to its evident meaning. They fulfilled this prime requisite. Their chief characteristic is the cumulative force of the argument. The ground for the premis is carefully prepared, the premis itself is clearly stated; nearly every possible objection is examined and answered; and then comes the conclusion. There is little or no repetition, but there is a wealth of illustration, a completeness of analysis, that convinces the reader, not only that the subject has been adequately treated, but that it has been exhausted. His style, reflecting his character, suits perfectly the subject matter. Simple in the best sense of the word, his intellectual processes were so clear that he never doubted the correctness of the conclusion which they led him. Apparently from his own point of view, he merely indicated the question at issue, and the inexorable rules of logic did the rest. Thus his opinions are simple, clear, dignified. Intensely interesting, the interest is in the argument, not in its expression. He had, in a wonderful degree, the power of phrase. He expressed important principles of law in language which tersely yet clearly conveyed his exact meaning. Not only is the Constitution interpreted largely as he taught the people of the United States to interpret it, but when they wish to express important constitutional principles which he enunciated they use his exact words. Again, his opinions show that he adhered closely to the words of the Constitution; indeed no one who has attempted to expound that instrument has confined himself more strictly to an examination of the text. In the proper, not in the historical, sense he was the strictest of strict constructionists, and as a result his opinions are practically devoid of theories of government, sovereignty and the rights of man.

A single illustration of his avoidance of all theory and his adherence to the words of the Constitution will suffice. In the case of the United States v. *Fisher* the constitutional question involved was the power of Congress to give to the United States a preference over all other creditors in the distribution of the assets of a bankrupt. Such an act can be upheld on the ground that all governments have necessarily the right to give themselves priority. Not so Marshall. To him the act must be supported, if supported at all, not on any theory of the innate nature of the government, national or otherwise, but as a reasonable means of carrying out one of the express powers of the Constitution. Thus he says, "If the powers which have been conferred on the Federal government, the right to make remittances by bills or otherwise and to take precautions which will render the transactions safe."

It is important to emphasize the fact that Marshall adhered in his opinions to the Constitution as written, not only because it is a fact which must be recognized if we are to understand the correct value of his work in the field of constitutional law, but also because there exists to-day a popular impression that by implication he stretched to the utmost the powers of the Federal government. This impression is due primarily to the ignorance of many of those who have undertaken to praise him. During his life he was charged by followers of the States Rights School of political thought with upholding Federal power in cases not warranted by the Constitution. Later, however, those who admired a strong national government, without taking the trouble to ascertain whether the old criticism by members of the States Rights Party was just, regarded the assumption on which it was founded as Marshall's best claim to his country's gratitude.

As a constitutional lawyer, Marshall stands without a rival. His work on international law and admiralty is of first rank. Though a good, he was not a great, common law or equity lawyer. In these spheres he was not merely not clear what was obscure, and his constitutional opinions which to-day are found least satisfactory are those in which the question to be solved necessarily involves the discussion of some common-law
conception, especially those cases in which he was required to construe the restriction imposed by the Constitution on any state impairing the obligation of contracts. His decision in the celebrated case of Dartmouth College v. Woodward, in which he held that a state could not repeal a charter of a private corporation, because a charter is a contract which a subsequent act of the state repealing the charter impairs, though of great economic importance, does not touch any fundamental question of constitutional law. The argument which he advances lacks the clearness and finality for which most of his opinions are celebrated. It is not certain with whom he thought the case was decided; with the corporation, or by the trustees of the corporation, or with those who had contributed money to its objects.

Of the wonderful persuasive force of Marshall's personality there is abundant evidence. His influence over his associates, already referred to, is but one example though a most impressive one. From the moment he delivered the opinion in Marbury v. Madison the legal profession knew that he was a great judge. Each year added to his reputation and made for a better appreciation of his intellectual and moral qualities. The bar of the United States Court during his chief-justiceship has its own idea of the brilliancy which the United States has ever known. Leaders, not only of legal, but political thought were among its members; one, Webster, was a man of genius and commanding position. To a very great degree Marshall impressed on the members of this bar and on the profession generally his own ideas of the correct interpretation of the Constitution and his own love for the union. He did this, not merely by his arguments but by the influence which was his by right of his strong, sweet nature. Statesmen and politicians, great and small, were at this time, almost without exception, members of the bar. To influence the political thought of the bar was to a great extent to influence the political thought of the people.

"In 1832 he married Mary Willis Ambler, the daughter of the then treasurer of Virginia. They had ten children, six of whom grew to full age. For the greater part of the forty-eight years of their married life Mrs Marshall suffered intensely from a nervous affliction. Her condition called out the love and sympathy of her husband's deep and affectionate nature. Judge Story tells us: 'That which, in a just sense, was his highest glory, was the purity, affectionateness, liberality and devotedness of his domestic life.' For the first thirty years of his chief-justiceship his life was a singularly happy one. He never had to remain in Washington for more than three months. During the rest of the year, with the exception of a visit to Raleigh, which his duties as circuit judge required him to make, and a visit to his old home in Fauquier county, he lived in Richmond. His house on Shockoe Hill is still standing.

On Christmas Day 1831 his wife died. He never was quite the same again. On returning from Washington in the spring of 1835 he suffered severe contusions, from an accident to the stage coach in which he was riding. His health, which had not been good, now rapidly declined and in June he returned to Philadelphia for medical attendance. There he died on the 6th of July. His body, which was taken to Richmond, lies in Shockoe Hill Cemetery under a plain marble slab, on which is a simple inscription written by himself. In addition to his decisions Marshall wrote a famous biography of George Washington (5 vols., 1824-1827; and ed., 2 vols., 1832), which though prepared hastily contains much material of value.

The principal sources of information are: an essay by James B. Thayer (Boston and New York, 1904); Great American Lawyers (Philadelphia, 1908), ii. 313-208, an essay by Wm. Draper Lewis; and Allan B. Macrader, John Marshall (Boston, 1888), in the "American Statesmen Series." The addresses delivered on Marshall Day, the 4th of February 1901, are collected by John F. Dillon (Chicago, 1903). In the "Appendix" to Dillon's collection will be found "the Descriptions of Joseph Story and the "Eulogy" by Horace Binney, both delivered on Marshall Day. For a study of Marshall's decisions, the Constitutional Decisions of John Marshall, edited by Joseph P. Collon, Jr. (New York and London, 1908), is of value. (W. D. L.)

**MARSHALL, J.---MARSHALL**

**MARSHALL, JOHN** (1818-1891), British surgeon and physiologist, was born at Ely, on the 11th of September 1818, his father being a lawyer of that city. He entered University College, London, in 1838, and in 1847 he was appointed assistant-surgeon at the hospital, becoming in 1866 surgeon and professor of surgery. He was professor of anatomy at the Royal Academy from 1873 till his death. In 1883 he was president of the College of Surgeons, also Bradshaw lecturer (on "Nerve-stretching for the relief or cure of pain"), Hunterian orator in 1885, and Morton lecturer in 1889. In 1867 he published his well-known textbook The Outlines of Physiology in two volumes. He died on the 10th of January 1891. "Marshall's fame," wrote Sir W. MacCormac in his volume on the Centenary of the College of Surgeons (1900), "rests on the great ability with which he taught anatomy in relation to art, on the introduction into modern surgery of the galvano-cautery, and on the operation for the excision of varicose veins. He was one of the first to show that cholera might be spread by means of drinking water, and issued a report on the outbreak of cholera in Broad Street, St James's, 1854. He also invented the system of circular wards for hospitals, and to him are largely owing the details of the method by which the London edict of 1849 for the isolation of the sick was carried into effect.

**MARSHALL, STEPHEN** (c. 1594-1655), English Nonconformist divine, was born at Godmanchester in Huntingdonshire, and was educated at Emmanuel College, Cambridge (M.A. 1622, B.D. 1629). After holding the living of Wethersfield in Essex he became vicar of Finchingfield in the same county, and in 1636 was reported for "want of conformity." He was a preacher of great power, and influenced the elections for the Short Parliament of 1640. Clarendon esteemed his influence on the parliamentary side greater than that of Laud on the royalists. In 1642 he was appointed lecturer at St Margaret's, Westminster, and delivered a series of addresses to the Commons in which he advocated episcopal and liturgical reform. He had a share in writing Smeckyynus, was appointed chaplain to the earl of Essex's regiment in 1642, and a member of the Westminster Assembly in 1643. He represented the English Parliament in Scotland in 1643, and attended the parliamentary commissions at the Uxbridge Conference in 1645. He waited on Archbishop Laud before his execution, and was chaplain to Charles I. at Holmby House and at Carisbrooke. A moderate and judicious presbyterian, he prepared with others the "Shorter Catechism" in 1647, and was one of the "Triers," 1654. He died in November 1655 and was buried in Westminster Abbey, but his body was exhumed and maltreated at the Restoration. His sermons, especially that on the death of John Pym in 1643, reveal eloquence and fervour. The only "systematic" work he published was A Defence of Infant Baptism, against John Toms (London, 1649).

**MARSHALL,** a city and the county-seat of Saline county, Missouri, U.S.A., situated a little W. of the centre of the state, near the Salt Fork of the La Mine River. Pop. (1890), 4297; (1900), 5986 (208 being foreign-born and 98 negroes); (1910) 4869. It is served by the Missouri Pacific and the Chicago & Alton railways. The city is laid out regularly on a high, undulating prairie. It is the seat of Missouri Valley College (opened 1859; coeducational), which was established by the Cumberland Presbyterian church, and includes a preparatory department and a conservatory of music. The court-house (1883), a Roman Catholic convent and a high school (1907) are the principal buildings. The Missouri colony for the feebleminded and epileptic (1890) is at Marshall. The principal trade is with the surrounding farming country. The municipality owns and operates the waterworks. Marshall was first settled and was made the county seat in 1830; it became a town in 1866 (re-incorporated 1870) and a city in 1878.

**MARSHALL,** a city and the county-seat of Harrison county, Texas, U.S.A., about 145 m. E. by S. of Dallas. Pop. (1890), 7120; (1900) 7853 (3769 negroes); (1910) 11,452. Marshall is served by the Texas & Pacific and the Marshall & East Texas railways, which have large shops here. Wiley University was
situated. In 1881, the town of Marshfield, located on the shores of Lake Michigan, was incorporated, and in 1843, it received a city charter in 1848, and in 1900 it adopted the commission form of government.

MARSHALL ISLANDS, an island group in the western Pacific Ocean (Micronesia) belonging to Germany. The group consists of a number of atolls ranged in two almost parallel lines, which run from N.W. to S.E. between 4° and 15° N. and 161° and 174° E. The north-east line, with fifteen islands, is called Ratak, the other, numbering eighteen, Raik. These atolls are of coralline formation and of irregular shape. They rise but a few feet above the sea, and the most prominent peak occurs on the island of Likieb, but is only 33 ft. The lagoon is scarcely more than 150 ft. deep and is accessible through numerous breaks in the reef. On the outward side the shore sinks rapidly to a great depth. The surface of the atolls is covered with sand, except in a few places where it has been turned into soil through the admixture of decayed vegetation. The reef in scarcely any instance exceeds 600 ft. in width.

The climate is moist and hot. The mean temperature being 82°-90° F. Easterly winds prevail all the year round. There is no difference between the seasons, which, though the islands belong to the northern hemisphere, have the highest temperature in January and the lowest in July. Vegetation, on the whole, is very poor. There are many coco-nut palms, bread-fruit trees (Artocarpus incisa), various kinds of bananas, yams and taro, and pandanus, of which the natives eat the seeds. From the bark of another plant they manufacture mats. There are few animals. Cattle do not thrive, and even poultry are scarce. Pigs, cats, dogs and rats have been imported. There are a few pigeons and aquatic birds, butterflies and beetles. Crustaceans and fish abound.

The natives are Micronesian of a brown brown colour, though lighter shades occur. Their hair is not woolly but straight and long. They practise tattooing, and show Papuan influence by distending the ear-lobes by the insertion of wooden disks. They are expert navigators, and construct curious charts of thin strips of wood tied together with fibres, some giving the position of the islands and some the direction of the prevailing winds. Their canoes carry sails and are made of the trunk of the bread-fruit tree. The people are divided into four classes, of which only two are allowed to own land. The islands lie entirely within the German sphere of interest, and the boundaries were agreed upon between Great Britain and Germany on the 10th of April 1889. Their area is estimated at 160 sq. m., with 15,000 inhabitants, who are apparently increasing, though the contrary was long believed. All but about 250 are natives. The admiral of the islands is the governor of German New Guinea, but a number of officials reside on the islands. There is no military force, the natives being of peaceful disposition. The chief hospital and seat of government is Jaluit. The most populous island is Majuro, with 1000 inhabitants. The natives are generally pagans, but a Roman Catholic mission has been established, and the American Mission Board maintains coloured teachers on many of the islands. There is communication with Sydney by private steamer, and a steamer sails between Jaluit and Ponape to connect with the French boats for Singapore. The chief products for export are copra, tortoise-shell, mother-of-pearl, sharks' fins and trepang. The native are clever boat-builders, and find a market for their canoes on neighbouring islands. They have made such progress in their art that they have even built seaworthy little schooners of 30 to 40 tons. The only other articles they make are a few small ornaments.

The Marshall Islands may have been visited by Alvaro de Saavedra in 1529, Captain Wallis touched at the group in 1767, and in 1788 Captains Marshall and Gilbert explored it. The Germans made a treaty with the chiefs of Jaluit in 1878 and annexed the group in 1885-1886. The town of Marshfield, located on the shores of Lake Michigan, was incorporated in 1881.

MARSHALLTOWN, a city and the county-seat of Marshall county, Iowa, U.S.A., near the Iowa River and about 60 m. N.E. of Iowa City. It was incorporated 1860, and its first city was established in 1842, was incorporated in 1843, and received a city charter in 1848; in 1900 it adopted the commission form of government.

MARSHALSEA, a prison formerly existing in Southwark, London. It was attached to the court of that name held by the steward and marshal of the king's house (see Lord Steward and Marshalsea). The site of its first establishment is unknown, but it existed as early as the reign of Edward III. It was consolidated in 1842 with the queen's bench and the Fleet, and was then described as "a prison for debtors and for persons charged with contempt of Her Majesty's courts of the Marshalsea, the court of the queen's palace of Westminster, and the high court of admiralty, and also for admiralty prisoners under sentence of courts martial." It was abolished in 1849. The Marshalsea Prison is described in Charles Dickens' "Little Dorrit."
MARSHMAN, an ancient people of Italy, whose chief centre was Marruvium, on the eastern shore of Lake Fucinus. They are first mentioned as members of a confederacy with the Vestini, Paetini and Marrucini (Livy. viii. 29, cf. viii. 6, and Polyb. ii. 24, 12). They joined the Samnites in 308 B.C. (Livy. iv. 41), and on their submission became allies of Rome in 304 B.C. (Livy. iv. 45). After a short-lived revolt two years later, for which they were punished by loss of territory (Livy. v. 3), they were readmitted to the Roman alliance and remained faithful down to the social war, their contingent (e.g. Liv. xiv. 46) being always regarded as the flower of the Italian forces (e.g. Hor. Od. ii. 20, 18). In this war, which, owing to the prominence of the Marsian rebels is often known as the Marsic War, they fought bravely against odds under their leader Q. Pompaedius Silo, and, though they were frequently defeated, the result of the war was the enfranchisement of the allies (see Rome: History, "The Republican"). The Marsi were a hardy mountain people, famed for their simple habits and indomitable courage. It was said that the Romans had never triumphed over them or without them (Appian). They were also renowned for their magicians, who had strange remedies for various diseases.

The Latin colony of Albensi Fucens near the north-west corner of Lake Fucinus was founded in the adjoining Aequian territory in 303, so that from the beginning of the 3rd century the Marsians were in touch with a Latin-speaking community, to say nothing of the Latin colony of Carsioli (298 B.C.) farther west. The earliest pure Latin inscriptions of the district seem to be C.I.L. ix. 3827 and 3848 from the neighbourhood of Supinum; its character generally is of the Graecan period, though it might be somewhat earlier.

Momsens ([Unteritalische Dialektien, p. 343]) pointed out that in the social war all the coins of Pompaedius Silo have the Latin legend "Italia," while the other leaders in all but one case used Oriental script.

The chief record of the dialect or patois we owe to the goddess Angitia, whose chief temple and grove stood at the north-west corner of Lake Fucinus, near the inlet to the emissarius of Claudius (restored by Prince Torlonia), and the modern village of Luco. She (or they, for the name is in the plural in the Latin inscription next cited) was widely worshipped in the central highlands (Sulmo, C.I.L. ix. 3074, Furfo Vestinorum, ibid. 3535) as a goddess of healing, especially skilled to cure serpent bites by charms and the herbs of the Marsian woods. Her worshippers naturally practised the same arts—as their descendants do (see A. de Nino’s charming collection of Uesi e costumi abruzzesi), their country being in Rome counted the home of witchcraft; see Hor. Sat. 1, 9, 29, Epod. 17, 28, &c.

The earliest local inscriptions date from about 300 to 150 B.C. and include the interesting and difficult bronze of Lake Fucinus, which seems to record a votive offering to Angitia, if A(n)cia, as is probable, was the local form of her name. Their language differs very slightly from Roman Latin of that date; for apparently contracted forms like Fauino instead of Fucino may really only be a matter of spelling. In final syllables the diphthongs ei, ei, ai, all appear as ë. On the other hand, the older form of the name of the tribe (dat. plur. Martes = Lat. Martis) shows its derivation and exhibits the assimilation of -io- into -iso- proper to many Osco dialects (see Osca Lingua) but strange to classical Latin.

See R. S. Conway, The Italic Dialects, pp. 290 seq. (from which some portions of this article are taken by permission of the syndics of the Camb. Univ. Press); on the Fucino-Bronze, ll. p. 27.

MARSIGLI [Latinized Marsilius], LUIGI FERDINANDO, Count (1658-1750), Italian soldier and scientific writer, was born at Bologna on the 9th of July 1658. After a course of scientific studies in his native city he travelled through Turkey collecting data on the military organization of that empire, as well as on its natural history. On his return he entered the service of the emperor Leopold (1682) and fought with distinction against the Turks, by whom he was wounded and captured in an
action on the river Raab, and sold to a pasha whom he accompanied to the siege of Vienna. His release was purchased in 1684, and he afterwards took part in the war of the Spanish succession. In 1703 he was appointed second in command under Count Arco in the defence of Alt-Breisach. The fortress surrendered to the duke of Burgundy, and both Arco and Marsigli were courteously treated; the former was condemned to death and the latter cashiered, although acquitted of blame by public opinion. Having thus been forced to give up soldiering, he devoted the rest of his life to scientific investigations, in the pursuit of which he made many journeys through Europe, spending a considerable time at Marseilles to study the nature of the sea. In 1712 he presented his collections to his native city, where they formed the nucleus of the Bologna Institute of Science and Art. He died at Bologna on the 1st of November 1730. Marsigli was a fellow of the London Royal Society and a member of the Paris Academy of Science.

Bibliography.—A list of his works, over twenty in number, is given in Nicerov's Memoria; his Breve ristretto del sogno fisico intorno alla storia del mare was published at Venice in 1711, and again at Amsterdam (in French) in 1725; the Osservazioni intorno al Bosforo Trionco in Rome (1681) and the Danubius panonico-myceus, a large work in six volumes containing valuable historic and scientific information on the Danubian countries, at the Hague (1725). See Fontenelle, "Eloge" in the Mém. de l'acad. des sciences (Paris, 1730); Quincy, Memorie su vita e de' reperti di Pietro Marsigli (Milan, 1741), and Fantuzzi's biography of Marsigli (Bologna, 1770).

MARSILIUS OF PADUA [MARSIGLIO MAINARDINO] (1270-1342), Italian medieval scholar, was born at Padua, and at first studied medicine in his own country. After practising various professions, among others that of a soldier, he went to Paris about 1311. The reputation which he had gained in the physical sciences soon caused him to be raised to the position of rector of the university (for the first term of the year 1313). While still practising medicine he entered into relations with another master of Paris, the philosopher John of Jandun, who collaborated with him in the composition of the famous Defensor pacis (1324), one of the most extraordinary political and religious works which appeared during the 14th century. A violent struggle had just broken out between pope John XXII. and Louis of Bavaria, king of the Romans, and the latter, on being excommunicated and called upon to give up the empire, only replied to the pope's threats with fresh provocations. Marsilius of Padua and John of Jandun, though they had both reason to be grateful for the benefits of John XXII., chose this moment to demonstrate, by plausible arguments, the supremacy of the Empire, its independence of the Holy See, and the emptiness of the prerogatives "usurped" by the sovereign pontiffs—a demonstration naturally calculated to give them a claim on the gratitude of the German sovereign.

The Defensor pacis, as its name implies, is a work intended to restore peace, as the most indispensable benefit of human society. The author of the law is the people, i.e. the whole body, or at least the most important part (volentor) of the citizens; the people should themselves elect, or at least appoint, the head of the government. For this purpose Marsilius quite naturally borrowed the formula of the constitutional law, above the scope of the laws, should have at his disposal only a limited armed force. This chief is responsible to the people for his breaches of the law, and in serious cases they can condemn him to death. The real cause of the trouble which prevails among men is the papacy, a "fictitious" power, the development of which is the result of a series of usurpations. Marsilius denies, not only to the pope, but to the bishops and clergy, any constitutional or right to pronounce on their own authority concerning the penitentials or indulgences, or in any way to impose the observance of the divine law. He is not opposed to penalties against heretics, but he would have them pronounced only by civil tribunals. Desiring to see the clergy practise a holy poverty, he proposes the suppression of tithes and the seizure by the secular power of the greater part of the property of the church. The clergy, thus deprived of its wealth, privileges and jurisdiction, is further to be deprived of independence, for the civil power is to have the right of appointing to benefices, &c. The supreme authority in the church is to be the council, but a council summoned by the emperor. The pope, no longer possessing any more power than other bishops (though Marsilius recognizes that the supremacy of the Church of Rome goes back to the earliest times of Christianity), is to content himself with a pre-eminence mainly of an honorary kind, without claiming to interpret the Holy Scriptures, define dogmas or distribute benefices; moreover, he is to be elected by the Christian people, or by the delegates of the people, i.e. the princes, or by the council, and these are also to have the power to punish, suspend or depose him. Such is this famous work, full of obscurities, redundancies and contradictions, in which the thread of the argument is sometimes lost in a labyrinth of reasonings and citations, both sacred and profane, but which nevertheless expresses, both in religion and politics, such audacious and novel ideas that it has been possible to trace in it, as it were, a rough sketch of the doctrines developed during the periods of the Reformation and of the French Revolution. The theory was purely democratic, but was all ready to be transformed, by means of a series of fictions and implications, into an imperialist doctrine; and in like manner it contained a visionary plan of reformation which ended, not in the separation of the church from the state, but in the subjection of the church to the state. To overthrow the ecclesiastical hierarchy, to deprive the clergy of all their privileges, and to reduce them to the rank of a simple citizen of a Christian republic, which governs itself, or rather submits to the government of Caesar—such is the dream formed in 1324 by two masters of the university of Paris.

When in 1326 Louis of Bavaria saw the arrival in Nuremberg of the two authors of the book dedicated to him, startled by the boldness of their political and religious theories, he was at first inclined to treat them as heretics. He soon changed his mind, however, and, admitting them to the circle of his intimates, loaded them with favours. Having become one of the chief inspirers of the imperial policy, Marsilius accompanied Louis of Bavaria to Italy, where he preached or circulated written attacks against the pope, especially at Milan, and where he came within the sight of the realization of his wildest utopias. To see a king of the Romans crowned emperor at Rome, not by the pope, but by those who claimed to be the delegates of the people (Jan. 17, 1328), to see John XXII. deposed by the head of the Empire (April 18), and a mendicant friar, Pietro de Corbara, raised by an imperial decree to the throne of St Peter (as Nicholas V.) after a sham of a popular election (May 12), all this was merely the application of principles laid down in the Defensor pacis. The two authors of this book played a most active part in the Roman Revolution. Marsilius, appointed imperial vicar, abused his power to persecute the clergy who had remained faithful to John XXII. In recompense for his services, he seems to have been appointed archbishop of Milan, while his collaborator, John of Jandun, obtained from Louis of Bavaria the bishopric of Ferrara.

Marsilius of Padua also composed a treatise De translatione imperii romanii, which is merely a rearrangement of a work of Landello Colonna, De jurisdictione imperatoris in causa matrimonialis, intended to prove the exclusive jurisdiction of the emperor in matrimonial affairs, or rather, to justify the interference of Louis of Bavaria, who, in the interests of his policy, had just annulled the marriage of the son of the king of Bohemia and the countess of Tirol. But, above all, in an unpublished work preserved at Oxford, the Defender minor, Marsilius completed and elaborated in a curious manner certain points in the doctrine laid down in the Defensor pacis. In it he deals with ecclesiastical jurisdiction, penances, indulgences, crusades and pilgrimages, vows, excommunication, the pope and the council, marriage and divorce. Here his democratic theory still more clearly leads up to a proclamation of the imperial omnipotence.

Marsilius of Padua does not seem to have lived long after 1342. But the scandal provoked by his Defender pacis, condemned by the court of Avignon in 1326, lasted much longer. Benedict XII. and Clement VI. censured it in turn; Louis of Bavaria
disowned it. Translated into French, then into Italian (14th century) and into English (16th century), it was known by Wycliffe and Luther, and was not without an influence on the Reform movement.

There are numerous manuscripts of the Defensor pacis extant. We will here mention only one edition, that given by Goldast, in 1614, in vol. i. of his Monarchia sacri imperii; an unpublished last chapter was published by Karl Müller, in 1883, in the Göttingische gelehrten Anzeigen, pp. 923-925. See also T. Lütow in the Zeitschrift für die Gesch. der Lit. 1879, p. 16. See also L. de Villanie, 1575–1634), prefixed to a work of 1594. See also W. Swinburne, Armenian Enterprise, 1575, 1614, 1874).

Wycliffe de Christo et de Deo, printed by Mr. G. Cane, London, 1594. See also W. Swinburne, Armenian Enterprise, 1575, 1614, 1874).

MARSIVAN, or MERZIFUN (anc. Phaezoneni?), a town in the Amašia sanjak of the Sivas vilayet of Asia Minor, situated at the foot of the Tashvan Dag. Pop. 3,000. It is a centre of Armenian missionary and educational enterprise, and the seat of Anatolia College, a theological seminary, and schools which were partly destroyed in the anti-Armenian riots of 1893 and 1895. There is also a Jesuit school. Marsivan is an unusually European place both in its aspect and the commodities procurable in the bazaar.

MARS- LA-TOUR, a village of Lorraine, between Metz and the French frontier, which formed part of the battlefield of the 16th of August 1870. The battle is often called the battle of Mars-la-Tour, though it is more usually named after Vionville. (See Metz, and Franco-German War.) At Mars-la-Tour occurred the destruction of the German 38th brigade.

MARSTON, JOHN (c. 1575–1634), English dramatist and satirist, eldest son of John Marston of Coventry, at one time lecturer of the Middle Temple, was born in 1575, or early in 1576. Swinburne notes his affinities with Italian literature, which may be partially explained by his parentage, for his mother was the daughter of an Italian physician, Andrew Guarini. He entered Brasenose College, Oxford, in 1592, taking his B.A. degree in 1594. The elder Marston in his will expresses regret that his son-to-be should leave his law-books and the furniture of his rooms in the Temple, had not been willing to follow his profession. John Marston married Mary Wilkes, daughter of one of the royal chaplains, and Ben Jonson said that "Marston wrote his father-in-law's preachers, and his father-in-law's sermons."

His first work was The Metamorphosis of Pigmalions Image, and certaine Satyres (1598). Pigmalion is an erotic poem in the metre of Venus and Adonis, and Joseph Hall attached a rather clumsy epigram to every copy that was exposed for sale in Cambridge. In the same year Marston published, under the pseudonym of W. Kinsayder, already employed in the earlier volume, his Scourge of Villainy, eleven satires, in the sixth of which he asserted that Pigmalion was intended to parody the amorous poetry of the time. Both this volume and its predecessors were burnt by order of the archbishop of Canterbury. The satires, in which Marston avowedly took Persius as his model, are coarse and vigorous. In addition to a general attack on the vices of his age he avenges himself on Joseph Hall who had assailed him in Virginiacum. He had a great reputation among his contemporaries. John Weever couples his name with Ben Jonson's in an epigraph. Francis Meres in Palladis Tamia (1598) mentions him among the satirists; a long passage is devoted to 'Monseur Kinsayder' in the Return from Parnassus (1606), and Dr Brinsley Nicholson has suggested that Furor poeciticus in that piece may be a satirical portrait of him. But his invective by its general tone, goes far to justify Mr W. J. Courthouse's judgment that "it is likely enough that in seeming to satirize the world without him, he is usually holding up the mirror to his own private mind."

On the 28th of September 1599 Henslowe notices in his diary that he lent "unto Mr Maxton, the new poete, the sume of forty shillings," as an advance on a play which is not named. Another hand has amended "Maxton" to "Mastone." The earliest plays to which Marston's name is attached are The History of Antonio and Mellida. The First Part; and Antonio's Revenge. The Second Part (both entered at Stationers' Hall in 1601 and printed 1602). The second part is preceded by a prologue which, in its gloomy forecast of the play, moved the admiration of Charles Lamb, who also compares the situation of Andrugio and Lucia to Lear and Kent, but the scene which he quotes gives a misleading idea of the play and of the general tenor of Marston's work.

The melodram and the exaggerated expression of these two plays offered an opportunity to Ben Jonson, who had already twice ridiculed Marston, and now pilloried him as Crispinus in The Poetaster (1601). The quarrel was patched up, for Marston dedicated his Malcontent (1604) to Jonson, and in the next year he prefixed commendatory verses to Sejanus. Far greater restraint is shown in The Malcontent than in the earlier plays. It was printed twice in 1604, the second time with additions by John Webster. The Dutch Courtesan (1608) and Parasitaster, or the Favone (1608) followed. In 1605 Eastward Hoe, a gay comedy of London life, which gave offence to the king's Scottish friends, caused the playwrights concerned in its production—Marston, Chapman and Jonson—to be imprisoned at the instance of Sir James Murray. The Wonder of Women, or the Tragedie of Sophonisba (1606), seems to have been put forward by Marston as a model of what could be accomplished in tragedy. In the preface he mocks at these authors who make a parade of their authorities and their learning, and the next play, What you Will (printed 1607; not probably written much earlier), contains a further attack on Jonson. The tragedy of The Inconstant Countess was printed in 1613, and again, this time anonymously, in 1616. It was not included in the collected edition of Marston's plays in 1633, and in the Duke of Devonshire's library there is a copy bearing the name of William Barkstead, the author of the poems, Myrrha, the Mother of Adonis (1607), and Hiren and the Fair Greek (1611). The piece contains many passages superior to anything to be found in Marston's well-authenticated plays, and Mr A. H. Bullen suggests that it may be Barkstead's version of an earlier one drafted by Marston. The character and history of Isabella are taken chiefly from "The Disordered Lyfe of the Countess of Celant" in William Paynter's Palace of Pleasure, derived eventually from Bandello. There is no certain evidence of Marston's authorship in Histriomastix (printed 1616, but probably produced before 1599), or in Jache Drums Entertainment, or the Comedie of Pasquill and Katherine (1616), though he probably had a hand in both. Mr R. Boy (Englische Studien, vol. xxx., 1901), in a critical study of Shakespeare's Troilus and Cressida, assigns to Marston's hand the 32nd of the play, which is a melodramatic, action-comedy with Hector, with the prolongation of an epilogue, and attributes to him the bombast and coarseness in the last scenes of the play. It will be seen that his undoubted dramatic work was completed in 1607. It is uncertain at what time he exchanged professions, but in 1616 he was presented to the living of Christchurch, Hampshire. He formally resigned his charge in 1631, and when his works were collected in 1633 the publisher, William Sheares, stated that the author "in his autumn and declining age was living "far distant from this place." Nevertheless he died in London, in the parish of Aldermanbury, on the 25th of June 1634. He was buried in the Temple Church.

Marston's works were first published in 1633, once anonymously as Tragedies and Comedies, and then in the two great works, Works of Mr John Marston. The Works of John Marston (3 vols.) were reprinted by Mr J. O. Halliwell (Phillipps) in 1856, and again by Mr. G. W. Alden. A Full and Complete Edition of the Works of Mr John Marston (3 vols.) was edited by Dr A. B. Grosart in 1879. The British Museum Catalogue tentatively assigns to Marston The Whipper of the Satyre his penname in a white sheet; or, the Beadle's Confusion (1601), a pamphlet in answer to The Whipping of the Satyre. For an account of the quarrel of Dekker and Marston with Ben Jonson see Dr R. A. Small, The
MARSTON, P. B.—MARSTON MOOR

Dame Quarrel between Bent, Jonson and the so-called Poetsasters in E. Krehling, Forschungen zur englischen Sprache und Literatur, pt. i. (1899). Jonson, John Marston" by Emil Koppel (Münchener Beiträge zur roman. und engl. Philologie, pt. x. 1895).

MARSTON, PHILIP BOURNE (1850-1887), English poet, was born in London on the 13th of August 1850. His father, JOHN WESTLAND MARSTON (1819-1890), of Lincolnshire origin, the friend of Dickens, Macready and Charles Keane, was the author of a series of metrical dramas which held the stage in succession to the ambitious efforts of John Tobin, Talma, Bulwer and Sheridan Knowles. His chief plays were The Patrician's Daughters (1871), Straithmore (1849), A Hard Struggle (1858) and Donna Diana (1863). He was looked up to as the upholder of the outworn tradition of the acted poetic drama, but his plays showed little vitality, and Marston's reviews for the Athenaenum, including one of Swinburne's Atalanta in Calydon, and his dramatic criticisms embodied in Our Recent Actors (1888) will probably claim a more enduring reputation. His Dramatic and Poetical Works were collected in 1876. The son, Philip Bourke, was born in a literary atmosphere. His sponsors were Philip James Bailey and Dinah Mulock (Mrs Craik). At his father's house near Chalk Farm he met authors and authors of his father's generation, and especially his brothers-in-law Sir Arthur O'Shaughnessy and Irving. From his earliest years his literary precocity was overshadowed by misfortunes. In his fourth year, in part owing to an accident, his sight began to decay, and he gradually became almost totally blind. His mother died in 1870. His fiancée, Mary Nesbit, died in 1871; his closest friend, Oliver Madox Brown, in 1874; his sister Cicely, his amanuensis, in 1878; in 1879 his remaining sister, Eleanor, who was followed to the grave after a brief interval by her husband, the poet O'Shaughnessy, and her two children. In 1882 the death of his mother-in-law, who had been his intimate and inspirational, and closely by the tragedy of another kindred spirit, the sympathetic pessimist, James Thomson ("B. V."), who was carried dying from his blind friend's rooms, where he had sought refuge from his latest miseries early in June of the same year. It is said that Marston came to dread making new friendships, for fear of evil coming to the recipients of his affection. In the face of such calamities it is not surprising that Marston's verse became more and more sorrowful and melancholy. The idylls of flower-life, such as the early and very beautiful "The Rose and the Wren", and were succeeded by dreams of sleep and by a sense of death. These qualities and gradations of feeling, reflecting the poet's successive ideals of action and quiescence, are traceable through his three published collections, Songtide (1871), All in All (1875) and Wind Voices (1883). The first and third, containing his best work, went out of print, but Marston's verse was collected in 1892 by Mrs Louise Chandler Moulton, a loyal and devoted friend, and herself a poet. Marston read little else but poetry; and of poetic values, especially of the intenser order, his judgment could not be surpassed in sensitiveness. He was saturated with Rossetti and Swinburne, and his imaginative power was remarkable. In his later years he endeavoured to make money by writing short stories in Home Chimes and other American magazines, through the agency of Mrs Chandler Moulton. His popularity in America far exceeded that in his own country. His health showed signs of collapse from 1883; in January 1887 he lost his voice, and suffered intensely from the failure to make himself understood. He died on the 31st of February 1887.

He was commemorated in Dr Gordon Hake's "Blind Boy," and in a fine sonnet by Swinburne, beginning "The days of a man are three score years and ten..." The Rossettian sketch of the blind poet by a friend, Mr Coulson Kernahan, in Sorrows and Song (1894), p. 127.

MARSTON MOOR, BATTLE OF, was fought on the 2nd of July 1644 on a moor (now enclosed) seven miles west of York, between the Royalist army under Prince Rupert and the Parliamentary and Scottish armies under the earl of Manchester, Lord Fairfax and Lord Leven. For the operations that preceded the battle see GREAT REBELLION. Rupert had relieved York and joined forces with the marquis of Newcastle's army that had defended that city, and the Parliamentarians and Scots who had besieged it had drawn off south-westward followed by the Royalists. On the morning of the 2nd of July, however, Rupert's attack on their rearguard forced them to halt and deploy on rising ground on the south edge of the moor, their position being defined on the right and left by Long Marston and Tockwith and divided from the Royalist army on the moor by a lane connecting these two villages. The respective forces were—Royalists about 18,000, Parliamentarians and Scots about 27,000. The armies stood front to front. On the Royalist right was half the cavalry under Rupert; the infantry was in the centre in two lines and the wing of cavalry was under General (Lord) Goring. The lane along the front was held by skirmishers. On the other side the cavalry of the Eastern Association under Lieutenant-General Cromwell and that of the Scots under Major-General Leslie (Lord Newark) formed the left, the infantry of the Eastern Association under Major-General Crawford, of the Scots under Lord Leven, and of the Yorkshire Parliamentarians under Lord Fairfax was in the centre and the Yorkshire cavalry under Sir Thomas Fairfax was on the right wing.

That afternoon there was a desultory cannonade, but neither side advanced. At last, concluding from movements in the enemy's lines that there would be no fighting that day, Rupert and Newcastle strolled away to their coaches and their soldiers dismounted and lay down to rest. But seeing this Cromwell instantly advanced his wing to the attack (5 p.m.). His dragoons drove away the skirmishers along the lane, and the line cavalry crossed into the moor. The general forward movement spread along the Parliamentary line from left to right, the Eastern Association infantry being the first to cross the road. In Rupert's momentary absence, the surprised Royalist cavalry rallied, the infantry rallied, and the line cavalry moved back to the eastern end of the moor. The latter was only made piecemeal as each unit crossed the lane and formed to the front. Rupert soon galloped up with his fresh second line and drove back Cromwell's men, Cromwell himself being wounded, but Leslie and the Scots Cavalry, taking ground to their left, swung in upon Rupert's flank, and after a hard struggle the hitherto unconquered cavalry of the prince was broken and routed. Then, being unlike other cavalry of the time, a thoroughly disciplined force, the Eastern Association cavalry rallied, leaving the pursuit to the Scots light horse. On the Parliamentary right, Goring had swept away Yorkshire horse, and although most of his troopers had followed in disorderly pursuit, Sir Charles Lucas with some squadrons was attacking the exposed right of Leven's infantry. At the same time the Parliamentary infantry had mostly crossed the lane and was fighting at close quarters and suffering severely, Newcastle's north-country "White-Coat" brigade driving back and finally penetrating their centre. Lord Leven gave up the battle as lost and rode away to Tadcaster. But the Scots on the right of the foot held firm against Lucas's attacks, and Cromwell and Leslie with their cavalry passed along the rear of the Royal army guided by Sir Thomas Fairfax (who though wounded in the rout of his Yorkshire horse had made his way to the other flank). Then, on the ground where Goring had routed Fairfax, Cromwell and Leslie won an easy victory over Goring's scattered and disordered horsemen. The Eastern Association infantry had followed the horse and was now in rear of the Royalists. The original Parliamentary centre of foot, a remnant, but one containing only the bravest and steadiest men, held fast, and soon the Royalist infantry was broken up into isolated regiments and Parliamentary forces by the Royalists swept away by the enemy. The White-Coats retreated into an enclosure and there defended themselves to the last man. The rest were cut down on the field or scattered in the pursuit and at midnight the Royalist army had ceased to exist. Some of Rupert's foot regiments made their way to York, but the dispirited garrison only held out for a fortnight. Rupert rallied some six thousand of the men and escaped over the hills into Lancashire, thence rejoining King Charles in
The marsupials, or "pouch" or "bag"), these marsupials in which the young are usually carried for some time after birth in a pouch on the under-surface of the body of the female. The group, which has also the alternative title of Didelphida, is by some authorities regarded as a sub-class of the mammalia of equal rank with the Monotremata, while by others it is brigaded with the placentals, so that the two together form a sub-class of equal grade with the one represented by the monotremes. There is much to be urged in favour of either view; and in adopting the former alternative, it must be borne in mind that the difference between monotremes and marsupials is very slight, the most important which separates the latter from placentals.

In elevating the marsupials to the rank of a sub-class the name Metatheria has been suggested as the title for the higher grade, with Marsupialia as the designation for the single order by which they are now represented. It is, however, less liable to cause confusion, and in many other ways more convenient to employ the better known term Marsupialia in both senses.

Marsupials may be defined as viviparous (that is non-egg-laying) mammals, in which the young are born in an imperfect condition, and are immediately attached to the teats of the mother. In the latter the foetus is, generally speaking, spoken of as the "pouch," and the front edge of the pelvis being always furnished with epipubic or "marsupial" bones. As a rule there is no allantoic placenta forming the means of communication between the blood of the parent and the foetus, and when such a structure does occur its development is incomplete. In all cases a more or less full series of teeth is developed, these being differentiated into incisors, canines, premolars and molars, when all are present; but only a single pair of teeth in each jaw has deciduous predecessors.

The pouch from which the marsupials take their name is supported by the two epipubic bones, but does not correspond to the temporary breeding-pouch of the monotremes. It may open either forward or backwards; and although present in the great majority of the species, and enclosing the teats, it may, as in many of the opossums, be completely absent, when the teats extend in two rows along the whole length of the under-surface of the body. Whether a pouch is present or not, the young are born in an exceedingly imperfect state of development, after a very short period of gestation, and are immediately transferred by the mother to the pouch, of which they often become attached for a considerable time; the milk being injected into their mouths at intervals by means of a special muscle which compresses the glands. In the case of the great grey kangaroo, for instance, the period of gestation is less than forty days, and the newly-born embryo, which is blind, naked, and unable to use its bud-like limbs, is little more than an inch in length.

As additional features of the sub-class may be mentioned the absence of a corpus callosum connecting the right and left hemispheres of the brain, and of a fossa in the septum between the two auricles of the heart. In the skull there are always vacuities, or unossified spaces in the bones of the palate, while the "angle," or lower hind extremity of each half of the lower jaw is strongly bent inwards so as to form a kind of shelf, and the alisphenoid bone takes a share in the formation of the tympanum, or auditory bladder, or bulla. Didelphida, the alternative name of the group was given in allusion to the circumstance that the uterus has two separate openings; while other features are the inclusion of the openings of the alimentary canal and the urino-genital sinus in a common sphincter, and the position of the scrotum in advance of the penis. The bandicoots alone possess a placenta. Lastly the number of trunk-vertebrae is always nineteen, while there are generally thirteen pairs of ribs.

As regards the teeth, in all cases except the wombats the number of upper incisors differs from that of the corresponding lower teeth. As already stated, there is no vertical displacement and succession of the teeth, except in the case of a single tooth on each side of each jaw, which is the third of the premolar series, and is preceded by a tooth having more or less the characters of a molar (see fig. 1). In some cases (as in rat-kangaroos) this tooth retains its proper function until the animal has nearly, if not quite, attained its full stature, and is not shed and replaced by its successor until all the teeth except the premolars and incisors have been shed and replaced. In others, as the thylacine, it is rudimentary, being shed or absorbed before any of the other teeth have cut the gum, and therefore functionless. It may be added that there are some marsupials, such as the wombat, koala, marsupial ant-cater and the dassies, in which no such deciduous tooth, even in a rudimentary state, has been discovered. In addition to this replacement of a single pair of functional teeth in each jaw, it has been discovered that marsupials possess rudimentary tooth-germs which never cut the gum. According to one theory, these rudimentary teeth, together with the one pair of functional teeth in each jaw that has vertical successors, represent the milk-teeth of placental mammals. On the other hand, it is impossible to believe that the functional dentition (other than the replacing premolar and the molars) correspond to the milk-dentition of placentals, and that the rudimentary tooth-germs represent a predental dentition. The question, however, is of academic rather than of practical interest, and whichever way it is answered does not affect our general conception of the nature and relationships of the group.

Unfortunately the homology of the functional series does not by any means end the uncertainty connected with the marsupial dentition; as there is also a difference of opinion with regard to the serial homology of some of the cheek-teeth. For instance, according to the older view, the dental formula in the thylacine or Tasmanian wolf is i. 1, c. 1, p. 3, m. 3 = 46. On the other hand, in the opinion of the present writer, this formula, so far as the cheek-teeth are concerned, should be altered to p. 1, m. 3, thus bringing it in accord, so far as the cheek-teeth are concerned, to the common marsupial formula of the single pair of replacing teeth the third premolars. It may be added that the formula given above shows that the marsupial dentition may comprise more teeth than the 44 which form the normal full placental complement.

As regards geographical distribution, existing marsupials, with the exception of two families, Didelphyidae and Epanorthidae, are limited to the Australian region, for the chief mammalian fauna of Australia, New Guinea, and some of the adjacent islands. The Didelphyidae are almost exclusively Central and South American, only one or two species ranging into North America. Fossil remains of members of this family have also been found in Europe in strata of the Oligocene period.

History.—The origin and evolution of the Australian marsupials have been discussed by Mr B. A. Bensley. In broad contrast to the views of Dr A. R. Wallace, this author is of opinion that marsupials did not effect an entrance into Australia till about the middle of the Tertiary period, their ancestors being probably opossums of the American type. They were then arboreal; but they speedily entered upon a rapid, although short-lived, course of evolution, during which leaping terrestrial forms like the kangaroos were developed. The short period of this evolution is at least one factor in the primitive grade of even the most specialized members of the group. In the advance of their molar teeth from a tritubercular to a grinding type, the author traces a curious parallelism between marsupials and placentals. Taking opossums to have been the ancestors of the group, the author considers that the present writer may be right in his view that marsupials entered Australia from Asia by way of New Guinea. On the other hand there is nothing absolutely decisive against their origin being southern.

Again, taking as a text Mr L. Dollo's view that marsupials were originally arboreal, that, on account of their foot-structure, they could not have been the ancestors of placentals, and that they themselves are degenerate placentals, Mr Bensley contrasts this with Huxley's scheme of mammalian evolution. According

---

1 The presence or absence of the corpus callosum has been much disputed; the latest researches, however, indicate its absence.
to the latter, the early monotremes which became specialized into modern monotremes, gave rise to the ancestors of the modern marsupials; while the modern placentals are likewise an offshoot from the ancestral marsupial stock. This phylogeny, the author thinks, is the most probable of all. It is urged that the imperfect placenta of the bandicoots instead of being vestigial, may be an instance of parallelism, and that in marsupials generally the allantois failed to form a placental connexion. Owing to the antiquity of both placentals and marsupials, the arboreal character of the feet of the modern forms of the latter is of little importance. Further, it is considered that too much weight has been assigned to the characters distinguishing monotes from other mammals, foetal marsupials showing a monotreme type of coracoid, while it is probable that in the long run it will be found impossible to maintain the essential dissimilarity between the milk-glands of monotremes and other mammals.

Another view is to regard both marsupials and placentals as derivatives from implacental ancestors more or less nearly related to the creodont carnivora, or possibly as independently descended from anomodont reptiles (see CREODONTA). Finally, there is the hypothesis that marsupials are the descendants of placentals, in which case, as was suggested by its discoverer, the placenta of the bandicoots would be a true vestigial structure.

Classification.

Existing marsupials may be divided into three main divisions or sub-orders, of which the first, or Polyprotodontia, is common to America and Australasia; the second, or Paucituberculata, is exclusively South American; while the third, or Diprotodontia, is as solely Australasian inclusive of a few in the eastern Austro-Malayan islands.

1. Polyprotodontia.—The Polyprotodontia are characterized by their numerous, small, sub-equal incisors, of which there are either five or four pairs in the upper and always three in the lower jaw, (fig. 2) and the generally strong and large canines, as well as by the presence of from four to five sharp cusps or tubercles on the crown of the molars. The pouch is often absent, and may open backwards. For the most part the species are carnivorous or insectivorous.

The first family is that of the true or American opossums—Didelphididae, in which there are five pairs of upper incisors, while the feet are of the presumed primitive arboreal type, the hind foot having the four outer toes subequal and separate, with the first opposable to them all. With the exception of the water-opossum, forming the genus Chironectes, all the living members of the family may be included in the genus Didelphys. The latter may, however, be split up into several sub-generic groups, such as Melachirus, Phiander, Marmass (Micaurell or Grymocnemis), Phalangia, Dromiciops, &c. The small South American forms included in Marmass, which lack the pouch, and have numerous teeth, and molar teeth of a primitive type, are doubtless the most generalized representatives of the group (see Opossum; and Water Opossum).

Nearly allied is the Australian family Dasyuridae, characterized by the presence of only four pairs of upper incisors, the generally small and rudimentary condition of the first hind toe, which can but seldom be opposed to the rest, and the absence of phalanges in the tail; the pouch being either present or absent, and the fore feet always five-toed. The stomach is simple, and there is no caecum to the intestine, although this is present in the opossums.

The largest representative of the family is the Tasmanian wolf, or thylacine, alone representing the genus Thylacinus, in which the dentition numbers i, 3, c, 1, p, 3, m, 1 = 46; with the incisors small and vertical, the outer one in the upper jaw being larger than the others. Summits of the lower incisors, before they are worn, with a deep transverse groove, dividing it into an anterior and a posterior cusp. Canines long, strong and conical. Premolars with compressed crowns, increasing in size from before backwards. Molars in general character resembling those of Sarcophilus, but of more simple form, the cusps being less distinct and not so sharply pointed. Deciduous molar very small, and shed before the animal leaves the mother's pouch. General form dog-like, with the head elongated, the muzzle pointed, and the ears moderate, erect and triangular. Fur short and closely applied to the skin. Tail of moderate length, thick at the base and tapering towards the apex, clothed with short hair. First hind toe (including the metacarpal bone) absent. Vertebrae: C. 7, D. 13, L. 6, S. 2, C. 23. Marsupial bones unspecialized. The gradual passage of the thick root of the tail into the body is a character common to the Tasmanian wolf and the aard-vark, and may be directly inherited from reptilian ancestors (see THYLACINE).</p>

The next genus is represented solely by the Tasmanian devil, Sarcophilus (or Diabulus) urinans, a medium-sized animal with a dental formula similar to that of the dasyures, but with teeth (fig. 2) approximating to those of the thylacine, though markedly different in details. The first hind toe is absent.

In the 'native cats,' or dasyures, constituting the genus Dasyurus, the dental formula is i, 3, c, 1, p, 3, m, 1 = 42. The upper incisors are nearly equal and vertical, with the first slightly longer, narrower, and separated from the rest. Lower incisors sloping forward and upward. Canines large and sharply pointed. First two premolars with compressed and sharp-pointed crowns, and slightly developed anterior and posterior accessory basal cusps. Molars with numerous sharp-pointed cusps. In the upper jaw the first two with crowns having a triangular free surface; the last small, simple, narrow and placed transversely. In the lower jaw the molars more compressed, with longer cusps; the last not notably smaller than the others. Ears of moderate size, prominent and obtusely pointed. First hind toe rudimentary, clawless or absent; its metatarsal bone always present. Tail generally long and well clothed with hair. Vertebrae: C. 7, D. 13, L. 6, S. 2, C. 18-20 (see Dasyure).

The genus Phascologale comprises a number of small marsupials, none exceeding a rat in size, differing from the dasyures in possessing an additional premolar—the dentition being i, 3, c, 1, p, 3, m, 1 = 46—and in having the teeth generally developed upon an insectivorous rather than a carnivorous pattern, the upper middle incisors being larger and inclined forward, the canines relatively smaller, and the molars with broad crowns, armed with prickly tubercles. The muzzle is pointed. Ears moderately rounded, and nearly naked. Fore feet with five sub-equal toes, with compressed, slightly curved pointed claws. Hind feet with the four outer toes sub-equal, with claws similar to those in the fore feet; the first toe almost always partially opposed, though small and nailless, sometimes absent.

In some respects intermediate between the preceding and the next genus is Dasyurus byrnei, of Central Australia, an animal of the size of a rat, with one lower premolar less than in Phascologale, without the first hind toe, and with a somewhat thickened tail. The pouch is incomplete, with two lateral folds, and the number of testes six.

Sminthopsis includes several very small species, with the same dental formula as Phascologale, but distinguished from that genus by the narrowness of the hind foot, in which the first toe is present, and the granulated or hairy (in place of broad, smooth and naked)
MARSUPIALIA

The curious habits of the marsupials are peculiar to the family. The ears are large, and the muzzle is small. The fur is soft and silky. The teeth are generally large, and the metacarpals and short, sharp, slightly curved, compressed claws. First toe represented by a rudimentary metacarpal bone; the fourth by a metacarpal and two small phalanges without a claw, and not reaching the middle of the metacarpal of the third; fifth entirely absent. Hind foot and tail short, with strong claws. The plantar surface is flattened, and the metatarsal joints are united. The terminal phalanges of the toes are united. The animal is restless, and its movements are rapid. Pouch opening backwards. 

Vertebræ: C, 7, D, 13, L, 6, S, 3, C, 23.

From Gould.

Fig. 5.—Gunn’s Bandicoot (Peramelus gunni),

as the terminal phalange, but with distinct claws; the fifth intermediate in length between these and the large claws developed, it is usually short. Hind feet with the functional toes reduced to two, the second and fourth toes, of equal length, with closely united metacarpals and short, sharp, slightly curved, compressed claws. First toe represented by a rudimentary metacarpal bone; the fourth by a metacarpal and two small phalanges without a claw, and not reaching the middle of the metacarpal of the third; fifth entirely absent. Hind foot and tail short, with strong claws. The plantar surface is flattened, and the metatarsal joints are united. The terminal phalanges of the toes are united. The animal is restless, and its movements are rapid. Pouch opening backwards. 

Vertebræ: C, 7, D, 13, L, 6, S, 3, C, 23.

The one species, from Western Australia, is the largest member of the family, being about the size of a rabbit, to which it bears sufficient superficial resemblance to have acquired the name of "native rabbit" from the colonists. It burrows in the ground, but in other respects resembles bandicoots in habits.

In the pig-footed bandicoot (Choeropus castanotis) the dentition generally resembles that of Peramelus, but the canines are less developed, and the upper jaw two-rooted. Limbs very slender; posterior nearly twice the length of the anterior. Fore feet with the functional toes reduced to two, the second and third equal in length, and closely united metacarpals and short, sharp, with short claws. First toe represented by a minute rudiment of a metacarpal bone; the fourth by a metacarpal and two small phalanges without a claw, and not reaching the middle of the metacarpal of the third; fifth entirely absent. Hind foot and tail short, with strong claws. The plantar surface is flattened, and the metatarsal joints are united. The terminal phalanges of the toes are united. The animal is restless, and its movements are rapid. Pouch opening backwards. 

Vertebræ: C, 7, D, 13, L, 6, S, 3, C, 23.

The only species of this genus is about the size of a small rat, found in the interior of Australia. Its general habits and food appear to resemble those of other bandicoots. A separate family, Notoryctidae, is represented by the marsupial mole (Notoryctes typhlops), of the deserts of south Central Australia, a small, golden-haired, burrowing creature, with long, slender, very sharp, and a short, naked stump tail. The limbs are five-toed, with the first and fourth toes of the front pair armed with enormous digging claws;
there are no external ear-conchs; and the dentition includes four pairs of upper, and three of lower, incisors, and distinctly triturribulcral cheek-teeth. The small poucb, supported by the usual epipubic bones, opens backwards. In correlation with its burrowing habits, some of the vertebrae of the neck and of the loins are respectively welded together. The eyes have degenerated to a greater extent than

MARSUPIALIA

Panciurculata are characterized by the presence of four pairs of upper and three of lower incisor teeth; the enlargement and forward inclination of the first pair of lower incisors, and the presence of four or five sharp cusps on the cheek-teeth, coupled with the absence of "syndactylism" in the hind limbs.

3. Diprotodonts.— The third and last sub-order of marsupials is the Diprotodontia, which is exclusively Australasian and includes the wombats, koala, cuscuses, kangaroos and their relatives. There are never more than three pairs of upper and one of lower incisors, of which the middle upper and the single lower pair are large and chisel-like (fig. 9); the canines are small or absent; the cheek-teeth have bluntly triturribulcular or transversely-ridged crowns in most cases; and the hind-feet are syndactylous. With one exception, the intestine has a caecum, and the pouch is large and opens forwards. The pouch should be added to the marsupials in recognition of a certain peculiarity in its ramifications whereby the brain of the diprotodonts differs markedly from that of the polyprotodonts and approximates to the placental type. Dr Einar Lönnberg has also recorded certain adaptive peculiarities in the stomach. Most of the species, particularly the specialized types, are more or less completely herbivorous.

The first family, Phascolomynidae, is typified by the wombats; but according to the view adopted by Mr H. Winge, and endorsed by Professor Max Weber, is also taken to include the koala. In this wider sense the family may be characterized as follows. The tympanic process of the alisphenoid bone of the skull is short, not covering the cavity of the tympanum, nor reaching the paroccipital process. The tail is rudimentary, the first hind-toe opposable, the first pair of upper incisors very large, but the second and third either absent or small and placed partially behind the larger pair; and only five pairs of cheek-teeth in each jaw. The stomach has a cardiac gland, and the number of teats is two.

In the wombats (Phascolomyx) the dentition is i. $c.$, p. + m. 1, total 24; all the teeth growing from persistent pulps, and the incisors large and chisel-like, with enamel only on the front surface. The cheek-teeth strongly curved, forming from the base to the summit about a quarter of a circle, the concavity being directed outwards in the upper and inwards in the lower teeth. The first of the series (which appears to have no predecessor) single-lobed; the other four composed of two lobes, each subtriangular in section. Limbs equal, stout and short. Fore-feet with five distinct toes, each furnished with a long, strong and slightly curved nail, the first and fifth considerably shorter than the other three. Hind-feet with a very short nailless first toe, the second, third and fourth toes partially united by integument, of nearly equal length, the fifth distinct and rather shorter; all four with long and curved nails. In the skeleton the second and third toes are distinctly more slender than the fourth, showing a tendency towards the character so marked in the following families. Tail rudimentary. Caecum very short and wide, with a vermiciform appendage (see Wombat).

In addition to remains referable to the existing genus, the Pleistocene deposits of Australia have yielded evidence of an extinct giant wombat constituting the genus Phascolon (Scepanodon).

The koala, or "native bear" (Phascolartus cinereus), which differs widely from the wombats in its arboreal habits, is less specialized and the dentition different from that of the Diprotodontia. The koala has upper incisors. The incisors

first to the fourth, with square crowns, each bearing four pyramidal cusps. The lower incisors are partially inclined forwards, compressed and tapering, bevelled at the ends. Check-teeth in continuous series, as in the upper jaw. Fore-feet with the two inner toes slightly separated from and opposable to the remaining three, all with strong curved and much compressed claws. Hind-foot (fig. 10) with the first toe placed far back, large and broad, the second and third (united) toes considerably smaller than the other two; the fourth the largest. No external tail. Fur dense and woolly. Ears of moderate size, thickly clothed with long hair.

Cecum very long and dilated, with numerous folds. Vertebrae: C. 7, D. 11, L. 4, S. 2, Ca. 8. Ribs eleven pairs (see Koala).

Here may be noticed three genera of large extinct marsupials from the Pleistocene of Australia whose affinities appear to ally them to the wombat-group on the one hand and to the phalangers on the other. The longest known is Diprolodon, an animal of the size of a rhinoceros, with a dental formula of 1. 4, c. 3, p. 4, m. 4, total 28. The first upper incisor very large and chisel-like, molars with prominent transverse ridges, as in Macropus, but without the longitudinal connecting ridge. Complete skeletons disinterred by Dr E. C. Stirling indicate that in the structure of the feet this creature presents resemblances both to the wombats and the phalangers, but to the latter. On the other hand, the considerably smaller Nototherium, characterized by its sharp and broad skull and smaller incisors, seems to have been much more wombat-like, and may perhaps have possessed similar burrowing habits.

The last of the three is Thylacoleo carnifex, so named on account of its supposed carnivorous habits. In the adult, the dentition (fig. 11) is i. 4, c. 3, p. + m. i, total 24. The first upper incisor is much larger than the others; canine and first two premolars rudimentary. In the lower jaw there are also one or two small and early deciduous premolars; third premolars of both jaws formed on the same type as that of the rat-kangaroos, but relatively much larger; molars rudimentary, tubercular. The functional teeth are reduced to one pair of large cutting incisors situated close to the middle line, and one great, cutting, compressed premolar, on each side above and below. As already mentioned, Thylacoleo was originally regarded as a carnivorous creature, but this view was subsequently disputed, and its diet supposed to consist of soft roots, bulbs and fruits, with an occasional small bird or mammal. Recently, however, the pendulum of opinion has swung back towards the original view: and Dr R. Broom believes Thylacoleo to have been "a purely carnivorous animal, and one which would be quite able to, and probably did, kill animals as large or larger than itself." The affinities of the creature are clearly with the phalangers.
second and third digits united, with sharp, compressed curved claws; the fourth and fifth free, with small flat nails. Ears of modern phalangers are hairy, externally clothed with short hairs, prehensile. Vertebrae: C. 7, D. 13, L. 5, S. 3, C. 24.

As indicated in the accompanying illustration, the long-boned phalangers are arboreal, feeding on small insects from long-tubed flowers by means of its extensible tongue.

The remaining members of the family may be included in the sub family Phalangerinae, characterized by the normal nature of the dentition (which shows rudimentary lower canines) and tongue. Cusipes and phalangers form a numerous group, all the members of which are perissodactyls, some of which, the Southern Divers, are provided with lateral expansions of skin enabling them to glide from tree to tree like flying-squirrels. The typical members of the group are the cuscuses (Phalanger), ranging from the Moluccas and Celebes to New Guinea, in which they are often found far from the females.

The true phalangers, or opossums of the colonists, constitute the genus Trichosurus, the ring-tailed species known as Phascolurus; the latter ranging to New Guinea. Dactylopsila is usually recognized by its atrodden fourth finger and paler-colored fur; the flying species are classed as Petaroides, Petaurus, Gymnobelides and Acrobates, the last no longer than a mouse; while Dromicius, Didelphus and Acrobates are allied types without parachutes (see Phalanger).

An equally brief notice must suffice of the kangaroo tribe or Macropodidae, since these receive a special notice elsewhere. The dentition is i, 3, 2, 3; p. 1, 1, 3, 3; m. 3, 3, 3, and those of the lower jaw frequently having a scissors-like action against one another. The broad molars are either bluntly tuberculate or transversely ridged; the outer side of the hind part of the lower jaw has a deep pocket; and the hind limbs are generally very long, with the structure of the foot similar to that of the bandicoot. The family is connected with the Phalangeridae by means of the musk-kangaroo (Hypsiprymnodon moschatus); forming the sub-family Hypsiprymnodontinae. Then come the rat-kangaroos, or kangaroo-rats, constituting the sub-family Nototheriinae; while the true kangaroos (Dendrolagus), rock-wallabies, or kangaroos (Macropus) form the Macropodinae (see Kangaroo).

Extinct Marsupials

Reference has been made to the Australasian Pleistocene genera Phascolonus, Diprotodon, Nototherium and Thylacoleon, whose affinities are with the wombats and phalangers. Some of the deposits have also yielded remains of extinct types of kangaroo, some of gigantic size, constituting the genera Sthenurus, Procotodon and Palorchestes. Numerous types more or less nearly allied to the phalangers, such as Burranyis and Trichis have also been described, as well as a flying form, Palaepotaurus. It is also interesting to note that the remains of these genera indicate the former occurrence of thylacines and Tasmanian devils on the Australian mainland. Of more interest is the imperfection of the Owenian beds in New South Wales, which apparently presents points of affinity both to phalangers and dasyures. From the Oligocene deposits of France and southern England have been obtained numerous remains of opossums referred to according to their anatomy; these have been separated generically from Diphylyx (in its widest sense) on account of differences in the relative sizes of the lower premolars, and the teeth of those in the Owenian have been placed in the family Protheroidea, a group forming three genera, the larger in the Eocene beds, the species of which I have been described, as well as a flying form, Palaepotaurus. It is also interesting to note that these genera indicate the former occurrence of thylacines and Tasmanian devils on the Australian mainland. Of more interest is the imperfect of the Owenian beds in New South Wales, which apparently presents points of affinity both to phalangers and dasyures.

The phrase "Marsupialia" has been extended from the over-riding term to include all the above genera. It is not generally regarded as a synonym of Sirenia, which includes the Monotremata.

MARSUPIALIA

Phalangeridae

Reference has been made to the Australasian Pleistocene genera Phascolonus, Diprotodon, Nototherium and Thylacoleon, whose affinities are with the wombats and phalangers. Some of the deposits have also yielded remains of extinct types of kangaroo, some of gigantic size, constituting the genera Sthenurus, Procotodon and Palorchestes. Numerous types more or less nearly allied to the phalangers, such as Burrenyis and Trichis have also been described, as well as a flying form, Palaepotaurus. It is also interesting to note that the remains of these genera indicate the former occurrence of thylacines and Tasmanian devils on the Australian mainland. Of more interest is the imperfect of the Owenian beds in New South Wales, which apparently presents points of affinity both to phalangers and dasyures. From the Oligocene deposits of France and southern England have been obtained numerous remains of opossums referred to according to their anatomy; these have been separated generically from Diphylyx (in its widest sense) on account of differences in the relative sizes of the lower premolars, and the teeth of those in the Owenian have been placed in the family Protheroidea, a group forming three genera, the larger in the Eocene beds, the species of which I have been described, as well as a flying form, Palaepotaurus. Marsupialia

MARSUPIAL MOLe—MARTEN, H.

Dromotheriidae, and apparently showing decided traces of reptilian affinity. It may be added that a few traces of mammals have been obtained from the English Wealden, among which an incisor tooth forerunners of certain types.

MARSUPIAL Mole (Notoryctes typhlops), the "Ur-quamata" of the natives, an aberrant protodont from central South Australia, constituting a family (Notoryctidae). This is a small burrowing animal, of a pale golden-yellow color, with short and silky hair, a horned shield on the nose, and a stumpy leathery tail. The feet are five-toed, and the third and fourth toes of the front pair armed with enormous claws adapted for digging. Neither ear-conches nor eyes are visible externally. There are but three pairs of incisor teeth in each jaw, and the upper molars are tricuspied. This animal spends most of its time burrowing in the sand in search of insects and their larvae, but occasionally makes its appearance on the surface.

MARSUS, DOMITIUS, Latin poet, the friend of Virgil and Tibullus, and contemporary of Horace. He survived Tibullus (d. 19 B.C.), but was no longer alive when Ovid wrote (c. A.D. 12) the epistle from Pontus (Ex Ponto, iv. 16) containing a list of poets. He was the author of a collection of epigrams called Ciciuta ("hemlock") from their bitter sarcasm, and of a beautiful epitaph on the death of Tibullus; of elegaic poems, probably of an erotic character; of an epic poem; and of a suite of verses on the taunt of a woman (De urbanitate). Martial often alludes to Marsus as one of his predecessors, but he is never mentioned by Horace, although a passage in the Odes (iv. 4, 19) is supposed to be an indirect allusion to the Amphairis (M. Haupt, Oppulsula, iii. 332).

See J. A. Weichert, Poetarum latinorum vitae et religiue (1830); R. Unger, De Dom. Marsni cicuta (Friedland, 1861).

MARSYS, in Greek mythology, a Phrygian god or Silenus, son of Hyagnis. He was originally the god of the small river of the same name near Celaenae, an old Phrygian town. He represented the roundness of the body—the one the accompaniment of the worship of Cybele, the other that of the worship of Apollo. According to the legend, Athena, who had invented the flute, threw it away in disgust, because it distorted the features. Marsys found it, and having acquired great skill in playing it, challenged Apollo to a contest with his lyre. Midas, king of Phrygia, who had been appointed judge, declared in favour of Marsys, and Apollo punished Midas by changing his ears into ass's ears. In another version, the Muses were judges and awarded the victory to Marsys. Midas, as well as Midias and Silenus, are associated in legend with Dionysus and belong to the cycle of legends of Cybele. A statue of Marsys was set up in the Roman forum and colonies as a symbol of liberty. The contest and punishment of Marsys were favourite subjects in Greek art, both painting and sculpture. In Florence there are several statues of Marsys hanging on the tree as he is going to be flayed (see GREEK ART, fig. 54, PL. II.); Apollo and the executioner complete the group. In the Lateran museum at Rome there is a statue representing Marsys in the act of picking up the flute, a copy of a masterpiece by Myron (Hyginus, Fab. 167, 191; Apollo, i. 4, 27; Ovid, Metam. 1382-406, xi. 145-193), for which see GREEK ART, fig. 64 (PL. III.).

MARTABAN, a town in the Thaton district of Lower Burma, on the right bank of the Salween, opposite Moulinie. It is said to have been founded in a.d. 573, by the first king of Pegu, and was once the capital of a powerful Talaing kingdom; but it is now little more than a village. Martaban is frequently mentioned by European travellers of the 16th century; and it has given the name of Martavans to a class of large vessels of glazed pottery, also known in India as Pegu jars. It was twice captured by the British, in 1824 and 1852. The Bay of Martaban receives the rivers Irrawaddy and Salween.

MARTELLO TOWER, a kind of tower formerly used in English coast defence. The name is a corruption of Motella. The Martello tower was introduced in consequence of an incident of the French revolutionary wars. In September 1793 a British squadron of three ships of the line and two frigates was ordered to support the Corsican insurgents. It was determined in the first place to take a tower on Cape Martella which commanded the only secure anchorage in the Gulf of San Florenzo. It was according to James, was named Martello, the latter being a tower with an 8-pounder in each wall, but the real derivation appears to be the name of a wild myrtle which grew thickly around. The tower, which mounted one 24-pounder and two 18-pounders on its top, was bombarded for a short time by the frigates, was then deserted by its little garrison, and occupied by a landing party. The tower was afterwards retaken by the French from the Corsicans. So far it had done nothing to justify its subsequent reputation. In 1794, however, a fresh attempt was made to support the insurgents. On the 7th of February 1800 troops were landed, and the tower was attacked by land and sea on the 8th. The "Fortitude" and "Juno" kept up a cannonade for 24 hours and then hauled off, the former being on fire and having sixty-two men killed and wounded. The fire from the batteries on shore produced no impression until a hot shot set fire to the "bass junk with which, to the depth of 5 ft., the immensely thick parapet was lined." The garrison of thirty-three men then surrendered. The armament was found to consist only of two 18-pounders and one 6-pounder. The strong resistance offered by these three guns seems to have led to the conclusion that towers of this description were specially formidable, and Martello towers were built in large numbers, and at heavy expense, along the shores of England, especially on the southern and eastern coasts, which in certain parts are lined with these towers at short intervals. They are structures of solid masonry, containing vaulted rooms for the garrison, and providing a platform at the top for two or three guns, which fire over a low masonry parapet. Access is provided by a ladder, communicating with a door about 20 ft. above the ground. In some cases (Exmouth, Cape) the towers were connected by a gangway to the nearest garrison. The chief defect of the tower was its weakness against vertical fire; its masonry was further liable to be cut through by breaching batteries. The French tours modèles were somewhat similar to the Martello towers; their chief use was to serve as keeps to unrevetted works. While the Martello tower owes its reputation and its widespread adoption in Great Britain to a single incident of modern warfare, the round masonry structure entered by a door raised high above the base is to be found in many lands, and is one of the earliest types of masonry fortification.

MARTEN, HENRY (1662-1688), English regicide, was the elder son of Sir Henry Marten, and was educated at University College, Oxford. As a public man he first became prominent in 1630 when he refused to contribute to a general loan, and in 1640 he entered parliament as one of the members for
MARTEN 785

Berkshire. In the House of Commons he joined the popular party, spoke in favour of the proposed bill of attainder against Strafford, and in 1642 was a member of the committee of safety. Some of his language about the king was so frank that Charles demanded his arrest and his trial for high treason. When the Great Rebellion broke out Marten did not take the field, although he was appointed governor of Reading, but in parliament he was very active. On one occasion his zeal in the parliamentary cause led him to open a letter from the earl of Northumberland to King Charles. His impropriety for this, says Glareanus, he was "cudgelled" by the earl; and in 1643, on account of some remark about extirpating the royal family, he was expelled from parliament and was imprisoned for a few days. In the following year, however, he was made governor of Aylesbury, and about this time took some small part in the war. Allowed to return to parliament in January 1646, Marten again advocated extreme views. He spoke of his desire to prepare the king for heaven; he attacked the Presbyterians, and, supporting the army against the parliament, he signed the agreement of August 1647. He was closely associated with John Lilburne and the Levellers, and was one of those who suspected the sincerity of Cromwell, whose murder he is said personally to have contemplated. However, he acted with Cromwell in bringing Charles I. to trial; he was one of the most prominent of the king's judges and signed the death warrant. He was then energetic in establishing the republic and in destroying the remaining vestiges of the monarchical system. He was chosen a member of the council of state in 1649, and as compensation for his losses and rewards of the war he was made Lord Mayor of London. A year later he was arrested and imprisoned for decrying the new political order. At the Restoration he was kindly treated, and was permitted to become a barrister, he secured a large practice and soon came to the front in public life. He was sent abroad on some royal business, was made chancellor of the diocese of London, was knighted, and in 1617 became a judge of the admiralty court. Later he was appointed a member of the court of high commission and, dean of the arches. He became a member of parliament in 1625, and in 1628 represented the university of Oxford, taking part in the debates on the petition of right.

MARTEN, a name originally belonging to the pine-marten (Mustela martes), but now applied to all members of the same genus of carnivorous mammals (see Carnivora). Martens are limited to the northern hemisphere, ranging throughout the greater part of the northern temperate regions of both Old and New Worlds, and southwards in America to 35° N. lat., while in Asia one species is met with in Java.

The species appear to be similar in their habits. They live in woods and rocky places, and spend most of their time in trees, although descending to the ground in quest of prey. They climb with great facility, and are agile and graceful in their movements. Some are said occasionally to devour berries and other fruit for food, but as a rule they are carnivorous, feeding chiefly on birds and their eggs, small mammals, as squirrels, hares, rabbits and moles, but chiefly mice of various kinds, and occasionally snakes, lizards and frogs. In proportion to their size they are among the most bloodthirsty of animals, though less so than the weasels. The female makes her nest of moss, dried leaves and grass in the hollow of a tree, but sometimes in a hole among rocks or ruined buildings, and produces several young at a birth, usually from four to six. Though wild and untameable to a great degree if captured when fully grown, if taken young they are docile, and have frequently been made pets, not having the strong unpleasant odour of the smaller Mustelidae. The pine-marten appears to have been partially domesticated by the Greeks and Romans, and used to keep houses clear from rats and mice. In the same way, according to Brian Hodgson, the yellow-bellied weasel (Putorius kathia) "is exceedingly prized by the Nepalese for its service in ridding houses of rats. It is easily tamed; and such is the dread of it in houses that the simple peasantry will not one will "apprehend a house where it is domiciled." It is, however, to the great value attached to the pelts of these animals that their importance to man is chiefly due. Though all yield fur of serviceable quality, the commercial value varies immensely, not only according to the species from which it is obtained, but according to individual variation, depending upon age, sex, season, and other circumstances. The skins from northern regions are more full and of a finer colour and gloss than those from more temperate climates, as are those of animals killed in winter compared to the same individuals in summer. Fashion has, moreover, set fictitious values upon slight shades of colour. Enormous numbers of animals are caught, chiefly in traps, to supply the demand of the fur trade, Siberia and North America being the principal localities from which they are obtained.

With the exception of the polecat (M. pennantii), the martens are much alike in size, general colouring and cranial and dental characters. The following description by Dr Elliott Coues of the American tree marten, M. americana, should apply almost equally well to most of the others. "It is almost impossible to describe the colour of the marten, except in general terms, without going into the details of individual variation, which are affected by age, sex, and local conditions. The animal is 'brown,' of a shade from orange to tawny to quite blackish; the tail and feet are ordinarily the darkest, the head lightest, often quite whitish; the ears usually have a whitish rim, while on the throat there is usually a large tawny-yellowish or orange-brown patch, from the chin to the fore legs, sometimes entire, sometimes broken into a number of smaller, irregular blotches, sometimes wanting, sometimes prolonged on the whole under surface, when the animal is white. The bamboo or polecat is 'brown' has a greyish cast, as far as the under fur is concerned, and is overlaid with rich lustrous blackish-brown in places where the body is uniformly hairy. The claws are whitish; the naked nose pad and whiskers are black. The tail occasionally shows interspersed white hairs, or a white tip."

The following are the best-known species:

*Mustela daurica* de Blainville, stone or white-breasted marten.---Distinguished from the following by the greater breadth of the skull, and some minute but constant dental characters, by a pure blackish-brown above, and cream-coloured bottom, with the pure white of the throat and breast. It inhabits the greater part of the continent of Europe, but is more southern than the next in its distribution, not being found in Sweden or Norway. The pelts of the polecat, behind the ears, the chin, and under the tail are blackish; under fur reddish-grey, with clear yellow tips; breast spot usually yellow, varying from bright orange to pale cream-colour or yellowish-white. Length of head and body 16 to 18 in., of tail (including
the hair) 9 to 12 in. This species is extensively distributed throughout northern Europe and Asia, and was formerly common in most parts of Great Britain and Ireland. It is still found in the northern counties of England and North Wales, but in decreasing numbers. In Scotland it is rare, but in Ireland may be found in almost every county occasionally. Though commonly called special work, Martens was chosen to afford it. His book on The Right of Private Property in War had appeared in 1869, and had been followed in 1872 by that upon The Office of Consul and Consular Jurisdiction in the East, which had been translated into German and republished at Berlin. These were the first of a long series of studies which won for their author a world-wide reputation, and raised the character of the Russian school of international jurisprudence in all civilized countries. First amongst them must be placed the great Recueil des traités et conventions conclus par la Russie avec les puissances étrangères (13 vols., 1874–1902). This collection, published in Russian and French in parallel columns, contains not only the texts of the treaties but also valuable introductions dealing with the respective conditions of which the treaties were the outcome. These introductions are based largely on unpublished documents from the Russian archives. Of Martens' original works his International Law of Civilized Nations is perhaps the best known; it was written in Russian, a German edition appearing in 1884–1885, and a French edition in 1887–1888. It displays much judgment and acumen, though some of the doctrines which it defends by no means command universal assent. More openly "tendentious" in character are such treatises as Russia and Europe (1885); Russia's Conflict with China (1881), The Egyptian Question (1882), and The African Conference of Berlin and the Colonial Policy of Modern States (1887). In the delicate questions raised in some of these works Martens stated his case with learning and ability, even when it was obvious that he was arguing as a special pleader. Martens was repeatedly chosen to act in international arbitrations. Among the controversies which he helped to adjust were that between Mexico and the United States—the first case determined by the permanent tribunal of The Hague—and the difference between Great Britain and France in regard to Newfoundland in 1891. He played an important part in the negotiations between his own country and Japan, which led to the peace of Portsmouth (Aug. 1905) and prepared the way for the Russo-Japanese convention. He was employed in laying the foundations for the Hague Conferences. He was one of the Russian plenipotentiaries at the first conference and president of the fourth conference—that on maritime law—at the second conference. His visits to the chief capitals of Europe in the early part of 1907 were an important preliminary in the preparation of the provisional programme. He was a judge of the Russian supreme prize court established to determine cases arising during the war with Japan. He received honorary degrees from the universities of Oxford, Cambridge and Yale; he was also awarded the Nobel Peace Prize in 1902. In April 1907 he addressed a remarkable letter to The Times on the position of the second Duma, in which he argued that the best remedy for the ills of Russia would be the dissolution of that assembly and the election of another on a narrower franchise. He died suddenly on the 26th of June 1909.

See T. E. Holland, in Journal of the Society of Comparative Legislation for October 1909, where a list of the writings of Martens appears.

MARTENS, GEORG FRIEDRICH VON (1756–1821), German jurist and diplomatist, was born at Hamburg on the 22nd of February 1756. Educated at the universities of Göttingen, Regensburg and Vienna, he became professor of jurisprudence at Göttingen in 1783 and was ennobled in 1789. He was a member of a commission of state by the elector of Hanover in 1808, and in 1810 was president of the financial council of the council of state of the kingdom of Westphalia. In 1814 he was appointed privy cabinet-councillor (Geheimer Kabinettsekretär) to the king of Hanover, and in 1816 went as representative of the king to the diet of the new German Confederation at Frankfurt, where he died on the 21st of February 1821.

Of his works the most important is the great collection of treaties Recueil des traités, &c.) from 1761 onwards. Of this the first seven volumes were published at Göttingen (1791–1801), followed by four more volumes (1831), all printed at the cost of the Government. G. F. von Martens edited the first four, the fifth being the
MARTENSEN—MARThA'S VINEYARD

work of K. von Martens, the others (6-9) by F. Saalfeld and (10-16) F. Murhard. A Nouveau supplément, in 3 vols., filling gaps in the previous collection, was also published by Murhard (Göttingen, 1839–1842). This was followed by Nouveau recueil ... continu ... erneuert von K. Martens, in 10 vols. (Cottbus, 1888–1895), edited in turn by F. Murhard, C. Murhard, J. Pinhas, C. Sämmer and J. Hopf, with a general index of treaties from 1493 to 1874 (1876). This was followed by Nouveau recueil (Cottbus, 1877–1892; Leipzig, 1897–1908). From vol. xi. on this series was edited by Felix Störk, professor of public law at Greifswald. In 1909 appeared vol. i. of a further Continuation (1896–1909) under the editorship of Professor Heinrich Triepel of Kiel University.

Of Martens’ other works the most important are the Préfaces du droit des gens modernes de l’Europe (1871; 3rd ed., Cottbus, 1897), a new ed. G. S. de la Perrière (1864), and Einführungen merkwürdiger Fälle des neueren europäischen Völkerrechtes, 2 vols. (Göttingen, 1890–1892); Cours diplomatique et table des relations de la France avec la Russie, 3 vols. (Berlin, 1891); Grundriss einer diplomatischen Gesch. der europ. Staatsbündel u. Friedensschlüsse seit dem Ende des 15. Jahrhunderts (ibid. 1892).

His nephew Karl von Martens (1790–1865), who at his death was minister resident of the grand-duke of Weimar at Dresden, published a Manuel diplomatique (Leipzig, 1823), re-issued as Guide diplomatique in two vols., in 1832 (4th ed. by Gellbrunn, 1866), a valuable textbook of the rules of international law and diplomacy: Causes célèbres du droit des gens (2 vols., ibid., 1827) and Nouvelles causes célèbres (2 vols., ibid., 1843), both republished, in 5 vols. (1858–1861); Recueil measurable et pratique de traités (7 vols., ibid., 1837). The last-named work was translated into various languages. The “official” eulogy he pronounced upon Bishop Jakob P. Mynster (1775–1854) in 1854, brought down upon his head the invectives of the philosopher Sören Kierkegaard. He died at Copenhagen on the 3rd of February 1854.

MARTENSEN, HANS LASSEN (1808–1884), Danish divine, was born at Flensburg on the 19th of August 1808. He studied in Copenhagen, and was ordained in the Danish Church. At Copenhagen he was lector in theology in 1838, professor extraordinary in 1840, court preacher also in 1845, and professor extraordinary in 1850. In 1854 he was made bishop of Seeland. In his studies he had come under the influence of Schleiermacher, Hegel and Franz Baader; but he was a man of independent mind, and developed a peculiar speculative theology which showed a disposition towards mysticism and theosophy. His considerable works included treatments of Christian ethics and dogmatics, on moral philosophy, on baptism, and a sketch of the life of Jakob Bochme, which exerted so marked an influence on the mind of the great English theologian of the 18th century, William Law. Martensen was a distinguished preacher, and his works were translated into various languages. The “official” eulogy he pronounced upon Bishop Jakob P. Mynster (1775–1854) in 1854, brought down upon his head the invectives of the philosopher Sören Kierkegaard. He died at Copenhagen on the 3rd of February 1854.

MARTHANUS, VINEYARD, an island including the greater part of Dukes county, Massachusetts, U.S.A., lying about 3 m. off the southern coast of that state. Its extreme length (east to west) is about 20 m., and its extreme width (north to south) about 93 m. Along its north-west and a portion of its north-east shore lies Vineyard Sound. Its principal bays are Vineyard Haven Harbor, a deep indentation at the northernmost angle of the island; and, on the eastern coast, Edgartown Harbor, Elizabeth Bay, both formed by the juxtaposition of Chappaquiddick Island. The surface is mainly flat, excepting a strip about 2 m. broad along the north-western coast, and the two western townships (Chilmark and Gay Head), which are hilly, with several eminences of 200 to 300 ft.—the highest, Prospect Peak, in Chilmark township, 308 ft. Gay Head Light, a beacon near the western extremity, stands among picturesque cliffs, 145 ft. above the sea. Along the southern coast are many ponds, all shut off from the ocean by a narrow strip of land, excepting Tisbury Great Pond, which has a small outlet to the sea. Others are Sengokontacket Pond on the eastern coast; Lagoon Pond, which is practically an arm of Vineyard Haven Harbor; and, about a mile east of the Harbor, Chappaquidett Pond. Martha’s Vineyard is divided into the following townships (from east to west): Edgartown (in the south-eastern part of the island), pop. (1910), 111; area, 207 sq. m.; Oak Bluffs (north-eastern portion), pop. (1910), 1084; area, 79 sq. m.; Tisbury, pop. (1910), 110; area, 71 sq. m.; West Tisbury, pop. (1910), 437; area, 305 sq. m.; Chilmark, pop. (1910), 282; area, 194 sq. m.; and Gay Head, pop. (1910), 162; area 52 sq. m. The population of the county, including the Elizabeth Isds. (Gosnold town, pop. 152), N. W. of Martha’s Vineyard; Chappaquiddick Island (Edgartown township), pop. (1910), 19; and the small land south-west of Martha’s Vineyard, was 4561 in 1900 (of whom 645 were foreign-born, including 70 Portuguese and 72 English-Canadians, and 154 Indians), and in 1910, 4504. The principal villages are Oak Bluffs on the north-east coast, facing Vineyard Sound; Vineyard Haven, in Tisbury township, beautifully situated on the west shore of Vineyard Haven Harbor, and Edgartown on Edgartown Harbor—all summer resorts. No Man’s Land, included politically in Chilmark township, lies about 6 m. south of Gay Head. It is about 13 m. long (east and west) and about 2 m. broad. It supported by sheep grazing; the neighbouring waters are excellent fishing ground. Martha’s Vineyard is served by steamship lines from Wood’s Hole and New Bedford to Vineyard Haven, Oak Bluffs, and Edgartown. The Martha’s Vineyard railway (from Oak Bluffs to the south-east extremity of the island, by way of Edgartown), opened in 1874, was not a financial success, and had been practically abandoned in 1909, but an electric line from Oak Bluffs to Vineyard Haven provides transit facilities for that part of the island.

For more than a century, whale fishing was practically the sole industry of Martha’s Vineyard. It was carried on at first from the shore in small boats; but by the first decade of the 18th century vessels especially built for the purpose were being used, and by 1750 shore fishing had been practically abandoned. The industry, seriously crippled by invasions of British troops during the War of American Independence —especially by a force which landed at Holmes’s Hole (Vineyard Haven) in September 1778—and again during the War of 1812, revived and was at its height in 1840–1850, only to receive a second black death during the 1870s. In the last decade of the 19th century its decline was rapid, not only because of the increasing scarcity of whales, but because of the introduction of the mineral oils, and by the end of the century whaling had ceased to be of any economic importance. Herring fishing, on both the north and the south shore, occupies a small percentage of the inhabitants, and there is also some deep-sea fishing. Sheep-raising, especially for wool, is an industry of considerable importance, and Dukes county is one of the three most important counties of the state in this industry.

Martha’s Vineyard was discovered in 1602 by Captain Bartholomew Gosnold, who landed (May 21) on the island now called No Man’s Land, and named it Martha’s Vineyard,1 which name was subsequently applied to the larger island. Captain Gosnold rounded Gay Head, which he named Dover Cliff, and established on what is now Cuttyhunk Island, which he called Elizabeth Island, the first (though, as it proved, a temporary) English settlement in New England. The entire line of sixteen islands, of which Cuttyhunk is the westernmost of the larger ones, have since been called the Elipabeth Islands; they form the dividing line between Buzzards Bay and Vineyard Sound, and in 1864 were incorporated as Gosnold town (pop. in 1905, 161) of Dukes county.

The territory within the jurisdiction of the Council for New England was parcelled in 1635 among the patentees in such

1 In the 17th century both “Martha’s Vineyard” and “Martin’s Vineyard” were used, and the latter appears in a book as early as 1608 and in another as late as 1669, and on a map as late as 1670. It seems probable that the original form was Martin, the name of one of Gosnold’s crew; according to some authorities the name Martha’s Vineyard was adopted by Mayhew in honour of his wife or daughter.
terms—owing to insufficient knowledge of the geography of the coast—that both William Alexander, earl of Stirling, and Sir Ferdinando Gorges, proprietor of Maine, claimed Martha’s Vineyard. In 1641 Stirling’s agent, Forrester, sold to Thomas Mayhew (1592–1682),

1

of Watertown, Massachusetts, for $200, the island of Nantucket, with several smaller islands, and also Martha’s Vineyard. It seems probable that Forrester acted without authority, and his successor, Forrester, was arrested by the Dutch in New Amsterdam and sent to Holland before he could confirm the transfer. In 1644 the Commissioners of the United Colonies, apparently at the request of the inhabitants of Martha’s Vineyard, annexed that territory, including Martha’s Vineyard. In 1671 Governor Francis Lovelace, of New York, appointed Mayhew governor for life of Martha's Vineyard; in 1683, the island, with Nantucket, the Elizabeth Islands, No Man’s Land, and Chappaquiddick Island were erected into Dukes county, and in 1605 the county was transferred to New York. Nantucket by order of the Massachusetts General Court. Under the new charter of Massachusetts Bay (1601), after some dispute between Massachusetts and New York, Martha’s Vineyard became a part of Massachusetts.

There is a tradition that the first settlement of Martha’s Vineyard was made in 1632, at or near the present site of Edgartown village, by several English families forming part of a company bound for Virginia, their ship having put in at this harbour on account of heavy weather. It is certain, however, that in 1642, the year after Thomas Mayhew bought the island, his son, also named Thomas Mayhew, and other persons established a plantation on the site of what is now Edgartown village. This settlement was at first called “Great Harbor,” but soon after Mayhew was appointed governor of the island it was named Edgartown, probably in honour of the only surviving son of the Duke of York. The younger Mayhew, soon after removing to Martha’s Vineyard, devoted himself to missionary work among the Indians, his work beginning at about the same time as that of John Eliot; he was lost at sea in 1657 while on his way to secure financial assistance in England, and his work was continued successfully by his father. 2 The township of Edgartown was incorporated in 1671, and is the county-seat of Dukes county. In 1783 several Edgartown families joined the association made up of Martha’s Vineyard, Nantucket, Providence and Newport whalers, who founded Hudson, on the Hudson river, in Columbia county, New York. Oak Bluffs had its origin as a settlement in the camp meetings, which were begun here in 1835, and by 1860 had grown to large proportions. As the village expanded

3

Mayhew was born at Tisbury, Wiltshire, was a merchant in Southampton, emigrated to Massachusetts about 1633, settled at Watertown, Mass., in 1635; was a member of the Massachusetts General Court in 1636–1644, and after 1644 or 1645 lived on Martha’s Vineyard.

4 It appears from a letter from Mayhew to Governor Andros in 1675 that about 1641 Mayhew obtained a conveyance to Martha’s Vineyard from Richard Vines, agent of Gorges. See F. B. Hough, Papers Relating to the Island of Nantucket, with Documents Relating to the Original Settlement of that Island, Martha’s Vineyard, etc. (Albany, N. Y., 1886).

5 In 1691, a boulder memorial was erected to the younger Mayhew on this “West Tisbury road, between the village of that name and Edgartown, marking the spot where the missionary had farewell with several hundred Indians. The Martha’s Vineyard Indians were subject to the Wampanoag tribe, on the mainland, were exposed watermen, and were much more numerous when the whites first came. Nearly all of them were converted to Christianity by the Mayhews, and they were friendly to the settlers during King Philip’s war. By 1675 the island had been large and prosperous, about 1764 to about 300. Soon after this they began to intermarry with negroes, and now only faint traces of them remain.

6 It took the name of Cottage City. In 1880 the township was incorporated under that name, which it retained until January 1907, when the name (and that of the village also) was changed to Oak Bluffs. Tisbury township was bought from the Indians in 1669 and was incorporated in 1671. Its principal village, Vineyard Haven, was called “Holmes’s Hole” (in honour of one of the early settlers) until 1871, when the present name was adopted. West Tisbury township was set off from Tisbury, and incorporated in 1892. Chilmark township was incorporated in 1894. Gay Head township was set off from Chilmark, and incorporated in 1870.

received in Spain in the first century of the empire. The success of his countrymen may have been the motive which induced Martial to remove to Rome when he had completed his education. This he did in A.D. 64, one year before the fall of Seneca and Lucan, who were probably his earliest patrons.

Of the details of his life for the first twenty years or so after he came to Rome we do not know much. He published some juvenile poems of which he thought very little in his maturing years, and he laughs at a foolish bookseller who would not allow them to die a natural death (i. 113). Martial had neither youthful passion nor youthful enthusiasm to make him preco- cent till he was past forty. His auctórum in a glass with published knowledge of that social life which was both his theme and his inspiration; and many of his best epigrams are among those written in his last years. From many answers which he makes to the remonstrances of friends—among others to those of Quintilian—it may be inferred that he was urged to practice at the bar, but that he preferred his own lazy Bohemian kind of life. He made many influential friends and patrons, and secured the favour both of Titus and Domitian. From them he obtained various privileges, among others the semestris triumphalis, or one which was repeated every other year, but on the whole he appears to have overlooked the importance of his privileges. In any case, however, in his application to the latter for more substantial advantages, although he commemorates the glory of having been invited to dinner by him, and also the fact that he procured the privilege of citizenship for many persons in whose behalf he appealed to him. The earliest of his extant works, that known by the name of Liber spectaculorum, was first published at the opening of the Colosseum in the reign of Titus, and relates to the theatrical performances given by him; but the book as it now stands was given to the world in or about the first year of Domitian, i.e. about A.D. 87. The favour of the emperor procured him the countenance of some of the worst creatures at the imperial court—among them of the notorious Crispinus, and probably of Paris, the supposed author of Juvenal's exile, for whose monument Martial afterwards wrote a eulogistic epitaph. The two books, numbered by editors xiii. and xiv., and known by the names of Xenia and Apophoresa—inscriptions in two lines each for presents,—were published at the Saturnalia of 84. In 86 he gave to the world the first two of the twelve books on which his reputation rests. From that time till his death, which occurred in the last year of his life, or in A.D. 103, Martial published a new book almost every year. The first nine books and the first edition of book x. appeared in the reign of Domitian; and book xi. at the end of A.D. 66, shortly after the accession of Nerva. A revised edition of book x., that which we now possess, appeared in A.D. 98, about the time of the entrance of Trajan into Rome. The last book was written after three years' absence in Spain, shortly before his death, which happened about the year A.D. 102 or 103.

These twelve books bring Martial's ordinary mode of life between the age of five-and-forty and sixty very fully before us. His regular home for five-and-thirty years was Rome. He lived at first up three pairs of stairs, and his "garret" overlooked the laurels in front of the portico of Agrippa. He had a small villa and unproductive farm near Nomentum, in the Sabine territory, to which he occasionally retired from the bores and noises of the city (ii. 38, xii. 57). In his later years he had also a small house on the Quirinal, near the temple of Quirinus. At the time when his third book was brought out he had retired for a short time to Cisalpine Gaul, in weariness, as he tells us, of his unremunerative attendance on the levees of the great. For a time he seems to have felt the charm of the new scenes which he visited, and in a later book (iv. 25) he contemplates the prospect of retiring to the neighbourhood of Aquileia and the Timavus. But the spell exercised over him by Rome and Roman society was too great; even the epigrams sent from Forum Cornelii and the Aemilian Way ring much more of the Roman forum, and of the streets, baths, porticos and clubs of Rome, than of the places from which they are dated. So too his motive for his final departure from Rome in A.D. 98 was a weariness of the burdens imposed on him by his social position, and apparently the difficulties of meeting the ordinary expenses of living in the metropolis (x. 96); and he looks forward to a return to the scenes familiar to his youth. The well-known epigram addressed to Juvenal (xii. 48) shows that for a time his ideal was realized; but the more trustworthy evidence of the prose epistle prefixed to book xii. proves that his con- tentment was of short duration, and that he could not live happily away from the literary and social pleasures of Rome. The one consolation of his exile was the society of a lady, Mar- cella, of whom he writes rather as if she were his patroness—and it seems to have been a necessity of his being to have always a woman in his society, and to purchase her with flattery and admiration.

During his life at Rome, although he never rose to a position of real independence, and had always a hard struggle with poverty, he seems to have known everybody, especially every one of any eminence at the bar or in literature. In addition to Lucan and Quintilian, he numbered among his friends or more intimate acquaintances Silius Italicus, Juvenal, the younger Pliny; and there were many others of high position whose society and patronage he enjoyed. The silence which he and Statius, although authors writing at the same time, have maintained towards some of the same subjects, maintains in regard to one another more than any other explanation but mutual dislike or want of sympathy. Martial in many places shows an undignified contempt for the artificial kind of epic on which Statius's reputation chiefly rests; and it seems quite natural that the respectable author of the Thebaid and the Silvae should feel little admiration for either the life or the works of the Bohemian epigrammatist.

Martial's faults are of the most glaring kind, and are exhibited without the least concealment. Living under perhaps the worst of the many bad emperors who ruled the world in the 1st century, he addresses him and his favourites with the most servile flattery in his lifetime, censures him immediately after his death (xii. 6), and offers incense at the shrine of his successor. He is not ashamed to be dependent on his wealthy friends and patrons for gifts of money, for his dinner, and even for his dress. We cannot feel sure that even what seem his sincerest tributes of regard may not be prompted by the hope of payment. Further, there are in every book epigrams which cannot be read with any other feelings than those of extreme distaste.

It is unnecessary to say that many have formed their whole estimate of Martial from them, and have declined to make any further acquaintance with him. Even those who greatly admire his genius, and find the freshest interest in his representation of Roman life and his sketches of manners and character, do not attempt to palliate his faults, though they may partially account for them by reference to the morals of his age and the circumstances of his life. The age was one when literature had either to be silent or to be servile. Martial was essentially a man of letters: he was bound either to gain favour by his writings or to starve. Even Statius, whose writings are in other respects irreproachable, is nearly as fulsome in his adulation. The relation of client to patron had been recognized as an honourable one by the best Roman traditions. No blame had attached to Virgil or Horace on account of the favours which they received from Augustus and Maecenas, or of the return which they made for these favours in their verse. That old honourable relationship had, however, greatly changed between Augustus and Domitian. Men of good birth and education, and sometimes even of high official position (Juven. i. 117), accepted the dole (sporgho). Martial was merely following a general fashion in paying his court to "a lord," and he made the best of the custom. In his earlier career he used to accompany his patrons to their villas at Baiae or Tibur, and to attend their morning levees. Later on he went to his own small country house, near Nomentum, and sent a poem, or a small volume of his poems, as his representative at the early visit. The fault of grossness Martial shares with nearly all ancient and many modern writers who treat of life from the baser or more ridiculous side. That he offends more than perhaps any of them is not, apparently, to be explained on
MARTIALIS—MLRTAL LAW

The ground that he had to amuse a peculiarly corrupt public. Although there is the most cynical effrontery and want of self-respect in Martial's use of language, there is not much trace of the satyr in him—much less, many readers will think, than in Juvenal.

It remains to ask, What were those qualities of nature and intellect which enable us to read his best work—even the great bulk of his work—with the freshest sense of pleasure in the present day? He had the keenest capacity for enjoyment, the keenest curiosity and power of observation. He had also a very just discernment. It is rare to find any one endowed with so quick a perception of the ridiculous who is so little of a caricaturist. He was himself singularly free from cant, pedantry or affectation of any kind. Though tolerant of much vices, he had a hearty scorn of hypocrisy. There are few better satirists of social and literary pretenders in ancient or modern times. Living in a very artificial age, he was quite natural, hating pomp and show, and desiring to secure in life only what really gave him pleasure. To live one's own life heartily from day to day without looking before or after, and to be one's self without trying to be that for which nature did not intend him, is the sum of his philosophy. Further, while tolerant of much that is bad and base—the characters of Crispinus and Regulus, for instance—he shows himself genuinely grateful for kindliness and appreciative of excellence. He has no bitterness, malice or envy in his composition. He professes to his own personal satisfaction that, though he is the character he claims for it, Pliny, in the short tribute which he pays to him on hearing of his death, says, "He had as much good-nature as wit and pungency in his writings" (Ep. iii. 21).

Honour and sincerity (fides and simplicitas) are the qualities which he most admires in his friends. Though many of his epigrams indicate a cynical disbelief in the character of women, yet others prove that he could respect and almost reverence a refined and courteous lady. His own life in Rome afforded him an example of domestic virtue; but his epigrams show that, even in the age which is known to the world, Menander was chiefly from the Satires of Juvenal, virtue was recognized as the purest source of happiness. The tenderest element in Martial's nature seems, however, to have been his affection for children and for his dependents.

The permanent literary interest of Martial's epigrams arises not so much from their verbal brilliancy, though in this they are unsurpassed, as from the amount of human life and character which they contain. He, better than any other writer, enables us to revive the outward spectacle of the imperial Rome. If Juvenal enforces the lesson of that time, and has penetrated more deeply into the heart of society, Martial has sketched its external aspect with a much fairer pencil and from a much more intimate contact with it. Martial was to Rome in the decay of its ancient virtue and patriotism what Menander was to Athens in its decline. They were both men of cosmopolitan rather than of a national type, and had a closer affinity to the life of Paris or London in the 18th century than to that of Rome in the days of the Scipios or of Athens in the age of Pericles. The form of epigram was fitted to the critical temper of Rome as the comedy of manners was fitted to the dramatic genius of Greece. Martial professes to be of the school of Catullus, Peso, and Marsus, and admits his inferiority only to the first. But, though he is a poet of a less pure and genuine inspiration he is a greater epigrammatist even than his master. Indeed the epigram bears to this day the form impressed upon it by his unrivalled skill.

AUTHORITIES.—The MSS. of Martial are divided by editors into three families according to the recession of the text which they offer. Of these the oldest and best is represented by three MSS., which contain only selected extracts. The second family is derived from an inferior source, a MS., which was edited in P. d'Orby Torquatus Gennadinius; it comprises four MSS., and contains the whole of the text. The third family, of which the MSS. are very numerous, also contains the whole text in a better state. It is, in fact, that of the other two; the best representative of this family is the MS. preserved in the Advocates' Library at Edinburgh.

The best separate edition of the text is that of Lindsay (Oxford, 1902); earlier editions of importance are those of Schneidewin (Leipzig, 1863), which is rare by the critical improvements of his commentary is that of L. Friedländer (Leipzig, 1886) in two volumes with German notes) and in the same scholar's Sittegeschichte Rom (1890) will be found that Elphinston (Edinburgh, 1782) is famous for its accuracy, which drew an epigram from Burns. (W. Y. S.)

MARTIALIS, QUINTUS GARGILIS, a Latin writer on horticultural subjects. He has been identified by some with the military commander of the same name, mentioned in a Latin inscription of A.D. 266 (C. I. L. viii. 9947) as having been life in the province of Asia (Asiæ) in Mauretania Caesariensis. Considerable fragments of his work (now called De Hortis), which treated of the cultivation of trees and vegetables, and also of their medicinal properties, have survived, chiefly in the body of and as an appendix to the Medicina Plinii (an anonymous 4th century handbook of medical recipes based upon Pliny, Nat. Hist. xxi.-xxii.). Extant sections treat of apples, peaches, quinces, almonds and chestnuts. Gargilus also wrote a treatise on the tending of cattle (De curis boarum), and a biography of the emperor Alexander Severus is attributed to him. Two of the Scipios historiae Augustae (Aelius Lampridius and Flavious Vellutus) to a Gargilus Martialis, who may be the same person.

BIBLIOGRAPHY.—Gargilus Martialis . . . fragmenta, ed. A. Mai (1846); Plinii secundi quae fertur medicina, ed. V. Rose (1876); De curis boarum, ed. E. Lommatzsch (1903) with Vegetius Renatus's Malomedicina; “Gargilus Martialis und die Medizin,” C. Chichorius in G. Curtius, Leipziger Studien. x. (1887), where the inscription referred to above is fully discussed; see also Teuffel-Schwalbe, Hist. of Roman Literature (Eng. trans.), § 380.

MARTIAL LAW. "Martial law" is an unfortunate term and in a sense a misnomer. It describes a suspension of ordinary law, rendered necessary by circumstances of war or rebellion. The confusion arose from the fact that the martial law, or autocratic military law before the introduction of articles of war, which were in their turn merged in the Army Act. But martial law is not a law in the proper sense of the term. It is the exercise of the will of the military commander, who takes upon himself the responsibility of suspending ordinary law in order to ensure the safety of the state. It is declared, by a proclamation issued by the executive, that martial law is inadequate to cope with the circumstances, and provides exceptional means of arrest and punishment of persons who resist the government or aid the enemy. Martial law is a proclamation, while invariably issued in order to give publicity to the suspension of ordinary law, does not invest the step with the force of law. It is simply military authority exercised in accordance with the laws and usages of war, and is limited by military necessity. Yet in reality it is part of common law which justifies acts done by necessity for the defence of the commonwealth when there is war. H. W. Hallock in his work on International Law (i. 544), says, "Martial law originates either in the prerogative of the crown, as in Great Britain, or from the exigency of the occasion, and is not one of the rights of sovereignty, and is essential to the existence of a state, as is the right to declare or to carry on war." This opinion, however, must be read, as regards the British Empire, with the passage in the Petition of Right which is reproduced in the preamble of each annual Army Act, and asserts the illegality of martial law in time of peace in the following terms:—"No man shall be fore-judged or subjected in time of peace to any kind of punishment within this realm by martial law." The Senate, whilst martial law is declared illegal in time of peace, is indirectly declared lawful in time of war and intestinal commotion when the courts are closed, or when there is no time for their cumbersome action. C. M. Clode, in Military Forces of the Crown, argues that the words of the Petition of Right and of the Military Act since the reign of Anne are plain in this respect "that . . . the crown possesses
MARTIAL LAW

791

the right of issuing commissions in war and rebellion." But he rightly adds that the military commander may permit the usual courts to continue their jurisdiction upon such subjects as he thinks proper. Legislative enactments have also sanctioned this special jurisdiction at various times, notably in 1798, 1799, 1801, and in 1803. These enactments lay down that exceptional powers may be exercised "whether the ordinary courts shall or shall not be open." As an invariable rule an act of indemnity has been passed on the withdrawal of martial law but only to protect any person in charge of the execution of martial law who has exceeded his powers in good faith.

There has been much discussion as to whether, in districts where martial law has not been proclaimed, a person can be sent for trial from such district into a district where martial law was in operation. It is argued that if the ordinary courts were open and at work in the non-proclaimed district recourse should be had to them. The Privy Council in 1792 (re Marais) refused leave to appeal where the Supreme Court of Cape Colony had declined to issue a writ of Habeas Corpus in these circumstances. Mr Justice Blackburn in his charge in R. v. Eyre says, "I have come to the conclusion that, looking at what martial law was, the bringing of a person into the proclaimed district to be tried might, in a proper case, be justified." The learned judge admits that there should be a power of summary trial, observing all the substantials of justice, in order to stamp out an insurrection by speedy trial.

Whilst martial law is the will of the commanders, and is only limited by the customs of war and the discretion of those who administer it, still, as far as practicable, the procedure of military law is followed, and a military court is held on the same lines as a court-martial. Charges are simply framed without technicalities. The prisoner is present, the evidence of prosecution and prisoner is taken on oath, the proceedings are recorded, and the sentence of the court must be confirmed according to the rules of the Army Act. Sentences of death and penal servitude must be referred to headquarters for confirmation. In the South African War (1899-1902) these limits of procedure were observed, and when possible will always be.

Entering more into detail, the term martial law has been employed in several senses:

1. As applied to the military forces of the crown, apart from the military law under the old Mutiny Acts, and the present annual Army Acts.
2. As applied to the enemy.
3. As applied to rebels.
4. As applied to civilian subjects who are not in rebellion, but in a district where the ordinary course of civil life cannot be maintained owing to war or rebellion.

2. "Martial law as applied to the enemy or the population of the enemy country," is in the words of the duke of Wellington, "the will of the general of the army, though it must be administered in accordance with the customs of war." But it is as affecting the subjects of the crown in rebellion that the subject of martial law really obtains its chief importance; and it is in this sense that the term is generally used; i.e. the suspension of ordinary law and the temporary government of the country, or parts of it, or all of it, by military tribunals. It has often been laid down that martial law in this sense is unknown to the law of England. A. V. Dicey, for instance, restricts martial law to a narrower expression for "the common right of the crown and its servants to repel force by force, in the case of invasion, insurrection, or riot, or generally of any violent resistance." But more than this is understood by the term martial law.

When the proposition was laid down that martial law in this sense is unknown to the law of England, it is to be remembered that fortunately in England there never had been a state at all similar to that prevailing in Cape Colony in 1900-1902. and it may perhaps be questioned whether the statement would have been made with such certainty if similar events had been present to the writers' minds.

In the charge delivered by Mr Justice Blackburn in the Jamaica case the law as affecting the general question of martial law was set out: "By the laws of this country," said Mr Justice Blackburn, "beginning at Magna Carta and getting more and more established, down to the time of the Revolution, when it was finally and completely established, a rebel who had been tried, convicted, and sentenced to death, could never be tried or punished except by due course of law; all crimes are to be determined by juries subject to the guidance of the judge; that is the general rule, and is established law. But from the earliest times there was this also which was the law and is the law still, that when there was a foreign invasion or an insurrection, it was the duty of every good subject, in obedience to the officers and magistrates, to resist the rebels, ... in such a case as that of insurrection prevailing so far that the courts of law cannot sit, there must really be anarchy unless there is some power to keep the people in order, before that principle the crown claimed the prerogative to exercise this power which has been continued and the proceedings by which it is exercised have been described. Whenever a disturbance was going on, other than the army. And further than that, the crown made this further claim against the insurgents, that whilst it existed, pending the insurrection and for a short time after its stoppage, the crown was entitled to act in the sense of using summary proceedings, to punish the insurgents and to check and stop the spread of the rebellion by summary proceedings against the insurgents, as was done to put out the rebellion. Now no doubt the extent to which the crown had power to do that has never been yet decided. Our law has been declared from time to time and has always been a practical science, that is, the judges have decided so much as was necessary for the particular case, and that has become part of the law. But it never has come to be decided what this precise power is."

So far as the United Kingdom is concerned the need has never arisen. It has always been found possible to employ the ordinary courts directly the rebels have been defeated in the field and have been made prisoners or surrendered. Fortunately in England only three occasions have arisen since the Revolution when the authority of the civil power was for a time, and then only partially, suspended," 1715, 1745 and 1780. Clode, Military Forces, i. 163, says: "Upon the threat of invasion followed by rebellion in 1715, the first action of the government was to issue a proclamation authorizing all officers, civil and military, by force of arms (if necessary) to suppress the rebellion." This, therefore, would only seem to fall within the limited sense in which Dicey understands martial law to be, the right of the crown and its servants to repel force by force. There is no need to emplace courts-martial who ought to be tried by the common law, and all the extraordinary acts of the crown were sanctioned by parliament. After the rebellion had been suppressed two statutes were passed, one for indemnity and the other for pardon. Before the revolution of 1745 similar action was adopted, a proclamation charging civil magistrates to do their utmost to prevent and suppress all riots, and acts of parliament suspending Habeas Corpus, providing for speedy trials; and of indemnity. In the Gordon Riots of 1780 a very similar power was pursued, and nothing was done which would not fall within Dicey's limitation. No prisoners were tried by martial law.

In Ireland the ordinary law was suspended in 1798 and 1801. In 1798 an order in Council was issued to all general officers commanding H.M. forces to punish all persons acting in, aiding, or in any way assisting the rebellion, according to martial law, either by death or otherwise, as to them should seem expedient for the suppression and punishment of all rebels; but the order was communicated to the Irish houses of parliament, who expressed their approval by addresses to the majority. It was during the operation of this order that Wolfe Tone's case arose. Tone, a subject of the king, was captured on board a French man-of-war, and condemned to death by a court-martial. Curran, his counsel, applied to the king's
MARTIGNAC—MARTIN (POPES)

MARTIGNAC published Bordeaux au mois de Mars 1815 (Paris, 1830), and an Etude historique sur les foundations d'Espagne et l'intervention française de 1823 (Paris, 1832). See also E. Daudet, Le Ministère de M. de Martignac (Paris, 1873).

MARTIGUES, a port of south-eastern France in the department of Bouches-du-Rhône, on the southern shore of the lagoon of Berre, and at the eastern extremity of that of Caronte, by which the former is connected with the Mediterranean. Pop. (1906), 4,778. Martigues is 23 m. W.N.W. of Marseilles by rail. It is divided into three quarters by canals, the place has been called the Venice of Provence. It is famous for its commerce (chiefly by coasting and fishing vessels), marine workshops, oil and soap manufactures and cool-drying works. A special industry consists in the preparation of bouchargue from the roes of the grey mullet caught in the salt lagoons, which rivals Russian caviare.

Built in 1529 by Raymond Bérenger, count of Provence, Martigues was made a viscountship by Joanna I, queen of Naples. Henry IV. made it a principality, in favour of a princess of the house of Luxembourg. It afterwards passed into the hands of the duke of Villars.

MARTIN, ST (c. 316-400), bishop of Tours, was born of heathen parents at Sabaria (Stein am Agger) in Pannonia, about the year 316. When ten years old he became a catechumen, and at fifteen he reluctantly entered the army. While stationed at Amiens he divided his cloak with a beggar, and on the following night had the vision of Christ making known to his angels this act of charity to Himself on the part of "Martinus, still a catechumen." Soon afterwards he received baptism, and two years later, having left the army, he joined Hilary of Poitiers, who wished to make him a deacon, but at his own request ordained him to the humbler office of an exorcist. On a visit home he converted his mother, but his zeal against the Arians roused persecution against him and for some time he lived an ascetic life on the desert island of Gallinaria near Genoa. Between 360 and 370 he was again with Hilary at Poitiers, and founded in the neighbourhood the monastery locoingense (Lauzon). In 371-372 the people of Tours chose him for their bishop. He did much to extirpate idolatry from his diocese and from France, and to extend the monastic system. To obtain privacy for the maintenance of his personal religion, he established the monastery of Marmoutier-les-Tours (Martini monasterium) on the banks of the Loire. At Trèves, in 385, he entreated that the lives of the Priscillianist heretics should be spared, and he ever afterwards refused to hold ecclesiastical fellowship with those bishops who had sanctioned their execution. He died at Candes in the year 406, and is commemorated on 26 November. Left only a few writings, the so-called Confessio being spurious. He is the patron saint of France and of the cities of Mainz and Würzburg. The Life by his disciple Sulpicius Severus is practically the only source for his biography, but it is full of legendary matter and chronological errors. Gregory of Tours gives a list of 206 miracles wrought by him after his death; Sidonius Apollinaris composed a metrical biography of him. The Feast of St Martin (Martinmas) took the place of an old pagan festival, and inherited some of its usages (such as the Martinsmänner, Martinsschauer, Martinshorn, and the like, in various parts of Germany); by this circumstance is probably to be explained the fact that Martin is regarded as the patron of drinking and jovial meetings, as well as of reformed drunkenards.

See A. Dupuy, Geschichte des heiligen Martins (Schaffhausen, 1855); J. G. Cazenove in Dict. chr. biog. ill. 838.

MARTIN (Martinus), the name of several popes.

Martin I. succeeded Theodore I. in June or July 643. He had previously acted as papal aposciarius at Constantinople, and was held in high repute for learning and virtue. Almost his first official act was to summon a synod (the first Lateran) for dealing with the Monothelite heresy. It met in the Lateran church, was attended by one hundred and five bishops (chiefly from Italy, Sicily and Sardinia, a few being from Africa and other quarters), held five sessions or "secretarii" from the 5th to the 31st of October 649, and in twenty canonis condemned the Monothelite heresy, its authors, and the writings by which
MARTIN, B. L. H.

Martin, B. L. H., was born on the 20th of February 1810 at St Quentin (Aisne), where his father was a judge. Trained as a notary, he followed this profession for some time but having achieved success with an historical romance, Wolfburn (1830), he applied himself to historical research. Becoming associated with Paul Lacroix (see Lacroix, Paul), in the Bibliothèque de la Révolution, a history of France, to consist of excerpts from the chief chroniclers and historians, with original matter filling up gaps in the continuity. The first volume, which appeared in 1833, encouraged the author to make the work his own, and his Histoire de France, in fifteen volumes (1833-1836), was the result. This magnus opus, rewritten and further elaborated (4th ed., 16 vols. and index, 1861-1865) gained for the author in 1856 the first prize of the Academy, and in 1860 the grand biennial prize of 20,000 francs. A popular abridgment in seven volumes was published in 1867. This, together with the continuation, Histoire de France depuis 1789 jusqu'à nos jours (6 vols. 1878-1883), gives a complete history of France, and superseded Sismondi's Histoire des Français.

This work is in parts defective; Martin's descriptions of the Gauls are based rather on romance than on history, and in this respect he was too much under the influence of Jean Reynaud and his cosmogenic philosophy. However he gave a great impetus to Celtic and anthropological studies. His knowledge of the middle ages is inadequate, and his criticisms are not discriminating. As a free-thinking republican, his prejudices often biased his judgment on the political and religious history of the ancien régime. The last six volumes, devoted to the 17th and 18th centuries, are superior to the earlier ones. Martin sat in the assemblée nationale as deputy for Aisne in 1877,
MARTIN, C.—MARTIN, L.

and was elected life senator in 1878, but he left no mark as a politician. He died in Paris on the 14th of December 1882.

MARTIN, CLAUD (1735-1800), French adventurer and officer in the army of the English East India Company, was born at Lyons on the 4th of January 1735, the son of a cooper. He went out to India in 1751 to serve under Dupleix and Lally in the Carnatic wars. When Pondicherry fell in 1761, he seems, like others of his countrymen, to have accepted service in the Bengal army of the English, obtaining an ensign's commission in 1763, and steadily rising to the rank of major-general. He was employed on the building of the new Fort William at Calcutta, and afterwards on the survey of Bengal under Rennell. In 1776 he was allowed to accept the appointment of superintendent of the arsenal of the nawab of Oudh at Lucknow, retaining his rank but being ultimately placed on half pay. He acquired a large fortune, and on his death (Sept. 13, 1800) he bequeathed his residuary estate to found institutions for the education of European children at Lucknow, Calcutta and Lyons, all known by the name of "La Martinière." That at Lucknow is the best known. It was housed in the palace that he had built called Constantia, which, though damaged during the Mutiny, was restored by the government of its founder. See S. C. Hill, The Life of Claud Martin (Calcutta, 1901).

MARTIN, FRANÇOIS XAVIER (1762-1849), American jurist and author, was born in Marseille, France, on the 17th of March 1762, of Provencal descent. In 1780 he went to Martinique, and before the close of the American war of Independence went to North Carolina, where (in New Bern) he taught French and learnt English, and set up as a printer. He studied law, and was admitted to the North Carolina bar in 1789. He published various legal books, and edited Acts of the North Carolina Assembly from 1775 to 1803 (2nd ed., 1809). He was a member of the lower house of the General Assembly in 1806-1807. In 1809 he was commissioned a judge of the superior court of the territory of Mississippi, and in March 1810 became judge of the superior court of the territory of Orleans. Here the law was in a chaotic condition, what with French law before O'Reilly's rule, then a Spanish code, and in 1808 the Digest of the Civil Laws, an adaptation by James Brown and Moreau Lislet of the code of Napoleon, which repealed the Spanish fueros, partidas, recapitulations and laws of the Indies only as they conflicted with its provisions. Martin published in 1811 and 1813 reports of cases decided by the superior court of the territory of Orleans. For two years from 1811 to 1813 Martin was associate judge of the newly established state of Louisiana, and then until March 1816 was a judge and (from 1836 to 1846) presiding judge of the supreme court of the state. For the period until 1830 he published reports of the decisions of the supreme court; and in 1816 he published two volumes, one French and one English, of A General Digest of the Acts of Legislatures of the Late Territory of Orleans and of the State of Louisiana. He won the name of the "father of Louisiana jurisprudence" and his work was of great assistance to Edward Livingston, Pierre Derbigny and Moreau Lislet in the Louisiana codification of 1821-1826. Martin's eyesight had begun to fail when he was seventy, and after 1836 he could no longer write opinions with his own hand.1 He died in New Brunswick on the 11th of December 1846.

Martin translated Robert J. Pothier On Obligations (1802), and wrote The History of Louisiana from the Earliest Period (2 vols. 1827-1829) and The History of North Carolina (2 vols., 1829). There

1 His holograph will in favour of his brother (written in 1844 and devising property worth nearly $400,000) was unsuccessfully contested by the state of Louisiana on the ground that the will was void as being a legal and physical impossibility, or as being an attempted fraud on the state, as under it the state would not receive a cent. The property went to the heirs of Martin (as intestate) in France.
Burr (q.v.) against the charge of treason in 1807. He has been described by the historian Henry Adams, writing of the Chase trial, as at that time the "most formidable of American advocates." Though he received a large income, he was so improvident that he was frequently in want, and on the 22nd of February 1822 the legislature of Maryland passed a remarkable resolution—the only one of the kind in American history—requiring every lawyer in the state to pay an annual licence fee of five dollars, to be handed over to trustees appointed "for the appropriation of the proceeds raised by virtue of this resolution to the use of Luther Martin." This resolution was rescinded on the 6th of February 1823. Martin died at the home of Aaron Burr in New York on the 30th of July 1836. In the same year a daughter of his, Maria Cre仅 (1742-1775), who was unjustly charged by Jefferson, in his Notes on Virginia, with the murder of the family of the Indian chief, John Logan, and whom Martin defended in a pamphlet long out of print.

See the biographical sketch by Henry P. Goddard, Luther Martin, the Federal Bull-Dog (Baltimore, 1887), No. 24 of the "Peabody Fund Publications," of the Maryland Historical Society.

MARTIN, SIR THEODORE (1816-1909), British author and translator, the son of a solicitor, was born at Edinburgh on the 4th of September 1816, and educated at the Royal High School and the University, from which he subsequently received the honorary degree of LL.D. He practised for some time as a solicitor in Edinburgh, but in 1846 went to London, where he became senior partner in the firm of Martin & Leslie, parliamentary agents. He early contributed to Fraser's Magazine and Tait's Magazine, under the signature of "Bon Gaultier," and in 1856, in conjunction with Professor Aytoun, he published the Book of Ballads under the same pseudonym. This work at once obtained popular favour. In 1858 he published a volume of translations of the Poems and Ballads of Goethe, and this was followed by a rendering of the Danish poet Henrik Hertz's lyric drama, King Ren's Daughter. The principal character in this drama, Iolanthe, was sustained by Helena Faucit (q.v.), who in 1851 became the author's wife. Martin's translations of Öhlschläger's dramas, Correggio (1854) and Aladdin, or the Wonderful Lamp (1857), widened the fame of the Danish poet in England. In 1860 appeared Martin's metrical translation of the Odes of Horace; and in 1870 he wrote a volume on Horace for the series of "Ancient Classics for English Readers." In 1882 his Horace labours were concluded by the publication of Odes; a whole works, with a life and notes, in two volumes. A poetical translation of Catullus was published in 1861, followed by a privately printed volume of Poems, Original and Translated, in 1863. The same translations of the Vita Nuova of Dante, and the first part of Goethe's Faust. A metrical translation of the second part of Faust appeared in 1866. Martin wrote a memoir of his friend Aytoun in 1867, and while engaged upon this work he was requested by Queen Victoria, to whom he was introduced by his friend Sir Arthur Helps, to undertake the Life of His Royal Highness the Prince Consort. The first volume of this well-known work was published in 1874. In 1878 Martin's translation of Heine's Poems and Ballads appeared. Two years later the Life of the Prince Consort was brought to a successful conclusion by the publication of the fifth volume. A knighthood was then conferred upon him. In the following November he was elected lord rector of the university of St Andrews. Martin's Life of Lord Lyndhurst, based upon papers furnished by the family, was published in 1883. In 1889 appeared The Song of the Bell, and other Poems and Translations from Schiller, Goethe, Uhland, and Others; in 1891 Martin's translation of Thackeray's English Martyrs; and in 1901 he published a biography of his wife. The kindly relations which subsisted between Queen Victoria and Sir Theodore Martin were continued after the completion of the Life of the prince consort up to the queen's death. Sir Theodore's account of these relations was privately printed in 1902, and, with King Edward's consent, for general publication in 1908. This little book, Queen Victoria as I knew her, throws a good deal of light on the queen's character and private life. Sir Theodore Martin died on the 15th of August 1900.

MARTIN, WILLIAM (1707-1810), English naturalist, the son of a hosier, was born at St Neots, Huntingdonshire, in 1707. He studied drawing at an early age from James Bolton at Halifax, and gained from him a taste for the study of natural history. In 1805 he was appointed drawing master in the grammar school at Macclesfield. Meanwhile he cultivated his taste for natural history, and was in 1796 elected a fellow of the Linnaean Society. He is best known for his early works on British fossils, entitled Petrifacata derbiensis or Figures and Descriptions of Petrifications collected in Derbyshire (1800); and Outlines of an Attempt to establish a Knowledge of Extranous Fossils, in the Trans. Scientific Soc. of Manchester (1809). He died at Macclesfield on the 31st of May 1810.

MARTIN, SIR WILLIAM FANSHawe (1802-1895), British admiral, son of Admiral of the Fleet Sir Thomas Byam Martin, controller of the navy, and grandson, on the mother's side, of Captain Robert Fanshawe, who commanded the "Namur" in Rodney's victory of the 12th of April 1782, was born on the 5th of December 1805. Entering the navy at the age of twelve, his father's interest secured his rapid promotion: he was made a lieutenant on the 15th of December 1820; on the 8th of February 1823 he was promoted to commander of the "Fly" sloops, his good service in the Manches- ter and the Saplings of British merchants at Calhau secured his promotion as captain on the 4th of June 1824. He afterwards served in the Mediterranean and on the home station. In 1849-1852 he was commodore commanding the Channel squadron, and gave evidence of a remarkable aptitude for command. He was made rear-admiral in May 1853, and for the next four years was superintendent of Portsmouth dockyard. He was made vice-admiral in February 1858, and after a year as a lord of the admiralty, was appointed commander-in-chief in the Mediterranean. The next seventeen years the navy was then bad. It was a tradition sprung from the wholesale shipment of goa-birds during the old war, that the men were to be treated without consideration; moreover the ships had been largely filled up with "bounty men" bought into the service with a £10 note without training. Out of this unpromising material Martin formed the fleet which was at that time the ideal of excellence. He had no war service, and, beyond the Italian disturbance of 1860-61, no opportunity for showing diplomatic ability. But his memory lives as that of the reformer of discipline and the originator of a fighting system of seamen. He became an admiral in November 1863, and on the 4th of December succeeded to the baronetcy which had been conferred on his grandfather. His last appointment was the command at Plymouth, 1866-1869, and in 1870 he was put on the retired list. In 1873 the G.C.B. was conferred on him, and in 1875 he was made rear-admiral. He died at Upton Grey, near Winchfield, on the 24th of March 1895. He was twice married, and left, besides daughters, one son, who succeeded to the baronetcy.

MARTIN OF TROPPAU, or MARTYNIE POLE (d. 1278), chronicler, was born at Troppau, and entered the order of St Dominie at Prague. Afterwards he went to Rome and became papal chaplain under Clement IV. and other popes. In 1278 Pope Nicholas III. appointed him archbishop of Gnesen, but he died at Bologna whilst proceeding to Poland to take up his new duties. Martin wrote some sermons and some commentaries on the canon law; but more important is his Chronicon pontificum et imperatorum, a history of the popes and emperors to 1277. Written at the request of Clement IV. the Chronicon is jejune and untrustworthy, and was mainly responsible for the currency of the legend of Pope Joan, and the only author of the institution of seven electors by the pope. Nevertheless it enjoyed an extraordinary popularity and found many continuators; but its value to students arises solely from the fact that it was used by numerous chroniclers during the 14th, 15th and 16th centuries. In the 15th century it was translated into French, and as part of the Chronique martinsienne was often quoted by controversialists. It has also been translated into German, Italian and Bohemian.

**MARTIN** (Fr. *Martin*), the *Hirundo urbica* of Linnaeus and *Chelidon urbica* of modern ornithologists, a bird well known throughout Europe, including even Lapland, where it is abundant, retiring in winter to the south of Africa. It also inhabits the western part of Asia, and appears from time to time in large flocks in India. The martin (or house-martin, as it is often called, to distinguish it from the sand-martin) commonly reaches its summer quarters a few days later than the *Swallow* (p. 5), with which it is often confused in spite of the differences between them, the martins' white rump and lower parts being conspicuous as it flies or clings to its nest attached to houses. This nest, made of the same material as the swallow's, is, however, a more difficult structure to rear, and a week or more is often occupied in laying its foundations—the builders clinging to the wall while depositing the mud of which it is composed. The base once fixed, the superstructure is often quickly added, till the whole takes the shape of the half or quarter of a hemisphere, and is finished with a lining of feathers mixed with a few bents or straws. The martin builds soon after its return, and a nest that has outlasted the winter is almost at once re-occupied. The bird usually in the course of the summer raises a second, or rarely a third, brood of offspring—though the latest broods often die in the nest, apparently through failure of food. What seem to be adults are observed in England every year so late as November, and sometimes within a few days of the winter solstice, but these late birds are almost certainly strangers.

The sand-martin, *Hirundo riparia* of Linnaeus and *Cotile riparia* of modern writers, differs much in appearance and habits from the former. Its smaller size, mouse-coloured upper surface and jerking flight distinguish it from the other British *Hirundo dividens*; but it is seldom discriminated, and, being the first of the family to return to its northern home, the so-called "early swallow" is nearly always of this species. Instead of the clay-built nest of the house-martin, this bird bores horizontal galleries in an escarpment. When beginning its excavation, it clings to the face of the bank, and with its bill loosens the earth, working from the centre outwards, and often hanging head downwards. The tunnel may extend to 4, 6, or even 9 ft. The gallery seems intended to be straight, but inequalities of the ground, and especially the meeting with stones, often causes it to take a sinuous course. At the end is formed a nest lined with a few grass-stalks and feathers. The sand-martin has several broods in the year, and is much more abundant in other parts of Europe. In its departure for the south, the kind of soil needed for its nesting habits makes it somewhat local, but no species of the order *Passeres* has a geographical range that can compare with this. In Europe it is found nearly to the North Cape, and thence to the Sea of Okhotsk. In winter it visits many parts of India and South Africa to the Transvaal. In America its range extends (having due regard to the season) from Melville Island to Caicara in Brazil, and from Newfoundland to Alaska.

The American *Phragmites nigricans* is a favourite in Canada and the United States. Naturally breeding in hollow trees, it readily adapts itself to the nest-boxes which are commonly set up for it; but its numbers are in some years and places diminished in a manner unexplained. The limits of its range in winter are not determined, chiefly owing to the differences of opinion as to the validity of certain supposed kindred species found in South America; but according to some authorities it reaches the border of Patagonia, while in summer it is known to inhabit lands within the Arctic Circle. The male is almost

1 The older English form, martlet (French, *Marlette*), is, except in heralds' language, almost obsolete, and when used is now applied in some cases to a regular than a small martlet (p. 5). The bird called martin by French colonists in the Old World is a myna (*Acridotheres*). (See Grackle.)

wholly of a glossy steel-blue, while the female is duller in colour above, and beneath of a brownish-grey.

Birds that may be called martins occur almost all over the world except in New Zealand, which is not regularly inhabited by any member of the family. The ordinary martin of Australia is the *Petrochelidon nigricans* of most ornithologists, and another and more beautiful form is the ariel or fairy-martin of the same country, *Petrochelidon ariel*. This last builds a bottle-shaped nest of mud, as does also the rock-martins of Europe, *Coltie reepics*. The eggs of martins are from four to seven in number, and generally white, while those of swallows usually have brown, grey or lilac markings. (A. N.)

**MARTINEAU, HARRYET** (1802-1876), English writer, was born at Norwich, where her father was a manufacturer, on the 12th of June 1802. The family was of Huguenot extraction (see Martin, *James*) and professed Unitarian views. The atmosphere of her home was industrious, intellectual and austere; she herself was clever, but weakly and unhappy; she had no sense of taste or smell, and moreover early grew deaf. At the age of fifteen the state of her health and nerves led to a prolonged visit to her father's sister, Mrs Kentish, who kept a school at Bristol. Here, in the companionship of amiable and talented people, her life became happier. Here, also, she fell under the influence of the Unitarian minister, Dr Lant Carpenter, from whose instructions, she says, she derived "an abominable spiritual rigidity and a truly respectable force of conscience strangely mingled together." From 1819 to 1830 she again resided chiefly at Norwich. About her twentieth year her deafness became confirmed. In 1821 she began to write anonymously for the *Monthly Repository*, a Unitarian periodical, and in 1823 she published *Devotional Exercises and Addresses, Prayers and Hymns*. In 1826 her father died, leaving a bare maintenance to his wife and daughters. His death had been preceded by that of his eldest son, and was shortly followed by that of a man to whom Harriet was engaged. Mrs Martineau and her daughters soon after lost all their means by the failure of the house where their money was placed. Harriet had to earn her living, and, being precluded by deafness from teaching, took up authorship in earnest. Besides reviewing for the *Repository* she wrote stories (afterwards collected as *Traditions of Palestine*), gained in one year (1830) three essay-prizes of the Unitarian Association, and eked out her income by needlework. In 1831 she was seeking a publisher for a series of tales designed as *Illustrations of Political Economy*. After many failures she accepted disadvantageous terms from Charles Fox, to whom she was introduced by his brother, the editor of the *Repository*. The sale of the first of the series was immediate and enormous, the demand increased with each new number, and from that time her literary success was secured. In 1832 she moved to London, where she numbered among her acquaintances such men as Malthus, Monckton Milnes, Sydney Smith, Bulwer, and later Carlyle. Till 1834 she continued to be occupied with her political economy series and with a supplemental series of *Illustrations of Taxation*. Four stories dealing with the poor-law came out about the same time. These tales, direct, lucid, written without any appearance of effort, and yet practically effective, display the characteristics of their author's style. In 1834, when the series was complete, Miss Martineau paid a long visit to America. Here her open adhesion to the Abolitionist party, then small and very unpopular, gave great offence, which was deepened by the publication, soon after her return, of *Society in America* (1837) and a *Retrospect of Western Travel* (1838). An article in the *Westminster Review*, "The Martyr Age of the United States," introduced English readers to the struggles of the Abolitionists. The American books were followed by a novel, *Deerbrook* (1839)—a story of middle-class country life. To the same period belong a few little handbooks, forming parts of a *Guide to Service*. The veracity of her *Maid of All Work* led to a widespread belief, which she dispelled with some complacency, that she had once been a maid of all work herself.

In 1839, during a visit to the Continent, Miss Martineau's health broke down. She retired to solitary lodgings in Tyne-

MARTINEAU, JAMES (1805-1900), English philosopher and divine, was born at Norwich on the 21st of April 1805, the seventh child of Thomas Martineau and Elizabeth Rankin, the sixth, his senior by almost three years, being his sister Harriet (see above). He was descended from Gaston Martineau, a Hugenot surgeon and refugee, who married in 1693 Marie Pierre, an Amsterdam merchant, and settled soon afterwards in Norwich. His son and grandson—respectively the great-grandfather and grandfather of James Martineau—were surgeons in the same city, while his father was a manufacturer and merchant. James was educated at Norwich Grammar School under Edward Valpy, as good a scholar as his better-known brother Richard. But the boy proving too sensitive for the life of a public day school, was sent to Bristol to the private academy of Dr Lant Carpenter, under whom he studied for two years. On leaving he was apprenticed to a civil engineer at Derby, where he acquired "a store of exclusively scientific ideas," but also experienced the hunger of mind which forced him to look to religion for satisfaction. Hence came his "conversion," and the sense of vocation for the ministry which impelled him in 1822 to enter Manchester College, then lodged at York. Here he "woke up to the interest of moral and metaphysical speculations." Of his teachers, one, the Rev. Charles Wellbeloved, was, Martineau said, "a master of the true Lardner type, candid and catholic, simple and thorough, humanly fond indeed of the counsels of peace, but piously serving every bidding of sacred truth." "He never justified a prejudice; he could not be wrong in the admiration he never hurt an innocent feeling or overbore a serious judgment; and he set up within us a standard of Christian scholarship to which it must ever extol us to aspire." The other, the Rev. John Kenrick, he described as a man so learned as to be placed by Dean Stanley "in the same line with Blomfield and Thirlwall," and as "so far above the level of either vanity or dogmatism, that cynicism itself could not think of them in his presence."

On leaving the college in 1827 Martineau returned to Bristol to teach in the school of Lant Carpenter, in the following year was ordained for a Unitarian church in Dublin, whose senior minister was a relative of his own. But his career there was in 1832 suddenly cut short by difficulties growing out of the "regium donum," which had on the death of the senior minister fallen to him. He conceived it as "a religious monopoly" to which "the nation at large contributes," while "Presbyterians alone receive," and which placed him in a "relation to the state" so "seriously objectionable" as to be "impossible to hold." The invidious distinction it drew between Presbyterians on the one hand, and Catholics, Friends, freethinking Christians, unbelievers and Jews on the other, who were compelled to support a ministry they "conscienciously disapproved," offended his always delicate conscience; while possibly the intellectual and ecclesiastical atmosphere of the city proved uncongenial to his liberal magnanimity. From Dublin he was called to Liverpool, and there for a quarter of a century he exercised extraordinary influence as a preacher, and achieved a high reputation as a writer in religious philosophy. In 1840 he was appointed professor of mental and moral philosophy and political economy in Manchester New College, the seminary in which he had himself been educated, and which had now removed from York to the city after which it was named. This position he held for forty-five years. In 1853 the college removed to London, and four years later he followed it thither. In 1858 he was called to

Martineau's "Letter to the Dissenting Congregation of Eustace Street" (Dublin).

mouth, and remained an invalid till 1844. Besides a novel, The Hour and the Man (1840), Life in the Sickroom (1844), and the Playfellow (1841), she published a series of tales for children containing some of her most popular works: Settlers at Home, The Peasant and the Prince, Feats on the Fiord, &c. During this illness she for a second time declined a pension on the civil list, fearing to compromise her political independence. Her letter on the subject was published, and some of her friends raised a small annuity for her soon after.

In 1844 Miss Martineau underwent a course of mesmerism, and in a few months was restored to health. She eventually published an account of her case, which had caused much discussion, in sixteen Letters on Mesmerism. On her recovery she built herself "The Knoll," the house in which the greater part of her after life was spent. In 1845 she published three volumes of Forest and Game Law Tales. In 1846 she made a tour with some friends in Egypt, Palestine and Syria, and on her return published Eastern Life, Present and Past (1848). This work showed that as humanity passed through one another of the world's historic religions, the conception of the Deity and of Divine government became at each step more and more abstract and indefinite. The ultimate goal Miss Martineau believed to be philosophic atheism, but this belief she did not express explicitly declare. She published about this time Household Education, expounding the theory that freedom and rationality, rather than command and obedience, are the most effectual instruments of education. Her interest in schemes of instruction led her to start a series of lectures, addressed at first to the school children of Ambleside, but afterwards extended, at their own desire, to their elders. The subjects were sanitary principles and practice, the histories of England and North America, and the scenes of her Eastern travels. At the request of Charles Knight she wrote, in 1851, The History of the Thirty Years' Peace, 1616-1646, an excellent popular history written from the point of view of a "philosophical Radical," completed in twelve months.

In 1851 Miss Martineau edited a volume of Letters on the Laws of Man's Nature and Development. Its form is that of a correspondence between herself and H. G. Atkinson, and it expounds that doctrine of philosophical atheism to which Miss Martineau in Eastern Life had depicted the course of human belief as tending. The existence of a first cause is not denied, but it declared to be unknown, and the authors, while regarded by others as denying it, certainly considered themselves to be affirming the doctrine of man's moral obligation. Atkinson was a zealous exponent of mesmerism, and the prominence given to the topics of mesmerism and clairvoyance heightened the general disapprobation of the book, which caused a lasting division between Miss Martineau and some of her friends.

She published a condensed English version of the Philosophie Positive (1853). To the Daily News she contributed regularly from 1854 to 1866. Her Letters from Ireland, written during a visit to that country in the summer of 1854, appeared in that paper. She was for many years a contributor to the Westminster Review, and was one of the little band of supporters whose pecuniary assistance in 1854 prevented its extinction or forced sale. In the early part of 1855 Miss Martineau found herself suffering from heart disease. She now began to write her autobiography, but her life, which she supposed to be so near its close, was prolonged for twenty years. She died at "The Knoll" on the 27th of June 1875.

She cultivated a tiny farm at Ambleside with success, and her poorer neighbours owed much to her. Her busy life bears the constant impress of two leading characteristics—industry and sincerity. The verdict which she records on herself in the autobiographical sketch left to be published by the Daily News has been endorsed by posterity. She says—"Her original power was nothing more than was due to earnestness and intellectual clearness within a certain range. With small imaginative and suggestive powers, and therefore nothing approaching to genius, she could see clearly what she did see, and give a clear expression to what she had to say. In short, she could popularize while she could neither discover nor invent." Her judgment on large questions was clear and sound, and was always the judgment of a mind naturally progressive and Protestant.

occupy the pulpit of Little Portland Street chapel in London, which he did at first for two years in conjunction with the Rev. J. J. Taylor, who was also his colleague in the college, and then for twelve years alone. In 1866 the chair of the philosophy of mind and logic in University College, London, fell vacant, and Martineau became a candidate. But potent opposition was offered to the appointment of a minister of religion, and the chair went to George Croom Robertson—then an untutored man—between whom and Martineau a cordial friendship came to exist. In 1885 he retired, full of years and honours from the principalship of the college he had so long served and adorned. Martineau, who was in his youth denied the benefit of a university education, yet in his age found famous universities eager to confer upon him their highest distinctions. He was made L.L.D. of Harvard in 1872, S.T.D. of Leiden in 1874, D.D. of Edinburgh in 1884, D.C.L. of Oxford in 1888 and D.Litt. of Dublin in 1891. He died in London on the 11th of January 1900.

The life of Martineau was so essentially the life of the thinker, and so typical of the century in which he lived and the society within which he moved, that he can be better understood through his spoken mind than through his outward history. He was a man happy in his ancestry; he inherited the dignity, the reserve, the keen and vivid intellect, and the picturesque imagination of the French Huguenot, though they came to him chastened and purified by generations of Puritan discipline exercised under the gravest ecclesiastical disabilities, and of culture maintained in the face of exclusion from academic privileges. He had the sweet and patient temper which knew how to live, unrepining and unsoured, in the midst of the most watchful persecution, public and private; and it is wonderful how rarely he used his splendid rhetoric for the purposes of invective against the spirit and policy from which he must have suffered deeply while, it may be added, he never hid an innuendo under a metaphor or a trope. He was fundamentally too much a man of strong convictions to be correctly described as open-minded, for if nature ever determined any man's faith, it was his; the root of his whole intellectual life, which was too deep to be disturbed by any superficial change in his philosophy, being the feeling for God. He has, indeed, described in graphic terms the greatest of the more superficial changes he underwent; how he had "carried into logical and ethical problems the maxims and postulates of physical knowledge," and had moved within the narrow lines drawn by the philosophical instructions of the class-room, "interpreting human phenomena by the analogy of external nature"; how he served in willing captivity the "empirical and 'necessary' mode of thought," even though "shocked" by the dogmatism and acid humours of "certain distinguished representatives"; and how in a period of "second education" at Berlin, "under the admirable guidance of Hottinger and Trendelenburg," he experienced "a new intellectual birth" which, "was essentially the gift of fresh conceptions, the unsealing of hidden openings of self-consciousness, with unmeasured corridors and sacred halls behind; and, once gained, was more or less available throughout the history of philosophy, and lifted the darkness from the pages of Kant and even Hegel." But though this momentous change of view illuminated his old beliefs and helped him to re-interpret and re-articulate them, yet it made him no more of a thief than he had been before. And as his theism was, so was his religion and his philosophy. Certainly it was true of him, in a far higher degree than of John Henry Newman, that the being of God and himself were to his mind two absolutely self-luminous truths—though both his God and his self were almost infinitely remote from Newman's. And as these truths were self-evident, so the religion he deduced from them was, not only for his own moral and intellectual nature, but also for man as he conceived him, for history as he knew it, and for society as he saw it.

We may, alternatively, describe Martineau's religion as his applied philosophy or his philosophy as his explicated religion, and both as the expression of his singularly fine ethical and reverent nature. But to understand these in their mutual and explanatory relations it will be necessary to exhibit the conditions under which his philosophy found new into his religion, and the way in which it made him in his early life a preacher more emphatically than a teacher. In all he said and all he thought he had the preacher's eye and ear. He was not a writer, orator or speaker to multitudes. He addressed a comparatively small, but at times a skilled and critical audience, a congregation of thoughtful and devout men, who cultivated reverence and loved religion all the more that their own beliefs were limited to the great truths of self and self-interest. He was, with the majority of his contemporaries, disposed to induce the majority of these truths to be the greater that they so represented to him not only the most fundamental of human beliefs, but also all that a man might reasonably be expected to believe, though to believe with his whole reason and spirit, not according to the bent of his temperament, to him mere speculative ideas, but rather the ultimate realities of being and thought, the final truths as to the character and ways of God, the world, the last end of human existence, and the regulation of life. And so he became a positive religious teacher by virtue of the very ideas that made the words of the Hebrew prophets so potent and sublime. But he did more than interpret to his age the significance of man's ultimate telic beliefs; he gave them vitality by reading them through the consciousness of Jesus Christ. His religion was what he conceived the personal religion of Jesus to have been; and He was to him more a person to be imitated than an authority to be obeyed, rather an ideal to be revered than a being to be worshipped.

Martineau's mental qualities fitted him to fulfill these high interpretative functions. He was a great reader, a great thinker, with personal being and ethical qualities the most abstruse notions. To him space became a mode of divine activity, alive with the presence and activity of the Divine Essence; there was an arena where the divine hand guided and the divine will revealed itself. He did not believe in the Incarnation, yet he held deity to be in a sense manifest in humanity; its saints and heroes became, in spite of independent and great spirits of the day, a form of divine apotheosis, and all life was touched with the dignity and the grace which it owed to its source. The 19th century had no more reverent thinker than Martineau; the awe of the Eternal was the very atmosphere that he breathed, and he looked at man with the compassion of one whose thoughts were full of God.

To his function as a preacher we owe some of his most characteristic works, and what especially tells of him as a thinker may be said he won his way to wide and influential recognition—Endeavours after the Christian Life, 1st series, 1843; 2nd series, 1847; Hours of Thought, 1st series, 1870; 2nd series, 1879; the various hymn-books he issued at Dublin in 1851, at Liverpool in 1850, in London in 1873; and the Home Prayers in 1891. But besides the vocation he had freely selected and assiduously laboured to fulfill, two more external influences helped to shape Martineau's mind and define his problem and his work; the awakening of English thought to the problems which underlie both philosophy and religion, and the new and higher opportunities offered for their discussion in the press and periodicals. The constructive, modern, critical and speculative period of his life concerned mainly the idea of the church, the historical interpretation of the documents which described the persons who had created the Christian religion, especially the person and book of its founder; the nature and history of the natural and mature time chiefly related to the philosophy of religion and ethics. In one respect Martineau was singularly happy; he just escaped the period of the "Robinson Crusoe" type of religious individualism, with its XVII century echoes of the religious controversy. When his ministry began its fires were slowly dying down, though the embers still glowed. We feel its presence in his earliest notable work, The Rational of Religious Infinity, 1836; the unanswerable apologetics and rationalization of the German rationalists "for having preferred, by convulsive efforts of interpretation, to compress the memoirs of Christ and his apostles into the dimensions of ordinary life, rather than admit the operation of miracle on the one hand, or proclaim their abandonment of Christianity on the other." The echoes of the dying controversy are thus distinct and not very distant in this book, though it also offers its protest against the spirit of incipient unbelief in the institution of the Sacrament, and against the German rationalists "for having preferred, by convulsive efforts of interpretation, to compress the memoirs of Christ and his apostles into the dimensions of ordinary life, rather than admit the operation of miracle on the one hand, or proclaim their abandonment of Christianity on the other." The echoes of the dying controversy are thus distinct and not very distant in this book, though it also offers its protest against the spirit of incipient unbelief in the institution of the Sacrament, and against the.
to the defence of Unitarian doctrine, which had been assailed by certain Liverpool clergyman, of whom Fielding Ould was the most active. In 1823, in the midst of this controversy, Martineau published five discourses, in which he discussed "the Bible as the great autobiography of human nature from its infancy to its perfection," the "Deity of Christ," "Varicous Religious Opinion in Christendom," and "Principles of Philosophy without Ritual." He remained to the end a keen and vigilant apologist of the school in which he had been nursed. But the question of a day to-day (the destruction of the Yarmouth East TGX upon崇高, and a more drastic criticism of sacred history. Blanco White, "the rationalist A'Kempis," who had dared to appear as "a religious skeptic in God's presence," was four years later to be found in The English Church men and that which he had called "the inspirer of his youth," Theodore Parker. The latter, producing more radical ideas without any belief in a religious mind—and deepened and developed it. Within his own fold new light was breaking. To W. E. Channing (q.e.) whom Martineau had called "the inspirer of his youth," Theodore Parker, and "the greatest religious and philosophical paganism of his time," Martineau was "critical, not prophetic, since without immediateness of religious vision," and whose faith is "an escape from an alternative scepticism, which receives the telo not of his reason but of his heart," and whose method was deconstructive and stimulating activity. The philosophic principles and religious deductions of Dean Mansel he disliked as much as those of Newman, but he respected his arguments more. Apart from the Christian Church, both these men (including the Unitarian and Public School) were mutually influential; while Herbert Spencer in England and Comte in France afforded the antithesis needful to the developmental discovery of his own views. He came to know the German philosophy and criticism, especially the criticism of Baur and the Tübingen school, which affected profoundly his construction of Christian history. And these were strengthened by French influence in the person of those of Renan and of Kropotkin. The rise of evolution, and the new scientific way of looking at nature and her creative methods, compelled him to re-think and re-formulate his theistic principles and conclusions, especially as to the forms under which the relation of God to the world and His action within it could be conceived. Under the impulses which came from these various sides Martineau's mind moved and moved, and as it successively rose he became, by appreciation or criticism, responding to the dialectical issues which they raised.

In the discussion of these questions the periodical press supplied him with a vast opportunity of taking an effective part. At the literary activity was extended to the periodical press and he addressed his public, now as editor and now as leading contributor, in the Monthly Repository, the Christian Reformer, the Prospective, the Christian Examiner, these and other periodicals, especially in the second and fourth volumes. In his criticism of form of the actual contents of the two books, we are bound to confess that they constitute a wonderfully cogent and persuasive theistic argument. That argument may be described as a criticism of man and his world used as a basis for the construction of a reasoned idea of nature and being. Man and nature, thought and being, fitted each other. What was implicit in nature had become explicit in man; the problem of the individual was one with the problem of the interpretation of the universe. Emphasis was made to fall on the reason, the conscience and the will of the finite personality; and just as these were found to be native in him they were held to be immanent in the cause of his universe. What lived in time belonged to eternity; the macrocosm was the epiphany of the microcosm; the reason which reigned in man interpreted the law that was revealed in conscience and the power which governed human destiny, while the freedom which man realized was the direct negation both of necessity and of the operation of any fortuitous cause in the constituted.

It was not possible, however, that the theistic idea could be discussed in relation to nature only. It was necessary that it should be applied to history and to the forces and personalities active within the unfolding of the universe. Martineau, especially in his criticisms of the Bible, created the Christian religion. What did Jesus signify? What authority belonged to Him and to the books that contain His history and interpret His person? This was the problem which The Christian Reformer had to solve. The workmanship of the book is unequal: historical and literary criticism had never been Martineau's strongest point, although he had almost continuously maintained an amount of New Testament study, as his note-books show. In its speculative parts the book is quite equal to those that had gone before, but in its literary and historical parts there are indications of a mind in which a long-continued logic had become a rooted habit. While a companion of his sensations the Pauline and Johannine Christologies with the earlier Unitarian excesses in which he had been trained shows how much the literary style intended to represent a mind that had throughout its history lived and worked in a climate of investigations he here tried to conduct.

Martineau's theory of the religious society or church was that of an idealist rather than of a statesman or practical politician. He stood equally remote from the old Voluntary principle, that the "State had nothing to do with religion," and from the sacerdotal position that the clergy stood in an apostolic succession, and either constituted the Church or were the persons in whose hands its forms and ceremonies were handed on. He held two things intensely, a sacrosanct priesthood and an enforced uniformity. He may be said to have believed in the sanctity and sanctity of the state rather than of the Church. Statesmen he could trust as he would not trust ecclesiastics. And so he even propounded a scheme, which fell still-born, that would have

repealed uniformity, taken the church out of the hands of a clerical order, and allowed the coordination of sects or churches under the state. Not that he would have allowed the state to touch doctrine, to determine polity or discipline; but he would have had it to recognize historical achievement, religious character and capacity, and endow out of its ample resources those societies which had vindicated their right to be regarded as making for religion. His ideal may have been academic, but it was the dream of a mind that thought nobly both of religion and of the state.

Hunt, "Religious Thought in England in the 19th Century." (A. M. F.)

**MARTINET**, a military term (more generally used in a disparaging than in a complimentary sense) implying a strict disciplinarian or drill-master. The term originated in the French army about the middle of Louis XIV.'s reign, and was derived from the name of the regiment (1672-1789) of the King's regiment of foot and inspector-general of infantry drill, and trained that arm in the model regular army created by Louis and Louvois between 1660 and 1760. Martinet seems also to have introduced the copper pontoons with which Louis bridged the Rhine in 1672. He was killed, as a *maréchal de camp*, at the siege of Duisburg in the same year, being accidentally shot by his own artillery while leading the infantry assault. His death, and that of the Swiss captain Soury by the same discharge gave rise to a bon mot, typical of the polite ingratitude of the age, that Duisburg had only cost the king a maréchal and a mouse. The "martin" as a matter of fact shares with Vauban and other professional soldiers of Louis XIV. the glory of having made the French army the first and best regular army in Europe. Great nobles, such as Turenne, Condé and Luxembourg, led this army and inspired it, but their fame has obscured that of the men who made it manageable and efficient. It was about this time that the soldier of fortune, who joined a regiment with his own arms and equipment and had learned his trade by varied experience, began to give place to the soldier regularly enlisted as a recruit in permanent regiments and trained by his own officers. The consequence of this was the introduction of a uniform, or the nearly uniform system of drill and training, which in all essentials has endured to the present day. Thus Martinet was the forerunner of Leopold of Hessau and Frederick William, just as Jean Jacques de Foulrilles, the organizer of the cavalry, who was forced into an untimely charge at Sena fit (1674) by a brutal taunt of Condé, and there met his death, was the forerunner of Zieten and Seydlitz. These men, while differing from the creators of the Prussian army in that they contributed nothing to the tactics of their arms, at least made tactics possible by the thorough drilling and organization they imparted to the formerly heterogeneous and hardly coherent elements of an army.

**MARTÍNEZ DE LA ROSA, FRANCISCO DE PAULA** (1789-1862), Spanish statesman and dramatist, was born on the 10th of March 1789 at Granada, and educated at the university there. He won popularity with a series of epigrams on local celebrities published under the title of El Cementerio de monos. During the struggle against Napoleon he took the patriotic side, was elected deputy, and at Cadiz produced his first play, *Lo que puede un emperador*, a prose comedy in the manner of the younger Martini.

**La Viuda de Padilla** (1814), a tragedy modelled upon Alfieri, was less acceptable to the Spanish public. Meanwhile the author became more and more engrossed in politics, and in 1814 was banished to Africa, where he remained till 1820, when he was suddenly recalled and appointed prime minister. During the next three years he was the most unpopular man in Spain; denounced as a revolutionary by the Conservatives and as a reactionary by the Liberals, he alienated the sympathies of all parties, and his rhetoric earned for him the contemptuous nickname of *Rastita la Pastorela*. Exiled in 1823, he took refuge in Paris, where he issued his *Obras literarias* (1827), including his *Arte poética*, in which he exaggerated the literary theories already promulgated by Luzán. Returning to Spain in 1831, he became prime minister on the death of Ferdinand VII., but proved incapable of coping with the insurrectionary movement and resigned in 1834. He was ambassador at Paris in 1839-1840 and at Rome in 1842-1843, joined the Conservative party, held many important offices, and was president of congress and director of the Spanish academy at the time of his death, which took place at Madrid on the 7th of February 1862. As a statesman, Martín de la Rosa never rose above mediocrity. It was as a military man to be in place without real power, to struggle against a turbulent and democratic movement promoted by unscrupulous soldiers, and to contend with the intrigues of the king, the court camarilla and the clergy. But circumstances which hampered him in politics favoured his career in literature. He was not a great natural force; his early plays and poems are influenced by Moratin or by Meléndez Valdés; his *Espíritu del siglo* (1835) is an elegant summary of all the commonplaces concerning the philosophy of history; his *Doña Isabel de Solís* (1837-1846) is a weak imitation of Walter Scott's historical novels. Still his place in the history of Spanish literature is secure, if not eminent. Through an accident of history, he was thrown into relations with the leaders of the French romantic movement, and was so far impressed with the innovations of the new school as to write in French a romantic piece entitled *Aben-Humeya* (1830), which was played at the Porte Saint-Martin. The experiment was not unsuccessful, and on his return to Madrid Martín de la Rosa produced *La Conjunción de Venecia* (April 23, 1834), which entitled him to be called the pioneer of the romantic drama in Spain. The play is more reminiscent of Casimir Delavigne than of Victor Hugo; but it was unquestionably effective, and smoothed the way for the bolder essays of Rivas, García Gutiérrez and Hartzenbusch.

**MARTINI, GIOVANNI BATTISTA** (1706-1784), Italian musician, was born at Bologna on the 24th of April 1706. His father, Antonio Maria Martini, a violinist, taught him the elements of music and the violin; later he learned singing and harpsichord playing from Padre Pradieri, and counterpart from Antonio Ricciere. Having received his education in classics from the fathers of the oratory of San Filippo Neri, he afterwards entered upon a novitiate at the Franciscan monastery at Lago, at the close of which he was received as a Minorite on the 11th of September 1722. In 1725, though only nineteen years old, he received the appointment of chapel-master in the Franciscan church at Bologna, where his compositions attracted attention. At the invitation of amateurs and professional friends he opened a school of composition at which several celebrated musicians were trained; as a teacher he consistently declared his preference for the traditions of the old Roman school of composition. Padre Martini was a zealous collector of musical literature, and possessed an extensive musical library. Burney estimated it at 17,000 volumes; after Martini's death a portion of it passed to the Imperial library at Vienna, the rest remaining in Bologna, now in the Liceo Rossini. Most contemporary musicians speak of Martini with admiration, and Mozart's father consulted him with regard to the talents of his son. Aht Vogler, however, makes reservations in his praise, condemning his philosophical principles as too much in sympathy with those of Fox, which had already been expressed by F. Vailotti. He died at Bologna on the 4th of August 1784. *Il Elogio* was published by Pietro della Valle at Bologna in the same year.

The greater number of Martini's sacred compositions remain unpublished. The Liceo of Bologna possesses the MSS. of two organos; and a requiem, with the other pieces of the oratorio, are now in Vienna. *Litaniae alque antiphonae finales B. V. Mariae* were published at Bologna in 1734, as also twelve *Sonate d'intavolatura*; six *Sonate per l'organo ed il cembalo* in 1747; and *Duetti da camera* in 1763. Martini's most important works are his *Storia della musica* (Bologna, 1752-1781) and his *Saggio di contrapunto* (Bologna, 1714-1778). The former, of which the three published volumes relate only to ancient composition, is a most valuable interpretation of the author's vast plan, exhibits immense reading and industry, but is written in a dry and unattractive style, and is overloaded with matter which cannot be regarded as historical. At the beginning
MARTINI, S.—MARTINIQUE

and end of each chapter occur puzzle-canons, whereas the primary part or parts alone are given, and the reader has to discover the canon that fixes the period and the interval at which the response is to enter. Some of these are exceedingly difficult, but Cherubini solved the whole of them. The subject of the whole work, containing an important collection of examples from the best masters of the old Italian and Spanish schools, with excellent extracted for the edition of the treatise on "The Theory of Numbers as applied to Music." His celebrated canons, published in London, about 1800, edited by Pio Cianchettini, show him to have had a strong sense of musical humour.

MARTINI, DOLOMÉE (1283-1344), Siene painter, called also Simon Memmi, was more commonly, but not correctly, Simon Memmi! He was born in 1283. He followed the manner of painting proper to his native Siena, as improved by Duccio, which is essentially different from the style of Giotto and his school, and the idea that Simone was himself a pupil of Giotto is therefore wide of the mark. The Sienese style is less natural, dignified and reserved than the Florentine; it has less unity of expression, has more tendency to pictism, and is marked by exaggerations which are partly related to the obsesque Byzantine manner, and partly seem to forebode certain peculiarity of the fully developed art which we find prevalent in Michelangelo. Simone, in especial, tended to an excessive and rather affected tenderness in his female figures; he was more successful in single figures and in portraits than in large compositions of incident. He finished with scrupulous minuteness, and was elaborate in decorations of patterning, gilding, &c.

The first known fresco of Simone is the vast one which he executed in the hall of the Palazzo Pubblico in Siena—the "Madonna Enthroned, with the Infant," and a number of angels and saints; its date is 1315, at which period he was already an artist of repute throughout Italy. In S. Lorenzo Maggiore at Naples he painted a life-sized picture of King Robert crowned by his brother Lewis, bishop of Toulouse; this also is extant, but much damaged. In 1320 he painted for the high altar of the church of S. Caterina in Pisa the Virgin and Child between six saints; above are archangels, apostles and other figures. The compartmented portions of this work are now dispersed, some of them being in the academy of Siena. Towards 1321 he executed for the church of S. Domenico in Orvieto a picture of the Virgin kneeling before the Madonna attended by saints, now in the Fabbrica of the cathedral. In Assisi, and also frescoes in the chapel of San Martino, representing the life of that saint, ascribed by Vasari to Puccio Capanna, are now, upon internal evidence, assigned to Simone. He painted also, in the south transept of the lower church of the same edifice, figures of the Virgin and eight saints. In 1328 he produced for the sala del consilio in Siena a striking equestrian portrait of the victorious general Guidoriccio Fogliani of Ricci.

Simone had married in 1324 Giovanna, the daughter of Memmo (Guglielmo) di Filippuccio. Her brother, named Lippo Memmi, was also a painter, and was frequently associated with Simone in his work; and this is the only reason why Simone has come down to us with the family-name Memmi. They painted together in 1333 the "Annunciation" which is now in the Uffizi gallery. Simone kept a bottega (or shop), undertaking any ornamental work, and his gains were large. In 1339 he settled at the papal court in Avignon, where he made the acquaintance of Petrarch and Laura; and he painted for the poet a portrait, now, almost certainly, the original of the portrait of Petrarch's sonnets, in which Simone is eulogized. He also illuminated the book for the poet a copy of the commentary of Servius upon Virgil, now preserved in the Ambrosian library of Milan. He was largely employed in the decorations of the papal buildings in Avignon, and several of his works still remain—in the cathedral, in the hall of the consistory, and, in the two chapels of the palace, the stories of the Baptist, and of Stephen and of other saints. One of his latest productions (1342) is the picture of "Christ Found by his Parents in the Temple," now in the Liverpool Gallery. Simone died in Avignon in July 1344.

Some of the works with which Simone's name and fame have been generally identified are not now regarded as his. Such are the condemned frescoes of the Camaldolitan monastery of Santa Maria del Cerrano, and the "Assumption of the Virgin"; and the great frescoes in the Cappellone degli Spagnuoli, in S. Maria Novella, Florence, representing the Triumph of Religion through the work of the DominicanCOMMANDERS

MARTINIQUE, an island of the West Indies, belonging to the chain of the Lesser Antilles, and constituting a French colony, between the British islands of Dominica and St. Lucia. It is 25 m. S. of the one and 20 m. N. of the other, about 14° 30' N., 61° W. Its length is 40 m., its greatest width 21 m.; and the area comprises 380 sq. m. A cluster of volcanic mountains in the north, a similar group in the south, and a line of lower heights, form the backbone of the island. Its deep ravines and precipitous escarpments are reduced in appearance to gentle undulations by the drapery of the forests. The masif of Mont Pelé in the north is the culminating point of the island (1,870 ft.), while the chain of inferior (1063 ft.), but the mountains in the south are much lower. Mont Pelé is notorious for an appalling eruption in May 1902.

Of the numerous streams which traverse the few miles of country between the watershed and the sea (the longest radiating from Mount Carbet), about seventy-five are of considerable size, and in the rainy season become deep and often destructive torrents. On the north-west and north the coast is elevated and bold; and similar to the south, where a lateral range, branching from the backbone of the island, forms a blunt peninsula bounding the low-shored western bay of Port de France. The south. Another peninsula not very healthy for Europeans in the hotter months, but there are numerous sanatoria in the forest region at an elevation of about 1500 ft., where the average temperature is some 10° F. lower than that elsewhere. The area which is hilly, and with the exception of February are comparatively fresh and dry; those from the south (July to October) are damp and warm. From March to June easterly winds are prevalent.

The population increased from 162,861 in 1878 to 175,863 in 1888 and 203,781 in 1901. In 1902 the great eruption of Mont Pelé occurred, and in 1905 the population was only 185,034. The bulk of the population consists of Creole negroes and half-castes of various grades, ranging from the "Saçatra," who has retained hardly any trace of Caucasian blood, to the so-called "Sangmelé," with only a suspicion of negro conmixture. The capital of the island is Fort de France, on the west-coast bay of the same name, with a fine harbour defended by three forts, and a population of 18,000. The other principal centres of population are, on the west coast Lamentin, on the same bay as the capital, and on the east coast Le François and Le Robert. The colony is administered by a governor and council, and returns a senator and two deputies. There are elective municipal councils. The chief product is sugar, and some coffee, cocoa, tobacco and cotton are grown. The island is served by British, French and American steamship lines, and local communications are carried on by small coasting steamers and by subsidized mail coaches, as there are excellent roads. In 1905 the total value of the exports, consisting mainly of sugar, rum and cocoa, was £725,406, France taking by far the greater part, while imports were valued at £566,949, of which rather more than one-half by value came from France, the United States of America being the next principal importing country. In 1905,
the year following the eruption of Mont Pelé, exports were valued at $604,163.

Martinique, the name of which may be derived from a native form Madiana or Mantinino, was probably discovered by Columbus on the 15th of June 1502; although by some authorities its discovery is placed in 1493. It was at that time inhabited by Caribs who had expelled or incorporated an older stock. It was not until the 25th of June 1635 that possession was taken of the island in the name of the French Compagnie des Îles d'Amérique. Actual settlement was carried out in the same year by Pierre Belain, Sieur d'Ésnambuc, captain-general of the island of St Christopher. In 1637 his nephew Dyer Duparquet (d. 1658) became captain-general of the colony, now numbering seven hundred men, and subsequently obtained the seigneurial of the island by purchase from the company under the authority of the king of France. In 1654 welcome was given to three hundred Jews expelled from Brazil, and by 1656 there were at least five thousand people exclusive of the Caribs, who were soon after exterminated. Purchased by the French government from Duparquet's children for $200,000 livres, Martinique was assigned to the West India Company, but in 1674 it became part of the royal domain. The habitants (French landholders) at first devoted themselves to the cultivation of cotton and tobacco; but in 1659 sugar plantations were begun, and in 1723 the coffee plant was introduced. Slave labour having been introduced at an early period of the occupation, there were 60,000 blacks in the island by 1736. This slavery was abolished in 1838. Martinique had a full share of wars. In early days the Caribs were not brought under subjection without severe struggles. In 1666 and 1667 the island was attacked by the British without success, and hostilities were terminated by the treaty of Breda. The Dutch made similar attempts in 1674, and the British again attacked the island in 1693. Captured by Rodney in 1762, Martinique was next year restored to the French; but after the conquest by Sir John Jervis and Sir Charles Grey in 1793 it was retained for eight years; and, seized again in 1809, it was not surrendered till 1814. The island was the birth-place of the Empress Josephine.

Martinique has suffered from occasional severe storms, as in 1767, when 1600 persons perished, and M. de la Pagerie, father of the Empress Josephine, was practically ruined, and in 1839, 1851 and 1903, when much damage was done to the sugar crop. Earthquakes have also been frequent, but the most terrible natural disaster was the eruption of Mont Pelé in 1902, by which the town of St Pierre, formerly the chief commercial centre of the island, was destroyed. During the earlier months of the year various manifestations of volcanic activity had occurred; on the 25th of April there was a heavy fall of ashes, and on the 2nd and 3rd of May a heavy eruption destroyed extensive sugar plantations north of St Pierre, and caused a loss of some 50 lives. A few days later the news that the Soufrière in St Vincent was in eruption reassured the inhabitants of St Pierre, as it was supposed that this outbreak might relieve the volcano of Pelé. But on the 8th of May the final catastrophe came without warning; a mass of fire, compared to a flaming whirlwind, swept over St Pierre, destroying the ships in the harbour, among which, however, one, the "Roddam" of Scrutton, escaped. A fall of molten lava and ashes followed the flames, accompanied by dense gases which asphyxiated those who had thus far escaped. The total loss of life was estimated at 40,000. Consternation was caused not only in the West Indies, but in France and throughout the world, and at first it was seriously suggested that the island should be evacuated, but no countenance was lent to this proposal by the French government. Relief measures were undertaken and voluntary subscriptions raised. The material losses were estimated at £4,000,000; but, besides St Pierre, only one-tenth of the island had been devastated, and although during July there was further volcanic activity, causing more destruction, the economic situation recovered more rapidly than was expected.

Anderson (November 20, 1902), that investigated the land on behalf of the Royal Society; cf. T. Anderson, "Recent Volcanic Eruptions in the West Indies," in Geographical Journal, vol. xxi. (1903).

MARTINSBURG, a town and the county-seat of Berkeley county, West Virginia, U.S.A., about 74 m. W.N.W. of Washington, D.C. Pop. (1890) 7226; (1900) 7564 (678 negroes); (1910) 10,698. It is served by the Baltimore & Ohio and the Cumberland Valley railways; the former has repair shops here. It lies in the Lower Shenandoah Valley at the foot of Little North mountain, in the midst of a fruit-growing region, peaches and apples being the principal crops. Slate and limestone also abound in the vicinity. The town has a fine Federal Building, a post-office, a hotel, a public library, and a branch of the Central National Bank. There are three cotton mills and various manufactures, including hosiery, woolen goods, dressed lumber, &c. Martinsburg owns its waterworks, the supply being derived from a neighbouring spring. A town was laid out here a short time before the War of Independence and was named Martins-town in honour of Colonel Thomas Bryan Martin, a nephew of Thomas, Lord Fairfax (1692-1782); in 1778 it was incorporated under its present name. During the Civil War Martinsburg was occupied by several different Union and Confederate forces.

MARTINS FERRY, a city of Belmont county, Ohio, U.S.A., on the Ohio River, nearly opposite Wheeling, West Virginia. Pop. (1890) 6290; (1900) 7760, including 1033 foreign-born and 252 negroes; (1910) 9133. It is served by the Pennsylvania (Cleveland & Pittsburg Division), the Baltimore & Ohio, and the Wheeling & Lake Erie (Washash System) railways, and by several steamboat lines. The city is situated on two plateaus; the lower is occupied chiefly by factories, the upper by dwellings. Coal mining and manufacturing are the principal industries; among factory products are iron steel, tin, stoves, machinery and glassware. The municipality owns and operates the waterworks and an electric-lighting plant. A settlement was attempted here in 1785, but was abandoned on account of trouble with the Indians. In 1795 a town was laid out by Absalom Martin and was called Jefferson, but this, too, was abandoned, on
account of its not being made the county-seat. The town was laid out again in 1835 by Ehenezer Martin (son of Absalom Martin) and was called Martinsville; the present name was substituted a few years later. The Martins and other pioneers are buried in Walnut Grove Cemetery within the city limits. Martins Ferry was incorporated as a town in 1865 and charted as a city in 1885.

MARTINUZZI, GEORGE [GYÖRGY UTÉSENOVICH] (1482-1554), Hungarian statesman, who, since he usually signed himself "Frater Georgius," is known in Hungarian history as Frater György or simply The Frater, was born at Kamédi in Croatia, the son of Gregory Utésenovich, a Hungarian noble. His mother was a Martiniuzzi, a Venetian patrician family. From his eighth to his twelfth year he was attached to the court of John Corvinus; subsequently, entering the service of the Zapolya family, he saw something of warfare under John Zapolya but, tiring of a military life, he entered the Paulician Order in his twentieth year. His historical career began when his old patron Zapolya, now king of Hungary, forced to fly before his successful rival Ferdinand, afterwards the emperor Ferdinand I, sent him on a diplomatic mission to Hungary, due to the recent circuity that John recovered Buda (1529), and henceforth Frater György became his treasurer and chief counsellor. In 1534 he became bishop of Grosswardein; in 1538 he concluded with Austria the peace of Grosswardein, whereby the royal title and the greater part of Hungary were conceded to Zapolya. King John left the Frater the guardian of his infant son John Sigismund, who was proclaimed and crowned king of Hungary, the Frater acting as regent. He frustrated all the attempts of the queen mother, Isabella, to bring in the Austrians, and, when in 1541, an Austrian army appeared beneath the walls of Buda, he arrested the queen and applied to the Porte for help. On the 28th of August 1541, the Frater did homage to the sultan, but during his absence with the baby king in the Turkish camp, the grand vizier took Buda by subterfuge. Then only the Frater recognized the necessity of a composition with both Austria and Turkey. He attained it by the treaty of Gyula (Dec. 29, 1541), whereby western Hungary fell to Ferdinand, while Transylvania, as an independent principality under Turkish suzerainty, reverted to John Sigismund. It included, besides Transylvania proper, many Hungarian counties on both sides the rivers Tisza, and the important city of Kassa. It was the Frater's policy to preserve Transylvania neutral and intact by cultivating amicable relations with Austria without offending the Porte. It was a difficult policy, but succeeded brilliantly for a time. In 1545, encouraged by the growing unpopularity of Ferdinand, owing to his incapacity to defend Hungary against the Turks, the Frater was tempted to unite Austrian Hungary to Transylvania and procure the election of John Sigismund as the national king. But recognizing that this was impossible, he aimed at an alliance with Ferdinand on terms of relative equality, and to this system he adhered till his death. Queen Isabella, who hated the Frater and constantly opposed him, complained of him to the sultan, who commanded that either the traitor himself or his head should be sent to Constantinople (1550). A combination was then formed against him of the queen, the hospodars of Moldavia and Wallachia and the Turks; but the Frater shut the queen up in Gyula-Fehérvár, drove the hospodars out of Transylvania, defeated the Turks at Děva, and finally compelled Isabella to accept a composition with Austria very profitable to her family and to Transylvania, at the same time soothing the rage of the sultan by flatteries and gifts. This compact, a masterpiece of statesmanship, was confirmed by the diet of Kolozsvar in August 1551. The Frater retained the governorship of Transylvania, and was subsequently consecrated archbishop of Esztergom and received the red hat. Thus Hungary was once more united, but the inability of Ferdinand to defend it against the Turks, as promised, forced the Frater, for the common safety, to resume the payment of tribute to the Porte in December 1551. Unfortunately, the Turks no longer trusted a diplomatist they could not understand, while Ferdinand suspected him of an intention to secure Hungary for himself. When the Turks (in 1551) took Csanád and other places, the Frater and the imperial generals Castaldo and Pallavicini combined their forces against the common foe; but when the Frater privately endeavoured to mediate between the Turks and the Hungarians, Castaldo represented him to Ferdinand as a traitor, and asked permission to kill him if necessary. The Frater's secretary Marco Aurelio Ferrari was hired, and stabbed his master from behind at the castle of Alvinezy while reading a letter, on the 16th of December 1551; but the cardinal, though in his sixty-ninth year, fought for his life, and was only despatched with the aid of Pallavicini and a band of bravos. He was buried in the church of St. Francis at Gyula.

MARTIUS, CARL FRIEDRICH PHILIPP VON (1794-1868), German botanist and traveller, was born on the 17th of April 1794 at Erlangen, where he graduated M.D. in 1814, publishing as his thesis a critical catalogue of plants in the botanic garden of the university. He afterwards devoted himself to botanical study, and in 1817 he and J. B. von Spiex were sent to Brazil by the king of Bavaria. They travelled from Rio de Janeiro through several of the southern and eastern provinces of Brazil, and ascended the river Amazon to Tabatinga, as well as some of its larger affluents. On his return to Europe in 1820 he was appointed conservator of the botanic garden at Munich, and in 1826 professor of botany in the university there, and held both offices till 1864. He devoted his chief attention to the flora of Brazil, and in addition to numerous short papers he published the *Nova Genera et Species Plantarum Brasiliensium* (1823-1832, 3 vols.) and *Icones selectae Plantarum Cryptogamicarum Brasiliensium* (1827), both works being finely illustrated. An account of his travels in Brazil appeared in 3 vols. 4to, 1823-1831, with an atlas of plates, but probably the work by which he is best known is his *Flora Brasiliensis* (1817-1829) in 3 large folio volumes, of which one describes the palms discovered by himself in Brazil. In 1840 he began the *Flora Brasiliensis*, with the assistance of the most distinguished European botanists, who undertook monographs of the various orders. Its publication was continued after his death under the editorship of A. W. Eichler (1839-1887) until 1887, and subsequently of Ignaz von Urban. He also edited several works on the zoological collections made in Brazil by Spiex, after the death of the latter in 1836. On the outbreak of potato disease in Europe he investigated it and published his observations in 1842. He also published works and short papers on the aborigines of Brazil, on their civil and social condition, on their past and probable future, on their diseases and medicines, and on the languages of the various tribes, especially the Tupi. He died at Munich on the 13th of December 1868.

MARTOS, CHRISTINO (1830-1893), Spanish politician, was born at Granada on the 13th of September 1830. He was educated there and at Madrid University, where his Radicalism soon got him into trouble, and he narrowly escaped being expelled for his share in student riots and other demonstrations against the governments of Queen Isabella. He distinguished himself as a journalist on El Tribuno. He joined O'Donnell and Espartero in 1854 against a revolutionary cabinet, and shortly afterwards turned against O'Donnell to assist the Democrats and Progressists under Prim, Rivero, Castelar, and Sagasta in the unsuccessful movements of 1866, and was obliged to go abroad. His political career had not prevented Martos from rising into note at the bar, where he was successful for forty years. After remaining abroad three years, he returned to Spain to take his seat in the Cortes of 1860 after the revolution
of 1868. Throughout the revolutionary period he represented in cabinets with Prim, Serrano and Ruiz Zorrilla, and lastly under King Amadeus, the advanced Radical tendencies of the men who wanted to give Spain a democratic monarchy. After the abdication of Amadeus of Savoy, Martos played a prominent part in the proclamation of the federal republic, in the struggle between the executive of that republic and the permanent committee of the generals and milites, who later put an end to the executive and republic in April 1873. When the republicans triumphed Martos retired into exile, and soon afterwards into private life. He reappeared for a few months after General Pavia's coup d'état in January 1874, to join a coalition cabinet formed by Marshal Serrano, with Sagasta and Ulloa. Martos returned to the Bar in May 1874, and quietly looked on when the restoration took place at the end of that year. He stuck to his democratic ideals for some years, even going to Biarritz in 1881 to be present at a republican congress presided over by Ruiz Zorrilla. Shortly afterwards Martos joined the dynamic Left organized by Marshal Serrano, General Lopez Dominguez, and Moret, Becerra, Balaguer, and other quarid revolutionaries. He sat in several parliaments of the reign of Alphonso XII. and of the regency of Queen Christina, joined the dynastic Liberals under Sagasta, and gave Sagasta not a little trouble when the latter allowed him to preside over the House of Deputies. Having failed to form a rival party against Sagasta, Martos subsided into political insignificance, despite his great talent as an orator and debater, and died in Madrid on the 16th of January 1903.

MARTOS, a town of southern Spain, in the province of Jaen, 16 m. W.S.W. of Jaen, by the Jaen-Lucena railway. (Pop. 1900), 17,078. Martos is situated on an outlying western peak of the Jabiluz mountains, which is surmounted by a ruined castle and overlooks the plain of Andalusia. In the neighbourhood are two sulphurous springs with bathing establishments. The local trade is almost exclusively agricultural.

Martos perhaps stands on or near the site of the Tucti of Polenery, which was fortified and renamed Colonia Augusta Gemella by the Romans. By Ferdinand III. it was taken from the Moors in 1225, and given to the knights of Calatrava; it was here that the brothers Carvajal, commanders of the order, were in 1312 executed by command of Ferdinand IV. Before their death they summoned Ferdinand to meet them within thirty days at the judgment-seat of God. Ferdinand died a month later and thus received the popular name of el Emplazado—"the Summoned."

MARTYN, HENRY (1751-1812), English missionary to India, was born on the 15th of February 1781, at Truro, Cornwall. His father, John Martyn, was a "captain" or mine-agent at Gwennap. The lad was educated at Truro grammar school under Dr. Cardew, entered St. John's College, Cambridge, in the 1779, and was made a fellow and first Smith's prizeman in 1801. In 1802 he was chosen a fellow of his college. He had intended to go to the bar, but in the October term of 1802 he chanced to hear Charles Simeon speaking of the good done in India by a single missionary, William Carey, and some time afterwards he read the life of David Brainerd, the apostle of the Indians of North America. He resolved, accordingly, to become a Christian missionary. On the 22nd of October, 1803, he was ordained deacon at Ely, and afterwards priest, and served as Sir George's church in Holy Trinity, the charge of the neighbouring parish of Lothlor. He was about to offer his services to the Church Missionary Society, when a disaster in Cornwall deprived him and his unmarried sister of the provision their father had made for them, and rendered it necessary that he should obtain a salary that would support her as well as himself. He accordingly obtained a chaplaincy under the East India Company and left for India on the 5th of July 1805. For some months he was stationed at Aleen, near Serampur; in October 1806 he proceeded to Dinapore, where he was soon able to conduct worship among the natives in the company's established schools. In April 1809 he was transferred to Cawnpore, where he preached in his own compound, in spite of interruptions and threats. He occupied himself in linguistic study, and had already, during his residence at Dinapore, been engaged in revising the sheets of his Hindostani version of the New Testament. He now translated the whole of the New Testament into Hindi also, and into Persian twice. He translated the Psalms into Persian, the Gospels into Judaeo-Persic, and the Prayer-book into Hindostani, in spite of ill-health and "the pride, pedantry and fury of his chief munshi Sabat." Ordered by the doctors to take a sea voyage, he obtained leave to go to the Caspian Sea, and was now led by persuasion he wished to go to Arabia, and there compose an Arabic version. Accordingly, on the 1st of October 1810, having seen his work at Cawnpore crowned on the previous day by the opening of a church, he left for Calcutta, whence he sailed on the 7th of January 1811, for Bombay, which he reached on his thirtieth birthday. From Bombay he set out for Bushire, bearing letters from Sir John Malcolm to men of position there, as also at Shiraz and Isfahan. After an exhausting journey from the coast he reached Shiraz, and was soon plunged into discussion with the disputants of all classes. "Sufi, Mahomedian, Jew, and Jewish-Mahomedan, even Armenian, all anxious to test their powers of argument with the first English priest who had visited them." Having made an unsuccessful journey to Tabriz to present the shah with his translation of the New Testament, he was seized with fever, and after a temporary recovery, had to seek a change of climate. On the 12th of September 1812, he started with two Armenian servants, crossed the Araxes, rode from Tabriz to Erivan, from Erivan to Kars, from Kars to Erzerum, from Erzerum to Chilifik, urged on from place to place by a thoughtless Tartar guide, and, though the plague was raging at Tokat (near to his former residence), he again set out and finally arrived to stop there. On the 6th of October he died. Macaulay's youthful lines, written early in 1813, testify to the impression made by his career.

His Journals and Letters were published by Samuel Wilberforce in 1837. See also Lives by John Sargent (1819; new ed. 1885), and G. Smith (1892); and The Church Quarterly Review (Oct. 1881).

MARTYN, JOHN (1699-1768), English botanist, was born in London on the 12th of September 1699. Originally intended for a business career, he abandoned it in favour of medical and botanical studies. He was one of the founders (with J. J. Dillen and others) and the secretary of a botanical society which met for a few years in the Rainbow Coffee-house, Watling Street; he also started the Grub Street Journal, a weekly satirical review, which lasted from 1730 to 1737. In 1732 he was appointed professor of botany at Cambridge University, but, finding little encouragement and hampered by lack of appliances, he soon discontinued lecturing. He retained his professorship, however, till 1762, when he resigned in favour of his son Thomas (1735-1825), author of Flora rustic (1792-1794). Although he had not taken a medical degree, he long practised as a physician at Chelsea, where he died on the 29th of January 1768. His reputation chiefly rests upon his Historia plantarum rariorum (1758-1757), and his translation, with valuable agricultural and botanical notes, of the Eclogues (1749) and Georgics (1741) of Virgil. On resigning the botanical chair at Cambridge he presented the university with a number of his botanical specimens and books.

See memoir by Thomas Martyn in Memoirs of John Martyn and Thomas Martyn, by G. C. Gorham (1830).

MARTYR (G. μάρτυρ or μάρτυρ), a word meaning literally "witness" and often used in that sense in the New Testament e.g. Matt. xvii. 16; Mark xiv. 63. During the conflict between Paganism and Christianity when many Christians "testified" to the truth of their convictions by sacrificing their lives, the word assumed its modern technical sense. The beginnings of this use are to be seen in such passages as Acts xxii. 20; Rev. ii. 13, xiii. 7, 9. During the latter part of the first century the use of the word "witnesses" won the admiration of their brethren. Ardent spirits craved the martyr's crown, and to confess Christ in persecution was to attain a glory inferior only to that won by those who actually died. Confessors were visited in prison, martyrs' graves were scenes of pilgrimage, and the day on which
MARTYROLOGY—MARVELL, ANDREW

they suffered was celebrated as the birthday of their glory. Martyrlogy was the most popular literature in the early Church. While the honour paid to martyrdom was a great support to early champions of the faith, it was attended by serious evils. It was thought that martyrdom would atone for sin, and imprisoned confessors not only issued to the Churches commands which were regarded almost as inspired utterances, but granted pardons in rash profusion to those who had been excommunicated by the regular clergy, a practice which caused Cyprian and his fellow bishops much difficulty. The zeal of Ignatius (c. 115), who begs the Roman Church to do nothing to avert from him the martyr’s death, was natural enough in a spiritual knight-errant, but others in later days, especially in Phrygia and North Africa, the passion became artificial. Fanatics sought death by insulting the magistrates or by breaking idols, and in their enthusiasm for martyrdom became self-centred and forgetful of their normal duty. None the less it is true that these men and women endured torments, often unthinkable in their cruelty, and death rather than abandon their faith. The same phenomena have been witnessed, not only in the conflicts within the Church that marked the 13th to the 16th centuries, but in the different mission fields, and particularly in Madagascar and China.

MARTYROLOGY, a catalogue or list of martyrs, or, more exactly, of saints, arranged in the order of their anniversaries. This is the now accepted meaning in the Latin Church. In the Greek Church the nearest equivalent to the martyrology is the Synaxarium (q.v.). As regards form, we should distinguish between simple martyrologies, which consist merely of an enumeration of names, and historical martyrologies, which also include stories or biographical details. As regards documents, the most important distinction is between local and general martyrologies. The former give a list of the festivals of some particular Church; the latter are the result of a combination of several local martyrologies. We may add certain compilations of a factitious character, to which the name of martyrology is given by analogy, e.g. the Martyrologie universel de Châtelain (1703). As types of local martyrologies we may quote that of Rome, which contains the Deposita episcoporum of the chronograph of 354; the Gothic calendar of Ulfila’s Bible, the calendar of Carthage published by Mabillon, the calendar of fasts and vigils of the Church of Tours, going back as far as Bishop Perpetius (d. 400) and preserved in the Historia francorum (xi. 31) of Gregory of Tours. The Syrian martyrology discovered by Wright (Journal of Sacred Literature, 1886) gives the idea of a general martyrology. The most important ancient martyrology preserved to the present day is the compilation falsely attributed to St Jerome, which in its present form goes back to the end of the 6th century. It is the result of the combination of a general martyrology of the Eastern Churches, a local martyrology of the Church of Rome, some general martyrologies of Italy and Africa, and a series of local martyrologies of Gaul. The task of critics is to distinguish between its various constituent elements. Unfortunately, this document has reached us in a lamentable condition. The proper names are distorted, repeated or misplaced, and in many places the text is so corrupt that it is impossible to understand it. With the exception of a few traces of borrowings from the Passions of the martyrs, the composition is in the form of a simple martyrology. Of the best-known historical martyrologies, the oldest are those which go under the name of Bede and of Florus (Acta sanctorum. Martii, vol. ii.); of Wandelbert, a monk of Prüm (842); of Rhabanus Maurus (c. 843); of Ado (d. 873); of Notker (896); and of Wolfhard (c. 906 v. Analecta bollandiana, xvii. 11). The most famous is that of Usuard (c. 875), on which the Roman martyrology was based. The first edition of the Roman martyrology appeared at Rome in 1583. The third edition, which appeared in 1584, was approved by Gregory XIII., who imposed the Roman martyrology upon the whole Church. In 1586 Baronius published his annotated edition, which in spite of its omissions and inaccuracies is a mine of valuable information.

The chief works on the martyrologies are those of Rosweyde, who in 1613 published at Antwerp the martyrology of Ado (also edition of Giorgi, Rome, 1745); of Sollerus, to whom we owe a learned edition of Usuard (Analect. sanctorum, vols. vi. and vii.); and of Florus, who published in 1688 an annotated edition of the Martyrology of St Jerome. The critical edition of the latter by J. B. de Rossi and Mgr. L. Duchesne, was published in 1894, in vol. ii. of the Acta sanctorum. The historical martyrologies taken as a whole have been studied by Dom Quentin (1908). There are also numerous editions of calendars or martyrologies of less universal interest, and commentaries upon them. Mention ought to be made of the famous calendar of Naples, compiled on by Mazocchi (Naples, 1744) and Sabbatini (Naples, 1744).

MARULLUS, MICHAEL TARCHANIOTA (d. 1500). Greek scholar, poet, and soldier, was born at Constantinople. In 1478 when the Turks captured Constantinople, he was taken to Ancona in Italy, where he became the friend and pupil of J. J. Pontanus, with whom his name is associated by Ariosto (Orl. Fur. xxvii. 8). He received his education at Florence, where he obtained the patronage of Lorenzo de’ Medici. He was the author of epigrams and hymni naturales, in which he happily imitated Lucretius. He took no part in the work of translation, but he was happy to plan some great work when he was drowned, on the 10th of April 1500, in the river Cecina near Volterra. He was a bitter enemy of Political Monarchy. His chief rival he had been in the affections of the beautiful and learned Alessandra Scala. He is remembered chiefly for the brilliant emendations on Lucretius which he left unpublished; these were used for the Juntine edition (Munro’s Lucretius, Introduction).

The hymns, some of the epigrams, and a fragment, De Principium instituione, were reprinted in Paris by C. M. Satas in Documents littéraux relatifs à l’histoire de la Grèce au moyen âge, vol. vii. (1888).

MARUM, MARTIN VAN (1750-1837), Dutch man of science, was born on the 20th of March 1750 at Groningen, where he graduated in medicine and philosophy. He began to practise medicine at Haarlem, but devoted himself mainly to lecturing on physical subjects. He became secretary of the scientific society of that city, and under his management the society was advanced to the position of one of the most noted in Europe. He was also entrusted with the care of the collection left to Haarlem by P. Teiyler van der Hulst (1702-1770). His name is not associated with any discovery of the first order, but his researches (especially in connexion with electricity) were remarkable for their number and variety. He died at Haarlem on the 26th of December 1837.

MARUTS, in Hindu mythology, storm-gods. Their numbers vary in the different scriptures, usually three or seven sixty. In the Vedas they are called the sons of Rudra. They are the companions of Indra, and associated with him in the wielding of thunderbolts, sometimes as his equals, sometimes as his servants. They are armed with golden weapons and lightnings. They supply those of (Vrinda) Volterra. Their principal characteristics are storms and earthquakes. Various myths surround their birth. A derivative word, Maruti or Maroti, is the popular name throughout the Deccan for Hanuman (q.v.).

MARVELL, ANDREW (1621-1678), English poet and satirist, son of Andrew Marvel and his wife Anne Pease, was born at the rectory house, Winsted, in the Holderness division of Yorkshire, on the 31st of March 1621. In 1642 his father exchanged the living of Winsted for the mastership of Hull grammar school. He also became lecturer at Holy Trinity Church and
MARVELL, ANDREW

master of the charterhouse in the same town. Thomas Fuller (Worthies of England, ed. 1811, i. 165) describes him as "a most excellent preacher." The younger Marvell was educated at Hull grammar school until his thirteenth year, when he matriculated on the 14th of December 1633 (according to a doubtful statement in Wood's Athen. Oxon.) at Trinity College, Cambridge. It is related by his early biographer, Thomas Cooke, that he was induced by some Jesuit priests to leave the university. After some months, he was discovered by his father in a bookseller's shop in London, and returned to Cambridge. He contributed two poems to the Musa Camdeniana in 1637, and in the following year he received a scholarship at Trinity College, and took his B.A. degree in 1639. His father was drowned in 1640 while crossing the Humber in company with the daughter of a Mrs Skinner, almost certainly connected with the Cyrillack Skinner to whom two of Milton's sonnets are addressed. It is said that Mrs Skinner adopted Marvell and provided for him at her death. The Conclusion Book of Trinity College, Cambridge, registers the decision (Sept. 24, 1641) that he with others should be excluded from further advantages from the college either because they were married, or did not attend their "days" or "acts." He travelled for four years on the Continent, visiting Holland, France, Italy and Spain. In Rome he met Richard Flecknoe, whom he satirized in the amusing verses on "Flecnoe, an English priest at Rome."

Although Marvell ranks as a great Puritan poet his sympathies were at first with Charles I., and in the lines on "Tom May's Death" he found no words too strong to express his scorn for the highwayman. Nevertheless, Marvell was no partisan, but had a passion for law and order. He acquiesced, accordingly, in the strong rule of Cromwell, but in his famous "Horatian Ode upon Cromwell's Return from Ireland" (1650) he inserts a tribute to the courage and dignity of Charles I., which forms the best-known section of the poem. In 1650 he became tutor to Lord Fairfax's daughter Mary, afterwards duchess of Buckingham, then in her twelfth year. During his life with the Fairfaxs at Nunappper, Yorkshire, he wrote the poems "Upon the Hill and Grove at Billborough" and "On Appleton House." Doubtless the other poems on country life, and his exquisite "garden poetry" may be referred to this period. "Clorinda and Damon" and "The Nymph complaining for the Death of her Faun" are good examples of the beauty and simplicity of much of this early verse. But he had affinities with John Donne and the metaphysical poets, and could be obscure on occasion.

Marvell was acquainted with Milton probably through their common friends, the Skinners, and in February 1653 Milton sent him with a letter to the lord president of the council, John Bradshaw, recommending him as "a man of singular desert for the publick service," and offering to undertake his case himself. This parcel of papers induced Marvell to write at each post—that is, every two or three days—both on local interests and on all matters of public interest. The discreet reserve of these letters, natural at a time when the post office was a favourite source of information to the government, contrasts curiously with the freedom of the few private letters which state opinions as well as facts. Marvell's constituents, in their turn, were not unmindful of their member. He makes frequent references to their presents, usually of Hull ale and of salmon, and he regularly drew from them the wages of a member, six-and-eighthence a day during session.

The development of Marvell's political opinions may be traced in the satirical verse he published during the reign of Charles II., and in his private letters. With all his admiration for Cromwell, he had retained his sympathies with the royal house, and had loyally accepted the Restoration. In 1667 the Dutch fleet sailed up the Thames, and Marvell expressed his wrath at the gross mismanagement of public affairs in "Last Instructions to a Painter," a satire which was published as a broadside and in verse. Elected to the parliament of 1660, Marvell had published in 1665 a gratulatory poem on the duke of York's victory in that year over the Dutch as "Instructions to a Painter for the drawing up and posture of his Majesty's forces at sea." A similar form was adopted in Sir John Denham's four satirical "Directions to a Painter," and Marvell writes on the same model. His indignation was well grounded, but he had no scruples in the choice of the weapons he employed in his warfare against the corruption of the court, which he paints even blacker than do contemporary memoir writers; and his satire often descends to the level of the lampoon. The most execusable of his scandalous verses are perhaps those on the duchess of York. In the same year he attacked Lord Clarendon, evidently hoping that with the removal of the "betray of England and Flanders" matters would improve. But in 1672 when he wrote his "Poem on the Statue in the Stocks-Market" he had no illusions left about Charles, whom he describes as too often "purchased and sold," though he concludes with "Yet we'd rather have him than his begot brother."

"An Historical Poem," "Advice to a Painter," "Britannia and Raleigh," and similar lines make up the last collection of Marvell's poems, published in 1674. In these Marvell parodies the state of the country in a strain of verse which has never lost its power. It is remarkable that the same advice in prose language is occasionally as effective as in the original poetry. In the last-named poem, probably written early in 1674, Raleigh pleads that "His god-like good to save a fallen king," but Britannia has at length decided that the tyrant cannot be divided from the Stuart, and proposes to reform the state;
on the republican model of Venice. These and other equally bold satires were probably handed round in MS., or secretly printed, and it was not until after the Revolution that they were collected with those of other writers in Poems on Affairs of State (3 pts., 1689; 4 pts., 1703-1707). Marvell’s controversial prose writings are wittier than his verse satires, and are free from the scrupulosity which defaces the “Last Instructions to a Painter.” A short and brilliant example of his irony is “His Majesty’s Most Gracious Speech to both Houses of Parliament” (printed in Grotari, ii. 431 seq.), in which Charles is made to take the house into the Freemasons’ confidence on his domestic affairs.

Marvell was among the masters of Jonathan Swift, who, in the “Apology” prefixed to the Tale of a Tub, wrote that his answer to Samuel Parker could be still read with pleasure, although the pamphlets that provoked it were long since forgotten. Parker had written a Discourse of Ecclesiastical Polity (1670) and other polemics against Dissenters, to which Marvell replied in The Rehearsal Transposed (2 pts., 1672 and 1673). The book contains some passages of dignified eloquence, and some coarse vituperation, but the prevailing tone is that of grave and ironical banter of derision as “Mr Bayes.” Parker was attacked, says Bishop Burnet (Hist. of His Own Time, ed. 1823, i. 451), “by the liveliest droll of the age, who wait in a burlesque strain, but with so peculiar and entertaining a conduct, that, from the king down to the tradesman, his books were read with great pleasure.” He certainly humbled Parker, but whether this effect extended, as Burnet asserts, to the whole party, is doubtful. Parker had intimated that Milton had a share in the first part of Marvell’s reply. This Marvell emphatically denied (Grotari, iii. 498). He points out that Parker had, like Milton, profited by the royal clemency, and that he had not met him at Milton’s house. He takes the opportunity to praise Milton’s “great learning and sharpness of wit,” and to the second edition of Paradise Lost (1674) he contributed some verses of just and elegant praise.

His Mr Smirke, or the Divine in Mode ... (1676) was a defence of Herbert Croft, bishop of Hereford, against the criticisms of Dr Francis Turner, master of St John’s College, Cambridge. A far more important work was An Account of the Growth of Popery and Arbitrary Government in England, more particularly from the Long Protrusion of Parliament ... (1677). This pamphlet was written in the same outspoke tone as the verse satires, and brought against the court the indictment of nursing designs to establish absolute monarchy and the Roman Catholic religion at the same time. A reward was offered for the author, whose identity was evidently suspected, and it is said that Marvell was in danger of assassination. He died on the 16th of August 1678 in consequence of an overdose of an opiate taken during an attack of ague. He was buried in the church of St Giles-in-the-Fields, London. Joint administration of his estate was granted to one of his creditors, and to his widow, Mary Marvell, of whom we have no previous mention.

As a humorist, and as a great “parliament man,” no name is of more interest to a student of the reign of Charles II. than that of Marvell. He had friends among the republican thinkers of the times. Aubrey says that he was intimate with James Harrington, the author of Oceana, and he was probably a member of the “Rota” club. In the heyday of political infamy, he, a needy man, obliged to accept wages from his constituents, kept his political virtue unspotted, and he stood throughout his career as the champion of moderate and tolerant measures. There is a story that his old schoolfellow, Danby, was sent by the king to offer the incorruptible poet a place at court and a gift of £1000, which Marvell refused with the words: “I live here to serve my constituents; the ministry may seek men for their purpose; I am not one.” When self-indulgence was the ordinary habit of town life, Marvell was a temperate man. His personal appearance is described by John Aubrey: “He was of a middling stature, pretty strong set, roundish faced, cherry checcked, hazel eyed, brown haired. In his conversation he was modest and of very few words.” (“Lives of Eminent Persons,” printed in Letters ... in the 17th and 18th Centuries, 1813).

Among Marvell’s works is also a Defence of John Howe on God’s Presence ... (1678), and among the spurious works fatherec on him are: A Seasonable Argument ... for a new Parliament (1677), The True and Most Complete Answer from a Parliament Man ... (1678), and a translation of Suetonius (1672). Marvell’s satires were no doubt first printed as broadsides, but very few are still extant in that form. Such of his poems as were printed during the durance of his party are prefixed to the volume of his works. The earliest edition of his non-political verse is Miscellaneous Poems (1681), edited by his wife, Mary Marvell. The political satires were printed as A Collection of Poems on Affairs of State (1683, 1684), an Edition of Million of M-M, &c. and other Eminent Wits (1686), with second and third parts in the same year. The works of Andrew Marvell contained in these two publications were also edited by his widow. The first (2 vols., 1681) was reprinted in 1686, and a second edition was reprinted by Thomas Davies in 1772. Marvell’s next editor was Captain Thompson of Hull, who was connected with the poet’s family, and made further additions from a commonplace book. Among later editors were Dr A. B. Grotari’s laborious work, which, in spite of many defects of style, remains indispensable to the student. The Complete Works of Verse and Prose of Andrew Marvell, M.A. (4 vols., 1872-1875) forms part of his “Fuller Working Library.” See also the admirable edition of the Poems and Satires of Andrew Marvell, ... (2 vols., 1892) in the “Muses’ Library,” where a full bibliography of his works and of the commentaries on them is provided.

The same edition was reprinted of some Satires of Andrew Marvell (ed. Edward Wright, 1904), and Andrew Marvell (1905), by Augustine Birrell in the “English Men of Letters” series.

MARX, HEINRICH KARL (1818-1883), German socialist, and head of the International Working Men’s Association, was born on the 5th of May 1818 in Trèves (Rhenish Prussia). His father, a Jewish lawyer, in 1824 went over to Christianity, and he and his whole family were baptised as Christian Protestants. The son went to the high grammar school at Trèves, and from 1835 to the universities of Bonn and Berlin. He studied first law, then history and philosophy, and in 1841 took the degree of doctor of philosophy. In Berlin he had close intimacy with the most prominent representatives of the young Hegelians—the brothers Bruno and Edgar Bauer and their circle, the so-called “Freien.” He at first intended to settle as a lecturer at Bonn University, but his Radical views made a university career out of the question, and he accepted work on a Radical paper, the Rheinische Zeitung, which expounded the ideas of the most advanced section of the Rhenish Radical bourgeoisie. In October 1842 he became one of the editors of this paper, which, however, after an incessant struggle with press censors, was suppressed in the beginning of 1843. In the summer of this year Marx married Jenny von Westphalen, the daughter of a high government official. Through her mother Jenny von Westphalen was a lineal descendant of the earl of Argyle, who was beheaded under James II. She was a most faithful companion to Marx during all the vicissitudes of his career, and died on the 2nd of December 1851; he outliving her only fifteen months.

Already in the Rheinische Zeitung some socialist voices had been audible, couched in a somewhat philosophical strain. Marx, though not accepting these views, refused to criticize them until he had studied the question thoroughly. For this purpose he went in the autumn of 1843 to Paris, where the socialist movement was then at its intellectual zenith, and where he, together with Arnold Ruge, the well-known literary leader of Radical Hegelianism, was to edit a review, the Deutsch-französische Jahrbücher, of which, however, only one number appeared. It contained two articles by Marx—a criticism of Bruno Bauer’s treatment of the Jewish question, and an introduction to a criticism of Hegel’s philosophy of the law. Both articles showed that the social emancipation of the Jews could only be achieved together with the emancipation of society from Judaism, i.e. commercialism. The second declared that in Germany no partial political emancipation was possible; there was now only one class from which a real and reckless fight against authority was to be expected—namely, the proletariat. But the proletariat could not emancipate itself except by breaking all the chains, by dissolving the whole constituted society, by recreating man as a member of the commonwealth in the place of established states and classes. “Then the day of German resurrection will be announced by the crowning of the Gallican cock.” Both
articles thus relegated the solution of the questions then promi-
nent in Germany to the advent of socialism, and so far
resembled in principle other socialist publications of the time.
But the way of reasoning was different, and the final words
of the last quoted sentence pointed to a political revolution,
to begin in France as soon as the industrial evolution had
created a sufficiently strong proletariat. In contradistinc-
tion to most of the socialists of the day, Marx laid stress
upon the political struggle as the lever of social emancipa-
tion. In some letters which formed part of a correspondence
between Marx, Ruge, Ludwig Feuerbach, and Mikhail Bakunin,
published as an introduction to the review, this opposition of
Marx to socialist “dogmatism” was enunciated in a still
more pronounced form: “Nothing prevents us,” he said, “from
combining our criticism with the criticism of politics, from
participating in politics, and consequently in real struggles. We
will not, then, oppose the world like doctrinarians with a new
principle: here is truth, kneel down here! We expose new prin-
ciples to the world and the principles of the world itself. We
do not tell it: ‘Give up your struggles, they are rubbish, we will
show you the true war-cry.’ We explain to it only the real
object for which it struggles, and consciousness is a thing it must
acquire even if it objects to it.”

In Paris Marx met FRIEDRICH ENGELS (1820-1895), from whom
the Deutsche-französische Jahrbücher had two articles—a power-
fully written outline of a criticism of political economy, and a letter
on Carlyle’s Past and Present. Engels, the son of a wealthy
cotton-spinner, was born in 1820 at Barmen. Although destined
by his father for a commercial career, he attended a classical
school, and during his apprenticeship and whilst undergoing in
Berlin his one year’s military service, he had given up part of his
free hours to philosophical studies. In Berlin he had frequented
the society of the “Freien,” and had written letters to the
Rheinische Zeitung. In 1842 he had gone to England, his father’s
firm having a factory near Manchester, and had entered into con-
exion with the Oewente and Chartist movements, as well as
with German communists. He contributed to Owen’s New Moral
World and to the Chartist Northern Star, gave up much of his
abstract speculative reasoning for a more positivist conception of
things, and took to economic studies. Now, in September 1844,
on a short stay in Paris, he visited Marx, and the two found that
in regard to all theoretical points there was perfect agreement
between them. From that visit dates the close friendship and
uninterrupted collaboration and exchange of ideas which lasted
during their lives, so that even some of Marx’s subsequent works,
which he published under his own name, are more or less also the
work of Engels. The first result of their collaboration was the book
Die heilige Familie oder Kritik der kritischen Kritik, gegen
Bruno Bauer und die Kritikerin, a partial vindication of the
verseness of the high-sounding speculative radicalism of Bauer
and the other Berlin “Freie.” By aid of an analysis, which,
though not free from exaggeration and a certain diffuseness,
bears testimony to the great learning of Marx and the vigorous
discerning faculty of both the authors, it is shown that the
supposed superior criticism—the “critical criticism” of the
Bauer school, based upon the doctrine of a “self-conscious”
idea, represented by or incarnated in the critic—was in fact
inferior to the other Hegelian idealism. The socialist
and working-class movements in Great Britain, France and Germany
are defended against the superior criticism of the “holy”
Bauer family.

In Paris, where he had very intimate intercourse with Heinrich
Heine, who always speaks of him with the greatest respect,
and some of whose poems were suggested by Marx, the latter
contributed to a Radical magazine, the Vorwärts; but in conse-
quence of a request by the Prussian government, nearly the whole
staff of the magazine soon got orders to leave France. Marx
removed to Brüssels, where he shortly afterwards was joined
by Engels. In Brussels he published his second great work,
La Mère de la philosophie, a sharp rejoinder to the Philosophie
de la misère ou contradictions économiques of J. P. Proudhon.
In this he deals with Proudhon, whom in the former work he had
defended against the Bauers, not less severely than with the
latter. It is shown that in many points Proudhon is inferior to
both the middle-class economists and the socialists, that his
somewhat noisyly proclaimed discoveries in regard to political
economy were made long before by English socialists, and that
his main remedies, the “constitution of the labour-value” and
the establishment of exchange bazaars, were but a repetition of
what English socialists had already worked out much more
thoroughly and more consistently. Altogether the book shows
remarkable knowledge of political economy. In justice to
Proudhon, it must be added that it is more often his mode of
speaking than the thought underlying the attacked sentences
that is hit by Marx’s criticism. In Brussels Marx and Engels
also wrote a number of essays, wherein they criticized the
German literary representatives of that kind of socialism and
philosophic radicalism which was mainly influenced by the
writings of Ludwig Feuerbach, and deduced its theorems or
postulates from speculations on the “nature of man. They
mockingly nicknamed this kind of socialism “German or True
Socialism,” and ridiculed the idea that by disregarding historical
and class distinctions a conception of society and socialism
superior to that of the English and French workers and theorists
could be obtained. Some of these essays were published at the
time, two or three, curiously enough, by one of the attacked
writers in his own magazine; one, a criticism of Feuerbach
himself, was in a modified form published by Engels in 1885, but
others have remained in manuscript. They were at first intended
for publication in two volumes as a criticism of post-Hegelian
German philosophy, but the Revolution of 1848 postponed for a
time all interest in theoretical discussions.

In Brussels Marx and Engels came into still closer contact
with the socialist working-class movement. They founded a
German workers’ society, acquired a local German weekly, the
Brüsseler deutsche Zeitung, and finally joined a communist
society of German workers, the “League of the Just,” a secret
society which had its main branches in London, Paris, Brussels
and several Swiss towns. For this league, which till then had
adhered to the rough-and-ready communism of the gifted German
workman Wilhelm Weitling, but which now called itself “League
of the Communists,” and gave up its leanings towards conspiracy
and became an educational and propagandistic body, Marx and
Engels at the end of 1847 wrote their famous pamphlet, Manifest
der Kommunisten. It was a concise exposition of the history
of the working-class movement in modern society according
to their views, to which was added a critical survey of the existing
socialist and communist literature, and an explanation of the
attitude of the Communists towards the advanced opposition
parties in the different countries. Scarcely was the manifesto
published on the 20th. of February, the Revolution broke out in
France, and “the crowing of the Gallican cock” gave the signal
for an upheaval in Germany such as Marx had prophesied. After
a short stay in France, Marx and Engels went to Cologne in
May 1848, and there with some friends they founded the Neue
rheinische Zeitung, with the sub-title “An Organ of Democracy,”
a political daily paper on a large scale, of which Marx was the
chief editor. They took a frankly revolutionary attitude, and
directed their criticism to a great extent against the middle-class
democratic parties, who, by evading all decisive issues, delayed
the achievement of the upheaval. When in November 1848
the king of Prussia dissolved the National Assembly, Marx and his
friends advocated the non-payment of taxes and the organization
of armed resistance. Then the state of siege was declared in
Cologne, the Neue rheinische Zeitung was suspended, and Marx
was put on trial for high treason. He was unanimously acquit-
ted by a middle-class jury, but in May 1849 he was expelled from
Prussian territory. He went to Paris, but was soon given the
option of either leaving France or settling at a small provincial
place. He preferred the former, and went to England. He
settled in London, and remained there for the rest of his life.
At first he tried to reorganize the Communist League; but
soon a conflict broke out in its ranks, and after some of its
members had been tried in Germany and condemned for high
treason, Marx, who had done everything to save the accused, dissolved the Communist League altogether. Nor was a literary enterprise, a review, also called the *Neue rheinische Zeitung*, more successful; only six numbers of it were issued. It contained, however, some very remarkable contributions; and a series of articles on the career of the French Revolution of 1848, which first appeared there, was in 1859 published by Engels in book form under the title of *Die Klassenkämpfe in Frankreich von 1848* "by Karl Marx." Carlyle's *Latter Day Pamphlets*, published at that time, met with a very vehement criticism in the *Neue rheinische Zeitung*. The endeavours of Ernest Jones and others to revive the Chartist movement were heartily supported by Marx, who contributed to several of the Chartist journals of the period, mostly, if not wholly, without getting or asking payment. He lived at this time in great financial straits, occupied a few small rooms in Dean Street, Soho, and all his children then born died very young. At length he was invited to write letters for the *New York Tribune*, whose staff consisted of advanced democrats and socialists of the Fourierist school. For these letters he was paid at the rate of a guinea each. Part of them, dealing with the Eastern Question and the Crimean War, were republished in 1857 (London, Sonnenschein). Some were even at the time reprinted in pamphlet form. The co-operation of Marx, who was determinedly anti-Russian, since Russia was the leading reactionary power in Europe, was obtained by David Urquhart and his followers. A number of Marx's articles were written by Urquhartite committees, and Marx wrote a series of articles on the diplomatic history of the 18th century for the Urquhartite *Free Press* (Sheffield and London, 1856—1857). When in 1859 the Franco-Austrian War about Italy broke out, Marx denounced it as a Franco-Russian intrigue, directed against Germany on the one hand and the revolutionary movement in France on the other. He opposed those democrats who supported a war which in their eyes aimed at the independence of the Italian nation and promised to weaken Austria, whose superiority in Germany was the hindrance to German unity. Violent derogatory remarks directed against him by the well-known naturalist Karl Vogt gave occasion to a not less violent rejoinder, *Herr Vogt*, a book full of interesting material for the student of modern history. Marx's contention, that Vogt acted as an agent of the Bonapartist clique, seems to have been well founded, whilst it must be an open question how far Vogt acted from dishonourable motives. The discussions raised by the war also resulted in a great estrangement between Marx and Ferdinand Lassalle. Lassalle had taken a similar view of the war to that advocated by Vogt, and fought tooth and nail for it in letters to Marx. In the same year, however, was published the first result of his renewed economic studies the book *Zur Kritik der politischen Ökonomie*. It was the first part of a much larger work planned to cover the whole ground of political economy. But Marx found that the arrangement of his materials did not fully answer his purpose, and that many details had still to be worked out. He consequently altered the whole plan and sat down to rewrite the book, of which in 1867 he published the first volume under the title *Das Kapital*. In 1864, the International Working Men's Association was founded in London, and Marx became in fact, though not in name, the head of its general council. All its addresses and proclamations were penned by him and explained in lectures to the members of the council. The first years of the International went smoothly enough. Marx was then at his best. He displayed in the International a political sagacity and toleration which compare most favourably with the spirit of some of the publications of the Communist League. He was more of its teacher than an agitator, and his expositions of such subjects as education, trade unions, the working day, and cooperation were highly instructive. He did not hurry on by some resolutions, but put his proposals in such a form that they could be adopted by even the more backward sections, and yet contained no concessions to reactionary tendencies. But this condition of things was not permitted to go on. The anarchist agitation of Bakunin, the Franco-German War, and the Paris Commune created a state of things before which the International succumbed. Passions and prejudices ran so high that it proved impossible to maintain any sort of centralized federation. At the congress of the Hague, September 1872, the general council was removed from London to New York. But this was only a measure of the rest, the International was formally dissolved at a conference held in Philadelphia. That its spirit had not passed away was shown by subsequent international congresses, and by the growth and character of socialist labour parties in different countries. They have mostly founded their programmes on the basis of its principles, but are not always in their details quite in accordance with Marx's views. Thus the programme which the German socialist party accepted at its congress in 1875 was very severely criticized by Marx. This criticism, reprinted in 1881 in the review *Die neue Zeit*, is of great importance for the analysis of Marx's conception of socialism.

The dissolution of the International gave Marx an opportunity of returning to his scientific work. He did not, however, succeed in publishing further volumes of *Das Kapital*. In order to make it—and especially the part dealing with property in land—as complete as possible, he took up, as Engels tells us, a number of new studies, but repeated illness interrupted his researches, and on the 14th of March 1883 he passed quietly away.

From the manuscripts he left Engels compiled a second and a third volume of *Das Kapital* by judiciously and elaborately using complete and incomplete chapters, rough copies and excerpts, which Marx had at different times written down. Much of the copy used dates back to the 'sixties, i.e. represents the work as at first conceived by Marx, so that, e.g., the matter published as the third volume was in the main written much earlier than the matter which was used for compiling the second volume. The same applies to the fourth volume. Although the work thus revised and the four volumes promised in the preface to the book, it can only in a very restricted sense be regarded as complete. In substance and demonstration it must be regarded as a torso. And it is perhaps not quite accurate to speak of *Das Kapital*, if it is not quite accurate to call Engels' *Kapital I* a book, since the material that had enjoyed better health, would have given the world a much greater amount of scientific work of high value than is now the case. But it seems doubtful whether he would have brought *Das Kapital*, his main work, to a satisfactory conclusion.

*Das Kapital* proposes to show up historically and critically the whole mechanism of capitalist economy. The first volume deals with the circulation of capital, the second with the *production* of capital, the third with the movements of capital as a whole, whilst the fourth gives the history of the theories concerning capital. Capital is, according to Marx, the means of exploiting surplus-value. It is here distinguished from ground rent, ground-rent being the exploitation of terrestrial property, such as land, mines, rivers, &c., based upon the monopolist nature of such property. Surplus-value is created in the process of production. It is the value of a commodity which is created by the labour of the worker which is not given to the worker as a return—the wage—of the labour-force he expended in working. If at first taken by the employer, it is in the different phases of economic intercourse split up into the profit of industrial enterprise, commercial or merchants' profit, interest and ground rent. The value of any commodity consists in the labour expended on it, and is measured according to the time occupied by the labour employed on its production. Labour in itself has no value, being only the measure of value, but the labour-force of the worker has a value, the value of the means required to maintain the worker in normal conditions of social existence. It was, in fact, the determination of the value of labour-force, besides the purely economical, a moral and historical element enter. If to-day the worker receives a wage which covers the bare necessities of life, he is underpaid—he could receive the real value of his labour-force. For the value of any commodity is determined by its socially necessary costs of production (or in this case, maintenance). Socially necessary costs of production that commodities are produced in a commodity than is required by applying labour-force, tools, &c., of average or normal efficiency, and that the commodity is produced in such quantity as is required to meet the effective demand for it. As this general definition must not be limited to this case, the value of a commodity only graviates round its (abstract) value. But in the long run an equalization takes place, and for his further deductions Marx assumes that commodities are produced in a commodity than is otherwise with labour. The new value of the product must by necessity
be always higher than the value of the employed labour-force. Hence the capital employed in buying labour-force, i.e. in wages, is called variable capital. It is the tendency of capitalist production to reduce the amount spent in wages and to increase the amount invested in machinery, etc. For with natural and social law and other limitations of the working day, and the opposition to unlimited reduction of wages, it is not possible otherwise to cheapen production and beat competition. According to the proportion of constant to variable capital, the organic composition of capital, i.e. the proportion of the value of constant capital to the value of variable capital, is increased. The highest composition, the highest composition being that where proportionately the least amount of variable (wages) capital is employed.

The ratio of the wages which workmen receive to the surplus-value which they produce Marx calls the rate of surplus-value; that of the surplus-value produced to the whole capital employed is the rate of surplus production. But then, since the same proportion of surplus-value can increase and the rate of profit decrease, and this is the case. There is a temporary tendency of the rate of profit to decrease, i.e. by some other factors the contrary or temporary interrupted, profit is always decreased. Besides, by competition and movement of capitals the rates of profit in the different branches of trade are pressed towards an equalization in the share of an average rate of profit. This average rate or profits, added to the actual cost price of a given commodity, constitutes its price of production, and it is this price of production which actually appears to the empirical mind of the business man as the value of his commodity. But because the production of a given commodity disappears from the surface in a society where, as to-day, commodities are bought and sold against money and not exchanged against other commodities, and Marx according to it, is also to say the law of value ("labour-value") which in the last resort rules the prices and profits.

The tendency to cheapen production by increasing the relative proportion of constant capital—this is the characteristic of the modern capitalist plus that portion of the circulating capital which consists of raw and auxiliary materials, etc.—leads to a continuous increase in the size of private enterprises, to the concentration of capital. It is the larger enterprise that can and swallows the smaller. The number of dependent workmen—"proletarians"—is thus continuously growing, whilst employment only periodically keeps pace with the increase. Capital alternately attracts and repels workmen, and creates a constant surplus-population of workmen—a reserve-army for its requirements—which helps to lower wages and to keep the whole class in economic dependency. A decreasing number of workers and an increasing amount of capital and industrial progress, whilst the mass of misery, of oppression, of servitude, of deprivation, and of exploitation increases. But at the same time the working class continuously grows in numbers, and is disciplined, united and organized by the very mechanism of the capitalist mode of production. The centralization of the means of production and the socialization of the mode of production reach a degree of development which becomes incompatible with the old system. Then the knell of capitalist private property will have been rung. Those who used to proscribe will be expropriated. Individual property will again be social property. The property of the proletariat is the commonship of the earth and the means of production produced by labour.

These are the principal outlines of Das Kapital. Its purely economic analysis dominated by the concept of surplus-value. Its leading sociological principle is the materialist conception of history. This theory in Das Kapital only laid down by implication, but it was more completely explained in the preface to the second and third editions. According to it the material basis of life, the manner in which it and its requirements are produced, determines the form in which the social ideas and institutions of the time or historical epoch, so that fundamental changes in the former produce in the long run also fundamental changes in the latter. A set of social institutions answer to a given mode of production, and periods when the institutions no longer answer to the new conditions, become a revolution in social history, which go on until sufficient adjustment has taken place. The main subjective forces of the struggle between the old order and the new are those which society itself is divided into. The struggle between the communistic or semi-communistic tribes and the creation of states. And as long as society is divided into classes a class war will persist, sometimes in a more latent or disguised, sometimes in a more open or acute form, according to circumstances. In advanced capitalist society the classes between whom the decisive war takes place are the capitalist owners of the means of production and the non-proprietors or workers, who are in the same time of struggle and class war. The property of the non-proprietor cannot free itself without freeing all other oppressed classes, and thus its victory means the end of exploitation and political repression altogether. Consequently the state as a represents the entire human community, wins a free society.

Almost from the first Das Kapital and the publications of Marx and Engels connected with it have been subjected to all kinds of criticisms. The originality of its leading ideas has been disputed, the ideas themselves have been declared to be false or only partially true, and consequently leading to wrong conclusions; and it has been said of many of Marx's statements that they are incorrect, and that many of the statistics upon which he based his deductions do not prove what he wants them to prove. In response, it must be conceded that the disjunctiva of Marx's value theory and of his materialist conception of history are already to be found in an embryonic state in some of the works of the early nineteenth century. The passages from his works which are now known to have been quotations from the works of others are, however, not those that have been drawn from them, as generally supposed. This is an experience repeated over and over again in the history of deductive science, and is quite appropriate for the question of Marx's place in the history of socialism and social science.

It must further be admitted that in several places the statistical evidence upon which Marx bases his conclusions is insufficient or incorrect, and that much of his reasoning is based upon incorrect admissions—it repeatedly happens that he points out all the phenomena connected with a certain question, but afterwards ignores them and proceeds as if they did not exist. Thus, e.g., he speaks to the effect that one of the propositions of Malthus, viz., that the historical tendency of capitalist accumulation, of the decreasing number of magnates of capital as of an established fact. But all statistics show that the number of capitalists does not decrease, but increases; and in other places in Das Kapital this fact is indeed fully admitted, and even accentuated. Marx was, as the third volume shows, no otherwise that limited liability companies play an important part in the modern division of capital, or, that Marx himself was also out of sight, and confines the concentration of private enterprises with the centralization of fortunes and capitals. By these and other methods, he could not well foresee, he announces a coming evolution which is very unlikely to take place in the way described.

In this and in other features of his work a dualism reveals itself which is often accidental, and which is not a mark of a capitalist school. The philosophical method of Hegel, which is the predominant spirit of the scholar and the spirit of the radical revolutionary. Marx originally entitled his great social work Critique of Political Economy, but this is still the sub-title of Das Kapital. But the conception of critique or criticism has with Marx a very pronounced meaning. He uses them mostly as identical with fundamentally, opposing. Much as he had mocked the "critical criticism" of the Baurers, he is in this respect yet of their breed and relapses into their habits. He retained in principle the Hegelian dialectical method, of which he said that in order to be rationally employed it must be "turned upside down," i.e. put upon a materialist basis. Hegelian dialectics is not more of a basis for sociological science than this prescription. Strict materialist dialectics cannot conclude much beyond actual facts. Dialectical materialism is revolutionary in the sense that it recognizes no finality, but otherwise it is necessarily positivist in the general meaning of that term. But Marx's opposition to modern society was fundamental and revolutionary, answering to that of the proletarian to the bourgeoise. And here we come to the second, the more abstract fact, which is no longer dependent on the first, and to a very great extent did proceed, scientifically. Nothing was to be deduced from preconceived ideas; from the observed or theoretical point of view. No laws were laid upon the historical conclusion of the historical materialism which was already, is a preconceived idea; it is the announcement of a state of society logically opposed to the given one. Imperceptibly the historical materialism arrives at its conclusion by the simple movement of facts, and the real movement of facts is only considered so far as is compatible with the former. Science is violated in the service of speculation. The picture given at the end of the first volume answers to a conception that arrived, at by speculative socialism in the 'forties. True, Marx calls this chapter "the historical tendency of capitalist accumulation," and "tendency does not necessarily mean realization in every detail. But on the whole the language used there is much too absolute to allow of the interpretation that Marx only wanted to give a speculative picture of the goal to which capitalist accumulation would lead if unhampered by socialist opposition. The most important sentences of science. That the passage in question was meant to give in the main the true outline of the forthcoming social revolution. We are led to this conclusion even more from the remaining passages in the book after the last sentence to which we have referred, which it is there said that the change of capitalist property into social property will mean "only the expropriation of a few usurpers by the mass of the people." In short, the principal reason for the undeniable contradictions in Das Kapital is to be found in the fact that where Marx has to do with details or subordinate subjects he mostly notices the important changes which actual evolution had brought about in the original propositions in the book, and how far their presuppositions have been corrected by facts. But when he comes to general conclusions, he adheres in the main to the original propositions based upon the old incorrect presuppositions. There are many more mistakes of this kind, which will have to be estimated, so that, e.g., such important features as the difference of the changes of traffic and aggregation on modern life are scarcely considered at all, and industrial and political phenomena are never under their administrative aspect. With regard to the theory of surplus-value and its foundation, the theory of labour-value, so much be-
MARY

safety said that, its premises accepted, it is most ingeniously and methodically worked out. And since its principal contention is in any case so far true that the wage-earning workers as a whole produce more than they receive, the theory has the great merit of taking into account admittably rather than rubbing out the wages and surplus-produce and the growth and movements of capital. But the theory of labour-value as the determining factor of the exchange or market value of commodities can with justification be dismissed as quite inadequate to show what labor and the products of labor in fact are based on social demand or utility. Marx himself, in placing in the third volume what he calls the *law of value* in the abstract background and setting out its force more generally and developmentally for the first time, introduced elements of what in reality to-day is only true with regard to the production of the whole of social wealth. Thus understood, the conception of labour-value is quite unobjectionable, but it loses much of the significance of the determining factor of prices in modern society, justifies those who look upon the conception of labour-value as an abstract formula which does not apply to individual exchanges of commodities at all. There is still full of all sorts of situations and developments of a revolutionary standpoint, an anti-climax to the first volume. It is difficult to see how, after all that is explained there on the functions of the working class and the relations between industrial employers and employees, Marx could have returned to those sweeping conclusions with which the first volume ends. The great scientific achievement of Marx lies, then, not in these conclusions themselves, but in the method and results of the investigations in his philosophy of history. Here he has, as is now generally admitted, broken new ground and opened new ways and outlooks. Nobody before him had so clearly shown the role of the productive agencies in historical evolution: nobody so masterfully exhibited their great determining influence on the forms and ideologies of social organisms. The passages and chapters devoted to these matters in *Das Kapital* had also provided the indefatigable way in which he made painstaking studies of the minutest details connected with his researches. In the same year as Darwin's epoch-making work on the origin of species there appeared also Marx's work *Zur Kritik der politischen Ökonomie*, in which he explains in concise sentences in the preface that philosophy of history which has for the theory of the transformation or evolution of society at the same time the scientific basis for the political economy. Darwin had for the theory of the transformation of biological organisms.

### Bibliography

The main writings of Karl Marx and Friedrich Engels are available (we give only the titles of the original works and of their English translations): (1) Of Karl Marx alone: *La Misère de la philosophie, réponse à la philosophie de la misère de M. Proudhon* (Paris, 1846); *Das Kapital* (1867, 3rd ed., Stuttgart, 1883); *Lohnarbeit und Kapital, pamphlet, written 1848* (new ed., Berlin, 1891); *English ed., Wage, Labour and Capital* (London, 1900); *Die Klasseenkämpfe in Frankreich, 1838 to 1850* (Berlin, 1853); *Das Klassenkampfe des Kapitals* (Neue Folge, 1858; 3rd ed., Hamburg, 1889; Eng. ed., New York, 1890); *Entwürfe zu den Kölner Kommunenprozessen* (Basel, 1852; 2nd ed., Zürich, 1883); "*European Revolutions and Communist Revolutions* (reprints from the *New York Tribune*, 1851-1852; London, 1897); *The Eastern Question* (reprints from the *New York Tribune*, 1853-1856; London, 1898); *Zur Kritik der politischen Ökonomie* (Berlin, 1849; 3rd ed., Stuttgart, 1883); *Heinrich und Mary* (London, 1852); *La France, 1851* (London, 1871; new ed., 1894); *L’Alliance de la démo- cratie socialiste* (London, 1873); articles printed or reprinted in *Rheinische Zeitung* (1842-1843), *Deutsch-französischer Jahrbücher* (Paris, 1844), *Das westphälische Dampfbauern* (Bielefeld and Paderborn, 1845-1848), *Der Gesellschaftsspiel* (Elberfeld, 1846), *Deutsche brüßler Zeitung* (Brussels, 1847), *Neue rheinische Zeitung* (Düsseldorf, 1848); *The Civil War in France, 1851* (London, 1852-1858); *The New York Tribune* (New York, 1853-1860); *The Free Press* (Sheffield and London, 1856-1857); *Das Völker* (London, 1856); *Deutsch-französischer Jahrbücher* (Paris, 1844); *Das westphälische Dampfbauern* (Bielefeld and Paderborn, 1845-1848), *Der Gesellschaftsspiel* (Elberfeld, 1846), *Deutsche brüßler Zeitung* (Brussels, 1847), *Neue rheinische Zeitung* (Düsseldorf, 1848); *The Civil War in France, 1851* (London, 1852-1858); *The New York Tribune* (New York, 1853-1860); *The Free Press* (Sheffield and London, 1856-1857); *Das Völker* (London, 1856); *Deutsch-französischer Jahrbücher* (Paris, 1844); *Das westphälische Dampfbauern* (Bielefeld and Paderborn, 1845-1848), *Der Gesellschaftsspiel* (Elberfeld, 1846), *Deutsche brüßler Zeitung* (Brussels, 1847), *Neue rheinische Zeitung* (Düsseldorf, 1848); *The Civil War in France, 1851* (London, 1852-1858); *The New York Tribune* (New York, 1853-1860); *The Free Press* (Sheffield and London, 1856-1857); *Das Völker* (London, 1856); *Deutsch-französischer Jahrbücher* (Paris, 1844); *Das westphälische Dampfbauern* (Bielefeld and Paderborn, 1845-1848), *Der Gesellschaftsspiel* (Elberfeld, 1846), *Deutsche brüßler Zeitung* (Brussels, 1847), *Neue rheinische Zeitung* (Düsseldorf, 1848); *The Civil War in France, 1851* (London, 1852-1858); *The New York Tribune* (New York, 1853-1860); *The Free Press* (Sheffield and London, 1856-1857); *Das Völker* (London, 1856); *Deutsch-französischer Jahrbücher* (Paris, 1844); *Das westphälische Dampfbauern* (Bielefeld and Paderborn, 1845-1848), *Der Gesellschaftsspiel* (Elberfeld, 1846), *Deutsche brüßler Zeitung* (Brussels, 1847), *Neue rheinische Zeitung* (Düsseldorf, 1848); *The Civil War in France, 1851* (London, 1852-1858); *The New York Tribune* (New York, 1853-1860); *The Free Press* (Sheffield and London, 1856-1857); *Das Völker* (London, 1856); *Deutsch-französischer Jahrbücher* (Paris, 1844); *Das westphälische Dampfbauern* (Bielefeld and Paderborn, 1845-1848), *Der Gesellschaftsspiel* (Elberfeld, 1846), *Deutsche brüßler Zeitung* (Brussels, 1847), *Neue rheinische Zeitung* (Düsseldorf, 1848); *The Civil War in France, 1851* (London, 1852-1858); *The New York Tribune* (New York, 1853-1860); *The Free Press* (Sheffield and London, 1856-1857); "Of Friedrich Engels alone: (1) of the archeological sources of the New Testament times; besides the subject of the present notice there are mentioned (1) "Mary, the wife of Clopas," who was perhaps the mother of James the little (Luke 8:19), and of Joseph; (2) Mary Magdalen, i.e. of Magdala; (3) Mary of Bethany, sister of Martha and Lazarus; (4) Mary, the mother of Mark; and (5) Mary, another unknown benefactress of the apostle Paul (Rom. 16:6).
Mary's marriage after the birth of Christ is a useful argument for the reality of the Incarnation against gnostic notions, and spring relies upon the references to the Lord's brothers as disproving the Docetism with which he had to contend. The 

\[\text{εὐαγγελία} \text{ though very ancient, is in reality a doctrine of non-Catholic origin, and first occurs in a work prescribed by the earliest papal } \text{Index librorum prohibitorum (attributed to Gelasius) as heretical, the so-called } \text{Protevangelium Jacobi, written, it is generally admitted, within the 2nd century. According to this very early source, which seems to have formed the basis of the later } \text{Liber de infantia Mariae et Christi salvatoris et Evangelium de nativitate Mariae, the name of Mary's father,} \text{ Joseph, is the } \text{Liber Joseph Patriarcha, the son of Judah, living in Jerusalem; he had long been married to Anna her mother, whose continual childlessness had become a cause of much humiliation and sorrow to them both. The birth of a daughter was at last angelically predicted to each parent separately. From her third to her twelfth year } \text{Mary was in the Temple as if she were a dove that dwelt there, and she received food from the hand of an angel. }\]

When she became nubile a guardian was sought for her by the priests among the widowers of Israel; lest she should defile the temple by matrimony; and a rich man, called Silo, who had a family, was indicated for this charge by a miraculous token. Some time afterwards the announcement took place; when the Virgin's pregnancy was discovered, Joseph and she were brought before the high priest, and, though asserting their innocence in all sincerity, were acquitted only after they had been tried with "the water of the ordeal of the Lord" (Num. v. 11). Numerous details regarding the birth at Bethlehem are then given. The perpetual physical virginity of Mary, naively insisted upon in this apocryphon, is alluded to only with a half belief and a "some say." by Clement of Alexandria (Strom. vii. 16), but became of much importance to the leaders of the Church in the 4th century, as for example to Ambrose, who says in Ezek. xliv. 1-3 a prophetic indication of so great a mystery. Those who continued to believe that Mary, after the miraculous birth of Jesus, had become the mother of other children by Joseph came accordingly to be spoken of as her enemies—Antidicomarianitae (Epiphanius) or Antidicomariats (Augustine)—and the first-mentioned author devotes a whole chapter (ch. 79) of his great work upon heresies to their condemnation. For holding the same view Bonosus of Sardica was condemned by the synod of Capua in 391. To Jerome the perpetual virginity not only of Mary but even of Joseph appeared of so much consequence that while a young man he wrote (387) the long and vehement tract Against Helvidius, in which he was the first to broach the theory (which has since gained wide currency) that the brethren of our Lord were children neither of Mary by her husband nor of Joseph by a former marriage, but of another Mary, sister to the Virgin and wife of Cleopas or Alpheus. At last the epithet of άδειακός was authoritatively applied to the Virgin by the council of Chalcedon in 451, and the doctrine implied has ever since been an undisputed point of orthodoxy both in the Eastern and in the Roman Churches, some even seeking to hold the Anglican Church committed to it on account of the general declaration (in the Homilies) of concurrence in the decisions of the first four general councils.

\[\text{Her Absolute Sinlessness.—While much of the apocryphal literature of the early sects in which she is repeatedly spoken of as "undefiled before God" would seem to encourage some such doctrine as this, many passages from the acknowledged fathers of the Church could be cited to show that it was originally quite unknown to Catholicism. Even Augustine repeatedly asserts that she was born in original sin (De gen. ad lit. x. 18), and the } \text{locus classicus regarding her possible immunity from actual transgression, on which the subsequent doctrine of Lombardus and his commentators was based, is simply an extremely guarded passage (De nat. et grat. ch. 36), in which, while contradicting the assertion of Pelagius that many had lived free from sin, he wishes exception to be made in favour of }\]

\[\text{the holy Virgin Mary, of whom out of honour to the Lord I wish no question to be made where sins are treated of for how do we know what mode of grace wholly to conquer sin may have been bestowed upon her who was found meet to conceive and bear Him of whom it is certain that He had no sin." A writer so late as Ancel (Curs des humo, ii. 16), declares that "the Virgin herself whence He (Christ) was assumed was conceived in iniquity, and in sin did her mother conceive her, and with original sin was she born, because she too sinned in Adam in whom all sinned," and the same view was expressed by Cyril of Alexandria in the council of 431, of the immaculate conception from the time in the 12th century, when the canons of Lyons sought to institute a festival in honour of her "holy conception," and were remonstrated with by Bernard, see } \text{IMMACULATE CONCEPTION. The epithets applied to her in the Greek Church are such as άλωνων, πνεύματος, δύνα, παναγία; but in the East generally no clear distinction is drawn between immunity from actual sin and original sinlessness. }\]

\[\text{For a peculiar relation to the Godhead, which specially fits Her for successful intercession on behalf of mankind, it seems probable that the epithet θεοφόρος ("Mother of God") was first applied to Mary by theologians of Alexandria towards the close of the 3rd century; but it does not occur in any genuine extant writing of that period, unless we are to assign an early date to the apocryphal } \text{Transitus Mariae, in which the word is of frequent occurrence. In the 4th century it is met with frequently, being used by Eusebius, Athanasius, Didymus and Gregory of Nazianzus, the latter declaring that the man who believes not Mary to have been θεοφόρος has not entered in God (Orat. ii. p. 738). If its use was first recommended by a desire to bring into prominence the divinity of the Incarnate Word, there can be no doubt that latterly the expression came to be valued as directly honourable to Mary herself and as corresponding to the greatly increased esteem in which she personally was held throughout the Catholic world, so that when Nestorius and others began to dispute its propriety, in the following century, their temerity was resented, not as an attack upon the established orthodox doctrine of the Nicene Creed, but as thrusting a more vulnerable and more tender part of the popular faith. It is significant in illustration of the drift of theological opinion to refer to the first sermon of Proclus, preached on a certain festival of the Virgin (σαγηγον παρεθέσθη) at Constantinople about the year 450 or that of Cyril of Alexandria delivered in the church of the Virgin Mary at the opening of the council of Ephesus in 431. In the former the orator speaks of "the holy Virgin and Mother of God," as the spotless treasure-house of virginity, the spiritual paradise of the second Adam; the workshop in which two natures were welded together, the one bridge between God and men; in the latter she is saluted as the "mother and virgin," "through whom (δι' αυτής) the Trinity is glorified and worshipped, the cross of the Saviour exalted and honoured, through whom heaven triumphs, the angels are made glad, devils driven forth, the tempter overcome, and the fallen creature raised up even to heaven." The response which such language found in the popular heart was sufficiently shown by the shouts of joy with which the Ephesian mob heard of the deposition of Nestorius, escorting his judges with torches and incense to their homes, and celebrating the occasion by a general illumination. The causes which in the preceding century had led to this exaltation of the Mother of God in the esteem of the Catholic world are not far to seek. On the one hand the solution of the Arian controversy, however correct it may have been theoretically, undoubtedly had the practical effect of 2 See Gieseler (KG, Bd. i. Abhth. 1), who points out instances in which the apocryphal zeal went so far as to call David θεοφόρος and James ἄδειακος. 3 Labbé, Conc. iii. 51. Considerable extracts are given by Augusti (Denkwr. iii.) and also Milman (Lat. Chris. i. 185), who characterizes much of it as a "wild labyrinth of untranslatable metaphor."}
MARY

813

of relegating the God-man redeemer for ordinary minds into a faraway region of "remote and awful Godhead," so that the need for a mediator to deal with the very Mediator could not fail to be felt. On the other hand, the religious instincts of mankind are very ready to pay worship, in grosser or more refined forms, to the idea of womanhood; at all events many of those who became professing Christians at the political fall of paganism entered the Church with such instincts (derived from the nature-religions in which they had been brought up) very fully developed. Probably it ought to be added that the comparative colourlessness with which the character of Mary is presented, not only in the canonical gospels but even in the most copious of the apocrypha, left greater scope for the untramelled exercise of devout imagination than was possible in the case of Christ, in the circumstances of whose humiliation and in whose recorded utterances there were many things which the religious consciousness found difficulty in understanding or in adapting to itself. At all events, from the time of the council of Ephesus, to exhibit figures of the Virgin and Child became the approved expression of orthodoxy, and the relationship of motherhood in which Mary had been formally declared to stand to God1 was instinctively felt to give the fullest and freest sanction of the Church to that invocation of her aid which had previously been resorted to only hesitatingly, and occasionally. Previously to the council of Ephesus, however, the practice had obtained complete recognition, so far as we know, in those circles only in which one or other of the numerous redactions of the Transitus Mariae passed current.2 There was a decided picture of Mary coming to Christ's aid upon every man calling upon, or praying to, or naming the name of Thine handmaid;3 to which His answer is, "Every soul that calls upon Thy name shall not be ashamed, but shall find mercy and support and confidence both in the world that now is and in that which is to come in the presence of My Father in the heavens." But Gregory of Nazianzus also, in his panegyric upon Justina, mentions with incidental approval that in her hour of peril she "imposed Mary the Virgin to the aid of a virgin in her danger."4 Of the growth of the Marian cultus, alike in the East and in the West, after the decision at Ephesus it would be impossible to trace the history, however slightly, within the limits of the present article. Justina in one of his laws bespeaks her advocacy for the empire, and he inscribes the high altar in the new church of St Sophia with her name. Narses looks to her for directions on the field of battle. The emperor Heraclius bears her image on his banner. John of Damascus speaks of her as the sovereign lady to whom the whole creation has been made subject by her son. Peter Damian recognizes her as the most exalted of all creatures, and apostrophizes her as defined and endowed with all power in heaven and in earth, yet not forgetful of our race.5 In a word, popular devotion gradually developed the entire system of doctrine and practice which Protestant contro-

1 The term 珏iKon does not actually occur in the canons of Ephesus. It is found, however, in the creed of Chalcedon.

2 It is true that Irenaeus (Iren. v. 19, 1) in the passage in which he draws his well-known parallel and contrast between the first and second Eve (cf. Justin, Dial. c. Tryph. 100), to the effect that "as the human race fell into bondage to death by a virgin, so is reestablished and restored to its former condition of happiness by the Advocate of Eve; but it seems certain that this word is a translation of the Greek ἀναπτύσσει, and implies hostility and subjection to that which is translated as the Advocate of Eve.

3 It is probable that the commemorations and invocations of the Virgin which occur in the present texts of the ancient liturgies of "St James" and "St Mark" are due to interpolation. In this connection it is noteworthy that in the Antiochene Ephesians (Iren. 79) against the "Collyriadians," certain women in Thrace, Scythia and Arabia, who were in the habit of worshipping the Virgin (αιειομένη κοίμησις) as offering a refuge (ἀκούσπις), and of Mary as the "advocate" of Eve; but it seems certain that this word is a translation of the Greek ἀναπτύσσει, and implies hostility and subjection to that which is translated as the Advocate of Eve.

4 The points taught in the catechism are—that she is truly the Mother of God, and the second Eve, by whose means we have redemption; that she is the queen of all the Virgin Mary, as the one of the features of their worship. He rebukes them for offering the worship which was due to the Trinity alone; "let Mary be held in honour, but by no means worshipped." The cultus was probably inaugurated by the council of Sardica in 343.

the Western Church seems to be that found in the proceedings of the synod of Salzburg in 800; it is also spoken of in the thirty-sixth chapter of the letter of the bishop of Laon in 815. It was not at that time universal, being mentioned as doubtful in the capitularies of Charlemagne. The doctrine of the bodily assumption of the Virgin into heaven, alleged in the year 527, and renewed and extended as a matter of sordid bargaining from the first. Mary was little more than two years old when she was proposed in marriage to the dauphin, son of Francis I. Three years afterwards the French alliance was broken off, and in 1522 she was fiancée to her cousin the young emperor Charles V. by the Treaty of Windsor. No one, perhaps, seriously expected either of these arrangements to endure; and, though we read in grave state papers of some curious compliments and love tokens (really the mere counters of diplomacy) professedly sent by the girl of nine to her powerful cousin, not many years passed away before Charles released himself from this engagement and made a more convenient match. In 1526 a new arrangement was made of the royal household, and it was thought right to give Mary an establishment of her own along with a council on the borders of Wales, for the better government of the Marches. For some years she accordingly kept her court at Ludlow, while new arrangements were made for the disposal of her hand. She was now proposed as a wife, not for the dauphin as before, but for his father Francis I, who had just been redeemed from captivity at Madrid, and who was only too glad of an alliance with England to mitigate the severe conditions imposed on him by the emperor. Wolsey, however, on this occasion, only made use of the princess as a bait to enhance the terms of the compact, and left Francis free in the end to marry the emperor's sister.

It was during this negotiation, as Henry afterwards pretended, that the question was first raised whether Henry's own marriage with Catherine was a lawful one. Grammont, bishop of Tarbes, who was one of the ambassadors sent over by Francis to ask the princess in marriage, had, it was said, started an objection that she might possibly be considered illegitimate on account of her mother having been born to the wife of her father's brother. The statement was only a mere pretence to shield the king when the unpopularity of the divorce became apparent. It is proved to be untrue by the strongest evidence, for we have plenty full contemporary records of the whole negotiation. On the contrary, it is quite clear that Henry, who had already for some time conceived the project of a divorce, kept the matter a dead secret, and was particularly anxious that the French ambassadors should not know it, while he used his daughter's hand as a bait for a new alliance. The alliance itself, however, was actually concluded by a treaty dated Westminster, the 30th of April 1537, in which it was provided, as regards the Princess Mary, that she should be married either to Francis himself or to his second son Henry duke of Orleans. But the real object was only to lay the foundation of a perfect mutual understanding between the two kings, which Wolsey soon after went into France to confirm.

During the next nine years the life of Mary, as well as that of her mother, was rendered miserable by the conduct of Henry VIII. in seeking a divorce. During most of that period illegitimate and daughter seem to have been kept apart. Possibly Queen Catherine had the harder trial; but Mary's was scarcely less severe. Removed from court and treated as a bastard, she was, on the birth of Anne Boleyn's daughter, required to give up the dignity of princess and acknowledge the illegitimacy of her own birth. On her refusal her household was broken up, and she was sent to Hatfield to act as lady-in-waiting to her own infant half-sister. Nor was even this the worst of her trials; her very life was in danger from the hatred of Anne Boleyn. Her health, moreover, was indifferent, and even when [the service of the] Holy Sacrament, given to her at Buttes, Dr Buttes, to attend her, he declined to let her mother visit her. So also at her mother's death, in January 1536, she was forbidden to take a last farewell of her. But in May following another change occurred. Anne Boleyn, the real cause of all her miseries, fell under the king's displeasure and was put to death. Mary was then urged to make a humble submission to her father as the means of recovering his favour, and after a good deal of correspondence with the king's secretary, Cromwell, she actually did so. The terms exacted of her were not in the extreme, but there was no chance of making life tolerable otherwise. If indeed she was permitted to live at all; and the poor friendless girl, absolutely at the mercy of a father who could brook no contradiction, at length subscribed an act of submission, acknowledging the king as "Supreme Head of the Church of England under Christ," repudiating the pope's
authority, and confessing that the marriage between her father
and mother “was by God’s law and man’s law incestuous and
unlawful.”

No act, perhaps, in the whole of Henry’s reign gives us a
more painful idea of his revolting despotism. Mary was a
high-spirited girl, and her wilderness of life was made
longer and lonelier by her position at that time as the only legitimate child
of her father, but her father himself compelled her to disown
the title and pass an unjust stigma on her own birth and her
mother’s good name. Nevertheless Henry was now reconciled
to her, and gave her a household in some degree suitable to
her rank. During the rest of the reign we hear little about
her except in connexion with a number of new marriage projects
taken up and abandoned successively, one of which, to the
count palatine Philip, duke of Bavarin, was specially repugnant
to her in the matter of religion. Her privy purse expenses
for nearly the whole of this period have been published, and
show that Hatfield, Beaulieu or Newhall in Essex, Richmond
and Hunsdon were among her principal places of residence.
Although she was still treated as of illegitimate birth, it was
believed that the king, having obtained from parliament the
extraordinary power to dispose of the crown by will, would
restore her to her place in the succession, and three years before
his death she was so restored by statute, but still under con-
ditions to be regulated by her father’s will.

Under the reign of her brother, Edward VI. she was again
subjected to severe trials, which at one time made her seriously
meditate taking flight and escaping abroad. Edward himself
indeed seems to have been personally not unkind to her, but
the religious revolution in his reign assumed proportions such
as it had not done before, and Mary, who had done sufficient
violence to her own convictions in submitting to a despotic
father, was not disposed to yield an equally tame obedience
to authority exercised by a factious council in the name of a
younger brother not yet come to years of discretion. Besides,
the prince was not naturally one of those whose nature
forced declaration formerly wrung from herself, no one really
regarded her as a bastard, and the full recognition of her rights
depended on the recognition of the pope as head of the Church.
Hence, when Edward’s parliament passed an Act of Uniformity
enjoining services in English and communion in both kinds,
the law appeared to her totally void of authority, and she
insisted on having Mass in her own private chapel under the
old form. When ordered to desist, she appealed for protection
to the emperor Charles V., who, being her cousin, intervened
for some time not ineffectually, threatening war with England
if her religious liberty was interfered with. But Edward’s
court was composed of factions of which the most violent
eventually carried the day. Lord Seymour, the admiral,
was attainted of treason and beheaded in 1549. His brother,
the Protector Somerset, met with the same fate in 1552. Dudley,
duke of Northumberland, then became paramount in the privy
council, and easily obtained the sanction of the young king
to those schemes for altering the succession which led imme-
diately after his death to the usurpation of Lady Jane Grey.
Dudley had, in fact, overawed all the rest of the privy council,
and when the event occurred he took such energetic measures
to give effect to the scheme that Lady Jane was actually recog-
nized as queen for some days, and Mary had even to fly from
Hunsdon into Norfolk. But the country was really devoted
to her cause, as indeed her right in law was unquestionable,
and before many days she was royally received in London,
and took up her abode within the Tower.

Mary’s reign was a reign of blood. Yet no one can say her
reign displayed a character very different from that which she still holds in popular
estimation. Her clemency towards those who had taken up
arms against her was altogether remarkable. She released
from prison Lady Jane’s father, Suffolk, and had difficulty
even in signing the warrant for the execution of Northumberland.
Lady Jane herself she fully meant to spare, and did spare till
after Wyatt’s formidable insurrection. Her conduct, indeed,
was in every respect conciliatory and pacific, and so far as they
depended on her personal character the prospects of the new
reign might have appeared altogether favourable. But un-
fortunately her position was one of peculiar difficulty, and the
policy on which she determined was far from judicious.
In-
experienced in the art of governing, she had no trusty councillor
but Gardiner; every other member of the council had been
more or less implicated in the conspiracy against her. And
though she valued Gardiner’s advice she was naturally led
to rely even more on that of her cousin, the emperor, who had
been her mother’s friend in adversity, and had done such material
service to herself in the preceding reign. Following the emperor’s
guidance she determined almost from the first to make his son
Philip her husband, though she was eleven years his senior.
She was also strongly desirous of restoring the old religion
and wiping out the stigma of illegitimacy upon her birth, so
that she might not seem to reign by virtue of a mere parlia-
mentary settlement.

Each of these different objects was attended by difficulties
or objections peculiar to itself; but the marriage was the most
unpopular of all. A restoration of the old religion threatened
to deprive the new owners of abbey lands of their easy and
comfortable acquisitions; and it was only with an express
reservation of their interests that the thing was actually accom-
plished. A declaration of her own legitimacy necessarily cast
a slur on that of her sister Elizabeth, and cut her off from the
succession. But the marriage promised to throw England into
the arms of Spain and place the resources of the kingdom at
the command of the emperor’s son. The Commons sent her
a deputation to entreat that she would not marry a foreigner,
and when her resolution was known insurrections broke out
in different parts of the country. Suffolk, whose first rebellion
had been pardoned, proclaimed Lady Jane Grey again in
Leicestershire, while young Wyatt raised the county of Kent
and, though denied access by London Bridge, led his men round
by Kingston to the very gates of London before he was repulsed.
And this was the only danger Mary showed great intrepidity,
and the rebellion was presently quelled; after which, unhappily,
she got leave to pursue her own course unchecked. She married
Philip, restored the old religion, and got Cardinal Pole to come
over and absolve the kingdom from its past disobedience to
the Holy See.

It was a more than questionable policy thus to ally England
with Spain—a power then actually at war with France. By
the treaty, indeed, England was to remain neutral; but the force
of events in the end forced her, as might have been expected,
to take part in the quarrel. Meanwhile the country was full
of faction, and seditious pamphlets of Protestant origin inflamed
the people with hatred against the Spaniards. Philip’s Spanish
followers met with positive ill-usage everywhere, and violent
outbreaks occurred. A year after his marriage Philip went
over to Brussels to receive from his father the government of
the Low Countries and afterwards the kingdom of Spain.
Much to Mary’s distress, his absence was prolonged for a year
and a half, and when he returned in March 1557 it was only
to commit England completely to the war; after which he went
back to Brussels in July, to return no more to England.

Hostilities with France were inevitable, because France
had encouraged disaffection among Mary’s subjects, even
during the brief truce of Vaucelles. Conspiracies had been
hatched by English refugees in Paris, and an attempt to seize
Scarbrough had been made with the aid of vessels from the
Seine. But perhaps the strangest thing about the situation
was that the pope took part with France against Spain; and
the marriage which Mary had contracted to bring England
back to the Holy See made her the wife of the pope’s enemy.
It was, moreover, this war with France that occasioned
the final calamity of the loss of Calais, which sank so deeply
into Mary’s heart some time before she died.

The cruel persecution of the Protestants, which has cast
so much infamy upon her reign, was not due, as commonly
supposed, to inhumanity on her part. When the kingdom
was reconciled to Rome and absolved by Cardinal Pole, it
MARY II.

(1662-1694), queen of England and wife of King William III., elder daughter of James, duke of York, afterwards King James II., by his first wife, Anne, daughter of Edward Hyde, 1st earl of Clarendon, was born in London on the 30th of April 1662. She was educated as a Protestant, and as it was probable that she would succeed to the English throne after the deaths of her uncle, Charles II., and her father, the choice of a husband was a political event of high importance. About 1672 the name of William, prince of Orange, was men-
tioned in this connexion; and after some hesitation on both sides caused by the condition of European politics, the betrothal of William and Mary took place in October 1677, and was quickly followed by their marriage in London on the 4th of November. Mary's married life in Holland does not appear to have been a happy one; and she soon became popular among the Dutch, she remained childless, while William treated her with neglect and even with insult; and her troubles were not diminished after her father became king of England in 1685.

James had treated his daughter very shabbily in money matters; and it was increasingly difficult for her to remain loyal to both father and husband when they were so divergent in character and policy. Although Mary never entirely lost her affection for her father the wife prevailed over the daughter; and after the birth of her half-brother, the prince of Wales, in 1688, she regarded the dethronement of James as inevitable. It cannot be said, however, that William merited this confidence. Possibly he was jealous of his wife as the heiress of the English throne, contrasting her future position with his own; but according to Burnet, who was then staying at the Hague, this cause of difference was removed by the tactful interference of Burnet himself. The latter asserts that having divined the reason of the prince's jealousy he mentioned the matter to the princess, who in her ignorance of statecraft had never considered the relative positions of herself and her husband with regard to the English throne; and that Mary, by telling the prince "she would do no more than her duty, and that she would do all in her power to make him king for life" (Burnet, Supplement, ed. Foxcroft, p. 300), probably mollified her husband's jealousy. On the other hand Macaulay's statement that henceforward there was "entire friendship and confidence" between them must be taken with some reserve. Mary shared heartily in the events which immediately preceded William's expedition to England in 1688. After the success of the undertaking she arrived in London in February 1689; and by her faithful adherence to her promise made a satisfactory settlement of the English crown possible. William and Mary were together proclaimed king and queen of England, and afterwards of Scotland, and were crowned on the 11th of April 1689. During the king's absence from England the queen, assisted by a committee of the privy council, was entrusted with the duties of government, which she performed faithfully, but which she gladly laid down on William's return. In these times of danger, however, she acted when necessary with courage and promptitude, as when in 1690 she directed the arrest of her uncle Henry Hyde, 2nd earl of Clarendon; but she was constantly anxious for William's safety, and unable to trust many of her advisers. She was further distressed by a quarrel with her sister Anne in 1692 following the dismissal of Marlborough, and this event somewhat diminished her popularity, which had hitherto been one of the mainstays of the throne. Weak in body and troubled in mind, the queen died at Kensington Palace from small-pox on the 28th of December 1694, and was buried in Westminster Abbey. Mary was a woman of a remarkably modest and retiring disposition, whose outstanding virtue was perhaps her unserving loyalty to William. Burnet has passed a few words on her pensive and melancholy disposition, but he has not failed to note that she was extremely pious and charitable; her blameless private life was in marked contrast with her surroundings, both in England and Holland; without bigotry she was greatly attached to the Protestant faith and to the Church of England; and she was always eager to improve the tone of public morals, and to secure a better observance of Sunday. Greenwich Hospital for Seamen was founded in her honour.

For the political events of Mary's life see William III. For her private life see Sir John Dalrymple, Memoirs of Great Britain and Ireland (London, 1790); Countess Bentinck, Lettres et mémoires de Marie, reine d'Angleterre (The Hague, 1880); Memoires et Lettres de Mary Queen of England (ed. by R. Doeber, Leipzig, 1886); F. J. L. Krämer, Marie II. Stuart (Utrecht, 1890); Agnes Strickland, Lives of the Queens of England (London, 1847); and O. Klopp, Der Fall des Hauses Stuart (Vienna, 1875-1888).
MARY QUEEN OF SCOTS (1542–1587), daughter of King James V. and his wife Mary of Lorraine, was born in December 1542, a few days before the death of her father, heart-broken by the disgrace of his arms at Solway Moss, where the disaffected nobles had declined to encounter an enemy of inferior force in the cause of a king whose systematic policy had been directed against the privileges of their order, and whose representative on the occasion was an unpopular favourite appointed general in defiance of their ill-will. On the 9th of September, the ceremony of coronation was duly performed upon the infant. A scheme for her betrothal to Edward, prince of Wales, was defeated by the grasping greed of his father, whose obvious ambition to annex the crown of Scotland at once to that of England aroused instantly the general suspicion and indignation of Scottish patriotism. In 1548 the queen of six years old was betrothed to the dauphin Francis, and set sail for France, where she arrived on the 13th of August. The society in which the child was thenceforward reared is known to readers of Brantôme as well as that of imperial Rome at its worst is known to readers of Suetonius or Petronius as well as that of papal Rome at its worst is known to readers of the diary kept by the domestic chaplain of Pope Alexander VI. Only in their pages can a parallel be found to the gay and easy record which reveals without sign of shame or suspicion of offence the daily life of a court compared to which the court of King Charles II. is as the court of Queen Victoria to the society described by Grammont. Debauchery of all kinds, and murder in all forms, were the daily matter of excitement or of jest to the brilliant circle which revolved around Queen Catherine de’ Medici. After ten years’ training under the tutelage of the woman whose main instrument of policy was the corruption of her own children, the queen of Scots, aged fifteen years and five months, was married to the eldest and feeblest of the brood on the 24th of April 1558. On the 17th of November Elizabeth became queen of England, and the princes of Lorraine—Francis the great duke of Guise, and his brother the cardinal—induced their niece and her husband to assume, in addition to the arms of France and Scotland, the arms of a country over which they asserted the right of Mary Stuart to reign as legitimate heiress of Mary Tudor. Civil strife broke out in Scotland between John Knox and the queen-dowager—between the self-styled “congregation of the Lord” and the adherents of the regent, whose French troops repelled the combined forces of the Scotch and their English allies from the beleaguered walls of Leith, little more than a month before the death of her mistress in the castle of Edinburgh, on the 10th of June 1560. On the 25th of August Protestantism was proclaimed and Catholicism suppressed in Scotland by a convention of states assembled without the assent of the absent queen. On the 9th of December Francis II. died; in August 1561 his widow left France for Scotland, having been refused a safe-conduct by Elizabeth on the ground of her own previous refusal to ratify the treaty made with England by her commissioners in the same month of the preceding year. She arrived nevertheless in safety at Leith, escorted by three of her uncles of the house of Lorraine, and bringing in her train her future biographer, Brantôme, and Chastelard, the first of all her voluntary victims. On the 21st of August she first met the only man able to withstand her; and their first passage of arms left, as he has recorded, upon the mind of John Knox an ineffaceable impression of her “profound mind, crafty wit and indurate heart against God and His truth.” And yet her acts of concession and conciliation were such as to offend on the opposite side could have approved. She assented, not only to the undisturbed maintenance of the new creed, but even to a scheme for the endowment of the Protestant ministry out of the confiscated lands of the Church. Her half-brother, Lord James Stuart, shared the duties of her chief counsellor with William Maitland of Lethington, the keenest and most liberal thinker in the country. By the influence of Lord James, in an interview with the earl of Morton, James Kirkcaldy, a tenant, was obtained for her to hear Mass celebrated in her private chapel—a licence to which, said the Reformer, he would have preferred the invasion of ten thousand Frenchmen. Through all the first troubles of her reign the young queen steered her skilful and dauntless way with the tact of a woman and the courage of a man. An insurrection in the north, headed by the earl of Huntly under pretext of rescuing from justice the life which his son had forfeited by his share in a homicidal brawl, was crushed at a blow by the Lord James against whose life, as well as against his sister’s liberty, the conspiracy of the Gordoners was aimed, and on whom, after the father had fallen in fight and the son had expiated his double offence on the scaffold, the leading rebel’s earldom of Murray was conferred by the gratitude of the queen. Exactly four months after the battle of Corrichie, and the subsequent execution of a criminal whom she is said to have “loved entirely,” had put an end to the first insurrection raised against her, Pierre de Boscobel de Chastelard, who had returned to France with the other companions of her arrival, and in November 1562 had revisited Scotland, exipated with his head the offence or the misfortune of a second detection at night in her bed-chamber. In the same month, twenty-five years afterwards, the execution of his mistress, according to the verdict of her contemporaries in France, avenged the blood of a lover who had died without uttering a word to realize the apprehension which (according to Knox) had before his trial impelled her to desire her brother “that, as he loved her, he would say Chastelard, and let him never speak word.” And in the same month, two years from the date of Chastelard’s execution, her first step was unconsciously taken on the road to Fotheringhay, when she gave her heart at first sight to her kinsman Henry, Lord Darnley, son of Matthew Stuart, earl of Lennox, who had suffered an exile of twenty years in expiation of his intrigues with England, and had married the niece of King Henry VIII., daughter of his sister Margaret, the widow of James IV., by her second husband, the earl of Angus. Queen Elizabeth, with the almost incredible want of tact or instinctive delicacy which distinguished and disfigured her vigorous intelligence, had recently proposed as a suitor to the queen of Scots her own low-born favourite, Lord Robert Dudley, the widower if not the murderer of Amy Robsart; and she now protested against the project of marriage between Mary and Darnley. Mary who had already married her kinsman in secret at Stirling Castle with Catholic rites celebrated in the apartment of David Rizzio, her secretary for correspondence with France, assured the English ambassador, in reply to the protest of his mistress, that the marriage would not take place for three months, when a dispensation from the pope would allow the cousins to be publicly united without offence to the Church. On the 29th of July 1562 they were accordingly remarried at Holyrood. The hapless and worthless bridegroom had already incurred the hatred of two powerful enemies, the earls of Morton and Glaucain; but the former of these took part with the queen against the forces raised by Murray, Glencain and others, under the nominal leadership of Hamilton, duke of Chatelherault, on the double plea of danger to the new religion of the country, and of the illegal proceeding by which Darnley had been proclaimed king of Scots without the needful constitutional assent of the estates of the realm. Murray was cited to attend the “raird” or array levied by the king and queen, and was duly denounced by public blast of trumpet for his non-appearance. He entered Edinburgh with his forces, but failed to hold the town against the car of Darnley. Darnley himself, backed by the advance of the royal army, which was now joined by James Hepburn, earl of Bothwell, on his return from a three years’
outlawed exile in France. He had been accused in 1562 of a plot to seize the queen and put her into the keeping of the earl of Arran, whose pretensions to her hand ended only when his insanity could no longer be concealed. Another new adherent was the son of the late earl of Huntly, to whom the forfeited honours of his house were restored a few months before the marriage of his sister to Bothwell. The queen now appealed to France for aid; but Castelnaud, the French ambassador, replied to her overtures by some sneering jest, which by his jesture to make peace with the malcontents. This counsel was rejected, and in October 1565 the queen marched an army of 18,000 men against them from Edinburgh; their forces dispersed in face of superior numbers, and Murray, on seeking shelter in England, was received with contumely by Elizabeth, whose half-hearted help had failed to support his enterprise, and whose intercession for his return found at first no favour with the queen of Scots. But the conduct of the besotted boy on whom at their marriage she had bestowed the title of king began at once to justify the enterprisers and to play into the hands of all who were his father's enemies, and the father set him on to demand the crown matrimonial, which would at least have assured to him the rank and station of independent royalty for life. Rizzio, hitherto his friend and advocate, induced the queen to reply by a reasonable refusal to this hazardous and audacious request. Darnley at once threw himself into the arms of the party opposed to the policy of the queen and her secretary—a policy which at that moment was doubly and trebly calculated to exasperate the fears of the religious and the pride of the patriotic. Mary was invited if not induced by the king of Spain to join his league for the suppression of Protestantism; while the actual or prospective enmity of Rizzio with Morton's office of chancellor, and the projected attainder of Murray and his allies, combined to inflame at once the anger and the apprehension of the Protestant nobles. According to one account, Darnley privately assured his uncle George Douglas of his wife's infidelity; he had himself, if he might be believed, discovered the secretary in the queen's apartment at midnight, under circumstances yet more unequivocally compromising than those which had brought Chaistelhar to the scaffold. Another version of the pitiful history represents Douglas as infusing suspicion of Rizzio into the empty mind of his nephew, and thus winning his consent to a deed already designed by others. A bond was drawn in which Darnley pledged himself to support the confederates who undertook to punish "certain privy persons" offensive to the state, "especially a strange Italian, called Davie"; another was subscribed by Darnley and the banished lords, then biding their time in Newcastle, which engaged him to procure their pardon and restoration, while pledging them to insure to him the enjoyment of the title he coveted, with the consequent security of an undisputed succession to the crown, despite the counter claims of the house of Hamilton, in case his wife should die without issue—a result which, intentionally or not, he and his fellow-conspirators did all that brutality could have suggested to accelerate and secure. On the 9th of March the palace of Holyrood was invested by a troop under the command of Morton, while Rizzio was dragged by force out of the queen's presence and slain without trial in the heat of the moment. The parliament was discharged by proclamation issued in the name of Darnley as king; and in the evening of the day the banished lords, whom it was to have condemned to outlawry, returned to Edinburgh. On the day following they were graciously received by the queen, who undertook to sign a bond for their security, but delayed the subscription till next morning under plea of sickness. During the night she escaped with Darnley, whom she had already seduced from the party of his accomplices, and arrived at Dunbar on the third morning after the slaughter of her favourite. From thence they returned to Edinburgh on the 28th of March, guarded by two thousand horsemen under the command of Bothwell, who had escaped from Holyrood on the night of the murder, to raise a force on the queen's behalf with his unprecedented popularity. The slayers of Rizzio fled to England, and were outlawed; Darnley was permitted to protest his innocence and denote his accomplices; after which he became the scorn of all parties alike, and few men dared or cared to be seen in his company. On the 19th of June a son was born to his wife, and in the face of his previous protestations he was induced to acknowledge himself the father. But, as Murray and his partisans returned to favour and influence no longer incompatible with that of Bothwell and Huntly, he grew desperate enough with terror to dream of escape to France. This design was at once frustrated by the queen's resolution, summoned him to declare his reasons for it in presence of the French ambassador and an assembly of the nobles; she besought him for God's sake to speak out, and not spare her; and at last he left her presence with an avowal that he had nothing to allege. The favour shown to Bothwell had not yet given occasion for scandal, though his character as an adventurous libertine was as notable as his reputation for military hardihood; but as the summer advanced his insolence increased with his influence at court and the general aversion of his rivals. He was richly endowed by Mary from the great and lesser spoils of the Church; and the three wardenships of the border, united for the first time in his person, gave the lord high admiral of Scotland a position of unequaled power. In the gallant discharge of its duties he was dangerously wounded by a leading outlaw, whom he slew in single combat; and while yet confined to Hermitage Castle he received a visit of two hours from the queen, who rode thither from Jedburgh and back through 20 miles of the wild borderland where her person was in perpetual danger from the freebooters whom her father's policy had driven and failed to extirpate. In the midst of this hideous thorns' fever, after which she removed by short stages to Craigmillar, where a proposal for her divorce from Darnley was laid before her by Bothwell, Murray, Huntly, Argyle and Lethington, who was chosen spokesman for the rest. She assented on condition that the divorce could be lawfully effected without impeachment of her son's legitimacy; whereupon Lethington undertook in the name of all present that she should be rid of her husband without any prejudice to the child—at whose baptism a few days afterwards Bothwell took the place of the putative father, though Darnley was actually residing under the same roof, and it was not till after the ceremonies that he was suddenly struck down by a sickness so violent as to excite suspicions of poison. He was removed to Glasgow, and left for the time in charge of his father; but on the news of his progress towards recovery a bond was drawn up for execution of the sentence of death which had secretly been pronounced against the twice-turned traitor who had earned his doom at all hands alike. On the 2nd of the next month (Jan. 1567) the queen visited her husband at Glasgow and proposed to remove him to Craigmillar Castle, where he would have the benefit of medicinal baths; but instead of this return he was conveyed on the last day of the month to the lonely and squalid shelter of the residence which was soon to be made memorable by his murder. Between the ruins of two sacred buildings, with the town-wall to the south and a suburban hamlet known to ill fame as the Thieves' Row to the north of it, a lodging was prepared for the titular king of Scotland, and fitted up with tapestries taken from the Gordons after the battle of Corrichie. On the evening of Sunday, the 9th of February, Mary took her last leave of the miserable boy who had so often and so mortally outraged her as consort and as queen. That night the fragile city was shaken out of sleep by an explosion of gunpowder which shattered to fragments the building in which he should have slept and perished; and the next morning the bodies of Darnley and a page were found strewn in a garden adjoined it, whither they had apparently escaped over a wall, to be despatched by the hands of Bothwell's attendant confederates. Upon a view which may be taken of Mary's conduct during the next three months depends the whole debatable question of her character. According to the professed champions of that character, this conduct was a tissue of such dastardly imbecility, such heartless irresolution as such brainless inconsistency as for ever to dispose of her time-honoured claim to the credit of intelligence and courage. It is certain that just three months
and six days after the murder of her husband she became the wife of her husband’s murderer. On the 11th of February she wrote to the bishop of Glasgow, her ambassador in France, a brief letter of simple eloquence, announcing her providential escape from a design upon her own as well as her husband's life. A reward of two thousand pounds was offered by proclamation for discovery of the murderer. Bothwell and others, his satellites or the queen’s, were instantly placarded by name as the criminals. Voices were heard by night in the streets of Edinburgh calling down judgment on the assassins. Four days after the discovery of the bodies, David Stewart, the bishop of the chapel of Holyrood with secrecy as remarkable as the solemnity with which Rizzio had been interred there less than a year before. On the Sunday following, Mary left Edinburgh for Seton Palace, 12 miles from the capital, where scandal asserted that she passed the time merrily in shooting-matches with Bothwell for her partner against Lords Seton and Huntly; other accounts represent Huntly and Bothwell as left at Holyrood in charge of the infant prince. Gracefully and respectfully, with statesmanlike yet feminine dexterity, the demands of Darnley’s fancied necessity and the murder of Rizzio were eluded by his daughter-in-law. Bothwell, with a troop of fifty men, rode through Edinburgh defiantly denouncing vengeance on his concealed accusers. As weeks elapsed without action on the part of the royal widow, while the cry of blood was up throughout the country, raising echoes from England and abroad, the murmur of accusation began to rise against her also. Murray, with his sister’s ready permission, withdrew to France. Already the report was abroad that the queen was bent on marriage with Bothwell, whose last year’s marriage with the sister of Huntly would be dissolved, and the assent of his wife’s brother purchased by the restitution of his forfeited estates. According to the Memoirs of Sir James Melville, both Lord Herries and himself resolved to appeal to the queen in terms of bold and earnest remonstrance against so desperate and scandalous a design; Herries, having been met with assurances of its unreality and professions of astonishment at the suggestion, instantly fled from court; Melville, evading the danger of a merely personal protest without backers to support him, laid before Mary a letter from a loyal Scot long resident in England, which urged upon her consideration and her conscience the danger and disgrace of such a project yet more freely than Herries had ventured to do by word of mouth; but the sole result was that it needed all the queen’s courage and resolution to rescue him from the violence of the man for whom, she was reported to have said, she cared not if she lost France, England and her own country, and would go with him to the world’s end in a white petticoat before she would leave him. On the 28th of March the privy council, in which Bothwell himself sat, appointed the 12th of April as the day of his trial, Lennox, instead of the crown, being named as the accuser, and cited by royal letters to appear at “the humble request and petition of the said Earl Bothwell,” who, on the day of the trial, had 4000 armed men behind him in the streets, while the castle was also at his command. Under these arrangements it was not thought wonderful that Lennox discreetly declined the danger of attendance, even with 3000 men ready to follow him, at the risk of desperate street fighting. He pleaded Sickness, asked for more time, and demanded that the accused, instead of enjoying special favour, should share the treatment of other suspected criminals. But, as no particle of evidence on his side was advanced, the protest of his representative was rejected, and Bothwell, acquitted in default of witnesses against him, was free to challenge any persistent accuser to the ancient ordeal of battle. His wealth and power were enlarged by gift of the parliament which met on the 14th and rose on the 19th of April—a date made notable by the subsequent supper at Ainslie’s tavern, where Bothwell obtained the signatures of its leading members to a document affirming his innocence, and pledging the subscribers to maintain it against all challengers, to stand by him in all his quarrels and finally to promote by all means in their power the marriage by which they recommended the queen to reward his services and benefit the country. On the second day following Mary went to visit her child at Stirling, where his guardian, the earl of Mar, refused to admit more than two women in her train. It was well known in Edinburgh that Bothwell had a body of men ready to intercept her on the way back, and carry her to Dunbar—not, as was naturally inferred, without good assurance of her consent. On the 24th of April, as she approached Edinburgh, Bothwell accordingly met her at the head of 800 spearmen, assured her (as she afterwards averred) that she was in the utmost peril, and escorted her, together with Huntly, Lennox and Melville, who sat, in waiting set, in attendance, to Dunbar Castle. On the 3rd of May Lady Jane Gordon, who had become countess of Bothwell on the 22nd of February of the year preceding, obtained, on the ground of her husband’s infidelities, a separation which, however, would not under the old laws of Catholic Scotland have left him free to marry again; on the 7th, accordingly, the necessary divorce was pronounced, after two days’ session, by a clerical tribunal which ten days before had received from the queen a special commission to give judgment on a plea of somewhat apocryphal consanguinity alleged by Bothwell against the legitimacy of an illegitimate and for generations legitimate son of his wife. The fact was studiously evaded or concealed that a dispensation had been granted by the archbishop of St Andrews for this irregularity, which could only have arisen through some illicit connexion of the husband with a relative of the wife between whom and himself no affinity by blood or marriage could be proved. On the day when the first or Protestant divorce was pronounced, Mary and Bothwell returned to Edinburgh with every prepared appearance of a peaceful triumph. Lest her captivity should have been held to invalidate the late legal proceedings in her name, proclamation was made of forgiveness accorded by the queen to her captor in consideration of his past and future services, and her intention was announced to reward them by further promotion; and on the same day (May 12), he was duly created duke of Orkney and Shetland. The duke, as a conscientious Protestant, refused to marry his mistress according to the rites of her Church, and she, the chosen champion of its cause, agreed to be married to him, not merely by a Protestant but by one who before his conversion had been a Catholic bishop, and should therefore have been more hateful and contemptible in her eyes than any ordinary heretic, had not religion as well as policy, faith as well as reason, been absorbed or superseded by some more mastering passion or emotion. This passion or emotion, according to those who deny her attachment to Bothwell, was simply terror—the blind and irrational prostration of an abject spirit before the cruel force of circumstances and the crafty wickedness of men. Hitherto, according to all evidence, she had shown herself on all occasions, as on all subsequent occasions she indisputably showed herself, the most fearless, the most keen-sighted, the most ready-witted, the most high-spirited of women; gallant and generous, skilful and practical, never to be cowed by fortune, never to be cajoled by craft; neither more unselﬁsh in her ends nor more unscrupulous in her practice than might have been expected from her training and her creed. But at the crowning moment of trial there are those who assert their belief that the woman who on her way to the field of Corrichie had uttered her wish to be a man, that she might know all the hardship and all the enjoyment of a soldier’s life, riding forth “in jack and knapsack”—the woman who long afterwards was to hold her own for two days together without help of counsel against all the array of English law and English statesmanship, armed with inefﬁrable evidence and supported by the resentment of a nation—showed herself equally devoid of moral and of physical resolution; too senseless to realize the signiﬁcance and too heartless to face the danger of a situation from which the simplest exercise of reason, principle or courage must have rescued the most unsuspicious and inexperienced of honest women who was not helplessly deﬁcient in self-reliance and self-respect. The famous correspondence produced next year in evidence against her at the conference of York may have been, as her partisans affirm, so craftily garbled and falsiﬁed by interpolation, suppression, perversion, or
absolute forgery as to be all but historically worthless. Its acceptance or its rejection does not in any degree whatever affect, for better or for worse, the rational estimate of her character. The problem presented by the simple existence of the facts just summed up remains in either case absolutely the same.

That the coarse and imperious nature of the hardy and able ruffian who had now become openly her master should no less openly have shown itself even in the first moments of their inauspicious union is what any bystander of common insight must inevitably have foreseen. Tears, dejection and passionate expressions of a despair "wishing only for death," bore fateful and variable witness to her first sense of a heavier yoke than yet had galled her spirit and her pride. At other times her affectionate gaiety would give evidence as trustworthy of a fearless and improvident satisfaction. They rode out in state together, and if he kept cap in hand as a subject she would snatch it from him and clap it on his head again; while in graver things she took all due or possible care to gratify his ambition, by the insertion of a clause in their contract of marriage which made their joint signature necessary to all documents of state issued under the sign-manual. She despatched to France a special envoy, the bishop of Dunblane, with instructions setting forth at length the unparalleled and hitherto ill-required services and merits of Bothwell, and the necessity of compliance at once with his passion and with the unanimous counsel of the nation—a people who would endure the rule of no foreign consort, and whom none of their own countrymen were so competent to control, alike by wisdom and by valour, as the incomparable subject of her choice. These personal merits and this political necessity were the only pleas advanced in a letter to her ambassador in England. But that neither plea would avail her for a moment in Scotland she had ominous evidence on the thirteenth day after her marriage, when no response was made to the usual form of proclamation for a raid or levy of forces under pretext of a campaign against the rievers of the border. On the 6th or 7th of June Mary and Bothwell took refuge in Borthwick Castle, twelve miles from the capital, where the fortress was in the keeping of an adherent whom the diplomacy of Sir James Melville had succeeded in detaching from his allegiance to Bothwell. The fugitives were pursued and besiegured by the earl of Morton and Lord Hume, who declared their purpose to rescue the queen from the thralldom of her husband. He escaped, leaving her free to follow him or to join the party of her professed deliverers. But whatever cause she might have found since marriage to complain of his rigorous custody and domineering brutality was insufficient to break the ties by which he held her. Alone, in the disguise of a page, she slipped out of the castle at midnight, and rode off to meet him at a tower two miles distant. There she joined together, where they had together with the confederate lords on entering Edinburgh were welcomed by the citizens, and after three hours' persuasion Lethington, who had now joined them, prevailed on the captain of the castle to deliver it also into their hands. Proclamations were issued in which the crime of Bothwell was denounced, and the disgrace of the country, the thralldom of the queen and the mortal peril of her infant son, were set forth as reasons for summoning all the lieges of the chief cities of Scotland to rise in arms on three hours' notice and join the forces assembled against the one common enemy. News of his approach reached them on the night of June 14, and they marched before dawn with 2200 men to meet him near Musselburgh. Mary meanwhile had passed from Dunbar to Haddington, and thence to Seton, where 1600 men rallied to her side. On the 15th of June, one month from their marriage day, the queen and Bothwell, at the head of a force of fairly equal numbers but visibly inferior discipline, met the army of the confederates at Carberry Hill, some six miles from Edinburgh. Du Croc, the French ambassador, obtained permission through the influence of Maitland to convey to the queen the terms proposed by his leaders—that she and Bothwell should part, or that he should meet in single combat a champion chosen from among their number. Bothwell offered to meet any man of sufficient quality; Mary would not assent. As the afternoon wore on their force began to melt away by desertion and to break up for lack of discipline. Again the trial by single combat was proposed, and thrice the proposal fell through, owing to objections on this side or on that. At last it was agreed that the queen should yield herself prisoner, and Bothwell be allowed to retire in safety to Dunbar with the few followers who remained to him. Mary took leave of her first and last master with passionate anguish and many parting kisses; but in face of his enemies, and in hearing of the cries which burst from the ranks, demanding her death by fire as a murderer and harlot, the whole heroic and passionate spirit of the woman, represented by her admirers as a spiritless imbecile, flamed out in responsive threats to have all the men hanged and crucified, in whose power she now stood helpless and alone. She grasped the hand of Lord Lindsay as he rode beside her, and swore "by this hand" she would "have his head for this." In Edinburgh she was received by a yelling mob, which flaunted before her at each turn a banner representing the corpse of Darnley with her child beside it invoking on his knees the retribution of divine justice. From the violence of a multitude in which women of the worst class were more furious than the men she was sheltered in the house of the provost, where she repeatedly showed herself at the window, appealing aloud with dishevelled hair and dress to the mercy which no man could look upon her and refuse. At nine in the evening she was removed to Holyrood, and thence to the port of Leith, where she embarked under guard, with her attendants, for the island castle of Loch leven. On the 2oth a silver casket containing letters and French verses, miscalled sonnets, in the handwriting of the queen, was taken from the port of the castle, and brought by Bothwell to bring it from Edinburgh to Dunbar. Even in the existing versions of the letters, translated from the lost originals and retranslated from this translation of a text which was probably destroyed in 1603 by order of King James on his accession to the English throne—even in these possibly disfigured versions, the fiery pathos of passion, the fierce and piteous fluctuations of spirit between love and hate, hope and rage and jealousy, have an eloquence apparently beyond the imitation or invention of art (see Casket Letters1). Three days after this discovery Lord Lindsay, Lord Ruthven and Sir Robert Melville were despatched to Lochleven, there to obtain the queen's signature to an act of abdication in favour of her son, and another appointing Murray regent during his minority. She submitted, and a commission of regency was established till the return from France of Murray, who, on the 15th of August, arrived at Lochleven with Morton and Athole. According to his own account, the expostulations as to her past conduct which preceded his admonitions for the future were received with tears, confessions and attempts at extenuation or excuse; but when they parted that day on good terms she had regained her usual spirits. Nor for the Casket Letters is the same reason to stand. In spite of the close keeping in which she was held, with the daughters of the house for bedfellows. Their mother and the regent's, her father's former mistress, was herself not impervious to her prisoner's lifelong power of seduction and subjugation. Her son George Douglas fell inevitably under the charm. A rumour transmitted to England went so far as to assert that she had proposed to him their common half-brother Murray as a fourth husband for herself; a later tradition represented her as the mother of both. A third report was that she was unapprovable as either, asserted that a daughter of Mary and Bothwell, born about this time, lived to be a nun in France. It is certain that the necessary removal of George Douglas from Lochleven enabled him to devise a method of escape for the prisoner on the 25th of March, 1568, which was frustrated by detection of her white hands under the disguise of a laundress. But a younger member of the household, Willie Douglas, aged eighteen, whose devotion was afterwards remembered and his safety cared for by Mary at a time of utmost risk and perplexity to herself, succeeded on the 2nd of May in assisting her to escape by a 1It is to be observed that the above conclusion as to the authen-
ticity of the Casket Letters is the same as was reached on dif-
ferent grounds by the most recent research on the subject.—Ed. E. B.
postern gate to the lake-side, and thence to a boat to the main-
land, where George Douglas, Lord Seton and others were await-
ing her. Thence they rode to Seton's castle of Niddry, and
next day to Hamilton palace, round which an army of 6000 men
was soon assembled, and whither the new French ambassador
to Scotland hastened to pay his duty. The queen's abdication
was revoked, messengers were despatched to the English and
French courts, and word was sent to Murray at Glasgow that
he must resign the regency, and should be pardoned in common
with all offenders against the queen. But on the day when
Mary arrived at Hamilton Murray had summoned to Glasgow
the feudatories of the Crown to take arms against the insurgent
enemy. Having written to Elizabeth of her need of help to her
kinswoman, provided she would accept of English
intervention and abstain from seeking foreign assistance; but
the messenger came too late. Mary's followers had failed to
retake Dunbar Castle from the regent, and made for Dumbarton
instead, marching two miles south of Glasgow, by the village
of Langside. Here Murray, with 4500 men, under leaders of
high distinction, met the 6000 of the queen's army, whose ablest
man, Herries, was as much distracted by Mary as by every one
else, while the Hamiltons could only be trusted to think of their
own preservation. Emissaries for Elizabeth were sent, with the
promise of a grant of the house of Lennox, tallying so exactly with the text of the
letter as to have been cited in proof that the latter must needs be
a forgery. Elizabeth, on the close of the evidence, invited
Mary to reply to the proofs alleged before she could be admitted
to her presence; but Mary simply desired her commissioners to
withdraw from the conference. She declined with scorn the pro-
sal made by Elizabeth through Knollys, that she should sign a
second abdication in favour of her son. On the 10th of January,
1569, the judgment given at the conference acquitted Murray and his adherents of rebellion, and confirming that nothing had been
proved against Mary—a verdict accepted by Murray as equiva-
 lent to a practical recognition of his office as regent for the infant
king. This position he was not long to hold; and the fierce
exultation of Mary at the news of his murder gave to those who
believed in her complicity with the murderer, on whom a pension
was bestowed by her unblushing gratitude, fresh reason to fear,
if her liberty of correspondence and intrigue were not restrained,
the likelihood of a similar fate for Elizabeth. On the 26th of Jan-
uary 1569 she had been removed from Bolton Castle to Tutbury
in Staffordshire, where proposals were conveyed to her, at the
instigation of Leicester, for a marriage with the duke of Norfolk,
to which she gave a graciously conditional assent; but the dis-
covery of these proposals consigned Norfolk to the Tower, and
on the outbreak of an insurrection in the north Mary, by Lord
Hunsdon's advice, was again removed to Coventry, when a body
of her intending deliverers was within a day's ride of Tutbury.
On the 23rd of January following Murray was assassinated; and
a second northern insurrection was crushed in a single sharp fight
by Lord Hunsdon. In October Cecil had an interview with Mary
at Bradford, on which the conditions of his position were
that she should go to the throne in compliance with French demands were debated
at length. The queen of Scots, with dauntless dignity, refused
to yield the castles of Edinburgh and Dumbarton into English
keeping, or to deliver up her fugitive English partisans then in
Scotland; upon other points they came to terms, and the articles
were signed the 10th of October. On the same day Mary wrote to
Elizabeth, requesting with graceful earnestness the favour of an
interview which might reassure her against the suggestion that
this treaty was a mere pretence. On the 28th of November she
was removed to Sheffield Castle, where she remained for the next
fourteen years in charge of the earl of Shrewsbury. The detection
of a plot, in which Norfolk was implicated, for the invasion of
England by Spain on behalf of Mary, who was then to take him
as the fourth and most contemptible of her husbands, made
necessary the reduction of her household and the stricter
confinement of her person. On the 28th of May 1572 a
command from both houses of parliament for her execution as
well as Norfolk's was generously rejected by Elizabeth; but
after the punishment of the traitorous pretender to her affections,
upon whom the conspirators had cast, and the publication of affectionate protestation, she fell into "a passion of
sickness" which convinced her honest keeper of her genuine
grief for the ducal castris. A treaty projected on the news of
the massacre of St Bartholomew, by which Mary should be sent
back to Scotland for immediate execution, was broken off by
the death of the earl of Mar, who had succeeded Lennox as regent;
and was it found possible to come to acceptable terms on a like
understanding with his successor Morton, who in 1577 sent a
proposal to Mary for her restoration, which she declined, in
the peril of her hand; and on the 21st of October she gave the
first sign of consent to the suggestion of a divorce from Bothwell.
On the 26th of October the charge of complicity in the murder of
Darnley was distinctly brought forward against her in spite of
Norfolk's reluctance and Murray's previous hesitation. Eliza-
beth, by the mouth of her chief justice, formally rebuked the
audacity of the subjects who durst bring such a charge against
their sovereign, and challenged them to advance their proofs.
They compiled by the production of an indictment under five
heads, supported by the necessary evidence of documents. The
number of English commissioners was increased, and they were
bound to preserve secrecy as to the matters revealed. Further
evidence was compiled, and the commissioners at Dumbarton
proceeded to take Elizabeth, which was a sentence of death. The
letters as to have been cited in proof that the latter must needs be
a forgery. Elizabeth, on the close of the evidence, invited
Mary to reply to the proofs alleged before she could be admitted
to her presence; but Mary simply desired her commissioners to
withdraw from the conference. She declined with scorn the pro-
sal made by Elizabeth through Knollys, that she should sign a
second abdication in favour of her son. On the 10th of January,
1569, the judgment given at the conference acquitted Murray and his adherents of rebellion, and confirming that nothing had been
proved against Mary—a verdict accepted by Murray as equiva-
 lent to a practical recognition of his office as regent for the infant
king. This position he was not long to hold; and the fierce
exultation of Mary at the news of his murder gave to those who
believed in her complicity with the murderer, on whom a pension
was bestowed by her unblushing gratitude, fresh reason to fear,
if her liberty of correspondence and intrigue were not restrained,
the likelihood of a similar fate for Elizabeth. On the 26th of Jan-
uary 1569 she had been removed from Bolton Castle to Tutbury
in Staffordshire, where proposals were conveyed to her, at the
instigation of Leicester, for a marriage with the duke of Norfolk,
to which she gave a graciously conditional assent; but the dis-
covery of these proposals consigned Norfolk to the Tower, and
on the outbreak of an insurrection in the north Mary, by Lord
Hunsdon's advice, was again removed to Coventry, when a body
of her intending deliverers was within a day's ride of Tutbury.
On the 23rd of January following Murray was assassinated; and
a second northern insurrection was crushed in a single sharp fight
by Lord Hunsdon. In October Cecil had an interview with Mary
at Bradford, on which the conditions of his position were
that she should go to the throne in compliance with French demands were debated
at length. The queen of Scots, with dauntless dignity, refused
to yield the castles of Edinburgh and Dumbarton into English
keeping, or to deliver up her fugitive English partisans then in
Scotland; upon other points they came to terms, and the articles
were signed the 10th of October. On the same day Mary wrote to
Elizabeth, requesting with graceful earnestness the favour of an

necessary the reduction of her household and the stricter
confinement of her person. On the 28th of May 1572 a
command from both houses of parliament for her execution as
well as Norfolk's was generously rejected by Elizabeth; but
after the punishment of the traitorous pretender to her affections,
upon whom the conspirators had cast, and the publication of affectionate protestation, she fell into "a passion of
sickness" which convinced her honest keeper of her genuine
grief for the ducal castris. A treaty projected on the news of
the massacre of St Bartholomew, by which Mary should be sent
back to Scotland for immediate execution, was broken off by
the death of the earl of Mar, who had succeeded Lennox as regent;
and was it found possible to come to acceptable terms on a like
understanding with his successor Morton, who in 1577 sent a
proposal to Mary for her restoration, which she declined, in
suspicion of a plot laid to entrap her by the policy of Sir Francis Walsingham, the most unscrupulously patriotic of her English enemies, who four years afterwards sent word to Scotland that the execution of Morton, so long the ally of England, would be answered by the execution of Mary. But on that occasion Elizabeth again refused her assent either to the trial of Mary or to her transference from Sheffield to the Tower. In 1581 Mary accepted the advice of Catherine de' Medici and Henry III, that she should allow her son's title to reign as king of Scotland conjointly with herself when released and restored to a share of the throne. This plan was but part of a schemed plot, which involved England by her kinsman the duke of Guise, who was to land in the north and raise a Scottish army to place the released prisoner of Sheffield beside her son on the throne of Elizabeth. After the overthrow of the Scottish accomplices in this notable project, Mary poured forth upon Elizabeth a torrent of pathetic and eloquent reproach for the many wrongs she had suffered at the hands of her hostess, and pledged her honour to the assurance that she now aspired to no kingdom but that of heaven. In the spring of 1583 she retained enough of this saintly resignation to ask for nothing but release and the resuming of her station in the government of Scotland; but Lord Burghley not unreasonably preferred, if feasible, to reconcile the alliance of her son with the detention of his mother. In 1584 the long-suffering earl of Shrewsbury was relieved of his fourteen years' charge through the involuntary good offices of his wife, whose daughter by her first husband had married a brother of Darnley; and their orphan child Arabella, born in England, of royal descent on the father's side, was now, in the hopeful view of her grandmother, a more plausible claimant than the king or queen of Scots to the inheritance of the English throne. In December 1583 Mary had been before the French ambassador her first complaint of the slanders spread by Lady Shrewsbury and her sons, who were ultimately compelled to confess the falsehood of their imputations on the queen of Scots and her keeper. It was probably at the time when a desire for revenge on her calumniators made her think the opportunity good and safe for discharge of such a two-edged dart at the counter and the queen that Mary wrote, but abstained from despatching, the famous and terrible letter in which, with many gracious excuses and professions of regret and attachment, she transmits to Elizabeth a full and vivid refutation of the hideous gossip retailed by Bess of Hardwick regarding her character and person at a time when the reporter of these abominations was on friendly terms with her husband's royal charge. In the autumn of 1584 she was removed to Wingfield Manor under charge of Sir Ralph Sadler and John Somers, who accompanied her also on her next removal to Tutfby in January 1585. A letter received by her in that cold, dark and unhealthy castle, of which fifteen years before she had made painful and malodorous experience, assured her that her son would acknowledge her only as queen-mother, and provoked at once the threat of a parent's curse and an application to Elizabeth for sympathy. In April 1585 Sir Amyas Paulet was appointed to the office of which Sadler, accused of careless indulgence, had requested to be relieved; and on Christmas Eve she was removed from the hateful shelter of Tutfby to the castle of Chartley in the same county. Her correspondence in cipher thence with her English agents abroad, intercepted by Walsingham and deciphered by his secretary, gave eager encouragement to the design for a Spanish invasion of England under the prince of Parma,—an enterprise in which she would do her utmost to make her son take part, and in case of his refusal would induce the Catholic nobles of Scotland to betray him into the hands of Philip, from whose tutelage he should be released only on her demand, or if after her death he should wish to return, nor then unless he had become a Catholic. But even these patriotic and maternal schemes to consign her child and re-consign the kingdom to the keeping of the Inquisition, incarnate in the widower of Mary Tudor, were superseded by the attraction of a conspiracy against the throne and life of Elizabeth. Anthony Babington, in his boyhood a ward of Shrewsbury, resident in the household at Sheffield Castle, and thus subjected to the charm before which so many victims had already fallen, was now induced to under-take the delivery of the queen of Scots by the murder of the queen of England. It is maintained by those admirers of Mary who assume her to have been an almost absolute imbecile, gifted with the power of imposing herself on the world as a woman of unsurpassed ability, that, while cognisant of the plot for her deliverance by English rebels and an invading army of foreign auxiliaries, she might have been innocently unconscious that this conspiracy involved the simultaneous assassination of Elizabeth. In the conduct and detection of her correspondence with Babington, traitor was playing against traitor, and spies were utilized against assassins, with as little success as was required or expected in the diplomacy of the time. As in the case of the casket letters, it is alleged that forgery was employed to inter-polate sufficient evidence of Mary's complicity in a design of which it is thought credible that she was kept in ignorance by the traitors and murderers who had enrolled themselves in her service,—that one who pensioned the actual murderer of Murray and a would-be murderer of Elizabeth was incapable of approving what her keen and practised intelligence was too blunt and torpid to detect, or incapable of conferring on it the general design. In August the conspirators were netted, and Mary was arrested at the gate of Tixall Park, whither Paulet had taken her under pretence of a hunting party. At Tixall she was detained till her papers at Chartley had undergone thorough research. That she was at length taken in her own toils even such a dullard as her admirers depict her could not have failed to understand; that she was no such dastard as to desire or deserve such defeners the whole brief course of her remaining life bore consistent and irrefragable witness. Her first thought on her return to Chartley was one of loyal gratitude and womanly sympathy. She cheered the wife of her English secretary, now under arrest, with promises to answer for her husband to all accusations brought against him, took her new-born child from the mother's arms, and in default of clergy baptized it, to Paulet's Puritan horror, with her own hands by her own name. The next or the twin-born impulse of her indomitable nature was, as usual in all times of danger, one of passionate and high-spirited defiance on discovering the seizure of her papers. A fortnight afterwards her 'keys and her money were, confiscated, while she, bedridden and unable to move her hand, could only ply the terrible weapon of a bitter and fiery tongue. Her secretaries were examined in London, and one of them gave evidence that she had first heard of the conspiracy by letter from Babington, of whose design against the life of Elizabeth she thought it best to take no notice in her reply, though she did not hold herself bound to reveal it. On the 25th of September she was removed to the strong castle of Fotheringay in Northamptonshire. On the 6th of October she was desired by letter from Elizabeth to answer the charges brought against her before certain of the chief English nobles appointed to sit in commission on the cause. In spite of her first refusal to submit, she was induced by the arguments of the vice-chamberlain, Sir Christopher Hatton, to appear before this tribunal on condition that her protest should be registered against the legality of its jurisdiction over a sovereign, the next heir of the English crown. On the 14th and 15th of October 1586 the trial was held in the hall of Fotheringay Castle. Alone, "without one counsellor on her side among so many," Mary conducted the whole of her own defence with courage incomparable and unsurpassable ability. Pathos and indignation, subtility and simplicity, personal appeal and political reasoning, were the alternate weapons with which she fought against all odds of evidence or inference, and disputed step by step every inch of debatable ground. She repeatedly insisted on the production of proof in her own handwriting as to her complicity with the project of the assassins who had expiated their crime on the 20th and 21st of the month preceding. When the charge was shifted to the question of her intrigues with Spain, she took her stand reputedly her own right to convey whatever right she possessed, though now no kingdom was left her for disposal, to whomsoever she might choose. One single slip she made in the whole course of
MARY QUEEN OF SCOTS

her defence; but none could have been more unluckily character- istic and significant. When Burghley brought against her the unanswerable charge of having at that moment in her service, and in receipt of an annual pension, the instigator of a previous attempt on the life of Elizabeth, she had the unwary audacity to cite in her justification the pensions allowed by Elizabeth to her adversaries in Scotland, and especially to her son. It is remarkable that just two months later, in a conversation with her keepers, she again made use of the same extraordinary argument in reply to the same inevitable imputation, and would not be brought to profess that the two pensions were not hers.

But except for this single instance of oversight or perversity her defence was throughout a masterpiece of indomitable ingenuity, of delicate and steadfast courage, of womanly dignity and genius. Finally she demanded, as she had demanded before, a trial either before the estates of the realm lawfully assembled or else before the queen in council. So closed the second day of the trial; and before the next day’s work could begin a note of two or three lines hastily written at midnight informed the commissioners that Elizabeth had suddenly determined to adjourn the expected judgment and transfer herself to the state-chamber. But here, on the 27th of October, the commissioners again met; and one of them alone, Lord Zouch, dissented from the verdict by which Mary was found guilty of having, since the 1st of June preceding, compassed and imagined divers matters tending to the destruction of Elizabeth. This verdict was conveyed to her, about three weeks later, by Lord Buckhurst and Robert Beale, clerk of the privy council. At the intimation that her life was an impediment to the security of the received religion, “she seemed with a certain unwonted alacrity to triumph, giving God thanks, and rejoicing in her heart that she was held to be an instrument” for the restoration of her own faith. This note of exultation as in martyrdom was maintained with unflinching courage to the last. She wrote to Elizabeth and the duke of Guise two letters of almost matchless eloquence and pathos, admirable especially for their loyal and grateful remembrance of all her faithful servants. Between the date of these letters and the day of her execution wellnigh three months of suspense elapsed. Elizabeth, fearless almost to a fault in face of physical danger, constant in her confidence even after discovery of her narrow escape from the poisoned bullets of household conspirators, was completely free to a crime in face of subtler and more complicated peril. She rejected with resolute dignity the intercession of French envoys for the life of the queen-dowager of France; she allowed the sentence of death to be proclaimed and welcomed with bonfires and bell-ringing throughout the length of England; she yielded a respite of twelve days to the pleading of the French ambassador, and had a charge trumped up against him of participation in a conspiracy against her life; at length, on the 1st of February 1587, she signed the death-warrant, and then made her secre- taries write word to Paulet of her displeasure that in all this time he should not of himself have found out some way to shorten the life of his prisoner, as in duty bound by his oath, and thus relieve her singularly tender conscience from the guilt of bloodshed. Paulet, with loyal and regretful inclination, declined the disgrace proposed to him in a suggestion “to shed blood without law or warrant”; and on the 7th of February the ears of Shrewsbury and Kent arrived at Fotheringay with the commis- sion of the council for execution of the sentence given against her prisoner. Mary received the announcement with majestic tranquillity, expressing in dignified terms her readiness to die, her consciousness that she was a martyr for her religion, and her total ignorance of any conspiracy against the life of Elizabeth. At night she took a graceful and affectionate leave of her atten- dants, distributed among them her money and jewels, wrote out in full the various legacies to be conveyed by her will, and charged her apothecary Goring with her last messages for the king of Spain. In these messages the whole nature of the woman was revealed. Not a single friend, not a single enemy, was forgotten; the slightest service, the slightest wrong, had its place assigned in her faithful and implacable memory for retribution or reward. Forgiveness of injuries was as alien from her fierce and loyal spirit as forgetfulness of benefits; the destruction of England and its liberties by Spanish invasion and conquest was the strongest aspiration of her parting soul. At eight next morning she entered the hall of execution, having taken leave of the weeping envoy from Scotland, to whom she gave a brief message for her son; took her seat on the scaffold, listened with an air of even cheerful unconcern to the reading of her sentence, solemnly declared her innocence of the charge conveyed in it and her consolation in the prospect of ultimate justice, rejected piteously the proffered一台 that of water, that of food. And, as her head was laid on the block, her spirit, compact and unanswerable, still swung in the atmosphere of her faith, as though by the power of her lips she might recall the whole body of the people to the memory of her name, of her innocent sufferings, of her martyrdom.

Mary Stuart was in many respects the creature of her age, of her sex, and of her situation; but she had the noblest and most noteworthy qualities of her master; was beloved of her people, and had enough confidence in the justice of her cause for her conscience to count the world’s opinion or time. Even the detractors who defend her conduct on the plea that she was a dastard and a dupe are compelled in the same breath to retract this implied reproach, and to admit, with illogical acclamation and incongruous applause, that the world never saw more splendid courage at the service of more brilliant intelligence, that a braver if not “a rarer spirit never did steer humanity.” A kinder or more faithful friend, a deadlier or more dangerous enemy, it would be impossible to conceive of in the life of Mary Stuart. Passion alone could shake the double fortress of her impregnable heart and ever-active brain. The passion of love, after very sufficient experience, she apparently and naturally outlived; the passion of hatred and revenge was as inextinguishable in her inmost nature as the emotion of loyalty and gratitude. Of repentance it would seem that she knew as little as of fear, having been trained from her infancy in a religion where the Decalogue was supplanted by the Creed. Adept as she was in the most exquisite delicacy of dissimulation, the most salient note of her original disposition was daring rather than subtlety. Beside or behind the voluptuous or intellectual attitude of her mind or conduct, a charm of a fearless and frank simplicity, a genuine and enduring pleasure in small and harmless things no less than in such as were neither. In 1562 she amused herself for some days by living “with her little troop” in the house of a burgess of St Andrews “like a burgess’s wife,” assuring the English ambas- sador that she should not find the queen there,—“nor I know not myself where she is become.” From Sheffield Lodge, twelve years later, she applied to the archbishop of Glasgow and the cardinal of Guise for some pretty little dogs, to be sent her in baskets very warmly packed,—“for besides reading and working, I take pleasure only in all the little animals that I can get.” No lapse of reconciling time, no extent of comparative indulgence, could break her in to resignation, submission, or toleration of even partial restraint. Three months after the massacre of St Bartholomew had caused some additional restrictions to be placed upon her freedom of action, Shrewsbury writes to Burghley that “rather than continue this imprisonment she sticks not to say she will give her body, her son, and country for liberty”; nor did she ever show any excess of regard for any of the three. For her own freedom of will and of way, of passion and of action, she cared much; for her creed she cared something; for her country she cared less than nothing. She would have flung Scotland with England into the hell fire of Spanish Catholicism rather than forgo the faintest chance of personal revenge. Her profession of a desire to be instructed in the doctrines of Anglican Protestantism was so transparently a pious fraud as rather to afford confirmation than to arouse suspicion of her fidelity to the teaching of her church. Elizabeth, so shamefully her inferior in personal loyalty, fidelity and gratitude, was as clearly her superior on the one all-important point of patriotism. The
MARY OF BURGUNDY—MARY OF FRANCE

saving salt of Elizabeth's character, with all its wellnigh incredible mixture of heroism and egotism, meanness and magnificence, was simply this, that, overmuch as she loved herself, she did yet love England better. Her best though not her only fine qualities were national and political, the high public virtues of a good public servant; in the private and personal qualities which attract and attach a friend to his friend and a follower to his leader, no man or woman was ever more constant and more eminent than Mary Queen of Scots.

(A. C. S.)

BIBLIOGRAPHY.—The biography of Mary Stuart being virtually the queen's life, the historical record made by St. Placidus, the narrative written by St. Placidus, the list of Events relating to St. Placidus, the events which throw light on the first century of Elizabeth's life, the events which figure in the general histories of both countries, the most important original documents and voluminous papers preserved in State archives, with other MS. documents preserved at the British Museum, the Cambridge University Library, Hatfield and elsewhere. See especially the Reports of the Hist. MSS. Commission; Calendar of State Papers relating to Scotland and Mary Queen of Scots (Scottish Record Publ. 1898); Calendar of Letters and State Papers relating to English Affairs, principally in the Archives at Simancas (vols. i.–iv., 1892–1899); and the Calendars of State Papers: Domestic Series, Edw. VI. James I., Foreign Series, Elizabeth, Venice Series.

The most important unofficial contemporary works are the Histories of John Knox, Bishop John Lesley, George Buchanan, and Sir Matthew Pitsan and, more particularly, John Melville's Occurrents from the death of James IV., till 1575 (Bannatyne Club, 1834); Robert Burrill's "Diary" in S. J. G. Dalzel's Fragments of a Swiss Journal of the Reign of Mary, Queen of Scots, edited by her secretary Claude Nau, ed. by J. Stevenson (Edinburgh, 1853); Sir James Melville's Memoirs of his own Life (Bannatyne Club, 1827); Richard Bannatyne, Memoiries of Transactions in Scotland, and in the British and Hibernian Settlements, 1635; and the Memoirs of the Franchise. See "Histoire de l'étoile siècle (ed. by J. B. A. Tqtet, 5 vols. Paris, 1862), containing important original letters and documents; Thomas Wright's Queen Elizabeth and her Times (2 vols., London, 1838), containing a great number of Elizabethan men and women who refer to Mary, and others are to be found in Sir Henry Ellis's Original Letters Illustrative of English History (London, 1825–1846); much of Mary's own correspondence will be found in Prince A. Labouin and Edmond Hameau, Correspondance de Charles IX. avec de la France (Paris, 1838), selections from which have been translated into English by W. Turnbull in Letters of Mary Queen of Scots (London, 1845), and by Agnes Strickland in Letters of Mary Queen of Scots and Documents connected with her Personal History (3 vols., London, 1842). Among authorities not actually contemporary but written within a century of her death, which are of great importance, we may mention the Kirk of Scotland (8 vols., Edinburgh, 1842–1849); Archbishop Spottiswoode's Hist. of the Church of Scotland (ed. by M. Russell, 3 vols., Edinburgh, 1858); Sir J. R. McCulloch's History of the Church and State in Scotland (Spottiswoode Society ed., 1844), to which should be added the modern classic, George Grub's Ecclesiastical History of Scotland (4 vols., Edinburgh, 1861).

Of contemporary writers the most important on the subject are the Histories of England by Hume, Lingard and Froude; and the Histories of Scotland by Robertson, P. F. Tytler, John Hill Burton, Malcolm Laing and Andrew Lang. Numerous biographies of Mary Stuart have been published, as well as essays and treatises dealing with particular episodes in her life, of which the most worthy of mention are: George Chalmers, Life of Mary Queen of Scots (2 vols., London, 1812); Henry Glassford Bell, Life of Mary Queen of Scots (2 vols., Edinburgh, 1828–1831); the "Life in Agnes Strickland's Lives of the Queens of Scotland (8 vols., Edinburgh, 1850); J. D. Leader, Mary Queen of Scots in Captivity (Sheffield, 1898); Mrs Maxwell-Scott, The Tragedy of Fotheringay (London, 1895); Miss Aspinall, Life of Mary Stuart (London, 1883); Mrs Maxwell-Scott, History of Queen Mary (London, 1895); Mrs Maxwell-Scott, The Tragedy of Fotheringay (London, 1895); F. A. M. Mignet, Histoire de Marie Stuart (3 vols. Brussels, 1851); Martin Phillipps, Histoire du règne de Marie Stuart (5 vols., Paris, 1891); Sir John Skelton, Mary Stuart (London, 1893), Metieiland of Lethington and the Scotland of Mary Stuart (2 vols., Edinburgh, 1889); The Impeachment of Mary Stuart (2 vols., London, 1889); and The Marquis of Queen Mary of Scots, including the Defence of Mary Stuart (Edinburgh, 1889); Joseph Stevenson, Mary Stuart: The First Eighteen Years of her Life (2 vols., London, 1896); and by Fleure, The Life of Mary Stuart (2nd ed., 1698); Jane Stoddart, Girldhood of Mary Queen of Scots.

With special reference to the controversy concerning the Casket Letters, in addition to the article Casket Letters and the above-mentioned Life of Mary Stuart, John Stevenson has followed, as has also Walter Goddall, Examination of the Letters said to be written by Mary Queen of Scots to Bothwell (2 vols., Edinburgh, 1754), which contains the letters themselves; William Tytler, Inquiry into the Evidence against Mary Queen of Scots (2 vols., London, 1790); John Whitaker, Mary Queen of Scots Vindicated (3 vols., London, 1788); F. de Peyser, Mary Stuart, Bothwell and the Casket Letters (London, 1890); T. F. Henderson, The Casket Letters and Mary Queen of Scots (2 vols., 1899); Andrew Lang, The Mystery of Mary Stuart (London, 1900).

In 1590 Giovanni Francesco Savaro published a play La Maria Susanna, and since the historic person of Mary of Scots has been the subject of numerous poems and dramas, of which the most celebrated are Schiller's Maria Stuart, and three tragedies by A. C. Swinburne—Chastelard (1865), Bolvwell (1874), and Mary Stuart (1882).

MARY (1457–1482), duchess of Burgundy, only child of Charles the Bold, duke of Burgundy, and his wife Isabella of Bourbon, was born on the 13th of February 1457. As heiress of the rich Burgundian domains her hand was eagerly sought by a number of princes. When her father fell upon the field of Nancy, on the 5th of January 1477, Mary was not yet twenty years of age. Louis XI. of France seized the opportunity afforded by her rival's defeat and death to take possession of the duchy of Burgundy as a fief lapsed to the French crown, and also of Francke Comité, Picardy and Artois. He was anxious that Mary should marry the Dauphin Charles and thus secure the inheritance of the Netherlands for his descendants. Mary, however, distrusted Louis; declined the French alliance, and turned to her Netherland subjects for help. She obtained the help only at the price of great concessions. On the 11th of February 1477 she was compelled to sign a charter of rights, known as the Great Privilege, by which the provinces and towns of the Netherlands recovered all the local and communal rights which had been abolished by the arbitrary decrees of the dukes of Burgundy in their efforts to unite the Low Countries into a centralized state. Mary had to undertake not to declare war, make peace, or raise taxes without the consent of the States, and not to employ any but natives in official posts.

Such was the hatred of the people to the old regime that two influential councillors of Charles the Bold, the Chancellor Hugonet and the Sire d'Humbercourt, having been discovered in correspondence with the French king, were executed at Ghent despite the tears and entreaties of the youthful duchess. Mary now made her choice among the many suitors for her hand, and selected the archduke Maximilian of Austria, afterwards the emperor Maximilian I., and the marriage took place at Ghent on the 15th of August 1477. Affairs now went more smoothly in the Netherlands, the French aggression was checked, and internal peace was in a large measure restored, when the duchess met her death by a fall from her horse on the 27th of March 1482. Three children had been the issue of her marriage, and her elder son, Philip, succeeded to her dominions under the guardianship of his father.

See E. Münch, Maria von Burgund, nebst d. Leben v. Margaretha v. der Pfalz, mit einem Anhang und der Comarbe Mod. Hist. (vol. i., c. xii., bibliography, 1905).
at Abbeville on the 9th of October. The bridegroom was a broken man of fifty-two; the bride a beautiful, well-educated and charming girl of eighteen, whose heart was already engaged to Charles Brandon, duke of Suffolk, her future husband. The political marriage was, however, no long one. Mary was crowned queen of France on the 5th of November 1544; on the 1st of January following King Louis died. Mary had only been married with Louis by the promise that, on his death, she should be allowed to marry the man of her choice. But there was danger that the agreement would not be kept. In France the dukes of Lorraine and Savoy were mentioned as possible suitors, and meanwhile the new king, Francis I., was making advances to her, and only desisted when she confessed to him her previous attachment to Suffolk. The duke himself was at the head of the embassy which came from England to congratulate the new king, and to the detriment of his political mission he used the opportunity to win the hand of the queen. Francis good-naturedly promised to use his influence in her favour; Henry VIII. himself was not averse to the match, but Mary feared the opposition of the lords of the council, and, in spite of Suffolk's promise to the king not to take any steps in the matter until after his return, she persuaded him to marry her secretly before he left Paris. On their return to England in April, Suffolk was for a while in serious danger from the king's indignation, but was ultimately pardoned through Wolsey's intercession, on payment of a heavy fine and the surrender of all the queen's jewels and plate. The marriage was publicly solemnized on the 11th of May 1545. Suffolk had been already twice married, and his first wife was still alive. He thought it necessary later on (1548) to obtain a bull from Pope Clement VII. declaring his marriage with his first wife invalid and his union with Mary therefore canonical. Mary's life after this was comparatively uneventful. She lived mainly in the retirement of the country, but shared from time to time in the festivities of the court, and was present at the Field of the Cloth of Gold. She died on the 24th of June 1533. By the duke of Suffolk she had three children: Henry, born on the 11th of March 1516, created earl of Lincoln (1525), who died young; Frances, born on the 16th of July 1517, the wife of Henry Grey, marquess of Northampton, and mother of Lady Jane Grey (q.v.); and Eleanor.

MARY OF LORRAINE (1515-1560), generally known as Mary of Guise, queen of James V. and afterwards regent of Scotland, was born at Bayeux in the land of Normandy, with the elder children of Claude of Guise and Antoinette of Bourbon, and married in 1534 Louis II. of Orleans, duke of Longueville, to whom in 1535 she bore a son, Francis (d. 1551). The duke died in June 1537, and Mary was sought in marriage by James V., whose wife Magdalene died in July, and by Henry VIII. after the death of Jane Seymour. Henry persisted in his offers after the announcement of her betrothal to James V. Mary, who was made by adoption a daughter of France, received a papal dispensation for her marriage with James, which was celebrated by proxy in Paris (May 1538) and at Stirling on the 1st of August. James (b. May 1540) and Robert or Arthur (b. April 1541), died within a few days of one another in April 1541, and her husband died in December 1542, within a week of the birth of his daughter and heir, Mary, Queen of Scots. Cardinal David Beton, the head of the French and Catholic party and therefore Mary of Lorraine's friend and ally, produced a will of the late king in which the primacy in the regency was assigned to himself. John Knox accused the queen of undue intimacy with Beton, and a popular report of a similar nature, probably unfounded, was revived in 1544 by Sir Ralph Sadler, the English envoy on Beton's advice, and the regency fell to the heir presumptive James, Earl of Arran, whose inclinations were towards England and the Protestant party, and who hoped to secure the hand of the infant princess for his own son.

Mary of Lorraine was approached by the English commissioner, Sir Ralph Sadler, to induce her to further her daughter's marriage contract with Edward VI. She informed Sadler that Arran had asked her whether Henry had made propositions of marriage to herself, and that she had stated that "if Henry should mind or offer her such an honour she must account herself much beholding," and that she was "singularly well affected to Henry's desires." The queen, therefore, in June, not then one year old, and Edward VI. was signed on the 1st of July at Greenwich, and guaranteed that Mary should be placed in Henry's keeping when she was ten years old. The queen dowager and her daughter were carefully watched at Linlithgow, but on the 23rd of July 1543 they escaped, with the help of Cardinal Beton, to the safer walls of Stirling castle. When the queen's coronation in September Mary of Lorraine was made principal member of the council appointed to direct the affairs of the kingdom. She was constantly in communication with her kinsmen in France, and was already planning to secure for her daughter a French alliance, which was opposed on different grounds by all her advisers. She made fresh alliances with the earl of Angus and Sir George Douglas, and in 1544 she made a premature attempt to seize the regency; but a reconciliation with Arran was brought about by Cardinal Beton. The assassination of Beton left her the cleverest politician in Scotland. The English invasions of 1547, undertaken with a view to enforcing the English marriage, gave Mary the desired pretext for a French alliance. In June 1548 a French fleet, with provisions and 5000 soldiers on board, was sent to Savoy. André de Montalembert, seigneur d'Essé, landed at Leith to reinforce the Scots army, and laid siege to Haddington, then in the hands of the English. The Scottish parliament agreed to the marriage of the young queen with the dauphin of France, and, on the plea of securing her safety from English designs, she set sail from Dumbarton in August 1548 to complete her education at the French court.

Mary of Lorraine now gave her energies to the expulsion of the English and to the difficult task of keeping the peace between the Scots and their French auxiliaries. In September 1550 she visited France and obtained from Henry II. the confirmation of the dukedom and revenues of Châtelherault for the earl of Arran, in the hope of inducing him to resign the regency. On her way back to Scotland she was driven by storms to Portsmouth harbour and paid a friendly visit to Edward VI. Arran refused, however, to relinquish the regency until April 1554, when he resigned after receiving an assurance of his rights to the succession. The new regent had to deal with an empty exchequer and with a strong opposition to his daughter's marriage. The gift of high offices to state and to Frenchmen lent to the Protestant party the appearance of a national resistance to foreign domination. The hostility of Arran and his brother Archbishop Hamilton forced Mary into friendly relations with the lords who favoured the Protestant party. Soon after her marriage miners had been brought from Lorraine to dig for gold at Crawford Moor, and she now carried on successful mining enterprises for coal and lead, which enabled her to meet the expenses of her government. In 1554 she took into her service William Maitland of Lethington, who as secretary of state gained very great influence over her. She also provoked some stormy controversy, in September 1555, by the surreptitious translation for a letter which he had written to her, but the first revolt against her authority arose from an attempt to establish a standing army. When she provoked a war with England in 1557 the nobles refused to cross the border. In matters of religion she at first tried to hold the balance between the Catholic and Protestant factions and allowed the Presbyterian preachers the practice of their religion as long as they refrained from public preachings in Edinburgh and Leith. The marriage of Francis II. and her daughter Mary in 1558 strengthened her position, and in 1559 she relinquished her conciliatory tactics to submit to the dictation of her relatives, the Guises, by falling more into line with their religious policy. She was reconciled with Archbishop Hamilton, and
took up arms against the Protestants of Perth, who, incident to Knox, had destroyed the Charterhouse, where many of the Scottish kings were buried. The reformers submitted on condition that no foreign garrison was to be imposed on Perth and that the religious questions in dispute should be brought before the Scottish parliament. Mary of Lorraine broke the spirit of this agreement by garrisoning Perth with Scottish troops in the pay of France. The lords of the Congregation soon assembled in considerable force at Cupar Maitland Mary retreated to Edin-

burgh and thence to Dunbar, while Edinburgh opened its gates to the reformers, who issued a proclamation (Oct. 21, 1559) claiming that the regent was deposed. The lords of the Con-

gregation sought help from Elizabeth, while the regent had recourse to France, where an expedition under her brother, René of Lorraine, marquis of Elbeuf, was already in preparation. Mary, with the assistance of a French contingent, began to fortify Leith. The strength of her opponents was increased by the defection of Châtellerault and his son Arran; and an even more serious danger was the treachery of her secretary Maitland, who betrayed her plans to the lords of the Congregation. In October 1559 they made an unsuccessful attack on Leith and the seizure of an English convoy on the way to their army by John Hepburn, earl of Bothwell, increased their difficulties. Mary entered Edinburgh and conducted a campaign in Fife. Meanwhile Maitland of Lethington had been at the English court, and an English fleet under William Winter was sent to the Forth in January 1560 to waylay Elbeuf's fleet, which was, however, driven back by a storm to Calais. Elbeuf had been commissioned by Francis I. and Mary to take over Mary's regency on account of her failing health. An English army under Lord Grey entered Scotland on the 29th of March 1560, and the regent received an asylum in Edinburgh castle, which was held strictly neutral by John Erskine. When she knew that she was dying Mary sent for the lords of the Congregation, with whom she pleaded for the maintenance of the French alliance. She even consented to listen to the exhortations of the preacher John Willock. She died on the 11th of June 1560. Her body was taken to Reims and buried in the church of the nunnery of St Peter, of which her sister was abbess.

The chief sources for her history are the Calendar of State Papers for the reigns of Henry VIII. and Edward VI. in the Rolls Series; A. Teulet, Papiers d'état ... relatifs à l'histoire de l'Ecosse au XVIe siècle (Paris, 3 vols., 1851), for the Bannatyne Club; Hamilton Papers (2 vols., Edinburgh, 1859-1860), State Papers relating to Scotland and Mary Queen of Scots, 1547-1603 (Edinburgh, 2 vols., 1893-1899). &c. There is a Life in Miss Strickland's Queens of Scotland (vols. i.-ii.) based on original documents.

MARY OF MODENA—MARYBOROUGH

MARY OF MODENA [Maria Beatrice Anne Margaret Isabel d'Este] (1659-1718), queen of the English king James II., was the daughter of Alphonsio IV., duke of Modena, and the Duchess Laura, of the Roman family Martinozzi. She was born at Modena on the 5th of October 1658. Her education was strict, and her own wish was to be a nun in a convent of the order of the Visitation founded by her mother. As a princess she was not free to choose for herself, and was selected, mainly by the king of France, Louis XIV., as the wife of James, duke of York, heir-presumptive to the English throne. The duke had become a Roman Catholic, and it was a point of policy with the French king to provide him with a Roman Catholic wife. Mary Beatrice of Este was chosen partly on the ground of her known religious zeal, but also because of her beauty. The marriage was celebrated by proxy on the 30th of September 1673. She reached England in November. In later life she confessed that her first feelings towards her husband could only be expressed by tears. In England the duchess, who was commonly spoken of as Madam East, was supposed to be an agent of the pope, who had indeed exerted himself to secure her consent. Her beauty and her free manners secured her the respect of her brother-in-law, Charles II., and she lived on good terms with her husband's daughters by his first marriage, but she was always disliked by the nation. The birth of her first son (who died in infancy) on the 16th of January 1675 was regretted. During the Popish Plot, to which her secretary Coleman was a victim, she went abroad with her husband. After her husband's accession she suffered much domestic misery through his infidelity. Her influence on him was unfortunate, for she was a strong supporter of the Jesuit party which was in favour of extreme measures. Her second son, James Francis Edward, was born on the 10th of June (o.s.) 1688. The public refused to believe that the baby was Mary's child, and declared that a fraud had been perpetrated to secure a Roman Catholic heir. When the revolution had broken out, she made the disastrous mistake of consenting to escape to France (Dec. 10, 1688) with her son. She urged her husband to follow her to France when it was his manifest interest to stay in England, and when he went to Ireland she pressed incessantly for his return. Her daughter, Louise Maria, was born at St Germain on the 28th of June 1692. When her husband died on the 6th of September 1701, she succeeded in inducing King Louis to recognize her son as king of England, an act which precipitated the war of the Spanish Succession. Queen Mary survived her husband for seventeen years and her daughter for two. She received a pension of 100,000 crowns, which was largely spent in supporting Jacobite exiles. At the close of her life she had some success in obtaining payment of her jointure. She lived at St Germain or at Chaillot, a religious house of the Visitation. Her death occurred on the 7th of May 1718, and is said by Saint-Simon to have been that of a saint.

See Miss Strickland, Queens of England (vols. 9 and 10, London, 1850); Campana di Cavelli, Les Derniers Stuarts à Saint-Germain (London, 1871); and Martin Halle Mary of Modena (London, 1905).

MARY OF ORANGE (1631-1666), eldest daughter of the English king Charles I., was born in London on the 4th of November 1631. Her father wished her to marry a son of Philip IV., king of Spain, while her cousin, the elector palatine, Charles Louis, was also a suitor for her hand, but both proposals fell through and she became the wife of a Dutch prince, William, son of Frederick Henry, prince of Orange. The marriage took place in London on the 2nd of May 1641, but owing to the tender years of the bride it was not consummated for several years. However in 1642 Mary crossed over to Holland with her mother, Queen Henrietta Maria, and in 1644, as the daughter-in-law of the stadtholder, she began to take her place in public life. In 1647 her husband, William II., succeeded his father as stadtholder, but three years later, just after his attempt to capture Amsterdam, he died; a son, afterwards the English king William III., being born to him a few days later (Nov. 14, 1650). Mary was obliged to share the guardianship of her infant son with his grandmother Amelia, the widow of Frederick Henry, and with William, the elector of Bavaria. She was unpopular with the Dutch owing to her sympathies with her kinsfolk, the Stuarts, and at length public opinion having been further angered by the hospitality which she showed to her brothers, Charles II. and James, duke of York, she was forbidden to receive her relatives. From 1654 to 1657 the princess passed most of her time away from Holland. In 1657 she was appointed regent on behalf of her son for the principality of Orange, but the difficulties of her position led her to implore the assistance of Louis XIV., and the French king answered by seizing Orange himself. The position both of Mary and of her son in Holland was greatly bettered through the restoration of Charles II. in Great Britain. In September 1660 Mary journeyed to England. She was taken ill of small-pox, and died in London on the 24th of December 1660, her death, says Bishop Burnet, being "not much lamented."

MARYBOROUGH, a market town and the county town of Queen's County, Ireland. Pop. (1901), 2957. It lies in the broad lowland east of the Slieve Bloom mountains, the river Tinnoge, an affluent of the Barrow, and on the main line of the Great Southern & Western railway, by which it is 51 m. W.S.W. of Dublin. The town was chosen as county town in the reign of Mary (1556), in whose honour both town and county received their names. Its charter was granted in 1579,
MARYBOROUGH—MARYLAND

but its present appearance, save a bastion of the ancient castle, is wholly modern. There are flour-mills and a considerable general trade. Maryborough returned two members to the Irish Parliament from 1700 until 1800. The singular lofty rock of Dunamase or Dunmall, about 3 m. from the town, bears on its summit extensive ruins of a castle, originally belonging to the kings of Leinster, but probably built in the main by William Bruce (c. 1200) and dismantled in 1650 by Cromwell's troops.

MARYBOROUGH, a town of March county, Queensland, Australia, on the left bank and 25 m. from the mouth of the Mary river, 180 m. by rail N. of Brisbane. Pop. (1901), 10,159. It has a handsome court-house and town hall, the principal buildings. An Anglican Church of St Paul with a fine tower and plea of bells, and the grammar schools. There is a large shipbuilding yard, and breweries, distilleries, a tannery, boot factories, soap works, saw-mills, flour-mills, carriage works and iron foundries, besides extensive sugar factories in the neighbourhood. The largest smelting works in Australia are 5 m. distant, in which ore from all the states is treated. Maryborough is the port of shipment for a wide agricultural district yielding maize and sugar, and bang also the source of most of the saw-mill and foundries in the neighbourhood and is exported. Maryborough is also the chief coal exporting port in Queensland, the government railway wharf being in direct communication with the Burrum coal-fields.

MARYBOROUGH, a municipal town of Talbot county, Victoria, Australia, 112 m. by rail N.W. of Melbourne. Pop. (1901), 5633. It has fine government buildings, a town hall, a botanical garden, and numerous park lands. It is an important railway centre, and has extensive railway workshops, as well as coach factories, breweries and foundries. The gold mining of the district is from quartz and alluvial. Whisky and wine arc the chief agricultural products of the neighbourhood.

MARYLAND, a South Atlantic state of the United States, and one of the original thirteen, situated between latitudes 39° 53' and 39° 44' N. and longitudes 75° 4' and 70° 33' W. (the precise western boundary has not been determined). It is bounded N. by Pennsylvania and Delaware; E. by Delaware and the Atlantic Ocean; S. and W. by the Potomac river and its north branch, which separate it, except on the extreme W. border, from Virginia and West Virginia; W., also, by West Virginia. It is one of the small states of the Union—only seven are smaller—its total area being 12,577 sq. m. of which 2550 sq. m. are water surface.

Physical Features.—Maryland is crossed from north to south by each of the leading topographical regions of the east section of the United States—the Coastal Plain, the Piedmont Plateau, the Appalchian Mountains, and the Allegheny Plateau, with great diversity of surface. The portion within the Coastal Plain embraces nearly the whole of the south-east half of the state and is commonly known as tide-water Maryland. It is marked off from the Piedmont Plateau by a "Fall Line" extending from Washington (D.C.) north-east through Baltimore to a point a little south of the north-east corner of the state, and is divided by the Chesapeake Bay into two parts known as the East Shore and the West Shore. The East Shore is a low level plain, the least elevated section of the state. Along its entire Atlantic border extends the narrow sandy Sinepuxent Beach, which encloses a shallow lagoon of the same name, which is conserved at a cost of $20,000 a year. In the extreme north, it is very narrow, and Chincoteague at the south, where its width is in most places from 4 to 5 m. Between this and the Chesapeake to the west and north-west there is a slight general rise, a height of about 100 ft. being reached in the extreme north. A water-parting extending from north-east to south-west to the Atlantic border separates the East Shore into two drainage systems, though that next to the Chesapeake to the north is the most extensive of the two. The waters on the Chesapeake side is drained chiefly by the Pocomoke, Nan-ticoke, Choptank and Chester rivers, together with their numerous branches. The general direction of all of which is south-west. The branches of the Sinepuxent Bay reach the Union in 1860, and the broad and shallow valleys; the middle courses of the main streams wind their way through reed-covered marshes, the water ebbing and flowing with the tides. In the north-east the estuaries they enter are narrow and the water flows through low banks. The West Shore is somewhat more undulating than the East and also more elevated. Its general slope is from north-west to south-east; along the west border are points 300 ft. or more in height. The principal rivers crossing this section are the Patuxent, Patapsco and Gunpowder, through which the Potomac may be regarded as the southern boundary. These rivers, lined in most instances with terraces 30 to 40 ft. high on one or both sides, flow south-east into Chesapeake Bay through valleys bounded by low hills. The Fall Line to which reference is made is that portion of the main stream which extends from north-east to south-west a short distance west of the Chesapeake and the Cuyahoga River, on which Maryland and the Piedmont Plateau, is a zone in which a descent of about 100 ft. or more is made in many places within a few miles and in connection with this is marked by extensive alluvial plains and beds.

The part of Maryland within the Piedmont Plateau extends west from the Fall Line to the base of Catoctin Mountain, or the west border of Frederick county, and has an area of about 2500 sq. m. in general it is an upland with rolling hills and small valleys, and the principal streams are those that cross the West Shore of the Coastal Plain and here wind their way from Parr's Ridge toward the south-east in narrow steep-sided gorges through bed of the

The portion of the state lying within the Appalachian Region is commonly known as Western Maryland. To the eastward it abounds in mountains and valleys; to the westward it is a rolling upland in the west of the rolls of the Potomac Valley, with Catoctin Creek running through it from north to south, and the Blue Ridge Mountains (2400 ft.), near the Pennsylvania border, forming its west slope. Farther west the serrated crests of the Blue Ridge Mountains assumes its westward slope, with the portion Antietam Creek to the east and Conococheague Creek to the west flow rapidly in meandering trenches that in places exceed 75 ft. in depth. The Appalachian Ridges of the western portion begin with Mount Tammany in the north and end on the mountain barrier Martin's Ridge of more than 2000 ft. Overlooking them from the west are the higher ranges of the Alleghenies, among which the Savage, Backbone and Negro Mountains reach elevations of 3000 ft. or more. In the extreme west part of the state these mountains merge, as it were, into a rolling plateau, the Appalachian Plateau, having an average elevation of 2500 ft. All rivers of Western Maryland flow south into the Potomac except in the extreme west, where the waters of the Shenandoah and Potomac make their outlet through the Allegheny Mountains. Much more numerous are squirrels, rabbits, "ground-hogs" (woodchucks), opossums, skunks, weasels and minks. Many birds are found; hawks and owls, pheasants, red-winged blackbirds, partridge (also called quail or "Bob White"), ruffed grouse (elsewhere called partridge), woodcock, snipe, plover and Carolina rail still abound. The waters of the Chesapeake Bay are especially rich in oysters and crabs, and there, also, shad, alewives, "striped" (commonly called "rock") bass, menhaden, white perch and weak-fish ("sea-trout") occur in large numbers. Among the more common trees are several species of oak, pine, hickory, gums and maple, and the chestnut, the poplar, the beech, the cypress and the red cedar; the merchantable pine has been cut, but the chestnut and other hard woods of West Maryland are still found. Among the fruits here grown are peaches, persimmon and Chicassaw plum; grape-vines and a large variety of berry-bushes grow wild and in abundance.

Climate.—The climate of Maryland in the south-east is influenced by the ocean, in the north-west it is influenced by the mountains. The prevailing winds are westerly; but generally north-west in winter in the west section and west in summer in the south section. In the north-west the winter is mild, the normal summer rather hot; in the south the normal winter is cold, the normal summer cool. The normal average annual temperature for the entire state is between 33° and 35°. The average temperature from May 1 to August 31 is about 77° F. To Boettcherville and 26° F. at Sunnyside. The normal temperature for the entire state during July (the hottest month) is 75° F. and during January (the coldest month) 32° F. All the west is cooler in summer, yet both of the greatest extremes recorded since 1801 were at points not far apart in Western Maryland: 102° F. at Boettcherville and 26° F. at Sunnyside. The normal
annual precipitation for the state is about 43 in. It is greatest, about 53 in., on the east slope of Catoctin Mountain, owing to the elevations which obstruct the moisture-bearing winds, and is about 7 in. or less in the middle and western parts of the state. It is least, from 25 to 35 in., in the Greater Appalachian Valley, in the south on the West Shore, and along the Atlantic border. During spring and summer the precipitation throughout the state is about 2 in., but during the fall and winter it is less.

Soils and Agriculture.—The great variety of soils is one of the more marked features of Maryland. On the East Shore to the north is a marly, sandy soil, which is underlaid by clay, then a soil quite stiff with light coloured clay, while here and there, especially in the middle and south, are considerable areas both of light sandy soils and tidal marsh loams. On the Western Shore the sandy clay soils are extensive, but levels south from Baltimore to rather heavy loams overlying a yellowish clay on the rolling uplands and on the terraces along the Patomac and Patuxent. Crossing the state along the lower edge of the Piedmont Plateau, there is a continuation of the sandy clay soils; but on the rolling uplands and in some stream valleys to the west, the gabbro, is found, most largely in the north-east. Alluvial loams occupy the narrow river valleys; but the most common soil of the section is that formed from the erosion of the gabbro and clay, and there is a notable belt of the eastern part of Parr's Ridge in the Piedmont, the principal soils are those the character of which is determined either by decomposition red sandstone or by decomposed limestone. In the counties along the Potomac River and to the north, the soil is high, with peat and water as to be of little value for agricultural purposes. The soils of the Piedmont Plateau east of Parr's Ridge are, like the underlying rocks, exceptionally variable in colour. For the most part they are considerably heavier with clay than are those of the Coastal Plain, and better adapted to general agricultural purposes. Light loams, however, are found both in the Piedmont and south-eastern part, and the alluvial, is found, most largely in the north-east. Most of the state is underlaid by gabbro, and in no other state except South Carolina is so large a per cent, of the value of the crop, exceeded for fertilizers. In 1907, according to the U.S. Department of Agriculture, the corn crop was 22,196,000 bushels, valued at $1,106,000; the wheat crop was 14,763,000 bushels, valued at $14,172,000; the oat crop was 829,000 bushels, valued at $404,000; and the crop of rye was $1,550,000. On the east coast the heaviest yield was in the counties of Baltimore, with 7,920,000 bushels, while in the counties of Charles, St. Mary, Calvert, and Prince George, the yield was only 1,025,000 bushels, from which it steadily increased to 5,523,289 short tons in 1907. From 1722 until the War of Independence the iron-ore product of North and West Maryland was greater than that of any of the other colonies, but since then ores of superior quality have been discovered in other states and there is little or no iron used in Maryland. The chief of the agricultural products, is the tobacco. The Coastal Plain in Anne Arundel and Prince George's counties, has been comparatively of little importance—24,367 long tons in 1902. As far back as 1659 Maryland had a large lead mines, which have been found in the state, and attempts have been made to mine them, without much success. The Maryland building stone, of which there is an abundance of good quality, consists chiefly of the plenly burdened with variable and sandstones. Much of which is quarried in the east section of the Piedmont Plateau, and is the Cecil county, though some limestones, including those from which hydraulic cement is manufactured, and are obtained from the eastern part of the Piedmont Plateau and the east section of the Appalachian region; the value of stone quarried in the state in 1907 was $1,339,355, of which $1,183,755 was for millstones and $142,525 for lime stone. The value of marble, valued at $10,610; the value of sandstone, valued at $605,864, and the value of sandstone, valued at $3,767,451. The state laws for the protection of fish and shell-fish were long carefully enforced because of the fisherman's strong feeling against them, but this sentiment has slowly changed and improved. The return for the year 1905 showed an increase of $13,859, but was not exploited until railway transport became available. The return for the year 1905 showed an increase of $13,859, but was not exploited until railway transport became available. The return for the year 1905 showed an increase of $13,859, but was not exploited until railway transport became available. The return for the year 1905 showed an increase of $13,859, but was not
and meat-packing; cars and repairs by steam railways; shirts; cotton goods; malt liquors; and cigars and cigarettes. In the voted secondary centres are Cumberland, Hagerstown and Frederick, the building centre, but of the state's total the percentage in value of that manufactured there decreased from 82.5 in 1890 to 66.5 in 1900, and to 62.3 (of the factory product) in 1905. The largest secondary centres are Cumberland, Hagerstown and Frederick: the total value of whose factory products in 1905 was less than $10,000,000.

Gardening. - Tide-water Maryland is afforded rather unusual facilities of water transportation by the Chesapeake Bay, with its deep channel, numerous deep inlets and navigable tributaries, together with the Chesapeake and Delaware Canal, which crosses the isthmus between the two harbours, with those of the Delaware river and bay. As early as 1783 steps were taken to extend these facilities to the navigable waters of the Ohio, chiefly by improving the navigation of the Potomac above Georgetown. By 1828 this project was merged into a movement for a Chesapeake and Ohio canal along the same line. Ground was broken in 1828 and in 1850 the canal was opened to navigation from Georgetown to Cumberland, a distance of 185 miles. In 1878 and again in 1889 it was wrecked by a freshet, and since then has been of little service. However, on the same day that ground was broken for this canal, ground was also broken for the Baltimore & Ohio railroad, of which 15 were completed in 1853 and was one of the first of the railways in operation in the United States. Since then railway building has progressed steadily. In Maryland (and including the District of Columbia) there were 1,981 miles of railroad in 1850, 671 m. in 1870, and 1,040 m. in 1880; in 1890, in Maryland alone, the mileage was 1,270-04 m., and in 1900 it was 1,394-19 m. The more important railways are the Baltimore & Ohio, the Philadelphia & Washington (including the Delaware & Maryland and a consolidation of the Philadelphia, Wilmington & Baltimore, and the Baltimore & Potomac), the Western Maryland, the Central Pennsylvania, & Pittsburg & Western (by the Western Maryland), the Northern Central, the Maryland electric railways (including what was formerly the Baltimore & Annapolis Short Line), and the Washington, Baltimore & Annapolis electric railway. Baltimore is the chief railway centre and its harbour is one of the most important in the country.

Inhabitants. — The population of Maryland in 1850 was 924,434; in 1890, 1,042,390, an increase of 21.5 per cent; in 1900, 1,182,044 (14%); in 1910, 1,295,346 (increase 9%). Of the total population in 1900 there were 922,424 whites, 235,064 negroes, 94 Chinese, 1 Japanese and 3 Indians, the increase in the white population from 1890 to 1900 being 15.2%, while that of the negroes was only 9%. In 1900 there were 1,044,110 native born, 15,140 born in foreign countries, and 98,000 of foreign birth, 66,600 of whom were of foreign birth and 31,400 of whom were of foreign birth of foreign birth. The most numerous race of foreign birth was that of Germany, and 68,600 were residents of the city of Baltimore. The urban population, i.e. total population of cities of 4000 or more inhabitants, in 1900, was 572,705, or 48.2% of the total and an increase of 16.6% over that of 1890; while the rural population, i.e. population outside of incorporated places, was 359,055, an increase of about 8% over that of 1890. There are about 39 religious sects, of which the members of the Roman Catholic Church, which was prominent in the early history of Maryland, are far the most numerous, having in 1900 166,941 members out of 473,257 communicants of all denominations; in the same year there were 137,736 Methodists, 34,653 Protestant Episcopalians, 32,266 Lutherans, 30,028 Baptists, 17,895 Presbyterians and 13,442 members of the Reformed Church in the United States. The chief cities are Baltimore, pop. (1910) 558,485, Cumberland 21,839, Hagerstown 16,597, Frederick 10,411 and Annapolis 8609.

Government. — The state constitution of 1867, the one now in force, has been frequently amended, all that is required for its amendment having been voted for. Ballots are provided for the voters at each of the two houses of the General Assembly,   

provided that once in twenty years, beginning with 1887, the wish of the people in regard to calling a convention for altering the constitution shall be ascertained by a poll. Any constitution or constitutional amendment proposed by such constitutional convention comes into effect only if approved by a majority of the votes cast in a popular election. Since 1876 suffrage has been extended to all citizens of the state who are between the ages of 18 and 70, and to all persons of both sexes and of all ages who shall have lived within the state for one year and within the county or the legislative district of the city of Baltimore in which they may offer to vote for six months immediately preceding an election; persons convicted of larceny or other infamous crime and not since pardoned by the governor, as well as lunatics or those who have been convicted of bribery at a previous election are excepted. In 1908 the General Assembly passed a law providing for annual direct primary elections (outside of Baltimore; and making the Baltimore special primary law applicable to state as well as city officials), but, as regards state officers, making only a slight improvement upon previous conditions inasmuch as the county or district is the unit and the vote of county or district merely "instructs" delegates to the party's state nominating convention, representation in which is not strictly in proportion to population, the rural counties having an advantage over Baltimore; no nomination petition is required. In the same year a separate law was passed providing for primary elections for the choice of United States senators; but here also the method is not that of nomination by the people, but an election by the county or the legislative districts, or any part thereof, as the case may be, to choose delegates to the state and United States conventions, the number of these delegates varying in each county or district, or part thereof, according to the number of inhabitants, but not less than five, and not more than ten. In the city of Baltimore the number of delegates is determined by the city council.

The chief executive authority in general is vested in a governor elected by popular vote for a term of four years. Since becoming a state Maryland has had no lieutenant-governor except under the constitution of 1864; and the office of governor is to be filled in case of the incapacity by such person as the General Assembly may elect. Any citizen of Maryland may be elected to the office who is thirty years of age or over who has been a citizen of the state for five years immediately preceding election, and who is at the time of his election a qualified voter therein. Until 1898 the governor had a rather large appointing power, but since that date most of the more important offices have been filled by popular election. He, however, still appoints, subject to the confirmation of the senate, the secretary of state, the superintendent of public education, the commissioner of the land office, the adjutant-general, justices of the peace, notaries public, the members of numerous administrative boards, and other administrative officers. He is himself one of the board of education, of the board of public instruction, and of the board of managers of the universities. No veto power whatever was given to the governor until 1867, when, in the present constitution, it was provided that no bill passed by the legislature should become a law unless passed by a two-thirds vote of the members elected to each house, and an amendment of 1890 (ratified by the people in 1891) further provides that any item of a money bill may likewise be separately vetoed. The governor's salary is fixed by the constitution at $500 a year. Other executive officers are a treasurer, elected by joint ballot of the General Assembly for a term of two years, a comptroller elected by popular vote for a similar term, and an attorney-general elected by popular vote for four years.

The legislature, or General Assembly, meets biennially in even-numbered years, at Annapolis, and consists of a Senate and a House of Delegates. Senators are elected, one from each of the twenty-three counties and one from each of the four legislative districts of the city of Baltimore, for a term of four years, the terms of one-half expiring every two years. Delegates are elected for a term of two years, in each county and from each of the four districts of the city of Baltimore, according to population, as follows: for a population of 18,000 or less, two delegates; 18,000 to 28,000, three; 28,000 to 40,000, four; 40,000 to 55,000, five; 55,000 and upwards, six. Each legislative district of Baltimore is entitled to the number of delegates to which the largest county shall or may be entitled under the foregoing apportionment, and the General Assembly may from time to time alter the boundaries of Baltimore and the counties to equalize their population. This system of apportionment gives to the rural counties a considerable political advantage over the city of Baltimore, which is the result of the census of 1900, has only 4 out of 27 representatives of the Senate and only 24 out of 101 members of the House of Delegates. Since far back in the colonial era, no minister, preacher, or priest

1 The General Assembly regularly elected the governor during the period 1776–1838.
has been eligible to a seat in either house. A senator must be twenty-five years of age or over, and both senators and delegates must have lived in the state at least three years, and in the legislative district at least one year immediately preceding their election.

The constitution provides that no bill or joint resolution shall pass either house except by an affirmative vote of a majority of all the members elected to that house and requires that on the final vote the yeas and nays be recorded.

Courts. The administration of justice is entrusted to a court of appeals, circuit courts, special courts for the city of Baltimore, orphans' courts, and justice of the peace. The exclusive city of Baltimore, the state is divided into seven judicial circuits, in which are situated two or more courts of general and admiralty jurisdiction; and two associate judges, who at the time of their election must be members of the bar, at least thirty and seventy years of age, and residents of the county for at least five years. The seven chief judges so elected, together with one elected from the city of Baltimore, constitute the court of appeals, the governor with the advice and consent of the senate designating one of the members of that court. The court has appellate jurisdiction only. The three judges elected in each circuit constitute the circuit court of each of the several counties in such circuit. The courts have both original and appellate jurisdiction and are required to hold at least two sessions to which jurors shall be summoned every year in each county of its circuit, and if only two such terms are held, there must be two other and intermediate terms to which juries shall be summoned. The term of service of the judges on the circuit courts is for four years, in each county and in the city of Baltimore to constitute an orphans' court. The number of justices of the peace for each county is fixed by local law; they are appointed by the governor subject to the confirmation of the Senate, for a term of two years.

In the colonial era Maryland had an interesting list of governmental institutions. In the city of Baltimore, the Maryland trust, the Maryland bank, and the Maryland hospital. In the rural part of the state too, the two last are about all that remain and even these are in considerable measure subject to the special local acts of the General Assembly. In general, each county has from three to seven commissioners—the number is fixed by county laws—elected on a general ticket of each county for a term of from two to six years, entrusted with the charge and control of property owned by the county, empowered to appoint constables, judges of elections, coroners, and assessors of taxes, to fix rates of taxation, to levy taxes, to revise taxable valuations of real property, and open or close public roads.

In Maryland a wife holds her property as if single except that she can convey real estate only by a joint deed with her husband (this requirement being for the purpose of effecting a release of the husband's 'dower interest'), neither husband nor wife is liable for the separate debts of the other, and on the death of either the rights of the survivor in the estate of the other are about equal. Wife-beating is made punishable by whipping in goal, not exceeding forty lashes. Prior to 1801, a wife was granted by the legislature only the usufruct of her husband, this was finally changed to the marriage settlement, but not until 1891 it could be granted by either the legislature or the equity courts, since 1891 by the courts only. The grounds for a divorce a mensa et thoro, which may be granted for or for a limited time only, are adultery, desertion, cruel and inhuman treatment, or unreasonable jealousy. The grounds for a divorce a vinculo matrimonii the chief grounds are impotence at the time of marriage, adultery or deliberate abandonment for three years. There is no homestead exemption law and exemptions from levying executories in the cases of debtors in bankruptcy. In the case of property, besides wearing apparel and books and tools used by the debtor in his profession or trade, and to all money payable in the nature of insurance. Employers of workers in a clay or coal mine, stone quarry, or on a steam or street railway are liable for damage in an injury to any of their workmen where such injury is caused by the negligence of the employer or of any servant or employee of the employer. The chief of the bureau of labor statistics is directed in case of danger of a strike or lockout to seek to mediate between the parties and if unsuccessful in that, then to endeavour to secure their consent to the formation of a board of inquiry. The state penal and charitable institutions include a penitentiary at Baltimore; a house of correction at Jessups, two houses of refuge at Baltimore; a house of reformation in Prince George's county; St Mary's industrial school for boys at Baltimore; an industrial home for negro girls at Melvina; an asylum and training school for the feeble-minded at Owings Mills; an infirmary at Catonsville; and hospitals for the insane at Greenspring, the Springfield state hospital for the insane; the Maryland school for the deaf and dumb at Frederick city; and the Maryland school for the blind at Prince George's county. Each board is composed of a board appointed by the governor subject to the confirmation of the senate. Besides these there are a large number of state-aided charitable institutions. In 1900 there was created a board of charitable distribution (sections 1219-1221) Acts 1900, 419). Each board consists of four members, one elected by the governor for a term of two years, not more than four to be reappointed. There is also a state lunacy commission of four members, who are appointed for terms of four years, one annually, by the governor.

Education.—The basis of the present common school system was laid in 1865, after which a marked development was accomplished during the next ten years and in the succeeding decade, and the percentage of total illiteracy (i.e. inability to write among those ten years old and over) decreased from 19.3 in 1865 to 11.1 in 1900. The state school district none of which is to be more than four miles square. The state board is composed of the governor as its president, the state superintendent as its secretary, six other members appointed by the governor without the right to vote, the principals of the state and other normal schools. Prior to 1900 the principal of the state normal college was ex officio a member of the board, but this position has been appointed by the governor for a term of four years. Each county board is also appointed by the governor for a term of six years. In both the state and the county boards at least one-third of the members are not to be of the dominant political party and only one-third of the members are to be appointed every two years. The state board enacts by-laws for the administration of the system; its decision of controversies arising under the school law is final; it may suspend or remove a county superintendent for inefficiency or incompetency; it issues life state certificates, but applicants must have had seven years' term in the common schools, and, in order to be eligible for a certificate or a college or normal school diploma; and it pensions teachers who have taught successfully for twenty-five years in any of the public or normal schools of the state, who have reached the age of fifty, and who have taught for a minimum of teaching longer, the pension amounting to $200 a year. The legislature of 1908 passed a law under which the minimum pay for the state superintendent is raised from $1,500 to $2,000 a year, for three years' teaching, $400 after five years' teaching and $500 after eight years' teaching. By a law of 1904 all teachers who taught an average of 15 pupils were to receive at least $300. School books are purchased out of the proceeds of the school tax, but parents may purchase if they prefer. In 1908 the average school year was nine and seven-tenths months—ten in the cities and nine and four-tenths in the counties; the aim is ten months throughout, and a law of 1900 authorizes the county superintendents to read the average percentage of the funds set apart for it shall be withheld. A compulsory education law of 1902—to operate, however, only in the city of Baltimore and in Allegany county—requires the attendance of the whole school year of children between the ages of eight and twelve and also of those between the ages of twelve and sixteen who are not employed at home or elsewhere. A separate school for negro children is to be maintained in each of the cities, in which the population warrants it. The system is maintained by a state tax of 16 cents on each $100 of taxable property.

The state board of education establishes two normal schools and one agricultural college. One of the normal schools was opened in Baltimore in 1866, the other at Frostburg in 1904. Both are under the management of the state Board of Education, which appoints the trustees and sets the terms of the college; the superintendents are appointed by the state board.

There is besides, in Washington College at Chestertown, a normal department supported by the state and under the supervision of the state Board of Education. The Maryland Agricultural College, opened in 1867, is a state institution, its purpose being to train, as it is at College Park in Prince George's county, and is largely under state management. Maryland supports no state university, but John's Hopkins University, one of the leading institutions of its kind in the country, receives $25,000 a year from the state; the medical department of the university of Maryland receives an annual appropriation of about $2500, and St John's College, the academic department of the university of Baltimore, receives from the state $15,000 annually and gives for each county in the state one free scholarship and one scholarship covering all expenses. Among the principal institutions in the state are the university of Baltimore, an outgrowth of the Wilkes College (1807) in Baltimore, with a law school (reorganized in 1869), a dental school (1882), a school of pharmacy (1904), and, since 1897, a department of arts and sciences in St John's College (non-sect., opened in 1789) at Annapolis; Washington College, with a normal department (non-sect., opened in 1872) at Chestertown; Mount St Mary's College (Roman Catholic, 1868) at Emmitsburg; New College (Presbyterian, 1843) at Westminster; Catonsville College (Roman Catholic, opened in 1848) and Rock Hill College (Roman Catholic, 1857) near Ellicott City; Loyola College (Roman Catholic, non-sect., opened in 1851) at Baltimore; Goucher College (Methodist, founded 1884, non-sect., opened in 1874) in Baltimore; Millersville State College (Sixth Street, 1850) in Baltimore (ag.); the Peabody Institute at Baltimore; and the United States Naval Academy at Annapolis.

Revenue.—The state's revenue is derived from a general direct property tax, a licence tax, corporation taxes, a collateral inheritance
tax, fines, forfeitures and fees; and the penitentiary yields an annual net revenue of about $30,000. There is no provision for a general personal tax. A tax on the value of real estate is imposed, and the county commissioners assess the property, and the county treasurer and comptroller assesses the corporations, and the county commissioners (in the counties) and the appeal tax court (in the city of Baltimore) revise valuations of real property every two years. The property of persons living abroad with the consent of their government, and its enthusiasm over internal improvements, incurred an indebtedness of more than $16,000,000. To meet the interest, such heavy taxes were levied that in 1650 the debt was greater than the annual income, and in 1652 the state failed to pay what was due; but the accumulated interest had been funded by 1848 and was paid soon afterwards, the expenses of the government were curtailed by the constitution of 1851, and after the Civil War the amount of indebtedness decreased until in 1902 the funded debt was $6,909,326 and the net debt only $2,757,269.13, while on the 1st of October 1908 the net debt was $1,666,643.15, as a result of incurring the large debt, a clause in the constitution provides that there shall be a debt without providing by the imposition of taxes for the payment of the interest annually and the principal within fifteen years, except to meet a temporary deficiency not exceeding $50,000. The first bank of the state was established in 1790, and by 1877 there was one in each of twelve counties and several in Baltimore; in 1818-1820 and in 1837-1839 there were several serious bank failures, but there have been no serious failures since. A constitutional provision makes each stockholder in a state bank liable to the amount of his share or shares for all the bank’s debts and liabilities. A savings bank is taxed on its deposits, and a state bank is taxed on its capital-stock.

History.—The history of Maryland begins in 1632 with the procedure of Charles I. to grant a charter conveying almost unlimited territorial and governmental rights therein to George Calvert, first Lord Baltimore (1587-1632), and styling him his absolute lord and proprietor. George Calvert died before the charter had passed the great seal, but about two months later in the same year it was issued to his eldest son, Cecilus. In November 1633 two vessels, the “Ark” and the “Dove,” carrying at least two hundred colonists under Leonard Calvert (c. 1586-1647), a brother of the proprietor, as governor, sailed from Gravesend and arrived in Maryland late in March of the following year. Friendly relations were at the outset established with the Indians, and the province never had much trouble with that race; but with William Claiborne (1582-1676), the arch-enemy of the province as long as he lived, it was otherwise. He had opposed the grant of the Maryland charter, had established a trading post on Kent Island in Chesapeake Bay in 1613, and when commanded to submit to the new government he and his followers offered armed resistance. A little later, during his temporary absence in England, his followers on the island were reduced to submission; but in 1644, while the Civil War in England was in progress, he was back in the province assisting Richard Ingle, a pirate who claimed to be acting in the interest of parliament, in raising an insurrection which deprived Governor Calvert of his office for about a year and a half. Finally, the latter was restored, and all was quiet until 1658 in obedience to instructions from parliament which were originally intended to affect only Virginia, but were so modified, through the influence of Claiborne and some Puritan exiles from Virginia who had settled in Maryland, as to apply also to the plantations within Chesapeake Bay. Then the long continued unrest both in the mother country and in the province seems to have encouraged Josias Fendall, the proprietor’s own appointee as governor, to strike a blow against the proprietary government and attempt to set up a commonwealth in its place; but this revolt was easily suppressed, and order was generally preserved in the province from the English Restoration of 1660 to the English Revolution of 1688. Meanwhile an interesting internal development had been in progress. The proprietor was a Roman Catholic and probably it was his intention that Maryland should be an asylum for persecuted Roman Catholics, but it is even more clear that he was desirous of having Protestant colonists also. To this end he promised religious toleration from the beginning and directed his efforts accordingly; this led to the famous toleration act passed by the Assembly in 1649, which, however, extended its protection only to sects of the Church of England. Although the charter reserved to the proprietor the right of calling an assembly of the freemen or their delegates at such times and in such form and manner as he should choose, he surrendered in 1638 his claim to the sole right of initiating legislation. By 1650 the assembly had been divided into two houses, in one of which sat only the representatives of the freemen without whose consent no bill could become a law, and annual sessions as well as triennial elections were coming to be the usual order. When suffrage had thus come to be a thing really worth possessing, the proprietor, in 1675, sought to check the opposition by disfranchising all freemen who did not have a freehold of fifty acres or a visible estate of forty pounds sterling. But this step was followed by more and more impassioned complaints against him, such as: that he was interfering with elections, that he was summoning only a part of the delegates elected, that he was seeking to overawe those summoned, that he was abusing his veto power, and that he was keeping the government in the hands of Roman Catholics, who were mostly members of his own family. About this time also the northern and eastern boundaries of the province were beginning to suffer from the aggressions of William Penn. The territory now forming the state of Delaware was within the boundaries defined by the Maryland charter, but in 1682 it was transferred by the duke of York to William Penn and in 1685 Lord Baltimore’s claim to it was denied by an order in council, on the ground that it had been inhabited by Christians before the Maryland charter was granted. In the next place, although it was clear from the words of the charter that the parallel of 40° N. was intended for its north boundary, and although Penn’s charter prescribed that Pennsylvania should extend on the south to the “beginning of the fortieth degree of Northern Latitude,” a controversy arose with regard to the boundary between the two provinces, and there was a long period of litigation; in 1763-1767 Charles Mason and Jeremiah Dixon, two English mathematicians, established the line named from them (see MASON AND DIXON LINE), which runs along the parallel 39° 45′ 26″-3 N. and later became famous as the dividing line between the free states and the slave states. While the proprietor was absent defending his claims against Penn the English Revolution of 1688 was started. Owing to the death of a messenger there was long delay in proclaiming the new monarchs in Maryland; this delay, together with a rumor of a Popish plot to slaughter the Protestants, enabled the opposition to overthrow the proprietary government, and then the crown, in the interest of its trade policy, set up a royal government in its place, in 1692, without, however, divesting the proprietor of his territorial rights. Under the royal government the Church of England was established, the people acquired a strong control of their branch of the legislature and they were governed more by statute law and less by executive ordinance. The proprietor having become a Protestant, the proprietary government was restored in 1715. Roman Catholics were not permitted to hold distinguished offices. In 1736 Germans began to settle in considerable numbers in the west-central part of the colony, where they greatly promoted its industrial development but at the same time added much strength to the opposition. The first great dispute between proprietor and people after the restoration of 1715 was with regard to the extension of the English statutes to Maryland, the popular branch of the legislature vigorously contending that all such statutes except those expressly excluded to the province, and the lord proprietor contending that only those in which the dominions were expressly mentioned were in force there. Many other disputes speedily followed and when the final struggle between the English and French for possession in America came, although appropriations were made at its beginning to protect her own western frontier from the attacks of the enemy, a dead-lock between the two branches of the assembly prevented Maryland from responding to repeated appeals from the mother country for aid in the latter part of that struggle. This failure was used as an argument in favour of imposing the famous Stamp Act. Nevertheless, popular clamour against parliament on account of that measure was even greater than it had been against the proprietor. The stamp distributor was driven out, and the arguments of Daniel Dulany (1721-1797), the ablest lawyer in the province, against the act were quoted by speakers in Parliament for its repeal.
MARYLAND

In the years immediately preceding the Declaration of Independence Maryland pursued much the same course as did other leading colonies in the struggle—a vessel with tea on board was even burned to the water's edge—and yet when it came to the decisive act of declaring independence there was hesitation. As the contest against the proprietor had been nearly won, the majority of the best citizens desired the continuance of the old government and it was not until the Maryland delegates in the Continental Congress were found almost alone in holding back that their instructions not to vote for independence were rescinded. The new constitution drawn and adopted in 1776 to take the place of the charter was of an aristocratic rather than a democratic nature. Under it the property qualification for suffrage was a freehold of 50 acres or £30 current money, the property qualifications for delegates £500, for senators £1000, and for governor £5000. Four delegates were chosen from each county and two each from Baltimore and Annapolis, the same as under the proprietary government, population not being taken into account. Senators were chosen by a college of fifteen electors elected in the same manner as the delegates, and the governor by a joint ballot of the two houses of assembly. In 1802 negroes were disfranchised, and in 1810 property qualifications for suffrage and office were abolished. The system of representation that, with the rapid growth of population in the north-east sections, especially in the city of Baltimore, placed the government in the hands of a decreasing minority also began to be attacked about this time; but the fear of that minority which represented the tobacco-raising and slave-holding counties of south Maryland, with respect to the attitude of the majority toward slavery prevented any changes until 1837, when the opposition awakened by the enthusiasm over internal improvements effected the adoption of amendments which provided for the election of the governor and senators by a direct vote of the people, a slight increase in the representation of the city of Baltimore and the larger counties, and a slight decrease in that of the smaller counties. Scarcely had these amendments been carried when the serious financial straits brought on by debt incurred through the state's promotion of internal improvements gave rise to the demand for a reduction of governmental expenses and a limitation of the power of the General Assembly to contract debts. The result was the new constitution of 1851, which fully established representation in the counties on the basis of population and further increased that of Baltimore. The constitution of 1851 was however chiefly a patchwork of compromises. So, when during the Civil War Maryland was largely under Federal control and the demand arose for the abolition of slavery by the state, another constitutional convention was called, in 1864, which framed a constitution providing that those who had given aid to the rebels should be disfranchised and that only those qualified for suffrage in accordance with the new document could vote on its adoption. This was too revolutionary to stand long and in 1867 it was superseded by the present constitution. In national affairs Maryland early took a stand of perhaps far-reaching consequences in refusing to sign the Articles of Confederation (which required the assent of all the states before coming into effect), after all the other states had done so (in 1779), until those states claiming territory beyond the Allegheny Mountains and the Mississippi sold north of the Ohio, Virginia, New York, Massachusetts, and Connecticut—should have surrendered such claims. As those states finally yielded, the Union was strengthened by reason of a greater equality and consequently less jealousy among the original states, and the United States came into possession of the first territory in which all the states had a common interest and out of which new states were to be created. In the War of 1812 Frederick, Havre de Grace, and Freetown were burned by the British; but particularly noteworthy were the unsuccessful movements of the enemy by land and by sea against Baltimore, in which General Robert Ross (c. 1766-1814), the British commander of the land force, was killed before anything had been accomplished and the failure of the fleet to take Fort McHenry after a siege of a day and a night inspired the song The Star-Spangled Banner, composed by Francis Scott Key who had gone under a flag of truce to secure from General Ross the release of a friend held as a prisoner by the British and during the attack was detained on his vessel within the British lines. In 1861 Maryland as a whole was opposed to secession but also opposed to coercing the seceded states. During the war that followed the west section was generally loyal to the north while the south section favoured the Confederacy and had from the outset fought for its army; but most of the state was kept under Federal control, the writ of habeas corpus being suspended. The only battle of much importance fought on Maryland soil during the war was that of Sharpsburg or Antietam on the 17th and 18th of September 1862. As between political parties the state has usually been quite equally divided. From 1860 to 1960, however, the Whigs were in general a trifle the stronger; and from 1866 to 1895 the Democrats were triumphant; in 1865 a Republican governor was elected; in 1886 Maryland gave McKinley 52,322 votes more than it gave Bryan; and in 1904 seven Democratic electors and one Republican were chosen; and in 1908 five Democratic and three Republican.

The proprietors of Maryland were: Cecilius Calvert, second Lord Baltimore (1663?–1675) from 1632 to 1675; Charles Calvert, third Lord Baltimore (1675–1715) from 1675 to 1715; Benedict Leonard Calvert, fourth Lord Baltimore (1683–1715) from 1715 to 1715; Frederick Calvert, sixth and last Lord Baltimore (1734–1771) from 1771 to 1771; Henry Harford, from 1771 to 1776.

Maryland.

Proprietary.

Leonard Calvert 1634–1645
Richard Ingle (usurper) 1645
Edward Hill (chosen by the council) 1646
Leonard Calvert 1646–1647
Thomas Greene 1647–1649
William Stone 1647–1652
Richard Bennett
Edmund Curtis (parliament) 1652
William Claiborne
William Stone 1652–1654
William Fuller and others (appointed by the commissioners of parliament) 1663–1665
Josias Felland 1665–1666
Philip Calvert 1666–1668
Charles Calvert 1668–1666
Charles Calvert, third Lord Baltimore 1675–1766
Cecilius Calvert (titular) and Jesse Wharton (real) 1676
Thomas Notley 1676–1679
Charles Calvert, third Lord Baltimore 1679–1684
Benedict Leonard Calvert (titular) and council (real) 1684–1688
William Joseph (president of the council) 1688–1699
Protestant Associates under John Coode 1699–1692

Royal.

Sir Lionel Copley 1662–1663
Sir Edmund Andros 1663–1664
Francis Nicholson 1664–1699
Nathaniel Blackstone 1665–1699
Thomas Tench (president of the council) 1705–1704
John Seymour 1704–1709
Edward Lloyd (president of the council) 1709–1714
John Hart 1714–1715
John Hart 1715–1720
Charles Calvert 1716–1720
Benedict Leonard Calvert 1720–1727
Samuel Ogle 1727–1731
Charles Calvert, fifth Lord Baltimore 1732–1738
Samuel Ogle 1733–1742
Thomas Bladen 1742–1747
Samuel Ogle 1747–1752
Benjamin Tasker (president of the council) 1752–1753
Horatio Sharpe 1753–1769
Robert Eden 1769–1774
Robert Eden (nominal) and Convention and Council of Safety (real) 1774–1776

State.

Thomas Johnson 1777–1779
Thomas Sim Lee 1779–1784
William Paca 1785–1785
William Smallwood 1785–1785
John Eager Howard 1788–1791
George Plater 1

1 Died in office.
MARYPORT—MASACCIO

C. Steiner, Maryland during the English Civil War (2 vols., Baltimore, 1906–1907), one of the Johns Hopkins University Studies.

MARYPORT, a market town and seaport in the Cockermouth parliamentary division of Cumberland, England, 25 m. S.W. of Carlisle, on the Maryport & Carlisle Railway, 11,857. It is irregularly built on the shore of the Irish Sea and on the cliffs above, at the mouth of the river Ellen. Until 1750 there were only a few huts here, the spot being called Ellenfoot, but at this time the harbour was built by Humphrey Senhouse. In 1832 Maryport became an independent port with Workington, Whitehaven and Milom subordinate to it. Coal and pig-iron are exported from the mining district inland, and shipbuilding is carried on. There are also rope and sail works, iron-foundries, saw-mills, breweries and tanneries. On the hill north of the town there is a Roman fort which guarded the coast, and many remains of this period have been discovered. The fort was called Uxellodunum.

MARZABOTTO, a village of Emilia, Italy, in the province of Bologna, 17 m. S.S.W. of Bologna by rail. Pop. (1901), 617 (village); 5727 (commune). It lies in the valley of the Reno, 443 ft. above sea-level. In and below the grounds of the Villa Aria, close to it, are the remains of an Etruscan town of the 5th century B.C., protected on the west by the mountains, on the east and south by the river, which by a change of course has altered about half of the area of the town. The approach was by a causeway from the town to the villa: here remains of temples were found. The town lay below the modern high-road and was laid out on a rectangular plan divided by main streets into eight quarters, and these in turn into blocks or insulae. Cemeteries were found on the east and north of the site. The name of the place is unknown: it was partially inhabited later by the Gauls, but was not occupied by the Romans.

The discoveries of 1888–1889 (with references to previous works) are described by E. Brizio in Monumenti dei Lincei (1891), i, 249 sqq.

MASACCIO (1401–1428). Italian painter. Tommaso Guidi, son of a notary, Ser Giovanni di Simone Guidi, of the family of the Scheggia, who had property in Castel S. Giovanni di Val d’Arno, was born in 1402 (according to Milanesi, on the 21st of December 1401), and acquired the nickname of Masaccio, which may be translated “Lubberly Tom,” in consequence of his slovenly dressing and deportment. From childhood he showed a great inclination for the arts of design, and he is said to have studied under his contemporary Masolino da Panicale. In 1421, or perhaps 1423, he was enrolled in the guild of the specialist (drugists) in Florence, in 1424 in the guild of painters. His first attempt at painting was made in Florence, and especially in the “Brancacci Chapel” which he had rendered famous almost beyond rivalry in the annals of painting.

The chapel had been built early in the 15th century by Felice Michele di Piuvichese Brancacci, a noble Florentine. Masaccio’s work in it began probably in 1423, and continued at intervals until

1 Resigned on the 6th of May 1868.

2 Removed in 1874 to become (March 4, 1875) U.S. senator from Maryland.
he finally quitte Florence in 1428. There is a whole library-shelf of discussion as to what particular things were done by Masaccio and what by Masolino, and long after this by Filippino Lippi, and also to certain other paintings by Masaccio in the Carmine. He began with a trial piece, a majestic figure of St Paul, not in the chapel; this has perished. A monochrome work has much admired, for the Ranchacci Collection of the Convent of the Carmine, Florence, as a wonderful example, for that early period, of perspective and of grouping, has also disappeared; it contains portraits of Brunelleschi, Donatello and many others. In the cloister of the Carmine was discovered a portion of a painting by Masaccio representing a procession; but this, being in colours and not monochrome, does not appear to be the Brancacci procession. As regards the work of a chapel itself, the St Peter Chapel at San Marco, Masolino, who used to be credited with a considerable portion of them, did either nothing, or at most the solitary compartment which represents St Peter restoring Tabitha to life, and the same year, that is, 1428, the very year that Masolino, who had prepared his monochrome chapel, worked at the same time, as has been observed, a splendid example of the "Virgin and Child in the Lap of St Anna," is an exception. The so-called portrait of Masaccio in the Uffizi Gallery is more probably Filippino Lippi, and Filippino, or Botticelli, may be the real author of the head, at first termed a Masaccio, in the National Gallery, London.

MASAI, an Eastern Equatorial African peoples of Negro-Hamitic stock, speaking a Nilotic language. The Hamitic element, which is not great, has probably been derived from the Gallo. The Masai were probably isolated in the high mountains or plateaus which lie between the Nile and the Karanjo country. They there originally had their homes and there to-day the Latuka, who show affinities with them at this date. Famine or inter-tribal wars drove the Masai in the direction of Mount Elgon and Lake Rudolf. After a long settlement there they split into two groups, the Masai proper and the Wa-Kuaf or agricultural Masai, and this at no very remote date, as the two tribes speak practically the same language. The more powerful Masai were purely nomadic and pastoral, their wealth consisting in enormous herds. The Wa-Kuaf, losing their cattle to their stronger kinsmen, split up again into the Burkenjei, the Gwas Negishu, and the Nyarai (Enjamusi) and settled as agriculturists. Meantime the Masai became masters of the greater part of inner East Africa from Uugogo and the Manyame countries on the south and west to Mount Kenya and Galla-land on the north, and eastward to the hundred-mile strip of more or less settled Bantu country on the coast of the Indian Ocean. The Masai physical type is slender, but among the finest in Africa. A tall, well-made people, the men are often well over six feet, with slim wiry figures, chocolate-coloured, with eyes often slightly oblique like the Mongolians, but the nose especially being often almost Caucasian in type, with well formed bridge and finely cut nostrils. Almost all the men and women knock out the two lower incisor teeth. For this custom they give the curious explanation that lockjaw was once very common in Masai-land, and that it was found to be easy to feed the sufferer through the gap thus made. All the hair on the body of both sexes is pulled out with iron tweezers; a Masai with a moustache or beard is unknown. The hair of the head is shaved in women and married men; but the hair of a youth at puberty is allowed to grow till it is long enough to have thin strips of leather plaited into it. In this way, the hair, after a coating of red ochre and mutton fat, is made into pigtails, the largest of which hangs down the back, another over the forehead, and one on each side. The warriors smear their whole bodies with the clay and fat, mixed in equal proportion.

No tattooing or scarifying is performed on the men, but Sir Harry Johnston noticed women with parallel lines burnt into the skin round their hips; in both sexes there are elongated conical loops, through holes in which large disks of wood are thrust. Beard necklaces, bead and wood armlets are worn by men, and before marrying the Masai girl has that of the woman cut close, and the locks so tightly as to check the scalp development. The women wear dressed hides or calico; the old men wear a skin or cloth cape. The warriors wind red calico round their waist, a circle of ostrich feathers adorn their head, and the women, when setting out for a long journey, dress their hair in long white fur round the knee. Masai houses are of two kinds. The agricultural tribes build round huts with walls of reeds or sticks, and conical, grass-thatched roofs. The true Masai, however, live in houses surrounded with sticks of long hedges as milkman's hedgehogs as cups, and small three-legged stools cut out of a single block correctly, with action, liveliness and relief. Soon after his death, his work was recognized at its right value, and led to notable advances; and all the greatest artists of Italy, through studying the Brancacci chapel, became his disciples and champions.

Of the works attributed to Masaccio in public or private galleries hardly any are authentic. His chief works are: the San Domenico"
of wood and used by the elder men to sit on. The Masai are not hunters of big game except lions, but they eat the eland and kudu. The domestic animals are cattle, sheep, goats, hares, and monkeys and dogs. The dead are ordinarily not buried, but the bodies are carried a short distance from the village and left on the ground to be devoured by hyenas, jackals, vultures, and blackbirds. In the case of the eldest son or successor the skull is treasured as a charm. The medicine men of Masai are often the chiefs, and the supreme chief is almost always a medicine man.

On an old belief in a supreme being—Ngaia ("sky")—his aid is invoked in cases of drought by a ceremonial chant of the children, standing in a circle after sunset, each with a bunch of dry leaves in his hand. They have an ugly-looking war-dance, called moroto, for pills, the black, white, grey and red disciples. They believe there is no future for women or common people, but that such distinction is reserved for chiefs. Pythons and a species of snake are considered sacred, and are never molested.

A kind of worship is paid to the hyena in some districts: the whole tribe going into mourning if the beast crosses their path. The Masai also have a vague tree-worship, and a grass symbol.

When making peace a tuft is held in the right hand, and when the warriors start out on a raid their sweetheart throw grass after them or lay it in the forks of trees. But the oddest of their superstitious customs is the importance attached to splitting.

To spit upon a person or thing is regarded as a sign of reverence and goodwill, as among other Nilotic tribes. Newly born children are spit on by every one who sees them. Johnston states that every Masai child is expected to make the sign of the cross on a tree as soon as it is able to do so; and to the children who are able to write, they say: "If I spit on a tree, I spit on them."

The Masai has no love for work, and practises no industries. The women attend to their personal needs; and trades such as smelting and forging are left to enslaved tribes such as the Dorobo (Wandorobo). These manufacture spears with long blades and butts and the peculiar swords or simés like long slender leaves, very narrow towards the hilt and broad at the point. Most of the Masai live in the British East Africa Protectorate.

Johnston, Kilimanjaro Expedition 1898 and the Josephine Missionary Expedition Through Masai-land (1899); O. Baumann, Durch Masai-land zur Nilquelle (1894); F. Kalenberg, Auf dem Kriegsfeld gegen die Masai (1892).

MASANIELLO, an abbreviation of Tommaso Anello (1622–1647), an Amalfi fisherman, who became leader of the revolt against Spanish rule in Naples in 1647. Misgovernment and fiscal oppression having aroused much discontent throughout the two Sicilies, a revolt broke out at Palermo in May 1647, and the people of Naples followed the example of the Sicilians. The immediate occasion of the latter rising was a new tax on fruit, the ordinary food of the poor, and the chief instigator of the movement was Masaniello, who took command of the malcontents.

The outbreak began on the 7th of July 1647 with a riot at the city gates between the fruit-vendors of the environs and the police, and the next day to him to the Castel Sant'elmo. These customs office was burnt. The rioters then poured into Naples and forced their way into the palace of the viceroy, the hated Count d'Arcos, who had to take refuge first in a neighbouring convent, then in Castel Sant' Elmo, and finally in Castelnuovo. Masaniello attempted to discipline the mob and restrain its vandaliel instincts, and to some extent he succeeded; attired in his fisherman's garb, he gave audiences and administered justice from a wooden scaffold outside his house. Several rioters, including the duke of Maddaloni, an opponent of the viceroy, and his brother Giuseppe Caraffa, who had come to Naples to make trouble, were condemned to death by him and executed.

The mob, which every day obtained more arms and was becoming more intractable, terrorized the city, drove off the troops summoned from without, and elected Masaniello "captain-general"; the revolt was even spreading to the provinces. Finally, the viceroy, whose negotiations with Masaniello had been frequently interrupted by fresh tumults, ended by granting all the concessions demanded of him. On the 13th of July, through the mediation of Cardinal Filaromino, archbishop of Naples, and the intervention of the Milanese War Office, he was made citizen of the city, and was invested with the title of "leader of the most faithful people of Naples," by which the rebels were pardoned, the more oppressive taxes removed, and the citizens granted certain rights, including that of remaining
appearance. Mascara is a town of the French colonial type, few vestiges of the Moorish period remaining. Among the public buildings are two mosques, in one of which Abd-el-Kader preached the *jihad*. The town also contains the usual establishments attaching to the seat of a sub-prefect and the centre of a military subdivision. The principal industry is the making of wine, the white wines of Mascara being held in high repute. There is also a considerable trade in grains and oil. A branch railway eight miles long connects Mascara with the line from the seaport of Arzew to Ain Sefra. Access is also gained by this line to Oran, Algiers, &c. Pop. (1906) of the town, 18,989; of the commune, which includes several villages, 22,934; of the arrondissement, comprising eleven communes, 190,154.

Mascara (i.e. "mother of soldiers") was the capital of a Turkish beylik during the Spanish occupation of Oran from the 16th to the close of the 18th century; but for the most of that period it occupied a site about two miles distant from the present position. On the removal of the bey to Oran its importance rapidly declined; and it was an insignificant place when in 1632 Abd-el-Kader, who was born in the neighbourhood, chose it as the seat of his power. It was laid in ruins by the French under Marshal Clausel and the duke of Orleans in 1835, the amir retreating south. Being reoccupied by Abd-el-Kader in 1838, Mascara was again captured in 1841 by Marshal Boniface under General Lamy.

**MASCARENE ISLANDS** (occasionally *Mascarenhas*), the collective title of a group in the Indian Ocean east of Madagascar, viz. Mauritius, Réunion and Rodriguez (q.v.). The collective title is derived from the Portuguese navigator Mascarenhas, by whom Réunion, at first called Mascarinas, was discovered.

**MASCARON, JULES** (1634–1703), French preacher, was the son of a barrister at Aix. Born at Marseilles in 1634, he early entered the French Oratory, and obtained great reputation as a preacher. Paris confirmed the judgment of the provinces; in 1666 he was asked to preach before the court, and became a great favourite with Louis XIV., who said that his eloquence was one of the few things that never grew old. In 1673 he was appointed bishop of Tulle; eight years later he was transferred to the larger diocese of Agen. He still continued, however, to preach regularly at court, being especially in request for funeral orations. A panegyric on Turenne, delivered in 1675, is considered his masterpiece. His style is strongly tinged with *préciosité*; and his chief surviving interest is as a glaring example of the evils from which Bossuet delivered the French pulpit. During his later years he devoted himself entirely to his pastoral duties at Agen, where he died in 1703.

Six of his profuse sermons have been edited, with a biographical sketch of their author, by the Oratorian Borde in 1704.

**MASCERONI, LORENZO** (1750–1800), Italian geometer, was professor of mathematics at the University of Pavia, and published a variety of mathematical works, the best known of which is his *Geometria del compasso* (Pavia, 1797), a collection of geometrical constructions in which the use of the circle alone is postulated. Many of the solutions are most ingenious, and some of the constructions of considerable practical importance.

There is a French translation by A. M. Carette (Paris, 1798), who also wrote a biography of Masceroni. See Poggendorff, *Biog. Lit.*, Landwörterbuch.

**MASCOT** (Fr. slang: perhaps from Port. *macaco*, "monkey"); the term for any person, animal, or thing supposed to bring luck. The word was first popularized by Edmond Audran through his comic opera *La Mascotte* (1880), but it had been traced back to a dialectic use in Provence and Gascony, where it meant something which brought luck to a household. The suggestion that it is from *mascar* (masked or concealed), the provincial French for a child born with a caul, in allusion to the lucky destiny of such children, is improbable.

**MADJU, JUAN FRANCISCO** (1744–1817), Spanish historian, was born at Arzeu to the Jews. He joined the Company of Jesus on the 19th of December 1759, and became professor in the Jesuit seminaries at Ferrara and Ascoli. He visited Spain in 1799, was exiled, and returned in 1815, dying at Valencia on the 11th of April 1817. *His Storia critica di Spagna e della cultura spagnola in ogni genero* (2 vols., 1781–1784) was finally expanded into the *Historia critica de España y de la cultura española* (1783–1806), which, though it consists of twenty volumes, was left unfinished; had it been continued on the same scale, the work would have consisted of fifty volumes. Madjue wrote in a critical spirit and with a regard for accuracy rare in his time; but he is more concerned with small details than with the philosophy of history. Still, his narrative is lucid, and later researches have not yet rendered his work obsolete.

**MAI,* or *MAZERU,* the capital of Basutoland, British South Africa. It is pleasantly situated on the left bank of the Caledon river, 90 m. by rail E. by S. of Bloemfontein, and 40 m. N.E. of Wepener. It is in the centre of a fertile grain-growing district. Pop. (1904), 802, of whom 99 were Europeans. The principal buildings are Government House, the church of the Paris Evangelical Missionary Society, the hospital, and the railway station. (See *Basutoland*.)

**MASHAM, ABIGAIL,** Lady (d. 1734), favourite of Anne, queen of England, was the daughter of Francis Hill, a London merchant, her mother being an aunt of Sarah Jennings, duchess of Marlborough. The family being reduced to poor circumstances through Hill's speculations, Lady Churchill (as she then was), lady of the bedchamber to the Princess Anne, befriended her cousin Abigail, whom she took into her own household at St Albans, and for whom after the accession of the princess to the throne she procured an appointment in the queen's household about the year 1704. It was not long before Abigail Hill began to supplant her powerful and imperious kinswoman in the favour of Queen Anne. Whether she was guilty of the deliberate ingratitude charged against her by the duchess of Marlborough is uncertain. It is not unlikely that, in the first instance at all events, Abigail's influence over the queen was not so much due to subtle scheming on her part as to the pleasing contrast between her gentle and genial character and the dictatorial temper of the duchess, which after many years of undisputed sway had at last become intolerable to Anne. The first intimation of her protégé's growing favour with the queen came to the duchess in the summer of 1707, when she learned that Abigail Hill had been privately married to a gentleman of the queen's household named Samuel Masham, and that the queen herself had been present at the marriage. Inquiry then elicited the information that Abigail had for some time enjoyed considerable intimacy with her royal mistress, no hint of which had previously reached the duchess. Abigail was said to be a cousin of Robert Harley, earl of Oxford, and after the latter's dismissal from office in February 1708 she assisted him in maintaining confidential relations with the queen. The completeness of her ascendency was seen in 1710 when the queen compelled Marlborough, much to his will, to give an important command to Colonel John Hill, Abigail's brother; and when Sunderland, Godolphin and the other Whig ministers were dismissed from office, largely owing to her influence, to make way for Oxford and Bolingbroke. In the following year the duchess of Marlborough was also dismissed from her appointment at court, Mrs Masham taking her place as keeper of the privy purse. In 1711 the ministers, intent on bringing about the disgrace of Marlborough and arranging the Peace of Utrecht, found it necessary to secure their position in the House of Lords by creating twelve new peers; one of these was Samuel Masham, the favourite's husband, though Anne showed some reluctance to raise her bedchamber woman to a position in which she might show herself less ready to give her personal services to the queen. Lady Masham soon quarrelled with Oxford, and set herself to foster by all the means in her power the queen's growing personal distaste for her minister. Oxford's vacillation between the Jacobites and the adherents of the Hanoverian succession to the Crown probably strengthened the opposition of Lady Masham, who now warmly favoured the Jacobite party led by Bolingbroke and Atterbury. Altercations in the court, in the end, led to the duchess being relieved of her office, and the minister; and finally, on the 27th of July 1714, Anne dismissed Oxford from his office of lord high treasurer, and three days later gave the staff to the duke of Shrewsbury. Anne died...
on the 1st of August, and Lady Masham then retired into private life. She died on the 6th of December 1734.

Lady Masham was by no means a vulgar, ill-educated person she was represented to have been by her defeated rival, the Duchess of Marlborough; her extant letters, showing not a little refinement of literary style, prove the reverse. Swift, with whom both she and her husband were intimate, describes Lady Masham as "a person of a plain sound understanding, of great truth and sincerity, without the least mixture of falsehood or disguise." The barony of Masham became extinct when Lady Masham's son, Samuel, the 2nd baron, died in June 1776.

(R. J. M.)

MASHAM, SAMUEL CUNLIFFE LISTER, 1st Baron (1815-1906), English inventor, born at Calverley Hall, near Bradford, on the 1st of January 1815, was the fourth son of Ellis Cunliffe Masham (1774-1853), who successively took the names of Lister and Lister-Kay, and was the first member of parliament elected for Bradford after the Reform Act of 1832. It was at first proposed that he should take orders, but he preferred a business career and became a clerk at Liverpool. In 1838 he and his elder brother John started as worsted spinners and manufacturers in a new mill which their father built for them at Manningham, and about five years later he turned his attention to the problem of mechanical wool-combing, which, in spite of the efforts of E. Cartwright and numerous other inventors, still awaited a satisfactory solution. Two years of hard work spent in modifying and improving existing devices enabled him to produce a machine which worked well, and subsequently he consolidated his position by buying up rival patents, as well as by taking out additional ones of his own. His combing machines came into such use that though they were made for only £200 apiece he was able to sell them for £1,200, and the savings they effected in the cost of production not only brought about a reduction in the price of clothing, but in consequence of the increase in the sales created the necessity for new supplies of wool, and thus contributed to the development of Australian sheep-farming.

In 1853 he sent a sample of silk waste (the refuse left in the reeling silk from the cocoons) and asked whether he could find a way of utilizing the fibre it contained. The task occupied his time for many years and brought him to the verge of bankruptcy, but at last he succeeded in perfecting silk-combining apparatus which enabled him to make yarn that in one year sold for 23s. a pound, though produced from raw material costing only 6d. or 1s. a pound. Another important and lucrative invention in connexion with silk manufacture was his velvet loom for piled fabrics; and this, with the silk comb worked at his Manningham mill, yielded him an annual income of £20,000 for many years. But the business was seriously affected by the prohibitory duties imposed by America, and this was one reason why he was an early and determined critic of the British policy of free imports. In 1891 he was made a peer; he took his title from the little Yorkshire town of Masham, close to which is Swinton Park, purchased by him in 1888. In 1886 an Albert medal was awarded him for his inventions, which were mostly related to the textile industries, though he occasionally diverged to other subjects, such as an air-brake for railways. He was fond of outdoor sports, especially coursing and shooting, and was a keen patron of the fine arts. He died at Swinton Park on the 2nd of February 1906, and was succeeded in the title by his son.

MASHONA, a Bantu- negro people, inhabitants of Mashonaland, Southern Rhodesia. The name Mashona has been derived from the contemptuous term Amashushina applied by the Matabele to the aborigines owing to the habit of the latter of taking refuge in the rocky hills with which the country abounds. Before the Matabele invasion about 1830 most of Southern Rhodesia was occupied by the Makalanga, the Makorikori and the Banyai, all closely related. Most of them became subject to the Matabele, but although they suffered severely from their attacks, the Mashona preserved a certain national unity. In 1855 the Mashona wore the gold diggings which are scattered over their country; indeed as late as 1870 certain Mashona were still extracting gold from quartz (Geog. Jour. April 1906).

For the possible connexion of these people with the builders of the ruins at Zimbabwe and elsewhere, see Rhodesia: Archaeology; and Zimbabwe.

MASK (Fr. masque, apparently from med. Lat. mascus, masca, spectre, through Ital. maschera, Span. mascara), a covering for the face, taking various forms, used either as a protective screen or as a disguise. In the latter sense masks are mostly associated with the artificial faces worn by actors in dramatic representations, or assumed for exciting terror (e.g. in savage rites). The spelling "masque," representing the same word, is now in English used more especially for certain varieties of drama in which masks were originally worn (see Drama); while also "masquerade," particularly in the sense of a masked ball or an entertainment where the personages are disguised. Both "mask" and "masquerade" have naturally passed into figurative and technical meanings, the former especially for apotropoeis of face and body (bound of a fox, grotesque faces in sculpture), or as equivalent to "cloak" or "screen" (as in fortification or other military uses, fencing, &c.). And in the case of "death-masks" the term is employed for the portraitcasts, generally of plaster or metallic foil, taken from the face of a dead person (also similarly from the living), an ancient practice of considerable interest in art. An interesting collection made by Laurence Hutton (see his Portraits in Plaster, 1894), is at Princeton University in the United States. (For the historical mystery of the "man in the iron mask," see Iron MASK.)

The ancient Greek and Roman masks worn by their actors—hollow figures of heads—had the double object of identifying the performers with the characters assumed, and of increasing the power of the voice by means of metallic mouthpieces. They were derived like the drama from the rural religious festivities, the wearing of mock faces or beards being a primitive custom, connected no doubt with many early types of folklore and religion. The use of the dramatic mask was evolved in the later theatre through the mimes and the Italian popular comedy into pantomime; and the masquerade similarly came from Italy, where the domino was introduced from Venice. The domino (originally apparently an ecclesiastical garment) was a loose cloak with a small half-mask worn at masquerades and costume-balls by persons not otherwise dressed in character; and the word is applied also to the person wearing it.

See generally Altmann, Die Masken der Schauplader (1875; new ed., 1896); and Dale, Masks, Labrets and Certain Aboriginal Customs (1885); also Drama.

MASEKLYNE, NEVIL (1732–1811), English astronomer-royal, was born in London on the 5th of October 1732. The
solar eclipse of 1748 made a deep impression upon him; and having graduated as seventh wrangler from Trinity College, Cambridge, in 1755, and in 1761 was deputed by the Royal Society to make observations of the transit of Venus at St. Helena. During the voyage he experimented upon the determination of longitude by lunar distances, and ultimately effected the introduction of the method into navigation (q.e.). In 1765 he succeeded Nathaniel Bliss as astronomer-royal. Having energetically discharged the duties of his office during forty-six years, he died on the 9th of February 1811.

Maskelyne’s first contribution to astronomical literature was “A Proposal for Discovering the Annual Parallax of Sirius,” published in 1760 (Phil. Trans. l. 3. 889). Subsequent volumes of the same series contained his observations of the transits of Venus (1761 and 1769), on the tides at St. Helena (1762), and on various astronomical phenomena at St. Helena (1764) and at Barbados (1764). In 1763 he published the British Mariner’s Guide, which includes the suggestion that in order to facilitate the finding of longitude at sea lunar distances should be calculated beforehand for each vessel and published in a form accessible to navigators. The relative longitude of Greenwich, the general publication of Neats’ tables, was approved of by the government, and under the care of Maskelyne the Nautical Almanac for 1767 was published in 1766. He continued during the whole of his life the publication of a new edition of the Almanac annually. He further induced the government to print his observations annually, thereby securing the prompt dissemination of a large mass of data inseparable from their continuity and accuracy. Maskelyne took the assistance of the works of the different observatories was perfectly organized and methodically executed. He introduced several practical improvements, such as the measurement of time to tenths of a second; and he prevailed upon the government to reduce Bird’s mural quadrant by a repeating circle 6 ft. in diameter. The new instrument was constructed by E. Troughton; but Maskelyne did not live to see it completed. In 1770 he was suggested to the Royal Society the famous Schehallion experiment for the determination of the earth’s density and carried out his plan in 1774 (Phil. Trans. l. 9. 405), the apparent difference of latitude between two stations on opposite sides of the mountain being compared with the real difference of latitude obtained by triangulation. From Maskelyne’s observations Charles Hutton deduced a density for the earth 4.5 times that of water (ib. xlvii. 781). Maskelyne also took a great interest in various geodetical operations, notably the measurement of the length of a degree of latitude in Maryland and Pennsylvania (ibid. xlviii. 323), executed by Mason and Dixon in 1766-1768, and later the determination of the relative longitude of Greenwich and Paris (ib. xlviii. 151). On the French side the work was conducted by Cassi, Legendre, and Mêchon; on the English side by General Roy. This triangulation was the beginning of the great triangonometrical survey which has extended all over Europe. His observations appeared in four large folio volumes (1776-1811). Some of them were reprinted in S. Vincen’s Astronomy (vol. iii). (A. M. C.)

MASOLINO DA PANICALE (1383-1445), Florentine painter, was said to have been born at Panicale di Valdelsa, near Florence. It is more probable, however, that he was born in Florence itself, his father, Cristoforo Fini, who was an “imbicicatore,” or whitewasher, having been domiciled in the Florentine quarter of S. Croce. There is reason to believe that Tommaso, nicknamed Masolino, was a pupil of the painter Starnina, and was principally influenced in style by Antonio Veneziano; he may probably enough have been born in 1423; he died later than 1429, perhaps as late as 1440 or even 1447. Towards 1423 he entered the service of Filippo Scolari, the Florentine-born obergespann of Temeswar in Hungary, and stayed some time in that country, returning towards 1427 to Italy. The only works which can with certainty be assigned to him are a series of wall paintings executed towards 1428, commissioned by Cardinal Branda Castiglione, in the church of Castiglione d’Olena, not far from Milan, and another series in the adjoining baptistery, which is signed “Masolino detto il Florentia.” It was recovered in 1843 from a coating of whitewash, considerably damaged; its subject matter is taken from the lives of the Virgin and of SS Lawrence and Stephen. The series in the baptistery relates to the life and death of John the Baptist. The reputation of Masolino had previously rested almost entirely upon the considerable share which he was supposed to have had in the celebrated frescoes of the Brancacci Chapel, in the Church of the Carmine in Florence; he was regarded as the precursor of Masaccio, and by many the predecessor of Filippo Lippi, and as one of the originators of the Castiglione with the Brancacci frescoes, and from other data, it is very doubtful whether Masolino had any hand at all in the latter series. Possibly he painted in the Brancacci Chapel certain subjects which are now either destroyed or worked over. Several paintings assigned to Masolino on the authority of Vasari are now ascribed to Masaccio. (W. M. R.)

MASON, FRANCIS (1799-1874), American missionary, was born in York, England, on the 2nd of April 1799. His grandfather, Francis Mason, was the fourth in the Baptist Society in York, and his father, a shoemaker by trade, was a frequent lay preacher there. After working with his father as a shoemaker for several years, he emigrated in 1818 to the United States, and in Massachusetts was licensed to preach as a Baptist in 1827. In 1830 he was sent by the American Baptist Missionary Convention to labour among the Karens in Burma. Besides conducting a training college for native preachers and teachers at Tavoy, he translated the Bible into the two principal dialects of the Karens, the Sgaw and the Pwo (his translation being published in 1853, and Matthew, and the Psalms into the Bghai dialect. He also published a Dictionary of Kachchayon, with Cremsonathy and Vocabulary (1866). In 1852 he published a book of great value on the fauna and flora of British Burma, of which an improved edition appeared in 1860 under the title Burmah, its People and Natural Productions, and a third edition (2 vols.) revised and enlarged by W. Theobald in 1882-1883. He died at Rangoon on the 3rd of March 1874.

See his autobiography, The Story of a Working Man’s Life, with Sketches of Travel in Europe, Asia, Africa and America (New York, 1877).

MASON, GEORGE (1775-1792), American statesman, was born in Stafford county (the part which is now Fairfax county), Virginia, in 1775. His family was of Royalist descent and emigrated to America after the execution of Charles I. His colonial ancestors held official positions in the civil and military service of Virginia. Mason was a near neighbour and a lifelong friend of George Washington, though in later years they disagreed in politics. His large estates and high social standing, together with his personal ability, gave Mason great influence among the Virginia planters, and he became identified with many enterprises, such as the organization of the Ohio Company and the founding of Friendship and Maria (1749). He was a member of the Virginia House of Burgesses in 1776, and he drew up for Washington a series of non-importation resolutions, which were adopted by the Virginia legislature. In July 1774 he wrote for a convention in Fairfax county a series of resolutions known as the Fairfax Resolves, in which he advocated a congress of the colonies and suggested non-intercourse with Great Britain, a policy subsequently adopted by Virginia and later by the Continental Congress. He was a member of the Virginia Committee of Safety from August to December 1776, and of the Virginia Convention in 1777 and 1776 and in 1776 he drew up the Virginia Constitution and the famous Bill of Rights, a radically democratic document which had great influence on American political institutions. In 1780 he outlined the plan which was subsequently adopted by Virginia for ceding to the Federal government her claim to the “back lands,” i.e. to territory north and north-west of the Ohio river. From 1776 to 1788 he represented Fairfax county in the Virginia Assembly. He was a member of the Virginia House of Delegates in 1776-1780 and again in 1787-1788, and in 1787 was a member of the convention that framed the Federal Constitution, and as one of its ablest debaters took an active part in the work. Particularly notable was his opposition to the compromises in regard to slavery and the slave-trade. Indeed, like most of the prominent Virginians of the time, Mason was strongly in favour of the gradual abolition of slavery. He objected to the large and indefinite powers given by the completed Constitution to
MASON, G. H.—MASON, SIR J.

Congress, so he joined with Patrick Henry in opposing its ratification in the Virginia Convention (1788). Failing in this he suggested amendments, the substance of several of which was afterwards embodied in the present Bill of Rights. Declining an appointment as a United States Senator from Virginia, he retired to his home, Gunston Hall (built by him about 1738 and named after the family home in Staffordshire, England), where he died on the 7th of October 1792. With James Madison and Thomas Jefferson, Mason carried through the Virginia legislature measures disestablishing the Episcopal Church and prohibiting all forms of work on Sunday. He was a radical republican, who believed that local government should be kept strong and central government weak; his democratic theories had much influence in Virginia and other southern and western states.

See Kate Mason Rowland, Life and Writings of George Mason (2 vols., New York, 1892).

MASON, GEORGE HEMMING (1818-1872), English painter, was born at Westley Abbey, the eldest son of a Staffordshire county gentleman. He was educated at King Edward's School, Ledbury, under the first new master for the school for 4 years under Dr Watt of that city. But all his thoughts being given to art, he abandoned medicine in 1844 and travelled for a time on the Continent, finally settling in Rome, where he remained for some years and sought to make a living as an artist. During this period he underwent many privations which permanently affected his health; but he continued to labour assiduously, making studies of the picturesque scenery that surrounded him, and with hardly any instruction except that received from Nature and from the Italian pictures he gradually acquired the painter's skill. At least two important works are referable to this period: "Ploughing in the Campagna," shown in the Royal Academy of 1857, and "In the Salt Marshes, Campagna," exhibited in the following year. After Mason's return from the continent, in 1858, when he settled at Westley Abbey, he continued for a while to paint Italian subjects from studies made during his stay abroad, and then his art began to touch in a wonderfully tender and poetical way the pleasant life of England, especially of his native Staffordshire, and the homely landscape in the midst of which that life was set. The first picture of this class was "Wind on the Wood," and it was followed—along with much else of admirable quality—by the painter's three greatest works: The "Evening Hymn" (1868), a band of Staffordshire mill-girls returning from their work; "Girls dancing by the Sea" (1869); and the "Harvest Moon" (1872). He left Staffordshire in 1885 and went to live at Hammersmith; and he was elected an associate of the Royal Academy in 1886. By that time he had fully established his position as an artist of unusual power and individuality. Mason died on the 22nd of October 1872. In his work he laboured under the double disadvantage of feeble and uncertain health, and a want of thorough art-training, so that his pictures were never produced easily, or without strenuous and long-continued effort. His art is great in virtue of the solemn paths which pervades it, of the dignity and beauty in rustic life which it reveals, of its keen perception of noble form and graceful motion, and of rich effects of colour and subdued light. In motif and treatment it has something in common with the art of Millet and Jules Breton, as with that of Frederick Walker among Englishmen; though he had neither the occasional uncouth robustness of Millet nor the first actuality of Jules Breton. His pictures "Wind on the Wood" and "The Cast Shoe" are in the National Gallery of British Art.

MASON, JAMES MURRAY (1708-1781), American political leader, was born in Fairfax County, Virginia, on the 3rd of November 1708, the grandson of George Mason (1725-1792). Educated at the university of Pennsylvania and the college of William and Mary, he was admitted to the bar in 1720. He was a member of the Virginia House of Delegates in 1826-1827 and 1828-1831 of the state Constitutional Convention of 1829, of the National House of Representatives (1837-1839), of the United States Senate from 1847 until July 1861 (when, with other Southern senators he was formally expelled—he had previously withdrawn), and of the Virginia Secession Convention in April 1861. Entering politics as a Jacksonian Democrat, Mason was throughout his career a consistent strict constructionist, opposing protective tariffs, internal improvements by the national government, and all attempts to restrict or control the spread of slavery, which he sincerely believed to be essential to the social and political welfare of the South. He was the author of the Fugitive Slave Act of 1850, and in 1860 was chairman of the Senate committee investigating the John Brown raid. After Lincoln's election as President he was one of the strongest advocates of secession in Virginia. He was appointed in August 1861 commissioner of the Confederate States to Great Britain. The British ship "Trent," upon which he and John Slidell, the commissioner to France, sailed, was intercepted (Nov. 8, 1861) by a United States ship-of-war (the "San Jacinto," Captain Charles Wilkes), and the two commissioners were seized and carried as prisoners to Boston. Great Britain immediately demanded their release, and war for a time seemed imminent; but owing mainly to the tactful diplomacy of the prince consort, Lincoln acknowledged that the seizure of Mason and Slidell was a violation of the rights of Great Britain as a neutral, and on the 1st of January 1862 released the commissioners. The incident has become known in history as the "Trent Affair." Mason at once proceeded to London, where, however, he was unable to secure official recognition, and his commission to Great Britain was withdrawn late in 1863. He remained in Europe, spending most of his time at Paris and holding blank commissions which he was authorized to fill in at his discretion in case the presence of a Confederate commissioner should seem desirable at any particular European court. These commissions, however, he did not use. After the war he lived for several years in Canada, but returned in 1869 to Virginia, and on the 28th of April 1871 died at Alexandria.

See The Public Life and Diplomatic Correspondence of James M. Mason, with some Personal History (Roanoke, Va., 1903), by his daughter, Virginia Mason; Sir Theodore Martin, Life of the Prince Consort.

MASON, SIR JOHN (1792-1866), English diplomatist, was born of humble parentage at Abingdon in 1792, and was educated at Oxford, where he became Fellow of All Souls in 1814. He was ordained before 1831. Most of his early years were spent on the Continent, where he witnessed the meeting between Henry VIII. and Francis I. at Calais in 1532, and where he was employed in collecting information for the English government, gaining in this work the reputation of a capable diplomatist. By his never-failing caution, moderation and pliancy, Mason succeeded in keeping himself in favour with four successive sovereigns of the Tudor monarchy. In 1557 he became secretary to the English ambassador at Madrid, Sir Thomas Wyatt; but when the latter was put on his trial for treason in 1551 Mason was un molested, and soon afterwards was appointed clerk of the privy council, and procured for himself sundry other posts and privileges. Mason was knighted and made dean of Winchester by Edward VI. He was one of the commissioners to negotiate the treaty by which Boulonne was restored to France in 1550, and in the same year he became English ambassador in Paris, where he helped to arrange the betrothal of Edward VI. to the princess Elizabeth of France. He returned to England at the end of 1551, became clerk of parliament, received extensive grants of land, and in 1552 was made chancellor of Oxford University. He was elected member of parliament in the same year. On the death of Edward VI., he at first joined the party of Northumberland and the Lady Jane Grey; but quickly perceiving his mistake he took an active part in procuring the proclamation of Mary as queen. Mason now received fresh tokens of royal favour, being confirmed in all his secular, though not in his ecclesiastical, offices; and in 1553 he was appointed English ambassador at the court of the emperor Charles V., of whose abdication at Brussels in October 1555 he wrote a vivid account. He took a prominent share in the
MASON, J.—MASON, W.

administrative business of the government in the first years of Elizabeth's reign, and largely influenced her foreign policy until his death, which occurred on the 20th of April 1566. Sir John Mason married Elizabeth, daughter of Sir Thomas Isley of Sundridge, Kent, and widow of Richard Hill. He had no children, and his heir was Anthony Wyckes, whom he had adopted, and who assumed the name of Mason and left a large family.

MASON, JOHN (1586-1633), founder of New Hampshire, U.S.A., was born in King's Lynn, Norfolk, England. In 1610 he commanded a small naval force sent by James I. to assist in subduing the Hebrides Islands. From 1615 to 1621 he was governor of the English colony on the north side of Conception Bay in Newfoundland; he explored the island, made the first English map of it (published in 1625), and wrote a descriptive tract entitled A Briefe Discourse of the Newfoundland (Edinburgh, 1626) to promote the colonization of the island by Scotchmen. Here he was brought into official relations with Sir Ferdinando Gorges, then a commissioner to regulate the Newfound-land fisheries. In March 1622 Mason obtained from the Council for New England, of which Gorges was the most influential member, a grant of the territory (which he named Mariana) between the Naumkeag or Salem river and the Merrimac river in the following August he and Gorges together received a grant of the region between the Merrimac and Kennebec rivers, and extending 60 m. inland. From 1625 to 1629 Mason was engaged as treasurer and paymaster of the English army in the wars which England was waging against Spain and France. Towards the close of 1629 Mason and Gorges agreed upon a division of the territory held jointly by them, and on the 7th of November 1629 Mason received from the Council a separate grant of the tract between the Merrimac and the Piscataqua, which he now named New Hampshire. Thinking that the Piscataqua river had its source in Lake Champlain, Mason with Gorges and a few other associates secured, on the 17th of November 1629, a grant of a region which was named Laconia (apparently from the number of lakes it was supposed to contain), and was described as bordering on Lake Champlain, extending 10 m. east and south from it and far to the west and north-west, together with 1000 acres to be located along some convenient harbour, presumably near the mouth of the Piscataqua. In November 1631 Mason and his associates obtained, under the name of the Piscataway Grant, a tract on both sides of the Piscataqua river, extending 30 m. inland and including also the Isles of Shoals. Mason became a member of the Council for New England in June 1632, and its vice-president in the following November; and in 1635, when the members decided to divide their territory among themselves and surrender their charter, he was allotted as his share all the region between the Naumkeag and Piscataqua rivers extending 60 m. inland, the southern half of the Isles of Shoals, and a ten-thousand acre tract, called Masonia, on the west side of the Kennebec river. In October 1635 he was appointed vice-admiral of New England, but he died early in December, before crossing the Atlantic. He was buried in Westminster Abbey. Forty-four years after his death New Hampshire was made a royal province.

See Captain John Mason, the Founder of New Hampshire (Boston, 1887; published by the Prince Society), which contains a memoir by C. W. Tuttle and historical papers relating to Mason's career, edited by J. J.杜尔.

MASON, JOHN YOUNG (1799-1839), American political leader and diplomatist, was born in Greenevesville, Virginia, on the 18th of April 1799. Graduating at the university of North Carolina in 1816, he studied law in the famous Litchfield (Connecticut) law school, and in 1819 was admitted to practice in Southampton county, Virginia. He served in the Virginia house of delegates in 1823-1827, in the state constitutional convention of 1829-1830, and from 1831 to 1837 in the National House of Representatives, being chairman of the committee on foreign affairs in 1835-1836. He was secretary of the navy in President Tyler's cabinet (1844-1845), and was attorney-general (1845-1846) and secretary of the navy (1846-1849), succeeding George Bancroft, under President Polk. He was president of the Virginia constitutional convention of 1851, and from 1853 until his death at Paris on the 3rd of October 1872, was United States minister to France. In this capacity he attracted attention by wearing at the court of Napoleon III. a simple diplomatic uniform (for this he was rebuked by Secretary of State W. L. Marcy, who had ordered American ministers to wear a plain civilian costume), and by joining with James Buchanan and Pierre Soule, ministers to Great Britain and Spain respectively, in drawing up (Oct. 1854) the famous Ostend Manifesto. Hawthorne called him a "fat-brained, good-hearted, sensible old man"; and in politics he was a typical Virginian of the old school, a state's rights Democrat, a strong friend of the Union, and a party leader of large ability. He was very fond of music, and was a competent violinist.

MASON, SIR JOSIAH (1795-1881), English pen-manufactur-er, was born in Kidderminster on the 23rd of February 1795, the son of a carpet-weaver. He began life as a street hawkew of cakes, fruits and vegetables. After trying his hand in his native town at shoemaking, baking, carpentering, blacksmithing, house-painting and carpet-weaving, he moved in 1814 to Birmingham. Here he found employment in the gilt-toy trade. In 1824 he set up on his own account as a manufacturer of split-rings by machinery, to which he subsequently added the making of steel pens. Owing to the circumstance of his pens being supplied through James Perry, the London stationer whose name they bore, he was less well known than Joseph Gillott and other makers, although he was really the largest producer in England. In 1874 the business was converted into a limited liability company. Besides his steel-pen trade Mason carried on for many years the business of electro-plating, copper-smelting, and india-rubber ring making, in conjunction with George K. Elkington. Mason was almost entirely self-educated, having taught himself to write when a shoemaker's apprentice, and in later life he felt his deficiencies keenly, it was this which led him in 1860 to establish his great orphanage at Erdington, near Birmingham. Upon it he expended about £300,000, and for this munificent endowment he was knighted in 1872. He had previously given a dispensary to his native town and an almshouse to Erdington. In 1880 Mason College, since incorporated in the university of Birmingham, was opened, the total value of the endowment being about £250,000. Mason died on the 16th of June 1881.

See J. T. Bunce, Josiah Mason (1882).

MASON, LOWELL (1702-1782), American musician, was born at Medfield, Massachusetts. For some years he led a business life, but was always studying music; and in 1727, as the result of his work in forming the collection of church music then on hand, he was appointed music master. In 1731 he published in the pamphlets of Thomas and Haydn Society, he moved to Boston and there first became president of the society and then founder of the Boston Academy of Music (1832). He published some successful educational books, and was a pioneer of musical instruction in the public schools, adopted in 1838. He received the degree of doctor of music from New York University in 1855. He died at Orange, New Jersey, on the 11th of August 1872.

His son William Mason (1829-1908), an accomplished pianist and composer, published an interesting volume of reminiscences, Memoirs of a Musical Life, in 1901.

MASON, WILLIAM (1757-1779), English poet, son of William Mason, vicar of Holy Trinity, Hull, was born on the 14th of February 1757, was educated at St. John's College, Cambridge, and took holy orders. In 1774 he wrote Musaens, a lament for Pope in imitation of Lydias, and in 1774 through the
influence of Thomas Gray he was elected a fellow of Pembroke College. He became a devoted friend and admirer of Gray, who addressed him as "Skroddles," and corrected the worst solecisms in his verses. In 1748 he published Isis, a poem directed against the supposed Jacobitism of the university of Oxford, which provoked Thomas Warton's Triumph of Isis. Mason conceived the ambition of reconciling modern drama with ancient forms by strict observance of the unities and the restricted time of action. The chief of his poems are Elfrida (1752) and Caractacus (1759), two frigid performances no doubt intended to be read rather than acted, but produced with some alterations at Covent Garden in 1772 and 1776 respectively. Horace Walpole described Caractacus as "laboured, uninteresting, and no more resembling the manners of Britons than of Japanese"; while Gray declared he had read the manuscript "not with pleasure only, but with emotion." In 1754 Mason was presented to the rectory of Aston, near Rotherham, Yorkshire, and in 1757 through the influence of the duke of Devonshire, and by the aid of Gray's letters, he also received the prebend of Holme in York Minster (1756), was made canon residuary in 1762, and in 1763 became precentor and prebendary of Driffield. He married in 1764 Mary Sherman, who died three years later. When Gray died in 1771 he made Mason his literary executor. In the preparation of the Life and Letters of Gray, which appeared in 1774, he had much help from Horace Walpole, with whom he corresponded regularly until 1774 when Mason opposed Fox's India Bill, and offended Walpole by thrusting on him political advice unasked. Twelve years of silence followed, but in the year before his death that correspondence was renewed in friendly terms. Mason died at Aston on the 7th of April 1797.

His correspondence with Gray and Walpole shows him to have been a man of cultivated tastes. He was something of an antiquary, a good musician, and an amateur of painting. He is said to have invented an instrument called the solenci, a modified pianoforte. Gray rewarded his faithful admiration with good-humoured kindness. He warned him against confounding Mona with the Isle of Man, or the Goths with the Celts, corrected his grammar, pointed out his plagiarisms, and laughed gently at his superficial learning. His powers show to better advantage in the unacknowledged satirical poems which he produced under the pseudonym of Malcolm MacGregor. In an edifying Gray's letters he took considerable liberties with his originals, and did not print all that related to himself.

Mason's other works included Odes (1776); The English Garden, a dactylic hexameter, verse, the first Book of which appeared in 1772, 1777, 1779 and 1780; An Heroic Epistle to Sir William Chambers (1774); an Ode to Mr Pinkie (1776) and an Epistle to the Duke of Devonshire (1777)—all these by "Malcolm Macgregor"; Essay, Historical and Critical, of Church Music (1753), and a lyric drama, Sappho (1797).

His poems were collected in 1764 and 1774, and an edition of his Works in 1783. His poems with a Life are included in Alexander Chalmers's English Poets. His correspondence with Walpole was edited by J. Mitford in 1851; and his correspondence with Gray by the same editor in 1853. See also the standard editions of the letters of Gray and of Walpole. There is a very pleasant picture of Mason's character in Southey's Doctor (ch. xxvii).

MASON AND DIXON LINE—MASONRY

present Washington county, was originally marked with milestones brought from England, every fifth of which bore on one side the arms of Baltimore and on the opposite side those of Penn; but the difficulties in transporting them to the westward were so great that many of them were not set up. Owing to the removal of the stone marking the north-east corner of Maryland, this point was again determined and marked in 1849-1850 by Lieut.-Colonel J. D. Graham of the U.S. topographical engineers; and as the western part of the boundary was not marked by stones, and local disputes arose, the line was again surveyed between 1901 and 1903 under the direction of a commission appointed by Pennsylvania and Maryland.

The use of the term "Mason and Dixon Line" to designate the boundary between the free and the slave states (and in general between the North and South) dates from the controversy over the Missouri Compromise in 1819-1820. As so used it may be defined as not only the Mason and Dixon Line proper, but also the line formed by the Ohio River from its intersection with the Pennsylvania boundary to its mouth, thence the eastern, northern and western boundaries of Missouri, and thence westward the parallel 36° 30'—the line established by the Missouri Compromise to separate free and slave territory in the "Louisiana Purchase," except as regards Missouri. It is to be noted, however, that the Missouri Compromise did not affect the territory later acquired from Mexico.

MASON CITY, a city and the county-seat of Cerro Gordo county, Iowa, U.S.A., on Lime Creek, in the northern part of the state. Pop. (1905, state census), 8357 (929 foreign-born, 1901). The city was incorporated in 1855, and the Mason City & Clear Lake (electric) railway, which connects Mason City with Clear Lake, a pleasure resort, 10 m. west of the city. At Mason City is Memorial University (co-educational; founded in 1900 by the National Encampment of the Sons of Veterans, and opened in 1902), dedicated to the Grand Army of the Republic, the special aim of which is to teach American history. The city is the site of a good school of education and art, and of two large iron and steel works. The city, with its surrounding territory, is noted for the numerous stone quarries in the vicinity. The manufactures include lime, Portland cement, brick and tile.

MASONRY, the art of building in stone. The earliest remains (apart from the primitive work in rude stone—see STONE MONUMENTS; ARCHAEOLOGY, &c.) are those of the ancient temples of India and Egypt. Many of these early works were constructed of stones of huge size, but it still remains a mystery how the ancients could have been able to quarry and raise to a considerable height above the ground blocks seven or eight hundred tons in weight. The methods of the modern mason are wholly different, and are based on the use of constructed masses of concrete, often faced with a species of rough cast. The early masonry seems to have been for the most part worked with the axe and not with the chisel. A very excellent example of the contrast between the earlier and later Norman masonry may be seen in the choir of Canterbury Cathedral. In those times the groining was frequently filled in with a light tufa stone, said by some to have been brought from Italy, but more probably from the Rhine. The Normans imported a great quantity of stone from Caen, it being easily worked, and particularly fit for the purposes of their magnificent edifices, and were also much used; and in the first Pointed period, Purbeck and Betersden marbles were employed for column shafts, &c. The methods of working and setting stone were much the same as at present, except that owing to difficulties of conveyance the stone was hauled to the building in small quantities on the back of the masons. The term "mason" is of French origin, and was used by the ancient French builders, who were also called "monachs," from the word monachus, a monk.

The English word "masonry" is from the French, which appears in the two forms, machin and masonn (from the last comes the modern Mr. Mason Beal). The word is well known in O. H. Ger. the word is maso, which survives in the German for stone-mason, Steinmetz. The med. Lat. form, machin, was connected with machina—obviously a guess. The Low Lat., machina or maccina, was introduced by Du Cange, but he was doubtless suggested as showing some connexion. Some popular Lat. form as macio or mattio is probably the origin. No Teut, word, according to the New English Dictionary, except that which appears in mattock, seems to have any bearing on the ultimate origin.
stones were used in much smaller sizes. As time went on the art of masonry advanced till in England, in point of execution, it at length rivalled that of any country.

Tools.—The mason's tools may be grouped under five heads—hammers and mallets, saws, chisels, setting-out and setting tools, and holdfasts.

There are several different kinds of iron hammers used by the stone worker; the mash hammer has a short handle and heavy head for use with chisels; the iron hammer, used in carving, is large and has a thick head which is used in conjunction with the mallet. The waller's hammer is used for roughly shaping stones in rubble work; the spalling hammer for roughly dressing stones in the quarry; the scabbling-hammer, for the same purpose, has an end pointed for use on hard stone; the pick has a long head pointed at both ends, weighs from 14 to 20 lb, and is used for rough dressing and splitting; the axe has a double wedge-shaped head and is used to bring stones to a fairly level face preparatory to their being worked smooth; the patent axe, or patent hammer, is formed with a number of plates with sharpened edges bolted together to form a head; the mallet of hard wood is used for the finishing chisel work and carving; and the dummy is of similar shape but smaller.

A hand saw similar to that used by the carpenter is used for cutting small soft stones. Larger blocks are cut with the two-handed saw worked by two men. For the largest blocks the frame saw is used, and is slung by a rope and pulleys fitted with balance weights to relieve the operator of its weight. The blade is of plain steel, the cutting action being supplied by sand with water as a lubricant constantly applied.

There are perhaps even more varieties of chisels than of hammers. The point and the punch have very small cutting edges, a quarter inch or less in width. The former is used on the harder stone, while the latter varieties of stone after the rough hammer dressing. The pitching tool has a wide thick edge and is used in rough dressing. Jammers are shafts of steel having a widened edge, and are used for boring holes in stone. Chisels are made with edges from a quarter-inch to one and a half inches wide; those that exceed this width are termed boasters. The chisel has a number of teeth from one-eighth to three-eighths wide, and is used on the surface of hard stones after the point has been used. The drag is a semi-circular steel plate, the straight edge having teeth cut on it. It is used to level down the surface of soft stones. Cockscuts are used for the same purpose on mouldings and are shaped to various curves. Wedges of various sizes are used for splitting stones and are inserted either in holes made with the jammers or in cuts made with the stone-pick.

The implements for setting out are similar to those used, by the bricklayer and other tradesmen, comprising the rule, square, set square, the bevel capable of being set to any required angle, compasses, spirit level, plumb-rule and bob and mortar trowels. Gauges and moulds are required in sinking moulds to the proper section.

Setting-out Tools.

Nippers. (Fig. 1.)—(1 in. = 1 ft.)

The nippers (fig. 1), or scissors, as they are sometimes termed, have two hooked arms fitting into notches in the opposite sides of the stone to be lifted. The arms are riveted together in the same way as a pair of scissors, the upper ends having rings attached for the insertion of a rope or chain which may be drawn through one of the notches by a pulley. They are also used for setting blocks too large to be set by hand. The cutting edges are nearly straight, and are cut by two polygonal regular hexagons, one of the edges of the stone being placed in one of the holes and the other in the other. Several holes are sunk in a stone and the two edges are cut with their edges as nearly parallel as possible. The reason for the use of this double chisel is that otherwise holes for the putlogs to rest in would have to be left in the wall, and obviously in an ashlar stone wall it would be impossible properly to make these good on the removal of the scaffold (see further SCAFFOLD). Setting-out Tools.—Stone freshly quarried is full of sap, and thus addition of being easily cut before the sap dries out, and the stone becomes much harder in consequence. For this reason, and because carriage charges are lessened by the emalleability of the stone, it is usual to hand them with the rough block, the stone for a building is often specifically ordered squared.

Vitrivius recommended that stone should be quarried in summer when driest, and that it should be seasoned by being allowed to lie two or three years before being used, to allow of proper seasoning.

In the erection of St Paul's Cathedral, Sir Christopher Wren required that the stone after being quarried should be exposed for three months on the sea-beach before its introduction into the building. The regular and determined action of the waves to a great extent a matter of practice to enable a man to become a good bricklayer, but beyond these a continual exercise of judgment is required of the workers, since there is for the most part to deal with masses of all forms and of all sizes.

Setting Stones.—All beds and joints should be truly worked and perfectly level. If the surface be convex it will give rise to wide unsightly joints; if concave the weight thrown on the stone will rest on the edges and probably cause them to "flush" or break off and disfigure the work. Large stones are placed in position with the aid of hoisting appliances and should be tried in position before being finally set. Great care should be taken to avoid forcing up the stone and lifting the stone in the process of handling, as it is impossible to make good such damage. All strafed stones—and this includes by far the most common faulty stones—properly to their place, and when necessary, when they should be laid on their natural bed, i.e., with their laminae horizontal.

The greatest strength of a stone is obtained when the laminae lie at right angles to the surface upon it. In the case of arches these layers should be parallel with the surface of the arch, and at right angles to the face of the arch. For cornices (except the corner-stones) and work of a like nature, the stone is set with the laminae either parallel and perpendicular to the face of the work. In many stones it is easy to determine the bed by moisturizing with water, when the laminae will become apparent. Some stones, however, it is impossible to set this way, and it is therefore advisable to have them marked in the quarry. A horizontal line in a quarry does not in all cases give the proper bed of the stone, for since the deposits were made ages ago natural upheavals have possibly occurred and the "bed" has been displaced.

For the shafts of columns especially it is necessary to have the layers horizontally placed, and a stone should be selected from a shaft with a bed of the required depth. An example of the omission of this precaution is visible in the arcing of the Royal Courts of Justice, London, where the small shafts of the front arcade in red sandstone have been turned with the laminae in a vertical position, with the result that nearly every shaft is flaking away or is cracked.

Use of Mortar.—See Brickwork. Of whatever quality the stone may be of a wall which is built, it should consist as much of stone and mortar as possible. The great strength of a wall depends upon the size, shape, and arrangement of its stones. The quality of stone alone is not to be taken as thin joints as possible. The joints should be well raked out and pointed in Portland cement mortar. This applies of course to sandstones, as marble and many limestones are stained by the use of Portland cement. For these reasons it is desirable to employ, composed of plaster of Paris, lime, and marble or stone-dust.

Bonding.—Bond (see Brickwork) is of not less importance in stone walling than in brickwork. In ashlar-work the work is bonded uniformly, the joints being kept perpendicularly one over the other; but in rubble-work, instead of making the joints recur one over the other in alternate courses they should be carefully made to lock, so as to give the strength of two or three courses or layers between a joint in one course and the joint that next occurs vertically above it in another course. In the through or transverse bonding of a wall a good proportion of header stones running about two-thirds of the distance through the width of the wall should be provided to link the whole structure together. The use of through stones, i.e., stones running through the whole thickness of the wall, or a mortise and tenon joint to back, is not to be recommended. Such stones are liable to fracture and convey damp to the internal face.

Shipl Joints.—As ashlar was the standard masonry great care must be exercised to prevent the different parts of a building setting unequally. When two portions of a building differing considerably in height are to be placed together, it is usual to employ a slip or hoisted joint instead of bonding the stone so as to allow the heavier work to settle to a greater extent than the low portion without causing any defect in the stones.

Walling.—There are broadly speaking two classes of stone walling: rubble and ashlar. Rubble walls are built of stones more or less irregular in shape and size and coarsely jointed. Ashlar walls are constructed of carefully worked blocks of regular dimensions and set with fine joints.
Random Rubble (fig. 3) is the roughest form of stonework. It is built with irregular pieces of stone usually less than 9 in. thick, loosely packed without much regard to courses, the interstices between the large stones being occupied by small ones, the remaining crevices filled up with mortar. Bond stones or headers should be used frequently in every 6 or 7 courses. This form of walling is much used in stone districts for boundary walls and is often set dry without mortar. For this work the mason uses no tool but the trowel to lay on the mortar, the scabbling hammer to break off the most repulsive irregularities from the stone, and the plumb-rule to keep his work perpendicular.

Coursed Rubble (fig. 4) is levelled up in courses 12 or 18 in. deep, the depth varying in different courses according to the sizes of the stones. The stones are dressed by the workman before he begins building, to obtain a fairly level bed and perpendicular face.

Irregularly Coursed Squared Rubble is a development of uncoursed random rubble, the stones in this case being squared with the hammer and roughly faced up with the axe. The courses jump abruptly from one level to another as the sizes of the blocks demand; the interstices are filled in with small pieces of stone called "snocks.

For Coursed Squared Rubble the stones are faced in a similar manner and set in courses, the depth of each course being made up of one or more stones.

In Regular Coursed Rubble all the stones in one course are of the same height.

Block-in-course is the name applied to a form of stone walling that has some of the characteristics of ashlar but the execution of which is much rougher. The courses are usually less than 12 in. high. It is much used by engineers for wersides and railway work where a good appearance is desired.

The Angle or Quoin of rubble-work are always carefully and precisely worked and serve as a gauge for the rest of the walling. Frequently the quoins and jambs are executed in ashlar, which gives a neat and finished appearance and adds strength to the work.

The name Ashlar is given, without regard to the finish of the face of the stone, to walling composed of stones carefully dressed, from 12 to 18 in. deep, the mortar joints being about an eighth of an inch or less in thickness. No stone except the hardest should exceed in length three times its depth when required to resist a heavy load and its breadth should be from one and a half to three times its depth. The hardest stone may have a length equal to four or perhaps five times its depth and a width three times its depth. The face of ashlar-work may be plain and level, or have rebated, chamfered, or moulded joints.

The great cost of this form of stonework renders the employment of a backing of an inferior nature very general. This backing varies according to the district in which the building operations are being carried on, being rubble stonework in stone districts and brick or concrete elsewhere, the whole being thoroughly tied together both transversely and longitudinally with bondstones. In England a stone much used for backing ashlar and Kentish rag rubble-work is a soft sandstone called "hassock.

In the districts where it is quarried it is much cheaper than brickwork. (For brickbacking see Brickwork.) Ashlar facing usually varies from 4 to 9 in. in thickness. The work must not be all of one thickness, but should vary in order that effective bond with the backing may be obtained. If the work is in courses of uneven depth the narrow courses are made of the greater thickness and the deep courses are narrow. It is sometimes necessary to secure the stone facing back with iron ties, but this should be avoided wherever possible, as they are liable to rust and split the stonework. When it is necessary to use them they should be covered with some protective coating. The use of a backing to a stone wall, besides lessening the cost, gives a more equitable temperature inside the building and prevents the transmission of wet by capillary attraction to the interior, which would take place if single stones were used for the entire thickness.

All work of this description must be executed in Portland cement, mortar of good strength, to avoid as much as possible the unequal settlement of the deep courses of stone facing and the narrower courses of the brick or rough stone backing. If the backing is of brick it should never be less than 9 in. thick, and whether of stone or brick it should be levelled up in courses of the same thickness as the ashlar.

There are many different sorts of walling, or modes of structure, arising from the nature of the materials available in various localities. That is perhaps of most frequent occurrence in which either squared, broken, or round flints are used. This, when executed with care, has a distinctly decorative appearance. To give stability to the structure, lacing courses of tiles, bricks or dressed stones are introduced, and brick or stone piers are built at intervals, thus forming a flint panelled wall. The quoins, too, in this type of wall are formed in dressed stone or brick work.

Uncoursed rubble built with irregular blocks of ragstone, an unstratified rock quarried in Kent, is in great favour for facing the external walls of churches and similar works (fig. 5).

Pointing.—As with brickwork this is generally done when the work is completed and before the scaffolding is removed. Suitable weather should be chosen, for if the weather be either frosty or too hot the pointing will suffer. The joints are raked out to a depth of half an inch or more, well wetted, and then rilled with a fine mortar composed specially to resist the action of the weather. This is finished flat or compressed with a special tool to a shaped joint, the usual forms of which are shown in fig. 6.

Three forms of keyed joints are shown (fig. 6).
ochre to tone it down. After six months or more the work is cleaned down with water and stiff bristle or wire brushes. Sometimes muriatic acid much diluted with water is used.

Technical Terms.—Of the following technical terms, many will be found embodied in the drawing of a gable wall (fig. 7), which shows the manner and position in which many different members are used.

Apex Stone.—The topmost stone of a gable forming a finial for the two sloping sides; it is sometimes termed a “saddle” (fig. 7).
MASONRY

845

Blocking Course, a heavy course of stone above a cornice to form a parapet and weigh down the back of the cornice (fig. 8).

FIG. 8.—(1 in. = 1 ft.)

Bed.—The bed surface upon which a stone is set or bedded should be worked truly level in every part. Many workmen to form a neat small patch or chip of mortar on the under side of the stone and thus when the stone is set all weight is thrown upon the edges with the frequent result that these are crushed.

When setting stones are placed on the top walls not covered by a roof, spanning their entire width and throwing off the rain and snow, thus keeping the interior of the wall dry. The fewer the number of joints the better the security, and for this reason it is best to form copings with as long stones as possible. To throw water off clear, and prevent it from running down the face of the wall, the coping should project an inch or two on each side and have a thrust worked on the under-side of the projections (fig. 7).

Corbel, a projecting course of moulded stone crowning a structure, forming a cup or finish and serving to throw away clear or other. A deep drip should always be worked in the upper members of a cornice to prevent the rain trickling down and disfiguring the face of the moulding and the wall below (fig. 8).

Corbel, a stone placed at the base of the sloping side of a gable wall to resist any sliding tendency of the sloping coping. Stones placed for a similar purpose at intervals along the sloping side, falling into the wall, are termed "knuckles" and have the section of the coping worked upon them (fig. 7).

Corbel Table, a line or small corbels placed at short distances apart supporting a parapet or arcade. This forms an ornamental feature which was much employed in early Gothic times. It probably originates from the machicolations of ancient fortresses.

Dripping, the finished stones of window and door jambs and quoins. For example, a "brick building with stone dressings" would have brick walls with stone door and window jambs, sills, and perhaps also stone quoins (fig. 7).

Draper, a square pattern formed on the face of the stonework by means of stones of different colours and varieties or by patterns carved on the surface (fig. 7).

Finden, a finishing ornament applied usually to a gable end (fig. 7).

Gablet, small gable-shaped carved panels frequently used in Gothic stonework for apex stones, and in spires, &c.

Gargoyle, a detail, not often met with in modern work, which consists of a waterspout projecting so as to throw the rain-water from the gutters clear of the walls. In early work it was often carved into grotesque shapes of animal and other forms.

Galleting.—The joints of rubble are sometimes enriched by having small galleted stones of extra strength thus gained and in order to give a finish to the work. The stones are laid alternately as stretchers and headers; the former are called outbands, the latter inbands (fig. 7).

Label Moulding, a projecting course of stone running round an arch. When not very large it is sometimes cut on the voussoir, but is usually made a separate course of stone. Often, and especially in the case of door openings, a small sinking is worked on the top surface of the voussoirs to give a gutter which leads to the sides any water that trickles down the face of the wall.

Lacing Stone.—This is placed as a voussoir in brick arches of wide span, to serve to bond or face several courses together (see Brickwork).

Lacing Course, a course of dressed stone, bricks or tiles, run at intervals in a wall of rubble or flint masonry to impart strength and tie the whole together (fig. 7).

Long and Short Work, a typical Saxon method of arranging quoin stones, that slabs and long narrow vertical stones being placed alter-

ately, Earls Barton church in Northamptonshire is an example of it in old work. In later work the long and short work, sometimes termed "block and start," is little used (fig. 7).

Parapet, a fence wall at the top of a wall at the eaves of the roof. The gutter lies behind, and waterways are formed through the parapet for the escape of the rain-water.

Plinth, a projecting base to a wall serving to give an appearance of stability to the work.

Quoin, the angle at the junction of two walls. Quoins are often executed in various dressed stone (fig. 7).

Rag-bolt, the iron of an iron bolt when required to be let into stone is roughed or ragged. A dovetailed mortise is prepared in the stone and the ragged end of the bolt placed in this, and the mortise filled in with molten lead or sand and sulphur (fig. 9).

Sill, the stone which forms a finish to the wall when at the bottom of an opening. Sills should always be weathered, slightly in the case of door sills, more sharply for windows, and thrust on that face. There are frequent continuations of the sills or head lines of windows (figs. 5 and 7).

Scolton.—In a thick wall the dressed stones forming the inside angles of the jamb of a window or door opening are termed scones. Slender small pieces of stone are used as scones in gable ends of building and in effecting external members to intercept rain-water and cause it to drop off the member clear of the work beneath (fig. 8).

The surface of exposed stone is weathered when it is worked to a slope so as to throw off the water. Cornices, copings, sills and string courses should all be so weathered.

Vouissoir, the wedge-shaped blocks of which an arch is built up.

Methods of finishing Face of Stones.—The self face or quarry face is the natural surface formed when the stone is detached from the mass in the quarry or when a stone is split. See-face, the surface formed by sawing. Hammer-dressed, Rock-faced, or Pitch-faced.—This face is used for ashlar-work, usually with a chisel-drafted margin around each block. It gives a very massive and solid appearance to the lower part of a masonry building. The stone is cut by a single blow, and is therefore the cheapest face to adopt for ashlar-work (fig. 7).

Broached and Pointed Work.—This face is also generally used with a chisel-drafted margin. The stone as left from the scabbling the quarry and the face of the stone is then marked down to an approximate level by the point. In broached work the grooves made by the tool are continuous, often running obliquely across the face of the stone (fig. 7). In pointed work the grooves are discontinuous; the surface is rough or fine pointed according as the point is used over every inch or half-inch of the stone. The point is used more upon hard stones than soft ones (fig. 7).

Toothed-Chiselled Work.—The cheapest method of dressing soft stones is by the toothed chisel which gives a surface very much like the pointed work of hard stones.

Dressed Work.—This surface is obtained with a chisel about two and a half inches wide, no attempt being made to keep the cuts in continuous lines.

Tooted Work.—This surface is somewhat similar to droved work and is done with a toothed chisel, the edge of which is about four inches wide, care being taken to make the cuts in continuous lines across the width of the stone.

Combed or Droved Work.—For soft stones the steel comb or drag is employed to remove all irregularities from the face and thus form a fine surface. These tools are specially useful for moulded work, as they are formed to fit a variety of curves.

Rubbed Work.—For this finish the surface of the stone is previously broached with the chisel, which is then approximately smooth face, and then the surface is rubbed until it is quite smooth with a piece of grit stone aided by fine sand and water as a lubricant. Marbles are polished by being rubbed with gritstone, then with pumice, and last with emery powder.

Besides these, the most usual methods of finishing the faces of stonework, there are several kinds of surface formed with hammers and various descriptions of hammers are more used on the continent of Europe and in America perhaps than in England, but they deserve notice here.
The toothed axe has its edges divided into teeth, fine or coarse according to the work to be done. It is used to reduce the face of limestones and sandstones to a condition ready for the chisel. The bush hammer has a heavy square-shaped double-faced head, upon which are cut projecting pyramidal points. It is used to form a surface full of little holes, and with it the face of sand and limestones may be brought to a somewhat ornamental finish. The patent hammer is used on granite and other hard rocks, which have been first dressed to a medium surface with the point. The fineness of the result is determined by the number of blades in the hammer, and the work is said to be "six," "eight," or "ten-cut" work according to the number of blades inserted or bolted in the hammer head. The crandall has an iron handle slotted at one end with a hole \( \frac{1}{2} \) in. wide and 3 in. long. In this slot are fixed by a key ten or eleven double-headed points of \( \frac{1}{2} \) in. square steel about 9 in. long. It is used for finishing sandstone and soft stones after the surface has been levelled down with the axe or chisel. It gives a fine pebbly sparkling appearance.

There are several methods of finishing stone which involve a great deal of labour and are therefore expensive to work, but which result in imparting a very stiff and unnatural appearance to the masonry.

Vermiculated Work. This is formed by carving a number of curling worm-like lines over the face of the block, sinking in between the worms to a depth of a fourth of an inch. The surface of the strings is worked smooth, and the sinkings are peck-marked with a pointed tool (fig. 7).

 Furrowed Work. In this case the stone is cut with a chisel into a number of small parallel grooves or furrows (fig. 7).

 Reticulated Face. This is a finish somewhat similar to vermiculated work, but the divisions are more nearly squares.

 Face Joints of Ashlar. The face joints of ashlar stone work are often sunk or rebated to form what are termed rusticated joints; sometimes the angles of each block are moulded or chamfered to give relief to the surface or to show a massive effect (fig. 7).

 Joints in Stonework. The joints between one block of stone and another are formed in many ways by cramps, dowels and joggles of various descriptions.

Dowels are used for connecting stones where the use of cramps would be impracticable, as in the joints of window mullions, the shafts of small columns, and in similar works (figs. 7, 8 and 20).

**Dowels.** Dowels for bed and side joints may be used. They are of slate, metal, or sometimes of hard wood.

There are many ways of making a joggle joint. The joggle may be worked on one of the stones so

**Joggles.** As to fit into a grooves in the adjoining stone, or of the stones and an independent joggle of slate, pebbles, or Portland cement fitted, the joggle being really a kind of dowel. The pebble joggle joint is formed with the aid of pebbles as small dowels fitted into mortises in the jointing faces of two stones and set with Portland cement; but joggles of slate have generally taken the place of pebbles. Portland cement joggles are formed by pouring cement grout into a vertical or oblique mortise formed by cutting a groove in each of the joining surfaces of the stones. What is known as a headed joggle, worked on the edges of the stones themselves, is shown in fig. 13.

Plugs or dowels of lead are formed by pouring molten lead through a channel into dovetailed mortises in each stone (figs. 14 and 15). When cold the metal is caulked to compress it tightly into the holes.

The saddle joint is used for cornices, and is formed when a portion of the stone next the joint is left raised so as to guide rain-water away from the joint (fig. 8).

Two forms of rebated joints for stone columns and piers are shown in fig. 9. In one form (shown in fig. 7) the stones forming the coping are thicker at their lower and rebated edge than at the top plain edge, giving a stepped surface. The other form has a level surface and the stones are the same thickness throughout and worked to a rebate on top and bottom edges. In laying stone roofs the joints are usually lapped over with an upper slab of stone.

**Joints in Spires.** Four forms of jointing for the battering stonework of spires are shown in fig. 16. A is a plain horizontal joint. B is a similar joint formed at right angles to the face of the work. This is the most economical form of joint, the stone being cut with its sides square with each other; but if the mortar in the joint decay moisture is allowed to penetrate. With these
forms dowelling is frequently necessary for greater stability. The joints C and D are more elaborate and much more expensive on account of the extra labour involved in working and fitting.

Where a concentrated weight is carried by piers or columns the bed joints are in many cases formed without the use of mortar, a thin sheet of milled lead being placed between the blocks of stone to fill up any slight inequalities.

**Moulded Work.**—The working of mouldings in stone is an important part of the mason's craft, and forms a costly item in the erection of a stone structure. Much skill and care is required to retain the arisings sharp and the curved members of accurate and proportionate outline. As in the case of wood mouldings, machinery now plays an important part in the preparation of stone moulded work. The process of working a stone by hand labour is as follows: The profile of the moulding is marked on to a zinc template on opposite ends of the stone to be worked; a short portion, an inch or two in length termed a "draught," is at each end worked to the required section. The remaining portion is then proceeded with, the craftsman continually checking the accuracy of his work with a straight-edge and zinc templates. A stone to be moulded by machinery is fixed to a moving table placed under a shaped tool which is fixed in an immovable portion of the machine, and is so adjusted as to cut or chip off a small layer of stone. Each time the stone passes under the cutter it is automatically moved a trifle nearer, and thus it gradually reduces the stone until the required shape is attained.

**Iron in Stonework.**—The use of iron dowels or cramps in stonework, unless entirely and permanently protected from oxidation is attended by the gravest risks: for upon the expansion of the iron by rusting the stone may split, and perhaps bring about a more or less serious failure in that portion of the building. A case in point is that of the church of St Mary-le-Strand, London, where the ashlar facing was secured to the backing with iron cramps; these were inefficiently protected from damp, with the result that many of the blocks have been split in consequence of rusting. John Smeaton in his Eddystone Lighthouse used dowels of Purbeck marble.

**Fig. 17.—(1 in. = 1 ft.)**

**Fig. 18.—(1 in. = 1 ft.)**
Stone Arches.—Stone arches are very frequently used both in stone and brick buildings. (For general definitions and terms see Brickwork.) They may be built in a great variety of styles, either flat, segmental, circular, elliptical or pointed. Each block, slotted properly in its place, is made as fine as possible. The stones must radiate from the centre from which the soffit or intrados is struck, or in the case of an ellip- tic intrados, the right angle being taken at the centre. The two or more voussoirs are of one stone, having a false joint in the centre; this is economical, and in some cases adds to the stability of the arch. Generally the arch is an essential part of the original design, or to give a keystone, the voussoirs being laid from each side of the keystone and sitting exactly in the centre of the arch. The keystone is not a necessity, arches being frequently formed with an intrados only; some do not hold the weight of the voussoirs precisely; therefore they slighted without lintels.

In very many cases it is desired to form square heads to openings of greater span than it is convenient to obtain lintels for in one piece, and some form of flat arch must therefore be adopted. The vous- soirs may be disposed by joggles worked on their joints, as in for example the weight of the superimposed wall is taken by a lintel with relieving arch above the back of the arch. Archs built to an elliptical form when used for large spans (of the form of a semi-circle (r or ft.) are liable to fail by the voussoirs at the centre being forced down, or else to burst up at the haunches. With arches of this description it is best to form a large ample head, and not to attempt the weight of the voussoirs.

Stone Tracery.—The designs of Gothic and other tracery stonework are almost infinite, and there are many methods, ingenious and otherwise, of working such work. Nearly all designs of tracery construction are planned on the principle of geometrical intersections. In the example illustrated in fig. 18 the method of setting out and finishing the tracery clearly shows the positions for the joints of the various parts. The jointing is the matter which must be carefully considered in order to avoid any waste of stone and labour. It will be observed that the right-hand side of the elevation shows the method of setting out the tracery; in the line of the various intersecting branches, the other half giving the completed design with the cusping drawn in the positions of joints. All the upper construction of windows and doors and of arches should be protected from superincumbent pressure by strong relieving arches above the labels, as shown in the figure, which should be worked with the ordinary masonry, and so on. The voussoirs pressure upwards over the face-work, which would be liable to flush or otherwise destroy the joints of the tracery.

Carving.—Stone carving is a craft quite apart from the work of the ordinary sculptor; it is not possible to explain in wood carving, as feeling and special training. Carving-stone should be of fine grain and sufficiently soft to admit of easy working. The Bath stones in England and the Caen stone of France are largely used for internal work, but if for the exteriors they should be treated with some chemical preservative. Carving is frequently done after the stone is built into position, the face being left rough—boasted—and projecting sufficiently for the intended design.

See E. Viollet-le-Duc, Dictionnaire raisonné de l’architecture française; W. R. Purchase, Practical Masonry; J. O. Baker, A Treatise on Masonry Construction; C. F. Mitchell, Brickwork and Masonry; W. Dack, The Art of Masonry in Britain. (J. Bt.)

MASPERO, GASTON CAMILLE CHARLES (1846-1913), French Egyptologist, was born in Paris on the 23rd of June 1846, his parents being of Lombard origin. While at school he showed a special taste for history, and when fourteen years old was already interested in hieroglyphic writings. It was now that he became a member of the École des Beaux Arts. In 1867 that Maspero met with an Egyptologist in the person of Mariette, who was then in Paris as commissioner for the Egyptian section of the exhibition. Mariette gave him two newly discovered hieroglyphic texts of considerable difficulty to study, and, self-taught, the young scholar produced translations of them in less than a fortnight, a great feat in those days when Egyptology was still almost in its infancy. The publication of these in the same year established his reputation. A short time was spent in assisting a gentleman in Peru, who was seeking to prove an Arvan affinity for the dialects spoken by the Indians of that country, to publish his researches; but in 1868 Maspero was back in France at more profitable work. In 1869 he became a teacher (rêpétiteur) of Egyptian language and archaeology at the École des Hautes Études; in 1874 he was appointed to the chair of Champollion at the Collège de France.

In November 1880 Professor Maspero went to Egypt as head of an archaeological mission despatched thither by the French government, which ultimately developed into the well-equipped institution, Frangé, is. This was but a few months before the death of Mariette, when Maspero succeeded as director-general of excavations and of the antiquities of Egypt. He held this post till June 1886; in these five years he had organized the mission, and his labours for the Bulak museum and for archaeology had been early rewarded by the discovery of the great cache of royal mummies at Deir el-Bahri in July 1881. Maspero now resumed his professorial duties in Paris until 1899, when he returned to Egypt in his old capacity as director-general of the department of antiquities. He found the collections in the Cairo Museum enormously increased, and he proceeded to extend the building on a new site at Ksar en-Nil in 1902. The vast catalogue of the collections made rapid progress under Maspero’s direction. Twenty-four volumes or sections were already published in 1909. The repairs and clearances at the temple of Karnak, begun in his previous tenure of office, led to the most remarkable discoveries in later years (see Karnak), during which a vast amount of excavation and exploration has been carried on also by unofficial but authorized explorers of many nationalities.

Among his best-known publications are the large Histoire ancienne des peuples de l’Orient classique (3 vols., Paris, 1885-1887, translated into English by Mrs McClure for the S.P.C.K.), describing the history of the whole of the nearer East from the beginning to the death of Alexander; a smaller Histoire des peuples de l’Orient, 1 vol., of the same scope, which has passed through six editions from 1875 to 1904; Études de mythologie et d’archéologie égyptiennes (Paris, 1893, &c.), a collection of reviews and essays originally published in various journals, and especially important as contributions to the study of Egyptian religion; L’Archéologie égyptienne (latest ed., 1907), of which several editions have been published in English. He also established the journal Recueil de travaux relatifs à la philologie et à l’archéologie égyptiennes et asiatiques; the Bibliothèque égyptologique, in which the scattered essays of the French Egyptologists are collected, with biographies. Among the Annales des Études de l’Egypte, a repository for official excavations, &c.

Maspero also wrote: Les Inscriptions des pyramides de Sakkara (Paris, 1894); Les Mummies royales de Deir el-Bahri (Paris, 1895); Les mummies égyptiennes populaires; Les monuments des Causières d’Égypte (1897), translated by Elizabeth Lee as New Light on Ancient Egypt (1905). M. Ö. messe; Fr. messe; Ger. Messe; Ital. messa; Iro. ecc. Lat. missa), a name for the Christian eucharistic service, practically confined since the Reformation to that of the Roman Catholic Church. The various orders for the celebration of Mass are with under Liturgy; a detailed account of the Roman order is given under Missa; and the general development of the eucharistic service, including the Mass, is described in the article Eucharist. The present article is confined (1) to the consideration of certain special meanings which have become attached to the word Mass and are the subject of somewhat acute controversy, (2) to the Mass in music.

The origin of the word missa, as applied to the Eucharist, is obscure. The first to discuss the matter is Isidore of Seville (Etym. vi, 19), who mentions an “evening office” (officium vesperum), and an office called missa. Of the latter he says: “Missa tempore sacrifici et, quando catechumeni foras mittuntur, clamat levita ‘si quis catechumenus remanit, exeat foras.’ Et inde missa, quia sacramentis altari interesse non possent, addit vinculum non dum regenerati sunt.” (“The missa is at the time of the sacrifice, when the catechumens are sent out, the deacon crying, ‘If any catechumen remain, let him go forth.’” Hence missa, because those who are as yet unregenerate—i.e. unbaptized—may not be present at the sacraments of the altar). This derivation of
the word Mass, which would connect it with the special formula of dismissal still preserved in the Roman Liturgy—"In, missa est"—once generally accepted, is now disputed. It is pointed out that the word missa long continued to be applied to any church service, even to the service of the Holy Eucharist (see numerous examples), and it is held that such services received their name of missal from the solemn form of dismissal with which it was customary to conclude them; thus, in the 4th century Pilgrimage of Eustochia (Silvia) the word missa is used indiscriminately of the Eucharist, other services, and the ceremony of dismissal. F. Kattenbusch (Herzog-Hauck, Realencyclop. s. "Messe") ingeniously, but with little evidence, suggests that the word may have had a double origin and meaning: (1) in the sense of dimissio, "dismissal"; (2) in that of missio, "commission." Though the latter theory is probably correct, it is certain that missae were more voluminous than any others which 16th-century composers attempted to handle in a continuous scheme. The practical limits of the church service made it impossible to break them up by setting each clause to a separate movement, a method by which 16th-century music composers contrived to set psalms and other long texts to compositions lasting an hour or longer. Accordingly, Palestrina and his great contemporaries and predecessors treated the Gloria and Credo in a style midway in polyphonic organization and rhythmic breadth between that of the elaborate motet (adopted in the Sanctus) and the homophonic reciting style of the Litany. The various ways in which this special style could be modified by the scale of the work, and with the greater and more elaborate parts, gave the Mass (even in its merely technical aspects) a range which made it to the 16th-century composer what the symphony is to the great instrumental classics. Moreover, as being inseparably associated with the highest act of worship, it inspired composers in direct proportion to their piety and depth of mind. Of course there were many of these men, of attacking the art-problem, and many other relations, true and false, between the compounding of the Gloria and Credo and of the various parts of the Mass and of motets. The story of the action of the council of Trent on the subject of corruption of church music is told elsewhere (see Missæ et Palestrina); and it has been recently paralleled by a decree of Pope Pius X., which has restored the 16th-century polyphonic Mass to a permanent place in the Roman Catholic Church music.

2. Instrumental Masses in the Neapolitan Form.—The next definite stage in the musical history of the Mass was attained by the Neapolitan composers who were first to reach musical coherence after the monodic revolution at the beginning of the 17th century. The fruit of their efforts came to maturity in the Masses of Mozart and Haydn. By this time the resources of music were such that the long and varied text of the Gloria and Credo inevitably either overbalanced the scheme or met with an obviously perfunctory treatment. It is almost impossible, without asceticism of a radically inartistic kind, to treat with the resources of instrumental music and free harmony such passages as that from the Crucifixus to the Resurrexit, without an emotional contrast, which inevitably for the homophonic treatment of the Sanctus into the background, and makes the Agnus Dei an inadequate conclusion to the musical scheme. So unfavourable were the conditions of 18th-century music for the formation of a good ecclesiastical style that only a very small proportion of Mozart's and Haydn's Mass music may be said to represent their ideas of religious music at all. The best features of their Masses are those that combine faithfulness to the Neapolitan forms with a contrapuntal richness such as no Neapo-
litan composer ever achieved. Thus Mozart's most perfect as well as most ecclesiastical example is his extremely terse Mass in F, written at the age of seventeen, which is scored simply for four-part chorus and solo voices accompanied by the organ with a largely independent bass and by two violins mostly in independent real parts. This scheme, with the addition of a pair of trumpets and trombones, is a successful attempt to revive the once popular 18th-century Masses developed or degenerated from this model. Trombones often played with the three lower voices, a practice of high antiquity surviving from a time when there were soprano trombones or cornetti (Zincken, a sort of treble serpent) to play with the sopranos.

3. Symphonic Masses.—The enormous dramatic development in the symphonic music of Beethoven made the problem of the Mass with orchestral accomplishment almost insoluble. This makes it all the more remarkable that Beethoven's second and only important Mass (in D, Op. 123) is not only the most dramatic ever penned but is, perhaps, the last classical Mass that is thoughtfully based upon the liturgy, and is not a mere musical setting of what happens to be a liturgic text. It was intended for the installation of Beethoven's friend, the archduke Rudolph, as archbishop of Olmütz; and, though not ready until two years after that occasion, it shows the most careful consideration of the meaning of a church service, no doubt of altogether exceptional length and pomp, but by no means impossible for its unique occasion. Immense as was Beethoven's dramatic force, it was equaled by his power of sublime repose; and he was accordingly able once more to put the supreme moment of the music where the service requires it to be, viz., in the Sanctus and Benedictus. In the Agnus Dei the circumstances of the time gave him something special to say which has never so imperatively demanded utterance since. Europe had been shattered by the Napoleonic wars. Beethoven read the final prayer of the Mass as a "prayer for inward and outward peace," and, giving it that title, organized it on the basis of a contrast between terrible martial sounds and the triumph of peaceful themes, in a scheme none the less spiritual and sublime because those who first heard it had derived their notions of the horror of war from living in Vienna during its bombardment. Critics who have lived in London during the relief of Mafeking have blamed Beethoven for his realism.

Schubert's Masses show rather the influence of Beethoven's not very impressive first Mass, which they easily surpass in interest, though they rather pathetically show an ignorance of the meaning of the Latin words. The last two Masses are later than Beethoven's Mass in D and contain many remarkable passages. It is evident from them that a dramatic treatment of the Agnus Dei was "in the air"; all the more so, since Schubert does not imitate Beethoven's realism.

4. Lutheran Masses.—Music with Latin words is not excluded from the Lutheran Church, and the Kyrie and Gloria are frequently sung in succession and entitled a Mass. Thus the Four Short Masses of Bach are called short, not because they are on a small scale, which is far from being the case, but because they consist only of the Kyrie and Gloria. Bach's method is to treat each clause of his text as a separate movement, alternating choruses with groups of arias; a method which was independently adopted by Mozart in those larger masses in which he transcends the Neapolitan type, such as the great unfinished Mass in C minor. This method, in the case of an entire Mass, results in a length far too great for a Roman Catholic service; and Bach's B minor Mass, which is such a setting of the entire text, must be regarded as a kind of oratorio. It thus has obviously nothing to do with the Roman liturgy; but as an independent setting of the text it is one of the most sublime and profoundly religious works in all art; and its unique perfection as a design is nowhere more evident than in its numerous adaptations of earlier works.

The most interesting of all these adaptations is the setting of the words: "Et expecto resurrectionem mortuorum et vitam venturi saeculi.—Amen." Obviously the greatest difficulty in any elaborate instrumental setting of the Credo is the inevitable anti-climax after the Resurrexit. Bach contrives to give this anti-climax a definite artistic value; all the more from the fact that his Crucifixus and Resurrexit, and the contrast between them, are among the most sublime and directly impressive things in all music. To the end of his Resurrexit chorus he appends an orchestral ritornello, summing up the material of the chorus in an elevated, occasional poss, and thereby utterly destroying all sense of finality in a manner of no less pleasing effect in the same time not in the least impairing the force and contrast of the whole—that contrast having inexpressibly asserted itself at the moment when it occurred. After this the ari "Et in spiritum sanctum," in which the next dogmatic clauses are enshrined like relics in a casket, furnishes a beautiful decorative design on which the listener can repose his mind; and then comes the voluminous ecclesiastical fugue, Confiteor unam sanctam, leading, as through the door and world-wide spaces of the Catholic Church, to that veil which is as dark as the eye of faith. At the words "Et expecto resurrectionem mortuorum," the music plunges suddenly into a slow series of some of the most sublime and mysterious modulations ever written, until it breaks out as suddenly into a vivace e allegro of broad but terse design, which comes to its climax very rapidly and ends as abruptly as possible, the last chord being carefully written as a short note without a pause. This gives the utmost possible effect of finality to the whole Credo, and contrasts admirably with the coldly formal instrumental end of the Resurrexit three movements further back. Now, such subtleties seem as if they must be unconscious on the part of the composer; yet here Bach is so far aware of his reasons that his vivace e allegro is an arrangement of the second chorus of a church cantata, Gott man lobet dich in der Stille; and in the cantata the chorus has introductory and final symphonies and a middle section with a da capo!

5. The Requiem.—The Missa pro defunctis or Requiem Mass has a far less definite musical history than the ordinary Mass; and such special musical forms as it has produced have little in common with each other. The text of the Dies Irae so imperatively demands either a very dramatic elaboration or none at all that even in the 16th century it could not possibly be set to continuous music on the lines of the Gloria and Credo. Fortunately, however, the Gregorian canto fermo associated with it is of exceptional beauty and symmetry; and the great 16th century masters either, like Palestrina, left it to be sung as plain-chant, or obviated all occasion for dramatic expression by setting it in verses (like their settings of the Magnificat and other canticles) for two groups of voices alternatively, or for the choir in alternation with the plain chant of the priest. Brahms's Deutsches Requiem has nothing to do with the Mass for the dead, being simply a large choral work on a text compiled from the Bible by the composer.

(D. F. T.)

MASSA, a town of Tuscany, Italy, the joint capital with Carrara of the province of Massa and Carrara, and sharing with it the episcopal see, 20 m. S.E. of Spezia by rail, 246 ft. above sea-level. Pop. (1901), 10,559 (town); 26,118 (commune). The Palazzo Ducale (now the prefecture) was erected in 1701, and was a summer residence of Napoleon's sister, Elisa Baciocchi, princess of Lucca, who caused the ancient cathedral opposite to be destroyed. The hills round the town yield marble, and there is a narrow-gauge railway to the Marina d'Anvena, where the marble is shipped.

MASSACHUSETTS (an Indian name, originally applied to a tribe of Indians), one of the original thirteen states of the American Union, bounded on the N. by Vermont and New Hampshire, on the E. by the Atlantic, on the S. by Rhode Island
was settled, the western counties were long connected commercially with New York than with Massachusetts, and this territory was long in dispute between the states.

The Connecticut is the most considerable stream, and is navigable by small craft. Its valley, much the richest portion of the state in the interior, is one of the handsomest features of its scenery. The Housatonic, in portions placid, in others wild and rapid, winding along the deflating barrier of the Hoosac Hills, is the most beautiful river of the state, despite the mercantile use of its valley. The Connecticut Valley stock rises in volume, runs in a charming valley through the extreme north-eastern corner, and affords immensely valuable water-power to Lowell, Lawrence, and Haverhill.

South of Cohasset the shore is sandy, with a few isolated rocky ledges and boulders. About Boston, and to the north of it, the shore is rocky and picturesque. Cape Cod, like a human arm stretched out to sea, is divided into the elbow facing Cope Bay to the south, the shoulder yellow and go from elbow to hand, is nowhere more than a few miles broad. It is a sandy ridge, dotted with summer resorts and cottages. Cape Ann and the wooded, rugged, rocky coast. It, too, is a summer recreation ground, with much beautiful scenery. Boston Harbor (originally known as Massachusetts Bay, a name which now has a much broader signification) is the finest roadstead on the coast. The extreme hook of the Cape Cod Peninsula forms Provincetown Harbor, which is an excellent and capacious port of refuge for vessels approaching Boston. Salem Harbor is the most considerable other haven on Massachusetts Bay; on Buzzard’s Bay, south of Cranberry Island, lie the ports of Dartmouth, New Bedford, and many others; among the harbours of the island are the excellent harbours of Gloucester and Marblehead, both frequented by summer residents. Gloucester has the largest fishery port on the coast, the chief fishing ports of the world. Buzzard’s Bay is also a popular summer resort.

The principal islands lie off the south coast. The largest is Martha’s Vineyard, about 20 m. long, with an extreme breadth of about 9 m. It has in Vineyard Haven a large capacious harbour, much frequented by wind-bound vessels seeking a passage round Cape Cod. The island is covered with stunted trees. Its population was formerly dependent wholly upon the sea; but its climate has made it a popular summer resort, Oak Bluffs being one of the chief resorts of the Atlantic coast. Further east, Nantucket, a smaller island of triangular shape, is likewise covered with stunted trees. Seal fisheries still continue, and are carried on in the same system as have been successfully continued for centuries. In the bay of the same name are the marvellous islands of the Monomoy group, and the Martha’s Vineyard group, a combination which will willow and aland, a natural phenomenon that is not infrequent in some degree primitive habits, though summer visitors are more and more affecting its life.

Flora and Fauna. —Massachusetts lies entirely in the humid area of the Transition life-zone, with the exception of the northernmost northern-western part of the state, which lies in the Boreal zone. Thus the original native trees and plants were those common to New England and eastern New York. The presence of a dense forest and ravines drives away the larger animals; there are some noxious weeds. The larger wild animals have disappeared, excepting an occasional black bear or deer. Of the smaller fur-bearers, fishers, minks, foxes, and raccoons are seen from time to time, and the common ferret and cat are occasionally found. The otter is seen very rarely, and the mink only in the most isolated districts; but foxes, skunks, weasels, musk-rats, rabbits, and grey and red squirrels are not uncommon. Copperhead snakes and rattlesnakes are occasionally seen, and serpents of various sorts are seen also. Some of game birds the most characteristic is the partridge (ruffe grouse), exclusively a woodland bird; the Wilson’s snipe and the woodcock are not uncommon in favourite localities, and several species of ducks are found especially in the bays and marshes near the coast during the seasons of migration. A stray eagle is sometimes seen. Very interesting to ornithologists are the few birds of prey, the eastern representative of the harrier (hen harrier) seen in the wild valleys of the west central part of the state, near Spencer; moraineic hills, extending, e.g. all along Cape Cod; eskers, kames and river terraces afford the plainest evidences of the extent of the glacial sheet. The Berkshire country—Berkshire, Hampshire, and Franklin counties—form the loveliest and most beautiful regions of the United States. It is a rolling hillland dominated by long, wooded hill-ridges, remarkably even-topped in general character, and extending for miles. The scenery is scores of charming lakes lie in the hollows. The district is often called the Lake Region of America, partly from the comparableness of its scenic beauties with the English Lake Country (Matthew Arnold, however, wrote: “The country is pleasing but not to be compared with Westmoreland. It is wide and open, and neither hills nor lakes are so effective.”), and partly from the parallelism of literary associations. It has been called, since 1850, and especially in much more recent years, a favoured locality for the summer residence of poets.

Owing to topography, and also to the manner in which Massachusetts
temperature of Boston is 48° F. In the interior it is slightly hotter. The mean summer temperature generally over the state is about 70° F., but in the western districts the summer is through a rapid spring. The ocean tempers the climate considerably on the seacoast. Boston Harbor has been frozen over in the past, but steamtugs plying constantly now prevent the occurrence of such events. In the interior, the winters are decided severe, and the springs and summers often late and cold. Williamstown has a winter mean of about 23° F. The yearly precipitation is about 39 to 45 in., decreasing inland, and is slightly less in the northern part of the state. Frequently, the ragged and the coast wind drizzle; the north-east winds bring the weather wave of spring and late autumn. In the summer and then the alluvial parts are often excessively dry and especially in the Berkshires a cool, pure and elastic atmosphere prevails, relatively dry, and altogether delightful.

Agriculture.—The soil, except in some of the valleys, is not naturally fertile. It is generally wasted in the parts. High cultivation, however, has produced valuable market-gardens about Boston and the larger towns; and industry has more than repaid the neglect. Of agricultural products is not great compared with that of other industries, but they are of great importance in the economy of the state. The total value of farm property in 1900 was $182,667,704, including livestock valued at $15,298,464. Of the increase in the total value of farm property between 1850 and 1900 more than half was in the decade 1850-1900; this increase being due partly to the rising value of suburban realty, but also to a development of the farming industry for manufacturing and marketing since 1880. The total value of farm products in 1899 was $2,429,274,756 (for expenditure for fertilizers $1,320,600); crops representing $417 and animal products $98,152,745. The percentages of the total crop value were hay and forage (39.1%) vegetables (23.9%), fruits and nuts (11.7%), forest products (8.4%), and flowers and plants (7.1%). Of the animal products 67.3% were dairy products, and 20.8% were poultry and eggs. Cereal crops have been for many years declining, although Indian corn is a valuable subsidiary to the dairy interest, which is the most thriving farm industry. The value of farms on which dairying was the chief source of income in 1900 was 46% of the total value of farm lands of the state; the corresponding percentages for livestock, vegetables, hay and grain, flowers and plants, fruit and tobacco, being respectively 21.3, 16.2, 9.3, 5.7, and 0.4%. The shrinking of these crops has been mainly responsible for the idea that Massachusetts is agriculturally decadent. Parallel to this shrinkage was the decrease in ranging sheep (62% from 1850-1900: 2.4% from 1890-1900), and cattle, once numerous in the hill counties of the west, and in the Connecticut Valley; Boston, then ranking after London as the second wool market of the world, and being at one time the chief packing centre of the country. Dairy cows increased, however, from 1890 to 1900 by 41.9% (1890-1900: 7.3%).

The amount of improved farm land decreased in the same period 39.4%, decreasing even more since 1880 than earlier, and amounting in 1900 to only 28% of the total area of the state. This decrease has been compensated by increased values of farm products, especially since the beginning of intensive agriculture. An unusual development of manufacturing, furnishing, food, and transportation facilities, are the main props of this new interest. Worcester and Middlesex counties are agriculturally foremost. Tobacco, which has been cultivated since colonial times, especially since 1850, is an own excellence of the Connecticut Valley, and is cultivated on its borders. In the swamps and bogs of the south-east coast cranberry culture is practised, this district producing in 1900 three-fifths of the entire yield of the United States. Abandoned farms aggregates (in 1890, 3.4% of the total farm area, and 6.85% in Hampshire county) are common, especially in the west and south-east.

Mining.—Granite is the chief mineral, and granite quarrying is the principal mineral industry of the state. In 1900 the value of manufactures based primarily upon the products of mines and quarries was $196,930,079, or 15% of the state's total manufacturing value. In 1900, 661 granite quarries were in operation, the value of its granite output, but in 1907 and 1908 it was second to Vermont. The value of the product (including a small output of igneous rocks) was in 1903, $3,151,027; in 1904, $2,554,748; in 1905, $2,541,319; in 1906, $3,537,416; in 1907, $2,528,777; in 1908, $2,026,473.

Granite boulders were used for construction in Massachusetts as early as 1695. Systematic quarrying of siliceous crystalline rocks began about 1798. Chester, Gloucester, and Sturbridge were large granite quarrying points. Granite quarries, opened in 1824, were probably the next to be worked regularly. The principal granite quarries are in Milford, (Worcester county), Quincy and Milton (Norfolk county), Rockport (Essex county) and Becket ( Berkshire county). Of the fourteen counties, the chief granite counties were Berkshire, Franklin, Worcester, Middlesex, and Essex. The first three quarried for the mass. name, and two in Hopkinton township, Middlesex county. B. K. Emerson and J. H. Perry classify this granite as post-Cambridgian. They describe it as a compact, massive rock, somewhat above greenstone, and in a region of mica schists and intercalated feldspars, and the blue of the quartz give it in some places a slight pinkish tint, and it is now used much as a building-stone under the name "pink granite." The Quincy granite district lies around the north-east end of the Blue Hill region, about 11 m. south of Boston. For monumental purposes this granite is classified as "medium," "dark," and "pale." The Quincy granite is often considered a granite, for the absence of mica and to the clearer cleavage of its hornblende and augite. The lightest of the monumental stone quarried at Quincy is called gold-leaf; it is bluish-grey, speckled with black. Another variety has small, rather widely separated cherry-red dots.

The Rockport granite is found along or near the seashore, between Rockport and Bay View, and within about three-quarters of a mile of Cape Ann. The granite is of two kinds, known commercially as "grey granite" and "green granite." Both varieties are hard and take a very high polish.

The Becker granite (known as "Chester dark" and "Chester light") is a muscovite-biotite granite varying from medium grey to medium bluish grey colour, and fine in texture. It is used for building.

In 1907 Massachusetts ranked sixth among the states in the value of its trap rock product ($432,004), and eighth in sandstone ($243,328). The value of the marble produced in the same year was $34,246,568; thereby realizing $1,035,198,989, of which $1,415,854 was the value of common brick) and in 1908 at $1,427,162 (of which $950,921 was the value of common brick). There are many mineral springs in the state, more than half being in Essex and Middlesex counties. The total amount of mineral water taken in 1900 was 5,491,664, of which 6% was market-

Manufactures.—Though only four states of the Union are smaller, only three exceeded Massachusetts in 1905 in the value of manufactured products (six exceeding it in population); and this despite very scant native resources of raw materials and a very limited home market. Historical priority of development, exceptionally extensive and well utilized water-power, and good transportation facilities are largely responsible for the exceptional rank of Massachusetts as a manufacturing state. This was doubtless due to the location of the states, Merrimac at Lawrence and Lowell, and on the Connecticut at South Hadley, and to a less extent at scors of other cities on the Merrimac, Nashua, and other rivers, excellent transportation and manufacturing facilities which have revolutionized industrial conditions since the beginning of the factory system have been invented by Massachusetts men; and the state contains various technical schools of great importance. The cotton manufacturing industry in 1900 took an increase from 1890 of 16.6%; that from 1890 to 1890 having been 40.7%. In textiles—cottons, worsteds, woolens and carpets—in boots and shoes, in rubber foot-ware, in fine writing paper, and in other minor products, it is the leading state of the country. The textile industries (the making of carpets and rugs, cotton goods, cotton smallwears, dyeing and finishing textiles, felt goods, felt hats, hosetry and knit goods, shoddy, silk and silk goods, woolen goods, and worsted goods), employed 32.5% of all manufacturing wage earners in 1905, and their product ($271,369,816) was 24.1% of the total, and of foreign import ($1,551,350) or small ($191,171,449) in cotton goods, being 28.9% of the total. The output of cotton goods was included with 11% for South Carolina, the nearest competitor of Massachusetts. There is a steadily increasing product of fine grade fabrics. The output of worsted goods in 1905 ($1,072,044) was more than three-tenths that of the entire country, Rhode Island being second with $44,477,596; in Massachusetts the increase in the value of this product was 26.2% between 1900 and 1905. The value of woolen goods in 1907 was $44,477,596; in Massachusetts the increase in the value of this product was 26.2% between 1900 and 1905. The value of woolen goods in 1907 was $44,477,596; in Massachusetts the increase in the value of this product was 26.2% between 1900 and 1905. The value of boots and shoes and cut stock in 1905 was $34,246,568, being 45.1% of the country's output, that of New York, the second state, being only 10.7% in this industry, as in the manufacture of cotton goods, Massachusetts has long been without serious rivalry; Brockton, Lynn, and
Haverhill, Marlboro and Boston, in the order named, being the principal centres. The third industry in 1905 was that of foundry and machine-shop products ($8,508,793), of which Boston and Worcester were the most popular centres. Lesser interests, in the order of importance, with the product value of each in 1905, were: rubber goods ($53,133,020), tanned, curried and finished leather ($33,528,999), in the manufacture of which Massachusetts was second only to New York (details in the production of which the state ranked second among the states of the Union); slaughtering and meat packing ($30,253,839), principally of hogs and sheep, in the manufacture of which Massachusetts was second only to New York; clothing ($21,724,056); electrical machinery, apparatus and supplies ($15,882,216); lumber ($12,656,530); iron and steel, works and rolling-mills products ($12,654,543); paper ($9,317,996); in the manufacture of which Massachusetts was second only to New York; furniture ($11,092,581); malt liquors ($10,880,410); creamery products ($9,593,931); anhydrous ammonia ($6,196,000); in the manufacture of which Massachusetts was third among the states.

Many of these industries have a history going back far into colonial times, some even dating from the first half of the 17th century. Textile products were really varied and of considerable importance before 1700. The policy of the British government towards such industries in the colonial period was in general restrictive. The monopolies and the export trade to the West Indies fostered home manufactures considerably, and the Embargo and Non-Intercourse Acts before the war of 1812, as well as that war itself, were responsible for the emergence of a large and rapidly transforming industry in Massachusetts. Improvements were introduced to the industry. The mill system was developed under a little before 1826 being 50-60% greater than in America. The first successful power loom in America was set up at Waltham in 1814; the loom was manufactured by Samuel Slater at Bridgeport in 1796. The cotton mill had been established in 1788, and the first real woollen factory at Byfield in 1794. Wool card machinery destined to revolutionize the industry was devised by Amos Whittomore (1790). railways was 2841-59 m. (2233-85 m. being main track). The Cape Cod canal, 12 m. long, from Sandwich on Barnstable Bay to Buzzard's Bay, was begun in June 1909, with a view to shortening the distance from Boston to New York and eliminating the danger of the voyage round Cape Cod.

Population.—The population of the state in 1910 was 3,366,416, the increases in successive decades after 1790 being respectively 11-6, 11-6, 10-6, 20-9, 34-8, 23-8, 18-4, 22-4, 25-6, 25-3 and 20%.

1 With the exception of Rhode Island, it is the most densely populated state in the Union, the average number to the square mile in 1900 being 349 (in 1910, 418-8), and the urban population, i.e. the population of places having above 8000 or more inhabitants, being 69-9% in 1890 and in 1900 76-4%.

The death-rates in the three decades above 25,000, 95-3%.

Population of the state in 1890, 1727,187, of which 1,546,292 were native-born (15-8%) and 280,903 immigrants (16-6%), a proportion of over 92% of the total 1727,187 being native-born.

To the natives of southern Italy, the most important of the foreign-born (29-5%) although since 1875 the proportion of Irish in the total population has considerably fallen.

The Irish and the leading foreign elements are Canadian English (18-7%), Canadian French (13-8%) and English (9-7%), these four constituting three-fourths of the foreign population.

Since 1885 the natives of southern Italy have greatly increased in number. Of the increase in total population from 1856-1805 only a third could be attributed to the excess of births over deaths; two-thirds being due to immigration from other states or from abroad. Boston is the second largest influx of the country. A large proportion of the Atlantic immigrants pass speedily to permanent homes in the west, but by far the greater part of the Canadian influx remains.

According to the census of 1910 there were 32 incorporated cities in Massachusetts, of which 6 had between 12,000 and 20,000 inhabitants; 3 between 20,000 and 25,000 (Gloucester, Medford and North Adams); 11 between 25,000 and 50,000 (Malden, Haverhill, Salem, Newton, Fitchburg, Taunton, Everett, Quincy, Pittsfield, Walpole, Chicopee); 7 between 50,000 and 100,000 (New Bedford, Lynn, Springfield, Lawrence, Somerville, Holyoke, Brockton); and 5 more than 100,000 (Boston, 670,585; Worcester, 145,686; Fall River, 119,895; Lowell, 106,394; Cambridge, 104,839).

The death-rates in the three decades from 1900 to 1905 were 29-5, 25-3, 26-0, 27-6, 24-2, 25-0, 28-7, 26-0, 27-0 and 24-2 per 1,000 and the death-rates 7-7, 20-7, 18-2, 20-8, 18-8, 18-9, 19-4, 19-4, 19-8, 19-6, 19-0 and 16-2.

The proportion uninhabited or unoccupied is closely given by the ratio of unmarried males to unmarried females (15 to 18 per 10,000 each), exceed more than twofold the diseases of next lowest fatality, cancer and cholera infantum.

Of males (1,097,591), engaged in 1900 in gainful occupations (47-1%) were 43-4 in manufacturing and mechanical pursuits (77-9% every 100 in 1870 and 73 in 1900), 27-1 in trade and transportation, 14-2 in domestic and personal service, 7-4 in agricultural pursuits and 4-2 in professional service. The corresponding percentages for females (1,165,467) were 46-4 in manufacturing (in 1890, 52%), 32-3 in domestic and personal service, 13-6 in trade and transportation, 7-3 in professional service and 0-6 in agriculture. Formerly farmers and fishermen were the great employments (15-6% of total stock), but since operatives of foreign birth or parentage have in great part

1 The population of the state was 372,876 in 1790; 422,845 in 1800; 472,040 in 1810; 523,287 in 1820; 610,408 in 1830; 737,690 in 1840; 994,514 in 1850; 1,231,066 in 1860; 1,475,351 in 1870; 1,783,085 in 1880; 2,235,043 in 1890; and 2,805,346 in 1900. In 1900, according to the state census, the population was 3,003,686, or about 7-7% more than in 1900.

2 The birth-rates every fifth (census) year up to 1895 varied for males from 21.9 in 1890 to 19.49 in 1845, and for females from 24.57 in 1845 to 60.66 in 1895.

3 The marriage rates in quinquennial periods up to 1905 was 19-6; 18-6, 21-0, 19-8, 15-6, 18-6, 18-6, 17-4 and 17-4; the ratio of marriages to the marriageable population was for males (above 16 years) 61-5, for females (above 14) 46-0; the fecundity of marriages seemed to have increased, being about twice as high for foreigners as for natives. See Annual Report of the Board of Health (1866) by S. W. Abbott; and Statistical Report of Births, Marriages and Deaths in Massachusetts (1906).

3 The number of representatives from 1832 to 1898 varied from 240 to 635, and the length of session from 58 to 206 days (since 1861 none of under 100 days), with an almost continual increase in both respects.

4 In 1900 the census enumerated 355 members of the Roman Catholic Church (a proportion exceeded only in New Mexico and in Rhode Island; 190 was in New Hampshire, Mississippi and Louisiana), and only 148 were communicants of Protestant bodies in 1900. In 1870 there were 106,066 Roman Catholics (out of a total of 1,562,621 communicants of all denominations), 119,106 Congregationalists, 80,894 Baptists, 65,496 Methodists, 13,300 Episcopalians and 88,000 Presbyterians.

5 Reference has been made to "abandoned farms" in Massachusetts. The desertion of farms was an inevitable result of the opening of the central regions of the west, but it is by no means characteristic of Massachusetts. The state has no extensive farms; it is, in fact, an excellent example of the interrelations of topography, soil and population. Many hill towns once thriving have long since become abandoned, desolate and comparatively inaccessible; they have, with the development of the summer resident's interests many will probably eventually regain prosperity. Almost half of the highland towns reached their maximum population before the opening of the 19th century, although Berkshire was scarcely settled till after 1760, and three-fourths of them before 1850. On the other hand three-fourths of the lowland towns reached their maximum since 1865, and half of them since 1875, and in the next six and a half times in the century, the upland diminished by an eighth. Socially and educationally the upland has furnished an interesting example of decadence. Since 1865 (at least) various parts of Cape Cod have shrunk greatly in population, agriculture and manufactures, and even in fishing interests; this reconstruction of industrial and social interests being, apparently, simply part of the general urban movement—a movement toward better opportunities. What prosperity or stability remains in various Cape Cod communities is largely due to foreign immigrants—especially British-Americans and Portuguese from the Azores, although the population remains, to a degree exceptional in northern states, of native stock.

Government.—Representative government goes back to 1634, and the bicameral legislature to 1644. The constitution of 1780, which still endures (the only remaining state constitution of the 18th century), was framed in the main by Samuel Adams, and as an embodiment of colonial experience and revolutionary principles, and as a model of constitution-making in the early years of independence, is of very great historical interest. It has been amended with considerable freedom (37 amendments up to 1907), but with more conservatism than has often prevailed in the constitutional reform of other states; so that the constitution of Massachusetts is not so completely in harmony with modern democratic sentiment as are the public opinion and statute law of the state. The commonwealth, for example, is still denominated "sovereign," and education is not declared a constitutional duty of the commonwealth. One unique feature is the duty of the supreme court to give legal advice, on request, to the governor and council. Another almost equally exceptional feature is the persistence of the colonial executive council, consisting of members chosen to represent divisions of the state, the governor's removal from his executive assent.

Massachusetts is also one of the few states in which the legislature meets in annual session. Townships were represented as such in this body (called the General Court) until 1856. Religious qualifications for suffrage and office-holding were somewhat relaxed, except in the case of...
MASSACHUSETTS

855

Roman Catholics, after 1861. Real toleration in public opinion grew slowly through the 18th century, removing the religious tests of voters; and a constitutional amendment in 1821 explicitly forbade such tests in the case of office-holders. Property qualifications for the suffrage and for office-holding—universal through colonial times—were abolished in the main in 1780. From 1821 to 1891 the payment of at least a poll-tax was a condition precedent to the exercise of the suffrage. An educational test (dating from 1857) is exacted for the privilege of voting, every voter being required to be able to read the constitution of the Commonwealth in the English language, and to write a simple declaratory sentence. The property qualifications of the governor was not abolished until 1892.

In the presidential election of 1866, when an unprecedentedly large vote was cast, the number of voters registered was nearly 26% of the population, and of these nearly 82% actually voted. Massachusetts is one of the only two states in the Union in which elections for state officers are held annually. In 1888 an act was passed providing for the use in state elections of a blanket ballot, on which the names of all candidates for each office are arranged alphabetically under the heading of that office, and there is no indication of the party of the candidate. A similar law was in force in the state of the kind in the country. The same method of voting has been adopted in about two-thirds of the townships of the state. A limited suffrage was conferred upon women in 1879. Every female citizen having the qualifications of a male voter may vote in the city and town elections for members of the school committee.

A householder with a family may, by recording the proper declaration in a registry of deeds, hold exempt from attachment, levy, execution, and sale for the payment of debts theretofore contracted an estate of homestead, not exceeding $800 in value, in a farm or lot with buildings thereon which he lawfully possesses by lease or other conveyance as his homestead. The exemption does not extend, however, to the prohibition of sale for taxes, and in case the householder's buildings are on land which he has leased those buildings are not exempt from sale or levy for the ground rent. If the householder is a tenant farmer he may have exemption of homestead only with her consent, and if he dies leaving a widow or minor children the homestead exemption survives until the youngest child is twenty-one years of age, or until the death of marriage of the widow, provided the widow or a child continues to occupy it.

The scope of state activity has become somewhat remarkable. In addition to the usual state boards of education (1837), agriculture (1852), railroad commissioners (1869), health (1869), statistics of labour, fisheries and game, charity (1879), the dairy bureau (1891), of insanity (1890), prison, highways, insurance and banking commissions, and others, there are now civil service rules (1884), uniformity of legislation, gas and electric lighting corporations, conciliation and arbitration in labour disputes (1886), &c., all of which are based upon the principle that the state shall not act as an employer of labour, but shall administer the laws of dentistry and medicine. Foods and drugs have been inspected since 1882. In general it may be said that the excellence of administrative results is noteworthy. The work of the Bureau of Statistics of Labor, of the Bureau of Health, of the Board of Railroad Commissioners, and of the Board of Conciliation and Arbitration, and the progress of civil service, have been remarkable for value and efficiency. Almost all state employees are under civil service rules; the same is true of the city of Boston; and of the clerical, stenographic, prison, police, civil engineering, fire, labour, foreman, inspection and bridge tender services of all cities; and under a law (1894) by which cities and towns may appoint board of examiners to determine the application of their civil service rules. Various other public services, including even common labourers of the larger towns, are rapidly passing under civil service regulation. Veterans of the Civil War are allowed a commutation of the service. In the settlement of labour disputes conciliatory methods were successful in the formative period, when the parties to disputes adopted customary attitudes of hostility and fought the law. These disputes were reconciled by the Board to a final agreement or to an agreement to arbitrate.1

1 In this earlier period (before 1900), thanks to the

However, every office-holder was, and every subject might be, required to take (though this was not a condition of the franchise) the oath prescribed by parliament. In the year of William and Mary, as a substitute for the oaths of Allegiance and Supremacy; and the same still applies to the signing of the Declaration.

In 1887-1900, out of 290 cases settled, only 107 were formal arbitrations, 124 agreements were effected by the mediation of the Board, 100 were effected otherwise while proceedings were pending, and in 59 cases the Board interposed when the parties preferred hostilities.

1 For a summary statement of state labour laws in the United States in 1903 see Bulletin 54 of the United States Bureau of Labor, September 1904; and for a summary of labour laws in force at the end of 1907 see 21st Annual Report (1907) of the U.S. Commissioner of Labor (Washington, 1908).
crossings of railways and highways, and in 1894 the commonwealth began the construction and maintenance of state highways.

Since 1895, in Boston, and since 1894, in Fall River, the administration of the city's public works have been vested in the hands of the mayor. In each city, the liquor licenses, has been in the hands of state commissioners (one commissioner in Boston, a board in Fall River) appointed by the governor. But though in each case the result has been an improved administration, no general law has been enacted to establish a separate organization for lighting its streets, building and maintaining sidewalks, and employing a watchman or policeman, the number of these organizations continues to increase. The powers of the selectmen are vested in the mayor and aldermen.

In Massachusetts, as in New England generally, the word "town" is used, officially and colloquially, to designate a township, and during the colonial era the New England town-meeting was a notable school form of life in self-government, which the town served as a centre for the management of land. A settlement or "plantation" was sometimes incorporated as a "town," and later as a town, the difference between the latter being a division of corporate government in the general court, while the former had no such right. The towns elected (until 1856) the deputies to the general court, and were the administrative units for the assessment and collection of taxes, the appointment of assessors and auditors, the militia, preserving the peace, for the building and repairing roads and bridges, and recording deeds, births, deaths and marriages. The town may, by a majority vote, pass an order or a discussion of questions relating to the management of the town as well as other matters of peculiar local concern, to determine the amount of taxes for town purposes, and to elect officers. All the citizens were expected to attend the annual town meeting, and such male inhabitants as were not citizens were privileged to attend and to propose and discuss measures, although they had no right to vote. Generally several villages have grown up in the same "town," and some of the more populous towns, usually those in which manufacturing industry has more than fairely been incorporated as "cities;" thus either a town or a city may now include a farming country and various small villages. Although the tendency in Massachusetts is towards chartering as cities rather than towns, which have a population of 12,000 or more, the democratic aspect of the town-meeting persists in many large municipalities which are still technically towns. Most "towns" hold their annual meeting in March, but some hold them in February and others in April. In the larger "towns" the officers elected at this meeting may consist of five, seven or nine selectmen, a clerk, a treasurer, and one or more assessors of the poor, one or more collectors of taxes, one or more auditors, one or more surveyors of highways, a road commissioner, a sewer commissioner, a school committee, a board of health, a fire department and a town clerk. In the smaller "towns" the number of selectmen may be limited to three, the selectmen may assess the taxes, be overseers of the poor, one or more constables may collect the county, the treasurer or constable may collect the county taxes. The selectmen may be limited to one year, or the selectmen, clerk, assessors and overseers of the poor may be elected for a term of three years, in which case a part only of the selectmen, assessors and overseers of the poor are elected each year. The selectmen have the general management of a "town" affairs during the interval between town-meetings. They may call special town-meetings; they appoint election officers and may appoint additional constables or public officers, and such minor officials as inspectors of milk, inspectors of buildings, gauger of measures, callers of streets and shops, fish warden and forester. A school committee consisting of at least 5 members, divided by town, is chosen each year, at the annual town-meeting or at a special meeting which is held in the same month. Any "town" having a village or district within its limits that contains 1000 inhabitants or more may authorize that village or district to incorporate as a village, and when so incorporated, to establish a separate organization for lighting its streets, building and maintaining sidewalks, and employing a watchman or policeman, the officers of such organization to include at least a prudential committee and a clerk. All laws relative to "towns" are applied to "cities" in so far as they are not inconsistent with general or special laws relative to the latter, and the powers of the selectmen are vested in the mayor and aldermen.

Education.—For cities of above 8000 inhabitants (for which alone comparative statistics are annually available), in 1902-1903 the ratio of average attendance to school enrollment, the average number of days' attendance of each pupil enrolled, and the value of school property per capita of pupils in average years was higher than in any other state; the average length of the school term was slightly exceeded in eight states; and the total cost of the schools per capita of pupils in average attendance ($39-05) was exceeded in six other states. In 1906 the average attendance in the public schools to the number of children (between 5 and 15 years) in the state was 69; in Barnstable county it was 95, and in Plymouth 92; and the lowest rate of any county was 68, that of Bristol. In the same year the amount of the various school taxes and other contributions was $30-33 for each child in the average membership of the public schools, and the highest amount for each child (counting the county) was $55-97 in Suffolk county, and in any town $68-01—Lincoln. The school system is not one of marked state centralization—as contrasted, e.g., with New York. A state board of education has general control, its secretary acting as superintendent of the state system in conjunction with local superintendents and committees. Women are eligible for these positions, and among the teachers in the schools they are greatly in excess over men (more than 1 to 1), especially in lower grades. No recognition exists in the schools of race, colour or religion. The proportion of the child population that attends schools is equalized in both two and three states of the Mississippi river. The services of Horace Mann (q.v.) as secretary of the state board (1837-1848) were productive of almost revolutionary benefits not only to Massachusetts but to the entire country. His reforms, which reached every part of the school system, were fortunately introduced just at the beginning of railroad and city growth. Since 1850 transit and compulsory attendance laws (the first compulsory education law was passed in 1863) have been enforced in conjunction with laws against child labour. In 1900 the average period of schooling per inhabitant 18 to 21 years old (inclusive) was 7-04 in the United States, and 7-17 in Massachusetts. (The same year the ratio of wealth productivity was 66 to 37.) Massachusetts stands "foremost in the Union in the universality of its provision for secondary education." The laws practically offer such education free to every child of the commonwealth. Illiterate persons not less than ten years of age constituted in 1900 5-9 % of the population; and 0-8, 14-6, 10-7 % respectively of native whites, foreign-born whites and negroes. More patents are issued, relatively, to citizens of the United States than to those of any other state except Connecticut. Post office statistics indicate a similarly high average intelligence.

The public school system includes common, high and normal schools, and various evening, industrial and trade schools. Many towns and cities maintain free evening schools. In 1894 manual training was made a part of the curriculum in all municipalities having 1000 inhabitants, and high schools are also colonized by high schools, academy schools and college-preparatory schools. The high schools enjoy an exceptional reputation. An unusual proportion of teachers in the public schools are graduates of the state normal schools, of which there are three: one at Amherst, one in Springfield, and one at Dedham. The former being the first normal school of the United

1. The usual allotment of the cost of this work is as follows: 65 % is paid by the railway company, 25 % by the commonwealth and 10 % by the municipality in which the crossing is located.

2. The cost was proportioned between the commonwealth and the local government in the proportion of 3 to 1.

3. Boston remained a township, governed by town-meetings, until 1869, when it had a population of 200,000. The government of Brookline (pop. in 1905, 25,436) is an interesting example of the adaptation of the township system to urban conditions. The town is frequently referred to as a model residential suburb; its budgets are balanced and expenses are kept down, among other reasons; it has established a township gymnasium. The town hall is not large enough for an assembly of all the voters, but actually the town meetings are usually limited to 2000 to 20,000, and since 1901 there has been in force a kind of referendum, under which any initiative act passed by a town-meeting attended by 700 or more voters may be referred, upon petition of 100 legal voters, to a regular vote at the polls. Each of the work of the town-meetings is done through special committees.

States. These two schools were removed subsequently to Framing-
ham (1853) and Westfield (1841), where they are still active; while
other schools, such as Salem (1857), Waverley (1874), Fitchburg (1895),
North Adams (1897), Hyannis (1897) and Lowell (1897), that at Framingham being open to women only.
There is also a state normal art school at Boston (1873) for both
sexes.

The commonwealth contributes to the support of textile schools in
cities in which 450,000 spindles are in operation. Such schools
can be found at Great Barrington, North Adams, Northampton,
and Lowell. The state also maintains a farm at Framingham,
which is operated for the reformation of criminal girls.

Various institutions for the education of the deaf, the blind and
disabled are under the supervision of the state board of
reformation. These include the Massachusetts School for the
Blind at Northampton, which is maintained by the state board
of education, and the Perkins Institution for the Blind at
Boston, which is also under the state board's control.

There are a number of private schools in Massachusetts, and
many of these are quite well known. For example, the Boston
Latin School, founded in 1635, is one of the oldest schools in
the country. The Boston Latin School is a coeducational school
that offers a rigorous curriculum and is known for its academic
excellence.

The state maintains a number of universities, including Harvard
University, founded in 1636, and medical schools, such as
Boston University, founded in 1839. These institutions play
a significant role in the state's educational system.

There are also many public libraries in Massachusetts, which are
funded by both the state and local governments. These libraries
provide access to a wide range of resources, including books,
periodicals, and electronic materials.

The state also supports a number of cultural institutions,
including art museums, historical societies, and theaters. These
institutions help to preserve and promote the state's cultural
heritage.

The state is also home to several significant museums, including
the Museum of Fine Arts in Boston, which houses a large
and diverse collection of art from around the world.

The state of Massachusetts has a long and storied history, and
its institutions play a significant role in shaping its future.
method used for the taxation of banks, insurance companies, railways, tramways, trust companies and corporations, some of them noteworthy. In the case of the corporations reality and machinery are taxed generally by the local authorities, and stock values by the commonwealth. The Boston stock exchange is the second of the country in the extent of the securities in which it deals. The proportion of the U.S. bonds among the total population is higher than that in any other state.

History.—It is possible that the coasts of Massachusetts were visited by the Northmen, and by the earliest navigators who followed Cabot, but this is only conjecture. In 1602 Bartholomew Gosnold landed at and named Cape Cod and coasted as far south as the present No-Man's Land, which he named Martin's or Martha's Vineyard, a name later transferred to a neighboring larger island. Pring and Champlain at a later date coasted along what is now Massachusetts, but the map of Champlain is hardly recognizable. The first sufficient explorations for cartographic record were made by John Smith in 1614, and his map was long the basis—particularly in its nomenclature—of later maps. Permanency of occupation, however, dates from the voyage of the "Mayflower," which brought about a hundred men, women and children who had mostly belonged to an English sect of Separatists, originating in Yorkshire, but who had passed a period of exile for religion's sake in Holland. In the early winter of 1620 they made the coast of Cape Cod; and after they had intended to make their landing farther south, within the jurisdiction of the Virginia Company, which had granted them a patent; but stress of weather prevented their doing so. Finding themselves without warrant in a region beyond their patent, and threatened with the desertion of disaffected members of their company (probably all servants or men of the "lesser" sort) unless concessions were made to these, they drew up and signed before landing a democratic compact of government which is accounted the earliest written constitution in history. After some exploration of the coast they made a permanent landing on the 21st of December 1620 (N.S.) at Plymouth, a harbor which had already been so named by John Smith in his maps of 1614 and 1616. During the first winter nearly one-half their number died from exposure, and the relations of the survivors with their partners of the London Company, who had insisted that for seven years the plantation should be managed as a joint stock company, were unsatisfactory. However, about thirty-five new colonists arrived in 1622 and ninety-six more in 1623. The abandonment of the communal system was begun in the latter year, and with the dissolution of the Virginia Company in 1624 Plymouth became a corporate colony with its chief authority vested in the whole body of freemen composed of the General Court. Upon the death of the first governor, John Carver, in the spring of 1621, the General Court chose William Bradford as his successor, and with him was chosen one assistant. The subsequent elections were annual, and within a few years the number of assistants was increased to seven. The General Court was the legislature and the electorate; the governor and assistants were the executive and the judiciary. The whole body of freemen composed the General Court until other towns than Plymouth had been organized, the first of which were Scituate in 1636 and Duxbury in 1637, and then the representative form of government was adopted and there was a gradual differentiation between Plymouth the town and Plymouth the colony. When it had become known that the colony was within the territory of the New England Council, John Pierce, in 1621, procured from that body a grant which made the colonists its tenants. A year later Pierce surrendered this and procured another, which in effect made him proprietor of the colony, but he was twice shipwrecked and once was driven out of Plymouth, so that it had no second planters. In 1629 Governor Bradford procured from the same council a definite grant of the tract which corresponds to the south-eastern portion of the present state. But all attempts to procure a royal charter for Plymouth Colony were unsuccessful, and in 1691 it was annexed to the Colony of Massachusetts Bay under what is termed the Provincial Charter.

King James having by patent in 1620 created a Council for New England to whom he made a large grant of territory, the council in 1628 made a sub-grant, confirmed by a royal charter that passed the seals on the 4th of March 1629, to the "Governor and Company of the Massachusetts Bay in New England." There had been various minor expeditions during the few years since Smith was on the coast before this company, in the Puritan interests, had sent over John Endecott with a party in 1628 to what is now Salem. In 1635 the government of the company, with questionable right (for the charter seems evidently to have contemplated the residence of the company in England), transferred itself to their territory, and under the leadership of John Winthrop laid the foundations anew of the Massachusetts colony, when they first settled Boston in the autumn of that year. While it served repeatedly, though not continuously, as governor of the colony till his death in 1649, his rejection in 1636 being due to a party of theological revolt which chose Henry Vane (afterwards Sir Henry) to the office. This was an incident in a famous episode, important rather as a symptom than in itself, namely, the Antinomian controversy, "New England's earliest protest against formulas," in which Vane and Ann Hutchinson took the lead in criticizing the official orthodoxy of the colony.

The magistrates successfully asserted themselves to the disadvantage of the patients of their criticisms (the synod being banished), and this was characteristic of the colony's early history. The charter gave the company control over the admission of "freemen" (co-partners in the enterprise, and voters), "full and absolute power and authority to correct, punish and rule" subjects settling in the territory comprised in their grant, and power to resist... by all fitting ways and means whatever all persons attempting the "destruction, invasion, detention or annoyance" of the plantation. Some writers deny the company's right under this instrument to rule at any rate what they did was to make the suffrage dependent on stringent religious tests, and to repress with determined zeal all theological "vagaries" and "whimsies." Criticism of church or magistrates was not tolerated. Laws were modelled closely on the Bible. The clergy were a ruling class. The government was frankly theocratic. Said Winthrop (1637): "We see not that any should have authority to set up any other exercises besides what authority hath already set up," and a synod at Cambridge in 1637 catalogued eighty-two "opinions, some blasphemous, others erroneous and all unsafe," besides nine "unwholesome expressions," all of which were consigned "to the devil of hell from whence they came." Another synod at Cambridge in 1647 more formally established the principle of state control. The legislation against Baptists (about 1644-1658) and the persecution of the Quakers (especially 1656-1662) partook of the brutality of the time, including scourging, boring of tongues, cutting of ears and in rare cases capital punishment. It cannot be denied that men like Roger Williams and some of the persecuted Quakers, though undenominational and aggressive at their core, created a spirit which to-day seems sweeter in tolerance and humanity than that of the Puritans. And it seems necessary to emphasize these facts because until about 1870 it was almost unchallenged tradition to regard the men of Massachusetts Bay as seekers and champions of "religious liberty." They left England, indeed, for liberty to discard the "poperies of the English Church, and once in Massachusetts they even discarded far more than those
“poperys.” But religious liberty in our modern sense they did not seek for themselves, nor accord to others; they abhorred it, they trampled on it, and their own lives they subjected to all the rigid restrictions to which they subjected others. They were narrow but strong; no better example can be imagined of what the French call “the defects of one’s qualities.” Their failures were small compared with those of their contemporaries in England and elsewhere in Europe, and public opinion did not long sustain violent protest of any opinion. More than once mobs freed Quaker prisoners. Also it is to be said that with the single exception of religious toleration the record of the state in devotion to human rights has been from the first a splendid one, whether in human principles of criminal law, or in the defence of the civil rights commonly declared in American constitutions. It was once generally assumed that the repression practised attained its end of securing harmony of opinion. The fact seems to be that intellectual speculation was as strong in America as in Puritan England; the assumption that the inhibition of its expression was good seems wholly gratuitous, and contrary to general convictions underlying modern freedom of speech. A safer opinion is probably that “the spiritual growth of Massachusetts withered under the shadow of dominant orthodoxy; the colony was only saved from mental atrophy by its vigorous political life” (J. A. Doyle). In literature the second half of the 17th century is a sterile waste of forbidding theology; and its life, judged by the present day, singularly sombre.

In addition to the few persons banished to Rhode Island, theological and political differences led many to emigrate thither. Others, discontented with Massachusetts autocracy and wishing, too, “to secure more room,” went to Connecticut (q.v.) where they established a bulwark against the Dutch of New York.

A witchcraft scare (at its worst in 1691-1697, though the earliest Connecticut case was in 1666-1667 and the earliest in Boston in 1648) led to another tragedy of ignorance. In all thirty-two persons were executed (according to W. F. Poole, about a thousandth part of those executed for witchcraft in the British Isles in the 16th and 17th centuries). Salem was the scene of the greatest excitement in 1691-1692.

Exceptionally honourable to the early colonists was their devotion to education (see Harvard University and Boston). Massachusetts Bay had a large learned element; it is supposed that about 1640 there was an Oxford or Cambridge graduate to every 250 persons in the colony. The earliest printing in the British-American colonies was done at Cambridge in 1639; it was not until 1674 that the authorities of the colony permitted printing, except at Cambridge. Boston and Cambridge remain leading publishing centres to-day. The first regular newspaper of Boston, the Boston Newsletter, was the pioneer American newspaper.

The early history was rendered unquiet at times by wars with the Indians, the chief of which were the Pequot War in 1637, and King Philip's War in 1675-76; and for better combining against these enemies, Massachusetts, with Connecticut, New Haven and New Plymouth, formed a confederacy in 1643, considered the prototype of the larger union of the colonies which conducted the War of American Independence (1775-83). The struggle with the Crown, which ended in independence, began at the foundation of the colony, with assumptions of power under the charter which the colonial government was always trying to maintain, and the crown was as assiduously endeavouring to counteract. More than half a century of struggle, the crown finally annulled the charter of the colony in 1684, though not until 1686 was the old government actually supplanted on the arrival of Joseph Dudley, a native of the colony, as president of a provisional council; later, Sir Edmund Andros was sent over with a commission to unite New York and New England under his rule. The colonists had been for many years almost independent; they made their own laws, they even appointed natives as officials, and the colonial interpretation of the old charter had in general been allowed to stand. Massachusetts had excluded the English Book of Common Prayer, she had restricted the franchise, laid the death penalty on religious opinions, and passed various other laws repugnant to the Crown, notably to Charles II. and James II.; she had caused laws and writs to run in her own name, she had neglected to exact the oath of allegiance to the sovereign, though carefully exacting an oath of fidelity to her own government, she had protected the regicides, she had coined money with her own seal, she had blocked legal appeals to the English courts, she had not compelled the observance of the magistrates' orders, she had coined money, and the revenue derived from the sale of licenses to ships of war and to cannon. The event was the recall of the charter aroused the strongest fears of the colonists. Andros speedily met determined opposition by measures undertaken relative to taxation and land titles, by efforts to secure a church for Episcopal service, and an attempt to curb the town meetings. His government was supported by a small party (largely an Anglican Church party), but was intensely unpopular with the bulk of the people; and—it is a disputed question, whether before or after news arrived of the landing in England in William of Orange—in April 1688 the citizens of Boston rose in revolution, deposed Andros, imprisoned him and re-established their old colonial form of government. Then came a struggle, carried on in England by Increase Mather as agent (1668-1692) of the colony, to secure such a form of government under a new charter as would preserve as many as possible of their old liberties. Plymouth Colony, acting through its agent in London, endeavoured to secure a separate existence by royal charter, but accepted finally union with Massachusetts when association with New York became the probable alternative. The province of Maine was also united in the new provincial charter of 1691, and Sir William Phips came over with it, commissioned as the first royal governor. As has been mentioned already, the new charter softened religious tests for office and the suffrage, and accorded “liberty of conscience” except to Roman Catholics. The old religious exclusiveness had already been greatly lessened: the clergy were less powerful, heresy had thrived under repression, Anglican churchmen had come to the colony and were borne with perforce, devotion to trade and commerce had weakened theological tests in favour of ideals of mere good order and prosperity, and a spirit of toleration had grown.

Throughout the continuance of the government under the provincial charter, there was a constant struggle between a prerogative party, headed by the royal governor, and a popular party who cherished recollections of their practical independence under the colonial charter, and who were nursing the sentiments which finally took the form of resistance in 1775. The inter-charter period, 1686-1691, is of great importance in this connexion. The popular majority kept up the feeling of hostility to the royal authority in recurrent combats in the legislative councils over the same questions which before the war had been raised. Though these antagonisms were from time to time forgotten in the wars with the French and Indians. During the earl of Bellomont's administration, New York was again united with Massachusetts under the same executive (1697-1701). The scenes of the recurrent wars were mostly distant from Massachusetts proper, either in Maine or on Canadian or Acadian territory, although some savage inroads of the Indians were now and then made on the exposed frontier towns, as, for instance, upon Deerfield in 1704 and upon Haverhill in 1708. Phips, who had succeeded in an attack on Port Royal, had ignominiously failed when he led the Massachusetts fleet against Quebec in 1696; and the later expedition of 1711 was no less a failure. The most noteworthy administration was that of William Shirley (1741-1749 and 1753-1756), who at one time was the commanding officer of the British forces in North America. He made a brilliant success of the expedition against Louisburg in 1745, William Pepperell, a Maine officer, being in immediate command. Shirley with Massachusetts troops also took part in the Oswego expedition of 1755; and Massachusetts proposed, and lent the chief assistance in the expedition of Nova Scotia in 1755 which ended in the removal of the Acadians. Her officers and troops also played an important part in the Crown Point and second Louisburg expedition (1758).
The first decided protests against the exercise of sovereign power by the crown, the first general moral and political revolt that marked the approach of the American War of Independence, took place in Massachusetts; so that the most striking events in the general history of the colonies as a whole from 1760 to 1775 are an intimate part of her annals. The beginning of the active opposition to the crown may be placed in the resistance, led by James Otis, to the issuing of writs (after 1752, Otis's famous argument against them being made in 1760-1761) to compel citizens to assist the revenue officers; followed later by the outburst of feeling at the imposition of the Stamp Act (1765), when Massachusetts took the lead in confronting the royal power. The governors put in office at this time by the crown were not of conciliatory temperaments, and the measures instituted in parliament (see United States) served to increase bitterness of feeling. Royal troops sent to Boston (several regiments, 1768) irritated the populace, who were highly excited at the time, until in an outbreak on the 4th of March 1770 a file of garrison troops shot down in self-defence a few citizens in a crowd which assailed them. This is known as the "Boston Massacre." The merchants combined to prevent the importation of goods which by law would yield the crown a revenue; and the patriots—as the anti-prerogative party called themselves—under the lead of Samuel Adams, instituted regular communication between the different towns, and afterwards, following the initiative of Virginia, with the other colonies, through "committees of correspondence"; a method of the utmost advantage thereafter in forcing on the revolution by intensifying and unifying the resistance of the colony, and by inducing the co-operation of other colonies. In 1773 (Dec. 16) a party of citizens, disguised as Indians and instigated by popular meetings, boarded some tea-ships in the harbour of Boston, and to prevent the landing of their taxable cargoes threw them into the sea; this incident is known in history as the "Boston tea-party." Parliament in retaliation closed the port of Boston (1774), a proceeding which only aroused more bitter feeling in the country towns and enlisted the sympathy of the other colonies. The governorship was now given to General Thomas Gage, who commanded the troops which had been sent to Boston. Everything forebode an outbreak. Most of the families of the highest social position were averse to extreme measures; a large number were not won over and became expatriated loyalists. The popular agitators, headed by Samuel Adams—with whom John Hancock, an opulent merchant and one of the few of the richer people who deserted the crown, leagued himself—forced on the movement, which became war in April 1775, when Gage sent an expedition to Concord and Lexington to destroy military stores accumulated by strengthening and unifying the resistance of the colony, and staying at Lexington. This detachment, commanded by Lord Percy, was assaulted, and returned with heavy loss. The country towns now poured their militia into Cambridge, opposite Boston; troops came from neighbouring colonies, and Artemas Ward, a Massachusetts general, was placed in command of the irregular force, which with superior numbers at once shut the royal army up in Boston. An attempt of the provincials to seize and hold a commanding hill in Charlestown brought on the battle of Bunker Hill (June 17, 1775), in which the provincials were driven from the ground, although they lost much less heavily than the royal troops. Washington, chosen by the Continental Congress to command the army, arrived in Cambridge in July 1775, and stretching his lines around Boston, forced its evacuation in March 1776. The state was not again the scene of any conflict during the war. Generals Henry Knox and Benjamin Lincoln were the most distinguished officers contributed by the state to the revolutionary army. Out of an assessment at one time upon the states of $5,000,000 for the expenses of the war, Massachu-
setts was charged with $820,000, the next highest being $800,000 for Virginia. Of the 23,791 troops sent by all the colonies into the field, reckoning by annual terms, Massachusetts sent 67,907, the next highest being 31,939 from Connecticut, Virginia furnishing only 26,678; and her proportion of sailors was very much greater still. In every campaign in every colony save in 1779—80 her soldiery were in absolute, and still more in relative, number greater than those of any other colony.

After the outbreak of the war a somewhat indefinite, heterogeneous provisional government was in power till a constitution was adopted in 1780, when John Hancock became the first governor. Governor James Bowdoin in 1786—1787 put down with clemency an almost bloodless insurrection in the western counties (there was strong disaffection, however, as far east as Middlesex), known as the Shays Rebellion, significant of the rife ideas of popular power, the economic distress, and the unsettled political conditions of the years of the Confederation. Daniel Shays (1747-1823), the leader, was a brave Revolutionary captain of no special personal importance. The state debt was large, taxation was heavy, and industry was unsettled; worthless paper money was in circulation, yet some men demanded more; debtors were made desperate by prosecution; the state government seemed weak, the Federal government contemptibly so; the local courts would not, or from intimidation feared to, punish the turbulent, and demagogues encouraged ideas of popular power. A convention of delegates representing the malcontents of numerous towns in Worcester county met at Worcester on the 15th of August 1786 to consider grievances, and a week later a similar convention assembled at Hatfield, Hampshire county. Encouraged by these and other conventions in order to obstruct the collection of debts and taxes, a mob prevented a session of the Court of Common Pleas and General Sessions of the Peace at Northampton on the 29th of August, and in September other mobs prevented the same court from sitting in Worcester, Middlesex and Berkshire counties. About 1000 insurgents under Shays assembled at Springfield on the 26th of September to prevent the sitting there of the Supreme Court, from which they feared indictments. To protect the court and the national arsenal at Springfield, for which the Federal government was powerless to provide a guard, Major-General William Shepard (1737-1817) ordered out the militia, called for volunteers, and supplied them with arms from the arsenal, and the court sat for three days. The Federal government now attempted to enlist recruits, ostensibly to protect the western frontier from the Indians, but actually for the suppression of the insurrection; but the plan failed from lack of funds, and the insurgents continued to interrupt the procedure of the courts. In January 1787, however, Governor Bowdoin raised an army of 4400 men and placed it under the command of Major-General Benjamin Lincoln (1733-1810). While Lincoln was at Worcester Shays planned to capture the arsenal at Springfield, but on the 25th of January Shepard's men dispersed the mob, with the result that Shays himself had to fly. On the 25th of February, his followers took another man as hostage, and in September other mobs prevented the same court from sitting in Berkshire county. About 150 prisoners. Subsequently the insurgents gathered in small bands in Berkshire county; but here, a league having been formed to assist the government, 84 insurgents were captured at West Stockbridge, and the insurrection practically terminated in an action at Sheffield on the 27th of February, in which the insurgents lost 2 killed and 30 wounded and the militia 1 killed and 1 wounded. Two of the insurgent leaders, Daniel Shays and Eli Parsons, escaped to Vermont soon after the rout at Petersham. Fourteen other insurgents who were tried by the Supreme Court in the spring of 1787 were found guilty of treason and sentenced to death. They were, however, held rather as hostages for the good behaviour of worse offenders who had escaped, and were pardoned in September. In February 1788 Shays and Parsons petitioned for pardon, and this was granted by the legislature in the following June. The outcome of the uprising was an encouraging test of loyalty to the commonwealth; and the insurrection is regarded as having been very potent in preparing public opinion throughout the country for the adoption of a stronger national government. The Federal Constitution was ratified by Massachusetts by only a small majority on the 6th of February 1788, after its
rejection had been at one time imminent; but Massachusetts became a strong Federalist state. Indeed, the general interest of her history in the quarter-century after the adoption of the Constitution lies mainly in her connexion with the fortunes of that great political party. Her leading politicians were out of sympathy with the conduct of national affairs (in the conduct of foreign relations, the distribution of political patronage, naval policy, the question of public debt) from 1804—when Jefferson's party showed its complete supremacy—onward; and particularly after the passage of the Embargo Act of 1807, which caused great losses to Massachusetts commerce, and, so far from being accepted by her leaders as a proper diplomatic weapon, seemed to them designed in the interests of the Democratic party. The Federalist preference for England over France was strong in Massachusetts, and her sentiment was against the war with England of 1812-15. New England's discontent culminated in the Hartford Convention (Dec. 1814), in which Massachusetts men predominated. The state, however, bore her full part in the war, and much of its naval success was due to her sailors.

During the interval till the outbreak of the Civil War in 1861, Massachusetts held a distinguished place in national life and politics. As a state she may justly be said to have been foremost in the struggle against slavery. She opposed the policy that led to the Mexican War in 1846, although a regiment was raised in Massachusetts by the personal exertions of Caleb Cushing. The leaders of the ultra non-political abolitionists (who opposed the formation of the Liberty party) were mainly Massachusetts men, notably W. L. Garrison and Wendell Phillips. The Federalist domination had been succeeded by Whig rule in the state; but after the death of the great Whig, Daniel Webster, in 1852, all parties disintegrated, re-aligning themselves gradually in an aggressive anti-slavery party and the temporizing Democratic party. First, for many years the Free-Soilers gained strength; then in 1855 in an extraordinary party upheaval the Know-Nothings quite broke up Democratic, Free-Soil and Whig organizations; the Free-Soilers however captured the Know-Nothings organization and directed it to their own ends; and by their junction with the anti-slavery Whigs there was formed the Republican party. To this the original Free-Soilers contributed as leaders Charles Sumner and C. F. Adams; the Know-Nothings, Henry Wilson and N. P. Banks; and later, the War Democrats, B. F. Butler—all men of mark in the history of the state. Charles Sumner, the most eminent exponent of the new party, was the state's senator in Congress (1851-1857). The feelings which grew up, and the movements that were fostered till they rendered the Civil War inevitable, received something of the impetus from Massachusetts which she had given a century before to the feelings and movements forerunning the War of American Independence. When the war broke out it was her troops who first received hostile fire in Baltimore, and turning their mechanical training to account opened the obstructed railroad to Washington. In the war thus begun she built, equipped and manned many vessels for the Federal navy, and furnished from 1861 to 1865 26,163 men (or, including final credits, probably more than 30,000 men) for the navy. During the war all but twelve small townships raised troops and every call, the excess throughout the state amounting in all to more than 15,000 men; while the total recruits to the Federal army (including re-enlistments) numbered, according to the adjutant-general of the state, 1,59,165 men, of which less than 7,000 were raised by draft. The state, as such, and the townships spent $2,905,517.10 in the war; and private contributions of citizens are reckoned in addition at about $9,000,000, exclusive of the aid to families of soldiers, paid then and later by the state.

Since the close of the war Massachusetts has remained generally steadfast in adherence to the principles of the Republican party, and has contributed to the development of the great industries, navigation, which was formerly the distinctive feature of its business prosperity, has under the pressure of laws and circumstances given place to manufactures, and the development of carrying facilities on the land rather than on the sea.

In the Spanish-American War of 1898 Massachusetts furnished 11,780 soldiers and sailors, though her quota was but 7388; supplementing from her own treasury the pay accorded them by the national government.

No statement of the influence which Massachusetts has exerted upon the American people, through intellectual activity, and even through vagary, is complete without an enumeration of the names which, to Americans at least, are the signs of this influence and activity. In science the state can boast of John Winthrop, the most eminent of colonial scientists; Benjamin Thompson (Count Rumford); Nathaniel Bowditch, the translator of Laplace; Benjamin Peirce and Morse the electrician; not to include an adopted citizen in Louis Agassiz. In history, Winthrop and Bradford laid the foundations of her story in the very beginning; but the best example of the colonial period is Thomas Hutchinson, and in later days Bancroft, Sparks, Parkman, Prescott, and Parkman. In poetry, a forerunner of the modern spirit in American verse was Richard Henry Dana; and later came Bryant, Longfellow, Whittier, Lowell and Holmes. In philosophy and the science of living, Jonathan Edwards, Franklin, Channing, Emerson and Theodore Parker. In education, Horace Mann; in philanthropy, S. G. Howe. In oratory, James Otis, Fisher Ames, Josiah Quincy, jurm., Webster, Choate, Everett, Sumner, Winthrop and Wendell Phillips; and, in addition, in statesmanship, Samuel Adams, John Adams and John Quincy Adams. In fiction, Hawthorne and Mrs Stowe. In law, Story, Parsons and Shaw. In scholarship, Ticknor, William M. Hunt, Horatio Greenough, W. W. Story and Thomas Ball. The "transcendental movement," which sprang out of German affiliations and produced as one of its results the well-known community of Brook Farm (1841-1847), under the leadership of Dr George Ripley, was a Massachusetts growth, and in passing away it left, instead of traces of an organization, a sentiment and an aspiration for higher thinking which gave Emerson his following. When Massachusetts was called upon to select for Statuary Hall in the capitol at Washington two figures from the long line of her worthies, she chose as her fittest representatives John Winthrop, the type of Puritanism and state-builder, and Samuel Adams (though here the choice was difficult between Samuel Adams and John Adams) as her greatest leader in the heroic period of the War of Independence.

Governors of Plymouth Colony

(Chosen annually by the people).

MASSACHUSETTS

Governors of Massachusetts
(Under the First Charter—chosen annually).

John Endecott 1 1629-1630
John Winthrop 1 1630-1634
John Winthrop 1 1634-1635
John Winthrop 1 1635-1636
John Winthrop 1 1636-1637
John Winthrop 1 1637-1640
Richard Bellingham 1640-1641
Thomas Dudley 1 1641-1644
Richard Bellingham 1644-1645
Richard Bellingham 1645-1646
Richard Bellingham 1646-1647
John Endecott 1647-1650
Thomas Dudley 1650-1651
John Endecott 1651-1654
Richard Bellingham 1654-1655
John Endecott 1655-1656
Richard Bellingham 1656-1657
John Leverett (acting, 1672-1673) 1657-1659
Simon Bradstreet 1659-1666
Sir Edmund Andros 1666-1669
Simon Bradstreet 1669-1672
Under Second Charter—appointed by the Crown.

Sir William Phips 1672-1690
William Stoughton (acting) 1694-1699
Richard Coote, earl of Bellomont 1699-1700
William Phips (acting) 1700-1701
Joseph Dudley 1702-1715
William Tailer (acting) 1715-1716
Samuel Shute 1716-1722
William Dummer (acting) 1722-1728
William Burnet 1728-1729
William Dummer (acting) 1729-1730
William Tailer (acting) 1730-1731
Jonathan Belcher 1731-1741
William Shirley 1741-1749
Spencer Phips (acting) 1749-1750
Spencer Phips 1750-1757
Thomas Pownal 1757-1760
Spencer Phips (acting) 1760-1761
Sir Francis Bernard, Bart. 1761-1769
Thomas Hutchinson (acting) 1769-1771
Thomas Hutchinson 1771-1773
John Gage 1 1774-1775
Under the Constitution.

John Hancock 1775-1780
James Bowdoin 1780-1785
John Hancock 1785-1786
Samuel Adams 1786-1792
Samuel Adams 1793-1794
James Bowdoin 1794-1797
Moses Gill (lieut.-governor; acting) 1797-1799
Caleb Strong 1800-1802
Jas. Sullivan 1802-1807
Levi Lincoln (acting) 1807-1808
Christopher Gore 1808-1810
Elbridge Gerry 1810-1812
Caleb Strong 1812-1816
John Brooks 1816-1823
William Eustis 1823-1825
Levi Lincoln 1825-1826
John Davis 1826-1829
Edward Everett 1829-1830
Marcus Morton 1830-1841
John Davis 1841-1843
John H. Clifford 1843-1844
George N. Briggs 1844-1845
George S. Boutwell 1845-1849
Amory Washburn 1849-1854
Henry J. Gardner 1854-1855
Nathaniel P. Banks 1855-1857

1 Endecott, by commission dated the 30th of April 1629, was made a deputy governor. London's plantation in the Massachusetts Bay. 2 Matthew Cradock, first governor of the Company, from the 4th of March 1629 to the 20th of October 1629, was succeeded on the latter date by John Winthrop, who, on reaching Salem on the 12th of June 1630 with the charter, superseded Endecott.

3 During three periods, 1701-1702, in February 1715, and from April to August 1737 the affairs of the colony were administered by an Executive Council.

4 General Gage was military governor, Hutchinson remaining nominally civil governor.

John A. Andrew 1861-1866
Alexander H. Bullock 1866-1869
William Calhoun 1869-1872
H. H. Washburn 1872-1874
Thomas Talbot (acting) 1874-1875
William Gaston 1875-1876
Alexander H. Rice 1876-1879
John Davis Long 1879-1880
Benjamin F. Butler 1880-1885
George D. Robinson 1885-1887
Oliver H. Howard 1887-1891
John A. Quay 1891-1892
William E. Russell 1892-1897
Joseph G. Greenhalge 1897-1900
Roger Wolcott 1900-1906
William L. Douglas 1907-1913
W. Murray Crane 1913-1923
Curtis L. Guild 1923-1929
Eben S. Draper 1929-1934
Eugene N. Foss 1933-1937

standard general history was that of J. G. Palfrey, History of New England (5 vols., Boston, 1856–1890), to the War of Independence. In the last twenty years or so, a number of bestsellers have been published with an unsparing eulogistic vein. Of importance in more modern views is a volume of Lectures Delivered… before the Lowell Institute… by Members of the Massachusetts Historical Society on Subjects Relating to the Earlier History of the State (Boston, 1862). Perhaps the most important of the lectures of G. E. Ellis, later expanded, and in the process somewhat weakened, into his Puritan Age and Rule in the Colony of the Massachusetts Bay, 1629–1685 (Boston, 1869). C. F. Adams, Massachusetts: its Histories and its History (Boston, 1893), for a critique of the "filiopticist" traditions of Massachusetts writers; also his Three Episodes of Massachusetts History, narrated in the Colloquial, and the Colloquial, and the town government in Quincy from 1634–1888 (2 vols., Boston, 1892). On town government see further E. Channing in Johns Hopkins University, Studies in History vol. ii. (1884). F. L. Aldrich in Antiquarian Society, new series, Proceedings, 3rd ed. (Boston, 1897). In the vol. 3 of J. R. Lowell are two on "New England two Centuries Ago" and "Witchcraft." For economic history, W. B. Weeden, Economic and Social History of New England, 1620–1800 (Boston, 1893), C. H. J. Douglas, The Financial History of Massachusetts… to the American Revolution (in Columbia University Studies, vol i., 1892). On the revolutionary epoch, Melten Chamberlain, John Adams… the Statesman (Boston, 1895), T. Hutchinson, Diary and Letters (2 vols., Boston, 1884–1886); H. A. Cushing, Transition from Provincial to Commonwealth Government in Massachusetts (Columbia University Studies in History, vol. iii., 1896); S. B. Harding, Content and Reformation of the Federal Constitution in Massachusetts (Harvard University Studies, New York, 1896); and on the Shays Rebellion compare J. P. Warren in American Historical Review (Oct., 1905). On New England discontent preceding 1812, Henry Adams, Documents Relating to New England Federalism, 1780–1812 (Boston, 1877); T. W. Higginson, Massachusetts in the Army and Navy during the War of 1812–95 (Official, Boston, 1887). On a list of the Federal societies and state consult A. M. Davis in Publications of the Colonial Society of Massachusetts, vol. i.; the most important are the Massachusetts Historical Society, founded in 1791, part of which is the Mass. Collections (Boston) and the American Antiquarian Society, established 1812, publishing Proceedings (Worcester). In many cases the most valuable material on various periods is indicated under the biographies (or under sections of the articles) of the individuals. In the above article, to which add Timothy Pickering, George Cabot, Joseph Warren, Elbridge Gerry, Benjamin F. Butler, G. S. Boutwell and George F. Hearst. Many townships have published their local records, and many township and county histories contain valuable matter of general interest (e.g. as showing in detail township action before the War of Independence), though generally weighted heavily with genealogy and matters of purely local interest. In American works of fiction, particularly of New England authors, the reader will find a wealth of description of Massachusetts and New England life, past and present, as in the writings of William D. Howells, Sarah Orne Jewett, and other famous American contemporaries.

MASSAGE, a wholesale indiscriminate killing of persons, and also, in a transferred sense, of animals. The word is adopted from the French; but its origin is obscure. The meaning and the old form maceule seem to point to it being a corruption of the Lat. macellum, butcher’s shop or shambles, hence meat market; this is probably from the root macc-, seen in мъхъдъя, to fight, мъкъря, sword, and Lat. macula, to sacrifice. Another theory is that the Old Eng. Ger. matthel, to cut in pieces; cf. mod. Ger. get Ministério, to massacre.

MASSAGE. The word massage has of late years come into general use to signify the method of treating disease or other physical conditions by manipulating the muscles and joints. According to Littré the word is derived from the Arabic mass, and has the specific meaning of "pressing the muscular parts of the body with the hands, and exercising traction on the joints in order to give suppleness and stimulate vitality." It was probably adopted from the Arabian physicians by the French, who have played a leading part in reviving this method of treatment, which has been practised from time immemorial, and by the most primitive people, but has from time to time fallen into disuse among Western nations. In the Odyssey the women are described as rubbing and kneading the heroes on their return from battle. In India, under the name "shampoo" (tāmpū), the same process has formed part of the native system of medicine from the most remote times; professional massers were employed there by Alexander the Great in 327 B.C. In China the method is also of great antiquity, and practised by a professional class; the Swedish gymnastic system instituted by Pehr Henrik Ling is derived from the book of Cong-Fou, the bronze of Ta-o-Sse. Hippocrates describes and enjoins the use of manipulation, especially in cases of stiff joints, and he was followed by other Greek physicians. Orbiusius gives an account of the application of friction with the bare hands, which exactly corresponds with the modern practice of massage. It is worthy of note that the treatment, after being held in high esteem by the leading Greek physicians, fell into disuse with the profession, apparently on account of its association with vicious abuses. The same drawback has made itself felt in the present day, and can only be met by the most scrupulous care in the choice of agents and the remnants of the art, among the Greeks, Romans, Egyptians, and later the Turks, massage is chiefly due partly of the ordinary procedure of the bath without any special therapeutic intention, and the usage has survived until to-day; but that mode of application was no doubt a refinement of civilised life. Medical rubbing is older and more elementary than bathing, as we see from its employment by savages. Probably it was evolved independently among different races from the natural instinct—shared by the lower animals—which teaches to rub, press or lick any part of the body in which uneasiness is felt, and is therefore the oldest of all therapeutic means.

According to Weiss, the therapeutic use of massage was revived in Europe by Hieronymus Fabricius ab Aquapendente (1537–1619), who applied it to stiff joints and similar conditions. Paracelsus in his De medicina Aegyptiorum (1591), gives a description of methodical massage as practised by the Egyptians quite on modern lines. Thereafter it appears to have been adopted here and there by individual practitioners, and various references are made to it, especially by French writers. The moderns have an essay written by Pierre Adolphe Pierry (1794–1879) for the late medical journal of whom the name is not remembered, has been written in 1818, but it was probably used before. The practice was gradually advocated by an increasing number of medical men. In Great Britain it was called "medical rubbing," and at Edinburgh Beveridge had a staff of eight trained male rubbers. A book written by Estradère in 1863 attracted much attention, but the man who contributed most to the modern popularity of massage was Metzger of Amsterdam, who began to use it tentatively in 1853, and then proceeded to study and apply it methodically. He published an essay on the subject in 1858. The science of massage and the improvements of the treatment were thereby begun.

At the same time, its application by Dr Silas Weir Mitchell to hysterical and other nervous conditions, in conjunction with the "rest cure," has done much to make it known.

Massage, as now practised, includes several processes, some of which are passive and others active. The former are carried out by an operator, and consist of rubbing and kneading the skin and deeper tissues with the hands, and exercising the joints by bending the patient's limbs. The active movements consist of a special form of gymnastics, designed to exercise particular muscles or groups of muscles. In what is called "Swedish massage" the operator moves the limbs while the patient resists, thus bringing the opposing muscles into play. Some writers insist on confining the word "massage" to the rubbing processes, and use the general term "manipulation."

to cover all the movements mentioned; but this is a verbal
subtlety of no importance. It is evident that alike among the
Greeks, the Orientals, and savage races, the two processes have
always been applied as part of the same treatment, and the
definition quoted above from Littre goes to show that the word
" massage " is properly applied to both.

Rubbing has been subdivided into several processes, namely (i)
stroking, (ii) rubbing, (iii) tapping. Some practitioners attach great importance to the application of a
particular process in a particular way. As a rule, oils and other
lubricants are not used. But, however it may be applied, the treat-
ment is a patterned process of mechanical irritation, massagery.

It has been shown by Lauter Brunton that more blood actually flows through the tissues during and after rubbing. The
number of capillaries, and, therefore, their total surface area, are also said to be increased (Mitchell). At the same time the
movement of the lymph stream is accelerated. In order to assist
the flow of blood and lymph, stroking is applied centripetally,
that is to say, upwards along the limbs and the lower part of the
body, downwards from the head. The effects of the increased
physiological activity set up are numerous. Functional ability is
restored to exhausted muscles by the removal of fatigue products
and the induction of a fresh blood supply; congestion is relieved;
collections of serous fluid are dispersed; secretion and excretion are
stimulated; local and general nutrition are improved. These
effects are conditions in which massage is mostly applied.

Such are various forms of paralysis and muscular wasting,
chronic and subacute affections of the joints, muscular rheumatism,
sciatia and other neuralgias, local congestions, sprains, contusions,
local injuries and local defects of head and body circulation from
the head relieves cerebral congestion. It has also been used in
anemia, hysteria and " neurasthenia," disorders of the female
organs, muscular affections, for the insomniac, for the insomnious,
for joint pains, for constipation, inflammatory and other affections of the eye,
including even cataract.

General massage is sometimes applied, as a form of passive exercise, to indolent persons whose tissues are
overloaded with the products of incomplete metabolism.

As with other methods of treatment, there has been a tendency
on the part of some practitioners to exalt it into a cure-all, and of
others to ignore it altogether. Of its therapeutic value, when
judiciously applied, there can be no doubt. It is for the individual
surgeon to say when and how it should be applied. Affections
to which it is not applicable are fevers, pregnancy, collections of
pus, acute inflammation of the joints, inflamed veins, fragile arteries,
wounds of the skin and, generally speaking, those conditions in which
it is not desirable to increase the circulation, or in which the
patient cannot bear handling. In such conditions it may have a very
injurious and even dangerous effect, and therefore should not be used
in a haphazard manner without competent advice.

The revival of massage in Europe and America has called into
existence a class of persons, the so-called "advanced" professional
masseurs, of both the male and female, who may be regarded as forming one branch of the
nursing profession. Some of these are trained in hospitals or other
institutions, some by private practitioners and some not at all. Some have been attached to surgical hospitals, others are hired on an
hourly basis and work with an independent identity. Others are
required for a good operator. One is physical strength. Deep
massage is very laborious work, and cannot be carried on for an
hour at a time. Another is physical dexterity, required for muscular work. Feels.
persons cannot practise it effectively at all. The duration of a sitting
may vary from five or ten minutes to an hour. For general massage
at least half an hour is required. A masseur should have strength
enough to do the work without too obvious exhaustion, which gives
the patient an unpleasant impression. A second requirement is
tactile and muscular sensibility. A person not endowed with a fine
sensibility of touch and resistance is liable to exert too great or too little
pressure; the one hurts the patient, the other is ineffectual. Then
skill and knowledge, which can only be acquired by a course of
instruction, are necessary. Finally, some patience and tact are
required for the proper treatment of independent parties. Independent masseurs
may possess all these qualifications in a higher degree than those
together with an institution, but they may also be totally devoid of
them, whereas connexion with a recognized hospital or society is a
guarantee for a certain standard of efficiency. In London there are
several such institutions, which train and send out both male
and female masseurs. The fee is 5s. an hour, or from two to four guineas a
week for work in the European continent, according to the
number and skill employed by some practitioners, the fee is considerably lower;
in the United States it is higher. For reasons mentioned above, it
is extremely difficult to ascertain what proportion of the patients
of their own sex. If this is not insisted upon, a valuable therapeutic
means will be in danger of falling into disrepute both with the medical profession and the general public.

(A. S.L.)

MASSAGETAE, an ancient warlike people described by
Herodotus (i. 203-216; ii. 22, 172) as dwelling beyond the
Araxes (i.e. the Oxus) in what is now Balkh and Bokhara.

It was against their queen Tomyris that Cyrus undertook the
expedition in which according to one story he met his end.
In their usages some tribes were nomads like the people of
Scythia (q.v.), others with their community of wives and
habit of killing and eating their parents recalled the Issedones (q.v.);
while the dwellers on the islands of Elba were fish-eating
mercenaries. Probably the name denoted no ethnical unity,
but included all the barbarous north-eastern neighbours of the
Persians. Herodotus says they only used gold and copper
(or bronze), not silver or iron. Their lavish use of gold has
caused certain massive ornaments from southern Siberia,
now in the Hermitage at St Petersburg, to be referred to the
Massagetae.

(E. H. M.)

MASSA MARITTIMA, a town and episcopal see of the province
of Grosseto, Tuscany, Italy, 24 m. N.N.W. of Grosseto direct
and 16 m. by rail N.E. of Follonica (50ths). The town W. of
Grosseto on the main coast railway), 1444 ft. above sea-level.
Pop. (1901), (town) 9219; (commune) 17,519. It has a cathed-
ral of the 13th century containing a Romanesque font (1267
with a cover of 1447) and a Gothic reliquary (1324) of the
saint Cernibe, to whom the cathedral is dedicated. The battle-
mented municipal palace of the 13th century is picturesqu.
There are mineral springs, mines of iron, mercury, lignite
and copper, with foundries, ironworks and olive-oil mills.
At Follonica on the coast, but in this commune, are the furnaces
in which are smelted the iron ore of Elba.

MASSAWA, or MASSOWAH, a fortified town on the African
cost of the Red Sea, chief port of the Italian colony of Eritrea,
in 15° 36' N. and 39° 28' E. Pop. about 10,000. The town
stands at the north end of the bay of Massawa and is built
don a coral island of the same name—where was the
original settlement—and partly on the islets of Tautlib and
Sheik Said, and the neighbouring mainland. Massawa Island
is from 20 to 25 ft. above the sea, its length does not exceed 3
m. and its breadth is about ½ m. The harbour is formed by the
channel between the island and the mainland. It affords
good anchorage in from 5 to 10 fathoms. The town
possesses several good public buildings, chiefly built of coral,
as are the houses of the principal European and Arab merchants.
Landward the town is guarded by forts erected by the Italians
since 1885. Water was formerly scarce; but in 1872 an ancient
aqueduct from Mokulli (5 m. distant westward) was restored
and continued by an embankment to the town. A railway
connects Massawa with Asmara, the capital of the colony.
Besides the Abyssinians, who speak a Tigré dialect corrupted
with Arabic words, the inhabitants comprise Italian officials
and traders, Greeks, Indians, Arabs from Yemen and Hadramut,
Gallas and Somalis. Massawa is the natural port for northern
Abyssinia but commerce is undeveloped owing to the lack
of rapid means of communication. The trade done consists
mainly in exporting hides, butter, Abyssinian coffee and cieet,
and importing European and Indian cotton goods and silks.
It increased in value from about £65,000 per annum in 1865
(the last year of Turkish control) to £2,400,000 to £2,800,000
between 1879 and 1881, when under the administration of Egypt.
Under the Italians trade greatly developed. The
returns for the five years 1901-1905 showed an average annual
value of £1,800,000, about two-thirds being imports.

The island of Massawa has probably been inhabited from
a very early date. It appears to have formed part of the
Abyssinian dominions for many centuries. It was at Massawa
(Matza, as it is called by the Portuguese chroniclers) that
Christopher da Gama and his comrades landed in July 1515
on their way to aid the Abyssinians against the Moslem invaders.
Captured by the Turks in 1557, the island remained a Turkish
possession until two centuries later. It was attended by a military
colony of Bosnians settled at Arkiko (a port on the bay 4 m. south of
Massawa Island) was appointed not only to defend it in case
of attack from the mainland, but to keep it supplied with water
in return for £140 per month from the town's customs. For
some time at the close of the 18th century Massawa was held
by the sultan of Mecca, and it afterwards passed to Mehmet Ali
of Egypt. The Turks were reinstated about 1850, but in 1865 they handed the island back to Egypt for an annual tribute of £1 million piastres. In February 1885 Massawa was occupied by an Italian force, the Egyptian garrison stationed there being withdrawn in the November following. See Egypt; Italy. Alexandria was the capital of the Italian colony until 1900 when the seat of administration was removed to Asmara (see ERITREA).

For a description of the town in 1769 see the Travels of James Bruce. At that time the governor, though appointed by the Turks, paid one half of the customs receipts to the negus of Abyssinia in return for the protection of that monarch.

MASSENA, André, or Andrea, duke of Rivoli, prince of Essling (1756-1817), the greatest of Napoleon's marshals, son of a small wine merchant, it is said of Jewish origin, was born at Nice on the 6th of May 1756. His parents were very poor, and he began life as a cabin boy, but he did not care much for the sea, and in 1775 he enlisted in the Royal-Italian regiment. He quickly rose to be under-officer-adjutant; but, finding his birth would prevent his ever getting a commission, he left the army in 1789, retired to his native city, and married. At the sound of war, however, and the word republic, his desire to see service increased, and he once more left Italy, and joined the 3rd battalion of the volunteers of the Var in 1791. In those days when men elected their officers, and many of the old commissioned officers had retired, promotion to a man with a knowledge of his drill was rapid; and by February 1792 Masséna was a lieutenant-colonel. His regiment was one of those in the army which occupied Nice, and in the advance to the Apennines which followed, his knowledge of the country, of the language, and of the people was so useful that in December 1793 he was already a general of division. In command of the advanced guard he won the battle of Saorgio in August 1794, capturing ninety guns, and after many successes he at last, on the 23rd of November 1793, with a superior force, and in seven days' fighting, in the victory of Loano, won by Schérer over the Austrians and Sardinians. In Bonaparte's great campaign of 1796-97 Masséna was his most trusted general of division; in each battle he won fresh laurels, up to the crowning victory of Rivoli, from which he afterwards took his title. It was during this campaign that Bonaparte gave him the title of enfant gâté de la victoire, which he was to justify till he met the English in 1810. In 1798 he commanded the army of Rome for a short time, but was displaced by the intrigues of his subordinate Berthier. Masséna's next important service was in command of the army in Switzerland, which united the army in Germany under Moreau, and that in Italy under Joubert. There he proved himself a great captain, as he had already proved himself a great lieutenant; the archduke Charles and Suvarov had each been successful in Germany and in Italy, and now turned upon Masséna in Switzerland. That general held his ground well against the archduke, and then suddenly, leaving Soult to face the Austrians, he transported his army to Zürich, where, on the 26th of September 1799, he entirely defeated Korsakov, taking 200 guns and 5000 prisoners. This campaign and battle placed his reputation on a level with that of his compatriot Bonaparte, and he might have made the revolution of Brumaire, but he was sincerely attached to the republic, and had no ambition beyond a desire to live well and to have plenty of money to spend. Bonaparte, now First Consul, sent him to Genoa to command the débris of the army of Italy, and he nobly defended Genoa from February to June to the very last extremity, giving time for Bonaparte to strike his great blow at Marengo. He now went to Paris, where he sat in the Corps Législatif in 1803, and actually defended Moreau without drawing upon himself the ill-will of Napoleon, who, well knew his honesty and lack of ambition.

In 1804 he was made one of the first marshals of France of the new régime, and in 1805 was decorated with the Grand Eagle of the Legion of Honour. In that year Napoleon needed an able general to keep in check the archduke Charles in Italy, while he advanced through Germany with the grand army. Masséna was chosen; he kept the archduke occupied till he received news of the surrender of Ulm, and then on the 30th of October defeated him in the battle of Caldiero. After the peace of Pressburg had been signed, Masséna was commanded at Marseilles. This was the kingdom of Naples, and to place Joseph Bonaparte on the throne. This task done, Napoleon summoned Masséna to Poland, where he as usual distinguished himself, and where he for the time gave up his republican principles. In 1808 he was made duke of Rivoli. In 1808 he was accidentally wounded by his old enemy Berthier when both were in attendance on the emperor at a shooting party, and he lost the sight of one eye. In the campaign in 1809 he covered himself with glory at Landshut and at Eckmühl, and finally at the battle of Aspern-Essling his magnifigent leadership made way of itself without him have been an appallingly disastrous fact. In the reverse of which the enemy could make no use. On the field of Wagram Masséna, though too ill to ride, directed from his carriage the movements of the right wing. For his great services he was created prince of Essling, and given the princely castle of Thouars. He was then ordered to Spain to "drive the English into the sea." (For the campaigns of 1810 and 1811, the advance to and the retreat from Torres Vedras see PENINSULAR WAR.) Masséna himself, with some justice, ascribed his failure to the frequent disobedience of his subordinates Ney, Reynier and Junot, and public opinion attributed his disobedience to the presence with the army of Masséna's mistress, and to the resentment thereat felt by the wives of the three generals. Still, unsuccessful as he was, Masséna displayed the determination of the defence of Genoa and the fidelity in expedients of the campaign of Zürich, and kept his army for five weary months close up to Wellington's impregnable position before retiring. His retreat through a devastated country was terrible, but his force of character kept his men together, and Ney having shown the worst side of his character now showed the best in the frequent and brilliant rear-guard combats in which he was engaged, and which the old marshal dismiss Ney from his command. Soon Masséna was once again ready to try his fortune, and he nearly defeated Wellington at Fuentes d'Oñoro, though much hampered by Bessières. But his recall soon followed this and he returned home to find his prestige gone. The old marshal felt he had a right to complain of Ney and of Napoleon himself, and, it is said, opened communications with Fouché and the remnant of the republican party. Whether this be true or not, Napoleon gave his greatest marshal no more employment in the field, but made him a lord high constable, a constant commission in the army, and command he still held at the restoration, when Louis XVIII. confirmed him in it, and with true Bourbon stupidity gave him letters of naturalization, as if the great leader of the French armies had not ceased to be an Italian. When Napoleon returned from Elba, Masséna, probably by the advice of Fouché, kept Marseilles quiet to await events, the greatest service he could do the royalists, but afterwards imputed to him as a fault. After the second restoration Masséna was summoned to sit on the court-martial which tried Marshal Ney, but, though he had been on bad terms with that general, and attributed his own disgrace to him, the old soldier could not be his comrade's judge. This refusal was used by the royalists to attack the marshal, against whom they raked up every offence they could think of. This annoyance shortened his life, and on the 4th of April 1817 the old hero died. He was buried in Père-la-Chaise, with only the word "Masséna" upon his tombstone.

In private life indolent, greedy, rapacious, ill-educated and morose, in war Masséna was, like Napoleon, the incarnation of battle. Only his indolence and his consequent lack of far-ranging imagination prevented him being a general of genius and strategy and tactics. This genius needed the presence of the enemy to stimulate it, but once it sprang to life Masséna became an ideal leader, absolutely brave, resourceful, unrelenting and indefatigable. He was as great a master of the strategy of forces in immediate contact—of gathering up as it were the threads of the fuge into a "stretto." For the planning of a whole perfect campaign he
had neither knowledge nor inclination, and he falls short therefore of the highest rank amongst great generals; but his place amongst the greatest of soldiers is beyond challenge.

See Thibault’s Éloge funèbre, and Koch’s Mémoires de Masséna (4 vols., 1849), a valuable work, carefully compiled. In more modern times E. Gachot has produced several important works dealing with Masséna’s campaigns.

MANNESCHN, CHRISTIAN KARL AUGUST LUDWIG VON (1758-1827), Prussian soldier, was born at Schmalkalden on the 16th of April 1758, and educated at Heilbronn and Stuttgart, devoting himself chiefly to mathematics. He became an officer of the cavalry in 1778, and this year he joined Frederick the Great in 1782. The pay of his rank was small, and his appointment on the quartermaster-general’s staff made it necessary to keep two horses, so that he had to write mathematical school-books in his spare time to eke out his resources. He was far however from neglecting the science and art of war, for thus early he had begun to make his name as a theorist as well as a mathematician. After serving as instructor in mathematics to the young prince Louis, he took part with credit in the expedition into Holland, and was given the order Pour le mérite. Of his career he has been written a Treatise on the military organization of the school of military engineering, leaving this post in 1792 to take part as a general staff officer in the war against France. He was awarded a prebend at Minden for his services as a topographical engineer on the day of Valmy, and after serving through the campaigns of 1793 and 1794 he published a number of memoirs on the military history of these years. He was chiefly occupied however with framing schemes for the reorganization of the then neglected general staff of the Prussian army, and many of his proposals were accepted. Bronsart von Schellendorf in his Duties of the General Staff says of Massenbach’s work in this connexion, “the organization which he proposed and in the main carried out survived even the catastrophes of 1806-1807, and exists even at the present moment in its original outline.” This must be accounted as high praise when it is remembered how much of the responsibility for these very disasters must be laid to Massenbach’s account. The permanent gain to the service due to his exertions was far more than formal, for it is to him that the general staff owes its tradition of thorough and patient individual effort. But the actual doctrine taught by Massenbach was not so much a method of operations as the doctrine of positions carried to a ludicrous excess; the claims put forward for the general staff, that it was to prepare cut-and-dried plans of operations in peace which were to be imposed on the troop leaders in war, were derided by the responsible generals; and the memoirs on proposed plans of campaign to suit certain political combinations were worked out in quite unnecessary detail. It was noteworthy that none of the proposed plans of campaign considered France as an enemy.

In 1805 came threats of the war with Napoleon which Massenbach had strongly opposed. He was made quartermaster-general (chief of staff) to Prince Hohenlohe, over whom he soon obtained a fatal ascendency. War was averted for a moment by the result of the battle of Austerlitz, but it broke out in earnest in October 1806. Massenbach’s influence clouded all the Prussian operations. The battles of Jena and Auerstedt were lost, and the capitulation of Prince Hohenlohe’s army was negotiated. Even suggestions of disloyalty were not wanting; an attempt to try him by court-martial was only frustrated by Prince Hohenlohe’s action in taking upon himself, as commander-in-chief, the whole responsibility for Massenbach’s actions. He then retired to his estate in the Posen province, and occupied himself in writing pamphlets, memoirs, &c. When his estates passed into the grand duchy of Warsaw, he chose to remain a Prussian subject, and on the outbreak of the war of liberation he asked in vain for a post on the Prussian staff. After the fall of Napoleon he took part in Württemberg politics, was expelled from Stuttgart and Heidelberg, and soon afterwards arrested at Frankfurt, delivered over to the Prussian authorities and condemned to fourteen years’ fortress imprisonment for his alleged publication of state secrets in his memoirs. He was kept in prison till 1826, when Frederick William III., having recovered from an accident, pardoned those whom he considered to have wronged him most deeply. He died on the 21st of November 1827, at his estate of Bialokosz, Posen.

The obituary in Neuer Nekrolog der Deutschen, pt. ii. (Ilmenau, 1827) is founded on a memoir (Der Oberst C. v. Massenbach) which was published at the beginning of his imprisonment.

MASSNET, JULES ÉMILE FRÉDÉRIC (1842-1912), French composer, was born at Montaud, on the 12th of May 1842. He studied at the Paris Conservatoire, where he obtained the Grand Prix de Rome in 1865 with the cantata David Rizio. Massenet became conductor of the Paris Opéra in 1868; for this he was paid well. His operas include the following: Le Grande tente, one act, opéra comique (1867); Don César de Bazan, three acts, opéra comique (1872); Le Roi de Lahore, five acts, opéra (1877); Héroïdiade, four acts (Brussels, 1881); Manon, five acts, opéra comique (1884); Le Cid, four acts, opéra (1883); Esclarmonde, four acts, opéra comique (1889); Le Mage, five acts, opéra (1891); Werther, four acts (Vienna, 1893); Thaïs, three acts, opéra (1894); Le Portrait de Manon, one act, opéra comique (1894); La Navarraise, two acts (Coven Garden, 1894); Sapho, opéra comique (1897); Intermezzo, three acts, opéra (1900); Le Jongleure de Notre Dame (Monte, 1902). Of these the most popular is Manon. Massenet’s other works include Marie Madeleine, sacred drama (1873); Eë, a mystery (1879); La Vierge, sacred legend (1880); six orchestral suites entitled Scènes hongroises, Scènes pittoresques, Scènes dramatiques, Scènes napolitaines, Scènes de storie, Scènes alsaciennes; music to the tragedy Les Erynyns, to Théodore, Le Crocodille, L’Hémat; a requiem, Narcisse; an idyll, Bilbiis; a Siècle antique; several sets of songs, entitled Poème d’avril, Poème d’amour, Poème d’hiver, Poème d’octobre, Poème pastoral, Poème du souvenir; also a large number of detached songs. He was professor of composition at the Conservatoire from 1878 to 1896, among his pupils being Hillelemacher, Marty, Brunou, Vidal, Pierré, Leroux and Charpentier. Massenet undoubtedly possesses a style of his own. He is at his best in music descriptive of the tender passion, and many of the love scenes in his operas are very beautiful.

MASSEREENE, JOHN CLOTWORTHY, 1ST VISCOUNT (d. 1663), Anglo-Irish politician, was son of Sir Hugh Crotworthy, sheriff of county Antrim. He was elected to the Irish parliament as member for Antrim in 1606, and was now a member both of the Short and of the Long Parliament in England. Crotworthy was a vehement opponent of the earl of Strafford, in whose impeachment he took an active share. He also took part in the prosecution of Archbishop Laud. Having unsuccessfully negotiated with Ormond for the surrender of Dublin to the Parliamentary forces in 1646, he was accused in the following year of having betrayed his cause, and also of embezzlement; in consequence of these charges he fled to the Continent, but returned to parliament in June 1648. On the 12th of December in that year he was arrested, and remained in prison for nearly three years. Having taken an active part in forwarding the Restoration, he was employed in Ireland in arranging the affairs of the soldiery and other adventurers who had settled in Ireland. Clotworthy in no way abated his old animosity against “papists” and high Anglicans, and he championed the cause of the Irish Presbyterians; but being personally acceptable to Charles II., his ecclesiastical views were overlooked, and on the 21st of November 1660 he was created Baron Loughneagh and Viscount Massereene in the Irish peerage, with remainder in default of male heirs to his son-in-law, Sir John Skeffington. Massereene died without male issue in September 1663, and the title devolved on Skeffington, whose great-grandson, the fifth viscount, was created earl of Massereene in 1756. The earldom became extinct on the death of the fourth earl without male issue in 1816, the viscountcy and barony of Loughneagh descending to his daughter Harriet, whose husband, Thomas Foster, took the name of Skeffington, and inherited from his mother in 1824 the titles of Viscount Ferrard and Baron Oriel of Colton in the Irish peerage, and from his father in 1828 that of Baron Oriel of Ferrard in the peerage of the United Kingdom.
MASSEY, SIR EDWARD—MASSILLON, J. B.

MASSEY, SIR EDWARD (c. 1619-c. 1674), English soldier in the Great Rebellion, was the son of John Massey of Caddington, Cheshire. Little is known of his early life, but it is said that he served in the Dutch army against the Spaniards. In 1639 he appears as a captain of pioneers in the army raised by Charles I. to fight against the Scots. At the outbreak of the Great Rebellion he was with the king at York, but he soon joined the Parliamentary army. As lieutenant-colonel under the earl of Stamford he became deputy governor of Gloucester, where he remained till towards the end of the first Civil War, becoming governor early in 1643. He conducted minor operations against numerous small bodies of Royalists, and conducted the defence of Gloucester against the king's main army in August 1643, with great steadiness and ability, receiving the thanks of parliament and a grant of £5000 for his services. In 1644 Massey continued to keep the field and to disperse the local Royalists, and on several occasions he measured swords with Prince Rupert. In May 1644 he was made general of the forces of the Western Association. In 1645 he took the offensive against Lord Goring and the western Royalists, advanced to the relief of Taunton, and in the autumn co-operated effectively with Sir Thomas Fairfax and the New Model army in the Langport campaign. After taking part in the desultory operations which closed the first war, he took his seat in the House of Commons as member for Gloucester. He then began to take an active part in politics on the Presbyterian side, and was one of the generals who was impeached by the army on the ground that they were attempting to revive the Civil War in the Presbyterian interests. Massey fled from England in June 1647, and though he resumed his seat in the house in 1648 he was again excluded by Pride's Purge, and after a short imprisonment escaped to Holland. Thence, taking the side of the king openly and definitely like many other Presbyterians, he accompanied Charles II. to Scotland. He fought against Cromwell at the bridge of Stirling and Inverkeithing, and commanded the advanced guard of the Royalist army in the invasion of England in 1651. It was hoped that Massey's influence would win over the towns of the Severn valley to the cause of the king, and the march of the army on Worcester was partly inspired by this expectation. However, he effected little, and after riding with the king for some distance from the field of Worcester, fell into the hands of his former comrades and was lodged in the Tower. He again managed to escape to Holland. While negotiating with the English Presbyterians for the restoration of Charles, he visited England twice, in 1654 and 1656. In 1660 he was active in preparing for Charles's return, and was rewarded by a knighthood and a grant of £5000. The rest of his life was spent in political, and occasionally in military and administrative business, and he is said to have died in Ireland in 1674.

MASSEY, GERALD (1828-1907), English poet, was born near Tring, Hertfordshire, on the 29th of May 1828. His parents were in humble circumstances, and Massey was little more than a child when he was set to hard work in a silk factory, which he afterwards deserted for the equally laborious occupation of plaiting straw. These early years were rendered gloomy by much distress and deprivation, against which the young man strove with increasing spirit and virility, educating himself in his spare time, and gradually cultivating his innate taste for literary work. He was attracted by the movement known as Christian Socialism, into which he threw himself with whole-hearted vigour, and so became associated with Maurice and Kingsley. His first public appearance as a writer was in connexion with a journal called the Spirit of Freedom, of which he became editor, and he was only twenty-two when he published his first volume of poems, Voices of Freedom and Lyrics of Love. These he followed in rapid succession by The Ballad of Babe Christabel (1854), War Waits (1855), Hollowed March (1856), and A Tale of Eternity (1856). Many years afterwards in 1880, he collected the best of these volumes, with additions, into a two-volume edition of his poems called My Lyrical Life. He also published works dealing with spiritualism, the study of Shakespeare's sonnets (1872 and 1890), and theological speculation. It is generally understood that he was the original of George Eliot's Felix Holt. Massey's poetry has a certain rough and vigorous element of sincerity and strength which easily accounts for its popularity at the time of its production. He treated the theme of Sir Richard Grenville before Tennyson thought of using it, with much force and vitality. Indeed, Tennyson's own praise of Massey's work is still its best eulogy, for the Laureate found in him a poet of fine lyrical impulse, and of a rich half-Oriental spirit. The inspiration of his poetry is essentially British; he was a patriot to the core. It is, however, as an Egyptologist that Gerald Massey is best known in the world of letters. He first published The Book of the Beginnings, followed by The Natural Genesis; but by far his most important work is Ancient Egypt: The Light of the World, published shortly before his death. He died on the 29th of October 1907.

See an article by J. Churton Collins in the Contemporary Review (May 1904).

MASSICUS, MONS, a mountain ridge of ancient Italy, in the territory of the Aurunci, and on the border of Campania and Latium—attributed by most authors to the latter. It projects south-west from the volcanic system of Rocca Monfina (see SusaA aurumca) as far as the sea, and separates the lower course of the Liris from the plain of Campania. It consists of limestone, with a superstratum of plocenic and volcanic masses, and was once an island; its highest point is 2661 ft. above sea level.

It was very famous for its wine in ancient times. There was just room along the coast for the road to pass through; the pass was guarded by the Auruncan town of Vescia (probably on the mountain side), which ceased to exist in 314 B.C. after the defeat of the Ausones, but left its name to the spot. Its successor, Sinussa, on the coast, a station on the Via Appia, was constructed in 312 B.C., and a colony was founded there in 295 B.C. It is not infrequently mentioned by classical writers as a place in which travellers halted. Here Virgil joined Horace on the famous journey to Brundusium. Domitian considerably increased its importance by the construction of the Via Latina, which joined the Via Appia here and ran to Cumae and Puteoli, and it was he, no doubt, who raised it to the position of colonia Flavia. The town was destroyed by the Saracens, but some ruins of it are still visible two miles north-west of the modern village of Mondragone. The mineral springs which still here were frequented in antiquity.

MASSIF, a French term, adopted in geology and physical geography for a mountainous mass or group of connected heights, whether isolated or forming part of a larger mountain system. A "massif" is more or less clearly marked off by valleys.

MASSILLON, JEAN BAPTISTE (1663-1742), French bishop and preacher, was born at Hyères on the 24th of June 1663, his father being a royal notary of that town. At the age of eighteen he joined the Congregation of the Oratory and taught for a time in the colleges of his order at Agen, and at Toulouse, and at the Seminary of Vienne. On the death of Henri de Villars, archbishop of Vienne, in 1693, he was commissioned to deliver a funeral oration, and this was the beginning of his fame. In obedience to Cardinal de Noailles, archbishop of Paris, he left the Cistercian abbey of Sept-Fonds, to which he had retired, and settled in Paris, where he was placed at the head of the famous seminary of Saint Magloire. He soon gained a wide reputation as a preacher and was selected to be the Advent preacher at the court of Versailles in 1699. He was made bishop of Clermont in 1717, and two years later was elected a member of the French Academy. The last years of his life were spent in the faithful discharge of his episcopal duties; his death took place at Clermont on the 18th of September 1742. Massillon enjoyed in the 18th century a reputation equal to that of Bossuet and of Bourdaloue, and has been much praised by Voltaire, D'Alembert and kindred spirits among the Encyclopédistes. His popularity was probably due to the fact that in his sermons he lays little stress on dogmatic questions, but treats generally of moral subjects, in which the secret of the human heart and the processes of man's reason are described with poetical feeling. He has also, more pertinently than his predecessor Bourdaloue, the latter having the credit of vigorous denunciation, Massillon that of gentle persuasiveness. Besides the Petit Carême, a sermon which he
MASEILLON—MASSINGER

delivered before the young king Louis XV. in 1718, his sermons on the Prodigal Son, on the small number of the elect, on death, for Christmas Day, and for the Fourth Sunday in Advent, may be perhaps cited as his masterpieces. His funeral oration on Louis XIV. is only noted now for the opening sentence: "Dieu seul est grand, mon père." But in truth Massillon is singularly free from unpopularity. His great literary power, his reputation for benevolence, and his known toleration and dislike of doctrinal disputes caused him to be much more favourably regarded than most churchmen by the philosophes of the 18th century.

The first edition of Massillon's complete works was published by his nephew, also an Oratorian (Paris, 1745-1748), and upon this, in 1806, volumes, successively enlarged, were issued. The best modern edition is that of the Abbé Blamignon (Paris, 1865-1868, 4 vols.; new ed. 1886).

MASSILLON, a city of Stark county, Ohio, U.S.A., on the Tuscarawas river and the Ohio canal, 8 m. W. of Canton, and about 50 m. S. by E. of Cleveland. Pop. (1900), 11,944 (1603 foreign-born); (1910), 13,879. It is served by the Pennsylvania (Pittsburg, E. Wayne & Chicago Division), the Baltimore & Ohio and the Wheeling & Lake Erie railways. Massillon is built upon a moraine, in a part of the state noted for its large deposits of coal and wheat and abounding in white sandstone, iron ore and potter's clay. The city has various manufactures, including iron, engines, furnaces, reapers, threshers and bottles. The total value of the factory products in 1905 was $3,707,013, an increase of 34.8% over that of 1900. The first settlement was made in 1825; in 1826 the town was laid out and named in honour of Jean Baptiste Massillon; it was incorporated a village in 1853, and became a city in 1868.

MASSIMO, or Massi, a Roman princely family of great antiquity, said to be descended from the ancient Massimi of republican Rome. The name is first mentioned in 1012 in the person of Leo de Maximis, and the family played a considerable part in the history of the city in the middle ages. The brothers Pietro and Francesco Massimi acquired fame by protecting and encouraging the German printer Ulrich Hahn, who came to Rome in 1467. In the 16th century the Massimi were the richest of the Roman nobles. A marquisate was conferred on them in 1544, and the lordship of Arcoli in 1574. To-day there are two branches of the Massimi, viz. the Principi Massimo, descended from a Massimo in the 17th century, and the Duke of Kignano, descended from Francesco Massimo (1772-1844). One of the sons of the present Prince Camillo Carlo Alberti, Don Fabrizio, married Princess Beatrice, daughter of Don Carlos of Bourbon (duke of Madrid), the pretender to the Spanish throne. The Palazzo Massimo in Rome was built by Baldassare Peruzzi by order of Pietro Massimo, on the ruins of an earlier palace destroyed in the sack of Rome in 1527.

See F. Gregorovius, Geschichte der Stadt Rom (Stuttgart, 1880); A. von Reumont, Geschichte der Stadt Rom (Berlin, 1868); Almanach de Gotha; J. H. Douglas, The Principal Noble Families of Rome (Rome, 1905).

MASSINGER, PHILIP (1583-1640), English dramatist, son of Arthur Massinger or Messanger, was baptized at St Thomas's, Salisbury, on the 24th of November 1583. He apparently belonged to an old Salisbury family, for the name occurs in the city records as early as 1415. He is described in his matriculation entry at St Alban Hall, Oxford (1602), as the son of a gentleman. Philip, who had been educated at St Alban Hall, was a member of parliament, and was attached to the household of Henry Herbert, 2nd earl of Pembroke, who recommended him in 1582 for the office of examiner in the court of the marches. The 3rd earl of Pembroke, the William Herbert whose name has been connected with Shakespeare's sonnets, succeeded to the title in 1601. It has been suggested that he supported the poet at Oxford, but the significant omission of any reference to him in any of Massinger's prefaces points to the contrary. Massinger left Oxford without a degree in 1606. His father had died in 1603, and he was perhaps dependent on his own exertions. The lack of a degree and the want of patronage from Lord Pembroke may both be explained on the supposition that he had become a Roman Catholic. On leaving University he returned to London to make his living as a dramatist, but his name cannot be definitely affixed to any play until fifteen years later, when The Virgin Martyr (ent. at Stationers' Hall, Dec. 7, 1612) appeared as the work of Massinger and Dekker. During these years he worked in collaboration with other dramatists. A joint letter, from Nathaniel Field, Robert Daborne and Philip Massinger, to Philip Henslowe, begs for an immediate loan of five pounds to release them from their "unfortunate extremity," the money to be taken from the balance due for the "play of Mr Fletcher's and ours." A second document shows that Massinger and Daborne owed Henslowe £5 on the 4th of July 1615. The earlier note probably dates from 1613, and from this time Massinger apparently worked regularly with John Fletcher, although in editions of Beaumont and Fletcher's works his co-operation is usually unrecognized. Sir Aston Cokayne, Massinger's constant friend and patron, refers in explicit terms to this collaboration in a sonnet addressed to Humphrey Moseley on the publication of his folio edition of Beaumont and Fletcher (Small Poems of Divers Sorts, 1658), and in an epitaph on the two poets he says:—

"And now one grave includes two unkind friends,"

After Philip Henslowe's death in 1616 Massinger and Fletcher began to write for the King's Men. Between 1623 and 1626 Massinger produced unsaid for the Lady Elizabeth's Men then playing at the Cockpit three pieces, The Parliament of Love, The Bondman and The Renegade. With the exception of these plays and The Great Duke of Florence, produced in 1627 by the Queen's servants, Massinger continued to write regularly for the King's Men until his death. The tone of the dedications of his later plays affords evidence of his continued poverty. Thus in the preface to The Maid of Honour (1632) he wrote, addressing Sir Francis Foljambe and Sir Thomas Bland: "I had not to this time subsisted, but that I was supported by your frequent courtseyes and favours." The prologue to The Guardian (licensed 1633) refers to two unsuccessful plays and two years of silence, when the author feared he had lost the popular favour. S. R. Gardiner, in an essay on "The Political Element in Massinger" (Contemp. Review, Aug. 1876), maintained that Massinger's dramas are before all else political, that the events of his day were as openly criticized in his plays as current politics. In 1632 there was a break in his production owing to his free handling of public matters. In 1631 Sir Henry Herbert, the master of the revels, refused to license an unnamed play by Massinger because of "dangerous matter as the deposing of Sebastian, King of Portugal," calculated presumably to endanger good relations between England and Spain. There is little doubt that this was the same piece as Believe as You List, in which time and place are changed, Antiochus being substituted for Sebastian, and Rome for Spain. In the prologue Massinger ironically apologized for his ignorance of history, and professed that "he had at fault if his picture comes near "a late and sad example." The obvious "late and sad example" of a wandering prince could be no other than Charles I.'s brother-in-law, the elector palatine. An allusion to the same subject may be traced in The Maid of Honour. In another play by Massinger, not extant, Charles I. is reported to have himself struck out a passage put into the mouth of Don Pedro, king of Spain, as "too insolent." The poet seems to have adhered closely to the politics of his patron, Philip Herbert, earl of Montgomery, and afterwards 4th earl of Pembroke, who had leanings to democracy and was a personal enemy of the duke of Buckingham. In The Bondman, dealing with the history of Timoleon, Buckingham is satirized as Gisco. The servility towards the Crown displayed in Beaumont and Fletcher's plays reflected the temper of the court of James I. The attitude of Massinger's heroes and heroines towards kings
Camillo's remarks on the limitations of the royal prerogative (Maid of Honour, act iv. sc. v.) could hardly be applicable to crossing the line, or to the Carthaginian, not Roman Carthaginian, who is certainly Roman; and the Carthaginian, 238-149 B.C., is generally referred to as a "stranger," which, however, implies nothing more than that he belonged to another parish.

The supposition that Massinger was a Roman Catholic rests upon three of his plays, The Virgin Martyr (licensed 1620), The Renegade (licensed 1624) and The Maid of Honour (c. 1621). The religious sentiment is certainly such as would be acceptable to an audience sympathetic to Roman Catholic doctrine. The Virgin Martyr, in which Dekker probably had a large share, is really a miracle play, dealing with the martyrdom of Dorothea in the time of Diocletian, and the supernatural element is freely used. Little stress can be laid on this performance as elucidating Massinger's views. It is not entirely his work, and the story is early Christian, not Roman Catholic. In The Renegade, however, the action is dominated by the beneficent influence of a Jesuit priest, Francisco, and the doctrine of baptismal regeneration obtained at the court of Philip II is solved by the decision of the heroine, Camilha, to take the veil. For this she is held up "to all posterity a fair example for noble maids to imitate." Among all Massinger's heroines Camilha is distinguished by genuine purity and heroism.

His plays have generally an obvious moral intention. He sets himself to work out a series of ethical problems through a succession of ingenious and effective plots. In the art of construction he has, indeed, few rivals. But the virtue of his heroes and heroines is rather morbid than natural, and often singularly divorced from common-sense. His dramatic personae are in general types rather than living persons, and their actions do not appear to spring inevitably from their characters, but rather from the exigencies of the plot. The heroes are too good, and the villains too wicked to be quite convincing. Moreover their respective goodness and villainy are too often represented as extraneous to themselves. This defect of characterization shows that English drama had already begun to decline.

It seems doubtful whether Massinger was ever a popular playwright, for the best qualities of his plays would appeal rather to politicians and moralists than to the ordinary playgoer. He contributed, however, at least one great and popular character to the English stage. Sir Giles Overreach, in A New Way to Pay Old Debts, is a sort of commercial Richard III., a compound of the lion and the fox, and the part provides many opportunities for a great actor. He made another considerable contribution to the comedy of manners in The City Madam. In Massinger's own judgment The Roman Actor was "the most perfect birth of his Minerva." It is a study of the tyrant Dominic, and of the results of despotic rule on the despot himself and his court. Other favourable examples of his grave and restrained art are The Duke of Milan, The Bondman and The Great Duke of Florence.

Massinger was a student and follower of Shakespeare. The form of his verse, especially in the number of run-on lines, approximates in some respects to Shakespeare's later manner. He is rhetorical and picturesque, but rarely rises to extraordinary felicity. His verse is never mean, but it sometimes comes perilously near to prose, and in dealing with passionate situations it lacks fire and directness.

The plays attributed to Massinger alone are: The Duke of Milan, a Tragedy (c. 1618, pr. 1623 and 1638); The Unnatural Combat, a Tragedy (c. 1619, pr. 1639); The Bondman, an Antient Storie (licensed 1623, pr. 1624); The Renegade, a Tragedomelie (licensed 1624, pr. 1625; republished 1648); The Picture, a Play of Honour (c. 1621, pr. 1632); The Maid of Honour (lic. 1620, pr. 1626); The Great Duke of Florence, a Comical Historie (lic. 1627, pr. 1635); The Emperor of the East, a Tragedomelie (lic. and pr. 1631), founded on the story of Theododus the Younger; Believe as You List (rejected by the censor in January, but licensed in May, 1631; pr. 1648-1649 for the Percy Society); The City Madam, a Comedie (lic. 1632, pr. 1658), which Mr Fleeley (Bib. Chron. of the Eng. Drama, iv. 213) says was performed in 1630, however, the Guardian (lic. 1633, pr. 1636) and The Basball Lover (lic. 1636, pr. 1645). A Very Woman, or The Respectable Girl, likely licenced 1628, is generally referred to his collaboration with Fletcher. The "exquisite temperance and justice" of this piece are, according to Swinburne, foreign to Fletcher's genius, and afford a striking example of Massinger's aristocratic shyness.

Twelve plays of Massinger are said to be lost, but the titles of some of these may be duplicates of those of existing plays. Five of these lost plays were MSS. used by John Warburton's cook for pie-maker's pie - a conjecture, which has no support. The massinger and Fletcher generally are assumed. The Hayward, a work with the crude and Fletcher is generally referred to with Beaufland and Fletcher. But it may be here noted that Mr R. Boyle has constructed an ingenious case for the joint authorship by Fletcher and Massinger of the two "Shakespearian ... plays, Henry VIII, and Two Noble Kinsmen (see the New Shakespeare Society's Transactions, 1884 and 1882). Mr Boyle sees the touch of Massinger in the first two acts of The Second Maiden's Tragedy (Landowienie MS., lic. 1611), a play with which the names of Fletcher and Tournere are also associated by different critics. The Fatal Dowry, a Tragedy (c. 1639, pr. 1640) is usually attributed to Fletcher, but Nicholas Rowe in his Fair Pensilien, was written in conjunction with Nathaniel Field; and The Virgin Martyr, a Tragedie (lic. 1620, pr. 1621), with Thomas Dekker.

Massinger's independent works were collected by Crotzer (4 vols., 1759, revised edition with introduction by Thomas Davies, 1779), by J. Moncke Mason (4 vols., 1779), by William Gifford (4 vols., 1805, 1813), by Hartley Coleridge (1846), by Lieut.-Colonel Cunningham (1859), and selected works in The English Drama: The 17th Century (1887-1889). Gifford's remains the standard edition, and formed the basis of Cunningham's text. It contains "An Essay on the Dramatic Writings of Massinger" by Dr John Ferriar.

Massinger has been the object of a good deal of criticism. A metrical examination of the plays in which Massinger was concerned is given in Englische Studien (Halle, v. 74, vii. 66, viii. 39, ix. 209-212) by Mr R. Boyle, who also contributed the life and the dates of the poet in the Dictionary of National Biography. The sources of his plays are dealt with by E. Kohl in Quellen Studien zu den Dramen Caesar's Massinissa (Munich, W. Kober, Reprint 1897). For detailed criticism, aside from the introductions to the editions quoted, A. W. Ward, Hist. of Eng. Dram. Lit. (1899), iii. 1-47, and F. C. Gleyer, Bibl. Chron. of the Eng. Drama (1891), under Fletcher; a general estimate of Massinger, dealing especially with his moral standpoint, is given in Sir Leslie Stephen's Hours in a Library (3rd series, 1879); Swinburne, in the Forsightly Reviews (July 1889), while acknowledging the justice of Sir L. Stephen's main structures, found much to say in praise of the poetic gift of Massingera.

MASSINISSA (c. 238-149 B.C.), king of Massinian or eastern Numidia. He was educated, like many of the Numidian chiefs, at Carthage, learnt Latin and Greek, and was an accomplished as well as a naturally clever man. Although his kingdom was nominally independent of Carthage, it really stood to it in a relation of vassalage; it was directly under Carthaginian influences, and was imbued to a very considerable extent with Carthaginian civilization. It was to this that Massinissa owed his fame and success; he was a barbarian at heart, but he had a variahy of culture, and to this he added the craft and cunning in which Carthaginian state men were supposed to excel. Yet while a young man (212) he forced his neighbour Syphax, prince of western Numidia, who had recently entered into an alliance with Rome, to fly to the Moors in the extreme west of Africa. Soon afterwards he appeared in Spain, fighting for Carthage with a large force of Numidian cavalry against the Romans under the two Scipios. The defeat of the Carthaginian army in 206 led him to cast in his lot with Rome. Scipio Africanus is said to have cultivated his friendship. Massinissa now quitted Spain for a while for Africa, and was again engaged in a war with Syphax in which he was decidedly worsted. Scipio's arrival in Africa in 204 gave him another chance, and no sooner had he joined the Roman general than he crushed his old enemy Syphax, and captured his capital Cirta (Constantine). Here occurs the romantic story of Sophonisba, daughter of the Carthaginian Hasdrubal, who had been promised in marriage to Massinissa, but had subsequently become the wife of Syphax. Massinissa, according to the story, married Sophonisba immediately after his victory, but was required by Scipio to dismiss her as a Carthaginian, and consequently an enemy to Rome.
MASSON, DAVID—MAST

To save her from such humiliation he sent her poison, with which she destroyed herself. Massinissa was now accepted as a loyal ally of Rome, and was confirmed by Scipio in the possession of his kingdom. In the battle of Zama (203) (see Punic Wars), he commanded the cavalry on Scipio's right wing, and materially assisted the Roman victory. For his services he received the kingdom of Numidia, and thus under Roman protection became master of the whole of Numidia, and his dominions completely enclosed the Carthaginian territories, now straitened and reduced at the close of the Second Punic War. It would seem that he had thoughts of annexing Carthage itself with the connivance of Rome. In a war which soon followed he was successful; the remonstrances of Carthage with Rome on the behaviour of her ally were answered by the appointment of Scipio as arbitrator; but, as though intentionally on the part of Rome, no definite settlement was arrived at, and thus the relations between Massinissa and the Carthaginians continued strained. Rome, it is certain, deliberately favoured her ally's unjust claims with the view of keeping Carthage weak, and Massinissa on his part was cunning enough to retain the friendship of the Roman people by helping them with liberal supplies in their wars against Perseus of Macedon and Antiochus. As soon as Carthage seemed to be recovering herself, and some of Massinissa's partisans were driven from the city into exile, his policy was to excite the fears of Rome, till at last in 149 B.C. war was declared—the Third Punic War, which ended in the final overthrow of Carthage. The king took some part in the negotiations which preceded the war, but died soon after its commencement in the nineteenth year of his age and the sixtieth of his reign.

Massinissa was an able ruler and a decided benefactor to Numidia. He converted a plundering tribe into a settled and civilized population, and out of robbers and marauders made efficient and disciplined soldiers. To his sons he bequeathed a well-stored treasury, a formidable army, and even a fleet. Circa (37), his capital, became a famous centre of Phoenician civilization. In fact Massinissa changed for the better the whole aspect of a great part of northern Africa. He had much of the Arab nature, was singularly temperate, and equal to any amount of fatigue. His fidelity to Rome was merely that of temporary expediency. He espoused now one side, and now the other, but on the whole supported Rome, so that orators and historians could speak of him as "a most faithful ally of the Roman people."

See Livy xxiv. 40, xxviii. 11, 35, 42, xxix. 27, xxx. 3, 12, 28, 37, xlii. 23, 29, xliii. 3, Polybios ii. 13, 44, xiv. 1, xxxii. 2, xxvii. 3; Avic. Hisp. 47, Punic. 11, 27, 102, Justin xxiii. 1; Ash. in Greenidge, Hist. of Rome (London, 1904).

MASSON, DAVID (1822–1907), Scottish man of letters, was born at Aberdeen on the 2nd of December 1822, and educated at the grammar school there and at Marischal College. Intending to enter the Church, he proceeded to Edinburgh University, where he studied theology under Dr Chalmers, whose friendship he enjoyed until the divine's death in 1847. However, abandoning his project of the ministry, he returned to his native city to undertake the editorship of the Banner, a weekly paper devoted to the advocacy of Free Kirk principles. After two years he resigned this post and went back to the capital, bent upon pursuing a purely literary career. There he wrote a great deal, contributing to Fraser's Magazine, Dublin University Magazine (in which appeared his essays on Chatterton) and other periodicals. In 1847 he went to London, where he found wider scope for his energy and knowledge. He was secretary (1851–1852) of the "Society of the Friends of Italy." In a famous interview with Mrs Browning at Florence he contested her admiration for Napoleon III. He had known De Quincey, whose biography he contributed in 1858 to the "English Men of Letters" series, and he was an enthusiastic friend and admirer of Carlyle. In 1852 he was appointed professor of English literature at University College, London, in succession to A. H. Clough, and from 1858 to 1865 he edited the newly established Macmillan's Magazine. In 1865 he was selected for the chair of rhetoric and English literature at Edinburgh, and during the early years of his professorship actively promoted the movement for the university education of women. In 1879 he became editor of the Register of the Scottish Parly Council, and in 1883 was appointed Historiographer Royal for Scotland. Two years later he resigned his professorship. His magnum opus in his Life of Milton in Connection with the History of His Own Time in six volumes, the first of which appeared in 1858 and the last in 1880. He also edited the library edition of Milton's Poetical Works (3 vols., 1874), and De Quincey's Collected Works (14 vols., 1889–1890). Among his other publications are Essays, Biographical and Critical (1856, reprinted with additions, 3 vols., 1874), British Novellists and their Styles (1859), Drummond of Hawthornden (1873), Chatterton (1873) and Edinburgh Sketches (1892). He died on the 6th of October 1907. A bust of Masson was presented to the senate of the university of Edinburgh in 1897. Professor Masson had married Rosaline Orme. His son Orme Masson became professor of chemistry in the university of Melbourne, and his daughter Rosaline is known as a writer and novelist.

MASSON, LOUIS CLAUDE FRÉDÉRIC (1847— ), French historian, was born at Paris on the 8th of March 1847. His father, Francis Masson, a solicitor, was killed on the 23rd of June 1848, when major in the garde nationale. Young Masson was educated at the college of Sainte Barbe, and at the lycée that he abandoned and then travelled in Germany and in England; from 1869 to 1880 he was librarian at the Foreign Office. At first he devoted himself to the history of diplomacy, and published between 1877 and 1884 several volumes connected with that subject. Later he published a number of more or less curious memoirs illustrating the history of the Revolution and of the empire. But he is best known for his books connected with Napoleon. In Napoleon inconnu (1883), Masson, together with M. Guido Biagi, brought out the unpublished writings (1786–1799) of the future emperor. These were notes, extracts from historical, philosophical and literary books, and personal reflections in which one can watch the growth of the ideas later carried out by the emperor with modifications necessitated by the force of circumstances and his own genius. But this was only one in a remarkable series: Joséphine de Beauharnais, 1763–1796 (1868); Joséphine, impératrice et reine (1890); Joséphine répudiée 1809–1814 (1901); L'Impératrice Marie Louise (1902); Napoleon et les femmes (1894); Napoleon et sa famille (9 vols., 1897–1907); Napoléon et son fils (1904); and Auteur de L'Ile d'Elbe (1908). These works abound in details and amusing facts, which throw much light on the events and men of the time, laying stress on the personal, romantic and dramatic aspects of history. The author was a member of the Académie française in 1903. From 1886 to 1889 he edited the review Arts and Letters, published in London and New York.

A bibliography of his works, including anonymous ones and those under an assumed name, has been published by G. Vicaire (Mémois de l'amateur des livres du XIXe siècle, tome v., 1904). Napoleon et les femmes has been translated into English as Napoleon and the Fair Sex (1894).

MAST (1) (O. Eng. meest; a common Teutonic word, cognate with Lat. modus; from the medieval Latinized form mastus comes Fr. nadt), in nautical language, the name of the spar, or straight piece of timber, or combination of spars, on which are hung the yards and sails of a vessel of any size. It has been ingeniously supposed that man himself was the first mast. He discovered by standing up in his prehistoric "dugout," or canoe, that the wind blowing on him would carry his craft along. But the origin of the mast, like that of the ship, is lost in times anterior to all record. The earliest form of mast which prevailed till the close of the middle ages, and is still in use for small vessels, was and is a single spar made of some tough and elastic wood; the conifers supply the best timber for the purpose. In sketching the history of the development of the mast, we must distinguish between the increase in the number erected, and the improvements made in the mast itself. The earliest ships had only one, carrying a single sail. So little is known of the rigging of
MASTABA—MASTER

A "jury mast" is a temporary mast put up by the crew when the spars have been carried away in a storm or in action, or have been cut away to relieve pressure in a storm. The word has been supposed to have found its way into English language by the process of fashioning to be short for "immortalism" or "immortalism"; it may be a mere fanciful sailor adaptation of "jury" in some connexion now lost. Skeat suggests that it is short for O. Fr. adjure, Lat. adjure, to aid. There is no reason to connect with four, day.

MAST (2) (Anglo-Saxon maest, food, common to some Teutonic languages, and ultimately connected with "meat"), the fruit of the beeche, oak, and other forest trees, used as food for swine.

MASTABA (Arab. for "bench"), in Egyptian architecture, the term given to the rectangular tombs in stone with raking sides and a flat roof. There were three chambers inside. In one the walls were sometimes richly decorated with paintings and had a low bench of stone in which on incense was burnt. The second chamber was either closed, with holes pierced in it through which a stream of incense was allowed, or was made into a narrow passage through which the fumes of the incense passed; this chamber contained the serdab or figure of the deceased. A vertical well-hole cut in the rock descended to a third chamber in which the mummy was laid.

MASTER (Lat. magister, related to magis, more, the corresponding minister is to minus, less; the English form is due partly to the O. Eng. maegister, and partly to O. Fr. maistre, mod. master; cf. Du. meester, Ger. Meister, Ital. maestro), one holding a position of authority, disposition or control over persons or things. The various applications of the word fall roughly into the following main divisions; as the title of the holder of a position of command or authority; as that of the holder of certain public or private offices, and hence a title of address; and as implying the relationship of a teacher to his pupils or of an employer to the persons he employs. As a title of the holder of an office, the use of the Lat. magister is very ancient. Magister equum, master of the horse, goes back to the early history of the Roman Republic (see dictator; and for the British office, Master of the Horse). In medieval times the title was of great frequency. In Du Cange (Glossarium) the article magister contains over 120 sub-headings. In the British royal household most of the offices bearing this title are now obsolete. Of the greater offices, that of master of the buckwheels was abolished by the Civil List Act 1901. The master of the household, master of the ceremonies, master of the king's music still survive. Since 1870 the office of master of the mint has been held by the chancellor of the exchequer, all the administrative and other duties being exercised by the deputy master.

At sea, a "master" is more properly styled "master mariner." In the merchant service he is the commander of a ship, and is by courtesy known as the captain. In the British navy he was the officer entrusted with the navigation under the captain. He had no royal commission, but a warrant from the Navy Board. Very often he had been a merchant captain. His duties are now performed by the staff commander or navigating lieutenant. The master-at-arms is the head of the internal police of a ship; the same title is borne by a senior gymnastic instructor in the army. In the United States navy, the master is a commissioned officer below the rank of lieutenant.

"Master" appears as the title of many legal functionaries (for the masters of the supreme court see CHANCERY; and KING'S BENCH, COURT OF; for masters in lunacy see INSANITY: § Law; see also MASTER OF THE ROLLS, below). The "master of the faculties" is the chief officer of the archbishop of Canterbury in his court of faculties. His duties are concerned with the appointment of notaries and the granting of special licences of marriage. The duties are performed ex officio by the judge of the provincial courts of Canterbury and York, who is also dean of Arches, in accordance with § 7 of the Public Worship
Regulation Act 1874. The “master of the Temple” is the title of the priest-in-charge of the Temple Church in London. It was formerly the title of the grand master of the Knights Templars. The priest-in-charge of the Templars’ Church was properly styled the custos, and this was preserved by the Knights Hospitallers when they were granted the property of the Templars at the dissolution of that order. The act of 1540 (22 Hen VIII), which dissolved the order of the Hospitallers, wrongly styled the custos master of the Temple, and the mistake has continued. The proper title of a bencher of the Inns of Court is “master of the Bench” (see INNS OF COURT). The title of “Master-General of the Ordinance” was revived in 1904 for the head of the Ordnance Department in the British military administration.

“Master” is the ordinary word for a teacher, very generally used in the compound “schoolmaster.” The word also is used in a sense transferred from this to express the relation between the founder of a school of religion, philosophy, science, art, &c., and his disciples. It is partly in this sense and partly in that of one whose work serves as a model or type of superlative excellence that such terms as “old masters” are used. In medieval universities magister was particularly applied to one who had been granted a degree carrying with it the licentia docendi, the licence to teach. In English usage this survives in the faculty of arts. The degree is that of artium magister, master of arts, abbreviated M.A. In the other faculties the corresponding degree is doctor of arts, abbreviated M.D. Like various other academic degrees it is used of a master’s degree in surgery, master chirurgiae, C. M. or M. Ch., and also in science, magister scientiarum, M.Sc. The academic use of “master” as the title of the head of certain colleges at the universities of Oxford and Cambridge is to be referred to the frequent application of the term to the holder of a presiding office in an institution.

Master was the usual prefix of address to a man’s name, though originally confined to people of some social standing. Probably under the influence of “mistress,” it was corrupted in sound to “mister,” and was abbreviated to “Mr.” In the case of the puisne judges of the High Court “Mr Justice” is still used as the proper official form of written address. The Speaker of the House of Commons is also formally addressed as “Mr Speaker.” In some Scottish peerages below the rank of earl, “master” is used in the courtesy title of the heir, e.g. the “Master of Ruthven.”

MASTER AND SERVANT. These are scarcely to be considered as technical terms in English law. The relationship which they imply is created when one man hires the labour of another for a term. Thus it is created by merely engaging another for the performance of a definite work, or by sending an article to an artificer to be repaired, or engaging a builder to construct a house. Nor would the employment of a man for a definite service of personal service—e.g. the engagement of a messenger for a single occasion—generally make the one master and the other servant. It was held, however, in relation to the offence of embezlement, that a drover employed on one occasion to drive cattle home from market was a servant within the statute. On the other hand, there are many decisions limiting the meaning of “servants” under wills giving a proxy in case of the death of servants generally. Thus “a person who was not obliged to give his whole time to the master, but was yet in some sense a servant,” was held not entitled to share in a legacy to the servants. These cases are, however, interpretations of wills where the intention obviously is to benefit domestic servants only. And so in other connexions questions may arise as to the exact nature of the relations between the parties whether they are master and servant, or principal and agent, or landlord and tenant, or partners, &c.

The terms of the contract of service are for the most part such as the parties choose to make them, but in the absence of express stipulations terms will be implied by the law. Thus, “where no time is limited either expressly or by implication for the duration of a contract of hiring and service, the hiring is considered as a general hiring, and in point of law a hiring for a year.” But “in the case of domestic and menial servants there is a well-known rule, founded solely on custom, that their contract of service may be determined at any time by giving a month’s warning or paying a month’s wages, but a domestic or other yearly servant, wrongfully quitting his master’s service, forfeits all claim to wages for that part of the current year during which he has served, and cannot claim the sum to which his wages would have amounted had he kept his contract, merely deducting therefrom one month’s wages. Domestic servants have a right by custom to leave their situations at any time on payment of a calendar month’s wages in advance, just as a master may discharge them in a similar manner” (Manley Smith’s Law of Master and Servant, chs. ii. and iii.). The following are sufficient grounds for discharging a servant: (i) wilful disobedience of any lawful order; (ii) gross moral misconduct; (iii) habitual negligence; (iv) incompetence or permanent disability caused by illness. A master has a right of action against any person who deprives him of the services of his servant, by enticing him away, harbouring or detaining him after notice, confining or disabling him, or by seducing his female servant. Indeed, the ordinary and only available action for seduction in English law is in form of a claim by a parent for the loss of his daughter’s services. The death of either master or servant in general puts an end to the contract. A servant wrongfully discharged may either treat the contract as rescinded and sue for services actually rendered, or he may bring a special action to recover the sum to which he may be entitled. The common law liabilities of a master towards his servants have been further regulated by the Workmen’s Compensation Acts (see EMPLOYER’S LIABILITY). A master is bound to provide food for a servant living under his roof, and willful breach of duty in that respect is a misdemeanour under the Offences against the Person Act 1861.

A servant has no right to demand “a character” from an employer, and if a character be given it will be deemed a privileged communication, so that the master will not be liable thereon to the servant unless it be false and malicious. A master by knowingly giving a false character of a servant to an intending employer may render himself liable—should the servant for example rob or injure his new master.

Reference may be made to the articles on LABOUR LEGISLATION for the cases in which special terms have been introduced into contracts of service by statute (e.g. Truck Acts).

MASTER OF THE HORSE, in England, an important official of the sovereign’s household. The master of the horse is the third dignitary of the court, and is always a member of the ministry (before 1782 the office was of cabinet rank), a peer and a privy councillor. He has the chief care of the royal horses and bounds of the sovereign, as well as the stables and coach-houses, the stud, mews and kennels, are within his jurisdiction. The practical management of the royal stables and stud devolves on the chief or crown equerry, formerly called the gentleman of the horse, who is never in personal attendance on the sovereign and whose appointment is permanent. The clerk marshal has the supervision of the accounts of the department before they are submitted to the Board of Green Cloth, and is in waiting on the sovereign on state occasions only. Exclusive of the sovereign’s liveries there are several extra and honorary equerries, one of whom is always in attendance on the sovereign and rides at the side of the royal carriage. They are always officers of the army, and each of them is “on duty” for about the same time as the lords and grooms in waiting. There are also several pages of honour in the master of the horse’s department, who must not be confounded with the pages of various kinds who are in the department of the lord chamberlain. They are youths aged from twelve to sixteen, selected by the sovereign in person, to attend on him at state ceremonies, two of them, arrayed in an antique costume, assist the groom of the stole in carrying the royal train.

In France the master of the horse ("Grand Écuéyur," or more usually "Monsieur le grand") was one of the seven great officers of the crown from 1617. As well as the superintendent of the royal
MASTER OF THE ROLLS—MASTODON 873

stables, he had that of the retinue of the sovereign, also the charge of the funds set aside for the religious functions of the court, coronations, &c. On the death of a sovereign he had the right to all the horses and saddles in the retinue of either of them. Distinct from the officer and independent of him, was the first esquire ("Premier Écuier"), who had charge of the horses which the sovereign used personally ("la petite écuyère"), and who attended on him when he retired to the stables and returned to the palace either in the presence of Louis XVI. Under Louis XVIII. and Charles X. the duties were discharged by the first esquire, but under Napoleon I. and Napoleon III. was revived the custom of transmitting it to the eldest son of his old esquire.

In Germany the master of the horse (Oberstallmeister) is a high court dignitary; but his office is merely titular, the superintendence of the king’s stables being carried out by the Oberstallmeister, an official corresponding to the crowne ducal equerry of England.

MASTER OF THE ROLLS, the third member of the Supreme Court of Judicature in England, the lord chancellor, president of the chancery division, being the first, and the lord chief justice, president of the king’s bench division, being the second. At first he was the principal clerk of the chancery, and as such had charge of the records of the court, especially of the register of original writs and of all patents and grants under the Great Seal. Until the end of the 15th century he was called either the clerk or the keeper of the rolls, and was appointed as the master or keeper of the rolls. The earliest mention of him as master of the rolls is in an act of 1495; and in another act of the same year he is again described as clerk of the rolls, showing that his official designation still remained unsettled. About the same period, however, the chief clerks of the chancery came to be called masters in chancery, and the clerk, master or keeper of the rolls was always the first among them, whichever name they bore. In course of time, from causes which are not very easy to trace, his original functions as keeper of the records passed away from him and he gradually assumed a jurisdiction in the court of chancery second only to that of the lord chancellor himself. In the beginning he only heard causes in conjunction with the other masters in chancery, and his decrees were invalid until they had been approved and signed by the lord chancellor. Sitting in the Rolls chapel or in the court in Rolls yard, he heard causes without assistance, and his decrees held good until they were reversed on petition either to the lord chancellor or afterwards to the lords justices of appeal. Before any judge with the formal title of vice-chancellor was appointed the master of the rolls was often spoken of as vice-chancellor, and in theory acted as such, sitting only when the lord chancellor was not sitting and holding his court in the evening from six o’clock to ten. Only since 1872 has the master of the rolls sat in the morning hours. By the Public Record Office Act 1838 the custody of the records was restored to him, and he is chairman of the State Papers and Historical Manuscripts Commission. Under the Judicature Act 1873, and the Appellate Jurisdiction Act 1876, he now always sits with the lords justices in the court of appeal (which usually sits in two divisions of three judges, the master of the rolls presiding over one division), whose decisions can be questioned only in the House of Lords. The master of the rolls was formerly eligible to a seat in the House of Commons—a privilege enjoyed by no other member of the judicial bench; 1 but he was deprived of it by the Supreme Court of Judicature Act 1873, which provides that all judges of the High Court of Justice and the court of appeal shall be incapable of being elected to or sitting in the House of Commons. The master of the rolls is always sworn of the privy council. His salary is $5000 a year.

See Lord Hardwicke, Office of the Master of the Rolls.

MASTIG, or MASTICH (Gr. μαστίγος, probably connected with μασθάος, to chew, since mastic is used in the East as a chewing gum), a resinous exudation obtained from the lentisk, Pistacia lentiscus, an evergreen shrub of the natural order Anacardiaceae. The lentisk or mastic plant is indigenous to the Mediterranean coast region from Syria to Spain, but grows also in Portugal, Morocco and the Canaries. Although experiments have proved that excellent mastic might be obtained in other islands in the archipelago, the production of the substance has been, since the time of Dioscorides, almost exclusively confined to the island of Chios. The mastic districts of that island are for the most part flat and stony, with little hills and few streams. The shrubs are about 6 ft. high. The resin is contained in the bark and not in the wood, and in order to obtain it numerous vertical incisions are made, during June, July and August, in the stem and chief branches. The resin speedily exudes and hardens into roundish or oval tears, which are collected, after about fifteen days, by women and children in little baskets lined with white paper or old cotton cloth. The ground around the trees is kept hard and clean, and the women and children go to them to prevent any droppings of resin from becoming contaminated with dirt. The collection is repeated three or four times between June and September, a fine tree being found to yield about 8 or 10 lb. of mastic during the season. Besides that obtained from the incisions, mastic of very fine quality spontaneously exudes from the small branches. The harvest is affected by showers of rain during the period of collection, and the trees are much injured by frost, which is, however, of advantage to the mastic districts where they grow. Mastic occurs in commerce in the form of small cylindrical pieces and of sheets of pebbles. They are transparent, with a glassy fracture, of a pale yellow or faint greenish tinge, which darkens slowly by age. During the 15th, 16th and 17th centuries mastic enjoyed a high reputation as a medicine, and formed an ingredient in a large number of medical compounds; but its use in medicine is now obsolete, and it is chiefly employed for making varnish.

Pistacia Khinjuk and P. cabulica, trees growing throughout Sind, Baluchistan and Cabul, yield a kind of mastic which is met with in the Indian bazaars under the name of Muskatgumdi, i.e. Roman mastic. This when occurring in the European market is known as East Indian or Bombay mastic. In Algeria P. atlantica yields a solid resin, which is collected and used by the Arabs as a masticatory. Cape mastic is the produce of Euryops multifidus, the resin bush, or harpaiss bosch of the Boers—a plant of the composite family. It grows abundantly in the Clanwilliam district. Dammar resin is sometimes sold under the name of West Indian mastic tree is the Bursera gymnifera and the Peruvian mastic is Schinus molle; but neither of these furnish commercial resins. The name mastic tree is also applied to a timber tree, Sider oxylon mastichodendron, nat. ord. Sapotaceae, which grows in the West Indies and on the coast of Florida.

MASTIGOPHORA, a group of Protozoa, moving and ingesting food by long flagella (Gr. μαστίγος, whip), usually few in number, and multiplying by fission, usually longitudinal, in the active condition. They were separated off from the rest of the old "Infusoria" by K. Düssing, and subdivided by O. Bütschli and E. R. Lankester into (1) Flagellata (q.v.), including Haemoflagellata (q.v.), (2) Dinoflagellata (q.v.) and Rhyynchocystiflagellata E. Haeckel (q.v.) = Rhyynchoflagellata E. R. Lankester. The Mastigophora are frequently termed Flagellata or Flagellates.

MASTODON (Gr. μαστός, breast, ὀδόν, tooth), a name given by Cuvier to the Pliocene and Miocene forerunners of the elephants, on account of the nipple-like prominences on the molar teeth of some of the species (fig. 2), which are of a much simpler type than those of true elephants. Mastodonts, like elephants, always have a pair of upper tusks, while the earlier ones likewise have a short pair in the lower jaw, which is prolonged into a snout-like symphysis for their support. These long-chinned mastodonts must have learned to charge as far as they were learned to charge, a kind of forming a genus by themselves (Tetrabelodon), well-known examples of this group being Tetrabelodon angustidens from the Miocene and T. longirostris (fig. 1 c) from the Lower Pliocene of the Continent. In the former the upper tusks are bent down so as to cross the tips of the short and chisel-like lower pair. These long-chinned mastodonts must have had an extremely elongated muzzle, formed by the upper lip and nose above and the lower lip below, with which they were able to reach the ground, the neck being probably rather longer than in elephants. On the other hand, in the short-chinned mastodonts, as represented by the Pleistocene North American Mastodon americanus and the Pliocene European M. turicensis (fig. 1), the chin had shrunk.
to the dimensions characteristic of elephants, with the loss of the lower incisors (or with temporary retention of rudimentary ones), while at the same time a true elephant-like trunk must have been developed by the shortening of the lower lip and the prolongation of the combined upper lip and nose.

Mastodons are found in almost all parts of the world. In Asia they gave rise to the elephants, while they themselves originated in Africa from ungulates of more normal type. (See PROBOSCIDEA.)

The upper tusks of the early mastodons differ from those of elephants in retaining longitudinal bands of enamel. The molar teeth are six in number on each side, increasing in size from both backwards, and, as in the elephants, with a horizontal succession, the anterior teeth being lost before the full development of the posterior ones, which gradually move forward, taking the place of those that are destroyed by wear. This process is, however, less fully developed than in elephants, and as many as three teeth may be in place in each jaw at one time. There is, moreover, in many species a vertical succession, affecting either the third, or the third and second, or (in one American species, Tetrabelodon productus) the first, second and third of the six molar teeth. These three are therefore reckoned as milk-molars, and their successors as premolars, while the last three correspond to the true molars of other mammals. The mode of succession of the teeth in the mastodons exhibits so many stages of the process by which the dentition of elephants has been derived from that of more ordinary mammals. It also shows that the anterior molars of elephants do not correspond to the premolars of other ungulates, but to the milk-molars, the early loss of which in consequence of the peculiar process of horizontal forward-moving species the summits of the ridges are divided into conical cusps, and those accessory cusps threatening around them (as in M. arenensis, fig. 2). When the summits of these are worn by mastication their surfaces present circles of dentine surrounded by a border of enamel, and as attrition proceeds different patterns are produced by the union of the bases of the cusps, a trefoil form being characteristic of some species.

Certain of the molar teeth of the middle of the series in both elephants and mastodons have the same number of principal ridges; those in front having fewer, and those behind a greater number. These teeth are distinguished as "intermediate" molars. In elephants there are only two, the last milk-molar and the first true molar (or the third and fourth of the whole series), which are alike in the number of ridges; whereas in mastodons there are three such teeth, the last milk-molar and the first and second molars (or the third, fourth and fifth of the whole series). In elephants the number of ridges on the intermediate molars always exceeds five, but in mastodons it is nearly always three or four, and the tooth in front has usually one fewer and that behind one more, so that the ridge-formula (i.e. a formula expressing the number of ridges on each of the six molar teeth) of most mastodons can be reduced either to 1, 2, 3, 3 or 2, 3, 3, 4, 4, 4. The three-ridged and four-ridged types occur both in Mastodon and Tetrabelodon.

MAS'UDI (ABD-AL-HASAN 'ALI IBN HUSAIN IBN 'ALI UL-MA'SUDI) (d. c. 956), Arabian historian, was born at Bagdad towards the close of the 9th century. Much of his life was spent in travel. After he had been in Persia and Kerman, he visited Isakhr in 955, and went in the following year to Maktan and Manchara, and back to Oman. He seems about this time to have been as far as China. After a visit to the shores of the Caspian Sea he visited Tiberias in Palestine, examined the Christian church there, and described its relics. In 943 he was in Antioch, studying the ruins, and two years later in Damascus. The last ten years of his life he spent in Syria and Egypt. His great object in life had been to study with his own eyes the peculiarities of every land and to collect whatever was of interest for archaeology, history and manners. Himself a Mahomedan Religion: Sects), he was singularly free from bigotry, and took his information, when necessary, from Persians, Jews, Indians, and even the chronicle of a Christian bishop.

His most extensive work was the Kitab akhbir us-Zamon or Annals, in 30 volumes with a supplement, the Kitab ul-Ausil, a chronological sketch of general history. Of these the first part only of the former is extant in MS, in Vienna, while the latter seems to be in the Bodleian Library, also in MS. The substance of the two was united by him in the work by which he is now best known, the Murijj ud-Dhahab wa Ma'diim ul-Jawahir ("Meadows of Gold and Mines of Precious Stones"), an historical work which he finished in 947. In 956 he finished a second edition of this and made it double its former size, but no copy of this seems to be extant. The original edition has been published at Bulaq and Cairo, and with French translation by C. Barbier de Meynard and Poyet de, in ten tomes, 9 vols., Paris, 1861-1877. An account of Mas'udi's works is to be found in de Saucy's memoir and in Goep'el's preface to his edition of the Tanbih, and of the works extant in C. Brockelmann's Gesch. der Arab. Literatur, 2. 114-145 (Weimar, 1898). C. Field's Tales of the Copts (1909) is based on Mas'udi.

(From Owen.)

FIG. 2.—Upper Molar of Mastodon arenensis, viewed from below.
MASULIPATAM—MATANZAS

MASULIPATAM, or BANDAR, a seaport of British India, administrative headquarters of the Kistna district of Madras, on one of the mouths of the river Kistna, 215 m. N. of Madras city. Pop. (1901), 39,507. Masulipatam was the earliest English settlement on the Coromandel coast, its importance being due to the fact that it was the bandar or port of Golconda. An agency was established there in 1611. During the wars of the Carnatic, the English were temporarily expelled the town, which was held by the French for some years. In 1759 the town and fort were carried by storm by Colonel Forde, an achievement followed by the acquisition of the Northern Circars (q.v.). In 1864 a great storm-wave swept over the entire town and is said to have destroyed 30,000 lives. Weavers form a large portion of the inhabitants, though their trade has greatly declined since the beginning of the 19th century. Their operations, besides weaving, include printing, bleaching and dressing. In former days the chintzes of Masulipatam had a great reputation abroad for the freshness and permanency of their dyes. Masulipatam is a station of the Church Missionary Society. The port is only a roadstead, where vessels anchor 5 m. out. A branch line from Bzovuda on the Southern Mahratta railway was opened in 1908. The chief educational institution is the Noble College of the C.M.S.

MAT (O. Eng. mettis, from late Lat. materia, whence Ital. matita, Ger. and Dan. matte, Du. mat, ctc.), an article of various sizes and shapes, according to the purpose for which it is intended, and used in the manufacture of writing materials (pencil or crayon, cotton or coco-nut fibre, straw, rushes, &c., or of paper or coarse twine. The finer fabrics are known as "matting" (q.v.). Mats are mainly used for covering floors, or in horticulture as a protection against cold or exposure for plants and trees. When used near the entrance to a house for people to wipe their boots on "door mats" are usually made of coarse coco-nut fibre, or india-rubber, cork, or of thickly coiled wire. Bags, rolls or sacks made of matting are used to hold coffee, flax, rice and other produce, and the term is often used with reference to the specific quantities of such produce, e.g. so many "mats" of coffee, rice, &c.

To be distinguished from the above is the term "mat" in glass painting, or giltting, meaning dull, unpolished or unburnished. This is the same as Ger. matt, dead, dull, cfr. mat-tleau, Med. Lat. malta, adapted from Persian mdt, dazzled, astonished, at a loss, helpless, and seen in "mate" in chess, from Pers. sbh mdt the king is dead.

MATABELE ("vanishing" or "hidden" people, so called from their appearance in battle, hidden behind enormous oxhide shields), a people of Zulu origin who began national life under the chief Mosilikatze. Driven out of the Transvaal by the Boers in 1835, Mosilikatze crossed the Limpopo with a military host which had been recruited from among the conquered and driven to him during his ten years' predominance in the Transvaal. In their new territories the Matabele absorbed into their ranks many members of the conquered Mashona tribes and established a military despotism. Their sole occupation was war, for which their laws and organization were designed to fit them. This system of constant warfare is, since the conquest of Matabeleland by the British in 1893, a thing of the past. The Matabele are now herdsmen and agriculturists. (See Rhodesia.)

MACHINAS (Span. matachín, clown, or masked dancer), bands of mummers or itinerant players in Mexico, especially popular around the Rio Grande, who wander from village to village during Lent, playing in rough-and-ready style a set drama based on the history of Montezuma. Dressed in fantastic Indian costumes and carrying rattles as their orchestra, the chief characters are El Monarca (the monarch) (Monte- zuma); Malinche, or Malintzin, the Indian mistress of Hernando Cortes; El Toro, "the bull," the malevolent "comic man" of the play, dressed in buffalo skin with the animal's horns on his head, a weather-beaten old man, "grandmother." With the help of a chorus of dancers they portray the descent of his people by Montezuma, the luring of him back by the wiles and smiles of Malinche, the final reunion of king and people, and the killing of El Toro, who is supposed to have made all the mischief.

MATADOR, a Spanish word meaning literally "killer," from matar, Lat. maestare, especially applied to the principal performer in a bull-fight, whose function it is to slay the bull (see BULL-FIGHTING). The word is also used of certain important cards in such games as quadrille, ombre, &c., and more particularly of a special form of the game of dominos.

MATAMOROS, a town and port of the state of Tamaulipas, Mexico, on the S. bank of the Rio Grande, 28 m. from its mouth, opposite Brownsville, Texas. Pop. (1900), 8347. Matamoros stands in an open plain, the commercial centre for a large district, but its import trade is prejudiced by the bar at the mouth of the Rio Grande, which permits the entrance of small vessels only. The exports include hides, wool and live stock. The importance of the town in the foreign trade of northern Mexico, however, has been largely diminished by the great railways. Formerly it was the centre of a large contra-band trade with Brownsville, Texas. Matamoros was founded early in the 19th century, and was named in honour of the Mexican patriot Mariano Matamoros (c. 1770-1814). In the war between the United States and Mexico, Matamoros was easily taken by the Americans on the 18th of May 1846, following General Zachary Taylor's victories at Palo Alto and Resaca de la Palma. Matamoros was occupied by the Mexican imperialists under Mejia in 1864, and by the French in 1866.

MATANZAS, an important city of Cuba, capital of Matanzas province, situated on a large deep bay on the N. coast, about 54 m. (by rail) E. of Havana. Pop. (1907), 36,009. There are railroads from Matanzas, S., and to the coast of San Isidro, ships to New York and by the coast steamers of the Herrera Line. The bay, unlike the other better harbours of the island, has a broad mouth, 2 m. across, but there is good shelter against all winds except from the N.E. A coral reef lies across the entrance. Three rivers emptying into the bay—the San Juan, Canimar and Yumuri—have deposited much silt, necessitating the use of lighters in loading and unloading large ships. The city is finely placed at the head of the bay, on a low, sloping plain backed by wooded hills, over some of which the city itself has spread. The conical Pan de Matanzas (1277 ft.) is a striking land-mark for sailors. The San Juan and Yumuri rivers divide Matanzas into three districts. The Teatro Esteban, Casino Español and Government House are noteworthy among the buildings. The broad Paseo de Marti (Alameda de Versalles, Paseo de Santa Cristina) extends along the edge of the harbour, and is perhaps the handsomest parkway and boulevard in Cuba. At one end is a statue of Ferdinand VII., at the other a monument to 63 Cubans executed by the Spanish Government as traitors for bearing arms in the cause of independence. A splendid military and commercial building is the Castillo de San Salvador (built in 1694-1695, reconstructed in 1772 and following years). There are two smaller forts, established in the 18th century. Near Matanzas are two of the most noted natural resorts of Cuba: the valley of the Yumuri, and the caves of Bellamar. Commanding the Yumuri Valley is the hill called Cumbre, on which is the Hermitage of Montserrat (1870), with a famous shrine. Matanzas is the second port of the island in commerce. Sugar and molasses are the chief exports. The city is the chief outlet for the sugar product of the province, which, with the province of Santa Clara, produces two-thirds of the crop of the island. There are many large warehouses, rum distilleries, sugar-mills and railway machine-shops. Matanzas is frequently mentioned in the annals of the 16th and 17th centuries, when its bay was frequented by buccaneers; but the city was not laid out until 1693. In the next year it received an ayuntamiento (council). Its prosperity rapidly increased after the establishment of free commerce early in the 19th century. In 1815 it was made a department capital. The mulatto poet, Gabriel de la Concepción Valdés, known as Plácido (1809-1844), was born in Matanzas, and was executed there for participation in the supposed conspiracy of negroes in 1844, which is one of the most famous episodes in Cuban history. The hurricanes of 1844 and 1846 are the only other prominent local events. American commercial influence has always been particularly strong.
Mataró—Match

Mataró (anc. Iluro), a seaport of north-eastern Spain, in the province of Barcelona, on the Mediterranean Sea and the Barcelona-Perpignan railway. Pop. (1900), 15,704. The streets of the new town, lying next the sea, are wide and regularly built; those of the old town, farther up the hill, still preserve much of their ancient character. The parish church of Santa Maria has some good pictures and wood carvings. The wine of the neighbourhood, which resembles port, is shipped in large quantities from Barcelona; and the district furnishes fine roses and strawberries for the Barcelona market. The leading industries are manufactures of linen and cotton goods, especially canvas and tarpaulin, and of soap, paper, chemicals, starch, glass, leather, spirits and flour. The railway to Barcelona, opened in October 1848, was the first to be constructed in Spain. Outside the town is the much-frequented carbonated mineral spring of Argentona.

Match: 1. O. Eng. gemaecca, a cognate form of "make," meaning originally "do" or "suitable for a pair, or one of a pair of objects, persons or animals. As particularly applied to a husband and wife, and hence to a marriage, the word is especially used of two persons or things which correspond exactly to each other. The verb " to match" has also the meaning to "pit one against each other," and is so applied in sport to an arranged contest between individuals or sides.

2. O. Fr. mescere; apparently from a latinized form of Gr. μική, mucus, from the nose, applied to the nozzle of a lamp; primarily the wick which conveys oil or molten wax to the flame of a lamp or candle (this use is now obsolete), and applied to various objects having the property of carrying fire. With early firearms a match, consisting of a cord of hemp or similar material treated with niter and other substances so that it continued to smoulder after it had been ignited, was used for firing the charge, being either held in the gunner's hand or attached to the cock of the musket or arquebus and brought down by the action of the trigger on the powder priming ("matchlock"); and more or less similar preparations, made to burn more or less rapidly as required ("quick-match" and "slow-match"), are employed as fuses in blasting and demolition work in military operations. The word "match" was further used of a splint of wood, tipped with sulphur so that it would readily ignite, but it now most commonly means a slip of wood or other combustible material, having its end covered with a composition which takes fire when rubbed either on any rough surface or on another specially prepared composition.

The first attempt to make matches in the modern sense may probably be ascribed to Godfrey Haukwitz, who, in 1680, acting under the direction of Robert Boyle, who at that time had just discovered how to prepare phosphorus, employed small pieces of it, coated by friction, in tight splints of wood dipped in sulphur. This device, however, did not come into extensive use owing to its danger and inconvenience and to the cost of the phosphorus, and till the beginning of the 19th century the flint and steel with tinder-box and sulphur-tipped splints of wood—"spunks" or matches—were the common means of obtaining fire for domestic and other purposes. The sparks struck off by the percussion of flint and steel were made to fall among the tinder, which consisted of carbonized fragments of cotton and flax. The entire mass of the tinder was set into a glow, developing sufficient heat to ignite the sulphur with which the matches were tipped, and thereby the splints themselves were set on fire. In 1805 one Chancel, assistant to Professor L. J. Thénard of Paris, introduced an apparatus consisting of a small bottle containing asbestos, saturated with strong sulphuric acid, with splints or matches coated with sulphur, and tipped with a mixture of chloride of potash and sugar. The matches so prepared, when brought into contact with the sulphuric acid in the bottle, ignited, and thus, by chemical action, fire was produced. In 1823 a decided impetus was given to the artificial production of fire by the introduction of the Döbereiner lamp, so called after its inventor, J. W. Döbereiner of Jena. The first really practical friction matches were made in England in 1827, by John Walker, a druggist of Stockton-on-Tees. These were known as "Congress" after Sir William Congreve, the inventor of the Congreve rocket, and consisted of wooden splints or sticks of cardboard coated with sulphur and tipped with a mixture of sulphide of antimony, chloride of potash and gum. With each box which was retailed at a shilling, there was supplied a folded piece of glass paper, the folds of which were to be tightly pressed together, while the match was drawn through between them. These were generally known as "Döbereiner matches", and a half year later. The so-called "Prometheans," patented by S. Jones of London in 1830, consisted of a short roll of paper with a small quantity of a mixture of chloride of potash and sugar at one end, a thin glass globule of strong sulphuric acid being attached at the same point. When the sulphuric acid was liberated by pinching the glass globule, it acted on the mixed chloride and sugar, producing fire. The phosphorus friction-match of the present day was first introduced on a commercial scale in 1833. It appears to have been made almost simultaneously in several distinct centres. The name most commonly connected with the early stages of the invention is that of J. Preschel of Vienna, who in 1833 had a factory in operation for making phosphorus matches, fuses, and amadou slips tipped with igniting composition. At the same time also matches were being made by F. Moldenhauer in Darmstadt; and for a long series of years Austria and the South-German states were the principal centres of the new industry.

But the use of ordinary white or yellow phosphorus as a principal ingredient in the igniting mixture of matches was found to be both disadvantageous and dangerous. It is a deadly poison, and its free dissemination in the air has caused many deaths, and to numerous cases of wilful murder and suicide. Workers also who are exposed to phosphoric vapours are subject to a peculiarly distressing disease which attacks the jaw, and ultimately produces necrosis of the jaw-bone ("phossy jaw"), though with scrupulous attention to ventilation and cleanliness much of the risk of the disease may be avoided. The most serious objections to the use of phosphorus, however, were overcome by the discovery of the modified form of that body known as red or amorphous phosphorus. That substance was utilized for the manufacture of the well-known "safety matches" by J. E. Lundström, of Jönköping, Sweden, in 1852; its employment for this purpose had been patented eight years previously by another Swede, G. E. Pasch, who, however, regarded it as an oxide of phosphorus. Red phosphorus is in itself a perfectly innocuous substance, and no evil effects arise from freely working the compositions of which it forms an ingredient. The fact again that safety matches ignite only in exceptional circumstances on any other than the prepared surfaces which accompany the match, whereas those which contain the wood, of which they make themselves contain the phosphorus required for ignition—this places them much less liable to cause accidental fires than other kinds.

The processes carried out in a match factory include preparing the splints, dipping them first in molten paraffin wax and then in the igniting composition, and filling the matches into boxes. All these operations are performed by complicated automatic machinery, in the development of which the Diamond Match Company of America has taken a leading part, with the minimum of manual intervention.

The chief element in the igniting mixture of ordinary or "strike anywhere" matches used to be common yellow phosphorus, contained in one or more hollow bodies, which readily part with oxygen under the influence of heat. Chief among these latter substances is chloride of potash, others being red lead, nitrate of lead, bichromate of potash and peroxide of manganese. But at the beginning of the 20th century many countries took steps to stop the use of yellow phosphorus owing to the danger to health attending its manipulation. In Sweden matches made with it have been prohibited since 1905 and 1906, two conferences, attended by representatives of most of the governments of Europe, were held at Berne to consider the question of prohibiting yellow phosphorus, but no general agreement was reached owing to the objections entertained by Sweden, Norway, Spain and Portugal, and also Japan. Germany, France, Italy, Denmark, Holland, Switzerland and Luxemburg, however, agreed to a convention whereby yellow phosphorus was prohibited as from 1912, and to this Great Britain expressed her adherence
and settle down to the work for about six months. Their first operation is to prepare an open space, called a *tataca*, about 6 ft. square, in which the surface of the soil is beaten hard and smooth with mallets. The leafy branches of the *mate* are then cut down and placed on the *tataca*, where they undergo a preliminary roasting from a fire kindled around it. An arch of poles, or of hurdles, is then erected above it, on which the *mate* is placed, a fire being lighted underneath. This part of the process demands some care, since the leaves have to be rendered brittle enough to be easily pulverized, and the aroma has to be developed, the necessary amount of heat being only learned by experience. After drying, the leaves are reduced to coarse powder in mortars formed of pits in the earth well rammed. *Mate* so prepared is called *cau guas* or *yerba do polos*, and is chiefly used in Brazil. In Paraguay and the vicinity of Parana in the Argentine Republic, the leaves are deprived of the midrib before roasting; this is called *cau-merti*. A very superior quality, or *cau-cujes*, is also prepared in Paraguay from the scarcely expanded buds. Another method of drying *mate* has been adopted, the leaves being heated in large cast-iron pans set in brickwork, in the same way that tea is dried in China; it is afterwards powdered by machinery.

*Mate* (Ilex *paraguariensis*).

Portion of plant, half natural size. Flower, drupe and nuts, twice natural size. Part of underside of leaf showing minute glands, natural size.

The different methods of preparation influence to a certain extent the value of the product: the *mate* prepared in Paraguay being considered the best, that of Oran and Paranaguá very inferior. The leaves when dried are packed tightly in sewn or oblong packages made of raw hides, which are then carefully sewed up. These shrink as they expose themselves to the sun, and in a couple of days, form compact parcels each containing about 200 lb of tea; in this form it keeps well. The tea is generally prepared for use in a small silver-mounted calabash, made of the fruit of *Creositia cujete* (Cuca) or of *Lagenaria* (Cabaço), usually about the size of a large orange, the tapering end of the latter serving for a handle. In the top of the calabash, or *mate*, a circular hole about the size of a florin is made, and through this opening the tea is sucked by means of a bombilla. This instrument consists of a small tube 6 or 7 in. long, formed either of metal or a reed, which at one end a bulb made either of extremely fine basket-work or of metal perforated with minute holes, so as to prevent the particles of the tea-leaves from being drawn up into the mouth. Some sugar and a little hot water are first placed in the gourd, the *yerba* is then added, and finally the vessel is filled to the brim with boiling water, or milk previously heated by a spirit lamp.

The word *cau* signified the plant in the native Indian language. The word *mate* (or, rather, *match*) was a similar name to the word of the Inca, and originally means a calabash. The Paraguay tea was called at first *yerba do mate*, and then, the *yerba* being dropped, the name *mate* came to signify the same thing.

1. *I. gigantea*, *I. ovalifolia*, *I. Humboldtiana*, and *I. nigromaculata*, besides several varieties of these species, are also used for preparing *mate*.
MATERA—MATHEMATICS

A little burnt sugar or lemon juice is sometimes added instead of milk. The beverage is then handed round to the company, each person taking a draught with a bombilla. It is best served in the same glass used for about three times. The infusion, if not drunk soon after it is made, rapidly turns black. Persons who are fond of maté drink it before every meal, and consume about 1 oz. of the leaves per day.

In the Kew Park, London, theii has been a restorative drink, this being a much-prized article of luxury, and is the first thing offered to visitors. The “gaschu” of the plains will travel on horseback for weeks asking no better fare than dried beef washed down with copious draughts of maté, and for it he will forego any other luxury, such as sugar, rice or biscuit. Maté acts as a restorative after great fatigue in the same manner as tea. Since it does not lose its flavour so quickly as tea by exposure to the air and damp, it is more acceptable to travellers.

Since the beginning of the 17th century maté has been drunk by all classes in Paraguay, and it is now used throughout Brazil and the neighbouring countries.

The virtues of this substance are due to the occurrence in it of caffeine, of which a given quantity of maté, as prepared for drinking, contains definitely less than a similar quantity of tea or coffee. It is less aromatic than either of these, and thus is, on all scores, less open to objection. See Seully, Brazil (London, 1886); Mansfield, Brazil (London, 1886); Christy, New Commercial Plants, No. 3 (London, 1886); Diez Huerfano, “Matera,” p. 128.

MATERA, a city of Basilicata, Italy, in the province of Potenza, from which it is 68 m. E. by road (13 m. S. of the station of Altamura), 1312 ft. above sea-level. Pop. (1901), 17,801.

It is built on a level plateau and part in deep valleys adjoining, the tops of the campaniles of the lower portions being on a level with the streets of the upper. The principal building is the cathedral of the archbishopric of Acerenza and Matera, formed in 1203 by the union of the two bishoprics, dating respectively from 300 and 398. The western façade of the cathedral in latter part is the utmost richness of decoration is lavished on the south front which faces the piazza. Almost in the centre of this south façade is an exquisitely sculptured window, from which letters from the Greek patriarch at Constantinople used to be read. The campanile is 175 ft. high. In the vicinity are the troglodyte caverns of Monte Scaglioso, still inhabited by some of the lower classes, and other caves with 13th-century frescoes.

Neolithic pottery has been found here, but the origin of the town is unknown. Norman-Sicilian style was a building of William Bras de Fer and his successors. It was the chief town of the Basilicata from 1664 till 1811, when the French transferred the administration to Potenza.

MATERIALISM (from Lat. materia, matter), in philosophy, the theory which regards all the facts of the universe as matters of fact, and particular explanations all psychical processes by physical and chemical changes in the nervous system. It is thus opposed both to natural realism and to idealism. For the natural realist stands upon the common-sense position that minds and material objects have equally effective existence; while the idealist explains matter by mind and denies that mind can be explained by matter. The various forms into which materialism may be classified correspond to the various causes which induce men to take materialistic views. Naïve materialism is due to a cause which, still, perhaps, has not fully died. In the natural difficulty which persons who have had no philosophical training experience in observing and appreciating the importance of the immaterial facts of consciousness. The pre-Socratists may be classed as naïve materialists in this sense; though, as at that early period the contrast between matter and spirit had not been fully realized and matter was credited with properties that belong to life, it is usual to apply the term hylozoism (q.v.) to the earliest stage of Greek metaphysical theory. It is not difficult to discern the influence of naïve materialism in contemporary thinking. We see it in Huxley, and more in Haeckel, whose materialism (which he chooses to term "monism") is evidently conditioned by ignorance of the history and present position of speculation. Cosmological materialism is that form of the doctrine in which the dominant motive is the formation of a comprehensive world-scheme: in anti-religious materialism the motive is hostility to established dogmas which are connected, in the Christian system especially, with certain forms of spiritual doctrine. Such a motive weighed much with Hobbes and with the French materialists of the 18th century, such as La Mettrie and d’Holbach. The cause of materialism is the natural bias of physicians towards explaining the health and disease of mind by the health and disease of their bodies, and this bias received its greatest support from the doctrine of insanity, which is now fully recognized as conditioned by disease of the brain. To this school belong Drs Maudsley and Mercier. The highest form of the doctrine is scientific materialism, by which term is meant the doctrine so commonly adopted by the physicist, zoologist and biologist.

It may perhaps be fairly said that materialism is at present a necessary methodological postulate of natural-scientific inquiry. The business of the scientist is to explain everything by the physical causes which are comparatively well understood and to exclude the interference of spiritual causes. It was the great work of Descartes to exclude rigorously from science all explanations which were not scientifically verifiable; and the prevalence of materialism at certain epochs, as in the enlightenment of the 18th century and in the German philosophy of the middle 19th, were occasioned by special need to vindicate the scientific position, in the former case against the Church, in the latter case against the pseudo-science of the Hegelian dialectic. The chief definite periods of materialism are the pre-Socratic and the post-Aristotelian in Greece, the 18th century in France, and in Germany the 19th century from about 1850 to the present time. In England materialism has been endemic, so to speak, from Hobbes to the present time, and English materialism is more important perhaps than that of any other country. But, from the national distrust of system, it has not been elaborated into a consistent metaphysic, but is rather traceable as a tendency harmonizing with the spirit of natural science. Hobbes, Locke, Hume, Mill and Herbert Spencer are not systematic materialists, but show tendencies towards materialism.

See Metaphysics; and Lange’s History of Materialism.

MATER MATUTA (connected with Lat. matutina, “morning”), an old Italian goddess of dawn. The idea of light being closely connected with childbirth, whereby the infant is brought into the light of the world, she came to be regarded as a double of Juno, and was identified by the Greeks with Eileithyia. Matuta had a temple in Rome in the Forum Boarium, where the festival of Matralia was celebrated on the 11th of June. Only married women were admitted, and none who had been married more than once were allowed to crown her image with garlands. Under these bellicose influences, she became a goddess of sea and harbours, the Ino-Leucothea of the Greeks. In this connexion it is noticeable that, as Ino tended her nephew Dionysus, so at the Materalia the participants prayed for the welfare of their nephews and nieces before that of their own children. The transformation was complete in 174 B.C., when Tiberius Sempronius Gracchus, after the conquest of Sardina, placed in the temple of Matuta a map commemorative of the campaign, containing a plan of the island and the various engagements. The progress of navigation and the association of divinities of the sky with maritime divinities were thus brought about, although the memory of her earlier function as a goddess of childbirth survived till imperial times.

Ovid, Fasti, vi. 475; Livy xii. 28; Plutarch, Questions romanæ, 16, 17.

MATHEMATICS (Gr. μαθηματικη, μαθηματικη, “learning” or “science”), the general term for the various applications of mathematical thought, the traditional field of which is number and quantity. It has been usual to define mathematics as "the science of discrete and continuous magnitude." Even Leibnitz, 1 who initiated the modern point of view, follows the tradition in thus confining the scope of mathematics properly so called, while apparently conceiving it as a department of a yet wider science of reasoning. A short

consideration of some leading topics of the science will exemplify both the plausibility and inadequacy of the above definition. Arithmetic, algebra, and the infinitesimal calculus, are sciences directly connected with integral numbers, rational (or fractional) numbers, and real numbers generally, which include incommensurable numbers. It would seem that "the general theory of discrete and continuous quantity" is the exact description of the topics of these sciences. Furthermore, can we not complete the circle of the mathematical sciences by adding geometry? Now geometry deals with points, lines, planes and cubic contents. Of these all except points are quantities: lines involve lengths, planes involve areas, and cubic contents involve volumes. Also, as the Cartesian geometry shows, all the relations between points can be expressed in terms of geometric quantities. Accordingly, at first sight it seems reasonable to define geometry in some such way as "the science of dimensional quantity." Thus every subdivision of mathematical science would appear to deal with quantity, and the definition of mathematics as "the science of quantity" would appear to be justified. We have now to consider the reasons for rejecting this definition as inadequate.

Types of Critical Questions.—What are numbers? We can have two apples and ten pears. But what are "five" and "ten" apples or pears? Also in addition to the cardinal numbers there are the ordinal numbers: the fifth apple and the tenth pear claim thought. What is the relation of "the fifth" and "the tenth" to "five" and "ten"? "The first rose of summer" and "the last rose of summer" are parallel phrases, yet one explicitly introduces an ordinal number and the other does not. Again, "half a foot" and "half a pound" are easily defined. But in what sense is there "a half," which is the same for "half a foot" as "half a pound"? Furthermore, incommensurable numbers are defined as the limits arrived at as the result of certain procedures with rational numbers. But how do we know that there is anything to reach? We must know that √2 exists before we can prove that any procedure will reach it. An expedition to the North Pole has nothing to reach unless the earth rotates.

Also in geometry, what is a point? The straightness line and the planeness of a plane require consideration. Furthermore, "congruence" is a difficulty. For when a triangle "moves," the points do not move with it. So what is it that keeps unified in the moving triangle? Thus the whole method of measurement in geometry is described in the elementary textbooks and the old treatises is obscure to the last degree. Lastly, what are "dimensions"? All these topics require thorough discussion before we can rest content with the definition of mathematics as the general science of magnitude; and by the time they are discussed the definition has evaporated. An outline of the modern answers to questions such as the above will now be given. A critical defence of them would require a volume.1

Cardinal Numbers.—A one-one relation between the members of two classes a and b is any method of correlating all the members of a to all the members of b, so that any member of a has one and only one correlate in b, and any member of b has one and only one correlate in a. A one-one relation implies that all those classes for which a one-one correlation with a exists. Thus the cardinal number of a is itself a class, and furthermore a is a member of it. For a one-one relation can be established between the members of a and b by the simple process of correlating each member of a with itself. Thus the cardinal number one is the class of unit classes, the cardinal number two is the class of doublets, and so on. Also a unit class is any class with the property that it possesses a member x such that, if y is any member of the class, then x and y are identical. A doublet is any class which possesses a member x such that the modified class formed by all the other members except x is a unit class. And so on for all the finite classes, which are to be defined inductively. The cardinal number zero is the class of classes with no members; but there is only one such class, namely the null class. Thus this cardinal number has only one member. The operations of addition and multiplication of two finite classes a and b, are defined by taking two classes a and b, satisfying the conditions (1) that their cardinal numbers are respectively the given numbers, and (2) that they contain no member in common, and then by defining for each of a and b two classes, respectively their classes of respective members in a and b, these classes are defined to be respectively the required sum and product of the cardinal numbers in question. We need not here consider the details of this process.

With these definitions it is now possible to prove the following six premises applying to finite cardinal numbers, from which Peano2 has shown that all arithmetic can be deduced:—

1. Cardinal numbers are zero and one.
2. Zero is a cardinal number.
3. If a is a cardinal number, a+1 is a cardinal number.
4. If s is any class and zero is a member of it, also if when x is a cardinal number, s and s+x are classes, then the whole class of cardinal numbers is contained in s.
5. If a and b are cardinal numbers, and a+1 = b+1, then a=b.
6. If a is a cardinal number, then a+1 ≠ 0.

It may be noticed that (iv) is the familiar principle of mathematical induction. Peano in an historical note refers its first explicit employment, although without a general enunciation, to Maurolycus in his work, Arithmeticorum libri duo (Venice, 1575).

But now the difficulty of confusing mathematics to being the science of number and quantity is immediately apparent. For there is no self-contained science of cardinal numbers. The proof of the premises requires an elaborate investigation into the general properties of classes, relations which are described by the strictest reasoning from our ultimate logical principles. Also it is purely arbitrary to erect the consequences of these six premises into a separate logical system. They express the properties of the highest value, but they are in no sense the necessary premisses which must be proved before any other propositions of cardinal numbers can be established. On the contrary, the premises of arithmetic can be put in other forms, and, furthermore, an indefinite number of propositions of arithmetic can be proved directly from logical principles without mentioning them. Thus, while arithmetic may be regarded as a branch of deductive reasoning concerning classes and relations which is independent of the establishment of propositions concerning cardinal numbers, it must be added that the introduction of cardinal numbers makes no great addition to the general principles of mathematics. It is no more than an interesting subdivision in a general theory.

Ordinal Numbers.—We must first understand what is meant by "an order is, by serial arrangement." An order of a set of things is to be sought in that relation holding between members of the set which constitutes that order. The set viewed as a class has many orders. Thus the telegraph posts along a certain road have a space-order very obvious to our senses; but they have also a time-order according to dates of erection, perhaps more important to the postal authorities who replace them after fixed intervals. A set of cardinal numbers have an order of magnitude, often called a serial order. For instance, if we number the set of integers according to the Peano series, we will have an order of magnitude of our cardinal numbers, and if we number the integers 1, 2, 3, ... then if two numbers a and b are a and b, then a=b.

With these ideas it is now possible to define the relations of preceding and succeeding, and thereby establish the following six premises concerning orders and relations which are essential in the statement of the definitions of ordinals and in the proofs of their properties. The reference of the premises to the cardinal numbers is indicated by the common reference of "any members" to "any numbers." The conditions are arranged in the order in which they are necessary.

1. If x has the relation R to y, x is between y and a; (2) It is transitive, so that if x has the relation R to y, and y to z, then x has the relation R to z. (3) It has the property "succession" (i.e. if x has the relation R to y, then in all such cases x has the relation R' to y', and conversely, interchanging the dashes on the letters, R, R', x, and y). (4) Finally, it is evident that the ordinal similarity of two relations implies the cardinal similarity of their fields, but not conversely. Also, two relations need not be identical in order to be ordinally similar; but if one is serial, so is the other. The relation of a relation is the class whose members are those relations which are serially similar to the original relation in that they include the original relation itself. The relation of a relation should be compared with the cardinal number of a class. When a relation is serial its relation is often called its serial type. The addition and multiplication of two on-numbers is defined by taking two relations R and S, such that (1) their fields have no

2 Cf. Formulario mathematico (Turin, ed. of 1903); earlier formulations of the bases of arithmetic are given in the editions of 1808 and of 1901. The variations are only trivial.
Thus left

**Contor's Infinite Numbers.**—Owing to the correspondence between the finite cardinals and the finite ordinals, the propositions of cardinal-arithmetic are transferred to ordinal arithmetic by the following method. The definition of the cardinal number of a class applies when the class is not finite, and it can be proved that there are different infinite cardinal numbers, and that there is a least infinite cardinal number, denoted by , which corresponds to the letter . Similarly, a class of serial relations, called well-ordered serial relations, can be defined, such that their corresponding relation-numbers include the ordinals, and also indicate the potential priority of cardinal relations over ordinal relations. Hence, the union of the finite ordinals, the fields of the relations belonging to them are not finite. These relation-numbers are not the infinite numbers of the class of serial relations, but the algebraic of the infinite ordinals do not correspond to that of the infinite ordinals. The theory of these extensions of the ideas of number is dealt with in the article NUMBER. It will suffice to mention here that Peano's fourth premiss of arithmetic do not hold for infinite cardinals or for infinitesimals. Consider, for instance, the addition of the number 0 on the number line, where the points represent the number, and the line is the real number. The addition of the number 0 to the number line has the effect that every point on the line represents a number that is one unit greater than the corresponding point on the original line. This is the definition of addition in arithmetic, and it is valid for all points on the line. Similarly, the addition of the number 0 to the number line has the effect that every point on the line represents a number that is one unit greater than the corresponding point on the original line. This is the definition of addition in arithmetic, and it is valid for all points on the line. However, in arithmetic, the addition of the number 0 to the number line has the effect that every point on the line represents a number that is one unit greater than the corresponding point on the original line. This is the definition of addition in arithmetic, and it is valid for all points on the line.
of classes and relations from the ultimate logical premises. In the
course of this process, undertaken for the first time with the rigour of
mathematical logic, all mathematical contradictions became
eliminated. That first discovered is known as Burali-Forti's contradiction, and
consists in the proof that there both is and is not a greatest
infinite ordinal number. But these contradictions do not depend upon
and are not traceable to Russel's discovery of the character of a set,
number in any form. This contradiction arises from considering
the class possessing as members all classes which are not members of
themselves. It will be observed that this is equivalent to saying that \( x \) is
not \( x \). Accordingly, to say that \( y \) is
a \( y \) is equivalent to saying that \( w \) is not a \( w \). An analogous contradiction can be found for relations. It follows that a careful
evaluation of the theory of classes and relations is required. Note that
classes are here required in extension, so that the class of
human beings and the class of rational featherless bipeds are identical;
similarly for relations, which are to be determined by the end
result only and not by the means by which they are arrived at.
In what sense then can it be one? This problem of "the one and
the many" has been discussed continuously by the philosophers. All
the contradictions can be avoided, and yet the use of classes and
relations can be preserved as required by mathematics, and indeed
by common sense, by a theory which denies to a class—or relation—
existence or being in any sense in which the entities composing it—or related by it—exist. Thus, to say that a pen is an entity and the
class of pens is an entity is merely a play upon the word "entity". The
second sense of "entity" (if any) is indeed derived from the first, but has a more complex significance. Consider an incomplete
process, in which the sense in which an entity which
is to be involved in it is represented by an undetermined \( x \), which may
stand for any entity. Call it a propositional function; and, if \( x \) be
assigned to it, the propositional function becomes an
argument. Two propositional functions \( \phi \) and \( \gamma \) are extending
identical if any determination of \( x \) in \( \phi \) which converts \( \phi \) into a true
proposition also converts \( \gamma \) into a true proposition, and conversely for \( \phi \) and \( \gamma \). Now consider a propositional function in
which the variable argument \( \chi \) is itself a propositional function.
If \( F \) is true when, and only when, \( \chi \) is determined to be either \( \phi \) or something other, the
proposition \( F \) is of the form which is ordinaril recognized
as being about the class determined by \( \phi \) taken in extension—that is,
the class of entities for which \( \phi \) is a true proposition when \( \chi \) is
determined to be \( \phi \) by itself holds for solutions
which arise from the consideration of propositional functions with
two or more variable arguments. It is then possible to
by a parallel elaboration what is meant by classes of classes,
classes of relations, relations between classes, and so on. Accord-
ingly, the number of a class of relations can be defined, or of a class of
classes, and so on. This theory is in effect a theory of the use
of classes and relations, and does not decide the philosophic question
as to the sense (if any) in which a class in extension is one entity.
It does indeed say that it is an entity in the sense in which one of
its members is an entity. Accordingly, it is a fallacy for any
distributor of \( x \) to state that \( x \) is an \( x \) for \( x \) having the meaning of propositions. Note that for any
determination of \( x \), \( x \) is an \( x \) and \( x \) is not an \( x \), are neither of them
fallacies but are actually meaningless, according to this theory. Thus
Russell has found a way of attacking the question by examination of the other contradictions which shows that they vanish also.

Applied Mathematics. The selection of the topics of mathe-
matical inquiry among the infinite variety open to it has been
guided by the useful applications, and indeed the abstract theory
has only recently been disentangled from the empirical elements
connected with these applications. For example, the application
of the theory of cardinal numbers to classes of physical events
involves in practice some process of counting. It is only recently
that the succession of processes which is involved in any act of
counting has been seen to be irrelevant to the idea of number.
Indeed, it is only by experience that we can know that any
definite process of counting will give the true cardinal number
of some class of entities. It is important to imagine a universe in which any act of counting by a being in it annihilated
some members of the class during the time and only counting the
survivors of the class. Thus, it is necessary to transpose the work of
Nicesa illustrates this point: "When the Bishops took their

places on their thrones, they were 318; when they rose up to be
called over, it appeared that they were 319; so that they never
could make the number come right, and whenever they approached
the last of the series, he immediately turned into the likeness of
his next neighbour. Whatever be the historical worth of this
cry, it cannot safely be said that it cannot be disproved by a
little reasoning from the premises of abstract logic. The most
we can do is to assert that a universe in which such things are
liable to happen on a large scale is unfitted for the practical
application of the theory of cardinal numbers. The application
of the theory of real numbers to physical quantities involves
analogous considerations. In the first place, some physical
process of addition is presupposed, involving some inductively
law of permanence during that process. Thus in the
theory of mass we must know that two pounds of lead when
put together will counterbalance in the scales two pounds of
sugar, or a pound of lead and a pound of sugar. Furthermore,
the sort of continuity of the series (in order of magnitude) of
rational numbers is known to be different from that of the series
of real numbers. Indeed, mathematicians now reserve "con-
 tinuity" as the term for the latter kind of continuity; the mere
property of having an infinite number of terms between any two
terms is called "compactness." The compactness of the series
of rational numbers is consistent with quasi-gaps in it—that is,
with the possible absence of limits to classes in it. Thus the
class of rational numbers would be vacuous if there are any
less than \( x \) has to the upper limit among the rational numbers. But among the
real numbers all classes have limits. Now, owing to the neces-
sary imprecision of measurement, it is impossible to discriminate
directly whether any kind of continuous physical quantity
possesses the compactness of the series of rationals or the contin-
uiety of the series of real numbers. In calculations the latter
assumption is made because of its mathematical simplicity. But,
the assumption has certainly no a priori grounds in its favour.
and it is not very easy to see how to base it upon experience.
It is possible that if it is to be supported at all, it can be
be estimated by counting the number of corpuscles (whatever
they may be) which go to form it, then a body with an irrational
measure is intrinsically impossible. Similarly, the
continuity of space apparently rests upon sheer assumption
unsupported by any a priori or experimental grounds. Thus
the current applications of mathematics to the analysis of
phenomena can be justified by no a priori necessity.

In one sense there is no science of applied mathematics. When once the fixed conditions which any hypothetical group
of entities may be subject to have been established, and the
deduction of the further propositions, which also hold respec-
ting them, can proceed in complete independence of the question
as to whether or no any such group of entities can be found in
the world of phenomena. Thus rational mechanics, based on
the Newtonian Laws, viewed as mathematics is independent
of its supposed application, and hydrodynamics remains a coherent
and respected science though it is extremely improbable that
any perfect fluid exists in the physical world. But this unend-

ingly small point of view cannot be the last word upon the
matter. For no one can doubt the essential difference between
characteristic treatises upon "pure" and "applied" mathematics.
The difference is a difference in method. In pure mathematics
the propositions which a set of entities are to satisfy are given, and
a group of interesting deductions are sought. In "applied
mathematics" the "deductions" are given in the shape of
the experimental evidence of natural science, and the
hypotheses from which the "deductions" can be deduced are sought.
Accordingly, every treatise on applied mathematics, properly
so-called, is directed to the criticism of the "laws" from which
the reasoning starts, or to a suggestion of results which experi-
ment may hope to find. Thus if it calculates the result of some
experiment, it is not the experimentalist's well-attested results
which are on their trial, but the basis of the calculation.
Newton's Hypotheses non fingo was a proud boast, but it rests
upon an entire misconception of the capacities of the mind
in dealing with external nature.
Synopsis of Existing Developments of Pure Mathematics.—A complete classification of mathematical sciences, as they at present exist, is to be found in the International Catalogue of Scientific Literature published by the British Society for the Advancement of Science. It was drawn up by an international committee of eminent mathematicians, and thus has the highest authority. It would be unfair to criticize it from an exacting philosophical point of view. The present writer, in any case, is not at all concerned with the quantity of yearly output in the various branches, and that the liability of various topics as a matter of fact to occur in connexion with each other, should modify the classification. Under the general heading "Fundamental Notions" occur the subheadings "Foundations of Arithmetic," with the topics rational, irrational and transcendingal numbers, and others; "Algebra," with the topics complex numbers, quaternions, ausdehnungslehre, vector analysis, matrices, and algebra of logic; and "Theory of Groups," with the topics finite and continuous groups. For the subjects of the latter two, see the subheadings "Group Theory; DF: Infnitesimal Calculus; Number; Quaternions; Vector Analysis." Under the general heading "Algebra and Theory of Numbers," occur the subheadings "Elements of Algebra," with the topics rational polynomials, permutations, &c., partitions, probabilities; "Linear Substitutions," with the topics determinants, &c., linear substitutions, general theory of quanties; "Theory of Algebra," with the topics arrangement, elimination, transformation of and approximation to, theory of Galois, &c., "Theory of Numbers," with the topics congruences, quadratic residues, prime numbers, particular irrational and transcendental numbers. For the algebraic sciences, including see also the heads "Algebraic Forms; Arithmetic; Combinatorial Analysis; Determinants; Equations; Fraction, Continued; Interpolation; Logarithms; Moduli; Probability," etc. In the "analysis," the general heading "Analysis" occur the subheadings "Foundations of Analysis," with the topics theory of functions of real variables, series and other infinite processes, principles and elements of the differential and of the integral calculus, definite and indefinite integrals, etc. For the subheadings see also the heads "Theory of Functions of Complex Variables," with the topics functions of one variable and of several variables; "Algebraic Functions and Their Integrals," with the topics algebraic functions of one or more variables, elliptic functions and theta functions, Abelian integrals; "Other Special Functions," with the topics Euler's, Legendre's, Bessel's, and autonomic functions; "Mechanical and Physical Functions," with the topics existing, absolute, relative, with symbolical, methods of solution, general theory; "Differential Forms and Differential Invariants," with the topics differential forms, including 1-forms, transformation of differential forms, including tangential (or contact) transformations, differential invariants; "Analytical Methods connected with Physical Subjects," with the topics harmonic analysis, Fourier's series, the differential equations of applied mathematics, Dirichlet's problem, "Difference Equations and Functions," with the topics difference, sum, and product of the general algebraic, and of other series, equations of difference, equations of infinite differences and functional equations. For the subjects of this heading see the articles DIFFERENTIAL EQUATIONS, CONDUCTION, DIFFUSION, PROBABILITY, FUNCTION OF REAL VARIABLES; FUNCTION COMPLEX; GROUPS, THEORY OF; INFSNITESIMAL CALCULUS; MAXIMA AND MINIMA; SERIES; SPHERICAL HARMONICS; TRIGONOMETRY; VARIATIONS, C. Of the latter two, see also the general heading "Geometry," the subheadings "Foundations," with the topics principles of geometry, non-Euclidean geometries, hypertopes, methods of analytical geometry, "Surveyary Geometry," with the topics planimetry, stereometry, trigonometry, descriptive geometry; "Geometry of Conics and Quadrics," with the implicit topics; "Algebraic Curves and Surfaces of Degree higher than the Second," with the implicit topics; "Transformations and General Methods for figuring," with the topics collineation, duality, transformations, correspondence, groups of points on algebraic curves and surfaces, genus of curves and surfaces, enumerative geometry, conics, quadrics, surfaces of the third degree, etc., etc., "figurations in hyperspace; "Infsnitesimal Geometry; applications of Differential and Integral Calculus to Geometry," with the topics kinematic geometry, curvature, rectification and quadrature, special transcendental curves and surfaces; "Differential Geometry; applications of Differential Equations to Geometry," with the topics curves on surfaces, minimal surfaces, surfaces determined by differential properties, conformal and other representation of surfaces on others, deformation of surfaces, orthogonal and isometric surfaces. For the subjects under this heading see the articles CURVATURE, CURVATURE LINE, CURVATURE TENSOR, CURVATURE TENSORS, GEOMETRY, AXIOMS OF; GEOMETRY, EUCLIDEAN; GEOMETRY, PROJECTIVE; GEOMETRY, ANALYTICAL; GEOMETRY, LINc.; KNOTS, MATHEMATICAL THEOREY OF; MENSURATION; MODELS; PROJECTIONS, GEOMETRY, SYMMETRIC, GEOMETRY. This survey of the existing developments of pure mathematics confirms the conclusions arrived at from the previous survey of the theoretical principles of the subject. Functions, operations, transformations, correspondences, are lost names for various types of relations. A group is a class of relations possessing a special property. Thus the modern ideas, which have so powerfully extended and unified the subject, have loosed their connexion with number and "quantity," while bringing ideas of form into the subject. A subject, however, must indeed ever remain the great topic of mathematical interest, as it is in reality the great topic of applied mathematics. All the world, including savages who cannot count beyond five, daily "apply" to it. The progress of the human species is practically illustrated by the fact that it is best studied as a department of a science wider than itself. 

Synopsis of Existing Developments of Applied Mathematics.—Section 2 of the International Catalogue deals with mechanics. The heading "Measurement of Dynamical Quantities" includes the topics units, measurements, and the constant of gravitation. The topics of this head are: "Geometry and Kinematics of Particles and Solid Bodies"; "Principles of Rational Mechanics"; "Statics of Particles, Rigid Bodies, etc."; "Kinetics of Particles, Rigid Bodies, etc."; "General Analytical Mechanics"; "Statics and Dynamics of Fluids"; "Hydraulics and Fluid Resistances"; "Elasticity." For the subjects of this general heading see the articles MECHANICS; DYNAMICAL; PYROSCOPE; HARMONIC ANALYSIS; WAVE, HYDROMECHE; ELASTICITY; METRON, LAW OF; ENERGY; ENERGETICS; ASTRONOMY (Celestial Mechanics); TIDE. Mechanics (including dynamical astronomy) is that subject among those "applied" which is the most significant. The whole has been mentioned in "applied" mechanics—mathematics—that is to say, which is studied with the deductive spirit of the pure mathematician, and not with the covert inductive intention overlaid with the superficial forms of descriptive applications which dominate the modern development of the "applied" sciences. Every branch of physics gives rise to an application of mathematics. A prophecy may be hazarded that in the future these applications will dominate the mathematical literature. For such an application of mathematics to a hypothetical substraction of the universe, uniform under all the diverse phenomena. This reflection is suggested by the following articles: AETHER; MOLECULE; CAPILLARY ACTION; DIFFUSION; DECAYATION; REACTION.
MATHER, COTTON

and of heat, were now largely developed. This school of mathematical thought lasted beyond the middle of the century, after which a change and further development can be traced. In the next and last period the progress of pure mathematics has been dominated by the critical spirit introduced by the German mathematicians under the guidance of Leibniz, who was characterized by his ideas, such as Abel. Also such ideas as those of invariants, groups and of form, have modified the entire science. But the progress in all directions has been too rapid to admit of any one adequate characterization. During the same period a brilliant group of mathematical physicists, notably Lord Kelvin (W. Thomson), H. V. Helmholtz, J. C. Maxwell, H. Hertz, have transformed applied mathematics by systematically basing their deductions upon the Law of the conservation of energy, and the hypothesis of an ether pervading space.

BIBLIOGRAPHY.—References to the wording and meaning of the various branches of mathematics are given in the appropriate articles. It must suffice here to refer to sources in which the subject is considered as one whole. Most philosophers refer in their works to mathematics rather than particular statements in the ideas of number and magnitude, or in their consideration of the alleged a priori and necessary truths. A bibliography of such references would be in effect a bibliography of metaphysics, or rather, perhaps, of the found. In modern philosophy, as explained in this article, was Leibniz, who, however, was so far in advance of contemporary thought that his ideas remained neglected and undeveloped until recently; cf. Oeuvres de fragments inédits de Leibniz, by A. de la Gorce (Paris, 1718), and his retranslated in English under the title Essays on the Theory of Numbers (Chicago, 1901). These works of G. Cantor and Dedekind were in the last years of philosophy. Also of G. Peano (with various collaborators of the Italian school), Formulaire de mathématique (Turin, various editions, 1908-1910; the earlier editions are the more interesting philosophically); Field, The Foundations of Science (New York, 1911); Clifford, The Common Sense of the exact Sciences (London, 1888); H. Poincaré, La Science et l'Hypothèse (Paris, 1st ed., 1902), English translation under the title, Science and Hypothesis (London, 1905); L. Couturat, Les Principes des mathématiques (Paris, 1903); E. Mach, Die Mechanik in ihrer Entwickelung (Prague, 1885), English translation under the title, The Science of Mechanics (London, 1893); K. Pearson, The Grammar of Science (London, 1st ed., 1892; 2nd ed., 1900, enlarged); A. Cayley, Presidential Address (Brit. Assoc., 1881); B. Russell and A. N. Whitehead, Principia Mathematica (Cambridge, 1911). For the history of mathematics the one complete and complete source is M. Cantor's Vorlesungen über Geschichte der Mathematik (Leipzig, 1st Bd., 1880; 2nd Bd., 1892; 3rd Bd., 1898; 4th Bd., 1908; 1st Bd., von den dritten Zeiten bis zum Jahre 1200. K. Hatt, Geschichte der Mathematik, 2 vols. (Leipzig, vol. 1650-1758; 4th part); W. R. Ball, A Short History of Mathematics (London 1st ed., 1888, 3 subsequent editions, enlarged and revised, and translated into French and Italian. (A. N. W.)

MATHER, COTTON (1665–1728), American Congregational clergyman and author, was born in Boston, Massachusetts, on May 13, 1665. He was the son of Richard Mather, and the eldest child of Cotton Mather, the celebrated divine. His mother was Maria, daughter of John Cotton. After studying under the famous Ezekiel Cheever (1614–1708), he entered Harvard College at twelve, and graduated in 1678. While teaching (1678–1685), he began the study of theology, but soon, on account of an impediment in his speech, discontinued it and took up medicine. Later, however, he conquered the difficulty and finished his preparation for the ministry. He was elected assistant pastor in his father's church, the North, or Second, Church of Boston, in 1681 and was ordained as his father's colleague in 1685. In 1688, when his father went to England as agent for the colony, he was left at twenty-five in charge of the largest congregation in New England, and he ministered to it for the rest of his life. He soon became one of the most influential men in the colonies. He had much to do with the witchcraft case of Salem; in 1692 when the magistrates appealed to the Boston clergy for advice in regard to the witchcraft cases in Salem he drafted their reply, upon which the prosecutions were based; in 1690 he had written Memorable Providences Relating to Witchcraft and Possessions, and even his earlier diaries have many entries showing his belief in diabolical possession and his fear and hatred of it. Thinking as he did that the New World had been the undisturbed realm of Satan before the settlements were made in Massachusetts, he considered it natural that the Devil should make a peculiar effort to bring moral destruction on these godly invaders. He used prayer and fasting to deliver himself from evil entanglement; and when he saw ecstatic and mystical visions promising him the Lord's help and great usefulness in the Lord's work, he feared that these revelations might be of diabolical origin. He used his great influence to bring the suspected persons to trial and punishment. He attended the trials, investigated many of the cases himself, and wrote sermons on witchcraft, the Memorable Providences and The Wonders of the Invisible World (1703), which increased the excitement of the people. Accordingly, when the prosecutions ceased and the reaction set in, much of the blame was laid upon him; the influence of Judge Samuel Sewall, after he had come to think his part in the Salem delusion a great mistake, was turned against the Mathers; and the liberal leaders of Congregationalism in Boston, notably the Brattleys, found a this vulnerable point in Cotton Mather's armour and used their knowledge to much effect, notably by assisting Robert Calef (d. c. 1723) in the preparation of More Wonders of the Invisible World (1700) a most useful criticism of Cotton Mather's part in the delusion at Salem.

Mather took some part as adviser in the Revolution of 1689 in Massachusetts. In 1690 he became a member of the Corporation (probably the youngest ever chosen as Fellow) of Harvard College, and in 1707 he was greatly disappointed at his failure to be chosen president of that institution. He received the degree of D.D. from the University of Glasgow in 1710, and in 1713 was made a Fellow of the Royal Society. Like his father he was deeply gripped by the liberal theology and Church polity of the new Brattle Street Congregationalists, and opposed his pastor Benjamin Colman, who had been irregularly ordained in England and by a Presbyterian body; but with his father he took part in 1700 in services in Colman's church. Harvard College was now controlled by the Liberals of the Brattle Street Church, and as it grew farther and farther away from Calvinism, Mather looked with increasing favour upon the college in Connecticut; before September 1701 he had drawn up a scheme for a college," which the oldest document now in the Yale archives; and finally (Jan. 1718) he wrote to a London merchant, Elihu Yale, and persuaded him to make a liberal gift to the college, which was named in his honour. During the smallpox epidemic of 1721 he attempted in vain to have treatment by inoculation employed, for the first time in America; and for this he was bitterly attacked on all sides, and his life was at one time in danger; but, nevertheless, he used the treatment on his son, who recovered, and he wrote An Account of the Method and further Success of Inoculating for the Small Pox in London (1721). In addition he advocated temperance, missions, Bible societies, and the education of the negro; favoured the establishing of libraries for working men and of religious organizations for young people, and organized societies for other branches of philanthropic work. His later years were clouded with many sorrows and disappointments; his relations with Governor Joseph Dudley were unfriendly; he lost much of his former prestige in the Church—his own congregation dwindled—and in the college; his uncle John Cotton was expelled from his
MATHER, INCREASE

charge in the Plymouth Church; his son Increase turned out a ne'er-do-well; four of his children and his second wife died in November 1713; his wife's brothers and the husbands of his sisters were ungodly and violent men; his favourite daughter Katherine, who "understood Latin and read Hebrew fluently," died in 1716; his third wife went mad in 1719; his personal enemies circulated incredible scandals about him; and in 1724–1725 he saw a Liberal once more preferred to him as a new president of Harvard. He died in Boston on the 13th of February 1728 and is buried in the Copp's Hill burial-ground, Boston. He married (d. 1676) his first wife, the Rev. Mr. chocolate (1676), and in 1715 to Mrs Lydia George (d. 1734). Of his fifteen children only two survived him.

Though self-conscious and vain, Cotton Mather had on the whole a noble character. He believed strongly in the power of prayer and repeatedly had assurances that his prayers were heard; and when he was disappointed by non-fulfilment of his grief and depression were terrible. His spiritual nature was high-strung and delicate; and this condition was aggravated by his constant study, his huge fashions and his frequent outbursts of anger, according to his diary, he kept sixty fasts and twenty vigils. In his later years his diaries have less and less of personal detail, and repeated entries prefaced by the letters "G.D." meaning Good Device, embodying precepts of kindliness and practical Christianity. He was remarkable for his godliness, his enthusiasm for knowledge, and his prodigious memory. He became a skilled linguist, a widely read scholar—though much of his learning was more curious than useful—a powerful preacher, a valued citizen, and a voluminous writer, and did a valuable work for the intellectual and spiritual quelling of New England. He worked with might and main for the continuation of the old theocracy, but before he died it had given way before an increasing Liberalism—even Yale was infected with the Episcopalianism that he hated.

Among his four hundred or more published works, many of which are sermons, tracts and letters, the most notable is his *Magnalia Christi Americana; or the Ecclesiastical History of New England, from Its First Planting in the Year 1605 unto the Year of Our Lord, 1698.* Begun in 1659 and finished in 1697, this work was published in London, in 1702, in one volume, and was republished in Hartford in 1829 and in 1853-1855, in two volumes. It is in seven books and is a historical record of the settlement and religious history of New England. It is often inaccurate, and it abounds in far-fetched conceits and odd and pragmatic features. Its style, though, in the natural and the artificial, it is consistent, dignified and rhetorical; the book is valuable for its facts and its pictures of the times, and it did much to make Mather the most eminent American writer of his day. Other works include: *A Poem Dedicated to the Memory of the Reverend and Excellent Mr Uriah Oakes (1662); The Present State of New England (1690); The Life of the Renowned John Eliot (1691),* later included in Book III. of the *Magnalia; The Short History of New England (1694); Bonificosis,* usually believed as *Essays To Do Good* (Boston, 1710; Glasgow, 1825; Boston, 1843), one of his principal books and one which had a shaping influence on the life of Benjamin Franklin; *Psallierum Americanum* (1718), a blank verse translation of the Psalms from the original Hebrew; *The Christian Philosopher: A Collection of the Best Discoveries in Nature, with Religious Improvements* (1721); *Parentator* (1724), a memoir of his father; *Routa Disciplinae* (1656); an account of the Discipline in New England churches; *Manulectio ad Ministerium: Directions for a Candidate of the Ministry,* one of the most readable of his books. He also left a number of works in manuscript, including diaries, a medical treatise and a huge commentary on the Bible, entitled *Biblia Americana.*

Cotton Mather's son, Samuel Mather (1706-1785), also a clergyman, graduated at Harvard in 1723, was pastor of the North Church, Boston, from 1732 to 1742, when, owing to a dispute among his congregation over revivals, he resigned to take charge of a church established for him in North Bennett Street.

Among his works are *The Life of Cotton Mather* (1729); *An Apology for the Liberties of the Churches in New England* (1738), and *America Invitam to the Ancients* (1773). (W. L. C.)

MATHER, INCREASE (1639-1723), American Congregational minister, was born in Dorchester, Massachusetts, on the 21st of June 1639, the youngest son of Richard Mather. He entered Harvard in 1651, and graduated in 1656. On his eighteenth birthday, he preached his first sermon; in the same year he went to visit his eldest brother in Dublin, and studied there at Trinity College, where he graduated M.A. in 1658. He was chaplain to the English garrison at Guernsey in April–December 1659 and again in 1661; and in the latter year, refusing valuable livings in England offered on condition of conformity, he returned to America. In the winter of 1661–1662 he began to preach to the Second (or North) Church of Boston, and was ordained there on the 27th of May 1664. As the learned Cotton Mather, his father's church, died in 1662, he opposed the Half-Way Covenant adopted by the Synod and defended by Richard Mather and by Jonathan Mitchell (1624-1668) of Cambridge; but soon afterwards he "surrendered a glad captive" to "the truth so victoriously cleared by Mr Mitchell," and like his father and his son became one of the chief exponents of the Half-Way Covenant. He was bitterly opposed, however, to the liberal practices that followed the Half-Way Covenant and (after 1677) in particular to the "Stoddardianism," the doctrine of Solomon Stoddard (1645-1729) that all "such Persons as have a good Conversation and a Competent Knowledge may, come to the Lord's Supper," only those of openly immoral life being excluded. In May 1679 Mather was a petitioner to the General Court for the call of a Synod to consider the reformation in New England of "the Evils that have Provoked the Lord to bring his Judgments," and when the "Reforming Synod" met in September it appointed him one of a committee to draft a creed; this committee reported in May 1680, at the Synod's second session, of which Mather was moderator, the Savoy Declaration (slightly modified, especially in the Civil Magistrate), which was approved but was not made mandatory on the churches by the General Court, and in 1708 was reaffirmed at Saybrook, Connecticut. With the Cambridge Platform of 1646, drafted by his father, the Confession of 1680, for which Increase Mather was largely responsible, was printed as a book of doctrine and government for the churches of Massachusetts.

After the threat of a *Quo Vadis* writ in 1683 for the surrender of the Massachusetts charter, Mather used all his tremendous influence to persuade the colonists not to give up the charter; and the Boston freemen unanimously voted against submission. The royal agents immediately afterwards sent to London a treasonable letter, falsely attributed to Mather; but its spuriousness seems to have been suspected in England and Mather was not "fetch'd over and made a Sacrifice." He became a leader in the opposition to Sir Edmund Andros, to his secretary Edward Randolph, and to Governor Joseph Dudley. He was chosen by the General Court to represent the colony's interests in England, eluded officers sent to arrest him, and in disguise boarded a ship on which he reached Weymouth on the 6th of May 1688. In London he acted with Sir Henry Ashurst, the resident agent, and had two or
three fruitless audiences with James II. His first audience with William III. was on the 9th of January 1689; he was active in influencing the Commons to vote (1689) that the New England charters should be restored; and he published A Narrative of the Miseries of New-England, By Reason of an Arbitrary Government Erected there Under Sir Edmund Andros (1688), A Brief Relation for the Confirmation of Charter Privileges (1691), and other pamphlets. In 1690 he was joined by Elisha Cooke (1638–1715) and Thomas Oakes (1644–1719), additional agents, who were uncompromisingly for the renewal of the old charter. Mather, however, was instrumental in securing a new charter (signed on Oct. 7, 1691), and prevented the annexation of the Plymouth Colony to New York. The nomination of officers left to the Crown was reserved to the agents. Mather had expressed strong dissatisfaction with the clause giving the governor the right of veto, and regretted the less theocratic tone of the charter which made all freemen (and not merely church members) electors. With Sir William Phips, the new governor, a member of Mather's church, he arrived in Boston on the 14th of May 1692. The value of his services to the colony at this time is not easily over-estimated. In England he won the friendship of divines like Baxter, Tillotson and Hillis, and gave them precious suggestions in their controversies with the Presbyterians and Congregationalists. He was at heart an expense throughout his stay, and even greater than his financial loss was his loss of authority and control in the church and in Harvard College because of his absence.

Mather had been acting president of Harvard College in 1681–1682, and in June 1685 he again became acting president (or rector), but still preached every Sunday in Boston and would not comply with an order of the General Court that he should reside in Cambridge. In 1701 after a short residence there he returned to Boston and wrote to the General Court to "think of another President for the College." The opposition to him had been increasing in strength, his resignation was accepted, and Samuel Willard took charge of the college as vice-president, although he also refused to reside in Cambridge. That Mather's administration of the college was excellent is admitted even by his harsh critic, Josiah Quincy, in his History of Harvard University. 1 The Liberal party, which now came into control in the college repeatedly disappointed the hopes of Cotton Mather (q.v.) that he might be chosen president, and by its ecclesiastical laxness and its broader views of Church policy forced the Mathers to turn from Harvard to Yale as a truer school of the prophets.

The Liberal leaders, John Leverett (1662–1724), William Brattle (1662–1713)—who graduated with Leverett in 1680, and with him as tutor controlled the college during Increase Mather's absence in England—William Brattle's eldest brother, Thomas Brattle (1658–1713), and Ebenezer Pemberton (1671–1717), pastor of the Old South Church, desired an "enrichment of the service," and greater liberality in the matter of baptism. In 1687 the Second Boston Church, in which Cotton Mather had been his father's colleague since 1663, upbraided the Charlestown Church "for bowing the liberties of the churches in their late putting into the hands of the whole inhabitants the choice of a minister." In 1690 Increase Mather published The Order of the Gospel, which severely (although indirectly) criticized the methods of the "Liberals" in establishing the Brattle Street Church and especially the ordination of their minister Benjamin Colman by a Presbyterian body in London; the Liberals replied with The Gospel Order Revised, which was printed in New York to lend colour to the (partly true) charge of its authors that the printers of Massachusetts would print nothing hostile to Increase Mather. 2 The autocracy of the Mathers in church, college, colony and press, had slipped from them. The later years of Mather's life were spent almost entirely in the work of the ministry, now beginning to be a less varied career than when he entered on it. He died on the 23rd of August 1723. He married in 1662 Maria, daughter of Sarah and John Cotton. His first wife died in 1714; and in 1715 he married Ann Lake, widow of John Cotton, of Hampton, N.H., a grandson of John Cotton of Boston.

Increase Mather was a great preacher with a simple style and a splendid voice, which had a "Tontious Cogency," to quote his son's phrase. His style was more simple and more vernacular than his son's. He was an assiduous student, commonly spending sixteen hours a day at his books. He owed his learning (to quote Justin Winsor's contrast between Increase and Cotton Mather) "usually left his natural ability and his education free from entanglements." He was not so much self-seeking and personally ambitious as eager to advance the cause of the church in which he so implicitly believed. That it is a mistake to consider him a narrow churchman is shown by his assisting in 1718 at the ordination of Elisha Callender in the First Baptist Church of Boston. Like the most learned of divines of his time he was a believer in "pragmatical impressions"; his Essay on the Records of Illustrious Providences: Wherein an Account is Given of many Remarkable and very Memorable Events which have Happened in this Last Age, Especially in New England (1684) shows that he believed only less thoroughly than his son in witchcraft, though in his Cases of Conscience Concerning Evil Spirits (1663) he considered some current proofs of witchcraft inadequate. The revulsion of feeling after the witchcraft delusion undermined his authority greatly, and Robert's Catechism's More Wonders of the Invisible World (1690) was a personal blow to him as well as to his son. With Jonathan Edwards, than whom he was much more of a man of affairs, and with Benjamin Franklin, whose mission in England somewhat resembled Mather's, he may be ranked among the greatest Americans of the period before the War of Independence.

The first authority for the life of Increase Mather is the work of his son Cotton Mather, Parentator: Memoirs of Remarkables in the Life and Death of the Ener Memorable Dr Increase Mather (Boston, 1724); there are also a memoir and constant references in Cotton Mather's Magnalia (London, 1702) especially vol. iv.; there is an excellent sketch in the first volume of J. L. Sibley's Biographical Sketches of Graduates of Harvard University (Cambridge 1873); there is an exhaustive list of Mather's works (about 150 titles); there is much valuable matter in Williston Walker's Ten New England Authors (New York, 1901) and in his Creeds and Platforms of Congregationalism (New York, 1903). Also see ch. xii. of M. C. Tyler's History of American Literature, 1607–1776 (New York, 1878), and Barrett Wendell's Cotton Mather (New York, 1873). Mather's worth has been under-estimated by Josiah Quincy, Justin Winsor and other historians out of sympathy with his ecclesiastical spirit, who represent him as only an ambitious narrow-minded schemer.

Mather, Richard (1596–1666), American Congregational clergyman, was born in lowton, in the parish of Winwick, near Liverpool, England, of a family which was in reduced circumstances but entitled to bear a coat-of-arms. He studied at a free grammar school. When he was a boy he was appointed a master in his fifteenth year, and left it in 1612 to become master of a newly established school at Tuxthet Park, Liverpool. After a few months at Brasenose College, Oxford, he began in November 1618 to preach at Tuxthet, and was ordained there, possibly only as deacon, early in 1619. In August–November 1633 he was suspended for nonconformity in matters of ceremony; and in 1634 was again suspended by the visitors of Richard Neile, archbishop of York, who, hearing that he had never worn a surplice during the fifteen years of his ministry, refused to reinstate him and said that "it had been better for him that he had gotten Seven Bastards." He had a great reputation as a preacher in and about Liverpool; but, advised by letters of John Cotton and Thomas Hooker, and persuaded by his

1 Mather led the resistance to the royal demand instigated by Edward King. In 1673, for the annulment of the college charter, and after its restoration in 1684, Edward King, King James promised him a confirmation of the former charter; the new provincial charter granted by William and Mary confirmed all the rights he had thus far enjoyed; but the college was disallowed in England; and in 1666, 1697, 1699, and 1700, Mather repeated his efforts for a college charter.

2 Mather was made a licensor of the Press in 1674 when the General Court abolished the monopoly of the Cambridge Press. 
own elaborate formal “Arguments tending to prove the Removing from Old-England to New... to be not only lawful, but also necessary for them that are not otherwise tied, but free,” he left England and on the 17th of August 1635, and landed in Boston after an “extraordinary and miraculous deliverance” from a terrible storm. As a famous preacher he “was desired to Plimouth, Dorchester, and Roxbury.” He went to Dorchester, where the Church had been greatly depleted by migrations to Windsor, Connecticut; and where, after a delay of several months, in August 1637, was constituted, by the consent of magistrates and clergy a church of which he was “teacher” until his death in Dorchester on the 22nd of April 1690.

He was an able preacher, “aiming,” said his biographer, “to shoot his arrows not over his people’s heads, but into their Hearts and Consciences”; and he was a leader of New England Congregationalism, whose policy he defended and described in the tract Church Government and Church Covenant Discussed, in an Answer of the Elders of the Several Churches of New England to Two and Thirty Questions (written 1639; printed 1643), and in his Reply to Mr Rutherford (1647), a polemic against the Presbyterianism to which the English Congregationalists were then tending. He drafted the Cambridge Platform, an ecclesiastical constitution in seventeen chapters, adopted (with the omission of Mather’s paragraphs favoring “several callers” and “government” of the church strongly opposed) by the general synod in August 1646. In 1657 he drafted the declaration of the Ministerial Convention on the meaning and force of the Harvard Covenant; this was published in 1659 under the title A Disputation concerning Church Members and their Children in Answer to XXI. Questions. With Thomas Welde and John Eliot he wrote the “Bay Psalm Book,” or, more accurately, The Whole Booke of Common Prayers and Administration of the Sacraments and Other Rites and Ceremonies of the Church Expressly Translated (1660), probably the first book printed in the English colonies.

He married in 1634 Katherine Houlit or Holt (d. 1655), and secondly in 1656 Sarah Hankride (d. 1676), the widow of John Cotton. Of six sons, all by his first wife, four were ministers: Samuel (1626-1671), the first fellow of Harvard College who was a graduate, chaplain of Magdalen College, Oxford, in 1650-1653, and pastor (1656-1671, excepting suspension in 1660-1662) of St Nicholas’s in Dublin; Nathaniel (1635-1697), who graduated at Harvard in 1647, was vicar of Barnstaple, Devon, in 1656-1662, pastor of the English Church in Rotterdam, his brother’s successor in Dublin in 1671-1688, and then until his death pastor of a church in London; Eleazar (1657-1690), who graduated at Harvard in 1656 and after preaching in Northampton, Massachusetts, for three years, became in 1661 pastor of the church there; and Increase Mather (q.v.). Horace E. Mather, in his Lineage of Richard Mather (Hartford, Connecticut, 1890), gives a list of 80 clergymen descended from Richard Mather, of whom 29 bore the name Mather and 51 other names, the more famous being Storrs and Schaffanger.

See The Life and Death of That Reverend Man of God, Mr Richard Mather (Cambridge, 1670; reprinted 1850, with his Journal for 1635, by the Dorchester Antiquarian and Historical Society), with an introduction by Increase Mather, who may have been the author; W. B. Sprague’s Annals of the American Pulpit, vol. 1. (New York, 1857); Cotton Mather’s Magnalia (London, 1702); and an account of Richard Mather in Williston Walker’s Ten New England Leaders (New York, 1901); and the works referred to in the article on Increase Mather.

MATHERAN, a hill sanatorium in India, in the Kolaba district of Bombay, 2460 ft. above the sea, and about 30 m. E. of Bombay city. Pop. (1901), 5060. It consists of several thickly wooded ridges, on a spur of the Western Ghats, with a magnificent outlook over the plain below and the distant sea. First explored in 1830, it has since become the favourite resort of the middle classes of Bombay (especially the Parsis) during the spring and autumn months. It has recently been connected by a 2 ft. gauge mountain line with Neral station on the Great Indian Peninsula railway, 54 m. from Bombay.

MATHESON, George (1842-1900), Scottish theologian and preacher, was born in Glasgow in 1842, the son of George Matheson, a merchant. He was educated at the university of Glasgow, where he graduated first in classics, logic, and philosophy. In his twentieth year he became totally blind, but he held to his resolve to enter the ministry, and gave himself to theological and historical study. His first ministry began in 1868 at Innellan, on the Argyllshire coast between Dunoon and Toward. His books on Aids to the Study of German Theology, Can the Old Faith live with the New? The Growth of the Spirit of Christianity from the First Century to the Dawn of the Lutheran Era, established his reputation as a liberal and spiritually minded theologian; and Queen Victoria invited him to preach at Balmoral. In 1886 he removed to Edinburgh, where he became minister of St Bernard’s Parish Church. Here his chief work as a preacher was done. In 1879 the university of Edinburgh conferred upon him the honorary degree of D.D., and the same year he declined an invitation to the pastorate of Crown Court, London, in succession to Dr John Cumming (1807-1881). In 1881 he was chosen as Baird lecturer, and took for his subject “Natural Elements of Revealed Theology,” and in 1882 he was the St Giles lecturer, his subject being “Confucianism.” In 1890 he was elected a fellow of the Royal Society of Edinburgh, Aberdeen gave him its honorary LL.D., and in 1899 he was appointed Gifford lecturer by that university, but declined on grounds of health. In the same year he severed his active connexion with St Bernard’s. One of his hymns, “O love that will not let me go,” has passed into the popular hymnology of the Christian Church. He died suddenly of apoplexy on the 28th of August 1906. His exegesis owes its interest to his subjective resources rather than to breadth of learning; his power lay in spiritual vision rather than balanced judgment, and in the vivid apprehension of the factors which make the Christian personality, rather than in constructive doctrine.

MATHEW, THEOBALD (1790-1859), Irish temperance reformer, popularly known as Father Mathew, was descended from a branch of the Llandaff family, and was born at Thomas-town, Tipperary, on the 10th of October 1790. He received his school education at Kilkenny, whence he passed for a short time to Maynooth; from 1808 to 1814 he studied at Dublin, where in the latter year he was ordained to the priesthood. Having entered the Capuchin order, he, after a brief time of service at Kilkenny, joined the mission in Cork, which was the scene of his religious and benevolent labours for many years. The movement with which his name is most intimately associated began in 1838 with the establishment of a total abstinence association, which in less than nine months, thanks to his moral influence and eloquence, enrolled no fewer than 150,000 names. It rapidly spread to Limerick and elsewhere, and some idea of its popularity may be formed from the fact that at Nenagh 20,000 persons are said to have taken the pledge in one day, 70,000 at Galway in two days, and 70,000 in Dublin in five days. In 1844 he visited Liverpool, Manchester and London with almost equal success. Meanwhile the expenses of his enterprise had involved him in heavy liabilities, and led on one occasion to his arrest for debt; from this embarrassment he was only partially relieved by a pension of £500 granted by Queen Victoria in 1847. In 1849 he paid a visit to the United States, returning in 1851. He died at Queenstown on the 8th of December, 1856.

See Father Mathew, a Biography, by J. F. Maguire, M.P. (1863).

MATHEWS, Charles (1779-1853), English actor, was born in London on the 26th of June 1776. His father was “a serious bookseller,” who also officiated as minister in one of Lady Huntingdon’s chapels. Mathews was educated at Merchant Taylors’ School. His love for the stage was formed in his boyhood, when he was apprentice to his father, and the latter in 1794 unwillingly permitted him to enter on a theatrical engagement in Dublin. For several years Mathews had not only to content himself with thankless parts at a low salary, but in May 1803 he made his first London appearance at the Haymarket as Jabel in Cumberland’s The Jew and as Lingo in The Agreeable Surprise. From this time his professional career was an uninterrupted triumph. He had a powerful voice, a firm and expressive delivery, and a personality without the smallest change of dress. The versatility and originality of his powers were admirably displayed in his “At
Homes," begun in the Lyceum theatre in 1818, which, according to Leigh Hunt, "for the richness and variety of his humour, were as good as half a dozen plays distilled." Off the stage his simple and kind-hearted disposition won him affection and esteem. In 1832 Mathews visited America, his observation on his experiences there forming for the reader a most entertaining portion of his biography. From also very his health had been uncertain, and the toils of his profession gradually undermined it. In 1834 he paid a second visit to America. His last appearance in New York was on the 11th of February 1835, when he played Samuel Coddle in Married Life and Andrew Steward in The Lone House. He died at Plymouth on the 28th of June 1853. In 1837 he had married Eliza Kirkham Strong (d. 1862), and in 1803 Anne Jackson, an actress, the author of the popular and diverting Memoirs, by Mrs Mathews (4 vols., 1838-1839).

His son Charles James Mathews (1803-1878), who was born at Liverpool on the 26th of December 1803, became even better known as an actor. After attending Merchant Taylor's School he was articled as pupil to an architect, and continued for some years nominally to follow this profession. His first public appearance on the stage was made on the 7th of December 1835, at the Olympic, London, as George Rattleton in his own play The Humpbacked Lover, and as Tim Topple the Tiger in Leman Rode's Old and Young Stager. In 1838 he married Madame Vestris, then lessee of the Olympic, but neither his management of this theatre, nor subsequently of Covent Garden, nor of the part of the Prince of Wales, was marked by any success, although the introduction of scenery more realistic and careful in detail than had hitherto been employed was due to his enterprise. In the year of his marriage he visited America, but without receiving a very cordial welcome. As an actor he held in England an unrivalled place in his peculiar vein of light eccentric comedy. The easy grace of his manner, and the imperturbable solemnity with which he perpetrated his absurdities, never failed to charm and amuse; his humour was never broad, but always measured and restrained. It was as the leading character in such plays as The Game of Speculation, My Awful Dad, Cool as a Cucumber, Patter versus Clatter, and Little Teddledins, that he especially excelled. In 1856 Mme Vestris died, and in the following year Mathews again visited the United States, where in 1858 he married Mrs A. H. Davenport. In 1861 they gave a series of "At Homes" at the Haymarket theatre, which were almost as popular as had been those of the elder Mathews. Charles James Mathews was one of the few English actors who played in French successfully,—his appearance in Paris in 1863 in a French version of Cool as a Cucumber, written by himself, being received with that enthusiasm which marked other performances of the same year. He had also played there again in 1865 as Sir Charles Coldcream in the original play L'Homme blâmé (English version by Bouicaut, Used up). After reaching his sixty-sixth year, Mathews set out on a tour round the world, in which was included a third visit to America, and on his return in 1872 he continued to act without interruption till within a few weeks of his death on the 24th of June 1878. He made his last appearance in New York at Wallack's theatre on the 7th of June 1872, in H. J. Byron's Not such a Fool as He Looks. His last appearance in London was at the Opera Comique on the 1st of June 1877, in The Vicar of Bladon, as Mr. Stalybridge; he had also played there again in 1878, when he played Adonis Evergreen in his own comedy My Awful Dad.

MATTHEWS, THOMAS (1767-1781), British admiral, son of Colonel Edward Mathews (d. 1700), and grandson on his mother's side of Sir Thomas Armstrong (1624-1684), who was executed for the Rye House Plot, was born at Llandaff, Llandaff. He entered the navy and became a post-captain in 1709, promoted captain in 1709. During the short war with Spain (1718-20) he commanded the "Kent" in the fleet of Sir George Byng (Lord Torrington), and from 1722 to 1724 he had the command of a small squadron sent to the East Indies to repress the pirates of the coast of Malabar. He saw no further service till March 1741, when he was appointed to the command in the Mediterranean, and plenipotentiary to the king of Sardinia and the other courts of Italy. It is impossible to understand upon what grounds he was selected. As an admiral he was not distinguished; he was quite destitute of the experience and the tact required for his diplomatic duties; and he was on the worst possible terms with his second in command, Richard Lestock (1679-1746). Yet for the purpose which he was sent out in his double capacity was not altogether ill performed. In 1742 Mathews sent a small squadron to Naples to compel King Charles III., afterwards king of Spain, to remain neutral. It was commanded by commodore, afterwards admiral, William Martin (1668-1756), who refused to enter into negotiations, and gave the king half an hour in which to return an answer. In June of the same year a squadron of Spanish galleys, which had taken refuge in the Bay of Saint Tropez, was burnt by the fireships of Mathews' fleet. In the meantime a Spanish squadron of line-of-battle ships had taken refuge in Toulon, and was watched by the British fleet from its anchorage at Hyères. In February 1744 the Spaniards put to sea in company with a French force. Mathews, who had now returned to his flagship, followed, and an engagement took place on the 11th of February. The battle was highly creditable to the British fleet, and not very honourable to their opponents, but it is of the highest historical importance in the history of the line-of-battle ships, and the fighting and efficiency of the fleet in the 18th century, and it had a very bad effect in confirming the pedantic system of tactics set up by the old Fighting Instructions. The British fleet followed the enemy in light winds on the 10th of February, and became scattered. Mathews hoisted the signal to form the line, and then when night fell, to lie to. At that moment Lestock, who commanded in the rear, was at a considerable distance from the body of the fleet, and he ought undoubtedly to have joined his admiral before lying to, but he obeyed the second officer with the result, which it is impossible not to feel that he foresaw and desired, that when morning came he was a long way off the flag of Mathews. The enemy were within striking distance of the van and centre of the British fleet, and Mathews attacked their rear. The battle was ill fought, as it had been ill prepared. Lestock never came into action at all. One Spanish line-of-battle ship, the "Poder" (74), was taken, but afterwards burnt. Several of the British captains behaved very badly, and Mathews in a heat of confused anger bore down on the enemy out of his line, that he lost the lowest pitch rod away, and were still flying at his mast head. The French and Spaniards gave ground and not pursued by Mathews, though they were of inferior strength. Deep indignation was aroused at home by this naval miscarriage, and the battle led to more than twenty courts-martial and a parliamentary inquiry. The evils which had overrun the navy were clearly displayed, and in so far some good was done. It was shown for instance that one of the captains whose ship behaved worst was a man of extreme age who was nearly blind and deaf. One of the captains was so frightened at the prospect of a trial that he deserted on his way home and disappeared into Spain. Mathews returned home after the battle. In consequence of the parliamentary motion for inquiry, Lestock was brought to trial, and acquitted on the ground that he had obeyed orders. Then Mathews was tried in 1746, and was condemned to be dismissed the service on the ground that he had not only failed to pursue the enemy but had taken his fleet into action in a confused manner. He had in fact not waited till he had his fleet in a line with the enemy before bearing down on them, and he had disordered his own line. To the country at large it appeared strange that the man who had actually fought the battle was court-martialled, while the admiral who had kept at a distance was acquitted. Mathews looked upon his condemnation as the result of mere party spirit. Sheer pendency on the part of the officers forming
the court-martial affords a more satisfactory explanation. They judged that a naval officer was bound not to go beyond the Fleet Instructions as Mathews had undoubtedly done, and therefore condemned him. Their decision had a serious effect in fixing the rule that all battles, at any rate done against enemies of equal or nearly equal numbers, were to be fought on one pattern. Mathews died on the 2nd of October 1751 in London. There is a portrait of him in the Painted Hall at Greenwich.

In Beaton's Navesi and Military Memoirs, vol. 1, will be found a fair copy of the title of February 1763. It is fully dealt with by Montagu Burrows in his Life of Howe. The French account may be found in Troude's Batailles Navales de la France. The Spanish view is in the Vida de Don Josef Navarro by Don Josefa de Vargas. The battle led to a violent pamphlet controversy. The charges and findings at the courts-martial on both Lestock and Mathews were published at the time. The minor trials arising out of the action are collected in a folio under the title "Copies of all the Minutes and Proceedings taken at and upon the several Trials of Captain George Burris" (1746). A "Narrative" was published, or for, Lestock in 1744, and answered by, or on behalf of, Mathews under the title "Ad-M--s Conduct in the late Engagement. Vindicated" in 1748.

MATHY, KARL (1807-1868), Badenese statesman, was born at Mannheim on the 17th of March 1807. He studied law and politics at Heidelberg, and entered the Baden government department of finance in 1829. His sympathy with the revolutionary ideas of 1830, expressed in his paper the Zeitgeist, cost him his appointment in 1834, and made his way to Switzerland, where he contributed to the Jeune Suisse directed by Mazzini. On his return to Baden in 1840 he edited the Landtagszeitung (the Bulletin) at Carlshaus, and in 1842 he entered the estates for the town of Constance. He became one of the opposition leaders, and in 1847 helped to found the Deutsche Zeitung, a paper which eventually did much to further the cause of German unity. He took part in the preliminary parliament and in the assembly of Frankfort in 1848-1849, where he supported the policy of H. W. von Gagern, and after the refusal of Frederick William IV. to accept the imperial crown he still worked for the cause of unity. He was made finance minister in Baden in May 1849, but was dismissed after a few days of office. He then applied his financial knowledge to banking business in Cologne, Berlin, Gotha and Leipzig. He was recalled to Baden in 1862, and in 1864 became president of the new ministry of commerce. He sought to bring Baden institutions into line with those of northern Germany with a view to ultimate union, and when in 1866 Baden took sides with Austria against Prussia he sent in his resignation. After the war he became president of a new cabinet, but he did not live to see the realization of the policy for which he had striven. He died at Carlshaus on the 3rd of February 1868.

His letters during the years 1846-1848 were edited by Ludwig Mathy (Leipzig, 1899), and his life was written by G. Freytag (Leipzig, 2nd ed., 1872).

MATILDA (1102-1164), queen of England and empress, daughter of Henry I. of England, by Matilda, his first wife, was born in 1102. In 1109 she was betrothed to the emperor, Henry V., and was sent to Germany, but the marriage was delayed till 1114. Her husband died after eleven years of wedlock, leaving her childless; and, since both her brothers were now dead, she was recalled to her father's court in order that she might be recognized as his successor in England and Normandy. The Great Council of England did homage to her under considerable pressure. Their reluctance to acknowledge a female sovereign was increased when Henry gave her in marriage to Geoffrey Plantagenet, the heir of Anjou and Maine (1129); nor was it removed by the birth of the future Henry II. in 1133. On the old king's death both England and Normandy accepted his nephew, Stephen, of Mortain and Boulogne. Matilda and her husband were in Anjou at the time. They wasted the next few years in the attempt to win Normandy; but Earl Robert of Gloucester, the half-brother of the empress, at length induced her to visit England and raise her standard in the western shires, where his influence was supreme. Though on her landing Matilda only escaped capture through the misplaced chivalry of her opponent, she soon turned the tables upon him with the help of the Church and the barons of the west. Stephen was defeated and captured at Lincoln (1141); the empress was acclaimed lady or queen of England (she used both titles indifferently) and crowned at London. But the arrogance which she displayed in her prosperity alienated the Londoners and the papal legate, Bishop Henry of Winchester. Routed at the siege of Winchester, she was compelled to release Stephen in exchange for Earl Robert, and thenceforward her cause steadily declined in England. In 1148, having lost, by early death, her only principal supporter, she retired to Normandy, of which her husband had in the meantime gained possession. Henceforward she remained in the background, leaving her eldest son Henry to pursue the struggle with Stephen. She outlived Henry's coronation by ten years; her husband had died in 1151. As queen-mother she played the part of a mediator between her sons and political parties. Age mellowed her temper, and she turned more and more from secular ambitions to charity and religious works. She died on the 30th of January 1164.

MATILDA (1046-1115), countess or margraviné of Tuscany, popularly known as the Great Countess, was descended from a noble Lombard family. Her great-grandfather, Athone of Canossa, had been made count of Modena and Reggio by the emperor Otto I., and his grandmother had, in addition, acquired Mantua, Ferrara and Brescia. Her own father, Boniface II., the Pious, secured Tuscany, the duchy of Spoleto, the county of Parma, and probably that of Cremona; and was loyal to the emperor until Henry delimited against him. Through the murder of Count Boniface in 1052 and the death of her older brother and sister three years later, Matilda was left, at the age of nine, sole heiress to the richest estate in Italy. She received an excellent education under the care of her mother, Beatrice of Bar, the daughter of Frederick of Lorraine and aunt of Henry III., who, after a brief detention in Germany by the emperor, married Godfrey IV. of Lorraine, brother of Pope Stephen IX. (1057-1058). Thenceforth Matilda's lot was cast against the emperor in the great struggle over investiture, and for one-third of her life, held the See of Ravenna. Though subjected to the savage pontiffs, Gregory VII., Victor III., Urban II., Paschal II., with varying fortune, but with undaunted resolution. She aided the pope against the Normans in 1074, and in 1075 attended the synod at which Guibert was condemned and deprived of the archbishopric of Ravenna. Her hereditary fief of Canossa was the scene (Jan. 28, 1077) of the celebrated penance of Henry IV. before Gregory VII. She provided an asylum for Henry's second wife, Praxides, and urged his son Conrad to revolt against his father. In the course of the protracted struggle her villages were plundered, her fortresses demolished, and Pisa and Lucca temporarily lost, but she remained steadfast in her allegiance, and, before her death, had, by means of a league of Lombard cities which she formed, recovered all her possessions. The donation of her estates to the Holy See, originally made in 1077 and renewed on the 17th of November 1102, though never fully consummated on account of imperial opposition, constituted the greater part of the temporal dominion of the papacy. Matilda was twice married, first to Godfrey V. of Lorraine, surnamed the Hump-backed, who was the son of her step-father and was murdered by the death of February 1076; and secondly to the 17-year-old Welf V. of Bavaria, from whom she finally separated in 1095—both marriages of policy, which counted for little in her life. Matilda was an eager student: she spoke Italian, French and German fluently, and wrote many Latin letters; she collected a considerable library; she supervised an edition of the Pandects of Justinian; and Anselm of Canterbury sent her his Meditation. She combined her devotion to the papacy and her learning with very deep personal piety. She died after a long illness at Bologna, near Modena, on the 24th of July 1115, and was buried.
MATINS—MATRIX

in the Benedictine church at Polirone, whence her remains were taken to Rome by order of Urban VIII. in 1635 and interred in St Peter's.

The contemporary record of Matilda's life in rude Latin verse, by her chaplain Domnizione (Donizo or Domenico), is preserved in the Vatican Library. The best edition is that of Bembo in the Monumenta germ, hist. scriptores, xii. 348-409. The text, with an Italian translation, was published by F. Davoli under the title Vita della grande contessa Matilda di Canossa (Ragno 1868 seq.).

MATINS (Fr. matines, med. Lat. matutinae, sc. possibly sigillae, morning watches; from matutinus, "belonging to the morning"), a word now only used in an ecclesiastical sense for one of the canonical hours in the Roman Breviary, originally intended to be said at midnight, but sometimes said at dawn, after which "lauds" were recited or sung. In the modern Roman Catholic Church, outside monastic services, the office is usually said on the preceding afternoon or evening. The word is also used in the Roman Catholic Church for the public service held on Sunday mornings before the mass (see Breviary; and Hours, Canonical). In the Church of England since the Reformation matins is used for the order of public morning prayer.

MATLOCK, a market town in the western parliamentary division of Derbyshire, England, on the river Derwent, 17 m. N. by W. of Derby on the Midland railway. Pop. (1901), of urban district of Matlock, 5979; of Matlock Bath andScarthin Nick, 1810. The entire township includes the old village of Matlock, the commercial and manufacturing district of Matlock Bridge, and the fashionable health resorts of Matlock Bath and Matlock Bank. The town possesses cotton, corn and paper mills, while in the vicinity there are stone- quarries and lead mines. A peculiar local industry is the manufacture of so-called "petrified" birds' nests, plants, and other objects. These are steeped in water from the mineral springs until they become encrusted with a calcareous deposit which gives them the appearance of fossils. Ornaments fashioned out of spar and stalactites have also a considerable sale.

Matlock Bank, one and a half miles south of Matlock, having a separate railway station, overlooks the narrow and precipitous gorge of the Derwent, and stands in the midst of woods and cliffs, deriving its name from three medicinal springs, which first became celebrated towards the close of the 17th century. They were not known to the Romans, although lead-mining was carried on extensively in the district in the 1st and 2nd centuries A.D. The mean temperature of the springs is 68° F. Extensive grounds have been laid out for public use; and in the neighbourhood there are several fine stalactite caverns.

Sheltered among the moorlands of Darley, Matlock Bank has grown up about a mile north-east of the old village, and has become celebrated for the number and excellence of its hydro pathetic establishments. A tramway, worked by a single cable, over a gradient said to be the steepest in the world, affords easy communication with Matlock Bridge.

MATOS FRAGOSO, JUAN DE (1614?-1689), Spanish dramatist, of Portuguese descent, was born about 1614 at Alcaló (Alcota) in the Province of Evora, he proceeded to Madrid, where he made acquaintance with Perez de Montalban, and thus obtained an introduction to the stage. He quickly displayed great cleverness in hitting the public taste, and many contemporaries of superior talent eagerly sought his aid as a collaborator. The earliest of his printed plays is La Defensa de la fe y príncipe prodigioso (1651), and twelve more pieces were published in 1658. But though his popularity continued long after his death (January 4, 1689), Matos Fragoso's dramas do not stand the test of reading. His emphatic preciosity and sophistical insistence on the "point of honour" are tedious and unconvincing; in La Venganza en el despecho, in A lo que obliga un agrazio, and in other plays, he merely recasts, very adroitly, works by Lope de Vega.

MATRASS (mod. Lat. matriactum), a glass vessel with a round or oval body and a long narrow neck, used in chemistry, &c., as a digester or distiller. The Florence flask of commerce is frequently used for this purpose. The word is possibly identical with an old name "mattras" (Fr. matieres, matelas) for the bolt or quarel of a cross-bow. If so, some identity of shape is the reason for the application of the word; "bolt-head" is also used as a name for the vessel. Another connexion is that with the Arabic matria, a leather bottle.

Matriarchate ("rule of the mother"), a term used to express a supposed earliest and lowest form of family life, typical of primitive societies, in which the promiscuous relations of the sexes result in the child's father being unknown (see Family). In such communities the mother took precedence of the father in certain important respects, especially in line of descent and inheritance. Matriarchate is assumed on this theory to have been universal in prehistoric times. The prominent position then naturally assigned women did not, however, imply any personal power; since they were in the position of "sisters" rather than "mothers", they could not claim the sole relatives of their children and the only centre of any such family life as existed. The custom of tracing descent through the female is still observed among certain savage tribes. In Fiji father and son are not regarded as relatives. Among the Bechuana the chieftainship passes to a brother, not to a son. In Senegal, Loango, Congo and Guinea, relationship is traced through the female. Among the Tuareg Berbers a child takes rank, freeman's or slave's, from its mother.

MATRIMONY (Lat. matrimoniium, marriage, which is the ordinary English idea of marriage), a game at cards played with a full whist pack upon a table covered in imitation of a small bed. The names of the cards were originally labelled "Matrimonium," "Intrigue" and "Confederacy," and two smaller spaces, "Pair" and "Best." These names indicate combinations of two cards, any king and queen being "Matrimonium," any queen and knave "Intrigue," any king and knave "Confederacy," while any two cards of the same denomination form a "Pair" and the diamond ace is "Best." The dealer distributes a number of counters, to which an agreed value has been given, upon the compartments, and the other players do likewise. The dealer then gives one card to each player, face down, and a second, face up. If any turned-up card is the diamond ace, the player holding it takes everything on the space and the deal passes. If not turned, the diamond ace has only the value of the other three aces. If it is not turned, the players, beginning with the eldest hand, expose their second cards, and the resulting combinations, if among the five successful ones, win the counters of the corresponding spaces. If the counters on a space are not won, they remain until the next deal.

MATRIX, a word of somewhat wide application, chiefly used in the sense of a bed or enclosing mass in which something is shaped or formed (Late Lat. matrix, womb; in classical Latin matrix was only applied to an animal kept for breeding). Matrix is thus used of a mould of metal or other substance in which a design or pattern is made in intaglio, and from which an impression in relief is taken. In die-sinking and coinage, the matrix is the hardened steel mould from which...
the die-punches are taken. The term "seal" should strictly be applied to the impression only on wax of the design of the matrix, but is often used both of the matrix and of the impression (see Seals). In mineralogy, the matrix is the mass in which a crystal mineral or fossil is embedded. In mathematics, the name "matrix" is used of an arrangement of numbers or symbols in a rectangular or square figure. (See Algebraic Forms.)

In med. Latin matrix and the diminutive matricula had the meaning of a roll or register, particularly one containing the names of the members of an institution, as of the clergy belonging to a cathedral, collegiate or other church, or of the members of a university. From this use is derived "matriculation," the admission to membership of a university, also the name of the examination for such admission. Matricula was also the name of the contributions in men and money made by the various states of the Holy Roman Empire to the imperial treasury. The contributions made by the federal states to the imperial finances are called Matrículas, matricular contributions. (See Germany: Finance.)

MATROSS, the name (now obsolete) for a soldier of artillery, who ranked next below a gunner. The duty of a matross was to assist the gunners in loading, firing and sponging the guns. They were provided with firelocks, and marched with the store-wagons, acting as guards. In the American army a matross ranked as a private of artillery. The word is probably derived from Fr. matelot, a sailor.

MATSUKATA, Marquis (1835- ), Japanese statesman, was born at Kagoshima in 1835, being a son of a samurai of the Satsuma clan. On the completion of the feudal revolution of 1868 he was appointed governor of the province of Tosa, and having served six years in this office, was transferred to Tokyo as assistant minister of finance. As representative of Japan at the Paris Exhibition of 1878, he took the opportunity afforded by his mission to study the financial systems of the great European powers. On his return home, he held for a short time in 1880 the portfolio of home affairs, and was in 1881 appointed minister of finance. The condition of the currency of Japan was at that time deplorable, and national bankruptcy threatened. The coinage had not only been seriously debased during the closing years of the Tokugawa régime, but large quantities of paper currency had been issued and circulated, both by many of the feudal lords, and by the central government itself, as a temporary expedient for filling an impoverished exchequer. In 1878 depreciation had set in, and the inconvertible paper had by the close of 1881 grown to such an extent that it was then at a discount of 80% as compared with silver. Matsukata showed the government the danger of the situation, and urged that the issue of further paper currency should be stopped at once, the expenses of administration curtailed, and the resulting surpluses used in the redemption of the paper currency and in the creation of a specie reserve. These proposals were acted upon: the Bank of Japan was established, and the right of issuing convertible notes given to it; and within three years of the initiation of these financial reforms, the paper currency, largely reduced in quantity, was restored to its full par value with silver, and the currency as a whole placed on a solvent basis. From this time forward Japan's commercial and military advancement continued to make uninterrupted progress. But pari passu with the extraordinary impetus given to its trade by the successful conclusion of the war with China, the national expenditure enormously increased, rising within a few years from 80 to 250 million yen. The task of providing for this expenditure fell entirely on Matsukata, who had to face strong opposition on the part of the diet. But he distributed the increased taxation so equally, and chose its subjects so wisely, that the ordinary administrative expenditure and the interest on the national debt were fully provided for, while the extraordinary expenditure for military purposes was met from the Chinese indemnity. As far back as 1868 Matsukata perceived the advantages of a gold standard, but it was not until 1897 that his scheme could be realized. In this year the bill authorizing it was under his auspices submitted to the diet and passed; and with this financial achievement Matsukata saw the fulfillment of his ideas of financial reform, which were conceived during his first visit to Europe. Matsukata, who in 1884 was created Count, twice held the office of prime minister (1891-1892, 1896-1898), and during both his administrations he combined the portfolio of finance with the premiership; from October 1898 to October 1900 he was minister of finance only. His name in Japanese history is indissolubly connected with the financial progress of his country at the end of the 19th century. In 1902 he visited England and America, and he was created G.C.M.G., and given the Oxford degree of D.C.L. In September 1907 he was advanced to the rank of Marquis.

MATSYS (Massys or Metzys), Quintin (1466-1530), Flemish artist, was born at Louvain, where he first learned a mechanical art. During the greater part of the 15th century the centres in which the painters of the Low Countries most congregated were Bruges, Ghent and Brussels. Towards the close of the same period Louvain took a prominent part in giving employment to workmen of every craft. It was not till the opening of the 16th century that Antwerp usurped the lead which it afterwards maintained against Bruges and Ghent, Brussels, Mechlin and Louvain. Quintin Matsys was one of the first men of any note who gave repute to the guild of Antwerp. A legend relates how the smith of Louvain was induced by affection for the daughter of an artist to change his trade and acquire proficiency in painting. A less poetical but perhaps more real version of the story tells that Quintin had a brother with whom he was brought up by his father Josse Matsys, a smith, who held the lucrative offices of clockmaker and architect to the municipality of Louvain. It came to be a question which of the sons should follow the paternal business, and which carve out a new profession for himself. Josse the son elected to succeed his father, and Quintin then gave himself to the study of painting. We are not told expressly by whom Quintin was taught, but his style seems necessarily derived from the lessons of Dierick Bouts, who took to Louvain the mixed art of Memlinc and Van der Weyden. When he settled at Antwerp, at the age of twenty-five, he probably had a style with an impress of its own, which certainly contributed most importantly to the revival of Flemish art on the lines of Van Eyck and Van der Weyden. What particularly characterizes Quintin Matsys is the strong religious feeling which he inherited from earlier schools. But that again was permedated by realism which frequently degenerated into the grotesque. Nor would it be too much to say that the facial peculiarities of the boors of Van Steen or Ostade have their counterparts in the pictures of Matsys, who was not, however, trained to use them in the same homely way. From Van der Weyden's example we may trace the dryness of outline and shadeless modelling, the pitiless finish even of trivial detail, from the Van Eycks and Memlinc through Dierick Bouts the superior glow and richness of transparent pigments, which mark the pictures of Matsys. The date of his retirement from Louvain is 1491, when he became a master in the guild of painters at Antwerp. His most celebrated picture is that which he executed in 1508 for the joiners' company in the cathedral of his adopted city. Next in importance to that is the Marys of Scripture round the Virgin and Child, which was ordered for a chapel in the cathedral of Louvain. Both altar-pieces are now in public museums, one at Antwerp, the other at Brussels. They display great earnestness in expression, great minuteness of finish, and a general absence of effect by light or shade. As in early Flemish pictures, so in those of Matsys, superfusious care is lavished on jewelry, edgings and ornament. To the great defect of want of atmosphere such faults may be added as affectation, the result of excessive straining after tenderness in women, thinness of line, dryness of the air and of strokes. Yet in every instance an effort is manifest to develop and express individual character. This tendency in Matsys is chiefly illustrated in his pictures of male and female market bankers
of water were supposed to be different from those of air and indeed from those of any other substance. Then came Dalton’s Atomic Theory which taught that these molecules, in spite of their almost infinite variety, were all built up of still smaller bodies, the atoms of the chemical elements, and that the number of these smaller bodies was limited to the sixty or seventy types which represent the atoms of the substance regarded by chemists as elements.

In 1815 Prout suggested that the atoms of the heavier chemical elements were themselves composite and that they were all built up of atoms of the lightest element, hydrogen, so that all the different forms of matter are edifices built of the same material—the atom of hydrogen. If the atoms of hydrogen do not alter in weight when they combine to form atoms of other elements the atomic weights of all elements would be multiples of that of hydrogen; though the number of elements whose atomic weights are multiples or very nearly so of hydrogen is very striking, there are several which are universally admitted to have atomic weights differing largely from whole numbers. We do not know enough about gravity to say whether this is due to the change of weight of the hydrogen atoms when they combine to form other atoms, or whether the primordial form from which all matter is built up is something other than the hydrogen atom. Whatever may be the nature of this primordial form, the tendency of all recent discoveries has been to emphasize the truth of the conception of a common basis of matter of all kinds. That the atoms of the different elements have a common basis, that they behave as if they were identical in kind, and that the numbers of small particles of the same kind, is proved to most minds by the Periodic Law of Mendeléeff and Newlands (see ELEMENT). This law shows that the physical and chemical properties of the different elements are determined by their atomic weights, or to use the language of mathematics, the properties of an element are functions of its atomic weight. Now if we constructed models of the atoms out of different materials, the atomic weight would be but one factor out of many which would influence the physical and chemical properties of the model, we should require to know more than the atomic weight to fix its behaviour. If we were to plot a curve representing the variation of some property of the substance with the atomic weight we should not expect the curve to be a smooth one, for instance two atoms might have the same atomic weight and yet if they were made of different materials have no other property in common. The influence of the atomic weight on the properties of the elements is nowhere more strikingly shown than in the recent developments of physics connected with the discharge of electricity through gases, with radio-agents, with Röntgen rays, to cathode rays, to the rays emitted by radioactive substances, the quality of the secondary radiation emitted by the different elements are all determined by the atomic weight of the element. So much is this the case that the behaviour of the element with respect to these rays has been used to determine its atomic weight, when as in the case of Indium, uncertainty as to the valency of the element makes the result of ordinary chemical methods ambiguous.

The radioactive elements indeed furnish us with direct evidence of this unity of composition of matter, for not only does one element uranium, produce another, radium, but all the radioactive substances give rise to helium, so that the substance of the atoms of this gas must be contained in the atoms of the radioactive elements.

It is not radioactive atoms alone that contain a common constituent, for it has been found that all bodies can by suitable treatment, such as raising them to incandescence or exposing them to ultra-violet light, be made to emit negatively electrified particles, and that these particles are the same from whatever source they may be derived. These particles all carry the same charge of negative electricity and all have the same mass, this mass is exceedingly small even when compared with the mass of an atom of hydrogen, which until the discovery of these particles was the smallest mass known to science. These
MATTER

charged \( n \) constituents exert upon each other. Sir J. J. Thomson (Phil. Mag., March 1904, "Corpuscular Theory of Matter") has investigated the systems in steady motion which can be formed by various numbers of negatively electrified particles immersed in a sphere of uniform positive electrification, a case, which in consequence of the enormous volume of the units of positive electricity in comparison with that of the negative has much in common with the problem under consideration, and has shown that some of the properties of \( n \) systems of corpuscles vary in a periodic way suggestive of the Periodic Law in Chemistry as \( n \) is continually increased.

Mass on the Electrical Theory of Matter.—One of the most remarkable things about matter is the inconstancy of mass. When we take the electrical theory of matter the idea of mass takes new and interesting forms. This point may be illustrated by the case of a single electrified particle; when this moves it produces in the region around it a magnetic field, the magnetic force being proportional to the velocity of the electrified particle. In a magnetic field, however, there is energy, and the amount of energy per unit volume at any place is proportional to the square of the magnetic force at that place. Thus there will be energy distributed through the space around the moving particle, and when the velocity of the particle is small compared with that of light we can easily show that the energy in the region around the charged particle is \( \frac{\mu^2 e}{2} \), when \( v \) is the velocity of the particle, \( e \) its charge, \( a \) its radius, and \( \mu \) the magnetic permeability of the region round the particle. If \( m \) is the ordinary mass of the particle, the part of the kinetic energy due to the motion of this mass is \( \frac{1}{2} m v^2 \); thus the total kinetic energy is \( \frac{1}{2} \left( m + \frac{\mu^2 e}{a} \right) \). Thus the electric charge on the particle makes it behave as if its mass were increased by \( \frac{\mu^2 e}{a} \).

This increase in mass is due to the energy in the region outside the charged particle, it is natural to look to that region for this additional mass. This region is traversed by the tubes of force which start from the electrified body and move with it, and a very simple calculation shows that we should get the increase in the mass which is due to the electrification if we suppose that these tubes of force as they move carry with them a certain amount of the ether, and that this ether had mass. The mass of ether thus carried along must be such that the amount of it in unit volume at any part of the field is such that if this were to move with the velocity of light its kinetic energy would be equal to the potential energy of the electric field in the unit volume under consideration. When a tube moves this mass of ether only participates in the motion at right angles to the tube, it is not set in motion by a movement of the tube along its length. We may compare the mass which a charged body acquires in virtue of its charge with the additional mass which a ball apparently acquires when it is placed in water; a ball placed in water behaves as if its mass were greater than its mass when moving in vacuo; we can easily understand why this should be the case, because when the ball in the water moves the water around it must move as well; so that when a force acting on the ball sets it in motion it has to move some of the water as well as the ball, and thus the ball behaves as if its mass were increased. Similarly in the case of the electrified particle, which when it moves carries with it its lines of force, which grip the ether and carry some of it along with them. When the electrified particle is moved a mass of ether has to be moved too, and thus the apparent mass of the particle is increased. The mass of the electrified particle is thus resident in every part of space reached by its lines of force; in this sense an electrified body may be said to extend to an infinite distance; the amount of the mass of the ether attached to the particle diminishes so rapidly as we recede from it that the contributions of regions remote from the particle

\[ \frac{1}{\text{We may measure this velocity with reference to any axes, provided we refer the motion of all the bodies which come into consideration to the same axes.}} \]
are quite insignificant, and in the case of a particle as small as a corpuscle not one millionth part of its mass will be farther away from it than the radius of an atom.

The increase in the mass of a particle due to given charges varies as we have seen inversely as the radius of the particle; thus the smaller the particle the greater the increase in the mass. This is, however, true only for those as small as ordinary atoms the effect of any realizable electric charge is quite insignificant, on the other hand for the smallest bodies known, the corpuscle, there is evidence that the whole of the mass is due to the electric charge. This result has been deduced by the help of an extremely interesting property of the mass due to a charge of electricity, which is that this mass is not constant but varies with the velocity. This comes about in the following way. When the charged particle, which for simplicity we shall suppose to be spherical, is at rest or moving very slowly the lines of electric force are distributed uniformly around it in all directions; when the sphere moves, however, magnetic forces are produced in the region around it, while these, in consequence of electro-magnetic induction in a moving magnetic field, give rise to electric forces which displace the tubes of electric force in such a way as to make them set themselves so as to be more at right angles to the direction in which they are moving than they were before. Thus if the charged sphere were moving along the line AB, the tubes of force would, when the sphere was in motion, tend to leave the region near AB and crowd towards a plane through the centre of the sphere, and at right angles to AB, where they would be moving more nearly at right angles to themselves. This crowding of the lines of force increases, however, the potential energy of the electric field, and since the mass of the ether carried along by the lines of force is proportional to the potential energy, the mass of the charged particle will also be increased. The amount of variation of the mass with the velocity depends to some extent on the assumptions we make as to the shape of the corpuscle and the way in which it is electrified. The simplest expression connecting the mass with the velocity is that when the velocity is \( v \) the mass is equal to \( \frac{M_0}{1 - \frac{v^2}{c^2}} \) where \( c \) is the velocity of light. We see from this that the variation of mass with velocity is very small unless the velocity of the body approaches that of light, but when, as in the case of the \( \beta \) particles emitted by radium, the velocity is only a few per cent. less than that of light, the effect of velocity on the mass becomes very considerable; the formula indicates that if the particles were moving with a velocity equal to that of light they would behave as if their mass were infinite.

By observing the variation in the mass of a corpuscle as its velocity changes we can determine how much of the mass depends upon the electric charge and how much is independent of it. For since the latter part of the mass is independent of the velocity, if it predominates the variation in mass with velocity will then be that indicated by theory above. The experiment of Kaufmann (Göttingen Nach., Nov. 8, 1901), Bucherer (Ann. der Physik, xxviii. 513, 1909) on the masses of the \( \beta \) particles shot out by radium, as well as those by Hupka (Berichte der deutsch. physik. Gesell., 1909, p. 249) on the masses of the corpuscle in cathode rays are in agreement with the view that the whole of the mass of these particles is due to their electric charge.

The alteration in the mass of a moving charge with its velocity is primarily due to the increase in the potential energy which accompanies the increase in velocity. The connexion between potential energy and mass is general and holds for any arrangement of electrified particles; thus if we assume the electrical constitution of matter, there will be a part of the mass of any system dependent upon the potential energy and in fact proportional to it. Thus every change in potential energy, such as may occur when the two elements combine with evolution or absorption of heat, must be attended by a change in mass.

The amount of this change can be calculated by the rule that if a mass equal to the change in mass were to move with the velocity of light its kinetic energy would equal the change in the potential energy. If we apply this result to the case of the combination of hydrogen and oxygen, where the evolution of heat, about \( 210^9 \text{ ergs per gramme of reaction} \), is greater than in any other known case of chemical combination, we see that the change in mass would only amount to one part in 5000 million, which is far beyond the reach of experiment. The evolution of energy by radio-active substances is enormously larger than in ordinary chemical transformations; thus one gramme of radium emits per day about as much energy as is evolved in the formation of one gramme of water, and goes on doing this for thousands of years. We see, however, that even in this case it would require hundreds of years before the changes in mass became appreciable.

The evolution of energy from the greatest emanation given off by radium is more rapid than that from radium itself, since according to the experiments of Rutherford (Rutherford, Radio-activity, p. 432) a gramme of the emanation would evolve about \( 2 \times 10^4 \text{ ergs in four days} \); this by the rule given above would diminish the mass by about one part in 20,000; but since only very small quantities of the emanation could be used the detection of the change of mass does not seem feasible even in this case.

On the view we have been discussing the existence of potential energy in an electric field is always associated with mass; however there is potential energy there is mass, the electro-magnetic theory of light, however, a wave of light is accompanied by electric forces, and therefore by potential energy; thus waves of light must behave as if they possessed mass. It may be shown that it follows from the same principles that they must also possess momentum, the direction of the momentum being the direction along which the light is travelling; when the light is absorbed by an opaque substance the momentum in the light is communicated to the substance, which therefore behaves as if the light pressed upon it. The pressure exerted by light was shown by Maxwell (Electricity and Magnetism, 3rd ed., p. 440) to be a consequence of his electro-magnetic theory, its existence has been established by the experiment of Lebedew, of Nichols and Hull, and of Ponting.

We have hitherto been considering mass from the point of view that the constitution of matter is electrical; we shall proceed to consider the question of weight from the same point of view. The relation between mass and weight is, while the simplest in expression, perhaps the most fundamental and most mysterious property possessed by matter. The weight of a body is proportional to its mass, that is, the weights of a number of substances are equal the masses will be equal, whatever the substances may be. This result was verified to a considerable degree of approximation by Newton by means of experiments with pendulums; later, in 1850 Bessel by a very extensive and accurate series of experiments, also made on pendulums, showed that the ratio of mass to weight was certainly one part in 60,000 the same for all the substances examined by him, these included brass, silver, iron, lead, copper, ivory, water.

The constancy of this ratio acquires new interest when looked at from the point of view the electric theory of matter. We have seen that the atoms of all bodies contain corpuscles, that the mass of a corpuscle is only \( \frac{1}{\sqrt{T_F}} \) of the mass of an atom of hydrogen, that it carries a constant charge of negative electricity, and that its mass is entirely due to this charge, and can be regarded as arising from electrically gripped by the lines of force starting from the electrical charge. The question at once suggests itself, Is this kind of mass ponderable? does it add to the weight of the body? and, if so, is the proportion between mass and weight the same as for ordinary bodies? Let us suppose for a moment that this mass is not ponderable, so that the corpuscles increase the mass but not the weight of an atom. Then, since the mass of a corpuscle is \( \frac{1}{\sqrt{T_F}} \) of that of an atom of hydrogen, the addition or removal of one corpuscle would in the case of an atom of atomic weight \( x \) alter the mass by one part in \( 1700x \), without altering the weight, this would produce an effect of the
same magnitude on the ratio of mass to weight and would in the case of the atoms of the lighter elements be easily measurable in experiments of the same order of accuracy as those made by Bessel. If the number of corpuscles in the atom were proportional to the atomic weight, then the ratio of mass to weight would be constant whether the corpuscles were ponderable or not. If the number were not proportional there would be greater discrepancies in the ratio of mass to weight than is consistent with Bessel's experiments if the corpuscles had no weight. We have seen there are other grounds for concluding that the number of corpuscles in an atom is proportional to the atom weight, so that the constancy of the ratio of mass to weight for a large number of substances does not enable us to determine whether or not mass due to charges of electricity is ponderable or not.

There seems some hope that the determination of this ratio for radio-active substances may throw some light on this point. The enormous amount of heat evolved by these bodies may indicate that they possess much greater stores of potential energy than other substances. If we suppose that the heat developed by one gramme of a radio-active substance in the transformation when it undergoes before it reaches the non-radio-active stage is a measure of the excess of the potential energy in a gramme of this substance above that in a gramme of non-radio-active substance, it would follow that a larger part of the mass was due to electric charges in radio-active than in non-radio-active substances; in the case of uranium this difference would amount to at least one part in 20,000 of the total mass. If this extra mass had no weight the ratio of mass to weight for uranium would differ from the normal amount by more than one part in 20,000, a quantity quite within the range of pendulum experiments. It thus appears very desirable to make experiments on the ratio of mass to weight for radio-active substances. Sir J. J. Thomson, by swinging a small pendulum whose bob was made of radium bromide, has shown that this ratio for radium does not differ from the normal by one part in 2000. The small quantity of radium available prevented the attainment of greater accuracy. Experiments just completed (1910) by Southerns at the Cavendish Laboratory on this ratio for uranium show that it is normal to an accuracy of one part in 200,000; indicating that in non-radio-active, as in radio-active, substances the electrical mass is proportional to the atomic weight.

Though but few experiments have been made in recent years on the value of the ratio of mass to weight, many important investigations have been made on the effect of alterations in the chemical and physical conditions on the weight of bodies. These have all led to the conclusion that no change which can be detected by our present means of investigation occurs in the weight of a body in consequence of any physical or chemical changes yet investigated. Thus Landolt, who devoted a great number of years to the question whether any change in weight occurs during chemical combination, came finally to the conclusion that in no case out of the many he investigated did any measurable change of weight occur during chemical combination. Poynting and Phillips (Proc. Roy. Soc., 76, p. 445), as well as Southerns (78, p. 392), have shown that change in temperature produces no change in the weight of a body; and Poynting has also shown that neither the weight of a crystal nor the attraction between two crystals depends at all upon the direction in which the axis of the crystal points. The result of these laborious and very carefully made experiments has been to strengthen the conviction that the weight of a given portion of matter is absolutely independent of its physical condition or state of chemical combinations. It should, however, be noticed that we have as yet no accurate investigation as to whether or not any changes of weight occur during radio-active transformations, such for example as the emanation from radium undergone when the atoms themselves of the substance are disrupted.

It is a matter of some interest in connexion with a discussion of any views of the constitution of matter to consider the theories of gravitation which have been put forward to explain that apparently invariable property of matter—its weight. It would be impossible to consider in detail the numerous theories which have been put forward to account for gravitation; a concise summary of many of these has been given by Drude (Wied. Ann. 62, p. 1).

There are, however, two theories of gravitation, both old, which seem to be especially closely connected with the idea of the electrical constitution of matter. The first of these is the theory of two fluids of equal and opposite sign by means of which a body exerts a force of attraction on another body. This theory is due to Bessel and is the same as that of the old philosophers. The second theory is due to the fluid theory of electricity, that gravity is a kind of residual electrical effect, due to the attraction between the units of positive and negative electricity being a little greater than the repulsion between the units of electricity of the same kind. Thus on this view two charges of equal magnitude, but of opposite sign, would exert an attraction varying inversely as the square of the distance on a charge of electricity of either sign, and therefore an attraction on a system consisting of two charges equal in magnitude but opposite in sign forming an electrically neutral system. Thus if we had two neutral systems, A and B, consisting of m positive units of electricity and an equal number of negative, her A has m units of each kind, then the gravitational attraction between A and B would be inversely proportional to the square of the distance and proportional to m. The connexion between this view of gravity and that of the electrical constitution of matter is evidently very close, for if gravity arose in this way the weight of a body would only depend upon the number of units of electricity in the body. On the view that the constitution of matter is electrical, the fundamental units which build up matter are the units of electric charge, and as the magnitude of these charges does not change, whatever chemical or physical vicissitudes matter, the weight of matter ought not to be affected by such changes. There is one result of this theory which might possibly afford a means of testing it: since the charge on a corpuscle is equal to that on a positive unit, the weights of the two are equal; but the mass of the corpuscle is only \( \frac{1}{10} \gamma \psi \) of that of the positive unit, so that the acceleration of the corpuscle under gravity will be 1700 times that of the positive unit, which we should expect to be the same as that for ponderable matter or \( \psi \).

The acceleration of the corpuscle under gravity on this view would be \( 10^{-10} \). It does not seem altogether impossible that with methods slightly more powerful than those we now possess we might measure the effect of gravity on a corpuscle if the acceleration were as large as this.

The other theory of gravitation to which we call attention is that due to Le Sage of Geneva and published in 1818. Le Sage supposed that the universe was thronged with exceedingly small particles moving with very great velocities. These particles he called ultra-mundane corpuscles, because they came to us from regions far beyond the solar system. He assumed that these were so penetrating that they could pass through masses as large as the sun or the earth without being absorbed to more than a very small extent. There is, however, some absorption, and if bodies are made up of the same kind of atoms, whose dimensions are small compared with the distances between them, the absorption will be proportional to the mass of the body. So that the ultra-mundane corpuscles stream through the body a small fraction, proportional to the mass of the body, of their momentum is communicated to it. If the direction of the ultra-mundane corpuscles passing through the body were uniformly distributed, the momentum communicated by them to the body would not tend to move it in one direction rather than in another, so that a body, A, alone in the universe and exposed to bombardment by the ultra-mundane corpuscles would remain at rest. If, however, there were a second body, B, in the neighbourhood of A, B will shield A from some of the corpuscles moving in the direction BA; thus A will not receive as much momentum in this direction as when it was alone; but in this case it only received just enough to

A theory published after Drude's paper in that of Professor Osborne Reynolds, given in his Rede lecture "On an Inversion of Ideas as to the Structure of the Universe."
keep it in equilibrium, so that when B is present the momentum in the opposite direction will get the upper hand and A will move in the direction AB, and will thus be attracted by B. Similarly, we see that B will be attracted by A. Le Sage proved that the rate at which momentum was being communicated to A or B by the passage through them of his corpuscles was proportional to the product of the masses of A and B, and if the distance between A and B was large compared with their dimensions, inversely proportional to the square of the distance between them; in fact, that the forces acting on them would obey the same laws as the gravitational attraction between them. Clerk Maxwell (article "Atom," Ency. Brit., 9th ed.) pointed out that the loss of momentum from the ultra-mundane corpuscles to the body through which they passed involved the loss of kinetic energy by the corpuscles, and if the loss of momentum were large enough to account for the gravitational attraction, the loss of kinetic energy would be so large that if converted into heat it would be sufficient to keep the body white hot. We need not, however, suppose that this energy is converted into heat; it might, as in the case where Röntgen rays are produced by the passage of electrified corpuscles through matter, be transformed into the energy of a still more penetrating form of radiation, which might escape from the gravitating body without heating it. If it is a case of the loss of a corpuscle, the result is not the same as in the machinery which Le Sage introduced for the purpose of his theory has a very close analogy with things for which we have now direct experimental evidence. We know that small particles moving with very high speeds do exist, that they possess considerable powers of penetrating solids, though not, as far as we know at present, to an extent comparable with that postulated by Le Sage; and we know that the energy lost by them as they pass through a solid is to a large extent converted into a still more penetrating form of radiation, Röntgen rays. In Le Sage's theory the only function of the corpuscles is to act as carriers of momentum, any systems which possessed momentum, moved with a high velocity and had the power of penetrating solids, might be substituted for them; now waves of electric and magnetic force, such as light waves or Röntgen rays, possess momentum, move with a high velocity, and the latter at any rate possess considerable powers of penetration; so that we might formulate a theory in which penetrating Röntgen rays replaced Le Sage's corpuscles. Röntgen rays, however, when absorbed do not, as far as we know, give rise to more penetrating Röntgen rays as a result of the attraction, but either to less penetrating rays or to rays of the same kind.

We have confined our attention in this article to the view that the constitution of matter is electrical; we have done so because this view is more closely in touch with experiment than any other yet advanced. The units of which matter is built up on this theory have been isolated and detected in the laboratory, and we may hope to discover more and more of their properties. By seeing whether the properties of matter are or are not such as would arise from a collection of units having these properties, we can apply to this theory tests of a much more definite and rigorous character than we can apply to any other theory of matter.

MATTERHORN, one of the best known mountains (14,782 ft.) in the Alps. It rises S.W. of the village of Zermatt, and on the frontier between Switzerland (canton of the Valais) and Italy. Though on the Swiss side it appears to be an isolated obelisk, it is really but the butt end of a ridge, while the Swiss slope is not nearly as steep or difficult as the grand terraced walls of the Italian slope. It was first conquered, after a number of attempts chiefly by Koch, the 14th of July 1865, by Mr E. F. Whymper's party, three interesting results of which (general view of Zermatt, and A. P. Douglas, the Rev. C. Hudson and Mr Hadow) with the guide, Michel Croz, perished by a slip on the descent. Three days later it was scaled from the Italian side by a party of men from Val Tournanche. Nowadays it is frequently ascended in summer, especially from Zermatt.

MATTEUCCI, CARLO (1811–1865), Italian physicist, was born at Forlì on the 20th of June 1811. After attending the École Polytechnique at Paris, he became professor of physics successively at Bologna (1832), Ravenna (1837) and Pisa (1840). From 1848 to 1850 he served as an active part in politics, and in 1860 was chosen an Italian senator, at the same time following, on invitation of the Italian telegraph lines. Two years later he was minister of education. He died near Leghorn on the 25th of June 1868.

He was the author of four scientific treatises: Lezioni di fisica (2 vols., Pisa, 1841), Lezioni sui fenomeni fisicochimici dei corpi viventi (Pisa, 1844), Manuale di telegrafo elettrico (Pisa, 1850) and Cours spécial sur l'électricité, le magnétisme et de rotation, &c. (Paris, 1854). His numerous papers were published in the Annales de chimie et de physique (1829–1858), and most of them also appeared at the time in the Italian scientific journals. They relate almost entirely to electrical phenomena, such as the magnetic rotation of light, the action of gas batteries, the effects of torsion on magnetism, the polarization of electrodes, &c., sufficiently complete accounts of which are given in Wiedemann's Galvanism. Nine memoirs, entitled "Electro-Physiological Researches," were published in the Philosophical Transactions, 1845–1860. See Bianchi's Carlo Matteucci e l'Italia del suo tempo (Rome, 1874).

MATTHEW, ST. (Matthew, probably a shortened form of the Hebrew equivalent to Theodorus), one of the twelve apostles, and the traditional author of the First Gospel, where he is described as having been a tax-gatherer or customs officer (Yohanan, 2: 15, 6), in the service of the tetrarch Herod. The circumstance of his call as a custom-house officer of Jesus, received as he sat in the "customs house" in one of the towns by the Sea of Galilee—apparently Capernaum (Mark ii. 11, 13), are briefly related in ix. 9. We should gather from the parallel narrative in Mark ii. 14, Luke v. 27, that he was at the time known as "Levi the son of Alpheus" (see Simon Cephas, Joseph Barnabas): if so, "James the son of Alpheus" may have been his brother. Possibly "Matthew" (Yahweh's gift) was his Christian surname, since two native names, neither being a patronymic, is contrary to Jewish usage. It must be added, however, that on the other hand it is very possible that he may have been distinguished in early times, as by Heracleon (c. 170 A.D.), and more dubiously by Origen (c. Celsum, i. 62), also apparently in the Syriac Didascalia (sec. iii.), xiv. 1. It has generally been supposed, on the strength of Luke's account (v. 29), that Matthew gave a feast in Jesus' honour (Mark viii. 1 sq.), but Mark (ii. 15), followed by Matthew (ix. 10), may mean that the meal in question was one in Jesus' own home at Capernaum (cf. v. 1). In the lists of the Apostles given in the Synoptic Gospels and in Acts, Matthew ranks third or fourth in the group of the fourteen (cf. Acts i. 13), and the importance in the apostolic age. The only other facts related of Matthew are: that on good authority concern him as Evangelist. Eusæus (H.E. ii. 24) says that he, like John, wrote only at the spur of necessity. "For Matthew, after preaching to Hebrews, when about to go also to others, committed to writing in his native tongue the Gospel that bears his name; and so by his writing supplied, for those whom he was leaving, the loss of his presence." The value of this tradition, which may be based on Papias, who certainly reported that "Matthew compiled the Oracles (of the Lord) in Hebrew," can be estimated only in connection with the study of the Gospel itself (see below). No historical use can be made of the artificial story, in Sanhedrin 43a, that Matthew was condemned to death by a Jewish court (see Lallib, Christ in the Talmud, 71 seq.). According to the Gnostic Heracleon, quoted by Clement of Alexandria (Strom. iv. 9), Matthew died a natural death. The tradition as to his ascetic diet (in Clem. Alex. Paedog. ii. 16) may be due to confusion with Matthias (cf. Mart. Mattheo, i. 1). The earliest legend as to his later labours, one of Syrian origin, places him in the Parthian kingdom, where he is said to have died a martyr (location, Ledo, where the bird Mabog on the Euphrates). This agrees with his legend as known to Ambrose and Paulinus of Nola, and is the most probable in itself. The legends which make him work with Andrew among theAnthropophagi near the Black Sea, or again in Ethiopia (Rufinus, and Socrates, H.E. i. 19), are due to confusion with Matthias, who from the first was associated in his Acts with Andrew (see M. Bonnet, Acta Apost. apocr., 1868, II. i. 65). Another
legend, his Martyrium, makes him labour and suffer in Mysore. He is commemorated as a martyr by the Greek Church on the 16th of November, and by the Roman on the 21st of September, the scene of his martyrdom being placed in Ethiopia. The Latin Breviary also affirms that his body was afterwards translated to Salerno, where it is said to lie in the church built by Robert Guiscard. In Christian art (following Jerome) the Evangelist Matthew is generally symbolized by the "man" in the imagery of Ezek. i. 10, Rev. iv. 7.

For the historical Matthew, see Ency. Bibl. and Zahn, Introd. to New Test., ii. 506 seq., 532 seq. For his legends, as under Mark.

(J. V. B.)

MATTHEW, TOBIAS, or TOBIE (1546-1628), archbishop of York, was the son of Sir John Matthew of Ross in Herefordshire, and of his wife Eleanor Crofton of Ludlow. He was born at Bristol in 1546. He was educated at Wells, and then in succession at University College and Christ Church, Oxford. He proceeded B.A. in 1564, and M.A. in 1566. He attracted the favourable notice of Queen Elizabeth, and his rise was steady though not very rapid. He was public orator in 1569, president of St. John's College, Oxford, in 1572, dean of Christ Church in 1576, vice-chancellor of the university in 1579, dean of Durham in 1583, bishop of Durham in 1595, and archbishop of York in 1606. In 1587 he had a controversy with the Jesuit Edmund Campion, and published at Oxford his arguments in 1586 under the title, Plissium et eminentissimi viri Tobiae Matheie, archiepiscopi olim Eboracensis concio apologetica adversus Componion. While in Spain, he was active in forwarding the recusants to conform to the Church of England, preaching hundreds of sermons and carrying out thorough visitations. During his later years he was to some extent in opposition to the administration of James I. He was exempted from attendance in the parliament of 1623 on the ground of age and infirmities, and died on the 20th of March 1628. His wife, Frances, was the daughter of William Barlow, bishop of Chichester.

His son, Sir TOBIE, or TOBIE, MATTHEW (1577-1655), is remembered as the correspondent and friend of Francis Bacon. He was educated at Christ Church, and was early attached to the court, serving in the embassy at Paris. His debts and dissipation were a great source of sorrow to his father, from whom he is known to have received at different times £14,000, the modern equivalent of which is much larger. He was chosen member for Newport in Cornwall in the parliament of 1601, and member for St. Albans in 1604. Before this time he had become the intimate friend of Bacon, whom he replaced as member for St. Albans. When peace was made with Spain, on the accession of James I., he wished to travel abroad. His family, who feared his vices and Catholicism, opposed his finding not to go beyond France. When once safe out of England he broke his word and went to Italy. The persuasion of some of his countrymen in France, one of whom is said to have been the Jesuit Robert Parsons, and a story he heard of the miraculous liquefaction of the blood of St. Januarius at Naples, led to his conversion in 1606. When he returned to England he was imprisoned, and many efforts were made to obtain his reconviction without success. He would not take the oath of allegiance to the king. In 1608 he was exiled, and remained seven years in France, mostly in Flanders and Spain. He returned in 1617, but went abroad again in 1619. His friends obtained his leave to return in 1621. At home he was known as the intimate friend of Gondomar, the Spanish ambassador. In 1623 he was sent to join Prince Charles, afterwards Charles I., at Madrid, and was knighted on the 23rd of October of that year. He remained in England till 1649, when he was finally driven abroad by the parliament, which looked upon him as an agent of the pope. He died in the English college in Ghent on the 13th of October 1655. In 1678 he published an Italian translation of Bacon's essays. The "Essay on Friendship" was written for him. He was also the author of a translation of The Confessions of the Incomparable Doctor St. Augustine, which led him into controversy. His correspondence was published in London in 1660.

MATTHEW, GOSPEL OF ST., the first of the four canonical Gospels of the Christian Church. The indications of the use of this Gospel in the two or three generations following the Christian Age (see Gospel) are more plentiful than of any of the others. Throughout the history of the Church, also, it has held a place second to none of the Gospels alike in public instruction and in the private reading of Christians. The reasons for its having impressed itself in this way and become thus familiar are in large part to be found in the characteristics noticed below. But in addition there has been from an early time the belief that it was the work of one of those publicans whose heart Jesus touched and led to follow Him the threeSynoptics contain an interesting account, but who is identified as Matthew (m.n.) only in this one (Matt. ix. 9-13 = Mark ii. 13-17 = Luke v. 27-32).

1. The Connexion of our Greek Gospel of Matthew with the Apostle whose name it bears.—The earliest reference to a writing by Matthew occurs in a fragment taken by Eusebius from the same work of Papaius from which he has given an account of the composition of a record by Mark (Euseb. Hist. Eccl. iii. 39; see Mark, Gospel of St.). The statement about Matthew is much briefer and is harder to interpret. In spite of much controversy, the same measure of agreement as to its meaning cannot be said to have been attained. This is the fragment: “Matthew, however, put together and wrote down the Oracles (τὰ Μην υφνάγουσα) in the Hebrew language, and each man interpreted them as he was able.” Whether “the elder” referred to in the passage on Mark, or some other like authority, was the source of this statement also does not appear; but it is probable that this was the case from the context in which Eusebius gives it. Conservative writers on the Gospels have frequently maintained that the writing here referred to was virtually the Hebrew original of our Greek Gospel which bears his name. And it is indeed likely that Papaius himself closely associated the latter with the Hebrew (or Aramaic) work by Matthew, of which he had been told, since the traditional connexion of this Greek Gospel with Matthew can hardly have begun later than this time. It is reasonable also to suppose that there was some ground for it. The description, however, of what Matthew did suits better the making of a collection of Christ’s discourses and sayings than the composition of a work corresponding in form and character to our Gospel of Matthew.

The next reference in Christian literature to a Gospel-record by Matthew is that of Irenaeus in his famous passage on the four Gospels (Adv. haer. iii. i. 1). He says that it was written in Hebrew; but in all probability he regarded the Greek Gospel, which stood first in his, as does it in our, enumeration, as in the strict sense a translation of the Apostle’s work; and this was the view of it universally taken till the 16th century, when some of the scholars of the Reformation maintained that the Greek Gospel itself was by Matthew.

The actual phenomena, however, of this Gospel, and of its relation to subsequent works based on it, cannot be explained consistently with either of these two views. It is a composite work in which two chief sources, known in Greek to the author of our present Gospel, have, together with some other matter, been combined. It is inconceivable that one of the Twelve should have proceeded in this way in giving an account of Christ’s ministry. One of the chief documents, however, here referred to seems to correspond in character with the description given in Papaius’ fragment of a record of the compilation of “the divine utterances” made by Matthew; and the use made of it in our first Gospel may explain the connexion of this Apostle’s name with it. In the Gospel of Luke also, it is true, this same source has been used for the teaching of Jesus. But the original Aramaic Logian document may have been more largely reproduced in our Greek Matthew. Indeed, in the case of one important passage (v. 17-48) this is suggested by a comparison with
Luke itself, and there are one or two others where from the character of the matter it seems not improbable, especially vi. 1-18 and xxiii. 1-5, 7b-10, 15-22. On the whole, as will be seen below, what appears to be a Palestinian form of the Gospel-tradition is most fully represented in this Gospel; but in many instances at least this may well be due to some other cause than the simple adherent adoption of the text.

2. The Plan on which the Contents is arranged.—In two respects the arrangement of the book itself is significant.

(a) As to the general outline in the first half of the account of the Galilean ministry (vv. 23-30). Immediately after relating the calling of the Twelve, and the executive organization of the new work, we have a comprehensive summary of Christ's work in Galilee under its two chief aspects, teaching and healing. In the sequel both these are illustrated. First, he gives in the Sermon on the Mount (v-vii.) a digest of the teaching required by the new community of the followers of Jesus generally, and a large portion of which probably also stood not far from the beginning of the Logian document. After this he turns to the third one of the points he has mentioned no miracle.

He now describes a number in succession, introducing all but the first of those told between Mark i. 23 and ii. 12, and also four specially remarkable ones, which occurred a good deal later according to Mark's order (Matt. viii. 26-34 = Mark iv. 21-50; Matt. ix. 18-26 = Mark v. 21-43); and he also adds some derived from another source, or other sources (vii. 5-13; ix. 27-34). Then, after another general description at ix. 35, similar to that at iv. 23, he brings together in the form of the people the more directly the compassion for them, and so introduces the mission of the Twelve (which again occurs later according to Mark's order, viz. at vii. 7 seq.), with the healing miracles in parallel form extended (ix. 36-xx. 42). Finally, the message of John the Baptist, and the revelations and the teachings that follow (x), bring out the significance of the preceding narrative. It should be observed that the people and the people are treated, not in the reply of Jesus to the messengers of the Baptist; and that in the discourse which follows their departure the perversity and unbelief of the people are strongly condemned, and the faith of the humble-minded is contrasted therewith. The greater part of the matter from ix. 37 to end of x. is taken from the Logian document. After this point, i.e. from x. 1 onwards, the first evangelist follows Mark's order (vi. 1-7 = Mark xi. 1-8, and x. 11-17 = Mark xii. 1-17). Then his Mark's Gospel breaks off, and another ending has been supplied; and gives in substance almost the whole of the Markan narrative, with the exception that he passes over the few narratives that he has (xii. 20-24) related elsewheri. At the same time he brings in additional matter in connexion with most of the Marcan sections.

(b) With the accounts of the words of Jesus spoken on certain occasions, which our first evangelist found given in one or another of his sources, he has combined other pieces, taken from other parts of the same source or from different sources, which seemed to him connected in subject, e.g. into the discourse spoken on a mountain, which began and ended with a prayer, while it was being presented by the evangelist, he has introduced some pieces which, as we infer from Luke, stood separately in that document (cf. Matt. vi. 19-21 with Luke xii. 13; Matt. vi. 25-31 = Mark i. 16-20; Matt. vii. 21-23 = Mark xi. 27-35; Matt. vii. 24-29 = Luke xii. 11-15). Again, the address to the Twelve in Mark vii. 7-11, in which Matthew is combined with an address to disciples, from the Logian source (Mark vii. 24-28 = Mark vii. 24-26; viii. 1-2). The seventy disciples (Luke x. 1-16). Our first evangelist has also added here various other sayings (Matt. x. 17-39, 42). Again, with the Markan parallel the charge of collusion with Satan and Christ's reply (Mark iii. 22-30), the first evangelist (xii. 24-31) combines the parallel account in the Logian document and adds Christ's reply to another attack (Luke xi. 14-16, 17-26, 29-32). These are some examples. He has in all, in this manner constructed eight discourses or collections of sayings, into which the greater part of Christ's teaching is gathered: (1) On the character of the heirs of the kingdom (v-vii.); (2) The Mission address (x.); (3) Teaching summarizing; and John the Baptist to an accusation and a challenge (xii. 22-24); (4) The teaching by parables (xii.); (5) On offences (xviii.); (6) Concerning the Scribes and Pharisees (xix.); (7) Concerning the sons of the kingdom (xx.); (xvi, xxv.). In this arrangement of his material the writer has given to many instances disregarded chronological considerations. But his documents also gave only very imperfect indications of the occasions of the parables, and the redactor of the Markan Gospel has been to give us an exceedingly effective representation of the teaching of Jesus.

In concluding verses of the Gospel, where the original Marcan parallel is wanting, the evangelist may still have followed in part that document while making additions as before. The account of the silencing of the Roman guard by the chief priests is the sequel to the story of the Resurrection (cf. Mark xv. 45-47 = Luke xxiv. 2-4); which at an earlier point are peculiar to Matthew (xxvii. 62-66, xxviii. 4). And, further, this matter seems to belong to the same cycle of tradition as the story of Pilate's wife and his throwing the guilt of the Crucifixion of Jesus upon the Jews, and the testimony borne by the Roman guard (as well as the centurion) who kept watch by the cross (xxvii. 52-60, 54), all which also are peculiar to this Gospel.

It cannot be or seem probable that these addings which had arisen through the desire to commend the Gospel to the Romans.

On the other hand, the meeting with Jesus of the evangelist in Galilee (xxvii. 16-20) is later material general to the message them related in Mark xvi. 7, as well as in Matt. xxviii. 7. Again, the commission to them to preach throughout the world is supported by the xxiv. 47, and by the present ending of Mark (xvi. 15), though neither of these mention Galilee as the place where it was given. The baptismal formula in Matt. xxviii. 19 is, however, peculiar, and in view of its non-occurrence in the Acts and in the Gospels elsewhere, probably an addition in accordance with Church usage at the time the Gospel was written.

3. The Palestinian Element.—Teaching is preserved in this Gospel which would have peculiar interest and be specially required in the home of Judaism. The best examples of this are the passages already referred to near end of §1, as probably derived from the Logian document. There are, besides, a good many turns of expression and sayings peculiar to this Gospel which have a Semitic cast, or which suggest a point of view that would be natural to Palestinian Christians, e.g. "kingdom of heaven" frequently for "kingdom of God"; xiii. 52 ("every scribe"); xxiv. 20 ("neither to a Sabbath"). See also v. 35 and xix. 9: x. 5, 23. Again, several of the quotations which are peculiar to this Gospel are not taken from the LXX., as those in the other Gospels and in the corresponding contexts in this Gospel commonly are, but are wholly or partly independent renderings from the Hebrew (ii. 6, 15, 18; vii. 17, xii. 17-21, 4c.).

Once more, there is somewhat more parallelism between the fragments of the Gospel according to the Hebrews and the Gospel than is the case with Luke, not to say Mark.

4. Doctrinal Character.—In this Gospel, more decidedly than in either of the other two Synoptics, there is a doctrinal point of view from which the whole history is regarded. Certain aspects which are of profound significance are dwelt upon, and this without there being any great difference between this Gospel and the other Synoptics in respect to the facts recorded or the beliefs implied. The effect is produced partly by the contents of the evangelist, which especially take the form of citations from the Old Testament; partly by the frequency with which certain expressions are used, and the prominence that is given in this and other ways to particular traits and topics.

He sets forth the restriction of the mission of Jesus during his life on earth to the people of Israel in a way which suggests at first sight a spirit of Jewish exclusiveness. But there are various indications that this is not the true explanation. In particular the evangelist brings out more strongly than either Mark or Luke the special relation of Jesus to the national religion of Israel, and the promised mission of the commission of Jesus to his disciples after his Resurrection to "make disciples of all the peoples." One may divine in all this an intention to "justify the ways of God" to the Jew, by proving that God in His faithfulness to His ancient people had given them the first opportunity of salvation through Christ, but that now their national privilege had been rightly forfeited. He was also specially concerned to show that prophecy is fulfilled in the life and work of Jesus, but the conception of this fulfilment which is presented to us is a large one; it is to be seen not merely in particular events or features of Christ's ministry, but in the Divine dispensation, new relations between God and men, and new rules of conduct which Christ has introduced. The divine meaning of the work of Jesus is thus made apparent, while of the majesty and glory of His person a peculiarly strong impression is conveyed.

Some illustrations in detail of these points are subjoined. Where there are parallels in the other Gospels they should be compared and the words in Matthew noted which in many instances serve to emphasize the points in question.

(a) The Ministry of Jesus among the Jewish People as their promised Messiah, their rejection of Him, and the extension of the Gospel to the Gentiles. The mission to Israel: Matt. i. 21; iv. 23 (note in these passages the use of δ λαός, which here, as generally in Matthew, denotes the chosen nation), ix. 33, 35, xv. 31. For the rule limiting
the work of Jesus while on earth see xxv. 24; and note διδώθησας in verse 22, which proves that Jesus did not himself enter the heathen borders, and for a similar rule prescribed to the disciples, x. 5, 6 and 23.

The rejection of Jesus by the people in Galilee, xi. 21; xiii. 13-15, and the prophetic allusions of the "nation," xxvii. 3, 47 and by the "whored nation," xxvii. 25; their condemnation xxiii. 38.

Mercy to the Gentiles and the punishment of the sons of the kingdom, xiii. 11-12, is a parallel commission to go to the Gentile peoples (διπλωμ) after Christ's resurrection (xxviii. 19).

(b) The Fulfilment of Prophecy.—In the birth and childhood of Jesus, i. 23; ii. 15, 18, 23. By these citations attention is drawn to the book which formed part of the mornings of the beginnings of the Saviour's life, the unexpected and secret manner of His appearing, the dangers to which from the first He was exposed and from which He escaped.

The ministry of Christ's forerunner, iii. 3. (The same prophecy, Isa. 40:3.) In the other gospels.

The ministry of Jesus. The quotations serve to bring out the significance of important events, especially such as were turning-points, and also to mark the broad features of Christ's life and work, iv. 15; viii. 17; xii. 18 seq.; xiii. 35; xvi. 5; xvii. 9.

(c) The Teaching on the Kingdom of God.—Note the collection of parables of the Kingdom in xiii.; also the use of βασιλεία ("the kingdom") without further definition as a term the reference of which could not be misunderstood, especially in the following phrases peculiar to this Gospel: τὴν εὐαγγελίζω τῆς βασιλείας ("the Gospel of the Kingdom") in xiii. 9, 14; τὰ δυνάμεις τῆς βασιλείας ("the kingdom of the kingdom") in xii. 10. The following descriptions of the kingdom, peculiar to this Gospel, are also interesting: (i) βασιλεία τῶν ἀνθρώπων ("the kingdom of their father") xiii. 43 and xiv. 7, as also among later fathers. (ii) השר שלום ("the kingdom") xxviii. 57. xxix. 41-44. These were to be fulfilled in the New era of the Old; the standard in mind is the law which "fulfilled" that previously given.

(e) The Christian Ecclesia.— Chap. xvi. 18, xviii. 17.

(f) The Messianic Dignity and Glory of Jesus.—The narrative in i. and ii. show the royalty of the new-born child. The title "Son of David" occurs with special frequency in this Gospel. The following instances are without parallels in the other Gospels: x. 27, xii. 23; xx. 22; xxi. 9; xxi. 15. The title "Son of God" is also used with somewhat greater frequency than in Mark and Luke: ii. 15; xii. 33; xvi. 16; xxii. 2 seq. (where it is implied); xxvii. 45-53.

The thought of the future coming of Christ, and in particular of the judgment to be executed by Him then, is much more prominent in this Gospel than in the others. Some of the following predictions are peculiar to it, while in several others there are additional touches: xii. 22, 23; x. 23, 24, 33; xiii. 39-43; xvi. 27, 28; xxvii. 28; xxiv. 3, 27, 30, 31, 37, 39; xxv. 31-46; xxxvi. 64.

(xvii. 19) is also impressed upon us by the signs at His crucifixion, some of which are related only in this Gospel, xxvii. 51-53, and by the sublime vision of the Risen Christ at the close, xxviii. 16-20.

(g) Time of Composition and Readers addressed.—The signs of dogmatic reflection in this Gospel point to its having been composed somewhat late in the 1st century, probably after Luke's Gospel, and this in accord with the conclusion that some insertions had been made in the Marcionian document used by this evangelist which were not in that used by Luke (see Luke, Gospel of St.). We may assign a.d. 80-100 as a probable time for the composition.

The author was in all probability a Jew by race, and he would seem to have addressed himself especially to Jewish readers; but they were Jews of the Dispersion. For although he was in specially close touch with Palestine, either personally or through the sources at his command, or both, his book was composed in Greek by the aid of Greek documents.

See commentaries by Th. Zahn (1903) and W. C. Allen (in the series of International Critical Commentaries, 1907); also books on the Four Gospels or the Synoptic Gospels cited at the end of Gospels of St. John. (V. H. S.)

MATTHEW CANTACUZENUS, Byzantine emperor, was the son of John VI. Cantacuzenus (q.v.). In return for the support which he gave to his father during his struggle with John V. II. Cantacuzenus he was allowed annex part of Thrace under his own dominion and in 1353 was proclaimed joint emperor. From his Thracian principality he levied several wars against the Servians. An attack which he prepared in 1350 was frustrated by the defection of his Turkish auxiliaries. In 1357 he was captured by his enemies, who delivered him to the rival emperor, John V. Compelled to abdicate, he withdrew to a monastery, where he busied himself with writing commentaries on the Scriptures.

MATTHEW OF PARIS (d. 1259), English monk and chronicler known to us only through his voluminous writings. In spite of its supreme importance, and of his knowledge of Greek and Latin, his language, his attitude towards foreigners attests that he was of English birth. He may have studied at Paris in his youth, but the earliest fact which he records of himself is his admission as a monk at St Alans in the year 1217. His life was mainly spent in this religious house. In 1248, however, he was sent to Norway as the bearer of a message from Louis IX. of France to Haakon VI.; he made himself so agreeable to the Norwegian sovereign that he was invited, a little later, to superintend the reformation of the Benedictine monastery of St Benet Holme at Trondheim. Although of such a nature was devoted to the composition of history, a pursuit for which the genius of St Alans had long been famous. Matthew edited anew the works of Abbot John de Cella and Roger of Wendover, which in their altered form constitute the first part of his most important work, the Chronica majora. From 1235, the point at which Wendover dropped his pen, Matthew continued the history on the plan which his predecessors had followed. He derived much of his information from the letters of important personages, which he sometimes inserts, but much more from conversation with the various informants of which the chief were Richard of Cornwall and Henry III. With the help of these he has appeared to have been on terms of intimacy. The king knew that Matthew was writing a history, and showed some anxiety that it should be as exact as possible. In 1257, in the course of a week's visit to St Alans, Henry kept the chronicler beside him night and day, and "guided my pen," says Paris, "with much good will and diligence." It is therefore curious that the Chronica majora should give so unfavourable an account of the king's policy. Luard supposes that Matthew never intended his work to see the light in its present form, and many passages of the autograph have been added to it, as in the case of the New with the Old; but the writer understood the danger which he ran. On the other hand, unexpurgated copies were made in Matthew's lifetime; though the offending passages are duly omitted or softened in his abridgment of his longer work, the Historia Anglorum (written about 1253), the real sentiments of the author must have been an open secret. In any case there is no ground for the old theory that he was an official historiographer.

Matthew Paris was unfortunately in a time when English politics were peculiarly suitable for narrative and description. Though he took a keen interest in the personal side of politics he has no claim to be considered a judge of character. His accounts of his contemporaries throw more light on his own prejudices than on their own. His work is always vigorous, but he imputes motives in the spirit of a partisan who never pauses to weigh the evidence or to take a comprehensive view of the situation. His redeeming feature is his capacity for narration for strength of character, even when it goes along with a policy of which he disapproves. Thus he praises Grosseteste, while he denounces Grosseteste's scheme of monastic reform. Matthew is a vehement supporter of the monastic orders against their rivals, the secular clergy and the mendicant friars. He is violently opposed to the court and the foreign favourites. He despises the king as a statesman, though for the man he has some kindly feeling. The frankness with which he attacks the court of Rome for its exactions is remarkable; so, too, is the intense nationalism which he displays in dealing with this topic. His faults of presentation are more often due to carelessness and narrow views than to deliberate purpose. But he is sometimes guilty of inserting rhetorical speeches which are not only fictitious, but also misleading as an account of the contemporary sentiments. He tampers with the documents which he inserts (as, for instance, the Carta Magna). His chronology is, for a contemporary, inexact; and he occasionally inserts duplicate versions of the same incident in different passages. He appears to have access to other authorities which are better known, e.g., the Carta Magna, and where other authorities exist and used with caution where he is sole informant. None the less, he gives a more vivid impression of his age than any other English chronicler; and it is a matter for regret that we have lost his great historical work, a byword of the eve of the crowning struggle between Henry III and the baronage.

AUTHORITIES.—The relation of Matthew Paris's work to those of John de Cella and Roger of Wendover may be best studied in H. R. Luard's edition of the Chronica majora (7 vols., Rolls series, 1872-1883), which contains valuable prefaces. The Historia
Matthew of Westminster—Matthew

Anglorum vitae historia minor (1057-1253) has been edited by F. Madden (3 vols., Rolls series, 1866-1869). Matthew Paris is often confused with "Matthew of Westminster," the reputed author of the Flores historiarum edited by J. R. Luard (2 vols., Rolls series, 1891). Matthew Paris, as compiled by various hands, is an edition of Matthew Paris with continuations extending to 1326. Matthew Paris also wrote a life of Edmund Rich (q.v.), which is probably the work written by Matthew Paris (H. Luard, d. 1893) pp. 543-588, though this is attributed by the editor to the monk Eustace; Vitae abbation S Albani (up to 1255) which have been edited by W. Watts (1840, &c.); and (possibly) the abbreviated chronicon (1000-1305) ed. by H. Madden, in the third volume of the Historia Anglorum. On the value of Matthew as an historian see F. Liebermann in G. H. Pertz's Scriptores xxviii. pp. 74-106; A. Jessopp's Studies by a Recuse (London, 1890); H. Pehn's Politische Charactter Mathaei Parisiensis (Leipzig, 1897). (H. W. C. D.)

Matthew of Westminster, the name of an imaginary person who was long regarded as the author of the Flores Historiarum. The error was first discovered in 1826 by Sir F. Palgrave, who said that Matthew was "a phantom who never existed," and later the truth of this statement was completely proved by H. R. Luard. 245 names of compilers have been handed down from that time by the later Parisians, on from whose Chronica majora the earlier part of the work was mainly copied, and from Westminster, the abbey in which the work was partially written.

The Flores historiarum is a Latin chronicle dealing with English history from the creation to 1326, although some of the earlier manuscripts end at 1306; it was compiled by various persons, and was partially continued and partly abridged, and from 1306 to 1262 was written by Robert of Reading (d. 1235) and another Westminster monk. Except for parts dealing with the reigns of Edward II and III, the work was first printed in 1826. Matthew Parker, archbishop of Canterbury, in 1557, and the best edition is the one edited with introduction by H. R. Luard for the Rolls series (London, 1890). It has been translated into English by C. D. Yonge (London, 1851). See Luard's introduction, and C. Bémont in the Revue critique d'histoire (Paris, 1891).

Matthews, Stanley (1824-1889), American jurist, was born in Cincinnati, Ohio, on the 21st of July 1824. He graduated from Kenyon College in 1840, studied law, and in 1842 was admitted to the bar of Maury county, Tennessee. In 1844 he became assistant prosecuting attorney of Hamilton county, Ohio; and in 1846-1849 edited a short-lived anti-slavery paper, the Cincinnati Herald. He was clerk of the Ohio House of Representatives in 1848-1849, a judge of common pleas of Hamilton county in 1850-1853, state senator in 1856-1858, and U.S. district-attorney for the southern district of Ohio in 1858-1861. First a Whig and then a Free-Soler, he joined the Republican party in 1861. After the outbreak of the Civil War he was commissioned a lieutenant of the 23rd Ohio, of which Rutherford B. Hayes was major; but saw service only with the 57th Ohio, of which he was colonel, and with a brigade which he commanded in the Army of the Cumberland. He resigned from the army in 1863, and was judge of the Cincinnati superior court in 1863-1864. He was a Republican presidential elector in 1864 and 1868. In 1872 he joined the Liberal Republican movement, and was temporary chairman of the Cincinnati convention which nominated Horace Greeley for the presidency, but in the campaign he supported Grant. In 1877, as counsel before the Electoral Commission, he opened the argument for the Republican electors of Florida and made the principal argument for the Republican electors of Oregon. In March of the same year he succeeded John Sherman as senator from Ohio, and served until March 1879. In 1881 President Hayes nominated him as associate justice of the Supreme Court, to succeed Noah H. Swayne; there was much opposition, especially in the press, to this appointment, because Matthews had been a prominent railway and corporation lawyer and had been one of the Republican "visiting statesmen" who witnessed the canvass of the vote of Louisiana1 in 1876; and the nomination had not been approved when the session of Congress expired. Matthews was renominated by President Garfield on the 15th of March, and the nomination was confirmed by the Senate (22 for, 21 against) on the 12th of May. He was an honest, impartial and conscientious judge. He died in Washington, on the 22nd of March 1880.

Matthews, August Heirich (1769-1835). German classical scholar, was born at Göttingen, on the 25th of December 1769, and educated at the university. He then spent some years as a tutor in Amsterdam. In 1798 he returned to Germany, and in 1802 was appointed director of the Friedrichsgymnasium at Altenburg, which post he held till his death, on the 6th of January 1835. Of his numerous important works the best-known are: Recoginitiones (3rd ed., 1833), translated into English by E. V. Blomfield (2nd ed., 1829), and his edition of Euripides (9 vols., 1813-1829), Grundriss der Geschichte der griechischen und römischen Litteratur (3rd ed., 1834, Eng. trans., Oxford, 1841) Lehrbuch für den ersten Unterricht in der Philosophie (3rd ed., 1833), Encyklopädie und Methodologie der Philosophie (1835). His Life was written by his son Constantin (1845). His brother, Friedrich Christian Matthews (1763-1822), rector of the Frankfort gymnasium, published valuable editions of Seneca's Letters, Aratus, and Dionysius Periegetes.

Matthews, the disciple elected by the prime minister in 1879, was a scholarly, imaginative Christian convert, who followed the advice of the Westminister monk, R. Luard, to fill the space left in the Twelve apostles designated by Judas Iscariot (Acts i. 21-26). Nothing further is recorded of him in the New Testament. Eusebius (Hist. Eccl., I. xii.) says he was, like his competitor, Barsabas Justus, one of the seventy, and the Syriac version of Eusebius calls him throughout not Matthias but Tolmai, i.e. Bartholomew, without confusing him with the Bartholomew who was originally one of the Twelve, and is often identified with the Nathanael mentioned in the Fourth Gospel (Expository Times, i. 566). Clement of Alexandria says some identified him with Zacchaeus, the Clementine Recognitions identify him with Barnabas, Hilgenfeld thinks he is the same as Nathanael.

Various works—a Gospel, Traditions and Apocryphal Words—were ascribed to him; and there is also extant The Acts of Andrew and Matthias, which places his activity in "the city of the cannibals" at Antioch. Clement of Alexandria quotes from the Traditions: (1) "Wonder at the things before you (suggesting, like Plato, that wonder is the first step to new knowledge); (2) If an elect man's neighbour sin, the elect man has sinned.

Matthias (1537-1619), Roman emperor, son of the emperor Maximilian II. and Maria, daughter of the emperor Charles V., was born in Vienna, on the 24th of February 1537. Educated by the diplomatist O. G. de Busbecq, he began his public life in 1577, soon after his father's death, when he was invited to assume the governorship of the Netherlands, then in the midst of the long struggle with Spain. He eagerly accepted this invitation, although it involved a definite breach with his Spanish kinsman, Philip II., and entering Brussels in January 1578 was named governor-general; but he was merely a cipher, and only held the position for about three years, returning to Germany in October 1581. Matthias was appointed governor of Austria in 1593 by his brother, the emperor Rudolph II., and two years later, when another brother, the archduke Ernest, died, he became a person of more importance as the eldest surviving brother of the unmarried emperor. As governor of Austria Matthias continued the policy of crushing the Protestants, although personally he appears to have been inclined to religious tolerance; and he dealt with the rising of the peasants in 1595, in addition to representing Rudolph at the imperial diets, and gaining some fame as a soldier during the Turkish War. A few years later the discontent felt by the members of the Habsburg family at the incompetence of the emperor became very acute, and the lead was taken by Matthias. Obtaining in May 1605 a reluctant consent from his brother, he took over the conduct of affairs in Hungary, where a revolt had broken out, and was formally recognized by the Habsburgs as their head in April 1606, and was promised the succession to the Empire. In June 1606 he concluded the peace of Vienna with the rebellious Hungarians, and was thus in a better position to treat with the sultan, with whom peace was made in November. This pacific policy was displeasing to Rudolph, the Tres Kurtne, but by having secured the support of the national party in Hungary and gathered an army, Matthias forced his brother to cede to him this
MATTHIAS I.

The short reign of the new emperor was troubled by the religious dissensions of Germany. His health became impaired and his indolence increased, and he fell completely under the influence of Melchior Klesl (q.v.), who practically conducted the imperial business. By Klesl's advice he took up an attitude of moderation and sought to reconcile the contending religious parties; but the proceedings at the diet of Regensburg in 1613 proved the hopelessness of these attempts, while their author was regarded with general distrust. Meanwhile the younger Habsburgs, led by the emperor's brother, the archduke Maximilian, and his cousin, Ferdinand, archduke of Styria, afterwards the emperor Ferdinand II., disinclining the peaceful policy of Klesl, had allied themselves with the unwilling Roman Catholics, while the question of the imperial succession was forcing its way to the front. In 1611 Matthias had married his cousin Anna (d. 1618), daughter of the archduke Ferdinand (d. 1595), but he was old and childless and the Habsburgs were anxious to retain his extensive possessions in the family. Klesl, on the one hand, wished the settlement of the religious difficulties to precede any arrangement about the imperial succession; the Habsburgs, on the other, regarded the question of the succession as urgent and vital. Meanwhile the disputed succession to the duchies of Cleves and Jülich again threatened a European war; the imperial commands were flouted in Cologne and Aix-la-Chapelle, and the Bohemians were again becoming troublesome. Having decided that Ferdinand should succeed Matthias as emperor, the Habsburgs had secured his election as king of Bohemia in June 1617, but were unable to stem the rising tide of disorder in that country. Matthias and Klesl were in favour of concessions, but Ferdinand and Maximilian met this move by seizing and imprisoning Klesl. Ferdinand had just secured his coronation as king of Hungary when there broke out in Bohemia those struggles which heralded the Thirty Years' War; and on the 20th of March 1619 the emperor died at Vienna.

For the life and reign of Matthias the following works may be consulted: J. Heiling, *Die Wahl des römischen Königs Matthias* (Braunschweig, 1881); A. Giediky, *Rudolf II. und seine Zeit* (Brünn, 1862-1868); F. MATTHIAS I., HUNYADI (1440-1490), king of Hungary, also known as Matthias Corvinus, a surname which he received from the raven (corvus) on his escutcheon, second son of János Hunyadi and Elizabeth Szilágyi, was born at Kolozsvár, probably on the 23rd of February 1440. His tutors were the learned János Vitéz, bishop of Nagyvárad, whom he subsequently raised to the primacy, and the Polish humanist Gregory Sanocki. The precocious lad quickly mastered the German, Latin and principal Slavonic languages, frequently acting as his father's interpreter at the reception of ambassadors. His military training proceeded under the eye of his father, whom he began to follow on his campaigns when only twelve years of age. In 1453 he was created count of Bisterceze, and was knighted at the siege of Belgrade in 1456. The same care for his welfare led his father to choose him a bride in the powerful Cilli family, but the young Elizabeth died before the marriage was consummated, leaving Matthias a widower at the age of fifteen. On the death of his father he was inveigled to Buda by the enemies of his house, and, on the pretext of being concerned in a purely imaginary conspiracy against Ladislaus V., was condemned to decapitation, but was spared on account of his youth, and on the king's death fell into the hands of George Podébrad, governor of Bohemia, the friend of the Hunyadis, in whose interests it was that a national king should sit on the Magyar throne. Podébrad treated Matthias hospitably and affidivated him with his daughter Catherine, but still detained him, for safety's sake, in Prague, even after a Magyar deputation had hastened thither to offer the youth the crown. Matthias was the elect of the Hungarian people, gratefully mindful of his father's services to the state and inimical to all foreign candidates; and though an influential section of the magnates, headed by the palatine László Garai and the voivode of Transylvania, Miklós Ujáki, who had been concerned in the judicial murder of Matthias's brother László, and hated the Hunyadis as semi-foreign upstarts, were fiercely opposed to Matthias's election, they were not strong enough to resist the manifest wish of the nation, supported as it was by Matthias's uncle Mihály Szilágyi at the head of 15,000 veterans. On the 24th of January 1458, 40,000 Hungarian noble men, assembled on the ice of the frozen Danube, unanimously elected Matthias Hunyadi king of Hungary, and on the 14th of February the new king made his state entry into Buda. The realm at this time was envirored by peril. The Turks and the Venetians threatened it from the south, the emperor Frederick III. from the west, and Casimir IV. of Poland from the north, both Frederick and Casimir claiming the throne. The Czech mercenaries under Gisakra held the northern counties and from thence plundered those in the centre. Meanwhile Matthias's friends had only pacified the hostile dignitaries by engaging to marry the daughter of the palatine Garai to their nominee, whereas Matthias not unnaturally refused to marry into the family of one of his brother's murderers, and on the 6th of February confirmed his previous nuptial contract with the daughter of George Podébrad, who shortly afterwards was elected king of Bohemia (March 2, 1458). Throughout 1458 the struggle between the young king and the magnates, reinforced by Matthias's own uncle and guardian Szilágyi, was acute. But Matthias, who began by deposing Garai and dismissing Szilágyi, and then proceeded to levy a tax, without the consent of the Diet, in order to hire mercenaries, easily prevailed. Nor did these complications prevent him from recovering the fortress of Gálmecb from the Turks, successfully invading Servia, and reasserting the suzerainty of the Hungarian crown over Bosnia. In the following year there was a fresh rebellion, when the emperor Frederick was actually crowned king by the malcontents at Vienna-Neustadt (March 4, 1459); but Matthias drove him out, and Pope Pius II. intervened so as to leave Matthias free to engage in a projected crusade against the Turks, which subsequent political complications, however, rendered impossible. From 1461 to 1465 the career of Matthias was a perpetual struggle punctuated by truces. Having come to an understanding with his father-in-law Podébrad, he was able to turn his arms against the emperor Frederick, and in April 1462 Frederick submitted to Matthias the holy crown for 60,000 ducats and was allowed to retain certain Hunyadi estates in Hungary for which concessions, extorted from Matthias by the necessity of coping with a simultaneous rebellion of the Magyar noble
in league with Podebrad's son Victorinus, the emperor recognized Matthias as the actual sovereign of Hungary. Once more was Matthias able to turn against the Turks, who were again threatening the southern provinces. He began by defeating Ali Pasha, and then penetrated into Bosnia, and captured the newly built fortress of Jajce after a long and obstinate defence (Dec. 1463). On returning home he was crowned with the holy crown on the 29th of March 1464, and, after driving the Czechs out of his northern counties, turned southwards again, this time recovering all the parts of Bosnia which still remained in Turkish hands.

A political event of the first importance now riveted his attention upon the north. Podebrad, who had gained the throne of Bohemia with the aid of the Hussites and Utraquists, had long been in ill odour at Rome, and in 1465 Pope Paul II. determined to depose the semi-Catholic monarch. All the neighbouring princes, the emperor, Casimir IV. of Poland and Matthias, were commanded in turn to execute the papal decree of deposition, and Matthias gladly placed his army at the disposal of the Holy See. The war began on the 31st of May 1468, but, as early as the 27th of February 1469, Matthias anticipated an alliance between George and Frederick by himself concluding an armistice with the latter. Meanwhile the Czech Catholics elected Matthias king of Bohemia, but this was contrary to the wishes of both pope and emperor, who preferred to partition Bohemia. But now George discomfited all his enemies by suddenly excluding his own son from the throne in favour of Ladislaus, the eldest son of Casimir IV., thus skilfully enlisting Poland on his side. The sudden death of Podebrad on the 22nd of March 1471 led to fresh complications. At the very moment when Matthias was about to profit by the disappearance of his most capable rival, another dangerous rebellion, headed by the irate and the chief dignitaries of the state, with the object of placing Casimir, son of Casimir IV., on the throne, paralysed Matthias's foreign policy during the critical years 1470-1471. He suppressed this domestic rebellion indeed, but in the meantime the Poles had invaded the Bohemian domains with 60,000 men, and when in 1474 Matthias was at last able to take the field against them in order to raise the siege of Breslau, he was obliged to fortify himself in an entrenched camp, whence he so skilfully harried the enemy that the Poles, impatient to return to their own country, made peace at Breslau (Feb. 1475) on an unfavourable basis, a peace subsequently confirmed by the congress of Olimutz (July 1475). During the interval between these peace, Matthias, in self-defence, again made war on the emperor, reducing Frederick to such extremities that he was glad to accept peace on any terms. By the final arrangement made between the contending princes, Matthias recognized Ladislaus as king of Bohemia proper in return for the surrender of Moravia, Silesia and Upper and Lower Lusatia, hitherto component parts of the Czech monarchy, till he should have redeemed them for 400,000 florins. The emperor promised to pay Matthias 100,000 florins as a war indemnity, and recognized him as the legitimate king of Hungary on the understanding that he should succeed him if he died without male issue, a contingency at this time somewhat improbable, as Matthias, only three years previously (Dec. 15, 1476), had married his third wife, Beatrice of Naples, daughter of Ferdinand of Aragon.

The endless tergiversations and depredations of the emperor speedily induced Matthias to declare war against him for the third time (1481), the Magyar king conquering all the fortresses in Frederick's hereditary domains. Finally, on the 1st of June 1482, Frederick, though defeated by his defeat at the battle of Szigetvár, surrendered himself and his victims into Vienna, which he henceforth made his capital. Styria, Carinthia and Carniola were next subdued, and Trieste was only saved by the intervention of the Venetians. Matthias consolidated his position by alliances with the dukes of Saxony and Bavaria, with the Swiss Confederation, and the archbishop of Salzburg, and was henceforth the greatest potentate in central Europe. His far-reaching hand even extended to Italy. Thus, in 1480, when a Turkish fleet seized Otranto, Matthias, at the earnest solicitation of the pope, sent Balazs Magyar to recover the fortress, which surrendered to him on the 10th of May 1481. Again in 1488, Matthias took Ancona under his protection for a time and occupied it with a Hungarian garrison.

Though Matthias's policy was so predominantly accidental that he soon abandoned his youthful idea of driving the Turks out of Europe, he at least succeeded in making them respect Hungarian territory. Thus in 1479 a huge Turkish army, on its return home from ravaging Transylvania, was annihilated at Szászváros (Oct. 13), and in 1480 Matthias recaptured Jajce, drove the Turks from Servia and erected two new military banates, Jajce and Srebrnik, out of reconquered Bosnian territory. On the death of Mohammed II. in 1481, a unique opportunity of the intervention of Europe in Turkish affairs presented itself. A civil war ensued in Turkey between his sons Bayezid and Jem, and the latter, being worsted, fled to the knights of Rhodes, by whom he was kept in custody in France (see BAYEZZ II.). Matthias, as the next-door neighbour of the Turks, claimed the custody of so valuable a hostage, and would have used him as a means of extorting concessions from Bayezid. But neither the pope nor the Venetians would hear of such a transfer, and the negotiations on this subject greatly embittered Matthias against the Curia. The last days of Matthias were not without their terrors. One of the greatest complications he quarrelled with his illegitimate son János (see CORVÝNS, JÁNOŠ); but Queen Beatrice, though childless, fiercely and openly opposed the idea and the matter was still pending when Matthias, who had long been crippled by gout, expired very suddenly on Palm Sunday, the 4th of April 1490.

Matthias Hunyadi was indisputably the greatest man of his day, and one of the greatest monarchs who ever reigned. The precocious and universality of his genius impress one the most. Like Napoleon, with whom he has often been compared, he was equally illustrious as a soldier, a statesman, an orator, a legislator and an administrator. But in all moral qualities the brilliant adventurer of the 15th was infinitely superior to the brilliant adventurer of the 19th century. Though naturally passionate, Matthias's self-control was almost superhuman, and throughout his stormy life, with his innumerable experiences of ingratitude and treachery, he never was guilty of a single cruel or vindictive action. His capacity for work was inexhaustible. Frequently half his nights were spent in reading, after the labour of his most strenuous days. There was no branch of knowledge in which he did not take an absorbing interest. He was, in fact, a scholar, and he did not cultivate and encourage. His court was a school of instruction, his court a nursery of poets and artists. Matthias was a middle-sized, broad-shouldered man of martial bearing, with a large fleshy nose, hair reaching to his heels, and the clean-shaven, heavy chinned face of an early Roman emperor.

See Vilmos Frakkói, King Matthias Hunyadí (Hung., Budapest, 1890, German ed., Freiburg, 1891); Ignác Académ History of the Hungarian Realm (Hung., vol. 1, Budapest, 1904); József Teleki, The Age of the Hunyadis in Hungary (Hung., vols. 3-5, Budapest, 1885-1890); V. Frakó's Life of János Vitéz (Hung. Budapest 1879); Karl Schorer, Die Eroberung Niederösterreichs durch Matthias Corvinus (Vienna, 1879); János Huszár, Matthias's Black Army (Hung. Budapest, 1890); Antonio Bonfini, Rerum hungaricarum decades (7th ed., Leipzig, 1771); Aeneas Sylvius, Opera (Frankfort, 1793); La Correspondance du prince Mathias (Hung. and Lat. Budapest, 1863); V. Frakó, The Embassies of Cardinal Carlino to Hungary (Hung., Budapest, 1889); Marzio Galeotti, De egregie sapientiæ et jocose ductis ac jocosi Mathiaee regis (Script. reg. hung. I.) (Vienna, 1746). Of the above the first is the best general sketch and is rich in notes; the second somewhat chauvinistic but excellently written; the third the best work for scholars; the seventh, eighth and ninth are the best contemporary works. (R.N.B.)

MATTHISSON, FRIEDRICH VON (1761-1831), German poet, was born at Hohendodeleben near Magdeburg, the son of the village pastor, on the 23rd of January 1761. After studying theology and philosophy at the university of Halle, he was appointed in 1781 master at the classical school Philanthropin in Dessau. This once famous seminary was, however, then rapidly decaying in public favour, and in 1784 Matthisson was glad to accept a travelling tutorship. He lived for two years with the Swiss author Bonstetten at Nyon on the lake of Geneva.
In 1794 he was appointed reader and travelling companion to the princes Louisa of Anhalt-Dessau. In 1812 he entered the service of the king of Württemberg, was ennobled, created counsellor of legation, but appointed intendant of the court theatre and chief librarian of the royal library at Stuttgart. In 1828 he retired and settled at Wörzitz near Dessau, where he died on the 12th of March 1831. Matthisson enjoyed for a time a great popularity on account of his poems, Gedichte (1757; 15th ed., 1831; new ed., 1876), which Schiller extravagantly praised for their melancholy sweetness and their fine descriptions of scenery. The verse is melodious and the language musical, but the thought and sentiments they express are too often artificial and insincere. His Adäde has been rendered famous owing to Beethoven's setting of the song. Of his tragedies, Die Elegie in den Ruinen eines alten Bergschlosses is still a favourite. His reminiscences, Erinnerungen (5 vols., 1810-1816), contain interesting accounts of his travels.

Matthisson's Schriften appeared in eight volumes (1825-1829), of which the first contains his poems, the remainder his Erinnerungen; a ninth volume was added in 1831 containing his biography by H. Döring. His Literarischer Nachlass, with a selection from his correspondence, was published in four volumes by F. R. Schoch in 1832.

MATTING, a general term embracing many coarse woven or plaited fibrous materials used for covering floors or furniture, for hanging as screens, for wrapping up heavy merchandise and for other miscellaneous purposes. In the United Kingdom, under the name of "coir" matting, a large amount of a coarse kind of carpet is made from coco-nut fibre; and the same material, as well as strips of cane, Manila hemp, various grasses and rushes, is largely employed in various forms for making door mats. Large quantities of the coco-nut fibre are woven in heavy looms, then cut up into various sizes, and finally bound round the edges by a kind of rope made from the same material. The mats may be of one colour only, or they may be made of different colours and in different designs. Sometimes the names of institutions are introduced into the mats. Another type of mat is made exclusively from the above-mentioned rope by arranging alternate layers in sinuous and straight paths, and then stitching the parts together. It is also largely used for the outer covering of ships' fenders. Perforated and otherwise prepared rubber, as well as wire-woven material, are also largely utilized for door and floor mats. Matting of various kinds is very extensively employed throughout India for floor coverings, the bottoms of bedsteads, fans and fly-flaps, &c.; and a considerable export trade in such manufactured goods is carried on. The materials used are mostly rushes or straw, from which the principal straws are the bulrushes Typha elephantina and T. angustifolia, leaves of the date palm (Phoenix sylvestris), of the dwarf palm (Chamaerops Richtiana), of the Palmyra palm (Borassus flabelliformis), of the coco-nut palm (Cocos nucifera) and of the screw pine (Pandanus odoratissimus), the munja or munj grass (Saccharum munja) and allied grasses, and the mat grasses Cyperus textilis and C. Pangorc, from the last of which the well-known Palghat mats of the Madras Presidency are made. Many of these Indian grass-mats are admirable examples of elegant design, and the colours in which they are woven are rich, harmonious and effective in the highest degree. Several useful household articles are made from the different kinds of grasses. The grasses are dyed in all shades and plaited to form attractive designs suitable for the purposes to which they are to be applied. This class of work obtains in India, Japan and other Eastern countries. Vast quantities of coarse matting used for packing furniture, heavy and coarse goods, flax and other plants, &c., are made in Russia from the bast or inner bark of the lime tree. This industry centres in the great forests of governments of Viatka, Nizhný-Novgorod, Kostroma, Kazan, Perm and Simbirsk.

MATTOCK (O.E. matuc, of uncertain origin), a tool having a double iron head, of which one end is shaped like an adze, and the other like a pickaxe. The head has a socket in the centre in which the handle is inserted transversely to the blades. It is used chiefly for grubbing and rooting among tree stumps in plantations and copses, where the roots are too close for the use of a spade, or for loosening hard soil.

MATTOON, an inland state of Brazil, bounded N. by Amazonas and Pará, E. by Goyaz, Minas Geraes, São Paulo and Paraná, S. by Paraguay and S.W. and W. by Bolivia. It ranks next to Amazonas in size, its area, which is largely unsowered and underpopulated, being 253,700 sq. m. Its population in 1890 was 118,025, in 1900. No satisfactory estimate of its Indian population can be made. The greater part of the state belongs to the western extension of the Brazilian plateau, across which, between the 14th and 16th parallels, runs the water-shed which separates the drainage basins of the Amazon and La Plata. This elevated region is known as the plateau of Matto Grosso, and its elevations so far as known rarely exceed 3000 ft. The northern slope of this great plateau is drained by the Araguaya-Tocantins, Xingé, Tapajós and Guaporé-Mamoré-Madeira, which flow northward, and, except the first, empty into the Amazon; the southern slope drains southward through a multitude of streams flowing into the Paraná and Paraguay. The general elevation in the south part of the state is much lower, and large areas bordering the Paraguay are swampy, partially submerged plains which the sluggish rivers are unable to drain. The lowland elevations in this part of the state range from 300 to 400 ft. above sea-level, the climate is hot, humid and unhealthy, and the conditions for permanent settlement are apparently unfavourable. On the highlands, however, which contain extensive open campos, the climate, though dry and hot, is considered healthy. The basins of the Paraná and Paraguay are separated by low mountain ranges extending north from the sierras of Paraguay. In the north, however, the ranges which separate the river valleys are apparently the remains of the table-land through which deep valleys have been eroded. The resources of Matto Grosso are practically undeveloped, owing to the isolated situation of the state, the costs of transportation and the small population.

The first industry was that of mining, gold having been discovered in the river valleys on the southern slopes of the plateau, and diamonds on the head-waters of the Paraguay, about Diamantino and in two or three other districts. Gold is found chiefly in placers, and in colonial times the output was large, but the deposits were long ago exhausted and the industry is now comparatively unimportant. As to other minerals little is definitely known. Agriculture exists only for the supply of local needs, though tobacco of a superior quality is grown. Cattle-raising, however, has received some attention and is the principal industry of the landowners. The forest products of the state include fine woods, rubber, ipecacuanha, sara- pirilla, jaborandi, vanilla and copaiba. There is little export, however, the only means of communication being down the Paraguay and Parana rivers by means of subsidized steamers. The capital of the state is Cuyabá, and the chief commercial town is Corumbá at the head of navigation for the larger river boats, and 1986 m. from the mouth of the La Plata. Communication between these two towns is maintained by a line of smaller boats, the distance being 517 m.

The first permanent settlements in Matto Grosso seem to have been made in 1716 and 1719, in the first year at Fortiquila and in the second at or near the site of Cuyabá, where rich placer mines had been found. At this time all this inland region was considered a part of São Paulo, but in 1748 it was made a separate capitania and was named Matto Grosso ("great woods"). In 1752 its capital was situated on the right bank of the Guaporé river and was named Villa Bella da Santissima Trindade de Matto Grosso, but in 1820 the seat of government was removed to Cuyabá and Villa Bella has fallen into decay. Matto Grosso became a province of the empire in 1889 and a republican state. It was invaded by the Paraguayans in the war of 1865-60.
city has a public library, a Methodist Episcopal Hospital, and an Old Folks' Home, the last supported by the Independent Order of Odd Fellows. Mattoon is an important shipping point for Indian corn and broom corn, extensively grown in the vicinity, and for fruit and livestock. Among its manufactures are foundry and machine shop products, stoves and bricks; in 1905 the factory product was valued at $1,368,781, an increase of 71.2% over that in 1900. The municipality owns the waterworks and an electric lighting plant. Mattoon was first settled about 1855, was named in honour of William Mattoon, an early landowner, who was first chartered as a city in 1857, and was reorganised under a general state law in 1878. WATTIGNIES (Oise), most of the Arp. al matera, cushion, whence Span. and Port. almadar, Ital. materasso), the padded foundation of a bed, formed of canvas or other stout material stuffed with wool, hair, flock or straw; in the last case it is properly known as a "pallasse" (Fr. paillasse, Lat. palaesc); but this term is often applied to an under-mattress stuffed with substances other than straw. The padded mattress on which lay the feather-bed has been replaced by the "wire-mattress," a network of wire stretched on a light wooden or iron frame which is then covered with a mattress of cloth or the state of the bedstead itself. The "wire-mattress" has taken the place of the "spring mattress," in which spiral springs support the stuffing. The term "mattress" is used in engineering for a mat of brushwood, faggots, &c., corded together and used as a foundation or as surface in the construction of dams, jetties, dikes, &c.

MATURIN, CHARLES ROBERT (1782-1824). Irish novelist and dramatist, was born in Dublin in 1782. His grandfather, Gabriel Jasper Maturin, had been Swift's successor in the deanship of St. Patrick. Charles Maturin was educated at Trinity College, Dublin, and became curate of Louth and then of St. Peter's, Dublin. His first novels, The Fatal Revenge; or, the Family of Montorio (1807), The Wild Irish Boy (1808), The Milestone Chief (1812), were issued under the pseudonym of "Dennis Jasper Murphy." All these were mercilessly ridiculed, but the irregular power displayed in them attracted the notice of Sir Walter Scott, who recommended the author to Byron. Through their influence Maturin's tragedy of Bertram was produced at Drury Lane in 1816, with Kean and Miss Kelly in the leading parts. A French version by Charles Nodier and Baron Taylor was produced in Paris at the Theatre Francais L'Ambigu. Two more tragedies, Manuel (1817) and Fredolfo (1819), were failures, and his poem The Universe (1821) fell flat. He wrote three more novels, Women (1818), Melmoth, the Wanderer (1820), and The Abigenses (1824). Melmoth, which forms its author's title to remembrance, is the best of them, and has for hero a kind of "Wandering Jew." Honoré de Balzac wrote a sequel to it under the title of Melmoth rectified à l'église (1833). Maturin died in Dublin on the 30th of October 1824. MATVYEEV, ARTEMON SERGEYEVICH (-1682). Russian statesman and reformer, was one of the greatest of the precursors of Peter the Great. His parentage and the date of his birth are uncertain. Apparently his birth was humble, but when the obscure figure of the young Artemon emerges into the light of history we find him equipped at all points with the newest ideas, absolutely free from the worst prejudices of his age, a ripe scholar, and even an author of some distinction. In 1671 the tsar Alexius and Artemon were already on intimate terms, and on the retirement of Ordlun-Nashchokin Matvyeev became the tsar's chief counsellor. It was at his house, full of all the wondering and erudite men of the west that Alexius, after the death of his first consort, Martha, met Matvyeev's favourite pupil, the beautiful Natalia Narishkina, whom he married on the 21st of January 1672. At the end of 1672 Matvyeev was raised to the rank of okolochma, and on the 1st of September 1674 attained the still higher dignity of bayar. Matvyeev remained paramount to the end of the reign and introduced play-acting and all sorts of refining western novelties into Muscovy. The deplorable physical condition of Alexius's immediate successor, Theodore III, suggested to Matvyeev the desirability of elevating to the throne the sturdy little tsarevich Peter, then in his fourth year. He purchased the allegiance of the streltst, or musketeers, and then, summoning the boyars of the council, earnestly represented to them that Theodore, scarce able to live, was surely unable to reign, and urged the substitution of little Peter. But the reactionary boyars, among whom were the near kinsmen of Theodore, proclaimed him tsar and Matvyeev was banished to Pustozerk, in northern Russia, where he remained till Theodore's death (April 27, 1682). Immediately afterwards Peter was proclaimed, tsar by the patriarch, and the first akas issued in Peter's name summoned the boyars to return to Moscow and acknowledge Peter's tsarissa Natalia. He reached Moscow on the 15th of May, prepared "to lay down his life for the tsar," and at once proceeded to the head of the Red Staircase to meet and argue with the assembled streltzi, who had been instigated to rebel by the anti-Petrine faction. He had already succeeded in partially pacifying them, when one of their colonels began to abuse the still hesitating and suspicious musketeers. Infuriated, they seized and flung Matvyeev into the square below, where he was hacked to pieces by their comrades. MAUBEUGE, a town of northern France, in the department of Nord, situated on both banks of the Sambre, here canalized, 233 m. by rail E. by S. of Valenciennes, and about 2 m. from the Belgian frontier. Pop. (1900), town 13,569, commune 21,520. As a fortress Maubeuge has an old enceinte of bastion trace which serves as the centre of an important entrenched camp of 18 m. in perimeter, constructed for the most part after the war of 1870, but since modernized and augmented. The town has a board of trade arbitration, a communal college, a commercial and industrial school; and there are important foundries, forges and blast-furnaces, together with manufacture of machine-tools, porcelain, &c. It is united by electric tramway with Hautmont (pop. 12,473), also an important metallurgical centre. Maubeuge (Malboisium) owes its origin to a double monastery, for men and women, founded in the 7th century by St Aldegonde, relics of whom are preserved in the church. It subsequently belonged to the territory of Hainault. It was attached to Leis der Graven by Louis XIV, and by Henry II, half-way up the town, by the Duke of Burgundy, and on the north at the top of the opposite hill is the ward of Upper Mauch Chunk, reached by the electric railway. An incline railway, originally used to transport coal from the mines to the river and named the "Switch-Back," now carries tourists up the steep slopes of Mount Pisgah and Mount Jefferson, to Summit Hills, a rich anthracite coal region, with a famous "burning mine," which has been on fire since 1832, and then back. An electric railway to the top of Flagstaff Mountain, built in 1906, was completed in 1901 to Lehighton, 4 m. south-
MAUCHLINE—MAUNDY THURSDAY

east of Mauch Chunk, where coal is mined and silk and stoves are manufactured, and which had a population in 1900 of 4639, and in 1910 of 5316. Immediately above Mauch Chunk the river forms a horseshoe; on the opposite side, connected by a bridge, is the borough of East Mauch Chunk (pop. 1900, 3458; 1910, 3548); and 2 m. up the river is Glen Onoko, with fine falls and cascades. The principal buildings in Mauch Chunk are the county court house, a county gaol, a Young Men's Christian Association building, and the Dimmick Memorial Library (1890). The borough was long a famous shipping point for coal. It now has ironworks and foundries, and in East Mauch Chunk there are silk mills. The name is Indian and means "Bear Mountain," this name having been used for a mountain on the Lehigh side of the river. The borough was founded by the Lehigh Coal and Navigation Company in 1818. This company began in 1827 the operation of the "Switch-Back," probably the first railway in the country to be used for transporting coal. In 1831 the town was opened to individual enterprise, and in 1850 it was incorporated as a borough. Mauch Chunk was for many years the home of Asa Packer, the projector and builder of the Lehigh Valley railroad from Mauch Chunk to Easton.

MAUCHLINE, a town in the division of Kyle, Ayrshire, Scotland, 9 m. and 8 m. N. by W. of Kilmarnock and 11 m. E. by N. of Ayr by the Glasgow and South-Western railway. It is situated on a gentle slope about 1 m. from the river Ayr, which flows through the south of the parish of Mauchline. It is noted for its manufacture of snuff-boxes and knick-knacks in wood, and of curling-stones. There is also some cabinet-making, besides spinning and weaving, and its horse fairs and cattle markets have more than local celebrity. The parish church, dating from 1835, stands in the middle of the village, and on the green a monument, erected in 1835, marks the spot where five Covenanters were killed in 1685. Robert Burns lived with his brother Gilbert on the farm of Mossiel, about a mile to the north, from 1784 to 1788. Mauchline kirkyard was the scene of the "Holy Fair"; at "Posie Nansie's" (Agnes Gibson's)—still, though much altered, a popular inn—the "Jolly Beggars" held their high jinks; near the church (in the poet's day an old, barn-like structure) was the Whiteford Arms inn, where on a pane of glass Burns wrote the epitaph on John Dove, the landlord; "auld Nance Tinnock's" house, with the date of 1744 above the door, nearly faces the entrance to the churchyard; the Rev. William Auld was minister of Mauchline, and died in 1782. He is buried in the kirkyard. Burns was one of "Daddy Auld's" elders; behind the kirkyard stands the house of Gavin Hamilton, the lawyer and firm friend of Burns, in which the poet was married. The bracs of Ballochmyler, where he met the heroine of his song, "The Lass o' Ballochmyler," lie about a mile to the south-east. Adjoining them is the considerable manufacturing town of Catrine (pop. 2340), with cotton factories, bleach fields and brewery, where Dr Matthew Stewart (1717-1783), the father of Dugald Stewart—had a mansion, and where there is a big water-wheel said to be inferior in size only to that of Laxey in the Isle of Man. Barskimming House, 2 m. south by west of Mauchline, the seat of Lord President Miller (1717-1779), was burned down in 1822. Near the confluence of the Fail and the Ayr was the scene of Burns's parting with Highland Mary.

MAUDE, CYRIL (1862— ), English actor, was born in London and educated at Charterhouse. He began his career as an actor in 1883 in America, and from 1896 to 1905 was co-manager with F. Harrison of the Haymarket Theatre, London. There he became distinguished for his quietly humorous acting in many parts. In 1900 he went into a management on his own account, and in 1907 opened his new theatre The Playhouse. In 1888 he married the actress Winifred Emery (b. 1862), who had made her London début as a child in 1875, and acted with Irving at the Lyceum between 1881 and 1887. She was a daughter of Samuel Anderson Emery (1817-1881) and grand-daughter of John Emery (1777-1822), both well-known actors in their day.

MAULE, a coast province of central Chile, bounded N. by Talca, E. by Linares and Nublo, and S. by Concepción, and lying between the rivers Maule and Itata, which form its northern and southern boundaries. Pop. (1885), 119,791; area, 2475 sq. m. Maule is traversed from north to south by the coast range and its surfaces are much broken. The Buchupureo river flows westward across the province. The climate is mild and healthy. Agriculture and stock-raising are the principal occupations, and hides, cattle, wheat and timber are exported. Transport facilities are afforded by the Maule and the Itata, which are navigable, and by a branch of the government railway from Cauquenes to Parral, an important town of southern Linares. The provincial capital, Cauquenes (pop., 1895, 5374, estimated 1893), is centrally situated on the Buchupureo river, on the eastern slopes of the coast cordillera, in the town and port of Constitución (pop., in 1900, about 7000) on the south bank of the Maule, one mile above its mouth, was formerly the capital of the province. The port suffers from a dangerous bar at the mouth of the river, but is connected with Talca by rail and has a considerable trade.

The Maule river, from which the province takes its name, is of historic interest because it is said to have marked the southern limits of the Inca Empire. It rises in the Laguna del Maule, an extensive lake, and flows westward across the province, discharging into the Pacific, into which it discharges in 35° 18' S. The upper part of its drainage basin, to which the Anuario hidrografico gives an area of 8000 sq. m., contains the volcanoes of San Pedro (18,800 ft.), the Descabezado (17,975 ft.), and others of the same group of lower elevations. The upper course and tributaries of the Maule, principally in the province of Linares, are largely used for irrigation.

MAULÉÓN, SAVARI DE (d. 1236), French soldier, was the son of Raoul de Mauléon, vicomte de Thouars and lord of Mauléon (now Chaillou-sur-Sèvre). Having espoused the cause of Arthur of Brittany, he was captured at Mirebeau (1202), and imprisoned in the château of Corfe. But John set him at liberty in 1204, gained him to his side and named him seneschal of Poitou (1202). In 1211 Savari de Mauléon assisted Raymond VI. count of Toulouse, and with him besieged Simon de Montfort in Castelnaudary. Philip Augustus bought his services in 1212 and gave him command of a fleet which was destroyed in the Flemish port of Damme. Then Mauléon returned to John, whom he aided in his struggle with the barons in 1215. He was one of those whom John designated on his deathbed for a council of regency (1216). The barons, alarmed at the advance of the French armies under Damietta. Returning to Poitou he was a second time seneschal for the king of England. He defended Saintonge against Louis VIII. in 1224, but was accused of having given La Rochelle up to the king of France, and the suspicions of the English again threw him back upon the French. Louis VIII. then turned over to him the defence of La Rochelle and the coast of Saintonge. In 1227 he took part in the rising of the barons of Poitiers and Anjou against the young Louis IX. He enjoyed a certain reputation for his poems in the langue d'oc.

MAULSTICK, or MAHLSTICK, a stick with a soft leather or padded head, used by painters to support the hand that holds the brush. The word is an adaptation of the Dutch mahlstok, i.e. the painter's stick, from molen, to paint.

MAUNDY THURSDAY (through O. Fr. mandé from Lat. mandatum, commandment, in allusion to Christ's words: "A new commandment give I unto you," after he had washed the disciples' feet) is the last day of Maundy Thursday. The word is always used in that sense and in that connection. Maundy Thursday is sometimes known as Sheer or Chare Thursday, either in allusion, it is thought, to the "sheering" of heads and beards in preparation for Easter, or more probably in the word's Middle English sense of "pure," in allusion to the ablutions of the day. The chief ceremony, as kept from the early middle ages onwards—the washing of the feet of twelve or more poor men or beggars—was in the Early Church almost unknown. Of Chrysostom and St Augustine, who both speak of Maundy Thursday
as being marked by a solemn celebration of the Sacrament, the former does not mention the foot-washing, and the latter merely alludes to it. Perhaps an indication of it may be discerned as early as the 4th century in a custom, current in Spain, northern Italy and elsewhere, of washing the feet of the catechumens towards the end of Lent before their baptism. It was not, however, universal, and in the 48th canon of the synod of Elvira (A.D. 306) it is expressly prohibited (cf. Corp. Jur. Can., c. 104, caus. i. qn. 1). From the 4th century ceremonial foot-washing became more and more usual, and this Maupassant, in his novel, has it be performed by the pope, all Catholic sovereigns, prelates, priests and nobles. In England the king washed the feet of as many poor men as he was years old, and then distributed to them meat, money and clothes. At Durham Cathedral, until the 16th century, every charity-boy had a monk to wash his feet. At Peterborough Abbey, in 1530, Wolsey made his maund in Our Lady's Chapel, having fifty-nine poor men whose feet he washed and kissed; and after he had wiped them he gave every of the said poor men twelve pence in money, three ells of good canvas to make them shirts, a pair of new shoes, a head-knot, and wine or water. Queen Elizabeth performed the ceremony, the paupers' feet, however, being first washed by the yeomen of the laundry with warm water and sweet herbs. James II. was the last English monarch to perform the rite. William III. delegated the washing to his almoner, and this was usual until the middle of the 18th century. Since 1754 the foot-washing has been abandoned, and the ceremony now consists of the presentation of Maundy money, officially called Maundy Pennies. These were first coined in the reign of Charles II. They come straight from the Mint, and have their edges unmilled. The service which formerly took place in the Chapel Royal, Whitehall, is now held in Westminster Abbey. A procession is formed in the nave, consisting of the lord high almoner representing the sovereign, the clergy and the yeomen of the guard, the latter carrying white and red purses in baskets. The clothes formerly given are now communed for in cash. The full ritual is gone through by the Roman Catholic archbishop of Westminster, and abroad it survives in all Catholic countries, a notable example being that of the Austrian emperor. In the Greek Church the rite survives notably at Moscow, St Petersburg and Constantinople. It is on Maundy Thursday that in the Church of Rome the sacred oil is blessed, and the chrisom prepared according to an elaborate rite which is given in the Pontificale.

MAUPASSANT, HENRI RENÉ ALBERT GUY DE (1850–1893), French novelist and poet, was born at the Château de Miromesnil in the department of Seine-Inférieure on the 4th August 1850. His grandfather, a landed proprietor of a good Lorraine family, owned an estate at Neuville-Champ-d’Oisel near Rouen, and bequeathed a moderate fortune to his son, a Paris stockbroker, who married Madeleine Laure Lepoitevin. Maupassant was educated at Yvetot and at the Rouen lycée. A copy of verses entitled Le Dieu créateur, written during his year of philosophy, has been preserved and printed. He entered the ministry of marine, and was promoted by M. Bardoux to the Cabinet de l’Instruction publique. A pleasant legend says that, in a report by his official chief, Maupassant is mentioned as not reaching the standard of the department in the matter of style. He may very well have been an unsatisfactory clerk, as he divided his time between rowing expeditions and attending the literary gatherings at the house of Gustave Flaubert, who was not, as he is often alleged to be, connected with Maupassant by any blood tie. Flaubert was not his uncle, nor his cousin, nor even his godfather, but merely an old friend of Madame de Maupassant, whom he had known from childhood. At the literary meetings Maupassant seldom shared in the conversation. Upon those who met him—Tourgeniev, Alphonse Daudet, Catulle Mendès, José-Maria de Heredia and Émile Zola—he left the impression of a simple young athlete. Even Flaubert, to whom Maupassant submitted some sketches, was not greatly struck by their talent, though he encouraged the younger man to persevere. Maupassant’s first essay was a dramatic piece twice given at Étretat in 1873, before an audience which included Tourgeniev, Flaubert and Melhac. In this indecorous performance, of which nothing more is heard, Maupassant played the part of a woman. During the next seven years he served a severe apprenticeship to Flaubert, who by this time realized his pupil’s exceptional gifts. In 1880 Maupassant published a volume of poems, Des Vers, against which the public prosecutor of Étaples took proceedings that were finally withdrawn through the influence of the senator Cordier. From Flaubert, who had himself been prosecuted for his first book, Madame Bovary, there came a letter congratulating him on his success, and telling him that Des Vers is an extremely interesting experiment, which shows Maupassant to us still hesitating in his choice of a medium; but he recognized that it was not wholly satisfactory, and that its chief deficiency—the absence of verbal melody—was fatal. Later in the same year he contributed to the Soirées de Mélan, a collection of short stories by MM. Zola, J.-K., Huysmans, Henry Céard, Léon Hennique and Paul Alexis; and in Beulé de swif the young unknown author revealed himself to his amazed collaborators and to the public as an admirable writer of prose and a master of the conte. There is perhaps no other instance in modern literary history of a writer beginning, as a fully equipped artist, with a genuine masterpiece. This early success was quickly followed by another. The volume entitled La Maison Tellier (1881) confirmed the first impression, and vanquished even those who were repelled by the author’s choice of subjects. In Mademoiselle Fif (1883) he repeated his previous triumphs as a conteur, and in this same year he, for the first time, attempted to write on a larger scale. Choosing to portray the life of a blameless girl, unfortunate in her marriage, unfortunate in her son, consistently unfortunate in every circumstance of existence, he leaves her, ruined and prematurely old, clanging to the tragic hope, which time, as one feels, will belie, that she may find happiness in her grandson. This picture of an average woman undergoing the constant agony of disillusion Maupassant calls Une Vie (1883), and as in modern literature there is no finer example of cruel observation, so there is no sadder book than this, while the effect of extreme truthfulness which it conveys justifies its sub-title—L’Humble vérité. Certain passages of Une Vie are of such a character that the sale of the volume at railway bookstalls was forbidden throughout France. The manner was brought before the chamber of deputies with the result of drawing still more attention to the book, and of advertising the Contes de la bécasse (1883), a collection of stories as improper as they are clever. Au soleil (1884), a book of travels which has the eminent qualities of lucid observation and exact description, was less read than Clair de lune, Miss Harriet, Les Sœurs Rondoli and Yvette, all published in 1883–1884 when Maupassant’s powers were at their highest level. Three further collections of short tales, entitled Contes et nouvelles, Monsieur Parent, and Contes du jour et de la nuit, issued in 1885, proved that while the author’s vision was as incomparable as ever, his fecundity had not improved his impeccable form. To 1885 also belongs an elaborate novel, Bel-ami, the cynical history of a particularly detestable, brutal scoundrel who makes his way in the world by means of his handsome face. Maupassant is here no less vivid in realizing his literary men, financiers and frivolous women than in dealing with his favourite peasants, boors and servants, to whom he returned in Toine (1886) and in La Petite roque (1886). About this time appeared the first symptoms of the malady which destroyed him; he wrote less, and though the novel Mont-Orial (1889) shows him apparently in undiminished possession of his faculty, Le Horlo (1887) suggests that he was already subject to alarming hallucinations. Restored to some extent by a sea-voyage, recorded in Sur l’eau (1888), he went back to short stories in Le Rosier de Madame Husson (1888), a burst of Rabelaisian humour equal to anything he had ever written. His novels Pierre et Jean (1888), Fort comme la mort (1886), and Notre cœur (1890) are penetrating studies touched with a profounder sympathy than had hitherto distinguished him; and this softening into pity for the tragedy of life is deepened in some of the tales included in Aventure beau (1890). One of these, Le Champ d’Olivier, is an unsurpassable example of
MAUPEOU

poignant, emotional narrative. With La Vie errante (1806), a volume of travels, Maupassant's career practically closed. Maupeou, a theatrical piece written in collaboration with M. Jacques Normand, was published in 1891. By this time inherited nervous maladies, aggravated by excessive physical exercises and by the imprudent use of drugs, had undermined his constitution. He began to take an interest in religious problems, and for a while made the Imitation his handbook; but his misanthropy deepened, and he suffered from curious delusions as to his wealth and rank. A victim of general paralysis, of which La Folie est une maladie et une passion was one symptom, he was the hero of the stories collected at Aix-les-Bains during the summer of 1891, and retired to Cannes, where he purposed passing the winter. The singularities of conduct which had been observed at Aix-les-Bains grew more and more marked. Maupassant's reason slowly gave way. On the 6th of January 1892 he attempted suicide, and was removed to Paris, where he died in the most painful circumstances on the 6th of July 1893. He is buried in the cemetery of Montparnasse. The opening chapters of two projected novels, L'Angélus and L'Amé étrangère, were found among his papers; these, with La Mort_mère, Maupeou's last work, were destroyed by fire in the thermal baths at Aix-les-Bains. (1893); and Le Colporteur and Le Père Milon (1898) and Le Caporal (1899), have been published posthumously. A correspondence, called Amitié amoureuse (1897), and dedicated to his mother, is probably unauthentic. Among the prefaces which he wrote for the works of others, only one—a translation of a French prose version of Mr Swinburne's Poems and Ballads—is likely to interest English readers.

Maupassant began as a follower of Flaubert and of M. Zola, but, whatever the masters may have called themselves, they both remained essentially romantiques. The pupil is the last shaven-haired "naturaliste" in the vogue; he even destroyed naturalism, since he did all that can be done in that direction. He had no psychology, no theories of art, no moral or strong social prejudices, no disturbing imagination, no wealth of perplexing ideas. It is no paradox to say that his marked limitations made him the incomparable artist that he was. Undisturbed by any external influence, his marvellous vision enabled him to become a supreme observer, and, given his literary sense, the rest was simple. He prided himself in having no invention; he described nothing that he had not seen. The peasants whom he had known as a boy figure in a score of tales; he saw in Government offices is set down in L'Héritage; from Algeria he gathers the material for Maçoa; he drinks the waters and builds up Mont-Oriol; he enters journalism, constructs Bel-amis; and, for the sake of precision, makes his brother, Hervé de Maupassant, sit for the infamous hero's portrait; he sees fashionable society, and, though it wearied him intensely, he transcribes its life in Fort comme la mort and Noire cœur. Fundamentally he finds all men alike. In every grade he finds the same ferocious, cunning, animal instincts at work: it is not a gay world, but he knows no other; he is possessed by the dread of growing old, of ceasing to enjoy; the horror of death haunts him like a spectre. It is an extremely simple outlook. Maupassant does not prefer good to bad, one man to another; he never pauses to argue about the meaning of life, a senseless thing which has the one advantage of yielding materials for art; his one aim is to discover the hidden aspect of visible things, to relate what he has observed, to give an objective rendering of it, and he has seen so intensely and so serenely that he is the most exact transcriber in literature. And as the substance is, so is the form: his style is exceedingly simple and exceedingly strong; he uses no rare or superluous word, and his content is so complete that if it only conveys the exact picture of the thing seen. In ten years he produced some thirty volumes. With the exception of Pierre et Jean, his novels, excellent as they are, scarcely represent him at his best, and of over two hundred contes a proportion must be rejected. But enough will remain to vindicate his claim to a permanent place in literature as an unmatched observer and the most perfect master of the short story.

(1891); a critical preface by the earl of Crewe to Pierre Jean (1902); A. Symons, Studies in Prose and Verse (1903). There are many references to Maupassant in the Journal des Consul, and some correspondence with Marie Bashkirtseff was printed with Further Memoirs of that lady in 1901. (J. F. K.)

MAUPEOU, RENÉ NICOLAS CHARLES AUGUSTIN (1714-1792), chancellor of France, was born on the 25th of February 1714, being the eldest son of René Charles de Maupou (1685-1773), who was president of the parlement of Paris from 1743 to 1757. He married in 1744 a rich heiress, Anne de Roncherolles, owner of Madame d'Epinay. Beginning his career as his father's right hand in the conflicts between the parlement and Christophe de Beaumont, archbishop of Paris, who was supported by the court. By 1763 and 1768, dates which cover the revision of the case of Jean Calas and the trial of the comte de Lally, Maupou was himself president of the parlement. In 1768, through the protection of Choiseul, whose fall two years later was in large measure his work, he became chancellor in succession to his father, who had held the office for a few days only. He determined to support the royal authority against the parlement, which in his judgment, provincial magistrates was seeking to arrogate to itself the function of the state. He allied himself with the duc d'Aiguillon and Madame du Barry, and secured for a creature of his own, the Abbé Terrail, the office of comptroller-general. The struggle came over the trial of the case of the duc d'Aiguillon, ex-governor of Brittany, and of La Chalotais, procurator-general of the province, who had been imprisoned by the governor for accusations against his administration. When the parlement showed signs of hostility against Aiguillon, Maupou read letters patent from Louis XV. annulling the court proceedings. Louis XV. replied with remonstrances from the parlement by a loi de justice, in which he demanded the surrender of the minutes of procedure. On the 27th of November 1770 appeared the Édit de règlement et de discipline, which was promulgated by the chancellor, forbidding the union of the various branches of the parlement and correspondence with the provincial magistrates. It also made a strike on the part of the parlement punishable by confiscation of goods, and forbade further obstruction to the registration of royal decrees after the royal reply had been given to a first remonstrance. This edict the magistrates refused to register, and it was registered in a loi de justice held by the ministers, which suspended its functions. After five summonses to return to their duties, the magistrates were surprised individually on the night of the 19th of January 1771 by musketeers, who required them to sign yes or no to a further request to return. Thirty-eight magistrates gave an affirmative answer, but on the exile of their former colleagues by lettres de cachet they retracted, and were also exiled. Maupou installed the council of state to administer justice pending the establishment of six superior courts in the provinces, and of a new parlement in Paris. Le tour des aides was next suspended.

Voltaire praised this revolution, applauding the suppression of the old hereditary magistrature, but in general Maupou's policy was regarded as the triumph of tyranny. The remonstrances of the princes, of the nobles, and of the minor courts, were met by exile and suppression, but by the end of 1777 the new system was established, and the Bar, which had offered a passive resistance, recommenced to plead. But the death of Louis XV. in May 1774 ruined the chancellor. The restoration of the parlements was followed by a renewal of the quarrels between the crown and the magistrates. Maupou and Terrail were replaced by Malecherbes and Turgot. Maupou lived in retreat until his death at Thuit on the 29th of July 1792, having lived to see the overthrow of the ancien régime. His work, in so far as it was directed towards the separation of the judicial and political functions and to the reform of the abuses attaching to a hereditary magistrature, was subsequently endorsed by the Revolution; but no justification of his violent methods or defence of his intriguing and avaricious character is possible. He aimed at securing absolute power for Louis XV., but his action was in reality a serious blow to the monarchy.
MAURET—MAUREV

The chief authority for the administration of Maupoue is the comte rends in his own justification presented by him to Louis XVI, in 1789, which included a dossier of his speeches and edicts, and is preserved in the Bibliothèque nationale. These documents, in the vast mass of material, due due to the collapse of the French administration, rendered the basis of the judicial system of France as established under the consulate (cf. C. F. Lebrun, Opinions, rapports et choix d'actes politiques, published posthumously in 1829). See further (Maupertuis, 1753), which contains the pamphlet directed against him; Journal hist. de la révolution opéré... par M. de Maupoue (7 vols., 1775); the official correspondence of Mercure-Argus, the letters of Mme d'Epinay; and Jules Flammemont, Le comte de Maupertuis, prefixed article, in (1887).

MAUPEOU, PIERRE LOUIS MOREAU DE (1698-1759), French mathematician and astronomer, was born at St. Malo on the 17th of July 1698. When twenty years of age he entered the military, becoming lieutenant in a regiment of cavalry, and employing his leisure on mathematical studies. After five years he tranquilly and was admitted in 1723 a member of the Academy of Sciences. In 1728 he visited London, and was elected a fellow of the Royal Society. In 1736 he acted as chief of the expedition sent by Louis XV. to Lapland to measure the length of a degree of the meridian. In 1738, he was chosen president of the Royal Academy of Sciences. In 1746, finding his health declining, he returned to France, but went in 1758 to Basel, where he died on the 27th of July 1759. Maupertuis was unquestionably a man of considerable ability as a mathematician, but his restless, gloomy disposition involved him in constant quarrels, of which his controversies with König and Voltaire during the latter part of his life furnishes examples.

The following are his most important works: Sur la figure de la terre (Paris, 1738); Discours sur la parallèle de la lune (Paris, 1741); Discours sur la figure des astres (Paris, 1742); Éléments de la géographie (Paris, 1742); Lettre sur la comète de 1742 (Paris, 1742); Astronomie nautique (Paris, 1745 and 1746); Vénus physique (Paris, 1745); Essai de cosmologie (Amsterdam, 1750). (See EARL, figure 09, and on his return home he became a member of almost all the scientific societies of Europe. In 1740 Maupertuis went to Berlin on the invitation of the king of Prussia, and took part in the battle of Mollwitz, where he was taken prisoner by the Austrians. On his release he returned to Berlin, and thence to Paris, where he was elected director of the Academy of Sciences in 1742, and in the following year was admitted into the Academy. Returning to Berlin in 1744, at the desire of Frederick II., he was chosen president of the Royal Academy of Sciences in 1746. Finding his health declining, he returned, in 1755, to the south of France, but went in 1758 to Basel, where he died on the 27th of July 1759. Maupertuis was unquestionably a man of considerable ability as a mathematician, but his restless, gloomy disposition involved him in constant quarrels, of which his controversies with König and Voltaire during the latter part of his life furnish examples.

MAUREPAS, JEAN FRÉDÉRIC PHÉLYPEAUX, COMTE DE (1701-1758), French statesman, was born on the 9th of July 1701 at Versailles, being the son of Jérôme de Pontchartrain, secretary of state for the marine and the royal household. Maurepas succeeded to his father's charge at fourteen, and began his functions in the royal household at seventeen, while in 1725 he undertook the actual administration of the navy. Although essentially light and frivolous in character, Maurepas was seriously interested in scientific matters, and he used the best brains of France to apply science to questions of navigation and of naval construction. He was disgraced in 1749, and exiled from Paris for an epigram against Madame de Pompadour. On the accession of Louis XVI., twenty-five years later, he became a minister of state and Louis XVI.'s chief adviser. He gave the French navy a new direction. He was entrusted with the supervision of the royal household and made Vergennes minister for foreign affairs. At the outset of his new career he showed his weakness by recalling to their functions, in deference to popular clamour, the members of the old parlement ousted by Maurepas, thus reconstituting the most dangerous enemy of the royal power. This step, and his intervention on behalf of the American states, helped to pave the way for the French revolution. Jealous of his personal ascendancy over Louis XVI., he intrigued against Turgot, whose disgrace in 1776 was followed after six months of disorder by the appointment of Necker. In 1781 Maurepas deserted Necker as he had done Turgot, and he died at Versailles on the 21st of November 1781.

Maurepas is credited with contributions to the collection of facetae known as the Étrennes de la Saint Jean (2nd ed., 1742). Four volumes of Mémoires de Maurepas, purporting to be collected by his secretary and afterward destroyed by the French government, are regarded as apocryphal. Some of his letters were published in 1896 by the Soc. de l'hist. de Paris. His Elégie in the Academy of Sciences was pronounced by Contorcer.

Maurer, Georg Ludwig von (1790-1872), German statesman and historian, son of a Protestant pastor, was born at Erlpohum, near därkheim, in the Rheins Palatinate, on the 2nd of November 1790. Educated at Heidelberg, he went in 1812 to reside in Paris, where he entered upon a systematic study of the ancient legal institutions of the Germans. Returning to Germany in 1814, he received an appointment under the Bavarian government, and afterwards filled several important official positions. In 1824 he published at Heidelberg his Geschichte des allgermanischen und namentlich allobayrischen öffentlichmündlichen Gerichtsverfahrens, which obtained the first prize of the academy of Munich, and in 1826 he became professor of law at the University of Munich, and remained there until his retirement from official life, and was soon offered an important post. In 1832, when Otto (Otho), son of Louis I., king of Bavaria, was chosen to fill the throne of Greece, a council of regency was nominated during his minority, and Maurer was appointed a member. He applied himself energetically to the task of creating institutions adapted to the requirements of a modern civilized community; but grave difficulties soon arose and Maurer was recalled in 1834, when he returned to Munich. This loss was a serious one for Greece. Maurer was the ablest, most energetic and most liberal-minded member of the council, and it was through his enlightened
efforts that Greece obtained a revised penal code, regular tribunals and an improved system of civil procedure. Soon after his recall he published Das griechische Volk in öffentlicher, kirchlicher und gesetzlicher Beziehung vor und nach dem Freiheitskampfe bis zum 31 Juli 1834 (Heidelberg, 1835–1836), a useful source of information for the history of Greece before Otto ascended the throne, and also for the labours of the council of regency to the time of the author’s recall. After the fall of the ministry of Karl von Abel (1788–1859) in 1847, he became chief Bavarian minister and head of the departments of foreign affairs and of justice, but was overthrown in the same year. He died at Munich on the 9th of May 1872. His only son, Conrad von Maurer (1853–1902), was a Scandinavian scholar of some reputation and like his father was a professor at the university of Munich.

Maurer’s important master contribution to history is a series of books on the early institutions of the Germans. These are: Einleitung zur Geschichte der Mark-, Hof-, Dorf- und Stadtvorverfassung und der öffentlichen Gewalt (Munich, 1854); Geschichte der Markenverfassung in Deutschland (Erlangen, 1863); Crocoschreibung, Frankenhoefe, der Bauernhoefe, and der Hofverfassung in Deutschland (Erlangen, 1862–1863); Geschichte der Dorferfassung in Deutschland (Erlangen, 1865–1866); and Geschichte der Städteverfassung in Deutschland (Bonn, 1868). Though the works do not contain sufficient authorities for the early history of the Germans. Among other works are, Das Stadt- und Landrechtsbuch Rufprecht von Freising, Geschichte der des der der romanischen Spielspiels (Stuttgart, 1850); Über die Freipflege (plegium liberaliter) (I. Entstehung und kleinen Juri in England (Munich, 1848); and Über die deutsche Reichsterritorial- und Reichsgeschichte (1836).

MAURETANIA, the ancient name of the north-western angle of the African continent, and under the Roman Empire also of a large territory eastward of that angle. The name had different significations at different times; but before the Roman occupation, Mauretania comprised a considerable part of the modern Morocco i.e. the northern portion bounded on the east by Algiers. Towards the south we may suppose it bounded by the Atlas range, and it seems to have been regarded by geographers as extending along the coast to the Atlantic as far as the point where that chain descends to the sea, in about 30° N. lat. (Strabo, p. 825). The magnificent plateau in which the city of Marrakesh is built seems to have been unknown to ancient geographers, and was certainly never included in the Roman Empire. On the other hand, the Gaetulians to the south of the Atlas range, on the date-plotting slopes towards the Sahara, seem to have owned a precarious subjection to the kings of Mauretania, as afterwards to the Roman government. A large part of the country is of great natural fertility, and in ancient times produced large quantities of corn, while the slopes of Atlas were well filled with forests, the most celebrated of these timber woods in ancient times, produced the celebrated ornamental wood called cedrus (Plin. Hist. Nat. 13–60), for tables of which the Romans gave fabulous prices. (For physical geography, see Morocco.)

Mauretania, or Maurisia, as it was called by Greek writers, signified the land of the Mauritius, a term still retained in the modern name of Moors (q.v.). The origin and ethnic affiliations of the race are uncertain; but it is probable that all the inhabitants of this northern tract of Africa were kindred races belonging to the great Barbier family, possibly with an intermingled fair-skinned race from Europe (see Tissot, Geographie de la province romaine d’Afrique, i. 409). In 118 B.C., Julius Cæsar, on the voyage to Africa, was attacked by the tribes of the Jurghutine War (110–106 B.C.), when Mauretania was under the government of Bocus, and seems to have been recognized as the Triginta Acraeae (Strabo, vii. 3). To the north of this territory, given, after the war, the western part of Jugurtha’s kingdom of Numidia, perhaps as far east as Saldae (Bougie). Sixty years later, at the time of the dictator Caesar, we find two Mauretanian kingd--ths, one of the river Bouregreg, and the other to the east under a Bocus; as to the date or cause of the division we are ignorant. Both these kings took Caesar’s part in the civil wars of Rome, and their territory enlarged him by Apianus (see Apian, B.C. 4, 54). In 25 B.C., after their death, their territories were divided among the three sons of Julia II. of Numidia (see under Juba), with the river Ampesga as the eastern frontier (Plin. v. 22: Ptol. 4, 3, 1). And after his son’s death by his latter was put to death by Caligula, and shortly afterwards Claudius incorporated the kingdom into the Roman state as two provinces.

Viz. Mauretania Tingitana to the west of the Mulucha and M. Caesariensis to the east of that river, the latter taking its name from the city Caesarea (formerly Iol), which Juba had named and adopted as his capital. Thus the dividing line between the two provinces was that which had originally separated Mauretania from Numidia (q.v.). These provinces were governed until the time of Diocletian by imperial procurators, and were occasionally united for military purposes. Under and after Diocletian, these provinces were in the hands of Spain, with which it was in all respects closely connected; while M. Caesariensis was divided by making its eastern part into a separate government, which was called M. Sitifensis from the Roman colony sitifis.

In the two provinces of Mauretania there were at the time of Pliny a number of towns, including seven (possibly eight) Roman colonies, Mauretania Tingitana and Sisae (Seurat) and others. Others were added later. These were mostly military foundations, and were designed for the purpose of securing civilization against the inroads of the natives, who were not in a condition to be used as material for town-life by the procurators, retaining their own clan organization. Of these colonies the most important, beginning from the west, were Lixus on the Atlantic, Tangier (Tanger), Rassaddir (Melilla, Melilla), Cartama (Tenes), Iol or Caesarea (Cherchel), Icosium (Algiers), Saldae (Bougie), Iglilgi (Jijel) and Sitifis (Setif). All these were on the coast but the last, which was some distance inland. Besides these Lixus and Tangier, the Roman municipia or opider cities were: (see Plin. v. 19 seq.), but, as has been made clear by French archaeologists who have explored these regions, Roman settlements are less frequent the farther we go west, and M. Tingitana has as yet yielded little of interest. The Sisae, founded by Consul Crassus in 106 B.C., was in a flourishing condition down to the irruption of the Vandals in A.D. 429; in the Notitia nearly a hundred and seventy episcopal See also the B.C. Historische der bayrischen Staatsarchivs G. L. v. Maurer (Munich, 1963).

In 1904 the term Mauretania was revived as an official designation by the French government, and applied to the territory north of the lower Senegal under French protection (see Senegal).}

To the authorities quoted under AFRICA, ROMAN, may be added here Gobeli, Die West-kuste Afrikas im Alterthum (W. W. F. *).

MAURIAC, a town of central France, capital of an arrondissement in the department of Cantal, 39 m. N.N.W. of Aurillac by rail. Pop. (1906), 2558. Mauriac, built on the slope of a volcanic hill, has a church of the 12th century, and the buildings of an old abbey now used as public offices and dwellings; the town owes its origin to the abbey, founded during the 6th century. It is the seat of a sub-prefect and has a tribunal of first instance and a communal college. There are marble quarries in the vicinity.

MAURICUS [or MAURITIUS], ST (d. c. 880), an early Christian martyr, who, with his companions, is commemorated by the Roman Catholic Church on the 22nd of September. The oldest form of his story is found in the Passio ascribed to Eucherius, bishop of Lyons, c. 450, who relates how the "Thesan" legion commanded by Mauritius was sent to north Italy to reinforce the army of Maximian. Maximian wished to use them in the war against Persia, but the Thesaeans were of this faith, they refused, and for this, after having been treacherously betrayed, the legion was exterminated at Octodurum (Martigny) near Geneva. In later versions this legend was expanded and varied, the martyrdom was connected with a refusal to take part in a great sacrifice ordered at Octodurum and the name of Exsuperius was added to that of Mauritius. Gregory of Tours (c. 559–593) speaks of a company of the same legion which suffered at Cologne.

The Magdeburg Centuries, in spite of Mauritius being the patron saint of Magdeburg, declared the whole legend fictitious. A. J. von Bordien La Legion thibebienne (Amsterdam, 1795); J. J. Hottinger in Helvetica Kirchengeschichte (Zurich, 1708); and F. W. Retberg, Kirchengeschichte Deutschlands (Göttingen, 1845–1848) have also demonstrated its untrustworthiness, while the Bollandists, De Riaz and Joh. Friedrich uphold it. Apart from the a priori improbability of a whole legion being martyred, the difficulties are multiplied by the statement of Claudian (De Bello Civ. 2, 33) that the isolated cases of officers being put to death for their faith occurred during Maximian's reign, and on some such cases the legend may be based. The century of Mauritius was a half between Maximian and Eucherius. The cult of St Mauritius and the Thesaeans is found in Switzerland (where two places bear the name in Valais,
besides St Moritz in Grisons), along the Rhine, and in north Italy. The foundation of the abbey of St Maurice (Aguzzano) in the Veneto is usually ascribed to St Maurus of Burgundy (514). Relics of the saint are preserved here and at Breg and Turin.

**MAURICE** (MAURICUS FLAVIUS TIBERIUS) (c. 539-602), East Roman emperor from 582 to 602, was of Roman descent, but a native of Arabissus in Cappadocia. He spent his youth at the court of Justin II, and, having joined the army, fought with distinction in the Persian War (578-581). At the age of fortythree he was declared Caesar by the empress Mauricia II, who bestowed upon him the title of his daughter Constantina.

Maurice brought the Persian War to a successful close by the restoration of Chosroes II to the throne (591). On the northern frontier he at first bought off the Avars by payments which compelled him to exercise strict economy in his general administration, but after 595 inflicted several defeats upon them through his general Crispus. By his strict discipline and his refusal to ransom a captive corps he provoked to mutiny the army on the Danube. The revolt spread to the popular factions in Constanti-

The work on military art (στρατεύμα) ascribed to him is a c

**MAURICE** (1521-1553), elector of Saxony, elder son of Henry, duke of Saxony, belonging to the Albertine branch of the Wettin family, was born at Freiberg on the 23rd of March 1521.

In January 1541 he married Agnes, daughter of Philip, landgrave of Hesse. In that year he became duke of Saxony by his father's death, and he continued Henry's work in forwarding the progress of the Reformation. Duke Henry had decreed that his inheri-

tance should be divided between his two sons, but as a partition was regarded as undesirable the whole of the duchy came to his elder son. Maurice, however, made generous provision for his brother Augustus, and the desire to compensate him still further was one of the minor threads of his subsequent policy. In 1542 he assisted the emperor Charles V against the Turks, in 1543 against William, duke of Cleves, and in 1544 against the French; but his ambition soon took a wider range. The harmonious relations which subsisted between the two branches of the House of Wettin, disturbed by the death of Margrave William in Cleves, a proceeding distasteful to the Saxon elector, John Frederick; and a dispute over the bishopric of Meißen having widened the breach, war was only averted by the mediation of Philip of Hesse and Luther.

About this time Maurice seized the idea of securing for himself the electoral dignity held by John Frederick, and his opportunity came when Charles was preparing to attack the league of Schmalkalden. Although educated as a Lutheran, religious questions had never seriously appealed to Maurice. As a youth he had joined the league of Schmalkalden, but this action, as well as his subsequent declaration to stand by the confession of Augsburg, cannot be regarded as the decision of his mature years. In June 1546 he took a decided step by making a secret agreement with Charles at Regensburg. Maurice was promised some rights over the archbishopric of Magdeburg and the bishopric of Halberstadt; immunity, in part at least, for his subjects from the Tridentine decrees; and the question of transferring the electoral dignity was discussed. In return the duke probably agreed to aid Charles in his proposed attack on the league as soon as he could gain the consent of the Saxon estate, or at all events to remain neutral during the impending war. The struggle began in July 1546, and in October Maurice declared war against John Frede-

rick. He secured the formal consent of Charles to the transfer of the electoral dignity and took the field in November. He had gained a few successes when John Frederick hastened from south Germany to defend his dominions. Maurice's ally, Albert Alcibiades, prince of Bayreuth, was taken prisoner at Rochlitz; and the duke, driven from electoral Saxony, was unable to prevent his own hands from being overrun. Salvation, however, was at hand. Marching against John Frederick, Charles V, aided by Maurice, gained a decisive victory at Mühlberg in April 1547, after which by the capitulation of Wittenberg John Frederick renounced the electoral dignity in favour of Maurice, who also obtained a large part of his kinman's lands. The formal investiture of the new elector took place at Augsburg in February 1548.

The plans of Maurice soon took a form less agreeable to the emperor. The continued imprisonment of his father-in-law, Philip of Hesse, whom he had induced to surrender to Charles and whose freedom he had guaranteed, was neither his greatest nor his only cause of complaint. The emperor had refused to complete the humiliation by which his aldermen had been granted to Magdeburg, which surrendered and remained in the power of Maurice, and in January 1552 a treaty was concluded with Henry II of France at Chambord. Meanwhile Maurice had refused to recognize the *Interim* issued from Augsburg in May 1548 as binding on Saxony; but a compromise was arranged on the basis of which the Leipzig *Interim* was drawn up for his lands. It is uncertain how far Charles was ignorant of the elector's preparations, but certainly he was unprepared for the attack made by Maurice and his allies in March 1552. When in May 1552 Charles had taken his check at the interview of Münnerstadt, Frederick and Charles, and had undertaken to make peace, and the Treaty of Passau, signed in August 1552, was the result. Maurice obtained a general amnesty and freedom for Philip of Hesse, but was unable to obtain a perpetual religious peace for the Lutherans. Charles stubbornly insisted that this question must be referred to the Diet, and Maurice was obliged to give way. He then fought against the Turks, and renewed his communications with Henry of France. Returning from Hungary the elector placed himself at the head of the princes who were seeking to check the career of his former ally, Albert, and by a combination of force made him a captive to Germany. The rival armies met at Siershausen on the 9th of July 1553, where after a fierce encounter Albert was defeated. The victor, however, was wounded during the fight and died two days later.

Maurice was a friend to learning, and devoted some of the secularized church property to the advancement of education. Very different estimates have been formed of his character. He has been represented as the saviour of German Protestantism on the one hand, and on the other as a traitor to his faith and a compromiser. As a political statesman he was probably the most skilful, and his policy was as a man of great ambition who, indifferent to religious con-

siderations, made good use of the exigencies of the time. He was generous and enlightened, a good soldier and a clever diplomatist. He left an only daughter Anna (d. 1577), who became the second wife of William the Silent, prince of Orange.

The elector's *Politisiche Korresponden*s has been edited by E. Brandenburg (Leipzig, 1900-1904); and a sketch of him is given by Frederic Aschaun in *A Réport and Discourse of the Affairs and State of Germany* (London, 1864-1865). See also F. A. von Leopold, *Moritz Herzog zu Sachsen* (Leipzig, 1841); G. Voigt, *Moritz von Sachsen* (Leipzig, 1876); E. Brandenburg, *Moritz von Sachsen* (Leipzig, 1898); S. Isselb., *Moritz von Sachsen als protestantischer Fürst* (Hamburg, 1898); J. Witter, *Die Beziehung und der Verkehr des Fürstentums Moritz mit König Ferdinand* (Jena, 1888); and W. O. M. Lassalle, *Deutsches Geschicht im Zeitalter der Reformation*, Bde. IV and V. (Leipzig, 1897-1902). See also *Maurice of Saxony* (by M. A. G.) in *Allgemeine deutsche Biographie*, Bd. XXII. (Leipzig, 1885). For

MAURICE, JOHN FREDERICK DENISON (1805-1872), English theologian, was born at Normanton, Suffolk, on the 9th of August, 1805. He was the son of William Maurice, a Unitarian minister, and entered Trinity College, Cambridge, in 1823, though it was then impossible for any but members of the Established Church to obtain a degree. Together with John Sterling (with whom he founded the Apostles' Club) he migrated to Trinity Hall, whence he obtained a first class in civil law in 1827; he then came to London, and gave himself to literary work, writing a novel, Eustace Conyers, and editing the London Literary Chronicle until 1830, and also for a short time the Athenæum. At this time he was much perplexed by his pietistic opinions, and he ultimately found relief in a decision to take a further university course and to seek Anglican orders. Entering Exeter College, Oxford, he took a second class in classics in 1831. He was ordained in 1834, and after a short curacy at Bubbenhall in Warwickshire was appointed chaplain of Guy's Hospital, and became thenceforward a sensible factor in the intellectual and social life of London. From 1839 to 1841 Maurice was editor of the Education Magazine. In 1840 he was appointed professor of English history and literature in King's College, and to this post in 1846 was added the chair of divinity. In 1845 he was made Boyle lecturer and Warburton lecturer. These chairs he held till 1853. In that year he published Theological Essays, wherein were stated opinions which savoured to the principal, Dr R. W. Jelf, and to the council, of unsound theology in regard to eternal punishment. He had previously been called on to clear himself from charges of heterodoxy brought against him in the Quarterly Review (1851), and had been acquitted by a committee of inquiry. Now again he maintained with great warmth of conviction that his views were in close accordance with Scripture and the Anglican standards, but the council, without specifying any distinct "heresy" and declining to submit the case to the judgment of competent theologians, ruled otherwise, and he was deprived of his professorships. He held at the same time the chaplaincy of Lincoln's Inn, for which he had resigned Guy's (1846-1860), but when he offered to resign this the bencher refused. Nor was he assailed in the incumbency of St. Peter's, Vere Street, which he held for nine years (1860-1869), and where he drew round him a circle of thoughtful people. During the early years of this period he was engaged in a historical capacity to the late Sir Samuel (afterwards Lord) Hare, arising out of the latter's Bampton lecture upon reason and revelation.

During his residence in London Maurice was specially identified with two important movements for education. He helped to found Queen's College for the education of women (1848), and the Working Men's College (1854), of which he was the principal. He strongly advocated the abolition of university tests (1853), and threw himself with great energy into all that affected the social life of the people. Certain abortive attempts at co-operation among working men, and the movement known as Christian Socialism, were the immediate outcome of his teaching. In 1866 Maurice was appointed professor of moral philosophy at Cambridge, and from 1870 to 1872 was incumbent of St Edward's in that city. He died on the 1st of April 1872.

He was twice married, first to Anna Barton, a sister of John Sterling's, secondly to a half-sister of his friend Archdeacon Hare. His son Major-General Sir J. Frederick Maurice (b. 1841), became a distinguished soldier and one of the most prominent military writers of his time.

Those who knew Maurice best were deeply impressed with the spirituality of his character. "Whenever he woke in the night," says his wife, "he was always praying." Charles Kingsley called him "the most beautiful human soul whom God has ever allowed me to meet with." As regards his intellectual attainments we may set Julius Hare's verdict "the greatest mind since Plato" over against Ruskin's "by nature puzzle-headed and indeed wrongly-headed." Such contradictory impressions bespeak a life made up of contradictory elements. Maurice was a man of peace, yet his life was spent in a series of conflicts; of deep humility, yet so polemical that he often seemed biased; of large charity, yet bitter in his attack upon the religious press of his time; a loyal churchman who detested the label "Broad," yet critical of the Church. With an intense capacity for visualizing the unseen, and a kindly dignity, he combined a large sense of humour. While most of the "Broad Churchmen" were influenced by ethical and emotional considerations in their repudiation of the dogma of everlasting torment, he was swayed by purely intellectual and theological arguments, and in questions of a more general liberty he often opposed the proposed Liberal theologians, though he as often took their side if he saw them hard pressed. He had a wide metaphysical and philosophical knowledge which he applied to the justification of the doctrines of the Church of England as understood by himself. His love to God as his Father was a passionate devotion which filled his life with a sweetness. The directness of his teaching was particularly impressive. He prophesied in London as Isaiah prophesied to the little towns of Palestine and Syria, "often with dark foreboding, but seeing through all unrest and confusion a new order of life coming out of the chaos of the past. He and at Cambridge Maurice gathered round him a band of earnest students, to whom he directly taught much that was valuable drawn from wide stores of his own reading, wide rather than deep, for he never was a literal speaking, a learned man. Still more did he encourage the habit of inquiry and research, more valuable than his direct teaching. In his Socratic power of convincing his pupils of their ignorance he did more than perhaps any other man of his time to awaken in those who came under his sway the desire for knowledge and the process of independent thought.

As a social reformer, Maurice was before his time, and gave his eager support to schemes for which the world was not ready. From an early period of his life in London the condition of the poor pressed upon him with consuming force; the enormous magnitude of the social questions involved was a burden which he could hardly bear. For many years he was the clergyman whom working men of all opinions seemed to trust even if their faith in other religious men and all religious systems had faded, and he had a marvellous power of attracting and instructing people.

His works cover nearly 40 volumes, often obscure, often tautological, and with no great distinction of style. But their high purer gifts of philosophic insight and admirable scholarship raised them in the history of the thought of his time. The following are the more important works—some of them were rewritten and in a measure recast, and the date given is not necessarily that of the first appearance in book form:

- Eustace Conyers, or the Brother and Sister, a novel (1834); The Kingdom of Christ (1834); Christmas Day and Other Sermons (1843); The Unity of the New Testament (1844); The Epistle to the Hebrews (1846); The Religions of the World (1847); Moral and Metaphysical Philosophy (at first an article in the Encyclopædia Metropolitana, 1848); The Church a Family (1850); The Old Testament (1851); Theological Essays (1852); The Prophets and Kings of the Old Testament (1855); Lectures on Ecclesiastical History (1854); The Doctrine of Sacrifice (1854); The Patriarchs and Lawgivers of the Old Testament (1855); The Epistles of St John (1857); The Commandments as Instruments of Integrity (1857); Defences of the Bunyan character, and of Bunyan's Parables; The Conscience; Lectures on Casuistry (1868); The Lord's Prayer, a Manual (1870). The greater part of these works were first delivered as sermons or lectures. He also contributed many papers and introductions to the works of friends, as to Archdeacon Hare's Charges, Kingsley's Saint's Tragedy, &c.

MAURICE, J. F. D.—MAURICE OF NASSAU, prince of Orange (1567-1625), the second son of William the Silent, by Anna, only daughter of the famous Maurice, elector of Saxony, was born at Dillenburg. At the time of his father's assassination in 1584 he was being educated at the university of Leiden, at the expense of the states of Holland and Zeeland. Despite his youth he was made stadtholder of these two provinces and president of the council of
The primary idea of the movement was not the undertaking of literary and historical work, but the return to a strict monastic régime and the faithful carrying out of Benedictine life; and throughout the most glorious period of Maurist history the literary work was not allowed to interfere with the due performance of the choral office and the other duties of the monastic life. Towards the end of the 18th century a tendency crept in, in some quarters, to relax the monastic observances in favour of study; but the constitutions of 1770 show that a strict monastic régime was maintained until the end. The course of Maurist history and work was checkered by the ecclesiastical controversies between the bishops of France and the French Church during the 17th and 18th centuries. Some of the monks identified the remembrance with the Jansenist cause; but the bulk, including nearly all the greatest names, pursued a middle path, opposing the lax moral theology condemned in 1670 by Pope Innocent XI., and adhering to those strong views on grace and predestination associated with the Augustinian and Thomist schools of Catholic theology; and like all the theological faculties and schools on French soil, they were bound to teach the four Gallican articles. It seems that towards the end of the 18th century a rationalistic and free-thinking spirit invaded some of the houses. The congregation was suppressed and their estates scattered at the revolution, but the last superior-general with forty of his monks dying on the scaffold in Paris. The present French congregation of Benedictines initiated by Dom Guéranger in 1833 is a new creation and has no continuity with the congregation of St Maur.

The great claim of the Maurists to the gratitude and admiration of posterity is their historical and critical school, which stands quite alone in history, and produced an extraordinary number of colossal works of erudition which still are of permanent value. The foundations of this school were laid by Dom Tarisse, the first superior-general, who in 1652 issued instructions to the superiors of the monasteries to train the young monks in the habits of research and of organized work. The pioneers in production were Ménard and d'Achery.

The following tables give, divided into groups, the most important Maurist works, along with such information as may be useful to students. All works are folio when not otherwise noted:

The 58 works in the above list comprise 199 great folio volumes and 39 in 4° or 8°. The full Maurist bibliography contains the names of some 220 writers and more than 700 works. The lesser works in large measure cover the same fields as those in the list, but the number of works of purely religious character, of piety, devotion and edification, is very striking. Perhaps the most wonderful phenomenon of Maurist work is that what was produced was only a portion of what was contemplated and prepared for. The French Revolution cut short many gigantic undertakings, the collected materials for which fill hundreds of manuscript volumes in the Bibliothèque nationale of Paris and other libraries of France. There are at Paris 31 volumes of Bertheau’s materials for the Historiens of the Crusades, not only in Latin and Greek, but in the oriental tongues; from them have been taken in great measure the Recueil des historiens des croisades, whereof 15 folio volumes have been published by the Académie des Inscriptions. There exist also the preparations for an edition of Rufinus and one of Eusebius, and for the continuation of the Papal Letters and of the Concilia Galliae at Paris. It is not known how much was left, but 236 volumes of materials for a Trésor généalogique. There are Benedictine Antiquities (37 vols.), a Monasticon Gallicanum and a Monasticon Benedictinum (54 vols.). Of the Histories of the Provinces of France barely half a dozen were printed, but all were in hand, and the collections for the others fill 800 volumes of MSS. The materials for a geography of Gaul and France in 50 volumesperished in a fire during the Revolution.

When these figures were considered, and when one contemplates the vastness of the works in progress during any decade of the century 1680-1780; and still more, when not only the quantity but the quality of the work, and the abiding value of most of it is realised, it will be recognized that the output was prodigious and unique in the history of letters, as coming from a single society. The qualities that have made Maurist work proverbial for sound learning are its practical tact and its thoroughness.

The chief source of information on the Maurists and their work is Dom Tassin’s Histoire littéraire de la congrégation de Saint-Maur (1770); it has been reduced to a bare bibliography and completed by de Lama, Bibliothèque des écrivains de la cong. de S.-M. (1882). The two works of de Broglie, Mabillon (2 vols., 1888) and Montfaucon (2 vols., 1891), give a charming picture of the inner life of the great Mersenne island, and its scenery is very varied and beautiful. Sketches of the lives of a few of the chief Maurists will be found in McCarthy’s Principal Writers of the Congr. of S. M. (1886). Use of information about their literary undertakings will be found in De Lescinsky’s Cabinet des MSS. de la Bibliothèque Nationale (1758). General information will be found in the standard authorities: Helvy, Hist. des ordres religieux (1718), vi. c. 37; Heimburger, Histoire des congrégations religieuses (1807), iii. p. 96; Wetz zu, Kungl Kongressen (1807), § 36; Lessen, Bévue de l’histoire des congrégations romaines (ed. 2) and Herzog-Hauck’s Realencyclopädie (ed. 3), the latter an interesting appreciation by the Protestant historian Otto Zöckler of the spirit and the merits of the work of the Maurists. (E. C. B.)

MAURITIUS, an island and British colony in the Indian Ocean (known whilst a French possession as the Ile de France). It lies between 57° 18’ and 57° 49’ E., and 19° 58’ and 20° 32’ S., 550 m. E. of Madagascar, 2300 m. from the Cape of Good Hope, and 9500 m. from England via Suez. The island is irregularly elliptical—somewhat triangular—in shape, and is 36 m. long from N.N.E. to S.S.W., and about 23 m. broad. It is 130 m. in circumference, and its total area is about 710 sq. m. (For map see MADAGASCAR.) The island is surrounded by coral reefs, so that the ports are difficult of access.

From its mountainous character Mauritius is a most picturesque island, and its scenery is very varied and beautiful. It has been admirably described by Bernardin de St. Pierre, who lived in the island towards the close of the 18th century, in Paul et Virginie. The most level portions of the coast districts are the north and north-east, all the rest being broken by hills, which vary from 500 to 2700 ft. in height. The principal mountain masses are the north-western or Pouce range, in the district of Port Louis; the south-western, in the districts of Rivière Noire and Savanne; and the south-eastern range, in the Grand Port district. In the first of these, which consists of one principal ridge with several lateral spurs, overlooking Port Louis, are the singular peak of the Pouce (3650 ft.), so called from its supposed resemblance to the human thumb; and the still loftier Pieter Botte (2685 ft.), a tall obelisk of bare rock, crowned with a globular mass of stone. The highest summit in the island is in the south-western mass of hills, the Piton de la Rivière Noire, which is 2711 ft. above the sea. The south-eastern group of hills consists of the Montagne du Bambou, with several spur running down to the sea. In the interior are extensive fertile plains, some 1200 ft. in height, forming the districts of Moka, Vacoas, and Plains de Wilmont; and from nearly the centre of the island an abrupt peak, the Piton du Milieu de l’Ile rises to a height of 1932 ft. Other prominent summits are the Trois Mamelles, the Montagne du Corps de Garde, the Signal Mountain, near Port Louis, and the Morne Brabant, at the south-west corner of the island.

The rivers are small, and none is navigable beyond a few hundred yards from the sea. In the dry season little more than brooks, they become raging torrents in the wet season. The principal stream is the Grande Rivière, with a course of about 10 m. There is a remarkable and very deep lake, called
Grand Bassin, in the south of the island, it is probably the extinct crater of an ancient volcano; similar lakes are the Mare aux Vacoas and the Mare aux Jones, and there are other deep hollows which have a like origin.

Of basaltic origin. has been largely destroyed by denudation. There are many caverns and steep ravines, and from the character of the rocks are captured by the streams. The island has few minerals, although iron, lead and copper are found in small quantities.

The greater part of the surface is composed of a volcanic breccia, with here and there lava-streams exposed in ravines, and sometimes on the surface. The islets and most of the smaller islands are composed of former volcanic rocks are found at considerable elevations. In the Black River Mountains, at a height of about 1200 ft., there is a clay-slate, and near Midlands, in the Grand Port group of mountains, a chioric whilst about 1700 ft above the sea, forming the hill of La Selle. This schist is much contorted, but seems to have a general dip to the south or south-east. Evidence of recent elevation of the island is furnished by masses of coral reef and broken branches standing at heights of 40 ft. above sea-level in the south, 12 ft. in the north and 7 ft. on the islands situated on the bank extending to the north-east.  

Climate.—The climate pleasant during the cool season of the year, but oppressively hot in summer (December to April), except in the elevated plains of the interior, where the thermometer ranges from 70° to 80° F., while in Port Louis and on the coast generally it is much higher. The annual rainfall at Port Louis is 75-6°. There are two seasons, the cool and comparatively dry season, from April to November, and the hotter season, during the same time. The temperature is about the same, and there is severe epidemics of malarial fever having frequently occurred, so that malaria appears to be endemic among the non-European population. The rainfall varies greatly in different parts of the island. Cluny in the Grand Port (south-eastern) district has a mean annual rainfall of 145 in.; Albion on the west coast is the driest station, with a mean annual rainfall of 31 in. The mean monthly rainfall is greatest in December and January, least in September and October. The Royal Alfred Observatory is situated at Pamplemousses, on the north-west or dry side of the island. From January to the middle of April, Mauritius, in common with the surrounding islands and the surrounding ocean from 8° to 30° of southern latitude is subject to severe cyclones, accompanied by torrents of rain, which often cause great destruction to houses and plantations. These hurricanes generally last about eight hours, but their surface is so frequent and violent that in former times, owing, it is thought, to the destruction of the ancient forests and the consequent drier condition of the atmosphere.

Animal and Flora.—Mauritian birds show a peculiar, tropical affinity of small size, its present fauna is very limited in extent. When first seen by Europeans it contained no mammals except a large fruit-eating bat (Pteropus vulgaris), which is plentiful in the woods; but several mammals have since been introduced. The native birds are limited in the interior region. Among these are two monkeys of the genera Macacus and Ceropithecus, a stag (Cerus hippolophus), a small hare, a shrew-like animal, and a hedgehog-like insectibora of Madagascar (Centetes canadus) which have probably both been brought from the larger island. The avifauna resembles that of Madagascar; there are species of a peculiar genus of caterpillar-shrikes (Campophagidae), as well as of the genera Pratincola, Hypstpetes, Phildina, Tchitorea, Zosterops, Pindilla, Colica- 

ialas and Coracopis, and peculiar forms of doves and parakeets

The living reptiles are small and few in number. The surrounding seas contain great numbers of fish; the coral reefs abound with a great variety of molluscs; and there are numerous land-shells. The ex- 

The destruction of the primate forests for the formation of coffee and sugar plantations has been considerable. The interior plains, in the river valleys and on the hills; and it is not now easy to distinguish between what is native and what has come from abroad. The principal timber tree is the ebony (Disopros ebenum) which is valuable for the construction of government houses and boats. There are also the coco-nut palm, an importation, but a tree which has been so extensively planted during the past two centuries has been made very plentiful; the palmiste (Palma dactylifera latifolia), the latanier (Corphy ambruzisifera) and the date-palm. The vavaco or vavaco, (Pandanus wiliis) is largely grown, the long tough leaves being used in the manufacture of burlap and the roots being also made of use; and in the few remnants of the original forests the traveller's tree (Lunaria speciosa), grows abundantly. A species of broad-leaved plant, very plentiful in the river valleys, is in the market. A large variety of fruit is produced, including the tamarind, mango, banana, pineapple, guava, shaddock, fig, avocado-pear, litchi, custard-apple and the mabolo (Disopros disolor), a fruit resembling the longan (Nephelium lappaceum). The fruits and vegetables of Europe have been introduced, as well as some of those peculiar to the tropics, including maize, millet, yams, manioc, dhoil, gram, &c. Small quantities of tea, rice and sago, are available in the market; as are many of the spices (pepper, ginger and allspice), and also cotton, indigo, betel, camphor, turmeric and vanilla. The Royal Botanical Gardens at Pample- 

Including the military and crews of ships in harbour, the total population in 1901 was 372,536. This total included 198,998 Indo-Mauritians, i.e., persons of Indian descent born in Mauritius, and 1,05,341 Indians. There were 3,993 Chinese, while the remaining 109,874 included persons of European, African, Arab, Persian or Portuguese, Malagasy, Malaya and Sinhalese. The Indian female population increased from 31,019 in 1861 to 115,986 in 1901. In the same period the non-Indian female population has increased, being 67,070 in 1861 and 55,485 in 1901. The Indo-Mauritians are now dominant in commercial, agricultural and domestic callings, and much town and agricultural land has been transferred from the Creole planters to Indians and Chinese. The tendency to an Indian peasant proprietorship is marked. Since 1864 real property to the value of over 11,25,000 has been acquired by Asians. Between 1881 and 1901 the number of sugar factories has been increased, and sugar being held in small parcels by Indians. The average death-rate for the period 1873-1901 was 32-6 per 1000. The average birth-rate in the Indian community is 37 per 1000; in the non-Indian community 31 per 1000. Many Mauritius Creoles have emigrated to South Africa. The great increase in the population since 1851 has made Mauritius one of the most densely peopled regions of the world, having 520 persons per square mile.

Chief Towns.—The capital and seat of government, the city of Port Louis, is on the north-west side of the island, in 20° 10' S., 57° 30' E. At the head of an excellent harbour, a deep inlet about a mile in width, the defile of the defiles, has been skillfully protected by Fort William and Fort George, as well as by the citadel (Fort Adelaide), and it has three graving-docks connected with the inner harbour, the depths alongside quays and berths being from 12 to 14 ft. The Castle of Good Hope, a massive structure through the port. Government House is a three-storeyed structure with broad
MAURITIUS

verandas, of no particular style of architecture, while the Protestant cathedral possesses a spire to which a golden bow and a crane have been added. The Roman Catholic cathedral is pretentious in style, but is tawdry in its interior. There are, besides, the town-hall, Royal College, public offices and theatre, large barracks and hospitals. Port Louis is governed by an elective municipal council, is surrounded by lofty hills and its unhealthy situation is aggravated by the difficulty of effective drainage owing to the small amount of rainfall. Though much has been done to make the town sanitary, including the provision of a good water-supply, the death-rate is generally over 44 per 1000. Consequently all those who can make their homes in the cooler upland localities resist the temptation of the tempting climate. More than 70,000 in 1891 and 53,000 in 1901. The favourite residential town is Curepipe, where the climate resembles that of the south of France, and the annual average temperature of the hot season is only 24.4°. From Port Louis by rail and 1800 ft. above the sea the town was incorporated in 1888 and had a population (1901) of 13,000. On the railway between Port Louis and Curepipe are other residential stations: Beau-Bassin, Rose Hill and Port St. Louis, pop. (1901), 4810, is a town on the shores of Grand Port on the south-east side of the island, Souillac a small town on the south coast.

Industries.—The Sugar Plantations.—The soil of the island is of considerable fertility; it is a ferruginous red clay, but so largely mingled with stones of all sizes that no plough can be used, and the land has not been prepared for cultivation. The greater portion of the plains is now a level sugar plantation; the bright green of the sugar fields is a striking feature in a view of Mauritius from the sea, and gives a peculiar beauty and freshness to the island. The cultivation of sugar is accompanied by other kinds of tropical produce, and it is to be regretted that the prosperity of the colony depends almost entirely on one article of production, for this confines the consumers when there is a failure, more or less, of the sugar crop. Guava, eatable in its natural state and by its use the natural fertility of the soil has been increased to a wonderful extent. Since the beginning of the 20th century some attention has been paid to the cultivation of tea and cotton, with encouraging results. Of the exports, sugar amounts on an average to about 95% of the total. The quantity of sugar exported rose from 71,000 tons in 1843 to 189,164 tons in 1877. The competition of beet-sugar and the increased bounty granted by various countries then began to tell on the production in Mauritius, the average crop for the seven years ending 1900-1906 being only 150,449 tons. The British Government, therefore, has increased the Factory to 189 tons. The average amount of sugar exported for the years 1904-1906 being 182,000 tons. The value of the crop was likewise seriously affected by the causes mentioned, and by various diseases which attacked the canes. Thus in 1878 the value of the sugar exported was £3,458,000; in 1888 it had sunk to £1,911,000, and in 1898 to £1,632,000. In 1900 the value was £1,922,000, and in 1905 it had risen to £2,172,000. India and the South African colonies between them take about two-thirds of the total sugar produced, the remainder is taken chiefly by Great Britain, Canada and Hong Kong. Next to sugar, asbest is the most important export, the average annual value of the year 1902 being £23,600. In addition, a considerable quantity of molasses and smaller quantities of rum, vanilla and coco-nut oil are exported. The imports are mainly foodstuffs, that is, cotton goods, wine, coal, hardware and haberdashery, and groceries. The rice comes entirely from Madagascar; cattle are imported from Madagascar, sheep from South Africa and Australia, and frozen meat from Australia. The average annual value of the imports for the ten years 1896-1905 was £2,153,159; the average annual value of the imports for the ten years 1896-1905 was £2,153,159; the average annual value of the imports for the ten years 1896-1905 was £2,153,159; the average annual value of the imports for the ten years 1896-1905 was £2,153,159; the average annual value of the imports for the ten years 1896-1905 was £2,153,159.

Communications.—There is a regular fortnightly steamer service between Mauritius and Port Louis, and between the following ports: Union Castle, and a four-weekly service with Colombo direct by the British India Steam Navigation Co., which is chiefly in Chinese hands. The average number of ships entering Port Louis is about 750,000 of which five-sevenths are of British. Cable communication exists with Madagascar, Seychelles, Singapore, and even on the mainland. A telegraph line was established in 1893, and the Mauritius section of the Cape-Australian cable, via Rodriguez, was completed in 1902.

Railways connect all the principal places and sugar estates on the island, that known as the Midland line, 36 miles long, beginning at road at Curepipe, and passing through Curepipe, where it is 182 ft. above the sea. The whole line is about 120 miles of railway, all owned and worked by the government. The first railway was opened in 1864. The roads are well kept and there is an extension of the sugar estates from the railway lines. Traction is also largely used. There is a complete telegraphic and telephonic service.

Government and Revenue.—Mauritius is a crown colony. The government is assisted by an executive council of five official and elected members, and a legislative council of 27 members, 8 sitting ex officio. It is administered by the governor and 10 elected on a moderate franchise. Two-fourth of the members represent St Louis, the 8 rural districts into which the island is divided each electing one member. At least one-third of the nominated members must be persons not holding any public office. The number of registered electors in 1908 was 6186. The legislative session usually lasts from April to December. Members may speak either in French or English. The average annual revenue of the colony for the ten years 1896-1905, was £1,359,000, the average annual expenditure during the same period £633,606. Upon the revenue there was a surplus in hand, but since that time expenditure has caused many exceptional occasions increased income, and the public debt in 1908 was £1,335,000, mainly incurred however on reproductive works.

Religion and Education.—The majority of the European inhabitants belong to the Roman Catholic faith. They numbered at the 1901 census 117,102, and the Protestants 662. French, Roman Catholics and the Church of Scotland are helped by state grants. At the head of the Anglican community is the bishop of Mauritius; the Earl of Minto has been governor of that island. The Mahomedans number over 30,000, but the majority of the Indian coolies are Hindus.

The educational system, as brought into force in 1900, is under a director of public instruction assisted by a committee and consists of two branches (1) superior or secondary instruction, (2) primary instruction. For primary instruction there are government schools and schools maintained by the Roman Catholics, Protestants and other bodies, to which the government gives grants in aid. In 1908 there were 67 government schools with 4840 scholars and 90 grant schools with 10,020 scholars, besides Hindu schools maintained by Endowments, of 100 and 377 scholars. In the years 1902-4, the average weekly grant given to the Protestants 3•8•0; Mahomedans 8•37•0; and Hindus and others 20•11•0. Secondary and higher education is given in the Royal College and the Government schools at Port Louis and Curepipe.

Defence.—Mauritius occupies a prominent position on the route between South Africa and India and in relation to Madagascar and East Africa, while in Port Louis it possesses one of the finest harbours in the Indian Ocean. A permanent garrison of some 3000 men is maintained in the island at a cost of about £180,000 per annum. To the cost of the troops Mauritius contributes 51% of its annual revenue—about £60,000.

History.—Mauritius appears to have been unknown to European nations, if not to all other peoples, until the year 1505, when it was discovered by Mascarenhas, a Portuguese navigator. It had then no inhabitants, and there seem to be no traces of a prehistoric occupation by any people. The island was retained for most of the 16th century by its discoverers, but they made no settlements in it. In 1508 the Dutch took possession of it. Here are in all over 10,000 people named by Pliny. But though the Dutch built a fort at Grand Port and introduced a number of slaves and convicts, they made no permanent settlement in Mauritius, finally abandoning the island in 1710. From 1715 to 1767 (when the French took possession) the island was held by agents of the French East India Company. In 1789, however, the island changed to "Isle de France." The Company was fortunate in having several able men as governors of its colony, especially the celebrated Mahé de Labourdinaux (q.v.), who made sugar
planning the main industry of the inhabitants. Under his direction roads were made, forts built, and considerable portions of the forest were cleared, and the present capital, Port Louis, was founded. Labourdonnais also promoted the planting of cotton and indigo, and is remembered as the free propagator and best of all the French governor. He also put down the maroons or runaway slaves who had long been the pest of the island. The colony continued to rise in value during the time it was held by the French crown, and to one of the intendents, Pierre Poivre, was due the introduction of the clove, nutmeg and other spices. Another governor was D'Entrecasteaux, whose name is kept in remembrance by a group of islands east of New Guinea.

During the long war between France and England, at the commencement of the 19th century, Mauritius was a continual source of much mischief to English Indiamen and other merchant vessels; and at length the British government determined upon an expedition for its capture. This was effectuated in 1810; and upon the restoration of peace in 1814 the possession of the island was confirmed to Britain by the Treaty of Paris. By the eighth article of capitulation it was agreed that the inhabitants should retain their own laws, customs, and religion; and thus the island is still largely French in language, habits, and predilections; but its name has again been changed to that given by the Dutch. One of the most distinguished of the British governors was Robert Farquhar (1758-1852), who did much to abolish the Malagasy slave trade and to establish friendly relations with the rising power of the Hova sovereign of Madagascar. Later governors of note were Sir Henry Barkly (1863-1871), and Sir J. Pope Hennessy (1883-1886 and 1888).

The history of the colony since its acquisition by Great Britain has been one of social and political evolution. At first all power was concentrated in the hands of the governor, but in 1832 a legislative council was constituted on which non-official nominated members served. In 1854–1885 this council was transformed into an elected body. Of more importance than the constitutional changes were the economic results which followed the freeing of the slaves (1834-1839)—for the loss of whose labour the planters received over £2,000,000 compensation. Coillies were introduced to supply the place of the negroes, immigration being definitely sanctioned by the government of India in 1842. Though under government control the system of cooie labour led to many abuses. A royal commission investigated the matter in 1871 and since that time the evils which were attendant on the system have been gradually remedied. One result of this system was the abolition of the two classes and the establishment of a new class of coolies, the laborers. This new class has been to reduce the descendants of the slave population to a small and unimportant class—Mauritius in this respect offering a striking contrast to the British colonies in the West Indies. The last half of the 19th century was, however, chiefly notable in Mauritius for the number of calamities which overtook the island. In 1854 cholera caused the death of 17,000 persons; in 1857 over 30,000 people died of malarial fever; in 1852 a hurricane of terrific violence caused immense destruction of property and serious loss of life; in 1893 great part of Port Louis was destroyed by fire. There were in addition several epidemics of small-pox and plague, and from about 1890 onward the continual decline in the price of sugar seriously affected the islanders, especially the Creole population. During 1902–1905 an outbreak of surra, which caused great mortality among draught animals, further tried the sugar planters and necessitated government help. Notwithstanding all these calamities the Mauritians, especially the Indo-Mauritians, have succeeded in maintaining the position of the colony as an important sugar-producing country.

Dependents—Dependent upon Mauritius and forming part of the colony are a number of small islands scattered over a large extent of the Indian Ocean. Of these the chief is Rodriguez (q.v.), just east of Mauritius. Considerably north-east of Rodriguez lie the Oil Islands or Chagos archipelago, of which the chief is Diego Garcia (see Chagos). The Cargados, Carayos or St Brandon islands, and also a number of small islands in the Bay of Bengal, include 250 m. N.N.E. of Mauritius. Until 1903 the Seychelles, Amirantes, Aldabra and other islands lying north of Madagascar were also part of the colony of Mauritius. In the year named they were ceded to France and are now part of the colony of the Seychelles, Farquhar and Coetivy, though geographically within the Seychelles area, remained dependent on Mauritius, being owned by residents in that island. In 1908, however, Coetivy was sold to Russia and the inhabited islands in the South Indian Ocean, included in an official list of the dependencies of Mauritius drawn up in 1880, were in 1908 transferred to France. The total population of the dependencies of Mauritius was estimated in 1905 at 4,000.

(1895); the Annual Reports on Mauritius issued by the Colonial Office, London; The Mauritius Almanach published yearly at Port Louis. A map of the island in six sheets on the scale of one inch to a mile was issued by the War Office in 1905. (J. St.)

MAURY, J. S. (1746-1817), French cardinal and archbishop of Paris, the son of a poor cobbler, was born on the 26th of June 1746 at Valrées in the Comtat-Venassin, the district in France which belonged to the pope. His acuteness was observed by the priests of the seminary at Avignon, where he was educated and took orders. He tried his fortune by writing dialogues of famous persons, then a favourite practice; and in 1771 his Dialogue of Fénelon was pronounced next best to Laharpe's by the Academy. The title of his book of 1770 to the Pope of Rome, delivered on St Louis delivered before the Academy in 1772, which caused him to be recommended for an abbacy. In 1777 he published under the title of Discours choisis his panegyrics on St Louis, St Augustine and Fénelon, his remarks on Bossuet and his Essai sur l'éloquence de la chaire, a volume which contains much good criticism, and remains a French classic. The book was often reprinted as Principes de l'éloquence. He became a favourite preacher in Paris, and was Lent preacher at court in 1781, when King Louis XVI. said of his sermon: "If the abbé had only said a few words on religion he would have disguised every possible subject." In 1781 he obtained the rich priory of Lyons, near Péronne, and in 1785 he was elected to the Academy, as successor of Lefranc de Pompignan. His morals were as loose as those of his great rival Mirabeau, but he was famed in Paris for his wit and gaiety. In 1780 he was elected a member of the states-general by the clergy of the bailliage of Péronne, and from the first proved to be the most able and persevering defender of the ancien régime, although he had drawn up the greater part of the cahier of the clergy of Péronne, which contained a considerable number of propositions so calculated to excite the most bitter animosity against the clergy. During the subsequent debates, he attempted to mitigate both in July and in October 1789; but after that time he held firmly to his party, when almost universally deserted by his friends. In the Constituent Assembly he took an active part in every important debate, combating with especial vigour the alienation of the property of the clergy. His life was often in danger, but his ready wit always saved it, and it was said that one bon mot would preserve him for a month.
MAURY, L. F. A.—MAURY, M. F.

When he did emigrate in 1792 he found himself regarded as a martyr to the church and the king, and was at once named archbishop in partibus, and extra nuncio to the diet at Frankfort, and in 1794 cardinal. He was finally made bishop of Montecassino, and settled down in that city, by Italian townsmen, but for long, he was driven from his retreat, and he sought refuge in Venice and St Petersburg. Next year he returned to Rome as ambassador of the exiled Louis XVIII at the papal court. In 1804 he began to prepare his return to France by a well-turned letter to Napoleon, congratulating him on restoring religion to France once more. In 1806 he did return; in 1807 he was again received into the Academy; and in 1810, on the refusal of Cardinal Fesch, was made archbishop of Paris. He was presently ordered by the pope to surrender his functions as archbishop of Paris. This he refused to do. On the restoration of the Bourbons he was summarily expelled from the Academy and from the archiepiscopal palace. He retired to Rome, where he was imprisoned in the castle of St Angelo for six months for his disobedience to the papal orders, and died in 1817, a year or two after his release, of disease contracted in prison and of chagrin. As a critic he was a very able writer, and Sainte-Beuve gives him the credit of discovering Father Jacques Bridiane, and of giving Bossuet his rightful place as a preacher above Massillon; as a politician, his wit and eloquence make him a worthy rival of Mirabeau. He said once that too much of the Revolution was done without being a grateful act if Louis XVIII. had remembered the courageous supporter of Louis XVI., and the pope the one intrepid defender of the Church in the states-general.

The Cours choisis du Cardinal Maury (5 vols., 1827) contain what is worth preserving. Mgr Ricard has published Maury's Correspondance diplomatique (2 vols., Lille, 1861). For his life and character see Vie du Cardinal Maury (1882; 2 vols., Lille, 1885). Mgr Ricard, L'Abbe Maury (1870); L'Abbe Maury avant 1789 (1873); L'Abbe Maury (1875); G. Bonet-Maury, Le Cardinal Maury aprés ses memoires et sa correspondance inedites (Paris, 1892); A. Aulard, Les Oeuvres de le constituante (Paris, 1885). Of the many libels written against him during the Revolution the most noteworthy are the Petit carmele de l'abbé Maury, with a supplement called the Seconde année (1790), and the Vie privée de l'abbé Maury (1790), claimed by J. R. Hébert, but attributed by some writers to Restif de la Bretonne. For further bibliographical details see J. M. Quérard, La France littéraire, vol. v. (1833).

MAURY, LOUIS PERDINAND ALFRED (1817-1892), French scholar, was born at Meaux on the 23rd of March 1817. In 1836, having completed his education, he entered the Bibliotheque Nationale, and afterwards the Bibliotheque de l'Institut (1844), where he devoted himself to the study of archaeology, ancient and modern languages, medicine and law. Gifted with a great capacity for work, a remarkable memory and an unbiassed and critical mind, he produced without great effort a number of learned pamphlets and books on the most varied subjects. He rendered great service to the Académie des Inscriptions et Belles Lettres, of which he had been elected a member in 1857. Napoleon III. employed him in research work connected with the Histoire de César, and he was rewarded, proportionately to his active, if modest, part in this work, with the positions of librarian of the Tuileries (1860), professor at the College of France (1862) and director-general of the Archives (1868). It was not, however, to the imperial favour that he owed these high positions. He used his influence for the advancement of science and higher education, and with Victor Duruy was one of the founders of the École des Hautes Études. He died at Paris four years after his retirement from the last post, on the 11th of February 1892.

BIBLIOGRAPHY.—His works are numerous: Les Promes au moyen âge and Histoire des légendes pieuses au moyen âge; two books filled with ingenious ideas, which were published in 1843, and reprinted after the death of the author, with numerous additions and corrections. The Légendes pieuses et du moyen âge (1856); Histoire des grands feasts de la Gaule and of l'ancienne France (1850, a 3rd ed. revised and appeared in 1867 under the title Les Fêtes de la Gaule and de l'ancienne France); La Terre et l'homme, a general historical sketch of coast, geography and ethnology, being the introduction to the Histoire universelle, by Victor Duruy (1844); Histoire des religions de la Grèce antique, (3 vols., 1857-1859); La Magie et l'astrologie dans l'antiquité et dans le moyen âge (1863); Histoire de l'Académie des sciences (1864); Histoire de l'Académie des Inscriptions et Belles Lettres (1865); a learned paper on the reports of French archeology, the Naval of the occasion exhibition (1867); a number of articles in the Encyclopédie moderne (1840-1851), in Michaud's Biographie universelle (1858 and seq.), in the Journal des savants in the Revue des deux mondes (1857, 1877, 1890-1850, &c.). A detailed bibliography is given in Longnon's Histoire de la légende, at the beginning of the volume Les Croyances et légendes du moyen âge.

MAURY, MATTHEW FONTAINE (1806-1873), American naval officer and hydrographer, was born near Fredericksburg in Spotsylvania county, Virginia, on the 24th of January 1806. He was educated at Harpeth academy, and in 1825 entered the navy as midshipman, circumnavigating the globe in the Vincennes, during a cruise of four years (1826-1829). In 1831 he was appointed master of the sloop "Falmouth" on the Pacific station, and subsequently served in other vessels before returning home in 1834, when he married his cousin, Ann Herndon. In 1835-1836 he was actively engaged in producing for publication a treatise on navigation, a remarkable achievement at so early a stage in his career; he was at this time made lieutenant, and gazetted astronomer to a South Sea exploring expedition, but resigned this position and was appointed to the survey of southern harbours. In 1839 he met with an accident which resulted in permanent lameness, and unfitted him for active service. In the same year he was made professor of the academy, and engaged in naval reform and other subjects, under the title of Scraps from the Lucky-Bag, which attracted much attention; and in 1841 he was placed in charge of the Dépôt of Charts and Instruments, out of which grew the United States Naval Observatory and the Hydrographic Office. He laboured assiduously to obtain observations as to the winds and currents by distributing to captains of vessels specially prepared log-books; and in the course of nine years he had collected a sufficient number of logs to make two hundred manuscript volumes, each with about two thousand observations, and during which time he began to write a series of popular articles on ocean meteorology. This led to an international conference at Brussels in 1853, which produced the greatest benefit to navigation as well as indirectly to meteorology. Maury attempted to organize co-operative meteorological work on land, but the government did not at this time take any steps in this direction. His oceanographical work, however, received recognition in all parts of the civilized world, and in 1855 it was proposed in the senate to remunerate him for his services by establishing a Retiring Board, engaged under an act to promote the efficiency of the navy, placed him on the retired list. This action aroused wide opposition, and in 1858 he was reinstated with the rank of commander as from 1855. In 1853 Maury had published his Letters on the Amazon and Atlantic Slopes of South America, and the most widely popular of his works, the Physical Geography of the Sea, was published in London in 1855, and in New York in 1856; it was translated into several European languages. On the outbreak of the American Civil War in 1861, Maury threw in his lot with the South, and became head of coast, harbour and river defences. He invented an electric torpedo for harbour defence, and in 1862 was ordered to England to purchase torpedo material, &c. Here he took active part in organizing a petition for peace to the American people, which was unsuccessful. Afterwards he became imperial commissioner of emigration to the emperor Maximilian of Mexico, and attempted to form a Virginian colony in that country. Incidentally he introduced there the cultivation of cinchona. The scheme of colonization was abandoned by the emperor (1866), and Maury, being then nearly his last duty during the war, retired to England, where he was presented with a testimonial raised by public subscription, and among other honours received the degree of LL.D. of Cambridge University (1868). In the same year, a general amnesty admitting of his return to America, he accepted the professorship of meteorology in the Virginia Military Institute, and settled at Lexington, Virginia, where he died on the 1st of February 1873.
AMONG works published by Maury, in addition to those mentioned, are the papers contributed by him to the Astronomical Observations of the United States Observatory, Letter concerning Lanes for Steamers crossing the Atlantic (1853); Physical Geography (1864) and Manual of Geography (1871). In 1859 he began the publication of a series of Nautical Monographs.

See Diana Fontaine Maury Corbin (his daughter), Life of Matthew Fontaine Maury (Lexington, 1888).

MAUSOLEUM—the tomb given to a monument erected to receive the remains of a deceased person, which may sometimes take the form of a sepulchral chapel. The term cenotaph (Gr. κενός, empty, τόφος, tomb) is employed for a similar monument where the body is not buried in the structure. The term "mausoleum" originated with the magnificent monument erected by Queen Artemisia in 335 B.C. in memory of her husband King Mausolus, of which the remains were brought to England in 1859 by Sir Charles Newton and placed in the British Museum. The tombs of Augustus and of Hadrian in Rome are perhaps the last monuments of the kind ever erected.

MAUSOLUS (more correctly MAUSSOLLES), satrap and practically ruler of Caria (377-353 B.C.). The part he took in the revolt against Artaxerxes Mmnon, his conquest of a great part of Lycia, Ionia and of several of the Greek islands, his co-operation with the Rhodians and their allies in the war against Athens, and the removal of his capital from Mysia, the ancient seat of the Carian kings, to Halicarnassus are the leading facts of his history. He is best known from the tomb erected for him by his wife Artemisia. The architects Satyrus and Pythis, and the sculptors Scopas, Leochares, Bryaxis and Timotheus, finished the work. See HALICARNASSUS. An inscription discovered at Mysia (Böckh, Inschr. gr. ii. 2691 c) details the punishment of certain conspirators who had made an attempt upon his life at a festival in a temple at Labranda in 353.

See Diod. Sic. xvi. 90, 3, xvi. 7, 4, 36, 2; Demosthenes, De Rhodiam urbem lib.; J. B. Bury, Hist. of Greece (1902), ii. 271; W. J. Jegede, Kleinasziatiscbe Studien (Marburg, 1852), pp. 226-226, and authorities under HALICARNASSUS.

MAUVE, ANTON (1838-1888), Dutch landscape painter, was born at Zaandam, the son of a Baptist minister. Much against the wish of his parents he took up the study of art and entered the studio of Van Os, whose dry academic manner had, however, but little attraction for him. He benefited far more by his intimacy with his friends Jozef Israels and W. Maris. Encouraged by their example he abandoned his early tight and highly finished manner for a freer, looser method of painting, and the brilliant palette of his youthful work for a tender lyric harmony which he expresses in soft tones of delicate greens, greys, and light blue. He excelled in rendering the soft hazy atmosphere that lingers over the green meadows of Holland, and devoted himself almost exclusively to depicting the peaceful rural life of the fields and country lanes of Holland—especially of the districts near Oosterbeek and Woerden, the sand dunes of the coast at Scheveningen, and the country near Laren, where he spent the last years of his life. A little sad and melancholy, his pastoral scenes are nevertheless conceived in a peaceful soothing lyrical mood, which is in marked contrast to the epic power and almost tragic intensity of J. F. Millet. There are fourteen of Mauve's pictures at the Mesdag Museum at the Hague, and two ("Milking Time" and "A Fishing Boat putting to Sea") at the Ryks Museum in Amsterdam. The Glasgow Corporation Gallery owns his painting of "A Flock of Sheep." The finest and most representative private collection of pictures by Mauve was made by Mr J. C. J. Drucker, London.

MAVRICORDATO, MAVRICOORDAT or MAVRICOARDATO, the name of a family of Phanariot Greeks, distinguished in the history of Turkey, of Austria and of modern Greece. The family was founded by a merchant of Chios, whose son Alexander Mavrocordato (c. 1635-1700), a doctor of philosophy and medicine of Bologna, became dragoman to the sultan in 1673, and was much employed in negotiations with Austria. It was he who drew up the treaty of Karlowitz (1699). He became a secretary of state, and was created a count of the Holy Roman Empire. His authority, with that of Hussein Kupruli and Rami Pasha, was supreme at the court of Mustapha II., and he did much to ameliorate the condition of the Christians in Turkey. He was disgraced in 1703, but was recalled to court by Sultan Murad IV. He left some historical, grammatical, &c. treatises of little value.

His son NICHOLAS MAVRICOARDATO (1670-1739) was grand dragoman to the Divan (1697), and in 1708 was appointed hospodar (prince) of Moldavia. Deposed, owing to the sultan's suspicions, in favour of Demetrius Cantacuzene, he was restored in 1711, and soon afterwards became hospodar of Walachia. In 1716 he was deposed by the Austrians, but was restored after the peace of Passarowitz. He was the first Greek set to rule the Danubian principalities, and was responsible for establishing the system which for a hundred years was to make the name of Moldavia famous. He adhered to the Greek manners, the Greek language and Greek costume, and set up a splendid court on the Byzantine model. For the rest he was a man of enlightenment, founded libraries and was himself the author of a curious work entitled Плектры патриотов (Bucharest, 1719). He was succeeded as grand dragoman (1709) by his son John (Ioannes), who was for a short while hospodar of Moldavia, and died in 1720.

Nicholas Mavrocordato was succeeded as prince of Walachia in 1730 by his son Constantine. He was deprived in the same year, but again ruled the principality from 1735 to 1741 and from 1750 to 1756. He occupied Moldavia from 1741 to 1744 and from 1748 to 1749. His rule was distinguished by numerous tentative reforms in the fiscal and administrative systems. He was wounded and taken prisoner in the affair of Galati during the Russo-Turkish War, on the 5th of November 1769, and died in captivity.

PRINCE ALEXANDER MAVRICOARDATO (1701-1865), Greek statesman, a descendant of the hospodars, was born at Constantinople on the 11th of February 1791. In 1812 he went to the court of his uncle Ioannes Caradja, hospodar of Walachia, with whom he passed into exile in Russia and Italy (1817). He was a member of the Hetairia Philhellen and was responsible for numerous attempts to introduce Greek letters of the Morea on the outbreak of the War of Independence in 1821. He was active in endeavouring to establish a regular government, and in January 1822 presided over the first Greek national assembly at Epidaurus. He commanded the advance of the Greeks into western Hellas the same year, and suffered a defeat at Peta on the 16th of July, but retrieved this disaster somewhat by his successful resistance to the first siege of Missolonghi (Nov. 1822 to Jan. 1823). His English sympathies brought him, in the subsequent strife of factions, into the opposite camp to that of Petros Mavromichalos; and though he held the portfolio of foreign affairs for a short while under the presidency of Petros (Petros Mavromichalos), he was compelled to withdraw from affairs until February 1825, when he again became a secretary of state. The landing of Ibrahim Pasha followed, and Mavrocordato again joined the army, only escaping capture in the disaster at Spathia (Spataeis), on the 9th of May 1815, by swimming to Navarino. After the fall of Missolonghi (April 22, 1826) he went into retirement, until President Capo d'Istria made him a member of the committee for the administration of war material, a position he resigned in 1828. After Capo d'Istria's murder (Oct. 9, 1831) and the resignation of his brother and successor, Agostino Capo d'Istria (April 13, 1832), Mavrocordato became minister of finance. He was vice-president of the National Assembly at Argos (July, 1832), and was appointed by King Otto minister of finance, and in 1833 premier. From 1834 onwards he was Greek envoy at Munich, Berlin, London and—after a short interlude as premier in Greece in 1841—Constantinople. In 1845, after the revolution of September, he returned to Athens as minister without portfolio in the Metaxas cabinet, and from April to October 1844 was head of the government formed after the fall of the "Russian" party. Going into opposition, he distinguished himself by his violent attacks on the Kolettis government. In 1844-1845 he was again head of the government for a few months. He died in Aegina on the 18th of August 1865.

MAWKMAI (Burmese မန္မော်မြို့), one of the largest states in the eastern division of the southern Shan States of Burma. It lies approximately between 19° 30’ and 20° 30’ N. and 97° 30’ and 98° 15’ E., and has an area of 2,787 sq. m. The central portion of the state consists of a wide plain well watered and under rice cultivation. The rest is chiefly hills in ranges running north and south. There is a good deal of teak in the state, but it has been ruinously worked. The sawbwa now works as contractor for government, which takes one-third of the net profits. Rice is the chief crop, but much tobacco of good quality is grown in the Langkô district on the Têng river. There is also a great deal of cattle-breeding. The population in 1901 was 29,454, over two-thirds of whom were Shans and the remainder Tai, Yancass, and Red Karens. The capital, MAWKMAI, stands in a fine rice plain in 20° 0’ N. and 97° 25’ E. It had about 150 houses when it first submitted in 1887, but was burnt out by the Red Karens in the following year. It has since recovered. There are very fine orange groves a few miles south of the town at Kantu-awn, called Kadugate by the Burmese.

MALENTIUS, MARCUS AURELIUS VALERIUS, Roman emperor from A.D. 306 to 312, was the son of Maximianus Herculis, and the son-in-law of Galerius. Owing to his great dignity and intelligence he was left out of account in the division of the empire which took place in 305. A variety of causes, however, had produced strong dissatisfaction at Rome with many of the arrangements established by Diocletian, and on the 28th of October 306, the public discontent found expression in the massacre of those magistrates who remained loyal to Flavius Valerius Severus and in the election of Maxentius to the imperial dignity. With the help of his father, Maxentius was enabled to put Severus to death and to repel the invasion of Galerius; his next steps were first to banish Maximianus, and then, after achieving two important victories against the rebellious governor, L. Domitius Alexander, to declare war against Constantine as having brought about the death of his father Maximianus. His intention of carrying the war into Gaul was anticipated by Constantine, who marched into Italy. Maxentius was defeated at Saxa Rubra near Rome and drowned in the Tiber while attempting to make his way across the Milvian bridge into Rome. He was a man of brutal and worthless character; but although Gibbon's statement that he was "just, humane and even partial towards the afflicted Christians" is probable that he never exercised any special hostility towards them.

To De Broglie, L'Église et l'empire Romain au quatrième siècle (1840) a mathematical analogy of the Romans towards Christianity generally, app. 8 in vol. ii. of J. B. Bury's edition of Gibbon (Zosimus ii. 9-18; Zonaras xii. 33, xii. 1; Aurelius Victor, Épit. 40; Eutropius, x. 2).

MAXIM, SIR HIRAM STEVENS (1845— ), Anglo-American engineer and inventor, was born at Sangerville, Maine, U.S.A., on the 5th of February 1840. After serving an apprenticeship with a coachbuilder, he entered the machine works of his uncle, Levi Stevens, at Pittsburg, Massachusetts, in 1864, and four years later he became a draughtsman in the Novelty Iron Works and Shipbuilding Company in New York City. About this period he produced several inventions connected with illumination by gas; and from 1877 he was one of the numerous inventors who were trying to solve the problem of making an efficient and durable incandescent electric lamp, in this connexion introducing the widely-used process of treating the carbon filaments by heating them in an atmosphere of hydrocarbon vapour. In 1880 he came to Europe, and soon began to devote himself to the construction of a machine-gun which should be automatically loaded and fired by the energy of the recoil (see MACHINE-GUN). In order to realize the full usefulness of the weapon, which was first exhibited in an underground range at Hatton Garden, London, in 1884, he felt the necessity of employing a smokeless powder, and accordingly he devised maximite, a mixture of trinitrocellulose, nitroglycerine and castor oil, which was patented in 1889. He also undertook to make a flying machine, and after numerous preliminary experiments constructed an apparatus which was tried at Bexley Heath, Kent, in 1894. (See FLIGHT.) Having been naturalized as a British subject, he was knighted in 1900. His younger brother, Hudson Maxim (b. 1853), took out numerous patents in connexion with explosives.

MAXIMA AND MINIMA, in mathematics. By the maximum or minimum value of an expression or quantity is meant primarily the "greatest" or "least" value that it can receive. In general, however, there are points at which its value ceases to increase and begins to decrease; its value at such a point is called a maximum. So there are points at which its value ceases to decrease and begins to increase; such a value is called a minimum. There may be several maxima or minima, and a minimum is not necessarily less than a maximum. For instance, the expression \( (x^2 + x + 2) \) can take all values from \(-\infty \) to \(-1\) and from \(+7 \) to \(+\infty \), but has, so long as \(x\) is real, no value between \(-1\) and \(+7\). Here \(-1\) is a maximum value, and \(+7\) is a minimum value of the expression, though it can be made greater or less than any assignable quantity.

The first general method of investigating maxima and minima seems to have been published in a.d. 1629 by Pierre Fermat. Particular cases had been discussed. Thus Euclid in book III. of the Elements finds the greatest and least straight lines that can be drawn from a point to the circumference of a circle, and in book VI. (in a proposition generally omitted from editions of his works) finds the parallelogram of greatest area with a given perimeter. Apollonius investigated the greatest and least distances of a point from the perimeter of a conic section, and discovered them to be the normals, and that their feet were the intersections of the conic with a rectangular hyperbola. Some remarkable theorems on maximum areas are attributed to Zenodorus, and preserved by Pappus and Theon of Alexandria. The most noteworthy of them are the following:—

1. Of polygons of \(n\) sides with a given perimeter the regular polygon encloses the greatest area.
2. Of two regular polygons of the same perimeter, that with the greater number of sides encloses the greater area.
3. The circle encloses a greater area than any polygon of the same perimeter.
4. The sum of the areas of two isosceles triangles on given bases, the sum of whose perimeters is given, is greatest when the triangles are similar.
5. Of segments of a circle of given perimeter, the semicircle encloses the greatest area.
6. The sphere is the surface of given area which encloses the greatest volume.

Serenus of Antissa investigated the somewhat trifling problem of finding the triangle of greatest area whose sides are formed by the intersections of the base and curved surface of a right circular cone of a plane drawn through its vertex.

The next problem on maxima and minima of which there appears to be any record occurs in a letter from Regiomontanus to Roder (July 4, 1471), and is a particular numerical example of the problem of finding the point on a given straight line at which two given points subtend a maximum angle. N. Tartaglia in his General trattato de numeri et mesuri (c. 1556) gives, without proof, a rule for dividing a number into two parts such that the continued product of the numbers and their difference is a maximum.

Fermat investigated maxima and minima by means of the principle that in the neighbourhood of a maximum or minimum the differences of the values of a function are insensible, a method virtually the same as that of the differential calculus, and of great use in dealing with geometrical maxima and minima. His method was developed by Huygens, Leibnitz, Newton and others, and in particular by John Hudd, who investigated maxima and minima of functions of more than one independent variable, and made some attempt to discriminate between maxima and minima, a question first definitely settled, so far as one variable is concerned, by Colin Maclaurin in his Treatise on Fluxions (1742). The method of the differential calculus was perfected by Euler and Lagrange.

John Bernoulli's famous problem of the "brachistochrone," or curve of quickest descent from one point to another under
MAXIMA AND MINIMA 919

sign. For the case of a single variable, $x$, corresponding to a value of $x$ given by the equation $dx/dx = 0$, a maxima or minimum is obtained if the negativeness of the first differential coefficient which does not vanish is such that there is no maximum or minimum unless $du/dx^2$ vanishes, and there is a maximum or minimum according as $du/dx^2$ is negative or positive. For this purpose, the first differential coefficient which does not vanish is either a maximum or minimum according as this is negative or positive. If it is odd, there is no maximum or minimum.

In the case of several variables, the quadratic

$$
\Sigma \frac{1}{2} \delta u \delta x_i + \Sigma \frac{1}{2} \delta u \delta y_j + \ldots
$$

must be one-signed. The condition for this is that the series of discriminants

$$
\delta u_1 \delta u_2 \delta u_3 \delta u_4 \ldots
$$

for a maximum or minimum at all and $\delta u_1 \delta u_2 \delta u_3 \delta u_4 \ldots$ both negative for a maximum, and both positive for a minimum. It is important to note that by the quadratic being one-signed is meant that it cannot be made to vanish except when $\delta u_1, \delta u_2, \ldots$ all vanish. If, in the case of two variables, $A$, $B$, and $C$ are

then the quadratic is one-signed unless it vanishes, but the value of $u$ is not necessarily a maximum or minimum, and the terms of the fourth or possibly fourth order must be taken account of.

Take for instance the function $u = x - xy^2 - y^3 + 2x^2 - y^2 + 2y + 3x$. Here the values $x = 0, y = 0$ satisfy the equations $\delta u/\delta x = 0, \delta u/\delta y = 0$, so that $x = 0, y = 0$ is a value of $u$, but it is neither a maximum nor a minimum although the terms of the second order are $(\delta x^2)$, and are therefore negative. Here $\delta u = 6x^2 - 2xy^2 - y^3 + 2y^2$, and by putting $\delta x = 0$ or an infinitesimal of the same order as $\delta y$, we can make the sign of $\delta u$ depend on that of $\delta y$, and so be positive or negative as we please.

On the other hand, if we take the function $u = 52x^2 - 2x^2y - y^3 + 2y^2 + 3x + y^2$, then $\delta u/\delta x = 0$, $\delta u/\delta y = 0$, and $\delta u/\delta t = 0$, which make zero a critical value of $u$, and here $\delta u = 6x^2 - 2xy^2 - y^3 + 2y^2$, which is always positive, because we can write it as the sum of two squares, viz. $(\delta x^2 - 2\delta xy + \delta y^2) + 2y^2$, so that in this case zero is a minimum of value $u$.

A critical value usually gives a maximum or minimum in the case of a function of one variable, and often in the case of several independent variables, but all maxima and minima, particularly absolutely greatest and least values, are not necessarily critical values. If, for example, $x$ is restricted to lie between the values $a$ and $b$, we have to consider in this interval, it follows that $\phi(x)$ is one-signed as $x$ increases from $a$ to $b$, so that $\phi(x)$ is increasing or diminishing all the time, and the greatest and least values of $\phi(x)$ are $\phi(a)$ and $\phi(b)$, though neither of them is a critical value. Consider the following example. Let $A$ be a point in a boat $a$ miles from the nearest point of the beach wishes to reach as quickly as possible a point $b$ miles from that point along the shore. The ratio of his walking to his rowing is cosec $a$. Where should he land?

Here let $AB$ be the direction of the beach, $A$ the nearest point to the boat $O$, and $B$ the point he wishes to reach. Clearly he must land, if at all, between $A$ and $B$. Suppose he lands at $P$. Let the angle $AOP = \theta$, so that $OP = a$, sec $\theta$, and $PB = b - a$ tan $\theta$. If his rate of rowing is $V$ miles an hour his time will be $a$ sec $\theta + \theta$ tan $\theta$ ahr.

Call this $T$. Then to the first power of $\delta u$, $ET = (a/\cos \theta \sin \theta - a) \cos \theta$ so that if $AOP = a$, $\theta$ and $PB = b - a$ tan $\theta$ have opposite signs from $\theta = 0$ to $\theta = a$, and the same signs from $\theta = a$ to $\theta = AOB$. So that when $AOP = a$, $T$ decreases from $\theta = 0$ to $\theta = a$. Here it is important that he should land at a point distant $a$ tan $\theta$ from $A$, unless $a$ tan $\theta < b$. When this is the case $ABT$ will have opposite signs throughout the whole range of $\theta$, so that $T$ decreases as $\theta$ increases, and he should row direct to $B$. In the first case the minimum value of $T$ is also a critical value; in the second case it is not.

The greatest and least values of the bending moments of loaded rods are often at the end of the divisions of the rods and not at points given by critical values. In the case of a function of several variables, $x_1, x_2, x_3, x_4$, not independent but connected by $m$ functional relations $\mu_1 = 0, \mu_2 = 0, \ldots, \mu_m = 0$, the maximum and minimum values of the variables; but Lagrange's "Method of undetermined Multipliers" is more elegant and generally more useful.

$$
\delta u = 0, \delta u = 0, \ldots, \delta u = 0
$$

Consider instead of $\delta u$, what is the same thing, $\delta u + \lambda_1 \delta \mu_1 + \lambda_2 \delta \mu_2 + \ldots + \lambda_m \delta \mu_m$, where $\lambda_1, \lambda_2, \ldots, \lambda_m$, are arbitrary multipliers. The terms of the first order in this expression are
MAXIMIANUS—MAXIMILIAN I. OF BAVARIA

Severus a captive to Rome, and also compelled Galerius to retreat, but in 308 he was himself driven by Maxentius from Italy into Illyricum, whence again he was compelled to seek refuge at Arelate (Arles), the court of his son-in-law, Constantine. Here a false report was received, or invented, of the death of Constantine, at that time absent on the Rhine. Maximilianus at once disregarding the succession, but was soon driven to Massilia (Marseillels), where, having been delivered up to his pursuers, he strangled himself.

See Zosimus ii. 7-11; Zonaras xii. 31-33; Eutropius ix. 20, x. 2, 3; Aurelius Victor p. 39. For the emperor Galerius Valerius Maximianus see GALERIUS.

MAXIMILIAN I. (1573-1611), called "the Great," elector and duke of Bavaria, eldest son of William V. of Bavaria, was born at Munich on the 17th of April 1573. He was educated at the Jesuits at the university of Ingolstadt, and began to take part in the government in 1591. He married in 1592 his cousin, Elizabeth, daughter of Charles II., duke of Lorraine, and became duke of Bavaria upon his father's abdication in 1597. He refrained from any interference in German politics until 1607, when he was entrusted with the duty of executing the imperial ban against the free city of Donauwörth, a Protestant stronghold. In December 1607 his troops occupied the city, and vigorous steps were taken to restore the supremacy of the older faith. Some Protestant princes, alarmed at this action, formed a union to defend their interests, which was answered in 1609 by the establishment of a league of which Maximilian took an important part. Under his leadership the war was set on foot, but his policy was strictly defensive and he refused to allow the league to become a tool in the hands of the house of Habsburg. Dissensions among his colleagues led the duke to resign his office in 1616, but the approach of trouble brought about his return to the league about two years later.

Having refused to become a candidate for the imperial throne in 1619, Maximilian was faced with the complications arising from the outbreak of war in Bohemia. After some delay he made a treaty with the emperor Ferdinand II., in October 1615, and in return for large concessions placed the forces of the league at the emperor's service. Anxious to curtail the area of the struggle, he made a treaty of neutrality with the Protestant Union, and occupied Upper Austria as security for the expenses of the campaign. On the 8th of November 1620 his troops under Count Tilly defeated the forces of Frederick, king of Bohemia and count palatine of the Rhine, at the White Hill near Prague. In spite of the arrangement with the union Tilly then devastated the Rhenish Palatinate, and in February 1623 Maximilian was imprisoned and invested with the dignity and the attendant office of imperial steward, which had been enjoyed since 1596 by the counts palatine of the Rhine. After receiving the Upper Palatinate and restoring Upper Austria to Ferdinand, Maximilian became leader of the party which sought to bring about Wallenstein's dismissal from the imperial service. At the diet of Regensburg in 1630 Ferdinand was compelled to assent to this demand, but the sequel was disastrous both for Bavaria and its ruler. Early in 1632 the Swedes marched into the duchy and occupied Munich, and Maximilian could only obtain the assistance of the imperialists. Upon the orders of Wallenstein, now restored to the command of the emperor's forces. The ravages of the Swedes and their French allies induced the elector to enter into negotiations for peace with Gustavus Adolphus and Cardinal Richelieu. He also proposed to disarm the Protestants by modifying the Restitution edict of 1629; but these efforts were abortive. In March 1647 he concluded an armistice with France and Sweden at Ulm, but the entreaties of the emperor Ferdinand III. led him to disregard his undertaking. Bavaria was again invaded, and the imperial forces defeated in May 1648 at Zusmarshausen. But the peace of Westphalia soon put an end to the struggle. By this treaty it was agreed that Maximilian should retain the electoral dignity, which was made hereditary in his family; and the Upper Palatinate was incorporated with Bavaria. The elector died at Ingolstadt on the 27th of September 1651. By his second wife,
II. OF BAVARIA

Maria Anne, daughter of the emperor Ferdinand II., he left two sons, Ferdinand Maria, who succeeded him, and Maximilian Philip. In 1839 a statute was erected to his memory at Munich by Louis I., king of Bavaria. Weak in health and feebly in frame, Maximilian had high ambitions both for himself and his dynasty, and was tenacious and resourceful in prosecuting his designs. By 1841, M. Joseph, Duke of Thurn and Taxis, was his prime minister. By 1851 Maximilian, in his political and military career, was known all over Europe. By his support he succeeded in preventing Germany from becoming the battleground of Europe, and although a rigid adherent of the Catholic faith, he was always subservient to the priest.

MAXIMILIAN I. (MAXIMILIAN JOSEPH) (1756-1829), king of Bavaria, was the son of the count palatine Frederick of Zweibrücken-Birkenfeld, and was born on the 27th of May 1756. He was carefully educated under the supervision of his uncle, Duke Christian IV. of Zweibrücken, took service in 1777 as a colonel in the French army, and rose rapidly to the rank of major-general. From 1782 to 1789 he was stationed at Strassburg, but at the outbreak of the revolution he exchanged the French uniform for his native service, and was appointed to a post in the Bavarian service. He was the ablest and most tenacious of the French generals, and was one of the most capable organizers of the revolutionary wars. On the 1st of April 1795 he succeeded his brother, Charles II., as duke of Zweibrücken, and on the 16th of February 1799 became elector of Bavaria on the extinction of the Sulzbach line with the death of the elector Charles Theodore.

The sympathy with France and with French ideas of enlightenment which characterized his reign was at once manifested. In the newly organized ministry Count Max Joseph von Montgelas (q.v.), who, after falling into disfavour with Charles Theodore, had acted for a time as Maximilian Joseph's private secretary, was the most potent influence, an influence wholly "enlightened" and French. Agriculture and commerce were fostered, the laws were ameliorated, a new criminal code drawn up, taxes and imposts equalized without regard to traditional privileges, while a number of religious houses were suppressed and their revenues used for educational and other useful purposes. In foreign politics Maximilian Joseph's attitude was from the German point of view less commendable. With the growing sentiment of German nationality he had from first to last no sympathy, and his attitude throughout was dictated by self-interest, and to the least Bavarian considerations. Until 1813 he was the most faithful of Napoleon's German allies, the relation being cemented by the marriage of his daughter to Eugène Beauharnais. His reward came with the treaty of Pressburg (Dec. 26, 1805), by the terms of which he was to receive the royal title and important territorial acquisitions in Swabia and Franconia to round off his kingdom. The style of king he actually assumed on the 1st of January 1806.

The new king of Bavaria was the most important of the princes beside Napoleon, who had not only the domination of the Rhine, and remained Napoleon's ally until the eve of the battle of Leipzig, when by the convention of Ried (Oct. 8, 1813) he made the guarantee of the integrity of his kingdom the price of his joining the Allies. By the first treaty of Paris (June 3, 1814), however, he ceded Tirol to Austria in exchange for the former duchy of Würzburg. At the congress of Vienna, too, which he attended in person, Maximilian had to make further concessions to Austria, ceding the quarters of the Inn and Hausruusk in return for a part of the old Palatinate. The king fought hard to maintain the contiguity of the Bavarian territories as guaranteed at Ried; but the most he could obtain was an assurance from Metternich in the matter of the Baden succession, in which he was also doomed to be disappointed (see BADEN: History, iii. 506).

At Vienna and afterwards Maximilian studiously opposed any reconstitution of Germany which should endanger the independence of Bavaria, and it was his insistence on the principle of full sovereignty being left to the German reigning princes that largely contributed to the loose and weak organization of the new German Confederation. The Federal Act of the Vienna congress was proclaimed in Bavaria, not as a law but as an international treaty. It was partly to secure popular support in his resistance to any interference of the federal diet in the internal affairs of Bavaria, partly to give unity to his somewhat heterogeneous territories, that Maximilian on the 26th of May 1818 granted a liberal constitution to his people. Montgelas, who had opposed this concession, had fallen in the previous year, and Maximilian had also reversed his ecclesiastical policy, signing on the 24th of October 1817 a concordat with Rome by which the powers of the clergy, largely curtailed under Montgelas's administration, were restored. The new parliament proved so intractable that in 1819 Maximilian was driven to appeal to the powers against his own creation; but his Bavarian "particularism" and his genuine popular sympathies prevented him from allowing the Carlsbad decrees to be strictly enforced within his dominions. The suspects arrested by order of the Mainz Commission he was accustomed to examine himself, with the result that in many cases the whole proceedings were quashed, and in not a few the accused dismissed with a present of money. Maximilian died on the 13th of October 1825 and was succeeded by his son Louis I.

In private life Maximilian was kindly and simple. He loved to play the part of Landesherr, walking about the streets of his capital en bourgeois and entering into conversation with all ranks of his subjects, by whom he was regarded with great affection. He was twice married: (1) in 1785 to Princess Wilhelmine Auguste of Hesse-Darmstadt, (2) in 1797 to Princess Caroline Friederike of Baden.

MAXIMILIAN II. (1811-1864), king of Bavaria, son of King Louis I. and of his consort Theresa of Saxe-Hildburghausen, was born on the 28th of November 1811. After studying at Göttingen and Berlin and travelling in Germany, Italy and Greece, he was introduced by his father into the council of state (1836). From the first he showed a studious disposition, declaring on one occasion that had he not been born in a royal cradle his choice would have been to become a professor. As crown prince, in the château of Hohenschwangau near Füssen, which he had himself built, he gathered about him an intimate society of artists and men of learning, and devoted his time to scientific and historical study. When the abdication of Louis I. (March 28, 1848) called him suddenly to the throne, his choice of ministers promised a liberal régime. The progress of the revolution, however, gave him pause. He strenuously opposed the unionist plans of the Frankfurt parliament, refused to recognize the imperial constitution devised by it, and assisted Austria in restoring the federal diet and in carrying out the federal execution in Hesse and Holstein. Although, however, from 1850 to 1852, when the government tended in the direction of absolutism, he refused to become the tool of the clerical reaction, and even incurred the bitter criticism of the Ultramontanes by inviting a number of celebrated men of learning and science (e.g. Liebig and Sybel) to Munich, regardless of their religious views. Finally, in 1859, he dismissed the reactionary ministry of von der Pfördten, and met the wishes of his people for a moderate constitutional government. In his German policy he was guided by the desire to maintain the union of the princes, and hoped to attain this as against the perilous rivalry of Austria and Prussia by the creation of a league of the "middle" and small states—the so-called Trias. In 1863, however, seeing what he thought to be a better way, he supported the project of reform proposed by Austria at the Fürstenrat of Frankfurt. The failure of this proposal, and the attitude of Austria towards the Confederation and in the Schleswig-Holstein question, undeceived him; but
before he could deal with the new situation created by the outbreak of the war with Denmark he died suddenly at Munich, on the 10th of March 1484.

Maximilian was a man of amiable qualities and of intellectual attainments far above the average, but as a king he was hampered by constant ill-health, which compelled him to be often abroad, and when at home to live much in the country. By his wife Maria Hedwig, daughter of Prince William of Prussia, whom he married in 1424, he had two sons, Louis II., king of Bavaria, and Otto, king of Bavaria, both of whom lost their reason.

MAXIMILIAN I. (1459-1519), Roman emperor, son of the emperor Frederick III. and Leonora, daughter of Edward, king of Portugal, was born at Vienna Neustadt on the 22nd of March 1459. On the 18th of August 1477, by his marriage at Ghent to Mary, who had just inherited Burgundy and the Netherlands from her father Charles the Bold, duke of Burgundy, he effected a union of great importance in the history of the house of Habsburg. He at once undertook the defence of his wife's dominions from an attack by Louis XI., king of France, and defeated the French forces at Guinegate, the modern Enguinegate, on the 7th of August 1479. But Maximilian was regarded with suspicion by the states of Netherlands, and after suppressing a rising in Ghent, he was compelled in February 1480 to leave the Netherlands; his wife, however, was still detained for the death of her husband. He was now recognized as guardian of his young son Philip and as regent of the Netherlands, but some of the states refused to agree to his demands and disorder was general. Maximilian was compelled to assent to the treaty of Arras in 1482 between the states of the Netherlands and Louis XI. This treaty provided that Maximilian's daughter Margaret should marry Charles, the dauphin of France, and have for her dower Artois and Franche-Comté, two of the provinces in dispute, while the claim of Louis on the duchy of Burgundy was tacitly admitted. Maximilian did not, however, abandon the struggle in the Netherlands. Having crushed a rebellion at Utrecht, he compelled the burghers of Ghent to restore Philip to him in 1485, and returning to Germany was chosen king of the Romans, or German king, at Frankfort on the 16th of February 1486, and crowned at Aix-la-Chapelle on the 9th of the following April. Again in the Netherlands, he made a treaty with Francis II., duke of Brittany, whose independence was threatened by the French regent, Anne of Beaujeu, and the struggle with France was soon renewed. This war was very popular with the trading cities of the Netherlands, and early in 1488 Maximilian, having recovered Bruges, was detained there as a prisoner for nearly three months, and only set at liberty on the approach of his father with a large force. On his release he had promised he would maintain the treaty of Arras and withdraw from the Netherlands; but he delayed his departure for nearly a year and took part in a punitive campaign against his captors and their allies. On his return to Germany he made peace with France at Frankfort in July 1489, and in October several of the states of the Netherlands recognized him as a regent. He continued to act as guardian of his son. In March 1490 the county of Tirol was added to his possessions through the abdication of his kinsman, Count Sigismund, and this district soon became his favourite residence.

Meanwhile the king had formed an alliance with Henry VII. king of England, and Ferdinand II., king of Aragon, to defend the possessions of the duchess Anne, daughter and successor of Francis, duke of Brittany. Early in 1490 he took a further step and was betrothed to the duchess, and later in the same year the marriage was celebrated by proxy; but Brittany was still occupied by French troops, and Maximilian was unable to go to the assistance of his bride. The sequel was startling. In December 1491 Anne was married to Charles VIII., king of France, and Maximilian's daughter Margaret, who had resided in France since her betrothal, was sent back to her father. The inaction of Maximilian at this time is explained by the condition of affairs in Hungary, where the death of king Matthias Corvinus had brought about a struggle for this throne. The Roman king, who was an unsuccessful candidate, took up arms, drove the Hungarians from Austria, and regained Vienna, which had been in the possession of Matthias since 1485; but he was compelled by want of money to retreat, and on the 7th of November 1491 signed the treaty of Pressegg with Ladislaus, king of Bohemia, who had obtained the Hungarian crown, by which treaty it was agreed that Maximilian should succeed to the crown in case Ladislaus left no legitimate issue. Having defeated the invading Turks at Villach in 1492, the king was eager to take revenge upon the king of France; but the states of the Netherlands would afford him no assistance. The German diet was indifferent, and in May 1493 he agreed to the peace of Senlis and regained Artois and Franche-Comté.

In August 1493 the death of the emperor left Maximilian sole ruler of Germany and head of the house of Habsburg; and on the 16th of March 1494 he married at Innsbruck Bianca Maria Sforza, daughter of Galeazzo Sforza, duke of Milan (d. 1476). At this time Bianca's uncle, Ludovico Sforza, was invested with the duchy of Milan in return for the substantial dowry which his niece brought to the king. Maximilian harboured the idea of driving the Turks from Europe; but his appeal to all Christian sovereigns was ineffectual. In 1494 he was again in the Netherlands, where he led an expedition against the rebels of Gelderland, assisted Perkin Warbeck to make a descent upon England, and further weakened the government of the Low Countries in Philip. His attention was next turned to Italy, and, alarmed at the progress of Charles VIII. in the peninsula, he signed the league of Venice in March 1495, and about the same time arranged a marriage between his son Philip and Joanna, daughter of Ferdinand and Isabella, king and queen of Castile and Aragon. The need for help to prosecute the war in Italy caused the king to call the diet to Worms in March 1495, when he urged the necessity of checking the progress of Charles. As during his father's lifetime Maximilian had favoured the reforming party among the princes, proposals for the next government of the empire were brought forward at Worms as a necessary preliminary to financial and military support. Some reforms were adopted, the public peace was proclaimed without any limitation of time and a general tax was levied. The three succeeding years were mainly occupied with quarrels between the diet, with two invasions of France, and a war in Gelderland against Charles, count of Egmont, who claimed that duchy, and was supported by French troops. The reforms of 1495 were rendered abortive by the refusal of Maximilian to attend the diet of 1496, and by the part taken in the working of the new constitution, and in 1497 he strengthened his own authority by establishing an Aulic Council (Reichsregiment), which he declared was competent to deal with all business of the empire, and about the same time set up a court to centralize the financial administration of Germany.

In February 1499 the king became involved in a war with the Swiss, who had refused to pay the imperial taxes or to furnish a contribution for the Italian expedition. Aided by France they defeated the German troops, and the peace of Basel in September 1499 was a serious check to the power of the empire. About this time Maximilian's ally, Ludovico of Milan, was taken prisoner by Louis XII., king of France, and Maximilian was again compelled to ask the diet for help. An elaborate scheme for raising an army was agreed to, and in return a council of regency (Reichsrat) was established, which amounted, in the words of a Venetian envoy, to a deputation of the king. The relations were now very strained between the reforming princes and Maximilian, who, unable to raise an army, refused to attend the meetings of the diet at Nuremberg, while both parties treated for peace with France. The hostility of the king rendered the council impotent. He was successful in winning the support of many of the younger princes, and in establishing a new court of justice, the members of which were named by himself. The negotiations with France ended in the treaty of Blois, signed in September 1504, when
Maximilian's grandson Charles was betrothed to Claude, daughter of Louis XII., and Louis, invested with the duchy of Milan, agreed to aid the king of the Romans to secure the imperial crown. A succession difficulty in Bavaria-Landshut was only decided after Maximilian had taken up arms and narrowly escaped with his life at Regensburg. In the settlement of this question, made in 1505, he secured a considerable increase of territory to the league and the league met the king of the Romans in 1506 he was at the height of his power. His enemies at home were crushed, and their leader, Berthold, elector of Mainz, was dead; while the outlook abroad was more favourable than it had been since his accession.

It is at this period that Ranke believes Maximilian to have entertained the idea of a universal monarchy; but whatever hopes he may have had were shattered by the death of his son Philip and the rupture of the treaty of Blois. The diet of Cologne discussed the question of reform in a halting fashion, but afforded the king supplies for an expedition into Hungary, to aid his ally Ladislaus, and to uphold his own influence in the East. Having established his daughter Margaret as regent for Charles in the Netherlands, Maximilian met the diet at Constance in 1507, when the imperial chamber (Reichskammergericht) was revised and took a more permanent form, and help was granted for an expedition to Italy. The king set out for Rome to secure his coronation, but Venice refused to let him pass through her territories; and at Trent, on the 4th of February 1508, he took the important step of assuming the title of Roman Emperor Elect, to stop the king of Poland, the head of the league, from attacking the Venetians, but finding the war unpopular with the trading cities of southern Germany, made a truce with the republic for three years. The treaty of Blois had contained a secret article providing for an attack on Venice, and this ripened into the league ofcambray, which was joined by the emperor in December 1509. He soon took the field, but after his failure to capture Padua the league broke up; and his sole ally, the French king, joined him in calling a general council at Pisa to discuss the question of Church reform. A breach with pope Julius followed, and at this time Maximilian appears to have entertained, perhaps quite seriously, the idea of seating himself in the chair of St Peter. After a period of vacillation he deserted Louis and joined the Holy League, which had been formed to expel the French from Italy; but unable to raise troops, he served with the English forces as a volunteer and shared in the victory gained over the French at the battle of the Spurs near Thérouanne on the 16th of August 1513. In 1500 the diet had divided Germany into six circles, for the maintenance of peace, to which the emperor at the diet of Cologne in 1502 added four others. Having made an alliance with Christian II., king of Denmark, and in March 1511 having defeated the Orange-antowust on the field of the king of Poland, Maximilian was again in Italy early in 1516 fighting the French who had overrun Milan. His want of success compelled him on the 4th of December 1516 to sign the treaty of Brussels, which left Milan in the hands of the French king, while Verona was soon afterwards transferred to Venice. He attempted in vain to secure the election of his grandson Charles as king of the Romans, and in spite of increasing infirmity was eager to lead the imperial troops against the Turks. At the diet of Augsburg in 1518 the emperor heard warnings of the Reformation, and his complaints were met by a repetition of the complaints preferred at the diet of Mainz in 1517 about the administration of Germany. Leaving the diet, he travelled to Wels in Upper Austria, where he died on the 12th of January 1519. He was buried in the church of St George in Vienna Neustadt, and a superb monument, which may still be seen, was raised to his memory at Innsbruck.

Maximilian had many excellent personal qualities. He was not handsome, but of a robust and well-proportioned frame. Simple in his habits, conciliatory in his bearing, and catholic in his tastes, he enjoyed great popularity and rarely made a personal enemy. He was a skilled knight and a daring hunter, and although not a great general, was intrepid on the field of battle. His mental interests were extensive. He knew something of six languages, and could discuss art, music, literature or theology. He reorganized the university of Vienna and encouraged the development of the universities of Ingolstadt and Freiburg. He was the friend and patron of many scholars, encouraged manuscripts to be copied and published, and wrote several treatises, consequently he continually devising plans for the better government of Austria, and although they ended in failure, he established the unity of the Austrian dominions Maximilian has been called the second founder of the house of Habsburg, and certainly by bringing about marriages between Charles and Joanna and between his grandson Ferdinand and Anna, daughter of Ladislaus, king of Hungary and Bohemia, he paved the way for the vast empire of the Habsburgs for the influence of the Habsburgs in eastern Europe. But he had many qualities less desirable. He was reckless and unstable, resorting often to lying and deceit, and never pausing to count the cost before he entered on a thing he desired.

For absurd and impracticable schemes in Italy and elsewhere he neglected Germany, and sought to involve its princes in wars undesirable for private aggrandizement or personal jealousy. Ignoring his responsibilities as ruler of Germany, he only considered the question of its government when in need of money and support from the princes. As the last of the knights he could not see that the old order of society was passing away and a new order arising, while he was fascinated by the glider of the medieval empire and spent the better part of his life in vague schemes for its recovery. He was "a man of indeterminate character, and the disarray of the disasters of Germany and Italy and exposed himself and the empire to the jeers of Europe.

Maximilian was also a writer of books, and his writings display his intellectuality. His main work was a Jagodier, a collection of words, is a treatise purporting to teach his grandson the art of hunting. He inspired the production of The Dangers and Adventures of a Reputable and Famous Knight Sir Teudank, an allegorical description of his adventures, his journey to Italy and the empire of Burgundy. The emperor's share in the work is not clear, but it seems certain that the general scheme and many of the incidents are due to him. It was first published at Nuremberg by Melchoir Pfingst in 1517, and was adorned with woodcuts by Hans Leonard Schäufelein. The Weishrubung was long regarded as the work of the emperor's secretary, Marx Treitschauweis, but it is now believed that it was written by another part of the emperor's family, or perhaps by himself. It is an unfinished autobiography containing an account of the achievements of Maximilian, who is called "the young white king." It was first published at Vienna in 1775. He also is acknowledged the author of Friedal, an allegorical account of the tournaments in which he took part during his wooing of Mary of Burgundy; Ehrenforten, Triumphwagen and Der weissen könig Stimmboorn, books concerning his own history and that of the house of Habsburg, and works on various subjects, as Das Stahlbuch, Die Baumeister und Die Gärtnerei. These works are all profusely illustrated, some by Albrecht Dürer, and in the preparation of the woodcuts Maximilian himself took part. The first four of the original editions of Maximilian's autobiographical and semi-autobiographical works has been published in nine volumes in the series "Maximilians Werke" by Grill (Vieen, 1860-1888). For this edition S. Laschitzer wrote an introduction to Sir Teudankd, Q. von Leitner to Friedal, and N. A. von Schultz to Der Weishrubung. The Holbein society issued a facsimile edition of Sir Teudank (London, 1862) and Triumphwagen (London, 1883).

cousin Maria, daughter of Charles V., he acted as the emperor's representative in Spain from 1548 to 1550, returning to Germany in December 1550 in order to take part in the discussion over the imperial succession. Charles V. wished his son Philip (afterwards king of Spain) to succeed him as emperor, but his brother Ferdinand, who had already been declared the next occupant of the imperial throne, and Maximilian objected to this proposal. At length a compromise was reached. Philip was to succeed Ferdinand, but during the former's reign Maximilian, as king of the Romans, was to govern Germany. This arrangement was not carried out, and is only important because the insistence of the emperor seriously disturbed the harmonious relations which had hitherto existed between the two branches of the Habsburg family; and the estrangement went so far that an illness which befall Maximilian in 1552 was attributed to poison given to him in the interests of his cousin and brother-in-law, Philip of Spain. About this time he took up his residence in Vienna, and was engaged mainly in the government of the Austrian dominions and in defending them against the Turks. The religious views of the king of Bohemia, as Maximilian had been called since his recognition as the future ruler of that country in 1549, had always been somewhat uncertain, and he had probably learned something of Lutheranism in his youth; but his amicable relations with several Protestant princes, which began about the time of the discussion over the succession, were probably due more to political than to religious reasons. He was closely connected in Vienna, as very intimate with Sebastian Pfauser (1520-1569), a court preacher with strong leanings towards Lutheranism, and his religious attitude caused some uneasiness to his father. Fears were freely expressed that he would definitely leave the Catholic Church, and when Ferdinand became emperor in 1558 he was prepared to assure Pope Paul IV. that his son should not succeed him if he took this step. Eventually Maximilian remained nominally an adherent of the older faith, although his views were tinged with Lutheranism until the end of his life. After several refusals he consented in 1560 to the banishment of Pfauser, and began again to attend the services of the Catholic Church. This uneasiness having been dispelled, in November 1562 Maximilian was chosen king of the Romans, or German king, at Frankfurt, where he was crowned a few days later, after assuring the Catholic electors of his fidelity to their faith, and promising the Protestant electors that he would publicly accept the confession of Augsburg when he became emperor. He also took the usual oath to protect the Church, and his election was afterwards confirmed by the papacy. In September 1563 he was crowned king of Hungary, and in November he was crowned king of Bohemia, in July 1564, succeeded to the empire and to the kingdom of Hungary and Bohemia.

The new emperor had already shown that he believed in the necessity for a thorough reform of the Church. He was unable, however, to obtain the consent of Pope Pius IV. to the marriage of the clergy, and in 1568 the concession of communion in both kinds to the laity was withdrawn. On his part Maximilian granted religious liberty to the Lutheran nobles and knights in Austria, and refused to allow the publication of the decrees of the Diet at Augsburg. Amongst the branches of the Habsburgs which were not part of the Protestants he met his first Diet at Augsburg in March 1566. He refused to accede to the demands of the Lutheran princes; on the other hand, although the increase of sectarianism was discussed, no decisive steps were taken to suppress it, and the only result of the meeting was a grant of assistance for the Turkish War, which had just been renewed. Collecting a large and splendid army Maximilian marched to defend his territories; but no decisive engagement had taken place when a truce was made in 1568, and the emperor continued to pay tribute to the sultan for Hungary. Meanwhile the relations between Maximilian and Philip of Spain had improved; and the emperor's increasingly cautious and moderate attitude in religious matters was doubtless due to the fact that the death of Philip's son, Don Carlos, had opened the way for the succession of Maximilian, or of one of his sons, to the Spanish throne. Evidence of this friendly feeling was given in 1570, when the emperor's daughter, Anne, became the fourth wife of Philip; but Maximilian was unable to moderate the harsh proceedings of the Spanish king against the revolting inhabitants of the Netherlands. In 1570 the emperor met the diet at Steinerne, and asked them to place his eastern borders in a state of defence, and also for power to repel the disorder caused by troops in the service of foreign powers passing through Germany. He proposed that his consent should be necessary before any soldiers for foreign service were recruited in the empire; but the estates were unwilling to strengthen the imperial authority, the Protestant princes regarded the suggestion as an attempt to prevent them from assisting their coreligionists in France and the Netherlands, and nothing was done in this direction, although some assistance was voted for the defence of Austria. The religious demands of the Protestants were still unsatisfied, while the policy of toleration had failed to give peace to Austria. Maximilian's power was very limited; it was inability rather than unwillingness that prevented him from yielding to the entreaties of Pope Pius V. to join in an attack on the Turks both before and after the victory of Lepanto in 1571; and he remained inert while the authority of the empire in north-eastern Europe was threatened. His last important act was to make a bid for the throne of Poland, either for himself or for his son Ernest. In December 1575 he was elected by a powerful faction, but the diet which met at Regensburg was loath to assist; and in October 1576 the emperor died, refusing on his deathbed to receive the last sacraments of the Church.

By his wife Maria he had a family of nine sons and six daughters. He was succeeded by his eldest surviving son, Rudolph, who had been chosen king of the Romans in October 1575. Another of his sons, Matthias, also became emperor; three others, Ernest, Albert and Maximilian, took some part in the government of the Habsburg territories or of the Netherlands, and a daughter, Elizabeth, married Charles IX. King of France.

The religious attitude of Maximilian has given rise to much discussion, and this has especially been the case in the publications of W. Goetz and E. Reimann in the Historische Zeitschrift, Bande VII., XV.,XXXII. and LXXVII. (Munich, 1870 fol.) should be consulted, and also O. H. Hopfen, Maximilian II. und der Komprbankaltheismus (Munich, 1895); C. Haupt, Melanchthons und seiner Lehrer Einfluß auf Maximilian II. (Wittenberg, 1897); F. Walter, Die Wahl Maximilians II. (Heidelberg, 1892); W. Goetz, Maximilian II. und der Wahl Kaiser Karls V. (Graz, 1893); and T. J. Scherg, Über die religiöse Entwicklung Kaiser Maximilians II. bis zu seiner Wahl zum römischen Könige (Würzburg, 1903). For a more general account of his life and work see Briefe und Akten zur Geschichte von Maximilian II. ed. by W. E. Schwarz (Paderborn, 1889-1891); M. Koch, Quellen zur Geschichte des Kaisers Maximilian II. in Archiven gesammelt (Leipzig, 1857-1861); R. Holtzmann, Kaiser Maximilian II. bis zu seiner Thronbesteigung (Berlin, 1903); E. Wertheimer, Zur Geschichte der Türkenniederlagen Maximilians II. (Vienna, 1875); L. von Ranke, Über die Zeiten Ferdinands I. und Maximilians II. in Band VII. of his Sämmtliche Werke (Leipzig, 1874), and J. Janssen, Geschichte des deutschen Volkes seit dem Ausgang des Mittelalters, Bande IV. to VIII. (Freiburg, 1885-1894), English translation by M. A. Mitchell and A. M. Christie (London, 1896 fol.).

MAXIMILIAN (1582-1607), emperor of Mexico, second son of Charles V. and the Freehold Francis Charles of Austria, was born on the 11th of July 1582. He was a particularly clever boy, showed considerable taste for the arts, and early displayed an interest in science, especially botany. He was trained for the navy, and threw himself into this career with so much zeal that he quickly rose to high command, and was mainly instrumental in creating the naval port of Trieste and the fleet with which Teghoffer won his victories in the Italian War. He had some reputation as a Liberal, and this led, in February 1585, to his appointment as vicerey of the Lombardo-Veneto. He met the writings of W. Maurel in the Princesse Charlotte, daughter of Leopold L., king of the Belgians. On the outbreak of the war of 1859 he retired into private life, chiefly at Trieste, near which he built the beautiful chateau of Miramar. In this same year he was first approached by Mexican exiles with the proposal to become the candidate
for the throne of Mexico. He did not at first accept, but sought to satisfy his restless desire for adventure by a botanical expedition to the tropical forests of Brazil. In 1863, however, under pressure from Napoleon III., and after General Forey's capture of the city of Mexico and the plebiscite which confirmed his proclamation of the empire, he consented to receive the crown. Thus Maximilian entered to the de facto administration of his brother, the emperor Francis Joseph, and involved the loss of all his rights in Austria. Maximilian landed at Vera Cruz on the 28th of May 1864; but from the very outset he found himself involved in difficulties of the most serious kind, which in 1866 made apparent to almost every one outside of Mexico the necessity for his abdicating. Though urged to this course by Napoleon himself, whose withdrawal from Mexico was the final blow to his cause, Maximilian refused to desert his followers. Withdrawing, in February 1867, to Querétaro, he there sustained a siege for several weeks, but on the 15th of May resolved to attempt an escape through the enemy's lines. He was, however, arrested before he could carry out this resolution, and after trial by court-martial was condemned to death. The sentence was carried out on the 19th of June 1867. His remains were conveyed to Vienna, where they were buried in the imperial vault early in the following year. (See Mexico.)

Maximilian's papers were published at Leipzig in 1867, in seven volumes, and the title Aus mexikanischen Zeitschriften, Gedichte, See Pierre de la Gorge, Hist. des Deux Empires, lv., liv. xxv., ii. (Paris, 1904); article on von Hoffinger in Allgemeine Deutsche Biographie, xxii. 70, where authorities are cited.

MAXIMINUS, GAIUS JULIUS VERUS, Roman emperor from a.d. 235 to 238, was born in a village on the confines of the Roman and barbarian parentage and was brought up as a shepherd. His immense stature and enormous feats of strength attracted the attention of the emperor Septimius Severus. He entered the army, and under Caracalla rose to the rank of centurion. He carefully absented himself from court during the reign of Heliogabalus, but under his successor Alexander Severus, was appointed supreme commander of the Roman armies. After the murder of Alexander in Gaul, hastened, it is said, by his instigation, Maximinus was proclaimed emperor by the soldiers on the 10th of March 235. The three years of his reign, which were spent wholly in the camp, were marked by great cruelty and oppression; the widespread discontent thus produced culminated in a revolt in Africa and the assumption of the purple by Gordian (q.v.). Maximinus, who was in Pannonia at the time, marched against Rome, and passing over the Julian Alps descended on Aquileia; while detained before that city he and his son were murdered in their tent by a body of praetorians. Their heads were cut off and despatched to Rome, where they were burnt on the Campus Martius by the exultant crowd.

Capitlanus, Maximini dux; Herodian vi. 8, vii. 1-5; Zosimus l. 13-15.

MAXIMINUS [MAXIMEN], GALERIUS VALERIUS, Roman emperor from a.d. 308 to 314, was originally an Illyrian shepherd named Daia. He rose to high distinction after he had joined the army, and in 305 he was raised by his uncle, Galerius, to the rank of Caesar, with the government of Syria and Egypt. In 308, after the elevation of Licinius, he insisted on receiving the title of Augustus; on the death of Galerius, in 311, he succeeded to the supreme command of the provinces of Asia, and when Licinius and Constantine began to make common cause with each other, Maximinus entered into a secret alliance with Maxentius. He came to an open rupture with Licinius in 313, sustained a crushing defeat in the neighbourhood of Heraclea Pontica on the 30th of April, and fled, first to Nicomedia and afterwards to Tarsus, where he died in August following. His death was variously ascribed "to despair, to poison, and to the divine justice." Maximinus has a bad name in Christian annals, as having renewed persecution after the publication of the toleration edict of Galerius, but it is probable that he has been judged too harshly.

See MacEntius; Zosimus ii. 8; Aurelius Victor, Epit. 40.

MAXIMS, LEGAL. A maxim is an established principle or proposition. The Latin term maximus is not to be found in Roman law with any meaning exactly analogous to that of a legal maxim in the modern sense of the word, but the treatises of many of the Roman jurists on Regulae definitiones, or Statuta juris, are, in some measure, collections of maxims. See a article on "Maxims" in Encyc. Brit. (Eng. Lang. and Rev. xx. 285); Fortescue (De laudibus, c. 8) and Du Cange treat maxima and regula as identical. The attitude of early English commentators towards the maxims of the law was one of unmixed adulation. In Doctor and Student (p. 26) they are described as "of the same strength and effect in the law as statutes be." Coke (Co. Litt. 11 a) says that a maxim is so called "Quia maxima est ejus dignitas et certissima auctoris, atque quod maxime omnibus probetur." "Not only, "observes Bacon in the Preface to his Collection of Maxims, "will the use of maxims be in deciding doubt and helping sounds of judgment, but, further, in grasping argument, in correcting unprofitable subtlety, and reducing the same to a more sound and substantial sense of law, in reclaiming vulgar errors, and, generally, in the amendment in some measure of the very nature and complexion of the whole law." A similar note was sounded in Scotland; and it has been well observed that "a glance at the pages of Morrison's Dictionary or at other early reports will show how frequently in the older Scots law questions respecting the rights, remedies and liabilities of litigants were determined by an immediate reference to legal maxims" (J. M. Irving, Encyc. Brit. i. "Maxims"). In later times less value has been attached to the maxims of the law, as the development of civilization and the increasing complexity of business relations have shown the necessity of qualifying the propositions which they enumerate (see Stephen, Hist. Crim. Law, li. 94 v. Vormouth v. France, 1887, 19 Q.B.D., per Lord Esler, at p. 653, and American authorities collected in Bouvier's Law Dict. s.v. "Maxim"). But both historically and practically they must always possess interest and value.

A brief reference need only be made here, with examples by way of illustration, to the field which the maxims of the law cover.

Commercing with rules founded on public policy, we may note the famous principle—Salus populi suprema lex (xii. Tables: Bacon, Maximes, reg. 12)—"the public welfare is the highest law." It is on this maxim that the coercive action of the State towards individual liberty in a hundred matters is based. To the same category belong the "Summa regnum proprio jurisdictionem facit (Co. Litt. 341 a)—"the best rule is that which advances liberty," which finds its application when the enforcement of foreign laws or judgments supposed to violate our own laws or the principles of our civilization in point of justice in those cases in which the United States has been an ally in the late war and which exempts Sunday from the lawful days for judicial acts. Among the maxims relating to the crown, the most important are Austin, Theat. desc. 229 (2 Rob. R. 304). "The King can do no wrong"—which enshrines the principle of ministerial responsibility, and Nullum tempus occurrit regi (2 Co. Inst. 273)—"lapse of time does not bar the crown," a maxim qualified by various enactments in modern times. Passing to the judicial office and the administration of justice, we may refer to the rules—Audi alteram partem—a proposition too familiar to need either translation or comment; Neminem esse judicem in propria causâ (12 Co. Rep. 114)—"no man ought to be in judgment in his own cause"—a maxim which English law and the legal systems based upon or allied to it, have embodied in an elaborate network of rules for judicial challenge; and the maxim attributable to the relative rank and dignity of judges (q.v. supra) in the matter of facts non respondunt judices, ad quaestionem legit non respondent juratores (8 Co. Rep. 155). The maxim Boni judicis est ampliare jurisdictionem (Ch. Prec. 329) is certainly erroneous as it stands, as a judge has no right to "extend his jurisdiction." If judicium is substituted for jurisdictionem, as Lord Mansfield said it should be (1 Burr. 304), the maxim is near the truth. A group of maxims which are often spoken of as embodying the principles of legal right and obligations may next be referred to: (a) Ubri juvatur reum (see Co. Litt. 197 b)—a maxim to which the evolution of the flexible "action on the case," by which wrongs unknown to the "original wrong" are dealt with, is due; (b) Actae Dei nemini facit iuris (Blackstone, ii. 112), which will not be taken with the gloss Damnum absque injuria—"there are forms of actual damage which do not constitute legal injury" for which the supplies no remedy; (b) Actae Dei nemini facit iuris (Blackstone, ii. 112) and its allied maxim, Lex non cogit legis (Co. Litt. 231 b)—on which the whole doctrine of ris major (force majeure) and impossible conditions in the law of contract has been
proclaimed Maximus emperor, he crossed over to Gaul, attacked Gratian (q.v.), and drove him from Paris to Lyons, where he was murdered by a partisan of Maximus. Theodosius being unable to avenge the death of his colleague, an agreement was made (384 or 385) by which Maximus was recognized as Augustus and sole emperor in Gaul, Spain and Britain, while Valentinian II. was to remain un molested in Italy and Illyricum, Theodosius retaining his "consulare dignitatem" in the East. In 387 Maximus crossed the Alps, Valentinian was speedily put to flight, while the invader established himself in Milan and for the time became master of Italy. Theodosius now took vigorous measures. Advancing with a powerful army, he twice defeated the troops of Maximus—at Siscia on the Save, and at Poetovio on the Danube. He then hurried on to Aquileia, where Maximus had shut himself up, and had him beheaded. Under the name of Maxen Wledig, Maximus appears in the list of Welsh royal heroes (see R. Williams, Bibl. Dict. of Eminent Welshmen, 1852; "The Dream of Maxen Wledig," in the Mabinogion.

Full account with classical references in H. Richter, Das weströmische Reich, besonders unter den Kaisern Gratian, Valentinian II. and Maximus (1865); see also H. Schiller, Geschichte der römischen Kaiserzeit, ii. (1887); Gibbon, Decline and Fall, ch. 27; Tillemont, Histoires des empereurs, vi. 1868.

III. Maximus Tyrannus, made emperor in Spain by the Roman general, Gerontius, who had rebelled against the usurper Constantine in 408. After the defeat of Gerontius at Arelate (Arles) and his death in 411 Maximus renounced the imperial title and was permitted by Constantine to retire into private life. About 418 he rebelled again, but, failing in his attempt, was seized, carried into Italy, and put to death at Ravenna in 422.

See Orosius vii. 42; Zosimus vi. 3; Sozomen ix. 3; E. A. Freeman, The Tyrants of Britain, Gaul and Spain, A.D. 406-411, in English Historical Review, i. (1886).

IV. Petronius Maximus, a member of the higher Roman nobility, had held several court and public offices, including those of profectus Romae (430) and Italiae (430-441 and 443), and consul (433, 443). He was one of the intimate associates of Valentinian III., whom he assisted in the palace intrigues which led to the death of Aetius in 454; but an outrage committed on the wife of Maximus by the emperor turned his friendship into hatred. Maximus was proclaimed emperor immediately after Valentinian's murder (March 16, 455), but after reigning less than three months, he was murdered by some Burgundian mercenaries as he was fleeing before the troops of Genesic, who, invited by Eudosia, the widow of Valentinian, had landed at the mouth of the Tiber (May or June 455).

SeeProcopius, Vas. i. 4; Sidonius Apollinaris, Panegyr. Avitii, c. xvi. 10; the Consularium; Gibbon, Decline and Fall, chs. 35, 36; Tillemont, Hist. des empereurs, vi.

MAXIMUS, ST. (c. 350-662), abbot of Chrysopolis, known as "the Confessor" from his orthodox zeal in the Monothelite (q.v.) controversy, or as "the monk," was born of noble parentage at Constantinople about the year 380. Educated with great care, he early became distinguished by his talents and acquisitions, and some time after the accession of the emperor Zeno (474-491), he settled in 560 within the walls of Constantinople. In 584, when the emperor, Vitiges, had abandoned the secular life and entered the monastery of Chrysopolis (Scutari), actuated, it was believed, less by any longing for the life of a recluse than by the dissatisfaction he felt with the Monothelite teachings of his master. The date of his promotion to the abbacy is uncertain. In 633 he was one of the party of Sophronius of Jerusalem (the chief original opponent of the Monothelites) at the council of Alexandria; and in 645 he was again in Africa, when he held in presence of the governor and a number of bishops the disputation with Pyrrhus, the deposed and harried patriarch of Alexandria, which resulted in the (temporary) conversion of his interlocutor to the Dyotheilite view. In the following year several African synods, held under the influence of Maximus, declared for orthodoxy. In 649, after the accession of Martin I., he went to Rome, and did much to fan the zeal of the new pope, who in

built up. In this category may also be classed Volenti non fit injuria (Wingate, Maximus), out of which sprang the theory—now profaned by political employment of the law of employers' liability; see Smith v. Boker, 1891, A.C. 325. Other maxims deal with rights of property—Qui prior est tempore, potior est juris (Co. Litt. 14 a), which consecrates the position of the best possessor when the same facts are shown to have occurred in the possession of different persons. Legal Maximis uti uli vnon laeser (9 Co. Rep. 59), which has played its part in the determination of the rights of adjacent owners; and Domus taceat qui sedet in artem (5 Co. Rep. 92)—"a man's house is his castle," a doctrine which has imposed limitations on the rights of execution creditors (see EXECUTION). In the laws of the relations there are the maxims Consensus non concussibilis facit justum (L. 15 a)—the consent of all parties constitutes a valid contract even if the law would hold it otherwise. Legal Maximis Legem patriae in servis neminem excusat, on which rests the ordinary citizen's obligation to know the law; and Vigilantius non dormientis juras subvenient (2 Co. Inst. 600), one of the maxims in accordance with which courts of equity will not, in deciding a case, consult legal rules, but use reason to arrive at a decision which they think just. Legal Maximis est, qui sequitur ius, i.e. the rule that he who follows the law must do equity. i.e. must act fairly, and that "equity looks upon that as done which ought not to be done" in the exercise of the "common right," the money of land directed to be sold, and of money directed to be invested in the purchase of land, is derived.

The principal collections of legal maxims are: English Law: Bacon, Collection of Some Principal Rules and Maxims of the Common Law (1630); Noy, Treatise of the principall Grounds and Maxims of the Law of England (1641, 8th ed., 1824); Wingate, Maximus of Reason (1728); France, Grandes et Rudiments de Droit et Equity (2nd ed. 1751); Loftt (annexed to his Reports, 1776); Broom, Institutes of the Law of England (7th ed. London, 1900). Scots Law: Lord Treanor, Latin Maxims and Phrases (2nd ed., 1876); Stair, Institutions of the Law of Scotland, with Index (Edinburgh, 1877); Amer. Judicature Soc. (American), English Legal Maxims (1885); A. S. Peloubet, Legal Maxims in Law and Equity (Cincinnati, 1878); (A. W. R.)

MAXIMUS, the name of four Roman emperors.

I. M. Claudius Pupienus Maximus, joint emperor with D. Caecilius Calvinus Balbinus during a few months of the year a.d. 238. Pupienus was a distinguished soldier, who had been proconsul of Bithynia, Achaia, and Gallia Narbonensis. At the advanced age of seventy-four, he was chosen by the senate with Balbinus to resist the barbarian Maximinus. Their complete equality is shown by the fact that each assumed the titles of pontifex maximus and princeps senatus. It was arranged that Pupienus should take the field against Maximinus, while Balbinus remained at Rome to maintain order, a task in which he signalized. A revolt of the praetorians was not suppressed till much blood had been shed and a considerable part of the city reduced to ashes. On his march, Pupienus, having received the news that Maximinus had been assassinated by his own troops, returned in triumph to Rome. Shortly afterwards, when both emperors were on the point of leaving the city on an expedition—Pupienus against the Persians and Balbinus against the Goths—the praetorians, who had always been in the habit of the senatorial emperors and cherished the memory of the soldier-emperors, seized the opportunity of revenge. When most of the people were at the Capitoline games, they forced their way into the palace, dragged Balbinus and Pupienus through the streets, and

See Capistrani, Life of Maximus and Balbinus; Herodian vii. 10, viii. 26; Orosius vii. 19; Eutropius ix. 2; Zosimus i. 14; Aurelius Victor, Caesar, p. 26; Def. Maximi imperatoris. der römischen Kaiserzeit, i. 2; Gibbon, Decline and Fall, ch. 7 and (for the chronology) appendix 12 (Bury's edition).

II. Magnus Maximus, a native of Spain, who had accompanied Theodosius on several expeditions and from 368 held high military rank in Britain. The disaffected troops having
MAXIMUS OF SMYRNA—MAX MÜLLER

October of that year held the (first) Lateran synod, by which not only the Monothelite doctrine but also the moderating ec theology of Heraclius and Typus of Constans II. were anathemized. About 653 Maximus, for the part he had taken against the latter document especially, was apprehended (together with the pope) by order of Constans, and carried to Constantinople. In 655, after repeated examinations, in which he maintained his theological opinions with memorable constancy, he was banished to Byzia in Thrace, and afterwards to Perberis. In 662 he was again brought to Constantinople and was condemned by a synod to be scourged, to have his tongue cut out by the root, and to have his right hand chopped off. After this sentence had been carried out he was again banished to Lazica, where he died on the 13th of August 662. He is venerated as a saint both in the Greek and in the Latin Churches. Maximus was not only a leader in the Monothelite struggle but a mystic who zealously followed and advocated the system of Pseudo-Dionysius, while adding to it an ethical element in the conception of the freedom of the will. His works had considerable influence in shaping the philosophy of John Scotus Erigena.

The most important of the works of Maximus will be found in Migne, Patrologia Graeca, xc. xcv., together with an anonymous life; an early fragment from his Commentary on the New Testament, Bünsen's Miscellaneous Heyden's Realencyclopädie, where the following classification is adopted: (a) exegetical, (b) scholion on the Fathers, (c) dogmatic and controversial, (d) ethical and ascetic, (e) miscellaneous. The details of the disposition of the manuscripts have been very fully and clearly in Helene's Concilien geschichte, iii. For further literature see H. Geiler in C. Krumbacher's Geschichte der byzantinischen Literatur (1897).

MAXIMUS OF SMYRNA, a Greek philosopher of the Neoplatonist school, who lived towards the end of the 4th century A.D. He was perhaps the most important of the followers of Iamblichus. He is said to have lived a rich and noble family, and exercised great influence over the emperor Julian, who was concomitant with Iamblichus. He became a disciple of the emperor, and his love of magic and theurgy, and by judicious administration of the emens won a high position at court. His overbearing manner made him numerous enemies, and, after being imprisoned on the death of Julian, he was put to death by Valens. He is a representative of the least attractive side of Neoplatonism. Attaching no value to logical proof and argument, he enlarged on the wonders and mysteries of nature, and maintained his position by the working of miracles. In logic he is reported to have agreed with Eusebius, Iamblichus and Foriphy in asserting the validity of the second and third figures of the syllogism.

MAXIMUS OF TYRE (CASSIUS MAXIMUS TVRVIUS), a Greek rhetorician and philosopher who flourished in the time of the Antonines and Commodus (2nd century A.D.). After the manner of the sophists of his age, he travelled extensively, delivering lectures on the way. His writings contain many allusions to the history of Greece, while there is little reference to Rome; hence it is inferred that he lived longer in Greece, perhaps as a professor at Athens. Although nominally a Platonist, he is really an Eclectic and one of the precursors of Neoplatonism. There are still extant by him forty-one essays or discourses (διαλέκτοι) on theological, ethical, and other philosophical commonplaces. With him God is the supreme being, one and indivisible though called by many names, accessible to reason alone; but as animals form the intermediate stage between plants and human beings, so there exist intermediaries between God and man, viz. daemons, who dwell on the confines of heaven and earth. The soul in many ways bears a great resemblance to the divinity; it is partly mortal, partly immortal, and, when freed from the fetters of the body, becomes a daemon. Life is the sleep of the soul, from which it awakes at death. The style of Maximus is superior to that of the ordinary sophistical rhetorician, but scholars differ widely as to the merits of the essays themselves.

Maximus of Tyre must be distinguished from the Stoic Maximus, tutor of Marcus Aurelius. Editions by J. Davies, revised with valuable notes by J. Markland (1869), C. Reiske (1857), and J. Delehaye (1862) have appeared (together with the complete works, ed. in the Didot series). Monographs by R. Rohdich (Beuthen, 1879); H. Hobein, De Maximo Tyrio quaestionis philol. (Jena, 1893). There is an English translation (1804) by Thomas Taylor, the Plutarch.

MAX MÜLLER, FRIEDRICH (1823–1900), Anglo-German orientalist and comparative philologist, was born at Dessau on the 6th of December 1823, being the son of Wilhelm Müller (1794–1827), the German poet, celebrated for his Phil-hellenic lyrics, who was ducal librarian at Dessau. The elder Müller had endeared himself to the most intellectual circles in Germany by his amiable character and his genuine poetic gift; his songs had been used by musical composers, notably Schubert; and it was his son's good fortune to meet in his youth with a succession of eminent friends, who, already interested in him for his father's sake, and charmed by the qualities which they discovered in the young man himself, powerfully aided him by advice and patronage. Mendelssohn, who was his godfather, dissuaded him from indulging his natural bent to the study of music; Professor Brockhaus of the University of Leipzig, where Max Müller matriculated in 1841, induced him to take up Sanskrit; Bopp, at the University of Berlin (1844), made the Sanskrit student a scientific comparative philologist; Schelling at the same university, inspired him with a love for metaphysical speculation, though failing to attract him to his own philosophy; Bunsen, at Paris in the following year, by teaching him Zend, started him on the track of inquiry into the science of comparative religion, and impelled him to edit the Rig Veda; and when, in 1846, Max Müller came to England upon this errand, Bunsen, in conjunction with Professor H. H. Wilson, prevailed upon the East India Company to undertake the expense of publication. Up to this time Max Müller had lived the life of a poor student, supporting himself partly by copying manuscripts, but Bunsen's introductions to Queen Victoria and the prince consort, and to Oxford University, 1401, and his foundation in 1849 of the University, of the printing of his Rig Veda at the University Press obliged him to settle in Oxford, a step which decided his future career. He arrived at a favourable conjuncture: the Tractarian strife, which had so long thrust learning into the background, was just over, and Oxford was becoming accessible to modern ideas. The young German excited curiosity and interest, and it was soon discovered that, although a genuine scholar, he was no mere bookworm. Part of his social success was due to his readiness to exert his musical talents at private parties. Max Müller was speedily subjected by the genus Anglicus. He was appointed depute Taylorian professor of modern languages in 1850, and the German government failed to tempt him back to Strassburg. In the following year he was made M.A. and honorary fellow of Christ Church, and in 1858 he was elected a fellow of All Souls. In 1854 the Crimean War gave him the opportunity of utilizing his oriental learning in vocabularies and schemes of transliteration. In 1857 he successfully essayed another kind of literature in his beautiful story Deutsche Liebe, written both in German and English. He had by this time become an extensive contributor to English periodical literature, and had written several of the essays subsequently collected as Chips from a German Workshop. The most important of them was the fascinating essay on "Comparative Mythology" in the Oxford Essays for 1856. His valuable History of Ancient Sanskrit Literature, so far as it illustrates the primitive religion of the Brahmans (and hence the Vedic period only), was published in 1859.

Though Max Müller's reputation was that of a comparative philologist and orientalist, his professional duties at Oxford were long confined to lecturing on modern languages, at least till his medieval lectures. In 1860 the death of Horace Hayman Wilson, professor of Sanskrit, seemed to open a more congenial sphere to him. His claims to the succession seemed incontestable, for his opponent, Monier Williams, though well qualified as a Sanskritist, lacked Max Müller's brilliant versatility, and although educated at Oxford, had held no University
office. But Max Müller was a Liberal, and the friend of Liberals in university matters, in politics, and in theology, and this consideration united with his foreign birth to bring the country clergy in such hosts to the poll that the voice of resident Oxford was overborne, and Monier Williams was elected by a large majority. It was the one great disappointment of Max Müller's life, and made a lasting impression upon him. It was, nevertheless, serviceable to his influence and reputation by permitting him to enter upon a wider field of subjects than would have been possible otherwise. Directly, Sanskrit philology received little more from him, except in connexion with his later undertaking of The Sacred Books of the East; but indirectly it exalted it more than any predecessor by proclaiming its commanding position in the history of the human intellect by his Science of Language, two courses of lectures delivered at the Royal Institution in 1851 and 1863. Max Müller ought not to be described as "the introducer of comparative philology into England." Prichard had proved the Aryan affinities of the Celtic languages by the methods of comparative philology so long before as 1831; Winning's Manual of Comparative Philology had been published in 1838; the discoveries of Bopp and Pott and Pictet had been recognized in brilliant articles in the Quarterly Review, and had guided the researches of Kaw- linson. But Max Müller undoubtedly did far more to popularize the subject than had been done, or could have been done, by any predecessor. He was on less sure ground in another department of the study of language—the problem of its origin. He wrote upon it as a disciple of Kant, whose Critique of Pure Reason he translated. His essays on mythology are among the most delightful of his writings, but their value is somewhat impaired by a too uncompromising adherence to the seductive generalization of the solar myth.

Max Müller's studies in mythology led him to another field of activity in which his influence was more durable and extensive, the study of comparative philology of religions. Here, so far as Great Britain is concerned, he does deserve the fame of an originator, and his Introduction to the Science of Religion (1873; the same year in which he lectured on the subject, at Dean Stanley's invitation, in Westminster Abbey, this being the only occasion on which a layman had given an address there) marks an epoch. It was followed by other works of importance, especially the four volumes of Gifford lectures, delivered between 1885 and 1892; but the most tangible result of the impulse he had given was the publication under his editorship, from 1879 onwards, of The Sacred Books of the East, in fifty-one volumes, including indexes, all but three of which appeared under his superintendence during his lifetime. These comprise translations by the most competent scholars of all the really important non-Christian scriptures of Oriental nations, which can now be appreciated without a knowledge of the original languages. Max Müller also wrote on Indian philosophy in his latter years, and his exertions to stimulate search for Oriental manuscripts and inscriptions were rewarded with important discoveries of early Buddhist scriptures, in their Indian form, made in Japan. He was on particularly friendly terms with native Japanese scholars, and after his death his library was purchased by the university of Tôkyô.

In 1868 Max Müller had been indemnified for his disappointment over the Sanskrit professorship by the establishment of a chair of Comparative Philology to be filled by him. He retired, however, from the actual duties of the post in 1875, when entering upon the editorship of The Sacred Books of the East. The most remarkable external events of his latter years were a series of lectures delivered at Strassburg in 1872, when he devoted his honorarium to the endowment of a Sanskrit lectureship, and his presidency over the International Congress of Orientalists in 1882. But his days, if uneventful, were busy. He participated in every movement at Oxford of which he could approve, and was intimate with nearly all its men of light and leading; he was a curator of the Bodleian Library, and a delegate of the University Press. He was acquainted with most of the crowned heads of Europe, and was an especial favourite with the English royal family. His hospitality was ample, especially to visitors from India, where he was far better known than any other European Orientalist. His distinctions, conferred by foreign governments and learned societies, were innumerable, and, having been naturalized shortly after his arrival in England, he received the high honour of being made a privy councillor. In 1893 and 1899 he published autobiographical reminiscences under the title of Aut Lang Sync. He was writing a more detailed autobiography when overtaken by death on the 28th of October 1900. Max Müller married in 1859 Georgiana Adelaide Grenfell, sister of the wives of Charles Kingsley and J. A. Froude. One of his daughters, Mrs Conybeare, distin-

Though undoubtedly a great scholar, Max Müller did not so much represent scholarship pure and simple as her hybrid types—the scholar-author and the scholar-courtier. In the former capacity, though manifesting little of the originality of genius, he rendered vast service by popularizing high truths among high minds. In his public and social character he represented Oriental studies with a brilliancy, and conferred upon them a distinction, which they had not previously enjoyed in Great Britain. There were drawbacks in both respects: the author was too prone to build upon insecure foundations, and the man of the world incurred censure for failings which may perhaps be best indicated by the remark that he seemed too much of a diplomatist. But the sum of foibles seems insignificant in comparison with the life of intense labour dedicated to the service of culture and humanity. Max Müller's Collected Works were published in 1903. (R. G.)
from the Tower of London through the courage and devotion of his wife Winifred (d. 1749), daughter of William Herbert, 1st marquess of Powis. He was attainted in 1716 and his titles became extinct, but his estates passed to his son William (d. 1776), whose descendant, William Constable-Maxwell, regained the title of Lord Herries in 1838.

The countess of Nithsdale wrote an account of her husband's escape, which is published in vol. i. of the Transactions of the Society of Antiquaries of Scotland.

The words may be added about other prominent members of the Maxwell family. John Maxwell (c. 1590-1647), archbishop of Tuam, was a Scottish ecclesiastic who took a leading part in helping Archbishop Laud in his flight in 1634. He was bishop of Ross from 1633 until 1638, when he was deposed by the General Assembly; then crossing over to Ireland he was bishop of Killala and Achonry from 1640 to 1645, and archbishop of Tuam from 1645 until his death in 1652.

James Maxwell (c. 1708-1762), who became a student of the Royal Society in 1736, was an amateur mathematician. He wrote a treatise on the "Kinetic Theory of Gases." It was published in 1745.

Robert Maxwell (1755-1817) was the author of Select Transactions of the Society of Improvers and was a great benefactor to Scottish agriculture. Sir Murray Maxwell (1775-1831), a naval officer, gained much fame by his courage in the defence of the British fleet at the battle of Trafalgar in 1805.

William Hamilton Maxwell (1792-1850), the Irish novelist, wrote, in addition to several novels, a Life of the Duke of Wellington (1839-1841) and again 1883), and a History of the Irish Rebellion in 1798 (1842-1845). He was a baronet, and the president of the Society of Antiquaries of Scotland, became well known as a writer on Irish and Scottish history.

Maxwell was educated at Marischal College, Aberdeen, from 1852 to 1854, and at the University of Edinburgh, where he graduated in 1859. He was elected a fellow of the Royal Society of Edinburgh in 1861.

The work of John Herschel, which had been continued by Maxwell, was of great importance. He used to say that, "When we speak of the velocity of light, we are speaking of its velocity in vacuo."

The velocity of light in vacuum should
be numerically the same as the ratio of the electromagnetic and electrostatic units. In fact, the means of the best determinations of each of these quantities separately agree with one another more closely than do the various values of either.

One of Maxwell's last great contributions to science was the editing (with copious original notes) of the Electrical Researches of the Hon. Henry Cavendish, from which it appeared that Cavendish, already famous by many other researches (such as the mean density of the earth, the composition of water, &c.), must be looked on as, in his day, a man of Maxwell's own stamp as a theorist and an experimenter of the very first rank.

In private life Clerk Maxwell was one of the most lovable of men, a sincere and unostentatious Christian. Though perfectly free from any trace of envy or ill-will, he yet showed on fit occasion his contempt for that pseudo-science which seeks for the applause of the ignorant by professing to reduce the whole system of the universe to a fortuitous sequence of uncaused events.

His collected works, including the series of articles on the properties of matter, such as "Atom," "Attraction," "Capillary Action," "Electricity," and "Magnetism," published in the Electrical and Mechanical Papers, were issued in two volumes by the Cambridge University Press in 1890; and an extended biography, by his former schoolfellow and lifelong friend Professor Lewis Campbell, was published in 1896.

MAXWELLTOWN, a burgh of barony and police burgh of Kirkcudbrightshire, Scotland. Pop. (1901), 5796. It lies on the Nith, opposite to Dumfries, with which it is connected by three bridges, being united with it for parliamentary purposes. It has a station on the Glasgow & South-Western line from Dumfries to Kirkcudbright. Its public buildings include a court-house, the prison for the south-west of Scotland, and an observatory and museum, housed in a disused windmill. The chief manufactures are woollens and hosiery, besides dyeworks and sawmills. It was a hamlet known as Bridgend up till 1850, and it was erected into a burgh of the first class by an Act of this encyclopaedia, were issued in two volumes by the Cambridge University Press in 1890; and an extended biography, by his former schoolfellow and lifelong friend Professor Lewis Campbell, was published in 1896.

MAY, PHIL (1864-1903), English caricaturist, was born at Worthing on 23rd April 1864, the son of a solicitor. His father died when the child was nine years old, and at twelve he had begun to earn his living. Before he was fifteen he had acted as time-keeper at a foundry, had tried to become a jockey, and had been on the stage at Scarborough and Leeds. When he was about seventeen he went to London with a sovereign in his pocket. He suffered extreme want, sleeping out in the parks and streets, until he obtained employment as designer to a theatrical costumer. He also drew posters and cartoons, and for about two years worked for the "Punch," until he was advised to go to Australia for his health. During the three years he spent there he was attached to the "Sydney Bulletin," for which many of his best drawings were made. On his return to Europe he went to Paris by way of Rome, where he worked hard for some time before he appeared in 1892 in London to resume his interrupted connexion with the "St Stephen's Review." His studies of the London "guttersnipe" and the coster-girl rapidly made him famous. His overflowing sense of fun, his genuine sympathy with his subjects, and his kindly wit were on a par with his artistic ability. He was often said that the extraordinary economy of line which was a characteristic feature of his drawings had been forced upon him by the deficiencies of the printing machines of the "Sydney Bulletin." It was in fact the result of a laborious process which involved a number of preliminary sketches, and of a carefully considered system of elimination. His later work included some excellent political portraits. He became a regular member of the staff of "Punch" in 1896, and in his later years his services were retained exclusively for "Punch" and the "Graphic." He died on the 4th of August 1903.

There was an exhibition of his drawings at the Fine Arts Society in 1895, and another at the Leicester Galleries in 1903. A selection of his drawings contributed to the periodical press and from Phil May's Annual and Phil May's Sketch Books, with a portrait and biography of the artist, entitled The Phil May Folio, appeared in 1903.

MAY, THOMAS (1595-1659), English poet and historian, son of Sir Thomas May of Mayfield, Sussex, was born in 1595. He entered Sidney Sussex College, Cambridge, in 1609, and took his B.A. degree three years later. His father having lost his fortune and sold the family estate, Thomas May, who was hampered by an impediment in his speech, made literature his profession. In 1620 he produced The Heir, an ingeniously constructed comedy, and, probably about the same time, The Old Couple, which was not printed until 1658. His other dramatic works are classical tragedies on the subjects of Antigone, Cleopatra, and Agrippina. F. G. Fleay has suggested that the more famous anonymous tragedy of Nero (printed 1642, reprints in A. H. Bullen's Old English Plays and the Mermaid Series) should also be assigned to May. But his most important work in the department of pure literature was his translation (1627) into heroic couplets of the Pharsalia of Lucretius. Its success led May to write a continuation of Lucretian's narrative down to the death of Caesar. Charles I. became his patron, and commanded him to write metrical histories of Henry II, Edward III., which were completed in 1658. His patron, the lord chamberlain, broke his staff across May's shoulders at a masque, the king took him under his protection as "my poet," and Pembroke made him an apology accompanied with a gift of £50. These marks of the royal favour seem to have led May to expect the posts of poet-laureate and city chronologer when they fell vacant on the death of Ben Jonson in 1637, but he was disappointed, and he forsook the court and attached himself to the party of the Parliament.

In 1646 he is styled one of the "secretaries" of the Parliament, and in 1647 he published his best known work, The History of the Long Parliament. In this official apology for the moderate or Presbyterian party, he professes to give an impartial statement of facts, unaccompanied by any expression of party or personal opinion. If he refrained from actual invective, he accomplished his purpose, according to Guizot, by "omission palliation and dissimulation." Accusations of this kind were foreseen by May, who says in his preface that if he gives more information about the Parliament men than their opponents it is that he was more conversant with them and their affairs. In a word, he followed this with a more or less definite bias, a Breviary of the History of the Parliament of England, in Latin and English, in which he defended the position of the Independents. He stopped short of the catastrophe of the king's execution, and it seems likely that his subservience to Cromwell was not quite voluntary. In February 1650 he was brought to London from Weymouth under a strong guard for having spread false reports of the Parliament and of Cromwell. He died on the 13th of November in the same year, and was buried in Westminster Abbey, but his remains were exhumed and buried in a pit in the yard of St Margaret's, Westminster. May's change of side made him many bitter enemies, and he is the object of scathing condemnation from many of his contemporaries.

There is a long notice of May in the Biographia Britannica. See also W. J. Courthope, Hist. of Eng. Poetry, vol. 3; and Guizot, Histoire des biographies sur la révolution d'Angleterre (pp. 403-426, ed. 1851).

MAY, or MEX(_e_), WILLIAM (d. 1660), English divine, was the brother of John May, bishop of Carlisle. He was educated at Cambridge, where he was a fellow of Trinity Hall, and in 1537, president of Queen's College. May heartily supported the Reformation, signed the Ten Articles in 1536, and helped in the production of The Institution of a Christian Man. He had close connexion with the diocese of Ely, being
successively chancellor, vicar-general and prebendary. In 1545 he was made a prebendary of St Paul's, and in the following year dean. His favourable report on the Cambridge colleges saved them from dissolution. He was dispossessed during the reign of Mary, but restored to the deanery on Elizabeth's accession. He died on the day of his election to the archbishopric of York.

MAY, the fifth month of our modern year, the third of the old Roman calendar. The origin of the name is disputed; the derivation from Mala, the mother of Mercury, to whom the Romans were accustomed to sacrifice on the first day of this month, is the most frequent. The present Romans used on May Day to go in procession to the grove of Egeria. From the 28th of April to the 2nd of May was kept the festival in honour of Flora, goddess of flowers. By the Romans the month was regarded as unlucky for marriages, owing to the celebration on the 9th, 11th and 13th of the Lemuria, the festival of the unhappy dead. This superstition has survived to the present day.

In medieval and Tudor England, May Day was a great public holiday. All classes of the people joined in such revels, and as a free man might "go a-Maying" in the woods. Branches of trees and flowers were borne back in triumph to the towns and villages, the centre of the procession being occupied by those who shouldered the maypole, glorious with ribbons and wreaths. The maypole was usually of birch, and set up for the day only; but in London and the larger towns the poles were of durable wood and permanently erected. They were special eyecatchers to the Puritans. John Stubbes in his Anatomy of Abuses (1583) speaks of them as those "stirruckyng Idols," about which the people "leape and daunce, as the heathen did." Maypoles were forbidden by the parliament in 1644, but came once more into favour at the Restoration, the last to be erected in London being that set up in 1661. This pole, which was of cedar, 134 ft. high, was set up by twelve British sailors under the personal supervision of James II., then duke of York and lord high admiral, in the Strand on or about the site of the present church of St Mary's-in-the-Strand. Taken down in 1717, it was conveyed to Wanstead Park in Essex, where it was fixed by Sir Isaac Newton as part of the support of a large telescope, presented to the Royal Society by a French astronomer.

The year 1661 was a prominent year in the history of Edinburgh. It was the year of the Great Fire of the city, which began on the 3rd of May and destroyed, in a few days, the greater part of the town. The fire was said to have been caused by a spark from a chimney, and was spread by the wind, which carried it from the east to the west of the city. The fire was not extinguished till the 11th of May, and caused a loss of property estimated at £100,000. The conflagration was succeeded by a period of peace and prosperity, and the city was soon restored to its former state.

Mayaguez, the third largest city of Porto Rico, a seaport, and capital of the department of Mayaguez, on the west coast, at the mouth of Rio Mayaguez, about 72 m. W. by S. of San Juan. Pop. of the city (1890), 1,151,875, including 138 negroes and 4711 of mixed races; (1910), 16,501; of the municipal district, 35,700 (1890), of whom 2687 were negroes and 9033 were of mixed races. Mayaguez is connected by the American railroad of Porto Rico with San Juan and Ponce, and it is served regularly by steamboats from San Juan, Ponce and New York, although its harbour is not accessible to vessels drawing more than 16 ft. of water. It is situated at the foot of Las Mesas Mountains, and commands picturesque views. The climate is healthy and good water is obtained from the mountain region. From the shipping district along the water-front a thoroughfare leads to the main portion of the city, about 1 m. distant. There are four public squares, in one of which is a statue of Columbus. Prominent among the public buildings are the City Hall (containing a public library), San Antonio Hospital, Roman Catholic churches, a Presbyterian church, the court-house and a theatre. The United States has an agricultural experiment station here, and the Insular Reform School is 1 m. south of the city. Coffee, sugar-cane and tropical fruits are grown in the surrounding country; and the business of the city consists chiefly in their export and the import of flour. Among the manufactures are sugar, tobacco and chocolate. Mayaguez was founded about the middle of the 18th century on the site of a hamlet which was first settled about 1680. It was incorporated as a town in 1836, and became a city in 1873. In 1841 it was nearly all destroyed by fire.

Mayavaram, a town of British India, in the Tanjore district of Madras, on the Cauvery river; junction on the South Indian railway, 174 m. S.W. of Madras. Pop. (1901), 24,776. It possesses a market of fine goods, and has a considerable trade in cotton. It is noted for its annual cotton fair. Egeria is a village in the suburbs of the town, in which the weavers live. During October and November the town is the scene of a great pilgrimage to the holy waters of the Cauvery.

Maybole, a burgh of barony and police burgh of Ayrshire, Scotland. Pop. (1901), 5802. It is situated 9 m. S. of Ayr and 50 m. S.W. of Glasgow by the Glasgow & South-Western railway. It is an ancient place, having received a charter from Duncan II. in 1193. In 1516 it was made a burgh of regality, but for generations it remained under the subjection of the Kennedys, afterwards earls of Cassillis and marquesses of Ailsa, the most powerful family in Ayrshire. Of old Maybole was the capital of the district of Carrick, and for long its characteristic feature was the family mansions of the barons of Carrick. The castle of the earls of Cassillis still remains. The public buildings include the town-hall, the Ashgrove and the Lumsden fresh-air fortnightly homes, and the Maybole combination poorhouse. The leading manufactures are of boots and shoes and agricultural implements. Two miles to the south-west are the ruins of Crossraguel (Cross of St Regulus) Abbey, founded about 1240. Kirkoswald, where Burns spent his seventh year, learning land-surveying, lies a little farther west. In the parish churchyard lie "Tam o' Shanter" (Douglas Graham) and "Souter Johnnie" (John Davidson). Four miles to the west of Maybole on the coast is Culzean Castle, the chief seat of the marquess of Ailsa, dating from 1777; it stands on a basaltic cliff, beneath which are the Coves of Culzean, once the retreat of outlaw and a resort of the fairies. Farther south are the ruins of Turnberry Castle, where Robert Bruce is said to have been born. A few miles to the north of Culzean are the ruins of Dunure Castle, an ancient stronghold of the Kennedys.
MAYEN, a town of Germany, in the Prussian Rhine province, on the northern declivity of the Eifel range, 16 m. W. from Coblenz, on the railway Andernach-Gerolstein. Pop. (1905), 13,435. It is still partly surrounded by the ruins of a castle and the remains of a Roman town, and the ruins of a castle rise above the town. There are some small industries, embracing textile manufactures, oil mills and tanneries, and a trade in wine, while near the town are extensive quarries of basalt. Having been a Roman settlement, Mayen became a town in 1291. In 1689 it was destroyed by the French.

MAYENNE, CHARLES OF LORRAINE, Duke of (1554-1611), second son of Francis of Lorraine, second duke of Guise, was born on the 26th of March 1554. He was absent from France at the time of the massacre of Saint Bartholomew, but took part in the siege of La Rochelle in the following year, when he was created duke and peer of France. He went with Henry of Valois, duke of Anjou (afterwards Henry III.), on his election as king of Poland, but soon returned to France to become the energetic supporter and lieutenant of his brother, the 3rd duke of Guise. In 1577 he gained conspicuous successes over the Huguenot forces in Poitou. As governor of Burgundy he raised his province in the cause of the League in 1585. The assassination of his brother at Blois on the 23rd and 24th of December 1588 left him at the head of the Catholic party. The Venetian ambassador, Mocenigo, states that Mayenne had warned Henry III. that there was a plot afoot to seize his person and to send him by force to Paris. At the time of the murder he was at Lyons, where he received a letter from the king saying that he had acted on his warning, and ordering him to retire to his government. Mayenne professed obedience, but immediately made preparations for marching on Paris. After a vain attempt to recover the persons of those of his relatives who had been arrested at Blois he proceeded to recruit troops in his own behalf, and of Burgundy and in Champagne. Paris was delivered to the house of Guise and had been roused to fury by the news of the murder. When Mayenne entered the city in February 1589 he found it dominated by representatives of the sixteen quarters of Paris, all fanatics of the League. He formed a council general to direct the affairs of the city and to maintain relations with the other towns faithful to the League. To this council each quarter sent four representatives, and Mayenne added representatives of the various trades and professions of Paris in order to consult on the revolution. He constituted himself "lieutenant-general of the state and crown of France," taking his oath before the parlement of Paris. In April he advanced on Tours. Henry III. in his extremity sought an alliance with Henry of Navarre, and the allied forces drove the leaguers back, and had laid siege to Paris, when the murder of Henry III. by a Dominican fanatic changed the face of affairs and gave new strength to the Catholic party.

Mayenne was urged to claim the crown for himself, but he was faithful to the official programme of the League and proclaimed Charles, cardinal of Bourbon, at that time a prisoner in the hands of Henry IV., as Charles X. Henry IV. retired to Dieppe, followed by Mayenne, who joined his forces with those of his cousin Charles, duke of Aumale, and Charles de Cossé, comte de Brissac, and engaged the royal forces in a succession of fights in the neighbourhood of Arques (September 1589). He was defeated and out-marched by Henry IV., who moved on Paris, but retreated before Mayenne's forces. In 1592 Mayenne received additions to his army from the Spanish Netherlands, and took the field again, only to suffer complete defeat at Ivry (March 14, 1590). He then escaped to Mantes, and in September collected a fresh army at Meaux, and with the assistance of Alexander Farnese, prince of Parma, sent by Philip II., raised the siege of Paris, which was about to surrender to Henry IV. Mayenne feared with reason the designs of Philip II., and his difficulties were increased by the death of Charles X., the "king of the league." The extreme section of the party, represented by the Sixteen, urged him to proceed to the election of a Catholic king and to accept the help and the claims of their Spanish allies. But Mayenne, who had not the popular gifts of his brother, the duke of Guise, had no sympathy with the demagogues, and himself inclined to the moderate side of his party, which began to urge reconciliation with Henry IV. and the Catholic League. Mayenne forthwith form the constitution against the revolutionary policy of the Sixteen, who during his absence from Paris took the law into their own hands and in November 1591 executed one of the leaders of the more moderate party, Barnabé Brsson, president of the parlement. He returned to Paris and executed four of the chief malcontents. The power of the Sixteen diminished from that time, but with it the strength of the League.1

Mayenne entered into negotiations with Henry IV. while he was still appearing to consider with Philip II. the succession to the French crown of the Infanta Elizabeth, grand-daughter of his mother Elizabeth of Valois, of Henry II. He demanded that Henry IV. should accomplish his conversion to Catholicism before he was recognized by the leaguers. He also desired the continuation to himself of the high offices which had accumulated in his family and the reservation of their provinces to his relatives among the leaguers. In 1593 he summoned the States General to Paris and placed before them the claims of the Infanta, but they protested against foreign intervention. Mayenne signed a truce at La Villette on the 31st of July 1593, at the request of the league to continue to exist, and the principal chiefs submitted. Mayenne finally made his peace only in October 1595. Henry IV. allowed him the possession of Chalon-sur-Saône, of Sceurse and Soissons for three years, made him governor of the Isle of France and paid a large indemnity. Mayenne died at Soissons on the 3rd of October 1611.

A Histoire de la vie et de la mort du duc de Mayenne appeared at Lyons in 1618. See also J. B. H. Capefigue, Hist. de la Réforme, de la ligue et du règne de Henri IV. (8 vols., 1834-1835) and the literature dealing with the house of Guise (q.v.).

MAYENNE, a department of north-west France, three-fourths of which formerly belonged to Lower Maine and the remainder to Anjou, bounded on the N. by Manche and Orne, E. by Sarthe, S. by Maine-et-Loire and W. by Ille-et-Vilaine. Area, 2012 sq. m. Pop. (1906), 305,457. Its ancient geological formations connect it with Brittany. The surface is agreeably undulating; forests are numerous, and the beauty of the cultivated portions is enhanced by the hedgerows and lines of trees by which the farms are divided. The highest point of the department, and indeed of the whole north-west of France, is the Mont des Avalois (1568 ft.). Hydrographically Mayenne belongs to the basins of the Loire, the Vilaine and the Sèvre, the first mentioned draining by far the larger part of the entire area. The principal stream is the Mayenne, which passes successively from north to south through Mayenne, Laval and Château-Gontier; by means of weirs and sluices it is navigable below Mayenne, but traffic is incumberable. The chief afluentes are the Jouanne on the left, and on the right the Colmont, the Ernee and the Oudon. A small area in the east of the department drains by the Erve into the Sarthe; the Vilaine rises in the west, and in the north-west two small rivers flow into the Sèvre. The climate of Mayenne is generally healthy except in the neighbourhood of the numerous marshes. The temperature is lower and the moisture of the atmosphere greater than in the neighbouring departments; the rainfall (about 32 in. annually) is above the average for France.

Agriculture and stock-raising are prosperous. A large number of horned cattle are reared, and in no other French department are

1 The estates of the League in 1593 were the occasion of the famous "Marches de Mayenne," mentioned by Vauban, but not printed at Tours in 1590. It was the work of a circle of men of letters who belonged to the politiques or party of the centre and ridiculed the League. The authors were Pierre Le Roy, Jean Pasquier, Népomucène Laurens, Jacques de Brissac, and Pierre Pithou. It opened with "La vertu du catholicon," in which a Spanish Quack (the cardinal of Plaisance) vaunts the virtues of his drug "catholicon composé," manufactured in the Escorial, while a Lorrainse, an abbot, and a certain Jean de Menippee, comte de Thionville, vaunt the "beneficibus" of the estates, with harangues delivered by Mayenne and the other chiefs of the League, followed. Mayenne's discourse is said to have been written by the jurist Pithou.
Mayenne—Mayer, J. R.

so many horses found within the same area; the breed, that of Craon, is famed for its strength. Craon has also given its name to the most prized breed of pigs in western France. Mayenne produces excellent butter and poultry and a large quantity of honey. The cultivation of the vine is very limited, and the most important crops, and a large quantity of flax and hemp is produced. Game is abundant. The timber grown is chiefly beech, oak, birch, elm, and chestnut. The department produces antimony, auriferous quartz and coal. Marble, slate, and other stone are quarried. There are several chalybeate springs. The industries include flour-milling, brick and tile making, brewing, cotton and wool spinning, and the production of various textile fabrics (especially ticking) for which Laval and Château-Gontier are the centres, agricultural implement making, wood and marble sawing, tanning and treading, leather goods, manufacture of furniture, furniture, and stone and textiles; the chief imports are coal, brandy, wine, furniture and clothing. The department is served by the Western railway. It forms part of the circumscriptions of the IVth army corps, the Academy (educational division) of Nantes, and the court of appeal of Angers. It comprises three arrondissements (Laval, Château-Gontier and Mayenne), with 27 cantons and 276 communes. Laval, the capital, is the seat of a bishopric of the province of Tours. The other principal towns are Château-Gontier and Mayenne, which are treated under separate headings. The following places are also of interest: Evron, which has a church of the 12th and 13th centuries; Juvigné, which has a very ancient church and contains remnants of a fine château of the 14th and 16th centuries; and Ste Suzanne, which has remains of medieval ramparts and a fortress with a keep on a high hill.

Mayenne, a town of north-western France, capital of an arrondissement in the department of Mayenne, 9 m. N.N.E. of Laval by rail. Pop., town 7003, commune 10,020. Mayenne is an old feudal town, irregularly built on hills on both sides of the river Mayenne. Of the old castle overlooking the river several towers remain, one of which has retained its conical roof; the vaulted chambers and chapel are ornamented in the style of the 13th century; the building is now used as a prison. The church of Notre-Dame, beside which there is a statue of Joan of Arc, was built in the 14th century; the choir was rebuilt in the 19th century. In the town is the statue, by David of Angers, to Cardinal Jean de Cheverus (1678-1836), who was born in Mayenne. Mayenne has a subprefecture, tribunals of first instance and of commerce, a chamber of arts and manufactures, and a board of trade-arbitration. There is a school of agriculture in the vicinity. The chief industry of the place is the manufacture of tickings, linen, handkerchiefs and calicoes.

Mayenne had its origin in the castle built here by Juhel, bishop of Chartres, for his sister Geoffrey, wife of John, in the beginning of the 11th century. It was taken by the English in 1067, and several times suffered capture by the opposing parties in the wars of religion and the Vendée. At the beginning of the 16th century the territory passed to the family of Guise, and in 1573 was made a duchy in favour of Charles of Mayenne, leader of the League.

Mayer, Johann Tobias (1723-1769), German astronomer, was born at Marbach, in Württemberg, on the 17th of February 1723, and brought up at Esslingen in poor circumstances. A self-taught mathematician, he had already published two original geometrical works when, in 1746, he entered J. B. Homann's cartographic establishment at Nuremberg. Here he introduced many improvements in map-making, and gained a scientific reputation which led (in 1751) to his election to the chair of economy and mathematics in the university of Göttingen. In 1754 he became superintendent of the observatory, where he laboured with great zeal and success until his death, on the 20th of February 1762. His first important astronomical work was a careful investigation of the light of the sun, by means of a spectroscope, at Nuremberg, 1750, and his chart of the full moon (published in 1755) is unsurpassed for half a century. But his fame rests chiefly on his lunar tables, communicated in 1752, with new solar tables, to the Royal Society of Göttingen, and published in their Transactions (vol. ii.). In 1755 he submitted to the English government an amended body of MS. tables, which James Bradley compared with the Greenwich observations, and found to be sufficiently accurate to determine the moon's place to 75', and consequently the longitude at sea to about half a degree. An improved set was afterwards published in London (1770), as also the theory (Theoria lunae fuxia systema Newtonii, 1767) upon which the tables are based. His widow, by whom they were sent to England, received in consideration from the British government a grant of £3000. Appended to the London edition of the solar and lunar tables are two short tracts—the one on determining longitude by lunar distances, together with a description of the repeating circle (invented by Mayer in 1752), the other on a formula for atmospheric refraction, which applies a remarkably accurate correction for temperature.

Mayer left behind him a considerable quantity of manuscript, part of which was collected by G. C. Lichtenberg and published in one volume (Opera inedita, Göttingen, 1800), and another part in an easy and accurate method for calculating eclipses; an essay on colour, in which three primary colours are recognized; a catalogue of 998 zodiacal stars; and a memoir, of any real value, on the proper motion of eighty stars, originally communicated to the Göttingen Royal Society in 1760. The manuscript residue includes papers on atmospheric refraction (dated 1753), on the motion of Mars as affected by the perturbations of Jupiter and the Earth (1750), and on terrestrial magnetism (1756). The last Mayer sought to explain the magnetic action of the earth by a modification of Euler's hypothesis, and made the first really definite attempt to establish a mathematical theory of magnetic action (C. Hansteen, Magnetismus der Erde, i. 283). E. Klinkerfuss published in 1881 photo-ideographic reproductions of Mayer's local charts and general map of the moon; and his star-catalogue was re-edited by F. Baily in 18$\pi$0 (Memoirs Roy. Astr. Soc. iv. 391) and by G. F. J. A. Auvers in 1894.

Mayer, Julius Robert (1815-1878), German physicist, was born at Heilbronn on the 25th of November 1814, studied medicine at Tübingen, Munich, and Paris, and became professor of physics and chemistry at Jena in 1840 as surgeon of a Dutch vessel obtained a medical post in his native town. He claims recognition as an independent a priori proponent of the "First Law of Thermodynamics," but more especially as having early and ably applied that law to the explanation of many remarkable phenomena, both com-}
MAYFLOWER's real merit consists in the fact that, having for himself made out, on inadequate and even questionable grounds, the conservation of energy, and having obtained (though by inaccurate reasoning) a numerical result correct so far as his data permitted, he applied the principle with great power and ingenuity to the explanation of numerous physical phenomena. His papers, which were republished in a single volume with the title Die Mechanik der Wärme (3rd ed., 1893), are of unequal merit. But some, especially those of 1862, Remanence and Magnetism, and those of 1864, Electricity, are still acknowledged as the best expositions of what really valuable work may be effected by a man of high intellectual powers, in spite of imperfect information and defective reasoning.

Different, and it would appear exaggerated, estimates of Mayflower are given in John Tyndall's papers in the Phil. Mag., 1863-1864 (whose avowed object was "to raise a noble and a suffering man to the station which his labours entitled him to," and to "write the life of E. Dühring's Robert Mayer, der Gießer des neunzehnten Jahrhunderts.

CHMETHNITZ, 1880. Some of the simpler facts of the case are summarized by Tait in the Phil. Mag., 1864, li. 289.

MAYFLOWER, the vessel which carried from Southampton, England, and a triumphant congress is held in Plymouth who established the first permanent colony in New England. It was of about 180 tons burden, and in company with the "Speedwell" sailed from Southampton on the 6th of August 1620, the two having on board 120 Pilgrims. After two trials the "Speedwell" was pronounced unsavoury, and the "Mayflower" sailed alone from Plymouth, England, on the 6th of September with the 100 (or 102) passengers, some 41 of whom on the 11th of November (0.8) signed the famous "Mayflower Compact" in Provincetown Harbor, and a small party of whom, including William Bradford, sent to choose a place for settlement, landed at what is afterward Cape Cod, Massachusetts, on the 11th of December (21st N.S.), an event which is celebrated, as Forefathers' Day, on the 22nd of December. A "General Society of Mayflower Descendants" was organized in 1894 by lineal descendants of the "Mayflower" to "preserve their memory, their records, their history, and all facts relating to them, their ancestors and their posterity." Every lineal descendent, over eighteen years of age, of any passenger of the "Mayflower" is eligible to membership. Branch societies have since been organized in several of the states and in the District of Columbia.

See Azel Ames, The May-Flower and Her Log (Boston, 1901); Blanche McManus, The Voyage of the Mayflower (New York, 1897); The General Society of Mayflower: Meetings, Officers and Members, arranged by Rate Societies, Ancestors and Their Descendants (New York, 1901). MAY-FLY. The Mayflies belong to the Ephemeridae, a remarkable family of winged insects, included by Linnaeus in his order Neuroptera, which derive their scientific name from χερσόνησος, in allusion to their very short lives. In some species it is possible that they have scarcely more than one day's existence, but others are far longer lived, though the extreme limit is probably rarely more than a week. The Mayfly has a very sharply defined characters, which separate its members at once from all other neuropterous (or pseudo-neuropterous) groups.

These insects are universally aquatic in their preparatory states. The eggs are dropped into the water by the female in large masses, resembling, in some species, bunches of grapes in miniature. Probably several months elapse before the young larvae are excluded. The sub-aquatic condition lasts a considerable time: in Cloeon, a genus of small and delicate species, Sir J. L. Cabaniss and Davis proved it to extend over more than six months; but in larger and more robust genera (e.g. Polingenia) there appears reason to believe that the greater part of three years is occupied in preparatory conditions.

The larva is elongate and campaniform. The head is rather large, and is furnished at first with five simple eyes of nearly equal size, but in later cases in size the homologies of the faceted eyes of the imago become clearer, where the maxillary palpi remain small. The antennae are long and thread-like, composed at first of few joints, but the number of these latter apparently increases at each molt. The mouthparts are well developed, consisting of an upper lip, powerful mandibles, maxillae with three-jointed palpi, and a deeply quadridapid labium or lower lip with three-jointed labial palpi. Distinct and conspicuous maxillulae are associated with the tongue or hypopharynx. There are three distinct and large thoracic segments, whereas the prothorax is narrowed in the others; the legs are much shorter and stouter than in the winged insects, with monomerous tarsi terminated by a single claw. The abdomen consists of ten segments, the tenth furnished with long and slender filamentous appendages, the sixth segment at first, but an intermediate one gradually develops itself (though this latter is often lost in the winged insect). Respiration is effected by means of external gills placed along both sides of the dorsum of the abdomen and hinder segments of the thorax. The gills form in some species they are entire plates, in others they are cut up into numerous divisions, in all cases traversed by numerous ramifications. According to the researches of Lubbock and of E. Joly, the wing-cases of larvae have no breathing organs, and respiration is effected through the skin.

Lubbock traced at least twenty moults in Cloeon; at about the tenth rudiments of the wing-cases are formed. At the end of the second year, the creature may be said to have entered its "nymph" stage, but there is no condition analogous to the pupa-stage of insects with complete metamorphoses.

There may be said to be three or four different modes of life in these larvae: some are fossorial, and form tubes in the mud or clay in which they live; others are found on or beneath stones; while others again swim and crawl freely, seeking water plants. It is probable that some are carnivorous, either attacking other larvae or subsisting on more minute forms of animal life; but others perhaps feed more exclusively on vegetable matters of a low type, such as diatoms.

The most aberrant type of larva is that of the genus Protopistoma, which was originally described as an entomoecean crustacean on account of the presence of a large carapace overlapping the greater part of the body. The limbature of the distal part of the anterior six abdominal segments unite with the wing-cases to form a large respiratory chamber, containing five pairs of tracheal gills, and the lateral side of the abdomen is a posterior orifice for the outflow of water. Species of this genus occur in Europe, Africa and Madagascar.

When the aquatic insect has reached its full growth it emerges from the water or seeks its surface; the thorax splits down the back and the winged form appears. But this is not yet perfect, although it has all the form of a perfect insect and is capable of flight; it is what is variously termed a "psuedo-imago" or "sub-imago." In the habits of all other insects, there yet remains a pellicle that has to be shed, covering every part of the body. This final moult is effected soon after the insect's appearance in the winged form; the creature seeks a temporary resting-place, the pellicle splits down the back, and the now perfect insect comes forth, often differing very greatly in colours and markings from the condition in which it was only a few moments before. If the observer takes up a suitable position near water, his coat is often soon covered with the cast sub-imaginal skins of these insects, which are often chosen by a worm to undergo its final change.

The winged insect differs considerably in form from its sub-aquatic condition. The head is smaller, often occupied almost entirely above in the male by the very large eyes, which in some species are curiously double in that sex, one portion being pillared, and forming what is termed a "turban," the mouth parts are aborted, for the creature is now incapable of taking nourishment either solid or fluid; the antennae are mere short bristles, consisting of two rather large basal joints and a multi-articulate thread. The prothorax is much narrower, whereas the other segments (especially the mesothorax) are greatly enlarged; the legs long and slender, the anterior pair often much longer than the body, the membrane of the four- or five-jointed but in some genera (e.g. Oligoneura and allies) the legs are aborted, and the creatures are driven helplessly about by the wind. The wings are carried erect; the anterior pair large, the posterior pair small, and usually abundant transverse reticulation; the posterior pair very much smaller, often lanceolate, and frequently wanting absolutely. The abdomen consists of ten segments, the first being much enlarged; at the end of the third or fourth segment the external rudimentary duct are remarkable archeological features of these insects, as has been pointed out by J. A. Palmen. The sexual act takes place in the air, and is of very short duration, but is apparently repeated several times with any rate in various species.

Ephemeridae are found all over the world, even up to the northern latitudes. F. J. Picket, A. E. Eaton and others have
MAYHEM—MAYMO

given us valuable works or monographs on the family; but the subject still remains little understood, partly owing to the great difficulty of preserving such delicate insects; and it appears probable they can only be satisfactorily investigated as moist preparations. The number of described species is less than 200, spread over many genera.

From the earliest times attention has been drawn to the enormous abundance of species of the family in certain localities. Johann Anton Scorpiol, writing in the 18th century, speaks of them as so abundant in one place in Carniola that in June twenty cart-loads were carried away for manure Polyomatiæ cælo, which, though not found in England, occurs in the Swiss parts of Europe (and is common at Paris), emerges from the water soon after sunset, and continues for several hours in such myriads as to resemble snow showers, putting out lights, and causing inconvenience to man, and annoyance to horses by entering their nostrils. In other parts of the world they have been recorded in multitudes that obscured passers-by on the other side of the street. And similar records might be multiplied almost to any extent. In Britain, although they are often very abundant, we have scarcely anything analogous.

Fish, as well known, devour them greedily, and enjoy a veritable feast during the short period in which any particular species appears. By anglers the common English species of Ephemeræ (sulcata and danica), but more especially the latter, which is more abundant) is known as the "may-fly," but the terms "green drake" and "bassard drake" are applied to conditions of the same species. Useful information on this point will be found in Ronalds's Fly-Fisher's Entomology, edited by Westwood.

Ephemeræ belong to a very ancient type of insects, and fossil imprints of allied forms occur even in the Devonian and Carboniferous formations.

There is much to be said in favour of the view entertained by some entomologists that the structural and developmental characteristics of may-flies are sufficiently peculiar to warrant the formation for them of a special order of insects, for which the names Agnatha, Plectoptera and Ephemeroptera have been proposed. (See Hexapoda, Neoptera.)

Bibliography.—Of especial value to students of these insects are A. E. Eaton's monograph (Trans. Linn. Soc. (2) iii. 1883-1885) and A. Yavuzesire's "Recherches sur l'organisation des larves" (Ann. Sci. Nat. Zoot. (6) xiii. 1882 (7) ix. 1890). J. A. Palmen's memoirs Zur Morphologie des Tracheenystems (Leipzig, 1877) and Über passende Anordnungen der Geschlechtsorgane bei Insekten (Helsingfors, 1884), contain important observations on may-flies. See also L. C. Miñá, Nat. Hist. Aquatic Insects (London, 1890); J. G. Needham and others (New York State Museum, Bull. 86, 1905).

(R. MLEC; G. H. C.)

MAYHEM (for derivation see MAIMING), an old Anglo-French term of the law signifying an assault whereby the injured person is deprived of a member proper for his defence in fight, e.g. an arm, a leg, a foreshoulder, &c. The loss of an ear, jaw, tooth, &c., was not mayhem. The most ancient punishment in English law was retaliative—membrum pro membro, but ultimately at common law fine and imprisonment. Various statutes were passed aimed at the offence of maiming and disfiguring, which is now dealt with by section 18 of the Offences against the Person Act 1861. Mayhem may also be the ground of a civil action, which had this peculiarity that the court on sight of the wound might increase the damages awarded by the jury.

MAYHEW, HENRY (1812-1887), English author and journalist, was a London solicitor, was born in 1812. He was sent to Westminster school, but ran away to sea. He sailed to India and on his return studied law for a short time under his father. He began his journalistic career by founding, with Gilbert Beckett, in 1831, a weekly paper, Figaro in London. This was followed in 1832 by a short-lived paper called The Thief; and he produced one or two successful farces. His brothers Horace (1816-1872) and Augustus Septimus (1826-1875) were also journalists, and with them Henry occasionally collaborated, notably with the younger in The Greatest Plague of Life (1847) and in Acting Charades (1850). In 1841 Henry Mayhew was one of the leading spirits in the foundation of Punch, of which he was for the first two years joint-editor with Mark Lemon. He afterwards wrote on all kinds of subjects, and published a number of volumes of no permanent reputation—humorous stories, travel and practical handbooks. He is credited with being the first to "write up" the poverty side of London life from a philanthropic point of view, with the collaboration of John Binny and others he published London Labour and London Poor (1851; completed 1864) and other works on social and economic questions. He died in London, on the 25th of July 1887. Horace Mayhew was for some years sub-editor of Punch, and was the author of numerous publications and plays. The books of Horace and Augustus Mayhew owe their survival chiefly to Cruikshank's illustrations.

MAYHEW, JONATHAN (1720-1766), American clergyman, was born at Martha's Vineyard on the 8th of October 1720, being fifth in descent from Thomas Mayhew (1592-1628), an early settler and the grantees (1641) of Martha's Vineyard. Thomas Mayhew (c. 1616-1657), the younger, his son John (d. 1689) and John's son, Experience (1673-1758), were active missionaries among the Indians of Martha's Vineyard and the vicinity. Jonathan was educated at Harvard in 1744. So liberal were his theological views that he was deprived of the vacant professorship of the West Church in Boston in 1747 only two ministers attended the first council called for the ordination, and it was necessary to summon a second council. Mayhew's preaching made his church practically the first "Unitarian" Congregational church in New England, though it was never officially Unitarian. In 1763 he published Observations on the Charter and Conduct of the Society for Propagating the Gospel in Foreign Parts, an attack on the policy of the society in sending missionaries to New England contrary to its original purpose of "Maintaining Ministers of the Gospel" in places "wholly destitute and unprovided with means for the maintenance of ministers and for the public worship of God;" the Observations marked him as a leader among those in New England who feared, as Mayhew said (1762), "that there is a scheme forming for sending a bishop into this part of the country, and that our Governor, a true churchman, is deeply in the plot." To an American reply to the Observations, entitled A Candid Examination (1763), Mayhew wrote a Defense; and after the publication of an Answer, anonymously published in London in 1764 and written by Thomas Seba, he published his own A Second Defense. He bitterly opposed the Stamp Act, and urged the necessity of colonial union (or "communion") to secure colonial liberties. He died on the 9th of July 1766. Mayhew was Dudleian lecturer at Harvard in 1765, and in 1740 had received the degree of D.D. from the University of Aberdeen.

MAYHEW, THOMAS, English 18th century cabinet-maker. Mayhew was the less distinguished partner of William Ince (q.v.). The chief source of information as to his work is supplied by his own drawings in the volumes of designs, The universal system of household furniture, which he published in collaboration with his partner. The name of the firm appears to have been Mayhew and Ince, but on the title page of this book the names are reversed, perhaps as an indication that Ince was the more extensive contributor. In the main Mayhew's designs are heavy and clumsy, and often downright extravagant, but he had a certain lightness of accomplishment in his applications of place to taste, a style of original talent he possessed little, yet it is certain that much of his Chinese work has been attributed to Chippendale. It is indeed often only by reference to books of design that the respective work of the English cabinet-makers of the second half of the 18th century can be correctly attributed.

MAYMO, a hill sanatorium in India, in the Mandalay district of Upper Burma, 3,500 ft. above the sea, with a station on the

1 Francis Bernard, whose project for a college at Northampton seemed to Mayhew and others a move to strengthen Anglicanism.
Manday-Lashio railway 422 m. from Rangoon. Pop. (1901), 62,223. It consists of an undulating plateau, surrounded by hills, which are covered with thin oak forest and bracken. Though not entirely free from malaria, it has been chosen for the summer residence of the lieutenant-governor; and it is also the permanent headquarters of the lieutenant-general commanding the Burma division, and of other officials.

**MAYNARD, Horace (1852-1864), French poet, was born at Toulouse in 1852. His father was consulier in the parlament of the town, and Francois was also trained for the law, becoming eventually president of Aurillac. He became secretary to Margaret of Valois, wife of Henry IV., for whom his early poetry was written. He was a pupil of Malherbe. It is said that in the workmanship of his lines he excelled Racan, but lacked his rival's energy. In 1634 he accompanied the Cardinal de Noailles to Rome and spent about two years in Italy. On his return to France he made many unsuccessful efforts to obtain the favour of Richelieu, but was obliged to retire to Toulouse. He never ceased to lament his exile from Paris and his inability to be present at the meetings of the Academy, of which he was one of the earliest members. The best of his poems is in imitation of Horace, "Alcipe, revoi dans nos bois." He died at Toulouse on the 23rd of October 1646. His works consist of odes, epigrams, songs and letters, and were published in 1646 by Marin le Roy de Gomberville.

**MAYNE, JASPER (1604-1672), English author, was baptized at Hatherleigh, Devonshire, on the 23rd of November 1604. He was educated at Westminster School and at Christ Church, Oxford, where he had a distinguished career. He was presented to two college livings in Oxfordshire, and was made D.D. in 1646. During the Commonwealth he was dispossessed, and became chaplain to the duke of Devonshire. At the Restoration he was made canon of Christ Church, archdeacon of Chichester, and chaplain in ordinary to the king. He wrote a farce, or comedy, *The City Match* (1639), which is reprinted in vol. xiii. of Hazlitt's edition of Dod's *Old Plays*, and a fantastic tragi-comedy entitled *The Amorous War* (printed 1648). After receiving ecclesiastical preferment he gave up poetry as unbecoming his profession. His other works comprise some occasional gems, a translation of Lucian's *Dialogues* (printed 1664) and a number of sermons. He died on the 6th of December 1672 at Oxford.

**MAYNOOTH, a small town of county Kildare, Ireland, on the Midland Great Western railway and the Royal Canal, 15 m. W. by N. of Dublin. Pop. (1901), 948. The Royal Catholic College of Maynooth, founded by an Act of the Irish parliament in 1795, is the chief seminary for the education of the Roman Catholic clergy of Ireland. The building is a fine Gothic structure by A. W. Pugin, erected by a parliamentary grant obtained in 1846. The chapel, with fine oak choir-stalls, mosaic pavements, marble altars and stained glass, and with adjoining cloisters, was dedicated in 1860. The average number of students is about 500—the number specified under the Act of 1845—and the full course of instruction is eight years. Near the college stand the ruins of Maynooth Castle, probably built in 1176, but subsequently extended, and formerly the residence of the Fitzgerald family. It was besieged in the reigns of Henry VIII. and Edward VI., and during the Cromwellian Wars, when it was demolished. The beautiful mansion of Carton is about 1 mile from the town.

**MAYO, Richard Southwell Bourke, 6th Earl of (1522-1582), British statesman, son of Robert Bourke, the 5th earl of Clanard, was born in Dublin on the 21st of February 1522, and was educated at Trinity College, Dublin. After travelling in Russia he entered parliament, and sat successively for Kildare, Coleraine and Corkermouth. He was chief secretary for Ireland in three administrations, in 1533, 1538 and 1566, and was appointed vicecy of India in January 1580. He consolidated the frontiers of India and met Shere Ali, amir of Afghanistan, in durbar at Umballa in March 1589. His reorganization of the finances of the country put India on a paying basis; and he did much to promote irrigation, railways, forests and other useful public works. Visiting the convict settlement at Port Blair in the Andaman Islands, for the purpose of inspection, the next year he was named to the convict on the 8th of February 1582. His successor was his son, Dermot. Sir Wyndham Bourke (b. 1581) who became 7th earl of Mayo.

See Sir W. W. Hunter, *Life of the Earl of Mayo* (1886), and *The Earl of Mayo in the Rulers of India Series* (1891).

**MAYO, a western county of Ireland, in the province of Connacht, bounded N. and W. by the Atlantic Ocean, N.E. by Sligo, E. by Roscommon, S. and S. by Galway. The area is 1,380,390 acres, or about 2157 sq. m., comprising the largest in Ireland after Cork and Galway. About two-thirds of the boundary of Mayo is formed by sea, and the coast is very much indented, and abounds in picturesque scenery. The principal inlets are Killary Harbour between Mayo and Galway; Clew Bay, in which are the harbours of Westport and Newport; Blacksod Bay and Broad Haven, which form the peninsula of the Mullet; and Killala Bay between Mayo and Sligo. The islands are very numerous, the principal being Inish Turk, near Killala, and Inishman, near Sligo, and falls into Killala Bay. The courses of the other streams are short, and except when swollen by rains their volume is small. The principal lakes are Lough Mask and Lough Corrib, on the borders of the county with Galway, and Loughs Conn in KIarry, Carrowmore Island in the north-west, Beltra in the west, and Carra adjoining Lough Mask. These loughs and the smaller loughs, with the streams generally, afford admirable sport with salmon, sea-trout and brown trout, and Ballina is a favourite centre.

**Geology.**—The wild and barren west of this county, including the great hills on Achill Island, is formed of "Dalmidian" rocks, schists and sandstones, with masses of granite near Belmullet. At Blacksod Bay the granite has been quarried as an ornamental stone. Nephin Beg, Nephin and Croagh Patrick are typical quartzite summits, the last named belonging possibly to a Silurian horizon but rising from a metamorphosed area on the south side of Clew Bay. The schists and gneisses of the Ox Mountain axis also enter the county north of Castlebar. The Mullen and Ben Gorm range, boundling the fine fjord of Killary Harbour, is formed of terraced Silurian rocks, from Bala to Ludlow age. These beds, with intercalated lavas, form the mountainous shore of Lough Mask, the east, like that of Lough Corrib, being formed of low Carboniferous Limestone. Since the Loughs, with Old Red Sandstone over them, come out at the west end of the Clew range at Ballaghadereen, Clew Bay, with its islands capped by grey breccias, is a marine valley, with thin strata of Carboniferous, and Old Red Sandstone coming out on the north side of this, from near Achill to Lough Conn. The country from Lough Conn northward to the sea is a lowland of Carboniferous Limestone, with L. Carboniferous Sandstone against the Dalmidian on the west.

**Industries.**—There are some very fertile regions in the level portion of the county, and the mountainous districts that are poor, the holdings are subdivided beyond the possibility of affording proper sustenance to their occupiers, and, except where fishing is combined with agricultural operations, the circumstances of the poorer people are among the most wretched in Ireland. The proportion of tillage to pasturage is roughly as 1 to 34. Oats and potatoes are the principal crops. Cattle, sheep, pigs and poultry are reared. Coarse linen and woollen cloths are manufactured to a small extent. At Foxford woolen-mills are established at a nunnery, in connexion with a scheme of technical instruction. Kiel, Belmullet and Ballycastle are the headquarters of sea and
coast fishing districts, and Ballina of a salmon-fishing district, and these fisheries are of some value to the poor inhabitants. A branch of the Midland Great Western railway enters the county from Athlone, in the south-west, which runs north to Ballina and Killala on the coast, branches diverging from Claremorris to Ballinrobe, and from Manulla to Westport and Achill on the west coast. The Limerick and Sligo line of the Great Southern and Western passes from south to north-east by way of Claremorris.

Population and Administration.—The population was 21,868 in 1891, and 190,166 in 1901. The decrease of population and the number of emigrants are slightly below the average of the Irish counties. Of the total population about 97% are rural and about the same percentage are Roman Catholics. The chief towns are Ballina (pop. 4,505), Westport (3,923) and Castlebar (3,985), the county town. Ballaghaderreen, Claremorris (Castlurcan), Crossmolina and Swinfen are lesser market towns; and Newport and Westport are small seaports on Clew Bay. The county includes nine baronies. Assizes are held at Castlebar, and quarter sessions at Ballina, Ballinrobe, Belmullet, Castlebar, Claremorris, Swinfen and Westport. In the Irish parliament two members were returned for the county, and two for the borough of Castlebar, but at the union Castlebar was disfranchised. The division since 1885 is into north, south, east and west parliamentary divisions, each returning one member. The county is in the Protestant diocese of Tuam and the Roman Catholic dioceses of Tuam, Achonry, Galway and Kilmacduagh, and Killala.

History and Antiquities.—Erris in Mayo was the scene of the landing of the chief colony of the Firbolges, and the battle which is said to have resulted in the overthrow and almost annihilation of this tribe took place also in this county, at Moytura near Cong. At the close of the 12th century what is now the county of Mayo was granted, with other lands, by king John to William, brother of Hubert de Burgh. After the murder of William de Burgh, 3rd earl of Ulster (1333), the Bourkes (de Burghs) of the collateral male line, rejecting the claim of William’s heiress (the wife of Lionel, son of Edward III) to the succession, succeeded in holding the bulk of the De Burgh possessions, what is now Mayo falling to the branch known by the name of MacWilliam Oughter, who maintained their virtual independence till the time of Elizabeth. Sir Henry Sydney, during his first viceroyalty, after making efforts to improve communications between Dublin and Connaught in 1566, arranged for the shiring of that province, and Mayo was made shire ground, taking its name from the monastery of Maio or Mageo, which was the seat of a bishop. Edwarthes at this period the MacWilliams continued to exercise very great authority and power, and were felagued in 1603, when “the MacWilliam Oughter,” the Michael Bourke, surrendered his lands and received them back, to hold them by English tenure, with the title of Viscount Mayo (see BURGH, DE). Large confiscations of the estates in the county were made in 1586, and on the termination of the wars of 1641; and in 1666 the restoration of his estates to the 4th Viscount Mayo involved another confiscation, at the expense of Cromwell’s settlers. Killala was the scene of the landing of a French squadron in connexion with the rebellion of 1798. In 1879 the village of Knock in the south-east acquired notoriety from a story that the Virgin Mary had appeared in the church, which became the resort of many pilgrims. There are round towers at Killala, Turlough, Meelick and Balla, and an imperfect one at Aughagower. Killala was formerly a bishopric. The monasteries were numerous, and many of them of considerable importance: the principal being those at Mayo, Ballyhaunis, Cong, Ballinrobe, Ballintober, Burrishoole, Cross or Holycross in the peninsula of Mullet, Moyne, Roserker or Rosserick and Templemore or Strade. Of the old castles the most ancient was in Moy, near Newport, said to have been built by the celebrated Grace O’Malley, and on the Deel Castle near Ballina, at one time the residence of the ears of Arranmore. See Hubert Thomas Knox, History of the County of Mayo (1908).

MAYOR, JOHN EYTON BICKERSTETH (1825— ), English classical scholar, was born at Baddegama, Ceylon, on the 12th of January 1825, and educated in England at Shrewsbury School and St John’s College, Cambridge. From 1863 to 1867 he was librarian of the university, and in 1872 succeeded H. A. J. Munro in the professorship of Latin. His best-known work, an edition of thirteen satires of Juvenal, is marked by an extraordinary wealth of illustrative quotations. His Bibliographical Clue to Latin Literature (1873), based on E. IIhüner’s Grundriss zu Vorlesungen über die römische Literaturgeschichte is a valuable aid to the student, and his edition of Cicero’s Second Philippic is widely used. He also edited the English works of J. Fisher, bishop of Rochester, i. (1876); Thomas Baker’s History of St John’s College, Cambridge (1869); Richard of Cirencester’s Cronica historiale de gestis regum Angliae 447–1066 (1863–1866); Roger Ascham’s Schoolmaster (new ed., 1883); the Latin Heptateuch (1889); and the Journal of Philology.

His brother, Joseph Bickersteth Mayo (1828— ), classical scholar and theologian, was educated at Rugby and St John’s College, Cambridge, and from 1870 to 1879 was professor of classics at King’s College, London. His most important classical works are an edition of Cicero’s De natura deorum (3 vols., 1880–1885) and Guide to the Choice of Classical Books (3rd ed., 1885, with supplement, 1896). He also devoted attention to theological literature and edited the epistles of St James (1875), St Jude and St Peter (1907), and the Miscellanea of Clement of Alexandria (ed., F. A. Hort, 1922). From 1887 to 1893 he was editor of the Classical Review. His Chapters on English Metre (1886) reached a second edition in 1900.

MAYOR (Lat. major, greater), in modern times the title of a municipal officer who discharges judicial and administrative functions. The legal form of the word is maire. In Germany the corresponding title is Bürgermeister, in Italy sindico, and in Spain alcalde. "Mayor" had originally a much wider significance. Among the nations which arose on the ruins of the Roman empire of the West, and which made use of the Latin spoken by their "Roman" subjects as their official and legal language, mayor and the Low Latin form of the word were found to be very convenient terms to describe important officials of both sexes who had the superintendence of others. Any female servant or slave in the household of a barbarian, whose business it was to overlook other female servants or slaves, would be quite naturally called a mairezza. So the male officer who governed the king’s household would be the major domus. In the households of the Frankish kings of the Merovingian line, the major domus, who was also variously known as the gubernator, procurator or praefectus palatii, was so great an officer that he ended by evicting his master, and was known as the "mayor of the palace" (q.v.). The fact that his office, became known in the family of Pippin of Heristal made the fortune of the Carolingian line. But besides the major domus (the major-domo), there were other officers who were majorzes, the major cubiculi, mayor of the bedchamber, and major equorum, mayor of the horse. In fact a word which could be applied so easily and with accuracy in so many circumstances was certain to be widely used by itself, or in its derivatives. The post-Augustine majorinus, "one of the larger kind," was the origin of the medieval Spanish merinos, who in Castillian was the merino, and sometimes the merino mayor, or chief merino. He was a judicial and administrative officer of the king’s. The gregum merius was the superintendent of the flocks of the corporation of sheep-owners called the meza. From him the sheep, and then the wool, have come to be known as merinos—a word identical in origin with the municipal title of mayor. The latter came directly from the heads of gilds, and other associations of freemen, who had their banner and formed a group on the populations of the towns, the mayories barbaric or rexiul.

In England the mayor is the modern representative of the lord bailiff or reeve (see Boroson). We find the chief magistrate of London bearing the title of portreeve for considerably more than a century after the Conquest. This official was elected by popular choice, a privilege secured from king John. By the beginning of the 11th century the title of portreeve 1 gave way to that of mayor as the designation of the chief officer of the city.
London, and the adoption of the title by other boroughs followed at various intervals.

A mayor is now in England and America the official head of a municipal government. In the United Kingdom the Municipal Corporations Act, 1852, s. 15, regulates the election of mayors. He is to be elected annually by the council of the borough from among the aldermen or councillors or persons qualified to be such. His term of office is one year, but he is eligible for re-election. He may appoint a deputy to act during his absence, but the latter must either be an alderman or councillor. A mayor who is absent from the borough for more than two months becomes disqualified and vacates his office. A mayor has the right to preside over the council for the year in which he is elected and the next year a justice of the peace for the borough. He must be the head of the council unless the council thinks reasonable. The office of mayor in an English borough does not entail any important administrative duties. It is generally regarded as an honour conferred for past services, and a mayor is expected to devote much of his time to ornamental functions and to preside over meetings which have for their object the advancement of the public welfare. His administrative duties are merely to act as returning officer at municipal elections, and as chairman of the meetings of the council.

The position and power of an English mayor contrast very strongly with those of the similar office in the United States. The latter is elected directly by the voters inside the city, usually for several years; and he has extensive administrative powers.

The English method of selecting a mayor by the council is followed for the important but non-functional (except in emergency) head of the government. There are more important cities of Italy, and in Germany, where, however, the central government must confirm the choice of the council. Direct election of the central government exists in Belgium, Holland, Denmark, Norway, Switzerland, the smaller towns of France, and Spain. As a rule, too, the term of office is longer in other countries than in the United Kingdom. In France election is for four years in Holland and Belgium, for five years in France for an indefinite period, and in Germany usually for twelve years, but in some cases for life.

In Germany the post may be said to be a professional one, the burgomaster being the head of the city magistracy, and requiring, in order to be eligible, a training in administration. German burgomasters are most frequently elected by promotion from another city. In France the maire, and a number of experienced members term and function, as it were, the hands of the executive committee, are elected directly by the municipal council from among its members. Most of the administrative work is left in the hands of the maire and his adjutants, the full council meeting comparatively seldom.

Further information will be found in the sections on local government in the articles on the various countries; see also A. Shaw, Municipal Government in Continental Europe; J. A. Fairlie, Municipal Administration; S. and B. Waithe, The Local Government; Redlich and Hirst, Local Government in England; A. L. Lowell, The Government of England.

MAJOR OF THE PALACE.—The office of mayor of the palace was an institution peculiar to the Franks of the Merovingian period. A landowner who did not manage his own estate placed the government of a stronghold (maior) who superintended the working of the estate and collected the revenues. When he had several estates, he appointed a chief steward, who managed the whole of the estates and was called the major domus. Each great personage had a major domus—the queen had hers, the king his; and since the royal house was called the palace, this officer took the name of "mayor of the palace." The mayor of the palace, however, did not remain restricted to domestic functions; he had the discipline of the palace and tried persons who resided there. Soon his functions expanded. If the king were a minor, the mayor had the safeguard of his education in the capacity of guardian (notarius), and often he was invested himself with a title of state. When the king came of age, the mayor exerted himself to keep this power, and succeeded. In the 7th century he became the head of the administration and a veritable prime minister. He took part in the nomination of the counts and dukes; in the king's absence he presided over the royal tribunal; and he often commanded the armies. When the custom of commemoration developed, the king charged the mayor of the palace to protect those who had commended themselves to him and to manage the affairs of the kingdom. In the main cities of the United Kingdom (London, York, Dublin) have acquired by prescription the title of mayor. In the chief city of London it seems to date from 1540. It has also been conferred during the closing years of the 19th century by letters patent on Birmingham, Bradford, Liverpool, Manchester, Bristol, Sheffield, Leeds, Cardiff, Bradford, Newcastle-on-Tyne, Belfast, Cork. In 1910 it was granted to Norwich. Lord mayors are entitled to be addressed as "right honourable."

MAYOR OF THE PALACE—MAYOW

In the case of London it seems to date from 1540. It has also been conferred during the closing years of the 19th century by letters patent on Birmingham, Bradford, Liverpool, Manchester, Bristol, Sheffield, Leeds, Cardiff, Bradford, Newcastle-on-Tyne, Belfast, Cork. In 1910 it was granted to Norwich. Lord mayors are entitled to be addressed as "right honourable."

MAYOW, JOHN (1643–1670), English chemist and physiologist, was born in London in May 1643. At the age of fifteen he went up to Wadham College, Oxford, of which he became a scholar a year later, and in 1660 he was elected to a fellowship at All Souls. He graduated in law (bachelor, 1663, doctor, 1670), but after he had completed his profession, and 1670 he became a fellow of the Royal Society. He was a fellow of All Souls and was a fellow of the Royal Society. The following year, after a marriage which was not altogether to his content, he died in London in September 1679. He published in Oxford in 1668 two tracts, on respiration and rickets, and in 1674 these were reprinted, the former in an enlarged and corrected form, with three others "De sal-nitro et spirito nitro-aereo," "De respiratione foetus in
939

utero et ovo," and "De motu musclei et spiritalibus animalibus" as Tractatus quinque medico-physici. The contents of this work, which was several times republished and translated into Dutch, German and French, show him to have been an investigator much in advance of his time.

Accepting as proved by Boyle's experiments that air is necessary for combustion, while he thought not that it formed a whole but by a "more active and subtle part of it." This part he called spiritus igneo-aereum, or sometimes nitro-aereum; for he identified it with one of the constituents of cane sugar, or acid potato port liquor which became formed by the fumes, of fixed alkali with a spiritus acidus. In combustion the particules nitro-aereum—either pre-existent in the thing consumed or supplied by the air—combined with the oxygenated spiritus and he inferred from his observation that their antimony, strongly heated with a burning glass, undergoes an increase of weight which can be attributed to nothing else but these particles. In respiration he asserted that the same particles are consumed because he found that when a small animal and a lighted candle were placed in a closed vessel full of air the candle first went out and soon afterwards the animal died, but if there was no candle present it lived twice as long. He concluded that this constituent of the air is absolutely necessary for life, and supposed that the lungs separate it from the atmosphere and pass it into the blood. It is also necessary, he inferred, for all muscular movements, and he thought there was reason to believe that the sudden contraction of muscle is produced by its combination with other combustible (salino-sulphurous) particles in the body; hence the heart, being a muscle, ceases to beat when respiration is stopped. Animal heat also, he says, is produced by the union of a certain number of nitro-aereum particles, breathed in with the air, with the combustible particles in the blood, and is further formed by the combination of these two sets of particles in muscle during muscular exertion. Mayow—who also gives a remarkably correct anatomical description of the mechanism of respiration—preceeded Priestley and Lavosier by a century in recognizing the existence of oxygen, under the guise of his spiritus nitro-aereum, as a separate entity distinct from the general mass of the air; he perceived the part it plays in combustion and in increasing the weight of the calecs of metals as compared with metals themselves; and, rejecting the common opinion of his time that the use of breathing is to cool the heart, or assist the passage of the blood from the right to the left side of the heart, or merely to agitate it, he saw in representation a mechanism for introducing oxygen into the body, where it is consumed for the production of heat and muscular activity, and even vaguely conceived of expiration as an excretory process.

MAYSVILLE, a city and the county-seat of Mason county, Kentucky, U.S.A., on the Ohio river, 60 m. by rail S.E. of Cincinnati. Pop. (1890) 5538; (1900) 6423 (1155 negroes); (1910) 6141. It is served by the Louisville & Nashville, and the Chesapeake & Ohio railways, and by steamboats on the Ohio river. Among its principal buildings are the Mason county public library (1878), the Federal building and Masonic and Odd Fellows' temples. The city lies between the river and a range of hills; at the back of the hills is a fine farming country, of which tobacco of excellent quality is a leading product. There is a large plant of the American Tobacco Company at Maysville, and among the city's manufactures are pulleys, ploughs, wheels, flax, flour, lumber, furniture, carriages, cigars, and ready-made and machine-shop products, bricks and cotton goods. The city is a distributing point for coal and other products brought to it by Ohio river boats. Formerly it was one of the principal hemp markets of the country. The place early became a landing point for immigrants to Kentucky, and in 1784 a double log cabin and a blockhouse were erected here. It was then called Limestone, from the creek which flows into the Ohio here, but several years later the present name was adopted in honour of John May, who with Simon Kenton laid out the town in 1787, and who in 1789 built a fort occupied by the Indians. Maysville was incorporated as a town in 1787, was chartered as a city in 1833, and became the county-seat in 1848.

In 1830, when the question of "internal improvements" by the National government was an important political issue, Congress passed a bill directing the government to aid in building a turnpike road from the Ohio river to Madison county. Androes, the surveyor, vetoed the bill on the ground that the proposed improvement was a local rather than a national one; but one-half the capital was then furnished privately, the other half was furnished through several state administrations. E. A. Bangs, who suggested the beginning of a system of turnpike roads built with state aid.

MAZAGAN (El Jadida), a port on the Atlantic coast of Morocco in 33° 16' N. 8° 26' W. Pop. (1908), about 12,000, of whom a fourth are Jews and some 400 Europeans. It is the port for Marrakesh, from which it is 110 m. nearly due north, and also for the fertile province of Dukâla. Mazagan presents from the sea a very un-Moorish appearance; it has massive Portuguese walls of hewn stone. The exports, which include beans, almonds, maize, chick-peas, wool, hides, wax, eggs, &c., were valued at £550,000 in 1900, £564,000 in 1904, and £624,000 in 1906. The imports, which include sugar, tea, rice, &c., were valued at £38,000 in 1900, £536,000 in 1904, and £530,000 in 1906. About 46% of the trade is with Great Britain and 34% with France. Mazagan was built in 1506 by the Portuguese, who abandoned it to the Moors in 1769 and established a colony, New Mazagan, on the shores of Pará in Brazil.

MAZEMAT, an industrial town of south-western France in the department of Tarn, 41 m. S.S.E. of Albi by rail. Pop. (1906), town, 11,370; commune, 14,386. Mazemat is situated on the northern slope of the Montagnes Noires and on the Arnette, a small sub-tributary of the Agout. Numerous establishments are employed in wool-spinning and in the manufacture of "swan-skins" and flannels, and clothing for troops, and hosiery, and there are important tanneries and leather-dressing, glove and dye works. Extensive commerce is carried on in wool and raw hides from Argentina, Australia and Cape Colony.

MAZANDARAN, a province of northern Persia, lying between the Caspian Sea and the Elburz range, and bounded E. and W. by the provinces of Turkmenia and Zanjan, N. and S. by the Caspian Sea, 220 m. in length and 60 m. in (mean) breadth, with an area 27,000 sq. m. and a population estimated at from 150,000 to 200,000. Mazandaran comprises two distinct natural regions presenting the sharpest contrasts in their relief, climate and produce. In the north the Caspian is encircled by the level and swampy lowlands, varying in breadth from 10 to 30 m., partly under impermeable jungle, partly under rice, cotton, sugar and other crops. This section is fringed northwards by the sandy beach of the Caspian, here almost destitute of natural harbours, and rises somewhat abruptly inland to the second section, comprising the northern slopes and spurs of the Elburz, which approach at points within 1 or 2 m. of the sea, and are almost everywhere covered with dense forest. The lowlands, rising but a few feet above the Caspian, and subject to frequent floods, are extremely marshy, while the highlands, culminating with the magnificent Demavend (19,400 ft.), enjoy a tolerably healthy climate. But the climate, generally hot and moist in summer, is everywhere capricious and liable to sudden changes of temperature, whence the prevalence of rheumatism, dropsy and especially ophthalmia, noticed by all travellers. Snow falls heavily in the uplands, where it often lies deep, even in summer. The direction of the long sandbanks at the river mouths, which project with remarkable uniformity from west to east, shows that the prevailing winds blow from the west and north-west. The rivers themselves, of which there are as many as fifty, are little more than mountain torrents, all rising on the northern slopes of Elburz, flowing mostly in independent channels to the Caspian, and subject to sudden freshets and inundations along their lower course. The chief are the Sardab-rud, Chalus, Herbaz (Lar in its upper course), Babul, Tejen and Nika, and all are well stocked with trout, salmon (saud-mak), perch (safid-mak), carp (kapur), bream (subula), sturgeon (sae-quih or saue-qi), and other fish, which with rice form the staple food of the inhabitants; the sturgeon supplies the caviare for the Russian market. Near their mouths the rivers, running counter to the prevailing winds and waves of the Caspian, form long sand-hills 20 to 30 ft. high and about 200 yds. broad, behind which are developed the so-called murd-b, or "dead waters," stagnant pools and swamps characteristic of this coast, and a main cause of its unhealthiness.

The chief produce is rice, cotton, sugar, a little silk, and fruits in great variety, including several kinds of the orange, lemon and citron. Some of the slopes are covered with extensive thickets of the pomegranate, and the wild vine climbs to a great height round the trunks of the forest trees. These woodlands
MAZARIN

are haunted by the tiger, panther, bear, wolf and boar in considerable numbers. Of the domestic animals, all remarkable for their small size, the chief are the black, humped cattle somewhat resembling the Indian variety, and sheep and goats.

Kinneir, Fraser and other observers speak unfavourably of the Mazandaran people, whom they describe as very ignorant and bigoted little savages, highly inquisitive and intolerant towards strangers. The peasantry, however, are far from dull, and betray much shrewdness where their interests are concerned. In the healthy districts they are stout and well made, and are excellent horsemen and a warlike race, furnishing some cavalry (500 men) and eight battalions of infantry (5600 men) to government. They speak a marked Persian dialect, but a TURKISH idiom closely akin to the Turkoman is current, one by Firuz Kuh, 186 m. long, the other by Bandjaz, 144 m. long, both in tolerably good repair. Except where crossed by these routes the airburz forms an almost impassable barrier to the settled tribes.

The administration is in the hands of a governor, the sub-governors of the nine districts of Amol, Barbarfush, Meshed-i-Sar, Sarí, Ashref, Farah-abad, Tunakabun, Kelarustak and Kujur into which the province is divided. There is fair security for life and property; and, although otherwise indifferently administered, the country is quite free from marauders; but local disturbances have latterly been frequent in the two last-named districts. The revenue is about £50,000, of which little goes to the state treasury, most being required for the governors, troops and pensions. The capital is Sarí, the other chief towns being Barbarfush, Meshed-i-Sar, Ashref and Farah-abad.

MAZARIN, JULES (1602-1661). French cardinal and statesman, elder son of a Sicilian, Pietro Mazarini, the intendant of the household of Philip Colonna, and of his wife Ortenzia Buffalini, a connexion of the Colonnas, was born at Piscina in the Abruzzi on the 14th of July 1602. He was educated by the Jesuits at Rome till his seventeenth year, when he accompanied Jerome Colonna as chancellor to the university of Alcalá in Spain. There he distinguished himself more by his love of gambling and his gallant adventures than by study, but made himself a thorough master, not only of the Spanish language and character, but also of that romantic fashion of Spanish living which, in order to help him to suppress the fact that he had never become the servant of a Spanish queen. On his return to Rome, about 1622, he took his degree as Doctor utriorique juris, and then became captain of infantry in the regiment of Colonna, which took part in the war in the Valetline. During this war he gave proofs of diplomatic ability, and Pope Urban VIII. entrusted him, in 1629, with the difficult task of putting an end to the war of the Mantuan succession. His success marked him out for further distinction. He was presented to two canonries in the churches of St John Lateran and St Maria Maggiore, and was consecrated priest; he negotiated the treaty of Turin between France and Savoy in 1632, became vice-legate at Avignon in 1634, and nuncio at the court of France from 1634 to 1636. But he began to wish for a wider sphere than papal negotiations, and, seeing that he had no chance of becoming a cardinal except by the aid of some great power, he accepted Richelieu's offer of entering the service of the king of France, and in 1639 became a naturalized Frenchman.

In 1640 Richelieu sent him to Savoy, where the regency of Christine, one of his favorites, was to be established and the latter taken under the orders of the king. He had never been consecrated priest; he negotiated the treaty of Turin between France and Savoy in 1632, became vice-legate at Avignon in 1634, and nuncio at the court of France from 1634 to 1636. But he began to wish for a wider sphere than papal negotiations, and, seeing that he had no chance of becoming a cardinal except by the aid of some great power, he accepted Richelieu's offer of entering the service of the king of France, and in 1639 became a naturalized Frenchman.

on the presentation of the king of France in December 1641. On the 4th of December 1642 Cardinal Richelieu died, and on the very next day the king sent a circular letter to all officials ordering them to send in their reports to Cardinal Mazarin, as they had formerly done to Cardinal Richelieu. Mazarin was thus acknowledged supreme minister, but he still had a difficult part to play. The king would not be content with his cousin, and to preserve power he must make himself necessary to the queen, who would in 1643, as regent, and do this without arousing the suspicions of the king or the distrust of the queen. His measures were ably taken, and when the king died, on the 14th of May 1643, to everyone's surprise her husband's minister remained the queen's. The king had by a royal edict cumbered the queen-regent with a council and other restrictions, and it was necessary to get the parlement of Paris to overrule the edict and make the queen absolute regent, which was done with the greatest complaisance. Now that the queen was all-powerful, it was expected she would at once dismiss Mazarin and summon her own friends to power. One of them, Potier, bishop of Beauvais, already gave himself airs as prime minister, but Mazarin had had the address to touch both the queen's heart by his Spanish gallantry and her desire for his son's glory by his skillful policy abroad, and he found himself able easily to overthrow the clique of Importantis, as they were called. That skilful policy was shown in every arena on which the great Thirty Years' War was being fought out. Mazarin had inherited the policy of France during the Thirty Years' War from Richelieu. He had inherited his dislike for the enrichment of the house of Austria, and in both of its branches, his desire to push the French frontier to the Rhine and maintain a counterpoise of German states against Austria, his alliances with the Netherlands and with Sweden, and his four theatres of war—on the Rhine, in Flanders, in Italy and in Catalonia.

During the last five years of the great war it was Mazarin alone who directed the French diplomacy of the period. He it was who made the peace of Brunssebro between the Danes and the Swedes, and turned the latter once again against the empire; he it was who sent Lione to make the peace of Castro, and combine the princes of North Italy against the Spaniards, and who made the peace of Ulm between France and Bavaria, thus detaching the emperor's best ally. He made one fatal mistake—his dream of the French frontier being the Rhine and the Scheldt, and that a Spanish princess might bring the Spanish Netherlands as dowry to Louis XIV. This roused the jealousy of the United Provinces, and they made a separate peace with Spain in January 1658; but the value of the French generals made the skill of the Spanish diplomatists of no avail, for Turenne's victory at Zusmarshausen, in 1666, having been won in advance of the treaty of Westphalia, was to be definitely signed in October 1668. This celebrated treaty belongs rather to the history of Germany than to a life of Mazarin; but two questions have been often asked, whether Mazarin did not delay the peace as long as possible in order to more completely ruin Germany, and whether Richelieu would have made a similar peace. To the first question Mazarin's letters, published by M. Chéruel, prove a complete negative, for in them appears the zeal of Mazarin for the peace. On the second point, Richelieu's letters in many places indicate that his treatment of the great counsellors was not an unmixed success, though, but then they would not have been hampered in France itself.

At home Mazarin's policy lacked the strength of Richelieu's. The Frondes were largely due to his own fault. The arrest of Broussel threw the people on the side of the parlement. His avarice and unscrupulous plundering of the revenues of the realm, the enormous fortune which he thus amassed, his supple ways, his nepotism, and the general lack of public interest in the great foreign policy of Richelieu, made Mazarin the especial object of hatred both by bourgeois and nobles. The irritation of the latter was greatly Mazarin's own fault; he had tried consistently to play off the king's brother Gaston of Orleans against Condé, and their respective followers against each other, and had also, as his carnets prove, jealously kept any courtier from getting into the good graces of the queen-regent except by his means, so
that it was not unnatural that the nobility should hate him, while the queen found herself surrounded by his creatures alone. Events followed each other quickly; the day of the barricades was followed by the peace of Rueil, the peace of Rueil by the arrest of the princes, by the battle of Rethel, and Mazarin's exile to Brühl before that unhappy house can be regarded as lost. It had been in exile at Brühl that Mazarin saw the mistake he had made in isolating himself and the queen, and that his policy of balancing every party in the state against each other had made every party distrust him. So by his counsel the queen, while nominally in league with De Retz and the parliamentary Fronde, laboured to form a purely royal party, wearied by civil dissensions, which should act for her and her son's interest alone, under the leadership of Mathieu Molié, the famous premier president of the parlement of Paris. The new party grew in strength, and in January 1652, after exactly a year's absence, 2, 303, 000, was returned to the court. Turenne had now become the royal general, and out-manoeuvred Condé, while the royal party at last grew to such strength in Paris that Condé had to leave the capital and France. In order to promote a reconciliation with the parlement of Paris Mazarin had again retired from court, this time to Sedan, in August 1652, but he returned finally in February 1653. Long had been the trial, and greatly had Mazarin been to blame in allowing the Frondes to come into existence, but he had retrieved his position by founding that great royal party which steadily grew until Louis XIV. succeeded him in the L'État. As the war had progressed, Mazarin had steadily followed Richelieu's policy of weakening the nobles on their country estates. Whenever he had an opportunity he destroyed a feudal castle, and by destroying the towers which commanded nearly every town in France, he freed such towns as Bourges, for instance, from their long practical subjection to the neighbouring great lord. The Fronde over, Mazarin had to build up afresh the power of France at home and abroad. It is to his shame that he did so little to further by encouraging the brick-and-mortar remains of feudalism, he did nothing for the people. But abroad his policy was everywhere successful, and opened the way for the policy of Louis XIV. He at first, by means of an alliance with Cromwell, recovered the north-western cities of France, though at the price of yielding Dunkirk to the Protector. On the Baltic, France guaranteed the Treaty of Oliva between her old allies Sweden, Poland and Brandenburg, which preserved her influence in that quarter. In Germany he, through Hugues de Lione, formed the league of the Rhine, by which the states along the Rhine renounced their alliances under the headship of France to be on their guard against the influence of the power of the Middle Rhine. By such means as these, war was induced to sue for peace, which was finally signed in the Isle of Pheasants on the Bidasso, and is known as the Treaty of the Pyrenees. By it Spain recovered Franche Comté, but ceded to France Roussillon, and much of French Flanders; and, what was of greater ultimate importance to Europe, Louis XIV. was to marry a Spanish princess, who was to renounce her claims to the Spanish succession if her dowry was paid, which Mazarin knew could not happen at present from the emptiness of the Spanish exchequer. He returned to Paris in declining health, and did not live to see the making of the Peace of the Pyrenees; after some political instruction to his young master he proceeded away at Vincennes on the 9th of March 1661, leaving a fortune estimated at from 18 to 40 million livres behind him, and his nieces married into the greatest families of France and Italy. 

The man who could have had such success, who could have made the Treaties of Westphalia and the Pyrenees, who could have weathered the storms of the Fronde and kept France at peace with itself and with Europe to Louis XIV., must have been a man of no mean powers and historians, relying too much on the brilliant memoirs of his adversaries, who are apt to rank him too low. That he had many a petty fault there can be no doubt; that he was avaricious and double-dealing was also undoubted; and his carnet show to what unworthy means he had recourse to maintain his influence, but none of this will be always debated, but both his carnet and the Brühl letters show the very real personal affection, amounting to passion on the queen's part, existed. Whether they were ever married may be doubted; but that hypo-

thesis is made more possible by M. Chéruel's having been able to prove in his book on Mazarin that the queen herself had never taken more than the minor orders, which could always be thrown off. With regard to France he played a more patriotic part than Condé or Turenne, for he never treated with the Spaniards, and his letter to the king that in his desire to enter into league with the English, he had the thoughts of his country in his heart. It is that immense mass of letters that prove the real greatness of the statesman, and disprove De Retz's portrait, which is carefully arranged to prove that his mind was of the same dimensions as his body. To concede that the master was the greater man and the greater statesman does not imply that Mazarin was but a foil to his predecessor. It is true that he could none of his schemes be carried out, of which the best was the plan of peace with the Turks, France which shine through Richelieu’s policy. Mazarin was not a Frenchman, but a citizen of the world, and always paid most attention to foreign affairs; in his letters all that could teach a diplomatist could be found. He had carefully elaborated, keen insight into men’s characters, cunning directions when to dissimulate or when to be frank. Italian though he was by birth, education and nature, France owed him a great debt for his skilful management during the early years of Louis XIV., and the king owed him yet more, for he had not only transmitted to him a nation at peace, but had educated for him his great servants and sons. In fact, it is to be feared that not only did he throw his famous library open to them, but he pensioned all their leaders, including Descartes, Vincent Voiture (1596–1665), Jean Louis Guez de Balzac (1597–1654) and Pierre Coste (1637-1700). The last-named was a savant, with whom he was on friendly terms, in the dedication of his Pompée, the line of Virgil: “Tu regere imperio populos, Romane, memento.”

AUTHORITIES.—All the earlier works on Mazarin, Louis XIV., his accounts of his administration, of which the best were Bazin’s Histoire de France sous Louis XIV., et sous le Cardinal Mazarin, 4 vols. (1866–1877), see also Chéruel’s Histoire de France pendant la minorité de Louis XIV., 4 vols. (1879–1880), which covers from 1643–1651, and its sequel Histoire de France sous le ministère de Cardinal Mazarin, 2 vols. (1881–1882), which is the first account of the period written by one able to sift the statements of De Retz and the memoir writers, and rest upon such documents as Mazarin’s letters and carnet. Mazarin’s Lettres, which must be carefully studied by any student of general views of policy, and the details in the Collection des documents inédits, 9 vols. For his carnet reference must be made to V. Cousin’s articles in the Journal des Scœurs; and Chéruel in Revue historique (1877), see also Chéruel’s Histoire de France pendant la minorité, &c., vol. 7 (1879), to which reference is made for his early life to Cousin’s Juvente de Mazarin (1865), and for the careers of his nieces to Renée’s Les Nieces de Mazarin (1856). For the Mazarin and later is to be written, see also A. Hackel, Mazarin (1903).

MAZAR-I-SHARIF, a town of Afghanistan, the capital of the province of Ghur. A town situated on the Lashkar Gah, it has long been the centre of the Afghan army north of the Hindu Kush mountains, the fortified cantonment of Dehshadi having been completed by Sirdar Ghulam Ali Khan and incorporated with Mazar. Mazar-i-Sharif also contains a celebrated mosque, from which the town takes its name. It is a large ornate building with minarets and a lofty cupola faced with shining blue tiles. It was built by Sultan Ali Mirza about A.D. 1420, and is held in great veneration by all Musalmans, and especially by Shiites, because it is supposed to be the tomb of Ali, the son-in-law of Mahomet.

MAZARRÓN, a town of eastern Spain, in the province of Murcia, 79 m. W. of Cartagena. Pop. (1900), 23,824. There are soap and flour mills and metallurgical factories in the town, and iron, copper and lead mines in the neighbouring Sierra de Alme- nara. A railway 5 m. long unites Mazarro to its port on the Mediterranean, where there is a suburb with 2,500 inhabitants (mostly engaged in the manufacture of wooden barks, a custom-house, and important leadworks. Outside of the suburb there are salt pans, most of the proceeds of which are exported to Galicia.

MAZATLÁN, a city and port of the state of Sinaloa, Mexico, 120 m. (direct) W.S.W. of the city of Durango, in lat. 23° 12' N., long. 106° 24' W. Pop. (1895), 15,852; (1900), 17,852. It is
MAZE—MAZZINI

the Pacific coast terminus of the International railway which crosses northern Mexico from Ciudad Porfírio Díaz, and a port of call for the principal steamship lines on this coast. The harbour is spacious, but the entrance is obstructed by a bar. The city is built on a small peninsula. Its public buildings include a fine town-hall, chamber of commerce, a custom-house and two hospitals, besides which there is a nautical school and a meteorological station, one of the first established in Mexico. The harbour is provided with a sea-wall at Olas Altas. A government wireless telegraph service is maintained between Mazatlán and La Paz, Lower California. Among the manufactures are saw-mills, foundries, cotton factories and ropeworks, and the exports are chiefly hides, ixtle, dried and salted fish, gold, silver and copper (bars and ores), fruit, rubber, tortoise-shell, and gums and resins.

MAZE, a network of winding paths, a labyrinth (q.v.). The word means properly a state of confusion or wonder and is probably of Scandinavian origin; cf. Norw. mas, exhausting labour, also chatter, masa, to be busy, also to worry, annoy; Swed. masa, to lounge, move slowly and lazily, to dream, muse. Skæt (Etym. Dict.) takes the original sense to be probably "to be lost in thought," "to dream," and connects with the root ma-man-, to think, cf. "mind," "man," &c. The word "maze" represents the addition of an inflexional suffix.

MAZEPA-KOLEDINSKY, IVAN STEPANOVICH (1647–1709), hetman of the Cossacks, belonging to a noble Orthodox family, was born possibly at Mazepistina, either in 1629 or 1644, the exact year of his birth being probably erroneous. He was the natural son of the Polish king, John Casimir, and completed his studies abroad. An intrigue with a Polish married lady forced him to fly into the Ukraine. There is a trustworthy tradition that the infuriated husband tied the naked youth to the back of a wild horse and sent him forth into the steppe. He was rescued and cared for by the Dnieperian Cossacks, and specifically became one of their ablest leaders. In 1687, during a visit to Moscow, he won the favour of the then all-powerful Vasily Golitsin, from whom he virtually purchased the hetmanship of the Cossacks (July 23). He took a very active part in the Azov campaigns of Peter the Great and won the entire confidence of the young tsar by his zeal and energy. He was also very serviceable to Peter at the beginning of the Great Northern War, especially in 1705 and 1706, when he took part in the Volhynian campaign and helped to construct the fortress of Pechersk. The power and influence of Mazepa were fully recognized by Peter the Great. No other Cossack hetman had ever been treated with such deference at Moscow. He ranked with the highest dignitaries in the state; he sat at the tsar's own table. He had been made one of the first cossacks to have a regimental patch, which was given to him by Peter the Great. Augustus of Poland had bestowed upon him, at Peter's earnest solicitation, the universally coveted order of the White Eagle. Mazepa had no temptations to be anything but loyal, and loyal he would doubtless have remained had not Charles XII. crossed the Russian frontier. Then it was that Mazepa, who had had doubts of the issue of the struggle all along, made up his mind that Charles, not Peter, was going to win, and that it was high time he looked after his own interests. Besides, he had his personal grievances against the tsar. He did not like the new ways Peter had interfered with his old ones. He was very jealous of the favourite (Menshikov), whom he suspected of a design to supplant him. But he proceeded very cautiously. Indeed, he would have preferred to remain neutral, but he was not strong enough to stand alone. The crisis came when Peter ordered him to co-operate actively with the Russian forces in the Ukraine. At this very time he was in communication with Charles's first minister, Count Piper, and had agreed to harbour the Swedes in the Ukraine and close it against the Russians (Oct. 1708). The last doubt disappeared when Menshikov was sent to supervise Mazepa. At the approach of his rival the old hetman hastened to the Swedish outposts at Horki, in Severia. Mazepa's treason took Peter completely by surprise. He instantly commanded Menshikov to get a new hetman elected and raze Baturin, Mazepa's chief stronghold in the Ukraine, to the ground. When Charles, a week later, passed Baturin by, all that remained of the Cossack capital was a heap of smouldering mills and ruined houses. The total destruction of Baturin, almost in sight of the Swedes, overawed the bulk of the Cossacks into obedience, and Mazepa's ancient prestige was ruined in a day when the metropolitan of Kiev solemnly communicated him from the high altar, and his coffin, after being dragged with contumely through the mud at Kiev, was publicly burnt by the common hangman. Henceforth Mazepa, perfere, attached himself to Charles. What part he took at the battle of Pultava is not quite clear. After the catastrophe he accompanied Charles to Turkey with some 1500 horsemen (the miserable remnant of his 80,000 warriors). The sultan refused to surrender him to the tsar, though Peter offered 300,000 ducats for his head. He died at Bender on the 22nd of August 1709.

See N. I. Kostomarov, Mazepa and the Mazepanias (Russ.) (St Petersburg), 1885; R. Niobet Bain, The First Romanoffs (London, 1905); S. M. Solovev, History of Russia, vol xv. (St Petersburg, 1895).

MAZER, the name of a special type of drinking vessel, properly made of maple-wood, and so-called from the spotted or "birds-eye" marking on the wood (Ger. Masur, spot, marking, especially on wood; cf. "measles"). These drinking vessels are shallow bowls without handles, with a broad flat foot and a knob or boss in the centre of the inside, known technically as the "foot." They were made from the 13th to the 16th centuries, as are the numerous wooden cups in use, and were ornamented with a rim bordered with containing generally of silver or silver gilt; the foot and the "foot" being also of metal. The depth of the mazers seems to have decreased in course of time, those of the 16th century that survive being much shallower than the earlier examples. There are examples with wooden covers with a metal handle, such as the Flemish and German mazers in the Franks Bequest in the British Museum. On the metal rim is usually an inscription, religious or bacchanalian, and the "foot" was also often decorated. The later mazers sometimes had metal straps between the rim and the foot.

A very fine mazer with silver gilt ornamentation 5 in. deep and 9½ in. diameter was sold in the Braikenridge collection in 1908 for £2300. It bears the London hall-mark of 1534. This example is illustrated in the article PLATE: see also DRINKING VESSELS.

MAZURKA (Polish for a woman of the province of Mazovia), a lively dance, originating in Poland, somewhat resembling the polka. It is danced in couples, the music being in 3/8 or 2 time.

MAZZARA DEL VALLO, a town of Sicily, in the province of Trapani, on the south-west coast of the island, 32 m. by rail S. of Trapani. Pop. (1901), 20,130. It is the seat of a bishop; the cathedral, established in 1066, was rebuilt in 1727 by Augustus. The castle, at the south-eastern angle of the town walls, was erected in 1723. The mouth of the river, which bears the same name, serves as a port for small ships only. Mazara was in origin a colony of Selinus: it was destroyed in 409, but it is mentioned again as a Carthaginian fortress in the First Punic War and as a post station on the Roman coast road, though whether it had municipal rights is doubtful.1 A few inscriptions of the imperial period exist, but no other remains of importance. On the west bank of the river are grooves cut in the rock, of uncertain date: and there are terraces in the neighbourhood resembling those of Syracuse, but on a smaller scale.

See A. Castiglione, Sulle case antiche della città di Mazara (Alcamo, 1878).

MAZZINI, GIUSEPPE (1805–1872), Italian patriot, was born on the 22nd of June 1805 at Genoa, where his father, Giacomo Mazzini, was a physician in good practice, and a professor in the university. His mother is described as having been a woman of great personal beauty, as well as of active intellect and strong affections. During infancy and childhood his health was extremely delicate; and it appears that he was nearly six years of age before he was quite able to walk; but he had already begun to devour books of all kinds and to show other signs of great intellectual precocity. He studied Latin with his first tutor, 1 Th. Mommsen in Corpus inscr. lat. (Berlin, 1883), x. 739.
The natural bent of his genius was towards literature, and in the course of the four years of his nominal connexion with the legal profession, he wrote a considerable number of essays and reviews, some of which have been wholly or partially reproduced in the critical and literary volumes of his Life and Writings. His first essay, characteristically enough on “Dante’s Love of Country,” was sent to the editor of the Anmologia fiorentina in 1826, but did not appear until some years afterwards in the Subalpina, where it made a considerable point in the Italian world. It was at this point in an attempt to follow the career of the mysterious and terrible conspirator who for twenty years out of the thirty third led a life of voluntary imprisonment (as he himself tells us) “within the four walls of a room,” and kept no record of dates, made no biographical notes, and preserved no copies of letters.” In 1833, however, he is known to have been concerned in an abortive revolutionary movement which took place in the Sardinian army; several executions took place, and he himself was laid under sentence of death. Before the close of the same year a similar movement in Genoa had been planned, but failed through the youth and inexperience of the leaders. At Geneva, also in 1833, Mazzini set on foot L’Europe Centrale, a journal of which one of the main objects was the emancipation of Savoy; but he did not confine himself to a merely literary agitation for this end. Chiefly through his agency a considerable body of German, Polish and Italian exiles was organized, and an armed invasion of the duchy planned. The frontier was actually crossed on the 1st of February 1834, but the attack ignominiously broke down without a shot having been fired. Mazzini, who personally accompanied the expedition, is no doubt correct in attributing the failure to dissensions with the Carbonari leaders in Paris, and to want of a cordial understanding between himself and the Savoyard Ramorino, who had been chosen as military leader.

In April 1834 the “Young Europe” association “of men believing in a future of liberty, equality and fraternity for all mankind, and desirous of consecrating their thoughts and actions to the realization of that future” was formed also under the influence of Mazzini’s enthusiasm; it was followed soon afterwards by a “Young Switzerland” society, having for its leading idea the formation of an Alpine confederation, to include Switzerland, Tyrol, Savoy and the rest of the Alpine chain as well. But La Jeune Suisse newspaper was compelled to stop within a year, and in other respects the affairs of the struggling patriotic society became embarrassed. He was permitted to remain at Grenchen in Solothurn for a while, but at last the Swiss diet, yielding to strong and persistent pressure from abroad, exiled him about the end of 1836. In January 1837 he arrived in London, where for many months he had to carry on a hard fight with poverty and the sense of spiritual loneliness, so touchingly described by himself in the first volume of the Life and Writings. Ultimately, as his stated command of the English language, he began to earn a livelihood by writing review articles, some of which have since been reprinted, and are of a high order of literary merit; they include papers on “Italian Literature since 1830” and “Paolo Sarpi” in the Westminster Review, articles on “Lamennais,” “George Sand,” “Byron and Goethe” in the Monthly Chronicle, and on “Lamartine,” “Carlyle,” and “The Minor Works of Dante” in the British and Foreign Review. In 1839 he entered into relations with the revolutionary committees sitting in Malta and Paris, and in 1840 he originated a working
Mazzini

men's association, and the weekly journal entitled Apostolato Popolare, in which the admirable popular treatise "On the Duties of Man" was commenced. Among the patriotic and philanthropic labours undertaken by Mazzini during this period of retirement in London may be mentioned a free evening school conducted by himself and a few others for some years, at which several hundreds of Italian children received at least the rudiments of secular and religious education. He also exposed and combated the infamous traffic carried on in southern Italy, where scoundrels bought small boys from poverty-stricken parents and carried them off to England and elsewhere to grind organs and suffer martyrdom at the hands of cruel taskmasters. The more Mazzini's influence increased, the more pious was his action; and the revolution, which was perhaps that which arose out of the conduct of Sir James Graham, the home secretary, in systematically, for some months, opening Mazzini's letters as they passed through the British post office, and communicating their contents to the Neapolitan government—a proceeding which was believed at the time to have led to the arrest and execution of the brothers Bandiera, Austrian subjects, who had been planning an expedition against Naples, although the recent publication of Sir James Graham's life seems to exonerate him from the charge. The prolonged discussion of the matter, and Mazzini's correspondence, along with the revolution-appointed to inquire into the matter, did not, however, lead to any practical result, unless indeed the incidental vindication of Mazzini's character, which had been recklessly assailed in the course of debate. In this connexion Thomas Carlyle wrote to The Times: "I have had the honour to know Mr Mazzini for a series of years, and, whatever I may think of his practical insight and skill in worldly affairs, I can with great freedom testify that he, if I have ever seen one such, is a man of genius and virtue, one of those rare men, numerable unfortunately but as units in this world, who are worthy to be called martyr souls; who, in silence, piously in their daily life, practise what is meant by that." Mazzini did not share the enthusiastic hopes everywhere raised in the ranks of the Liberal party throughout Europe by the first acts of Pius IX., in 1846, but at the same time he availed himself, towards the end of 1847, of the opportunity to publish a letter addressed to the new pope, indicating the nature of the religious and national mission which the Liberals expected him to undertake. The leaders of the revolutionary outbreaks in Milan and Messina in the beginning of 1848 had long been in secret correspondence with Mazzini, and at the time of his arrival in Paris, brought him early in the same year to Italy, where he took a great and active interest in the events which dragged Charles Albert into an unprofitable war with Austria; he actually for a short time bore arms under Garibaldi immediately before the reoccupation of Milan, but ultimately, after vain attempts to maintain the insurrection in the mountain districts, found it necessary to retire to Lugano. In the beginning of the following year he was nominated a member of the short-lived provisional government of Tuscany formed after the flight of the grand-duke, and almost simultaneously, when Rome had, in consequence of the withdrawal of Pius IX., been proclaimed a republic, he was declared a member of the constituent assembly there. A month afterwards, the battle of Novara having again decided against Charles Albert in the brief struggle with Austria, into which he had once more been drawn, Mazzini was appointed a member of the Roman triumvirate, with supreme executive power (March 23, 1849). The opportunity he now had for showing the administrative and political ability which he was believed to possess was more apparent than real, for the approach of the profoundly friendly French troops soon led to hostilities, and resulted in a siege which terminated, towards the end of June, with the assembly's resolution to discontinue the defence, and Mazzini's ignominious resignation. That he succeeded, however, for so long a time, and in circumstances so adverse, in maintaining a high degree of order within the turbulent city is a fact that speaks for itself. His diplomacy, backed as it was by no adequate physical force, naturally showed at the time to very great disadvantage, but his official correspondence and proclamations can still be read with admiration and intellectual pleasure, as well as his eloquent vindication of the revolution in his published "Letter to MM. de Tocqueville and de Falloux." The surrender of the city on the 30th of June was followed by Mazzini's not too precipitate flight by way of Marseilles into Switzerland, whence he once more found his way to London. Here in 1850 he became president of the National Italian Committee, and at the same time entered into close relations with Ledru-Rollin and Kossuth. He had a firm belief in the value of revolutionary attempts, however hopeless they might seem; he had a hand in the abortive rising at Mantua in 1852, and again, in February 1853, a considerable share in the ill-planned insurrection at Milan on the 6th of February. In his efforts to rouse the enthusiasm of the nation there was at once a certain shrewdness; and in 1854, he had gone far with preparations for renewed action when his plans were completely disconcerted by the withdrawal of professional supporters, and by the action of the French and English governments in sending ships of war to Naples. The year 1857 found him yet once more in Italy, where, for complicity in short-lived émeutes which took place at Genoa, Leghorn and Naples, he was again laid under sentence of death. Undiscouraged in the pursuit of the one great aim of his life by any such compulsion, he returned to England, and in August 1857, edited his new journal Pensiero e Azione, in which the constant burden of his message to the overcautious practical politicians of Italy was: "I am but a voice crying Action; but the state of Italy cries for it also. So do the best men and people of her cities. Do you wish to destroy my influence? Act!" The same tone was at a somewhat later date assumed in the letter he wrote to Victor Emmanuel, urging him to put himself at the head of the movement for Italian unity, and promising republican support. As regards the events of 1859-1860, however, it may be questioned whether, through his characteristic inability to distinguish between the ideally perfect and the practically possible, he did not actually hinder more than he helped the course of events by which the realization of so much of the great dream of his life was at last brought about. If Mazzini was the prophet of Italian unity, and Garibaldi its knight errant, to Cavour alone belongs the honour of having been the statesman by whom it was finally accomplished. After the irresistible pressure of the popular movement had led to the establishment not of an Italian republic but of an Italian kingdom, Mazzini could honestly enough write, "I too have striven to realize unity under a monarchical flag," but Cavour compelled him to add, "The Italian people are astray by a delusion at the present day, a delusion which has induced them to substitute material for moral unity and their own reorganization. Not so I. I bow my head sorrowfully to the sovereignty of the national will; but monarchy will never number me amongst its servants or followers." In 1865, by way of protest against the still uncalled sentence of death under which he lay, Mazzini was elected by Messina as delegate to the Italian parliament, but, feeling himself unable to take the oath of allegiance to the monarchy, he never took his seat. In the following year, when a general amnesty was granted after the cession of Venice to Italy, the sentence of death was at last removed, but he declined to accept such an "offering of oblivion and pardon for having loved Italy above all earthly things." In May 1869 he was again expelled from Switzerland at the instance of the Italian government for having conspired with Garibaldi; after a few months spent in England he set out (1870) for Sicily, but was promptly arrested at sea and carried to Gaeta, where he was imprisoned for two months. Events soon made it evident that there was little danger to fear from the contemplated rising, and the occasion of the birth of a prince was seized for restoring him to liberty. The remainder of his life, spent partly in London and partly at Lugano, presents no noteworthy incidents. For some time his health had been far from satisfactory, but the immediate cause of his death was an attack of pleurisy with which he was seized at Pisa, and which terminated fatally on the 10th of March 1872. The Italian parliament by a unanimous vote expressed the national sorrow with which the tidings of his death had been received, the president pronouncing an eloquent
MAZZONI, GIACOMO—MEADE, G. G.

cology on the departed patriot as a model of disinterestedness and self-denial, and one who had dedicated his whole life ungrudgingly to the cause of his country’s freedom. A public funeral took place at Pisa on the 14th of March, and the remains were afterwards conveyed to Genoa.

To the memory of Giacomo Mazzoni, mostly occasional, are very voluminous. An edition was begun by himself and continued by A. Saffi, Scritti editi e inediti di Giuseppe Mazzoni, in 18 vols. (Milan and Rome, 1861–1891) and published in two parts. The two most important are: The Political and Literary Writings of Joseph Mazzoni (1864–1870) and the two most systematic—Thoughts upon Democracy in Europe, a remarkable series of criticisms on Benthamism, St. Simonism, the Italian constitution and socialism, the day of the day, and the treatise On the Duties of Man, an admirable primer of ethics, dedicated to the Italian working-class—will be found in Joseph Mazzoni: a Memoir, by Mrs E. A. Venturi (1876), published in the Forbitten Review for February 1876. Of the 40,000 letters of Mazzoni only a small part have been published. In 1887 two hundred unpublished letters were printed at Turin (Duecento lettere inediti di Giuseppe Mazzoni, 1887), and for the first time Mazzoni’s correspondece between Mazzoni and Luigi A. Melegari during the early days of “Young Italy.” For the literary side of Mazzoni’s life see Peretti, Gli scritti letterari di Giuseppe Mazzoni (Turin, 1905).

Mazziò, Giacomo (1548–1598), Italian physician, was born at Cesena and died at Ferrara. A member of a noble family and highly educated, he was born to one of the most eminent savants of the period. He occupied chairs in the universities of Pisa and Rome, was one of the founders of the Della Crusca Academy, and had the distinction, it is said, of thrice vanquishing the Admirable Crichton in dialectic. His chief work in philosophy was an attempt to reconcile Plato and Aristotle, and in this spirit he published in 1597 a treatise In universum Platonis et Aristotelis philosophiam praeccludit. He wrote also De triplici hominum vita, wherein he outlined a theory of the infinite perfection and development of nature. Apart from philosophy, he was prominent in literature as the champion of Dante, and produced two works in the poet’s defence: Discorso composto in difesa della comedia di Dante (1572), and Della difesa della comedia di Dante (1587, reprinted 1888). He was an authority on ancient languages and philology, and gave a great impetus to the study of Dante and the Italian language. His principal works in poetry, were born at Florence, and educated at Pisa and Bologna. In 1887 he became professor of Italian at Padua, and in 1894 at Florence. He was much influenced by Carducci, and became prominent both as a prolific and well-read critic and as a poet of individual distinction. His chief volumes of verse are Versi (1880), Nuove poesie (1886), Poesie (1891), Voci della vita (1893).

Mead, Larkin Goldsmith (1835–1906), American sculptor, was born at Chesterfield, New Hampshire, on the 3rd of January 1835. He was a pupil (1853–1855) of Henry Kirke Brown. During the early part of the Civil War he was at the front for six months, with the army of the Potomac, as an artist for Harper’s Weekly; and in 1862–1865 he was in Italy, being attached at the time to the United States consulate at Venice, while William D. Howells, his brother-in-law, was consul. He returned to America in 1865, but subsequently went back to Italy and lived at Florence. His first important work was a statue of Ethan Allen, now at the State House, Montpelier, Vermont. His principal works are: the monument to President Lincoln, Springfield, Illinois; “Ethan Allen” (1870), National Hall of Statuary, Capitol, Washington; an heroic marble statue, “The Father of Waters,” New Orleans; and “Triumph of Ceres,” made for the Columbian Exposition, Chicago.

His brother, William Rutherford Mead (1846–1910), graduated at Amherst College in 1867, and studied architecture in New York under Russell Sturgis, and also abroad. In 1879 he and J. F. McKim, with whom he had been in partnership for two years as architects, were joined by Stanford White, and formed the well-known firm of McKim, Mead & White.

Mead, Richard (1873–1935), English physician, eleventh child of Matthew Mead (1830–1899), Independent divine, was born on the 11th of August 1873 at Stepney, London. He studied at Utrecht for three years under J. C. Graevius, having decided to follow the path of medicine, and was later in Leiden and attended the lectures of Paul Hermann and Archibald Pitcairn. In 1895 he graduated in philosophy and physic at Padua, and in 1896 he returned to London, entering at once on a successful practice. His Mechanical Account of Poisons appeared in 1702, and in 1703 he was admitted to the Royal Society, to whoseTransactions he contributed in that year a paper on the parasitic nature of scabies. In the same year he was elected physician to St Thomas’ Hospital, and appointed to read anatomical lectures at the Surgeons’ Hall. On the death of his father-in-law in 1706 he retired from his practice to devote his life to his profession; he attended Queen Anne on her deathbed, and in 1717 was appointed physician to George II., having previously served him in that capacity when he was prince of Wales. He died in London on the 16th of February 1754.

Besides the Mechanical Account of Poisons (2nd ed., 1708), Mead published a treatise De imperio solis et lunae in corpora hominum et morbi inde orundis (1704). A Short Discourse concerning Presumptual Coniagation, and the Method to be used to prevent it (1720), De variolis et morbilis dissertatio (1747), Medica sacra, sive de morbis insignioribus qui in hiblis memoraturant commentarius (1748). On the Scoury (1751) and Morbus et Monstra (1751). A Life of Mead by Dr. Matthew Meany appeared in 1755.

Mead. (1) A word now only used more or less poetically for the commoner form “meadow,” properly land laid down for grass and cut for hay, but often extended in meaning to include pasture-land. “Meadow” represents the oblique case, medwe, of O. Eng. mede, which comes from the root seen in “mow”; the word, therefore, means “mowed land.” Cognate words appear in other Teutonic languages, a familiar instance being Ger. maute, seen in place-names such as Zematt, Andermatt, &c. (See GRASS.) (2) The name of a drink made by the fermentation of honey mixed with water. Alcoholic drinks made from honey were common in ancient times, and during the middle ages throughout Europe. The Greeks and Romans knew of such under the names of ἰδρύμα and ὑδρομέλαι; mulsum was a form of meal with the addition of wine. The word is common to Teutonic languages (cf. Du. mede, Ger. Meß or Meßa), and is cognate with Gr. μέθυ, wine, and Sansk. mādhu, sweet drink. "Methegin," another word for mead, properly a medicated or spiced form of the drink, is an adaptation of the Welsh meddyg, which is derived from meddyg, healing (Lat. medicus) and iynys, liquor. It therefore means “spiced or medicated drink,” and is etymologically connected with “mead.”

Meade, George Gordon (1815–1872), American soldier, was born of American parentage at Cadiz, Spain, on the 31st of December 1815. On graduation at the United States Military Academy in 1835, he served in Florida with the 3rd Artillery against the Seminoles. Resigning from the army in 1836, he
became a civil engineer and constructor of railways, and was engaged under the war department in survey work. In 1842 he was appointed a second lieutenant in the corps of the topographical engineers. In the war with Mexico he was on the staffs successively of Generals Taylor, J. Worth and Robert Patterson, and was brevetted for gallantry at Monterey. Until the Civil War he was engaged in various engineering works, mainly in connexion with lighthouses, and later as a captain of topographical engineers in the survey of the northern lakes. In 1860 he was appointed brigadier-general of volunteers, and had command of the 2nd brigade of the Pennsylvania Reserves in the Army of the Potomac under General M'Call. He served in the Seven Days, receiving a severe wound at the action of Frazier's Farm. He was absent from his command until the second battle of Bull Run, after which he remained in the command of his division. He distinguished himself greatly at the battles of South Mountain and Antietam. At Fredericksburg he and his division won great distinction by their attack on the position held by Jackson's corps, and Meade was promoted major-general of volunteers, to date from the 29th of November. Soon afterwards he was placed in command of the V. corps. At Chancellorsville he displayed great intrepidity and energy, and on the eve of the battle of Gettysburg was appointed to succeed Hooker. The choice was unexpected, but Meade justified it by his conduct of the operations, and in the famous three days' battle led in person a charge against the rebel army at the battle of the Wheat Field, and the reward was the commission of brigadier-general in the regular army. In the autumn of 1863 a war of manœuvre was fought between the two commanders, on the whole favourably to the Union armies. Grant, commanding all the armies of the United States, joined the Army of the Potomac in the spring of 1864, and remained with it until the end of the war; but he continued Meade in his command, and successfully urged his appointment as major-general in the regular army (Aug. 18, 1864), eulogising him as the commander who had successfully met and disposed of the enemy and the army of the Potomac on the Confederate side. After the war Meade commanded successively the military division of the Atlantic, the department of the east, the third military district (Georgia and Alabama) and the department of the south. He died at Philadelphia on the 6th of November, 1872. The degree of LL.D. was conferred upon him by Harvard University, and his scientific attainments were recognized by the American Philosophical Society and the Philadelphia Academy of Natural Sciences. There are statues of General Meade in Philadelphia and at Gettysburg.

MEADE, WILLIAM (1789-1862), American Protestant Episcopal bishop, the son of Richard Kidder Meade (1746-1805), one of General Washington's aides during the War of Independence, was born on the 11th of November 1789, near Millwood, in that part of Frederick county which is now Clarke county, Virginia. He graduated as valedictorian in 1806 at the college of New Jersey (Princeton); studied theology under the Rev. Walter Addison of Maryland, and in Princeton; was ordained deacon in 1811 and priest in 1814; and preached both in the Stone Chapel, Millwood, and in Christ Church, Alexandria, for some time. He became assistant bishop of Virginia in 1829; was pastor of Christ Church, Norfolk, in 1834-1836; in 1841 became bishop of Virginia; and in 1842-1862 was president of the Protestant Episcopal Theological Seminary in Virginia, near Alexandria, delivering an annual course of lectures on pastoral theology. In 1819 he had acted as the agent of the American Colonization Society to purchase slaves, illegally brought into Georgia, which had become the property of that state and were sold publicly at Milledgeville. He had been prominent in the work of the Education Society, which was organized in 1818 to advance funds to needy students for the ministry of the American Episcopal Church, and in the establishment of the Theological Seminary near Alexandria, as he was afterwards in the work of the American Tract Society, and the Bible Society. He was a founder and president of the Evangelical Knowledge Society (1847), which, opposing what it considered the heterodoxy of many of the books published by the Sunday School Union, attempted to displace them by issuing works of a more evangelical type. A low Churchman, he strongly opposed Tractarianism. He was active in the case against Bishop Henry Uttick Onderdonk (1790-1858) of New York, who, because of intemperance, was forced to resign and was suspended from the ministry in 1844; in that against Bishop Benjamin Tredwell Onderdonk (1791-1861) of New York, who in 1845 was suspended from the ministry on the charge of intoxication and improper conduct; and in that against Bishop G. W. Doane of New Jersey. He fought against the threatening secession of Virginia, but acquiesced in the decision of the state and became presiding bishop of the Southern Church. He died in Richmond, Virginia, on the 14th of March 1862.

Among his publications, besides many sermons, were A Brief Review of the Episcopal Church in Virginia (1845); Wilford's, Cranmer, Jewel and the Prayer Book on the Incarnation (1850); Reasons for Loving the Episcopal Church (1852); and Old Churches, Ministers and Families of Virginia (1857); a storehouse of material on the ecclesiastical history of the state.

See The Life by John Johns (Baltimore, 1867).

MEADVILLE, a city and the county-seat of Crawford county, Pennsylvania, U.S.A., on French Creek, 36 m. S. of Erie. Pop. (1900), 10,291, of whom 912 were foreign-born and 173 were negroes; (1910 census) 12,750. It is served by the Erie, and the Pennsylva. & Lake Erie railways. Meadville is the seat of the Pennsylvania College of Music, of a commercial college, of the Meadville Theological School (1844, Unitarian), and of Allegheny College (co-educational), which was opened in 1815, came under the general patronage of the Methodist Episcopal Church in 1839, and in 1890 had 322 students (200 men and 122 women). Meadville is the commercial centre of a good agricultural region, which also abounds in oil and natural gas. The Erie Railroad has extensive shops here, which in 1903 employed 46-7% of the total number of wage-earners, and there are various manufactures. The factory product in 1905 was valued at $3,074,600, being 24-4% more than that of 1900. Meadville, the oldest settlement in N.W. Pennsylvania, was founded as a fortified post by David Mead in 1793, laid out as a town in 1795, incorporated as a borough in 1823 and chartered as a city in 1886.

MEAGHER, THOMAS FRANCIS (1823-1867), Irish nationalist and American soldier, was born in Waterford, Ireland, on the 3rd of August 1823. He graduated at Stonyhurst College, Lancashire, in 1845, and in 1844 began the study of law at Dublin. He became a member of the Young Ireland Party in 1845, and in 1847 was one of the founders of the Irish Confederation. In March 1848 he made a speech before the Confederation which led to his arrest for sedition, but at his trial the jury failed to agree and he was discharged. In the following July the Confederation created a "war directory" of five, of which Meagher was a member, and he and William Smith O'Brien travelled through Ireland for the purpose of starting a revolution. The attempt proved abortive; Meagher was arrested in August, and in October was tried for high treason before a special commission at Clonmel. He was found guilty and was condemned to death, but his sentence was commuted to life imprisonment in Van Diemen's Land, whither he was transported in the summer of 1849. Early in 1852 he escaped, and in May reached New York City. He made a tour of the cities of the United States as a popular lecturer, and then studied law and was admitted to the New York bar in 1855. He made two unsuccessful ventures in journalism, and in 1857 went to Central America, where he acquired material for another series of lectures. In 1861 he was captain of a company (which he had raised) in the 69th regiment of New York volunteers and fought at the first battle of Bull Run; he then organized an Irish brigade, of whose first regiment he was colonel until the 3rd of February 1862, when he was appointed to the command of this organization with the rank of brigadier-general. He took part in the siege of Yorktown, the battle of Fair Oaks, the seven days' battle before.
MEAL.—MEASLES

Richmond, and the battles of Antietam, Fredericksburg, where he
was wounded, and Chancellorsville, where his brigade was
reduced in numbers to less than a regiment, and General Meagher
resigned his commission. On the 23rd of December 1863 his
resignation was cancelled, and he was assigned to the command of
the military district of the Ohio River, with headquarters at Cin-
cinnati. At the close of the war he was appointed by President
Johnson secretary of Montana Territory, and there, in the
absence of the territorial governor, he acted as governor from
September 1866 until his death from accidental drowning in the
Missouri River near Fort Benton, Montana, on the 1st of July 1867.
He published "Speeches on the Legislative Independence of
Ireland (1852)."

W. F. Lyons, in Brigadier-General Thomas Francis Meagher
(New York, 1870), gives a eulogistic account of his career.

MEAL. (1) (A word common to Teutonic languages, cf. Ger.
Mahl, Du. meel; the ultimate source is the root seen in various
Teutonic words meaning "to grind," and in Eng. "milk," Lat.
mola, molère, Gr. μωλος), a powder made from the fictitious
part of any grain or pulse, with the exception of wheat, which is
known as "flour." In America the word is specifically applied
to the meal produced from Indian corn or maize, as in Scotland
and Ireland to that produced from oats, while in South Africa
the ears of the Indian corn itself are called "meales." (2)
Properly, eating and drinking at regular stated times of the day,
as breakfast, dinner, &c., hence taking of food at any time and
also the food provided. The word was in O.E. mæde, which also
had the meanings (now lost) of time, mark, measure, &c., which
still appear in many forms of the word in Teutonic languages;
thus Ger. mål, time, mark, cf. Denkmal, monument, Mahl, meal,
repast, or Du. maal, Swed. mål, also with both meanings. The
ultimate source is the pre-Teutonic root me- or ma-, to measure,
and the word thus stood for a marked-out point of time.

MEALIE, the South African name for Indian corn or maize.
The word as spelled represents the pronunciation of the Cape
Dutch millie, an adaptation of millo (da Indo), the millet of
India, the Portuguese name for millet, used in South Africa for
maize.

MEAN, an homonymous word, the chief uses of which may be
divided thus. (1) A verb with two principal applications, to
intend, purpose or design, and to signify. This word is in O.E.
maenan, and cognate forms appear in other Teutonic languages,
cf. Du. meenen, Ger. meinen. The ultimate origin is usually
taken to be the root men- or men, to think, the root of "mind." (2) An
adjective and substantive meaning "that which is in the middle." This
is derived through the O. Fr. men, meien or maeter, modern
moyen, from the late Lat. adjective medio, from medius, middle.
The law French form moyen is still preserved in certain legal
phrases (see Meene). The adjective "mean" is chiefly used in the sense of "average," as in mean temperature, mean
birth or death rate, &c.

"Mean" as a substantive has the following principal applica-
tions; it is used of that quality, course of action, condition, state,
&c., which is equally distant from two extremes, as in such phrases as the "golden (or happy) mean." For the philosophic
application see Aristotle and Ethics.

In mathematics, the term "mean," in its most general sense,
given to some function of two or more quantities which (1)
becomes equal to each of the quantities when they themselves
are made equal, and (2) is unaffected in value when the quantities
suffer any transpositions. The three commonest means are the
arithmetical, geometrical, and harmonic; of less importance are
the contraharmonical, arithmetico-geometrical, and quadratic.

From the sense of that which stands between two things,
"mean," or that which stands between "means," often with a singular construction, takes the further significance of agency, instrument, &c., of that which produces some result, hence resources capable of 
producing a result, particularly the pecuniary or other resources
by which a person is enabled to live, and so used either of employ-
ment or of property, wealth, &c. There are many adverbial
phrases, such as "by all means," "by no means," &c., which are
extensions of "means" in the sense of agency.

The word "mean" (like the French moyen) had also the sense of
muddling, moderate, and this considerably influenced the uses of "mean" (3). This, which is now chiefly used in the
sense of inferior, low, ignoble, or of avacious, penurious,
"stingy," meant originally that which is common to more
persons or things than one. The word in O. E. is gemæne, and
is represented in the modern German Gemein. It is cognate
with Lat. communis, from which "common" is derived. The
descent in meaning from that which is shared alike by
several to that which is inferior, vulgar or low, is paralleled by
the uses of "common."

In astronomy the "mean sun" is a fictitious sun which moves
uniformly in the celestial equator and has its right ascension
always equal to the sun's mean longitude. The time recorded
by the mean sun is termed mean-solar or clock time; it is regular
as distinct from the non-uniform solar or sun-dial time. The
"mean moon" is a fictitious moon which moves around the
earth with a uniform velocity and in the same time as the real
moon. The "mean longitude" of a planet is the longitude of
the "mean" planet, i.e. a fictitious planet performing uniform
revolutions in the same time as the real planet.

The arithmetical mean of n quantities is the sum of the quantities
divided by their number n. The geometrical mean of n quantities
is the nth root of their product. The harmonic mean of n quantities
is the reciprocal of the arithmetic mean of their reciprocals. The significance of the word "mean," i.e., middle, is seen by considering n instead of q quantities; these will be denoted by a, b, c. The arithmetical mean b, is obtained such that the expression for the form of
i.e. \( \frac{1}{n} \sum a_n \) will be true; the geometrical mean b places a, b, c in geometrical progression, i.e. in the proportion a:b:c or \( b^2 = ac \); and the harmonic mean places the quantities in harmonic proportion, i.e. \( \frac{1}{a} + \frac{1}{b} + \frac{1}{c} = \frac{3}{b} \). The latter is the quantity b given by the proportion \( ac = b^2 \). The arithmetico-geometrical mean of two
quantities is obtained by first forming the geometrical and arithmetical
means, then forming the means of these, and repeating
the process until the numbers become equal. They were invented
by Gauss to facilitate the computation of elliptic integrals.
The quadratic mean of n quantities is the square root of the arithmetical
mean of their squares.

MEASLES. (Morbilli, Rubela; the M. E. word is mases,
properly a diminutive of a word meaning "spot," O.H.G. mase,
cf. "mazer"; the equivalent is Ger. Masern; Fr. Rougeole), an
acute infectious disease occurring mostly in children. It is
mentioned in the writings of Rhazes and others of the Arabian
physicians in the 10th century. For long, however, it was held
to be a variety of small-pox. After the non-identity of these
two diseases had been established, measles and scarlet-fever continued
to be confounded with each other; and in the account given by
Thomson of Sydenham. The disease was first recognized in Europe
in 1670 and 1674 it is evident that even that accurate observers
were not as yet clearly perceived their pathological distinction, although
it would seem to have been made a century earlier by Giovanni
Filippo Ingrassias (1510-1580), a physician of Palermo.
The specific micro-organism responsible for measles has not been
definitely isolated.

Its progress is marked by several stages more or less sharply
defined. After the reception of the contagion into the system,
there follows a period of incubation or latency during which
the characteristic symptoms are not observable. This period
lasts for from ten to fourteen days, when it is
followed by the invasion of the symptoms specially characteristic
of measles. These consist in the somewhat sudden onset of
acute catarrh of the mucous membranes. At this stage minute
white spots in the buccal mucous membrane frequently occur;
when they do, they are diagnostic of the disease. Sneezing,
accompanied with a watery discharge, sometimes bleeding from
the nose, redness and watering of the eyes, cough of a short,
violent, and noisy character, with little or no expectation,
hoarseness of the voice, and occasionally sickness and diarrhœa,
are the chief local phenomena of this stage. With these there
is well-marked febrile disturbance, the temperature being elevated
(102°-104° F.), and the pulse rapid, while headache, thirst, and
restlessness are usually present. In some instances, these initial
symptoms are slight, and the child is allowed to associate with
MEASLES

others at a time when, as will be afterwards seen, the contagion of the disease is most active. In rare cases, especially in young children, convulsions usher in, or occur in the course of, this stage of invasion, which lasts as a rule for four or five days, the febrile symptoms, however, showing a tendency to undergo abatement after the second day. On the fourth or fifth day after the invasion, sometimes later, rarely earlier, the characteristic eruption appears on the skin, being first noticed on the brow, cheeks, chin, also behind the ears, and on the neck. It consists of small spots of a dusky red or crimson colour, just like flea-bites, slightly elevated above the surface, at first isolated, but tending to become grouped into patches of irregular, occasionally crescentic, outline, with portions of skin free from the eruption intervening. The face acquires a swollen and bloated appearance, which, taken with the catarrh of the nostrils and eyes, is almost characteristic, and renders the diagnosis at this stage a matter of no difficulty. The eruption spreads downwards over the body and limbs, which are soon thickly studded with the red spots or patches. Sometimes then become confluent over a considerable surface. The rash continues to come out for two or three days, and then begins to fade in the order in which first showed itself, namely from above downwards. By the end of about a week after its first appearance scarcely any trace of the eruption remains beyond a faint staining of the skin. Usually during convalescence slight peeling of the epidermis takes place, but much less distinctly than is the case in scarlet fever. At the commencement of the eruptive stage the fever, catarrh, and other constitutional disturbance, which were present from the beginning, become aggravated, the temperature often rising to 105° or more, and there is headache, thirst, furred tongue, and soreness of the throat, upon which red patches similar to those on the surface of the body may be observed. These symptoms usually decline as soon as the rash has attained its maximum, and often there occurs a sudden and extensive fall of temperature, indicating that the crisis of the disease has been eagerly anticipated. In favorable cases convalescence proceeds rapidly, the patient feeling perfectly well even before the rash has faded from the skin.

Measles may, however, occur in a very malignant form, in which the symptoms throughout are of urgent character, the rash but feebly developed, and of dark purple hue, while there is great prostration, accompanied with intense catarrh of the respiratory or gastro-intestinal mucous membrane. Such cases are rare, occurring mostly in circumstances of bad hygiene, both as regards the individual and his surroundings. On the other hand, cases of measles are often distinctly normal. Or there may remain as direct results of the disease chronic ophthalmia, or discharge from the ears with deafness, and occasionally a form of gangrene affecting the tissues of the mouth or cheeks and other parts of the body, leading to disfigurement and gravely endangering life.

Apart from those immediate risks there appears to be a tendency in many cases for the disease to leave behind a weakened and vulnerable condition of the general health, which may render children, previously robust, delicate and liable to chest complaints, and is in not a few instances the precursor of some of those tubercular affections to which the period of childhood and youth is liable. These various effects or sequelae of measles may be very marked, although in itself a comparatively mild ailment, although it should not be regarded with indifference, as it is doubtful whether any other disease of early life demands more careful watching as to its influence on the health. Happily many of those attending evils may by proper management be averted.

Measles is a disease of the earlier years of childhood. Like other infectious maladies, it is admittedly rare, though not unknown, in nurslings or infants under six months old. It is comparatively seldom met with in adults, but this is due to the fact that most persons have undergone an attack in early life. Where this has not been the case, the old suffer equally with the young. All races of men appear liable to this disease, provided that which constitutes the essential factor in its origin and spread exists, namely, contagion. Some countries enjoy long immunity from outbreaks of measles, but it has frequently been found in such cases that when the contagion has once been introduced the disease extends with great rapidity and virulence. This was shown by the epidemic in the Faroe Islands in 1846, where, within six months after the arrival of a single case of measles, more than three-fourths of the entire population were attacked and many perished; and the similarly produced and still more destructive outbreak in Fiji in 1873, in which it was estimated that about one-fourth of the inhabitants died from the disease in about three months. In both these cases the great mortality was due to the complications of the malady, specially induced by overcrowding, insanitary surroundings, the absence of proper nourishment and nursing for the sick, and the utter prostration and terror of the people, and to the disease being specially malignant, occurring on what might be termed virgin soil. It may be regarded as an invariable rule that the first epidemic of any disease in a community is specially virulent, each successive attack diminishing in intensity.

In many lands, such as the United Kingdom, measles is rarely absent, especially from large centres of population, where sporadic cases are found at all seasons. Every now and then epidemics arise from the extension of the disease among those members of a community who have not been in some measure protected by a previous attack. There are few diseases so contagious as measles, and its rapid spread in epidemic outbreaks is no doubt due to the well-ascertained fact that contagion is most potent in the earlier stages, even before its real nature has been understood by the characteristic appearances on the skin.

Hence the difficulty of timely isolation, and the readiness with which the disease is spread in schools and families. The contagion is present in the skin and the various secretions. While the contagion is generally direct, it can also be conveyed by the particles from the nose and mouth which, after being expelled, become dry and are conveyed as dust on clothes, toys, &c. Fortunately the germs of measles do not retain their virulence long under such conditions, comparing favourably with those of some other diseases. Treatment.—Treatment embraces the preventive measures to be adopted by the isolation of the sick at as early a period as possible. Epidemics have often, especially in limited localities, been curtailed by such a precaution. In families with little house accommodation this measure is frequently, for the reason given regarding the communicable period of the disease, ineflucntial; nevertheless where practicable it ought to be tried. The unaffected children should be kept from school for a time (probably about three weeks from the outbreak in the family would suffice), if no other case occurs in the interval, and all clothing in contact with the patient or nurses should be disinfected. In extensive epidemics it is often desirable to close the schools for a time. As regards special treatment, in an ordinary case of measles little is required beyond what is necessary in febrile conditions generally. Confinement to bed in a somewhat darkened room, into which, however, air is freely admitted is a desirable provision.
admitted; light, nourishing, liquid diet (soups, milk, &c.), water almost ad lib. to drink, and mild diaphoretic remedies such as the acetate of ammonia or ipecacuanha, are all that is necessary in the febrile stage. When the fever is very severe, sponging of the body may be necessary, but most of the damage done over to the patient is due to the coldness of the brain, as the cheeks and temples of the face are often the last to become cold. The special complications of measles are to be dealt with by those measures applicable for the relief of the particular symptoms (see BRONCHITIS; PNEUMONIA). The preparations of ammonia are of special efficacy. During convalescence the patient must be guarded from exposure to cold, and for a time after recovery the state of the health ought to be watched with a view of averting the evils, both local and constitutional, which too often follow this disease.

"German measles" (Rötheln, or Epidemic Rosacea) is a term applied to a contagious eruptive disease, having certain points of resemblance to measles, and also to scarlet fever, but exhibiting its distinct individuality in the fact that it protects from neither of these diseases. It occurs most commonly in children, but frequently in adults also, and is occasionally seen in extensive epidemics. Beyond confinement to the house in the eruptive stage, which, from the slight symptoms experienced, is often difficult of accomplishment, no special treatment is called for. There is little doubt that the disease is often mistaken for true measles, and many of the alleged second attacks of the latter malady are probably cases of rötheln. The chief points of difference are the following: (1) The absence of delirium. (2) The absence of general constitutional symptoms. (3) The appearance of only one eruption of rotheln, which, although as regards its locality and manner of progress similar to measles, differs somewhat in its appearance, the spots being of smaller size, paler colour, and with less tendency to grouping in crescentic patches. The rash attains its maximum in about one day, and quickly disappears. There is not the same increase of temperature in this stage as in measles. (3) The presence of white spots on the buccal mucous membranes, in the cases of measles. (4) The milder character of the symptoms of rötheln throughout its whole course, and the absence of complications and of liability to subsequent impairment of health such as have been seen to appertain to measles.

MEAT, a word originally applied to food in general, and so still used in such phrases as "meat and drink"; but now, except as an archaism, generally used of the flesh of certain domestic animals, slaughtered for human food by butchers, "butcher's meat," as opposed to "game," that of wild animals, "fish" or "poultry." Cognate forms of the O. Eng. mete are found in certain Teutonic languages, e.g. Swed. mat, Dan. mad and O. H. Ger. Mase. The ultimate origin has been disputed; the New English Dictionary considers probable a connexion with the root meaning "to produce." Mette in modern English means "be wet," and Eng. "mait," the fruit of the beechn as food for pigs. See DIETETICS; FOOD PRESERVATION; PUBLIC HEALTH; AGRICULTURE; and the sections dealing with agricultural statistics under the names of the various countries.

MEATH (pronounced with th soft, as in the), a county of Ireland in the province of Leinster, bounded E. by the Irish Sea, S.E. by Dublin, S. by Kildare and King's County, W. by Westmeath, N.W. by Cavan and Monaghan, and N.E. by Louth. Area 179,320 acres, or about 905 sq. m. In some districts the surface is varied by hills and swells, which to the west reach a considerable elevation, although the general features of a fine champion country are never lost. The coast, low and shelving, extends about 10 m., but there is no harbour of importance. Laytown is a small seaside resort, 5 m. S.E. of Drogheda. The Boyne enters the county at its south-western extremity, and flowing north-east to Drogheda divides it into two almost equal parts. At Navan it receives the Blackwater, which flows south-east to the sea. Both the rivers are noted for their trout, and salmon are taken in the Boyne. The Boyne is navigable for barges as far as Navan whence a canal is carried to Trim. The Royal Canal passes along the southern boundary of the county from Dublin.

In the north is a broken country of Silurian rocks with much igneous material, partly contemporaneous, partly intrusive, near Slane in the western part of the county, and sandstone terraces, the surface of which is generally broken and uneven, and which extend to the Dublin border, giving rise to a flat plain especially suitable for grazing. Outliers of Carboniferous strata occur on the surface; but the Coal Measures have all been removed by denudation.

The climate is genial and favourable for all kinds of crops, there being a climate than every other in Ireland. A small portion occupied by the Bog of Allen, the county is verdant and fertile. The soil is principally a rich deep loam resting on limestone gravel, but varies from a strong clayey loam to a light sandy gravel. Potatoes and turnips are the principal crops, but all decrease. The numbers of cattle, sheep and poultry, however, are increasing or well managed. Agriculture in the southern part of the county, as in the north, is carried on by hand-looms, and there are a few woolen manufactories. The main line of the Midland Great Western railway skirts the southern boundary, with a branch line north from Clonsilla to Navan and Kingscourt (county Cavan). From Kilmessan this line serves Trim and Athboy. From Drogheda (county Louth) a branch of the Great Northern railway crosses the county from east to west by Navan and Kells to Oldcastle.

The population (76,108 in 1841) is a little less than the average of the Irish counties, and emigration is heavy. Nearly 93% are Roman Catholics. The chief towns are Navan (pop. 3839), Kells (2428) and Trim (5513), the county town. Lesser market towns are Oldcastle and Athboy, an ancient town which received a charter from Henry IV. The county includes eighteen baronies. Assizes are held at Trim, and quarter sessions at Kells, Navan and Trim. The country is in the Protestant dioceses of Armagh, Kilmore and Meath, and in the Roman Catholic dioceses of Armagh and Meath. Before the Union there were fourteen members to parliament, but now only two members are returned for the north and south divisions of the county respectively.

History and Antiquities.—A district known as Meath (Midhe), and including the present county of Meath as well as Westminster and Longford, with parts of Cavan, Kildare and King's County, was formed by Tuathal (c. 130) into a kingdom to serve as menses land or personal estate of the Ard Ri or over-king of Ireland. Kings of Meath reigned until 1173, and the title was probably early a 15th century by their descendants, but at the date mentioned Hugh de Lacy obtained the lordship of the country and was confirmed in it by Henry II. Meath thus remained to the English Pale. But in 1290 it was declared a county in the reign of Edward I. (1296), and though it passed by descent to the possession of the Crown in the person of Edward IV., it was long before it was fully subdued and its boundaries clearly defined. In 1543 Westminster was created a county apart from that of Meath, but as late as 1598 Meath was still regarded as a province by some, who included in it the counties Westmeath, East Meath, Longford and Cavan. In the early part of the 17th century it was at last established as a county, and no longer considered as a fifth province of Ireland.

There are two ancient round towers, one at Kells and the other in the churchyard of Donaghmore, near Navan. By the river Boyne near Slane there is an extensive ancient burial-place called Brugh. Here are some twenty burial mounds, the largest of which is that of New Grange, a domed tumulus erected above a circular chamber, which is entered by a narrow passage enclosed by great upright blocks of stone, covered with carvings. The mound is surrounded by remains of a stone circle, and the whole forms one of the most remarkable extant erections of Irish kings. Tara (g., Gre.) is famous in history, especially as the seat of a royal palace referred to in the well-known lines of Thomas Moore. Monastic buildings were very numerous in Meath, among the more important being those of Duleek, which is said to have been the first ecclesiastical building in Ireland of stone and mortar; the extensive remains of Bective Abbey; and those of Clonard, where also were a cathedral and a famous college. Of the old fortresses, the castle of Trim still presents an imposing building. There are many fine old mansions.

MEAUX, a town of northern France, capital of an arrondissement in the department of Seine-et-Marne, and chief town of the agricultural region of Brie, 28 m. E.N.E. of Paris by rail. Pop. (1906), 11,089. The town proper stands on an eminence on the right bank of the Marne; on the left bank lies the old suburb of Le Marché, with which it is united by a bridge of the 16th century. Two rows of picturesque mills along a narrow stream are built across the river. The cathedral of St Stephen dates from the 12th to the 16th centuries, and was restored in
the 19th century. Of the two western towers, the completed one is that to the north of the façade, the other being disfigured by an unsightly slate roof. The building, which is 275 ft. long and 105 ft. high, consists of a short nave, with aisles, a fine transept, a choir and a sanctuary. The choir contains the statue and the tomb of Bossuet, bishop from 1681 to 1704, and the chapel of St. Médard has been reconstructed with the panels of that from which the "eagle of Meaux" used to preach. The transept terminates at each end in a fine portal surmounted by a rose-window. The episcopal palace (17th century) has several curious old rooms; the buildings of the choir school are likewise of some archaeological interest. A statue of General Raoulit (1870) stands in one of the squares.

Meaux is the centre of a considerable trade in cereals, wool, Brie cheeses, and other farm-produce, while its mills provide much of the flour with which Paris is supplied. Other industries are saw-milling, metal-foundling, distilling, the preparation of vermicelli and preserved vegetables, and the manufacture of mustard, hosiery, plaster and machinery. There are nursery-gardens in the vicinity. The Canal de l'Ourcq, which surrounds the town, and the Marne furnish the means of transport. Meaux is the seat of a bishopric dating from the 4th century, and has among its public institutions a sub-prefecture, and tribunals of first instance and of commerce.

In the Roman period Meaux was the capital of the Medii, a small Gallic tribe, and in the middle ages of the Brie. It formed part of the kingdom of Austria, and afterwards belonged to the counts of Vermandois and Champagne, the latter of whom established important markets on the left bank of the Marne. Its communal charter, received from them, is dated 1179. A treaty signed at Meaux in 1229 after the Albigensian War sealed the submission of Raymond VI, count of Toulouse. The town suffered much during the Jacquerie, the peasants receiving a severe check there in 1358; during the Hundred Years' War; and also during the Religious Wars, in which it was an important Protestant stronghold. The function of its bishop was transferred to Henry IV. in 1594. On the high-road for invaders marching on Paris from the east of France, Meaux saw its environs ravaged by the army of Lorraine in 1652, and was laid under heavy requisitions in 1814, 1815 and 1870. In September 1567 Meaux was the scene of an attempt made by the Protestants to seize the French king Charles IX., and his mother Catherine de' Medici. The plot, which is sometimes called the "enterprise of Meaux," failed, the king and queen with their courtiers escaping to Paris. This conduct, however, on the part of the Huguenots had doubtless some share in influencing Charles to assent to the massacre of St. Bartholomew.

MECCA (Arab. Makkah), 2 the chief town of the Hejaz in Arabia, and the great holy city of Islām. It is situated two camel marches (the resting-place being Bahra or Hadda), or about 45 m. almost due E., from Jidda on the Red Sea. Thus on a rough estimate Mecca lies in 21° 25' N., 35° 30' E. It is said in the Koran (Sur. xiv. 40) that Mecca lies in a sterile valley, and the old geographers observe that the whole Haram or sacred territory round the city is almost without cultivation or date palms, while fruit trees, springs, wells, gardens and green valleys are found immediately beyond. Mecca in fact lies in the heart of a mass of rough hills, intersected by a labyrinth of narrow valleys and passes, and projecting into the Tahmā or low country on the Red Sea, in front of the great mountain wall that divides the coast-lands from the central plateau, though in turn they are themselves separated from the sea by a second curtain of hills forming the western wall of the great Wādi Marr. The inner mountain wall is pierced by only two great passes, and the valleys descending from these embrace on both sides the Mecca hills.

Holding this position commanding two great routes between the lowlands and inner Arabia, and situated in a narrow and barren valley incapable of supporting an urban population, Mecca must have been from the first a commercial centre.2 In the palmy days of South Arabia it was probably a station on the great incense route, and thus Ptolemy may have learned the name, which he writes Makoraha. At all events, long before Meccah was regarded as Meṣk, and to the votaries of Mecca as a commercial centre and a privileged holy place, surrounded by an inviolable territory (the Haram), which was not the sanctuary of a single tribe but a place of pilgrimage, where religious observances were associated with a series of annual fairs at different points in the vicinity. Indeed in the unsettled state of the country commerce was possible only under the sanctions of religion, and through the provisions of the sacred truce which prohibited war for four months of the year, three of these being the month of pilgrimage, with those immediately preceding and following. The first of the series of fairs in which the Meccans had an interest was at Okaz on the easier road between Mecca and Taif, where there was also a sanctuary, and from it the visitors moved on to points still nearer Mecca (Majanna, and finally Dhuł-Majāţ, on the flank of Jebel Kākāb behind Arafa) where further fairs were held, culminating in the special religious ceremonies of the great feast at 'Arafa, Qaţala (Mozdālīfa), and Mecca itself. The system of intercalation in the lunar calendar of the heathen Arabs was designed to secure that the feast should always fall at the time when he dates, fruits and other merchandise were most readily to be obtained. How to attract the Bedouins by hospitality, bought up these wares in exchange for imported goods, and so became the leaders of the international trade of Arabia. Their caravans traversed the length and breadth of the peninsula. Syria, and especially Gaza, was their chief goal. The Syrian caravan intercepted, on its return, at Badr (see MAHOMET) represented capital to the value of 200,000, an enormous sum for those days.3

The victory of Mahommedanism made a vast change in the position of Mecca. The merchant aristocracy became satchets on the edge of Arabia, and Meccah, which belonged to a single tribe, passed into the hands of the Medine, the "aristocracy," and the great of Mecca, and the Hejāz strove for a time to maintain political as well as religious pre-eminence, the struggle was vain, and terminated on the death of Ibn Zubair, the Meccan pretendent to the caliphate, when the city was taken by Hajjāj (A.D. 692). The sanctuary and feast of Mecca received, however, a new prestige from the victory of Islām. Purged of elements obviously heathen, the Ka'ba became the holiest site, and the pilgrimage the most sacred ritual observance of Mahommedanism, drawing worshippers from so wide a circle that the confinement of the petty traders of the desert was no longer the main feature of the holy season. The pilgrimage retained its importance for the commercial well-being of Mecca; to this day the Meccans live by the Hajj—letting rooms, acting as guides and directors in the sacred ceremonies, as contractors and touts for land and sea transport, as well as exploiting the many benefactions that flow to the holy city; while the surrounding Bedouins derive support from the camel-transport it demands and from the subsidies by which they are engaged to protect or abstain from molesting the pilgrim caravans. But the ancient "fairs of heathenism" were given up, and the traffic of the pilgrim season, sanctioned by the Prophet in Sur. ii. 194, was concentrated at Minā and Mecca, where most of the pilgrims still have something to buy or sell, so that Minā, after the sacrifice of the feast day, presents the aspect of a huge international fancy fair.

2 Mecca, says one of its citizens, Wāqīḏi (Kremer's ed., p. 196, or Muh. in Med., p. 100), is a settlement formed for trade with Syria in summer and Abyssinia in winter, and cannot continue to exist if the trade is interrupted.

3 The details are variously related. See Birāni, p. 325 (E. T., p. 324); Asma'ī in Yaqūt, iii. 705, ed. 416, 421; Azraqī, p. 123 seq.; Bakrī, p. 651; Jebel Kākāb is a great mountain occupying the angle between W. Namān and the plain of Arafa. The peak is due north of Sheddād, the hamlet which Burckhardt (ii. 115) calls Sheddā. According to Azraqī, p. 50, the last shrine visited was that of the thin pole (Uzr). See p. 649 seq.

4 So we are told by Birāni, p. 62 (E. T., p. 73).

5 Wāqīḏi, ed. Kremer, pp. 20, 21; Muh. in Med., p. 39.
fair. In the middle ages this trade was much more important than it is now. Ibn Jubair (ed. Wright, p. 118 seq.) in the 12th describes the mart of Mecca in the eight days following the feast as full of gems, ungents, precious drugs, and all rare merchandise from India, Irak, Khorasan, and every part of the Moslem world.

The hills east and west of Mecca, which are partly built over and rise several hundred feet above the valley, so enclose the city that the air within it is only barred the valley at three points, where three gates led into the town. In the time of Ibn Jubair the gates still stood though the walls were ruined, but now the gates have only left their names to quarters of the town. At the northern or upper end was the Bâb el-Mâlî, or gate of the upper quarter, whence the road continues up the valley towards Minâ and Araf as well as towards Zeima and the Nejd. Beyond the gate, in a place called the Hâjjûn, is the chief cemetery, commonly called el-Mâlî, and said to be the resting-place of many of the companions of Mahomet. Here a cross-road, running over the hill to join the main Medina road from the western gate, turns off to the west by the pass of Kâdâl, the point from which the troops of the Prophet stormed the city (A.H. 8). Here too the body of Ibn Zubair was hung on a cross by Hâjjûn. The lower or southern gate, at the Masâlâha quarter, opened on the Yemen road, where the rain-water from Mecca flows off into an open valley. Beyond, there are mountains on both sides; on that to the east, commanding the town, is the great castle, a fortress of considerable strength. The third or western gate, Bâb el-Omra (formerly also Bâb el-Zibir, from a village of that name), lay almost opposite the great mosque, and opened on a road leading westwards round the southern spur of the Red Mountain. This is the way to Wâdi Fâtimâ and Medina, the Jîddâ road branch off from it to the left. Considerable suburbs now lie outside the quarter named after this gate; in the middle ages a pleasant country road led for some miles through partly cultivated land with good wells, as far as the boundary of the sacred territory and gathering place of the pilgrims at Tanim, near the mosque of Ayeshâ. This is the spot on the Medina road now called the Omra, from a ceremonial connected with it, which will be mentioned below.

The length of the sinuous main axis of the city from the farthest suburbs on the Medina road to the suburbs in the extreme north, now frequented by Bedouins, is, according to Burckhardt, 3500 paces. About the middle of this line the longitudinal thoroughfares are pushed aside by the vast courtyard and colonnades composing the great mosque, which, with its spacious arcades surrounding the Ka'ba and other holy places, and its seven minarets, forms the only prominent architectural feature of the city. The mosque is enclosed by houses with windows opening on the arcades and commanding a view of the Ka'ba. Immediately beyond these, on the side facing Jebel Abu Kabâb, a broad street runs south-east and north-west across the valley. This is the Masâ' (sacred course) between the eminences of Safâ and Merwa, and has been from very early times one of the most lively bazaars and the centre of Meccan life. The other chief bazaars are also near the mosque in smaller streets. The general aspect of the town is picturesque; the streets are fairly spacious, though ill-kept and filthy; the houses are very many of them well-built and four or five stories high, with terraced roofs and large projecting windows as in Jiddâ—a style of building which has not varied materially since the 10th century (Mukaddasî, p. 71), and gains in effect from the way in which the dwellings run up the sides and spurs of the mountains. Of public institutions there are baths, ribâts, or hospitals, for poor pilgrims from India, Java, &c., a hospital and a public kitchen for the poor.

The mosque is at the same time the university hall, where between two pilgrimage seasons lectures are delivered on Mahomedan law, doctrine and connected branches of science. A poorly provided public library is open to the use of students. The madrassahs or buildings around the mosque, originally intended as lodgings for students and professors, have long been let out to rich pilgrims. The minor places of visitation for such as the birthplaces of the prophet and his chief followers, are not notable. Both these and the court of the great mosque lie beneath the general level of the city, the site having been gradually raised by accumulated rubbish. The town in fact has little air of antiquity; genuine Arab buildings do not last long, especially in a valley periodically ravaged by tremendous floods when the tropical rains burst on the surrounding hills. The history of Mecca is full of the record of these inundations, unsuccessfully combated by the great dam drawn across the valley by the caliph Omar (Kuṭbeddin, p. 76), and later works of Mahdi's.

The fixed population of Mecca in 1878 was estimated by Assistant-Surgeon 'Abd el-Razzâq at 50,000 to 60,000; there is a large floating population—and that not merely at the proper season of pilgrimage, the pilgrims of one season often beginning to arrive before those of the former season have all dispersed. At the height of the season the town is much overcrowded, and the entire want of a drainage system is severely felt. Fortunately good water is tolerably plentiful; for, though the wells are mostly undrinkable, and even the famous Zamzam water only available for the first few days of the season, the underground supply, as drawn from beyond Arafà, completed by Sultan Selim II. in 1571, supplies to the public fountains a sweet and light water, containing, according to 'Abd el-Razzâq, a large amount of chlorides. The water is said to be free to townsmen, but is sold to the pilgrims at a rather high rate.

Medieval writers celebrate the copious supplies, especially of fine fruits, brought to the city from Taif and other fertile parts of Arabia. These fruits are still famous; rice and other foreign products are bought by sea to Jiddà; mutton, milk and butter are plentifully supplied from the desert. The industries all centre in the pilgrimage; the chief object of every Meccan—from the notables and sheikhs, who use their influence to gain custom for the Jidda speculators in the pilgrim traffic, down to the cicerones, pilgrim brokers, lodging-house keepers, and mendicants at the holy places—being to pillage the visitor in every possible way. The fanaticism of the Meccan is an affair of the purse; the mongrel population (for the town is by no means purely Arab) has exchanged the virtues of the Bedouin for the worst corruptions of Eastern town life, without casting off the ferocity of the desert, and it is hardly possible to find a worse certificate of character than the three parallel gashes on each cheek, called Tashrît, which are the customary mark of birth in the holy city. The unspeakable vices of Mecca are a scandal to all Islam, and a constant source of wonder to pious pilgrims. The slave trade has connexions with the pilgrimage which are not thoroughly clear; but under cover of the pilgrimage a great deal of importation and exporting of slaves goes on.

Since the fall of Ibn Zubair the political position of Mecca...
MECCA

The Great Mosque and the Ka'ba.—Long before Mahomet the chief sanctuary of Mecca was the Ka'ba, a rude stone building without windows, and having a door 7 ft. from the ground; and so named from its resemblance to a monstrous astragalus (die) of about 40 ft. cube, though the shapeless structure is not really an exact cube nor even exactly rectangular. The Ka’ba has been rebuilt more than once since Mahomet purged it of its idolatries, and the changes and additions of Islam have made the old form has been preserved, except in secondary details; so that the “Ancient House,” as it is titled, is still essentially a heathen temple, adapted to the worship of Islam by the clumsy fiction that it was built by Abraham and Ishmael by divine revelation as a temple of pure monotheism, and that it was only temporarily perverted to idol worship from the time when ‘Amr ibn Lohain introduced the statue of Hubal from Syria till the victory of Islam. This fiction has involved the superinvention of a new mythology over the old heathen ritual, which remains practically unchanged. Thus the chief object of veneration is the black stone, which is fixed in the external angle facing Safa. The building is not exactly oriented, but it may be called the south-east corner. Its technical name is the black corner, the others being named the Yemen (south-west), Syrian (north-west), and Irak (north-east) corners, from the lands to which they approximately point. The black stone is a small dark mass a span-long, with an aspect suggesting volcanic or meteoric origin, fixed at such a height that it can be conveniently kissed by a person of middle size. It is said that it was at first used as a stone in the temple of Astarte (not, as some authorities relate, by the Carmathians), and the pieces are kept together by a silver setting. The history of this heavenly stone, given by Gabriel to Abraham, does not conceal the fact that it was originally a fetish, the most venerated of a multitude of idols and sacred stones which stood all round the sanctuary in the time of Mahomet. The Prophet destroyed the idols, but he left the characteristic form of worship—the tawaf, or sevenfold circuit of the sanctuary, the worshipper kissing or touching the objects of his veneration—and besides the black stone he recognized the so-called “southern” stone, the same probably as that which is still touched in the tawaf at the Yemen corner (Mus. in Med. pp. 336, 425). The ceremony of the tawaf and the worship of stone fetishes was common to Mecca with other ancient Arabian sanctuaries. It was, as it still is, a frequent religious exercise of the Meccans, and the first duty of one who returned to the city or arrived there under a vow of pilgrimage; and thus the outside of the Ka’ba was and is more important than the inside. Islam did away with the worship of the Idin in high at least before the suppression of idolatry.

The exact measurements (which, however, vary with different authorities) are stated to be: sides 37 ft. 2 in. and 38 ft. 4 in.; ends 31 ft. 7 in. and 29 ft.; height 35 ft.

The Ka’ba of Mahomet’s time was the successor of an older building, said to have been destroyed by fire. It was constructed in the still usual rude style of Arabic masonry, with string courses of timber between the stones (like Solomon’s Temple). The roof rested on six pillars; the door was raised above the ground and approached by a stair (probably on account of the floods which often swept the valley); and worshippers left their shoes under the stair before entering. During the first siege of Mecca (A.D. 683), the building was burned down, the Ibn Zubair reconstructed it on an enlarged scale and in better style of solid ashlar-work. After his death his most glaring innovations (the introduction of two doors on a level with the entrance; the addition of the roof; and the encasements, which hide the Hijr) were corrected by Hajjaj, under orders from the caliph, but the building retained its more solid structure. The roof now rests on three pillars, and the height has been raised one-half. The Ka’ba was again entirely rebuilt after the flood of A.D. 1666, but since Hajjaj there seem to have been no structural changes.

Hobal was set up within the Temple over the pit that contained the most precious treasures of the sanctuary, a sacred lot to which the Meccans were accustomed to betake themselves in all matters of difficulty.

1 See Ibn Hisham i. 54; Araqzī p. 80 (‘Uzaa in Boa Marr); Yāḥāt iii. 139 (Sheykhd); Sā‘ūd p. 891 on Psalm xii. 9. Stones worshiped by circling round them bore the name dawur or dawāt (Kresh, Rel. d. Arché, p. 69). The later Arabs not unnaturally viewed it as imitated from that of Mecca (Yāḥāt iv. 622; cf. Dozy, Inscriptions de Mecca, p. 125, who draws very perversely from authorities).
MECCA

953

has been supplied by the invention of spots consecrated by recollections of Abraham, Ishmael and Hagar, or held to be acceptable places of prayer. Thus the space of ten spans between the black stone and the door, which is on the east side, between the black and Irak corners, and a man's height from the ground, is called the Multazam, and here prayer should be offered after the 'atwaf with outstretched arms and breast pressed against the house. On the other side of the door, against the same wall, is a splayed trough, which is said to mark the original site of the stone on which Abraham stood to build the Ka'ba. Here the growth of the legend can be traced, for the place is now called the "kneading-place" (Ma'jan), where the cement for the Ka'ba was prepared. This name and story do not appear in the older accounts. Once more, on the north side of the Ka'ba, there projects a low semicircular wall of marble, with an opening at each end between it and the walls of the house. The space within is paved with mosaic, and is called the Hijr. It is included in the 'atwaf, and two slabs of stone within it are called the graves of Ishmael and Hagar, and are places of acceptable prayer. Even the golden or gilded ma'ab (water-spout) that projects into the Hijr marks a place where prayer is heard, and another such place is the part of the west wall close to the Yemen corner.

The feeling of religious conservatism which has preserved the structural rudeness of the Ka'ba did not prohibit costly surface decoration. In Mahomet's time the outer walls were covered by a vell (or kiswa) of striped Yemen cloth. The caliphs substituted a covering of figured brocade, and the Egyptians sent up, still with each pilgrim caravan from Cairo a new kiswa of black brocade, adorned with a broad band embroidered with golden inscriptions from the Koran, as well as a richer curtain for the door.1 The door of two leaves, with its posts and lintel, is of silver gilt.

The interior of the Ka'ba is now opened but a few times every year for the general public, which ascends by the portable staircase brought forward for the purpose. Foreigners can obtain admission at any time for a special fee. The modern descriptions, from observations made under difficulties, are not very complete. Little change, however, seems to have been made since the time of Ibn Jubair, who describes the floor and walls as overlaid with richly variegated marbles, and the upper half of the walls as plated with silver thickly gilt, while the roof was veiled with coloured metal. Modern writers describe the place as windowless, but Ibn Jubair mentions five windows of rich stained glass from Irak. Between the three pillars of teak hung thirteen silver lamps. A chest in the corner to the left of one entering contained Korans, and at the Irak corner a space was cut off enclosing the stair that leads to the roof (to which each pilgrim caravan marched—Bith el-Rajma) was plated with silver by the caliph Motawakkil.

Here, in the time of Ibn Jubair, the Maqam or standing stone of Abraham was usually placed for better security, but brought out on great occasions.2

The houses of ancient Mecca pressed close upon the Ka'ba, the noblest families, who traced their descent from Kosa'i, the reputed founder of the city, having their dwellings immediately round the sanctuary. To the north of the Ka'ba was the Dar el-Nadwa, or place of assembly of the Koreish. The multiplication of pilgrims after Islam so soon made it necessary to clear away the nearest dwellings and enlarge the place of prayer around the Ancient House. Omar, Othman and Ibn Jubair had all a share in this work, but the great founder of the mosque in its present form, with its spacious area and deep colonnades, was the caliph Mahdi, who spent enormous sums in bringing costly pillars from Egypt and Syria. The work was still incomplete at his death in A.D. 785, and was finished in less sumptuous style by his successor. Subsequent repairs and additions, extending down to Turkish times, have left little of Mahdi's work untouched, though a few of the pillars probably date from his days. There are more than five hundred pillars in all, of very varied style and day-endurance—250 paces in length and 300 in breadth, according to Burckhardt's measurement—is entered by nineteen archways irregularly disposed.

After the Ka'ba the principal points of interest in the mosque are the well Zamzam and the Maqam Ibrahim. The former is a deep shaft enclosed in a massive vaulted building paved with marble, and, according to Mahomedan tradition, is the source (corresponding to the Beer-lahai-roi of Gen. xvi. 14) from which Hagar drew water for her son Ishmael. The legend tells that suds were long covered up and rediscovered by 'Abd al-Motajib, the grandfather of the Prophet. Sacred wells are familiar features of Semitic sanctuaries, and Islam, retaining the well, made a quasi-biblical story for it, and endowed its tepid waters with miraculous curative virtues. They are eagerly drunk by the pilgrims, or when poured over the body are held to give a miraculous refreshment after the fatigues of religious exercise; and the manufacture of bottles or jars for carrying the water to distant countries is quite a trade. Ibn Jubair mentions a curious superstition of the Meccans, who believed that the water rose in the shaft at the full moon, and fell back again by degrees. It was supposed that the water would not be plentiful during the month of Dhul-Qa'dah, and those who came to Mecca were advised to think of their abundance as a present gift from Allah.

Safah and Mecca.—In religious importance these two points or "hills," connected by the Mas'ah, stand second only to the Ka'ba. Safah is an elevated platform surrounded by a triple arch, and approached by a flight of steps. It is south-east of the Ka'ba, facing the black corner, and 76 paces from the "Gate of Safah," which is architecturally the chief gate of the mosque. Merwa is a similar platform, formerly covered with a single arch, on the corner of which stands the tower of the Mount called Jebel Kuwaykin. The course between these two sacred points is 493 paces long, and the religious ceremony called "safa" consists in traversing it seven times, beginning and ending at Safah. The lowest point on the line of the so-called green milestones, is done at a run. This ceremony, which, as we shall presently see, is part of the omra, is generally said to be performed in memory of Hagar, who ran to and fro between the two eminences vainly seeking water for her son. The observance, however, is certainly of pagan origin; and at one time there were idols on both the so-called hills (see especially Azraqi, pp. 74, 78).

The "Mirages and the Pilgrimage."—Before Islam the Ka'ba was the local sanctuary of the Meccans, where they prayed and did6

---
2. Ibn Jubair speaks of fourteen steps, Ali Bey of four, Burckhardt of three. The surrounding ground has not risen so that the old name "hill of the Ka'ba" is now inapplicable.

MECCA

sacrifice, where oaths were administered and hard cases submitted to divine sentence according to the immemorial custom of Semitic shrines. But, besides this, Mecca, with its famous pilgrimages, was also the place of a third, and perhaps the most important, pilgrimage. Pilgrimage to Mecca was with the ancient Arabs the fulfilment of a vow, which appears to have generally terminated—at least on the part of the well-to-do—in a sacrificial feast. A vow of pilgrimage might be made to Mecca as early as the month of Dhu Hijja, and the pilgrimage for it (shâbâ) is applied, for example, to the pilgrimage to Mâmat (Bahkti, p. 519). He who was under such a vow was bound by religious observances of abstinence from certain foodstuffs (e.g. hunting and slaughter of wild beasts), and he had to perform at his own expense the pilgrimage proper in a proper or partial way, or comb his hair till the fulfilment of the vow. This old Semitic usage has its close parallel in the vow of the Nazarite. It was not peculiar to the Meccan, however; at Taif, which is only a few miles away from Mecca, the vow is connected with the annual feast and market. The pilgrimage was so intimately connected with the well-being of Mecca, and had already such a hold on the Arabs of religious sentiment, that Mahomet could not afford to sacrifice it to an exact purity of religion, and thus the old usages were transplanted into Islam in the double form of the omra or vow of pilgrimage to Mecca, which can be discharged at any time, and the bâjj or pilgrimage at the great annual feast. The later closes with a visit to the Ka'bah, but its essential ceremonies lie outside Mecca, at the neighbouring shrines where the old Arabs gathered before the Meccan fair.

The day begins at some point outside the Haram (or holy territory), generally at Tanîm, both for convenience sake and because Ayêsha began the omra there in the year 10 of the Hegira. The pilgrim enters the old city through the gateway and takes the 'ejes, consisting of two cloths wound round his person in a way prescribed by ritual. His devotion is expressed in shouts of "Labâyka" (a word of obscure origin and meaning; he enters the great mosque, performing the first tawâf and the "sây" of Ayêsha, which has his head shaved and resumes his common dress. This ceremony is now generally combined with the bâjj, or is performed by every stranger or traveller who enters the holy city at the gate of Ayêsha. The dress of the pilgrim is ill-concealed by the legends of the sa'y of Hagar and of the tâwâf being first performed by Adam in imitation of the circuit of the angels about the throne of God; the meaning of their ceremonies seems to have been almost a blank to the Arabs before Islam, whose religion had become a mere formal tradition. We do not know to what deity the worship expressed in the tâwâf was properly addressed. There is a tradition that the Ka'bah was a temple of the Lord of the Throne (Shahista'tâ), p. 431); perhaps the most distinctive feature of the shrine may be sought in the sacrificial doves which still enjoy the protection of the shrine. These recall the sacrificial ceremonies of the ancient Semites and the worship of at least one element (cf. Herod. i. 131, iii. 8; Ephr. Syr., Op. Syr. ii. 457).

The Ka'bah, or holy shrine of the pilgrim omra has become so much an epoch of the bâjj that it is described by some European pilgrims as a mere visit to the mosque of Ayêsha; a better conception of its original significance is got from the Meccan feast of the seventh month (Kabah, a festival celebrated by the Abad, in A.D. 1814). Rabaj was one of the ancient sacred months, and the feast, which extended through the whole month and was a joyful season of hospitality and thanksgiving; no doubt represents the ancient feasts of Mecca more exactly than the ceremonies of the bâjj, in which old usage has been overlaid by traditions and glosses of Islam. The omra was performed by crowds from day to day, especially at new and full moon. The new moon celebration was nocturnal; the road to Tanîm, the Ma'âs, and the mosque were brilliantly illuminated; and the appearing of the moon was greeted with joyous exultations. A genuine old Arab market was held, for the wild Bedouins, who were driven by hunger to search for their cattle and fruits for clothing, and deemed that to absent themselves would bring drought and cattle plague in their homes. Though ignorant of the legal ritual and prayer, they performed the tawâf with enthusiasm, throwing themselves against the Ka'bah and clinging to its curtains as a child clings to its mother. They also made a point of entering the Ka'bah. The 29th of the month was the feast day, and it is said the Ka'bah was then given over to the liqâ, or poor, to make a sort of fair. They were allowed to offer their sacrifices in the Ka'bah to themselves without the presence even of the Sheyba. The central and essential ceremonies of the bâjj or greater pilgrimage to Mecca, and especially from its beginning to the 9th of Shaban (Dhu' Hilijja), the last of the Arab year; and every Moslem who is his own master, and can command the necessary means, is bound to join in these once in his life, or to have them fulfilled by a substitute

4 The latter perhaps was no part of the ancient omra; see Snouck-Hurgronje, "Het Mekkaanse Feest" (1880) p. 115 sqq.

5 The 27th was also a great day, but this day was in commemoration of the rebuilding of the Ka'bah by Ibn Jubair.

on his behalf and at his expense. By them the pilgrimage becomes as pure from sin as when he was born, and gains for the rest of his life the report and blessing with which the pilgrimage is consecrated. The religious ceremony may be compromised by offerings, but to miss the "standing" ( waqf) at Arafa is to miss the pilgrimage. Arafa or Ararat is a space, artificially limited, a round isolated hill called Mina, adjacent to Mecca, and with a road from Mecca to Taif. One leaving Mecca after midday can easily reach the place on foot the same evening. The road is first northwards to the city of Taif, and then southwards through the hilly desert to the village of Mina, which the road winds down from Mount Kûn. The lofty and rugged mountains of the Hodhlyef tower over the plain on the north side and overshadow the little hill of Mercy, which is one of those collective memories of an old Semitic tradition, which is still, in the same near Arifah, a 

4 The sacrifice is not indispensable except for those who can afford it and are combining the hajj with the omra.

On the similar peeling of the supposed graves of Abu Lahab and his wife (Ibn Jusair, p. 110) and of Abî Râghil at Mughammas, see Nöüdeke's translation of Tahari, p. 208.
and Irāk, the pilgrims who reach Medina from Yanbu and go on to Mecca, and those from all parts of the peninsula. Burckhardt in his travels in Arabia, and Landau at Arta in 50,000, 'Abd el-Razzāk in 1858 at 60,000. This great assemblage is always a dangerous centre of infection, and the days of Mina especially, spent under circumstances originally adapted only for aReineri, and afterwards divided purely by Ibn Bāṭūta. The Arabic historians are largely occupied with fabulous matter as to Mecca before Islam; for these legends the reader may refer to C. de Perceval's Ezaias. His little examination of the history opens very curiously from the distorted accounts of Abrahā's expulsion against the Je też, which fell but a few years before the birth of the Prophet, and is the first event in Meccan history which has confirmation from other sources. See Nöldeke's version of Tabari, p. 204 sqq. For the period of the Prophet, Ibn Hishām and Wākidī are valuable sources in topography as well as history. Of the special histories and descriptions of Mecca published by Wustenfeld (Chroniken der Stadt Mekka, 3 vols., 1857-1859, with an abstract in German, 1861), the most valuable is that of Azraqī. It has passed through the hands of several editors, but the oldest version goes back to the beginning of the 12th cent. (The University of Mecca, a History of the World, 1861) with Christi's Kühne's history (vol. iii. of the Chroniken) goes down with the additions of his nephew to A.D. 1902.

Of European descriptions of Mecca from personal observation the best is Burckhardt; Von Maltzan's Waschfahrt nach Mekka (1863) is frey, but very slight; 'Abd el-Razzāk's report to the government of India on the pilgrimage of 1853 is specially directed to sanitary questions. C. Snouck-Hurgronje, Mekka (2 vols., and a collection of photographs, The Hague, 1888-1888; gives a description of the Meccan sanctuary and of the public and private life of the Meccans as observed by the author during a sojourn in the holy city in the years 1884-1888 and a political history of Mecca from native sources from the Hegira till 1886. For the pilgrimage see particularly Snouck Hurgronje's Het Meekoonsche Feest (Leiden, 1880).

(Gr. R. S.)

MECHANICS. The subject of mechanics may be divided into two parts: (1) theoretical or abstract mechanics, and (2) applied mechanics.

1. THEORETICAL MECHANICS

Historically theoretical mechanics began with the study of practical contrivances such as the lever, and the name mechanics (Gr. μηχανική), which might more properly be restricted to the theory of mechanisms, and which was indeed used in this narrower sense by Newton, has clung to it, although the subject has long attained a far wider scope. In recent times it has been customary to adopt the term dynamics (from Gr. δύναμις, force) as including the study of the effects of force on bodies, whether at rest or in motion. The subject is usually expounded under the two divisions of statics and kinetics, the former dealing with the conditions of rest or equilibrium and the latter with the phenomena of motion as affected by force. To this latter division the old name of dynamics (in a restricted sense) is still often applied. The mere geometrical description and analysis of various types of motion, apart from the consideration of the forces concerned, belongs to kinematics. It is sometimes discussed as a separate theory, but for our present purposes it is more convenient to treat the kinematic motions as they are required. We follow also the traditional practice of dealing first with statics and then with kinetics. This is, in the main, the historical order of development, and for purposes of exposition it has many advantages. The laws of equilibrium are, in fact, necessarily included as a particular case under those of motion; but there is no real inconvenience in formulating as the basis of statics a few provisional postulates which are afterwards seen to be consequences of the general theory.

The whole subject rests ultimately on the Newtonian laws of motion and on some natural extensions of them. As these laws are discussed under a separate heading (Motion, Laws of), it is here only necessary to indicate the standpoint from which the present article is written. It is a purely empirical one. Guided by experience, we are able to frame rules which enable us to say with more or less accuracy what will be the consequences, or what were the antecedents, of a given state of things. These rules are sometimes dignified by the name of "laws of nature," but they have relation to our present state of knowledge and to the degree of skill with which we have succeeded in giving more or less compact expression to them. They are therefore liable to be modified from time to time, or to be superseded by more convenient or more comprehensive modes of statement. Again, we do not aim at anything so hopeless, or indeed so useless, as a complete description of any phenomenon. Some features are naturally more important or more interesting to us than others; by their relative simplicity and evident constancy they have the first hold on our attention, whilst those which are apparently accidental and vary from one occasion to another are ignored, or postponed for later examination. It follows that for the purposes of such description as is possible some process of abstraction is inevitable if our statements are to be simple and definite. Thus in studying the flight of a stone through the air we replace the body in imagination by a mathematical point endowed with a mass-coefficient. The size and shape, the complicated spinning motion which it is seen to execute, the internal strains and vibrations which doubtless take place, are all sacrificed in the mental picture in that attention may be concentrated on those features of the phenomenon which are in the first place most interesting to us. At a later stage in our subject the peculiarities of the force which is introduced; this hitherto we are able to fill in some details which were previously wanting, but others are still omitted. Again, the conception of a force as concentrated in a mathematical line is as unreal as that of a mass concentrated in a point, but it is a convenient fiction for our purpose, owing to the simplicity which it lends to our statements.

The laws which are to be imposed on these ideal representations are in the first instance largely at our choice. Any scheme of abstract dynamics constructed in this way, provided it be self-consistent, is mathematically legitimate; but from the physical point of view we require that it should help us to picture the sequence of phenomena as they actually occur. Its success or failure in this respect can only be judged a posteriori by comparison of the results with which it leads. It is to be noticed, moreover, that all available tests apply only to the scheme as a whole; owing to the complexity of phenomena we cannot assign any one of its postulates to verification apart from the rest.

It is from this point of view that the question of relativity of motion which is here felt to be a significant block on the very threshold of the subject, is to be judged. By "motion" we mean of necessity motion relative to some frame of reference which is conventionally spoken of as "fixed." In the earlier stages of our subject this may be any rigid, or apparently rigid, structure fixed relatively to the earth. If we meet with phenomena which do not fit easily into this view, we have the alternatives either to modify our assumed laws of motion, or to call to our aid adventitious forces, or to examine whether the discrepancy can be reconciled by the simpler expedient of a new basis of reference. It is hardly necessary to say that the latter procedure has hitherto been found to be adequate.

As a first step we adopt a system of rectangular axes whose origin is fixed in the earth, but whose directions are fixed by relation to the stars; in the planetary theory the origin is transferred to the sun, and afterwards to the mass-centre of the solar system; and so on. At each step there is a gain in accuracy and comprehensiveness; and the conviction is cherished that some system of rectangular axes exists with respect to which the Newtonian scheme holds with all imaginable accuracy.

A similar account might be given of the conception of time as a measurable quantity, but the remarks which it is necessary to make under this head will find a place later.
The following synopsis shows the scheme on which the treatment is based:—

Part I.—Statics.
1. Statics of a particle.
2. Statics of a system of particles.
3. Plane kinematics of a rigid body.
4. Plane statics.
5. Graphical statics.
7. Three-dimensional kinematics of a rigid body.
8. Three-dimensional statics.
10. Statics of inextensible chains.
11. Theory of mass-systems.

Part II.—Kinetics.
12. Rectilinear motion.
17. Two-dimensional problems.
18. Equations of motion in three dimensions.
20. Motion of a solid of revolution.
22. Equations of motion in generalized co-ordinates.

Part I.—Statics

§ 1. Statics of a Particle.—By a particle is meant a body whose position can for the purpose in hand be sufficiently specified by a mathematical point. It need not be “infinitely small,” or even small compared with ordinary standards; thus in astronomy such vast bodies as the sun, the earth, and the other planets can for many purposes be treated merely as points endowed with mass.

A force is conceived as an effort having a certain direction and a certain magnitude. It is therefore adequately represented, for mathematical purposes, by a straight line AB drawn in the direction in question, of length proportional (on any convenient scale) to the magnitude of the force. In other words, a force is mathematically of the nature of a “vector” (see Vector Analysis, Quaternions). In most questions of pure statics we are concerned only with the ratios of the various forces which enter into the problem, so that it is indifferent what unit of force is adopted. For many purposes a gravitational system of measurement is most natural; thus we speak of a force of so many pounds or so many kilogrammes. The “absolute” system of measurement will be referred to below in Part II, KINETICS. It is to be remembered that all “force” is of the nature of a push or a pull, and that according to the accepted terminology of modern mechanics such phrases as “force of inertia,” “accelerating force,” “moving force,” once classical, are proscribed. This rigorous limitation of the meaning of the word is of comparatively recent origin, and it is perhaps to be regretted that some more technical term has not been devised, but the convention must now be regarded as established.

The fundamental postulate of this part of our subject is that the two forces acting on a particle may be compounded by the “parallelogram rule.” Thus, if the two forces \( P, Q \) be represented by the lines \( OA, OB \), they can be replaced by a single force \( R \) represented by the diagonal \( OC \) of the parallelogram determined by \( OA, OB \). This is of course a physical assumption whose propriety is justified solely by experience. We shall see later that it is implied in Newton’s statement of his Second Law of motion. In modern language, forces are compounded by “vector-addition”; thus, if we draw in succession vectors \( HK, KL \) to represent \( P, Q \), the force \( R \) is represented by the vector \( HKL \) which is the “geometric sum” of \( HK, KL \).

By successive applications of the above rule any number of forces acting on a particle may be replaced by a single force which is the vector-sum of the given forces; this single force is called the resultant. Thus if \( AB, BC, CD, \ldots \), \( HK \) be vectors representing the given forces, the resultant will be given by \( R \). It will be understood that the figure \( ABCD \ldots \) need not be confined to one plane.

If, in particular, the point \( K \) coincides with \( A \), so that the resultant vanishes, the given system of forces is said to be in equilibrium—i.e. the particle could remain permanently at rest under its action. This is the proposition known as the polygon of forces. In the particular case of three forces it reduces to the triangle of forces, viz. “If three forces acting on a particle are represented as to magnitude and direction by the sides of a triangle taken in order, they are in equilibrium.” A sort of converse proposition is frequently useful, viz. if three forces acting on a particle be in equilibrium, and any triangle be constructed whose sides are respectively parallel to the forces, the magnitudes of the forces will be to one another as the corresponding sides of the triangle. This follows from the fact that all such triangles are necessarily similar.

As a simple example of the geometrical method of treating statical problems we may consider the equilibrium of a particle on a “rough” inclined plane. The usual empirical law of sliding friction is that the mutual action between two plane surfaces in contact, or between a particle and a curved or plane surface, cannot make with the normal an angle exceeding a certain limit \( \lambda \) called the angle of friction. If the conditions of equilibrium require an obliquity greater than this, sliding will take place. The precise value of \( \lambda \) will vary with the nature and condition of the surfaces in contact. In the case of a body simply resting on an inclined plane, the reaction must of course be vertical, for equilibrium, and the slope \( e \) of the plane must therefore not exceed \( \lambda \). For this reason \( \lambda \) is also known as the angle of repose. If \( e > \lambda \), a force \( P \) must be applied in order to maintain equilibrium; let \( \theta \) be the inclination of \( P \) to the plane, as shown in the left-hand diagram. The relations between this force \( P \), the gravity \( W \) of the body, and the reaction \( S \) of the plane are then determined by a triangle of forces \( HKL \). Since the inclination of \( S \) to the normal cannot exceed \( \lambda \) on either side, the value of \( P \) must lie between two limits which are represented by \( LHK, LKL \), in the right-hand diagram. Denoting these limits by \( P_1, P_2 \), we have

\[
P_1/W = LHK/HK = \sin(\alpha - \lambda)/\cos(\theta + \lambda),
\]

\[
P_2/W = LKL/HK = \sin(\alpha + \lambda)/\cos(\theta - \lambda).
\]

It appears, moreover, that if \( \theta \) be varied \( P \) will be least when \( LKH \) is at right angles to \( KL \), in which case \( P_2 = W \sin(\alpha - \lambda) \), corresponding to \( \theta = \lambda \).

Just as two or more forces can be combined into a single resultant, so a single force may be resolved into components.
acting in assigned directions. Thus a force can be uniquely resolved into two components acting in two assigned directions in the same plane with it by an inversion of the parallelogram construction of fig. 1. If, as is usually most convenient, the two assigned directions are at right angles, the two components of a force \( P \) will be \( P \cos \theta, P \sin \theta \), where \( \theta \) is the inclination of \( P \) to the direction of the former component. This leads to formulae for the analytical reduction of a system of co-planar forces acting on a particle. Adopting rectangular axes \( Ox, Oy \), in the plane of the forces, and distinguishing the various forces of the system by suffixes, we can replace the system by two forces \( X, Y \), in the direction of co-ordinate axes; viz.,

\[
\begin{align*}
X &= P \cos \theta_1 + P_1 \cos \theta_1 + \ldots = \Sigma (P \cos \theta) \\
Y &= P \sin \theta_1 + P_1 \sin \theta_1 + \ldots = \Sigma (P \sin \theta)
\end{align*}
\]

(1)

These two forces \( X, Y \), may be combined into a single resultant \( R \) making an angle \( \phi \) with \( Ox \), provided

\[
X = R \cos \phi, \quad Y = R \sin \phi
\]

(2)

whence

\[
R^2 = X^2 + Y^2, \quad \tan \phi = Y/X.
\]

(3)

For equilibrium we must have \( R = 0 \), which requires \( X = 0, Y = 0 \); in words, the sum of the components of the system must be zero for each of two perpendicular directions in the plane.

A similar procedure applies to a three-dimensional system.

Thus if, \( O \) being the origin, \( OH \) represent any force \( P \) of the system, the planes drawn through \( H \) parallel to the co-ordinate planes will enclose with the latter a parallelepiped, and it is evident that \( OH \) is the geometric sum of \( OA, AN, NH, \) or \( OA, OB, OC \), in the figure. Hence \( P \) is equivalent to three forces \( P_1, P_2, P_3 \) acting along \( Ox, Oy, Oz \), respectively, where \( l, m, n \), are the "direction-ratios" of \( OH \). The whole system can be reduced in this way to three forces

\[
X = \Sigma (P_1), \quad Y = \Sigma (P_2), \quad Z = \Sigma (P_3)
\]

(4)

acting along the co-ordinate axes. These can again be combined into a single resultant \( R \) acting in the direction \( (\lambda, \mu, \nu) \), provided

\[
X = R \lambda, \quad Y = R \mu, \quad Z = R \nu
\]

(5)

If the axes are rectangular, the direction-ratios become direction-cosines, so that \( \lambda^2 + \mu^2 + \nu^2 = 1 \), whence

\[
R^2 = X^2 + Y^2 + Z^2
\]

(6)

The conditions of equilibrium are \( X = 0, Y = 0, Z = 0 \).

§ 2. Statics of a System of Particles.—We assume that the mutual forces between the pairs of particles, whatever their nature, are subject to the "Law of Action and Reaction" (Newton's Third Law); i.e. the force exerted by a particle \( A \) on a particle \( B \), and the force exerted by \( B \) on \( A \), are equal and opposite in the line \( AB \). The problem of determining the possible configurations of equilibrium of a system of particles subject to extraneous forces which are known functions of the positions of the particles, and to internal forces which are known functions of the distances of the pairs of particles between which they act, is in general determinate. For if \( \mathfrak{n} \) be the number of particles, the \( 3\mathfrak{n} \) conditions of equilibrium (three for each particle) are equal in number to the \( 3\mathfrak{n} \) Cartesian (or other) co-ordinates of the particles, which are to be found. If the system be subject to frictionless constraints, e.g. if some of the particles be constrained to lie on smooth surfaces, or if pairs of particles be connected by inextensible strings, then for each geometrical relation thus introduced we have an unknown reaction (e.g. the pressure of the smooth surface, or the tension of the string), so that the problem is still determinate.

The case of the funicular polygon will be of use to us later. A number of particles attached at various points of a string are acted on by given extraneous forces \( P_1, P_2, P_3, \ldots \) respectively. The relation between the three forces acting on any particle, viz. the extraneous force and the tensions in the two adjacent portions of the string can be exhibited by means of a triangle of forces; and if the successive triangles be drawn to the same scale they can be fitted together so as to constitute a single force-diagram, as shown in fig. 6. This diagram consists of a polygon whose successive sides represent

the given forces \( P_1, P_2, P_3, \ldots \) and of a series of lines connecting the vertices with a point \( O \). These latter lines measure the tensions in the successive portions of string. As a special, but very important case, the forces \( P_1, P_2, P_3, \ldots \) may be parallel, e.g. they may be the weights of the several particles. The polygon of forces is then made up of segments of a vertical line. We note that the tensions have now the same horizontal projection (represented by the dotted line in fig. 7). It is further of interest to note that if the weights be all equal, and at equal horizontal intervals, the vertices of the funicular will lie on a parabola whose axis is vertical. To prove this statement, let \( A, B, C, D \ldots \) be successive vertices, and let \( A. B \ldots \) be the middle points of \( AC, BD \ldots \) then \( BH, CK \ldots \) will be vertical by the hypothesis, and since the geometric sum of \( BA, BC \) is represented by \( 2BH \), the tension in \( BA \); tension in \( BC \); weight at \( B \) as \( BA: BC: 2BH \).

The tensions in the successive portions of the string are therefore proportional to the respective lengths, and the lines \( BH, CK \ldots \) are all equal. Hence \( AD, BC \) are parallel and are bisected by the same vertical line; and a parabola with vertical axis can therefore be described through \( A, B, C, D \). The same holds for the four points \( B, C, D, E \) and so on; but since a parabola is uniquely determined by the direction of its axis and by three points on the curve, the successive parabolas \( ABCD, BCD \ldots \) must be coincident.

§ 3. Plane Kinematics of a Rigid Body.—The ideal rigid body is one in which the distance between any two points is invariably. For the present we confine ourselves to the consideration of displacements in two dimensions, so that the body is adequately represented by a thin lamina or plate.

The position of a lamina movable in its own plane is determinate when we know the positions of any two points \( A, B \) of it. Since the four co-ordinates (Cartesian or other) of these two points are connected by the relation which expresses the invariability of the length \( AB \), it is plain that virtually three independent elements are required and suffice to specify the position of the lamina. For instance, the lamina may in general be fixed by connecting any three points of it by rigid links to three fixed points in its plane. The three independent elements may be chosen in a variety of ways (e.g. they may be the lengths.
of the three links in the above example). They may be called (in a generalized sense) the co-ordinates of the lamina. The lamina when perfectly free to move in its own plane is said to have three degrees of freedom.

By a theorem due to M. Chasles any displacement whatever of the lamina in its own plane is equivalent to a rotation about some finite or infinitely distant point J. For suppose that in consequence of the displacement a point of the lamina is brought from A to B, whilst the point of the lamina which was originally at B is brought to C. Since AB, BC, are two different positions of the same line in the lamina they are equal, and it is evident that the rotation could have been effected by a rotation about J, the centre of the circle ABC, through an angle AJB. As a special case the three points A, B, C may be in a straight line; J is then at infinity and the displacement is equivalent to a pure translation, since every point of the lamina is now displaced parallel to AB through a space equal to AB.

Next, consider any continuous motion of the lamina. The latter may be brought from any one of its positions to a neighbouring one by a rotation about the proper centre. The limiting position J of this centre, when the two positions are infinitely close to one another, is called the instantaneous centre. If P, P' be consecutive positions of the same point, and P'Q' the corresponding angle of rotation, then ultimately PP' is at right angles to JP and equal to JP. δθ. The instantaneous centre will have a certain locus in space, and a certain locus in the lamina. These two loci are called pole-curves or centrodes, and are sometimes distinguished as the space-centre and the body-centre, respectively. In the continuous motion in question the latter curve rolls without slipping on the former (M. Chasles). Consider in fact any series of successive positions 1, 2, 3 . . . of the lamina (fig. 11); and let Jn, Jn, Jn . . . be the positions in space of the centres of the rotations by which the lamina can be brought from the first point to the second, from the second to the third, and so on. Further, in the position 1, let Jn, Jn', Jn'' . . . be the points of the lamina which have become the successive centres of rotation. The given series of positions will be assumed in succession if we imagine the lamina to rotate first about Jn until Jn comes into coincidence with Jn', then about Jn until Jn'' comes into coincidence with Jn', and so on. This is equivalent to imagining the polygon Jn Jn Jn . . . , supposed fixed in the lamina, to roll on the polygon Jn Jn Jn . . . , which is supposed fixed in space. By imagining the successive positions to be taken infinitely close to one another we derive the theorem stated. The particular case where both centrodes are circles is specially important in mechanism.

The theory may be illustrated by the case of three-bar motion. Let ABCD, be any quadrilateral formed of jointed links, if AB being held fixed, the quadrilateral be slightly deformed, it is obvious that the instantaneous centre J will be at the intersection of the straight lines AD, BC, since the displacements of the points D, C are necessarily at right angles to AD, BC, respectively. Hence these displacements are proportional to JD, JC, and therefore to DD', CC', where C'D' is any line drawn parallel to CD, meeting BC, AD in C', D', respectively.

The determination of the centrodes in three-bar motion is in general complicated, but in one case, that of the "crossed parallelogram" (fig. 13), they assume simple forms. We then have AB = DC and AD = BC, and from the symmetries of the figure it is plain that

\[ A + J \mathbf{B} = C + \mathbf{J} \mathbf{D} = \mathbf{A} \mathbf{D} \]

Hence the locus of J relative to AB, and the locus relative to CD, are equal ellipses of which A, B and C, D are respectively the foci. It may be noticed that the lamina in fig. 9 is not, strictly speaking, fixed, but admits of infinitesimal displacement, whenever the directions of the three links are concurrent (or parallel).

The matter may of course be treated analytically, but we shall only require the formulas for infinitely small displacements. If the origin of rectangular axes fixed in the lamina be shifted through a space whose projections on the original directions of the axes are \( \lambda, \mu, \) and if the axes are simultaneously turned through an angle \( \epsilon \), the co-ordinates of a point of the lamina, relative to the original axes, are changed from \( x, y \) to \( \lambda + x \cos \epsilon - y \sin \epsilon, \mu + x \sin \epsilon + y \cos \epsilon, \)

or \( \lambda + x - y \epsilon, \mu + x + y, \) ultimately. Hence the component displacements are ultimately

\[ \delta x = \lambda - y \epsilon, \delta y = \mu + x \epsilon \] (1)

If we equate these to zero we get the co-ordinates of the instantaneous centre.

§ 4. Plane Statics.—The statics of a rigid body rests on the following two assumptions:

(i) A force may be supposed to be applied indifferently at any point in its line of action. In other words, a force is of the nature of a "bound" or "localized" vector; it is regarded as resident in a certain line, but has no special reference to any particular point of the line.

(ii) Two forces in intersecting lines may be replaced by a force which is their geometric sum, acting through the intersection. The theory of parallel forces is included as a limiting case. For if O, A, B be any three points, and \( m, n \) any scalar quantities, we have in vectors

\[ m \cdot \overrightarrow{OA} + n \cdot \overrightarrow{OB} = (m + n) \overrightarrow{OC}. \] (1)

provided

\[ m \cdot \overrightarrow{CA} + n \cdot \overrightarrow{CB} = 0. \] (2)

Hence if forces \( P, Q \) act in OA, OB, the resultant R will pass through C, provided

\[ m = P/OA, \ n = Q/OB; \]

also

\[ R = P + Q. \ OC/OA + Q. OC/OB, \]

and

\[ P. AC : Q. CB = OA : OB. \] (3)

These formulae give a means of constructing the resultant by means of any transversal AB cutting the lines of action. If we now imagine the point O to recede to infinity, the forces \( P, Q \) and the resultant \( R \) are parallel, and we have

\[ R = P + Q. \ PC = Q. \ CB. \] (4)

When \( P, Q \) have opposite signs the point \( C \) divides \( AB \) externally on the side of the greater force. The investigation fails when \( P + Q = 0, \) since it leads to an infinitely small resultant acting in an infinitely distant line. A combination of two equal, parallel, but oppositely directed forces cannot in fact be replaced by anything simpler, and must therefore be recognized as an independent entity in statics. It was called by L. Euler, who first systematically investigated its properties, a couple.

We now restrict ourselves to the present to the systems of forces in one plane. By successive applications of (i) any
such coplanar system can in general be reduced to a single resultant acting in a definite line. As exceptional cases the system may reduce to a couple, or it may be in equilibrium.

The moment of a force about a point O is the product of the force into the perpendicular drawn to its line of action from O, this perpendicular being reckoned positive or negative according as O lies on one side or other of the line of action. If we mark off a segment AB along the line of action so as to represent the force completely, the magnitude is represented as to magnitude by twice the area of the triangle OAB, and the usual convention as to sign is that the area is to be reckoned positive or negative according as the letters O, A, B, occur in "counter-clockwise" or "clockwise" order.

The sum of the moments of two forces about any point O is equal to the moment of their resultant (P. Varignon, 1687).

Let AB, AC (fig. 16) represent the two forces, AD their resultant; we have to prove that the sum of the triangles OAB, OAC is equal to the triangle OAD, regard being had to signs. Since the side OA is common, we have to prove that the sum of the perpendiculars from B and C on OA is equal to the perpendicular from D on OA; these perpendiculars being reckoned positive or negative according as they lie to the right or left of AO.

Regarded as a statement concerning the orthogonal projections of the vectors AB and AC (or BD), and of their sum AD, on a line perpendicular to AO, this is obvious.

It is now evident that in the process of reduction of a coplanar system no change is made at any stage either in the sum of the projections of the forces on any line or in the sum of their moments about any point. It follows that the single resultant to which the system in general reduces is uniquely determinate, i.e. it acts in a definite line and has a definite magnitude and sense. Again it is necessary and sufficient for equilibrium that the sum of the projections of the forces on each of two perpendicular directions should vanish, and (moreover) that the sum of the moments about some one point should be zero. The fact that three independent conditions must hold for equilibrium is important. The conditions may of course be expressed in different (but equivalent) forms; e.g. the sum of the moments of the forces about each of the three points which are not collinear must be zero.

The particular case of three forces is of interest. If they are not all parallel they must be concurrent, and their vector sum must be zero. Thus three forces acting perpendicular

![Fig. 15](image_url)

![Fig. 16](image_url)

![Fig. 17](image_url)

to the sides of a triangle at the middle points will be in equilibrium provided they are proportional to the respective sides, and act all inwards or all outwards. This result is easily extended to the case of a polygon of any number of sides; it has an important application in hydrostatics.

Again, suppose we have a bar AB, resting with its ends on two smooth inclined planes which face each other. Let G be the centre of gravity (§ 11), and let AG = a, GB = b. Let a, b, be the inclinations of the planes, and the angle which the bar makes with the vertical. The position of equilibrium is determined by the consideration that the reactions at A and B, which are by hypothesis normal to the planes, must meet at a point J on the vertical through G. Hence

$$\frac{JG}{a} = \sin (\theta - \alpha)/\sin \alpha, \quad \frac{JG}{b} = \sin (\theta + \beta)/\sin \beta,$$

whence

$$\cot \theta = \frac{a \cot a - b \cot \beta}{a + b}. \quad (6)$$

If the bar is uniform we have $a = b$, and

$$\cot \theta = \frac{1}{2} (\cot a - \cot \beta). \quad (7)$$

The problem of a rod suspended by strings attached to two points of it is virtually identical, the tensions of the strings taking the place of the reactions of the planes.

Just as a system of forces is in general equivalent to a single force, so a given force can conversely be replaced by combinations of other forces, in various ways. For instance, a given force (and consequently a system of forces) can be replaced in one and only one way by three forces acting in three assigned straight lines, provided these lines be not concurrent or parallel. Thus if the three lines form a triangle ABC, and if the given force F meet BC in H, then F can be resolved into two components acting in HA, BC, respectively. And the force in HA can be resolved into two components acting in BC, CA, respectively. A simple graphical construction is indicated in fig. 19, where

![Fig. 18](image_url)

![Fig. 19](image_url)

the dotted lines are parallel. As an example, any system of forces acting on the lamina in fig. 9 is balanced by three determine tensions (or thrusts) in the three links, provided the directions of the latter are not concurrent.

If P, Q, R, be any three forces acting along BC, CA, AB, respectively, the line of action of the resultant is determined by the consideration that the sum of the moments about any point on it must vanish. Hence in "trilinear" co-ordinates, with ABC as fundamental triangle, its equation is $P \alpha + Q \beta + R \gamma = 0$. If $P : Q : R = a : b : c$, where $a$, $b$, $c$ are the lengths of the sides, this becomes the line at infinity, and the forces reduce to a couple.

The sum of the moments of the two forces of a couple is the same about any point in the plane. Thus in the figure the sum of the moments about O is $O \cdot P - P \cdot OB$ or $P \cdot AB$, which is independent of the position of O. This sum is called the moment of the couple; it must of course have the proper sign attributed to it. It easily follows that any two couples of the same moment are equivalent, and that any number of couples can be replaced by a single couple whose moment is the sum of their moments. Since a couple is for our purposes sufficiently represented by its moment, it has been proposed to substitute the name torque (or twisting effort), as free from the suggestion of any special pair of forces.

A system of forces represented completely by the sides of a plane polygon taken in order is equivalent to a couple whose
moment is represented by twice the area of the polygon; this is proved by taking moments about any point. If the polygon intersects itself, care must be taken to attribute to the different parts of the area their proper signs.

### Fig. 21.

Again, any coplanar system of forces can be replaced by a single force $R$ acting at any assigned point $O$, together with a couple $G$. The force $R$ is the geometric sum of the given forces, and the moment ($G$) of the couple is equal to the sum of the moments of the given forces about $O$. The value of $G$ will in general vary with the position of $O$, and will vanish when $O$ lies on the line of action of the single resultant.

The formal analytical reduction of a system of coplanar forces is as follows. Let $(x_1, y_1), (x_2, y_2), \ldots$ be the rectangular coordinates of any points $A_1, A_2, \ldots$ on the lines of action of the respective forces. The force at $A_1$ may be replaced by its components $X_1, Y_1$ parallel to the coordinate axes; that at $A_2$ by its components $X_2, Y_2$, and so on. Introducing at $O$ two equal and opposite forces $X_1 = 0$, in the same direction, we see that $X_1$ at $A_1$ may be replaced by an equal and parallel force at $O$ together with a couple $-\gamma X_1$. Similarly the force $Y_1$ at $A_1$ may be replaced by a force $Y_1$ at $O$ together with a couple $x_1 Y_1$. The forces $X_1, Y_1, \ldots$ at $O$ can thus be transferred to $O$ provided we introduce a couple $x_1 Y_1 - \gamma X_1$. Treating the remaining forces in the same way we get a force $X_1 + X_2 + \ldots$ or $2(Y)$ along $OX$, a force $Y_1 + Y_2 + \ldots$ or $2(X)$ along $OY$, and a couple $(x_1 Y_1 - y_1 X_1) + (x_2 Y_2 - y_2 X_2) + \ldots$ or $2(x X - y Y)$. The three conditions of equilibrium are therefore

$$\Sigma(x) = 0, \quad \Sigma(y) = 0, \quad \Sigma(x X - y Y) = 0.$$  \hspace{1cm} (8)

If $O'$ be a point whose co-ordinates are $(\xi, \eta)$, the moment of the couple when the forces are transferred to $O'$ as a new origin will be $\Sigma \xi(x - \xi)(y - \eta)$. This vanishes, i.e., the system reduces to a single resultant through $O'$, provided

$$\xi \Sigma(x) + \eta \Sigma(y) + 2 \xi \Sigma(xy - yx) = 0.$$  \hspace{1cm} (9)

If $\xi, \eta$ be regarded as current co-ordinates, this is the equation of the line of action of the single resultant to which the system is in general reducible.

If the forces are all parallel, making say an angle $\theta$ with $OX$, we may write $X_1 = P_1 \cos \theta, \ Y_1 = P_1 \sin \theta, \ X_2 = P_2 \cos \theta, \ Y_2 = P_2 \sin \theta, \ldots$. The equation (9) then becomes

$$\Sigma \xi(P) + \eta \Sigma(P) \sin \theta - 2 \xi \Sigma(P) \cos \theta = 0.$$  \hspace{1cm} (10)

If the forces $P_1, P_2, \ldots$ are turned in the same sense through the same angle about the respective points $A_1, A_2, \ldots$ so as to remain parallel, the value of $\theta$ is alone altered, and the resultant $\Sigma(P)$ passes always through the point

$$\vec{R} = \frac{\Sigma(x P)}{\Sigma(P)}, \vec{P} = \frac{\Sigma(y P)}{\Sigma(P)},$$  \hspace{1cm} (11)

which is determined solely by the configuration of the points $A_1, A_2, \ldots$ and by the ratios $P_1, P_2, \ldots$ of the forces acting at them respectively. This point is called the centre of the given system of parallel forces; it is finite and determinate unless $\Sigma(P) = 0$. A geometrical proof of this theorem, which is not restricted to a two-dimensional system, is given later (§ 11). It contains the theory of the centre of tension as ordinarily understood. For if we have an assemblage of particles whose mutual distances are small compared with the dimensions of the earth, the forces of gravity on them constitute a system of sensibly parallel forces, sensibly proportional to the respective masses. If now the assemblage be brought into any other position relative to the earth, without alteration of the mutual distances, this is equivalent to a rotation of the directions of the forces relatively to the assemblage, the ratios of the forces remaining unaltered. Hence there is a certain point, fixed relatively to the assemblage, through which the resultant of gravitational action always passes; this resultant is moreover equal to the sum of the forces on the several particles.

The theorem that any coplanar system of forces can be reduced to a force acting through any assigned point, together with a couple, has an important illustration in the theory of the distribution of shearing stress and bending moment in a horizontal beam, or other structure, subject to vertical extraneous forces. If we consider any vertical section $P$, the forces exerted across the section by the portion of the structure on one side on the portion on the other may be reduced to a vertical force $F$ at $P$ and a couple $M$. The force measures the shearing stress, and the couple the bending moment at $P$; we shall reckon these quantities positive when the senses are as indicated in the figure.

If the remaining forces acting on the portion of the structure on either side of $P$ are known, then resolving vertically we find $F$, and taking moments about $P$ we find $M$. Again if $PQ$ be any segment of the beam which is free from load, $Q$ lying to the right of $P$, we find

$$F_0 = F_2, \quad M_0 - M_2 = -F_0 P_2;$$  \hspace{1cm} (12)

hence $F$ is constant between the loads, whilst $M$ decreases as we travel to the right, with a constant gradient $-F$. If $PQ$ is a short segment containing an isolated load $W$, we have

$$P_0 - P_2 = -W, \quad M_0 = M_2;$$  \hspace{1cm} (13)

hence $F$ is discontinuous at a concentrated load, diminishing by an amount equal to the load as we pass the loaded point to the right, whilst $M$ is continuous. Accordingly the graph of $F$ for any system of isolated loads will consist of a series of horizontal lines, whilst that of $M$ will be a continuous polygon.

To pass to the case of continuous loads, let $x$ be measured horizontally along the beam to the right. The load on an element $dx$ of the beam may be represented by $wdx$, where $w$ is in general a function of $x$. The equations (12) are now replaced by

$$\delta F = -w dx, \quad \delta M = -F dx;$$

whence

$$F_0 - F_2 = -\int_w dx, \quad M_0 - M_2 = -\int w dx.$$  \hspace{1cm} (14)

The latter relation shows that the bending moment varies as the area cut off by the ordinate in the graph of $F$. In the case of uniform load we have

$$F = -w x - A, \quad M = \frac{w x^2}{2} - Ax + B;$$  \hspace{1cm} (15)

where the arbitrary constants $A, B$ are to be determined by the conditions of the special problem, e.g., the conditions at the ends of the beam. The graph of $F$ is a straight line; that of $M$ is a parabola with vertical axis. In all cases the graphs due to different distributions of load may be superposed. The figure shows the case of a uniform heavy beam supported at its ends.

§ 5. Graphical Statics.—A graphical method of reducing a plane system of forces was introduced by C. Culmann (1864). It involves the construction of two figures, a force-diagram and a funicular polygon. The force-diagram is constructed by placing end to end a series of vectors representing the given forces in

### Fig. 25.
magnitude and direction, and joining the vertices of the polygon thus formed to an arbitrary pole O. The funicular or link polygon has its vertices on the lines of action of the given forces, and its sides respectively parallel to the lines drawn from O in the force-diagram; in particular, the two sides meeting in any vertex are respectively parallel to the lines drawn from O to the ends of that side of the force-polygon which contains the corresponding force. The relations will be understood from the annexed diagram, where corresponding lines in the force-diagram (to the right) and the funicular (to the left) are numbered similarly. The sides of the force-polygon may in the first instance be arranged in any order; the force-diagram can then be completed in a doubly infinite number of ways, owing to the arbitrary position of O; and for each force-diagram a simply infinite number of funiculars can be drawn. The two diagrams being supposed constructed, it is seen that each of the given systems of forces can be replaced by two components acting in the sides of the funicular which meet at the corresponding vertex, and that the magnitudes of these components will be given by the corresponding triangle of forces in the force-diagram; thus the force r in the figure is equivalent to two forces represented by Or and rz. When this process of replacement is complete, each terminated side of the funicular is the seat of two forces which neutralize one another, and there remain only two uncompensated forces, viz., those resident in the first and last sides of the funicular. If these sides intersect, the resultant acts through the intersection, and its magnitude and direction are given by the line joining the first and last sides of the force-polygon (see fig. 26, where the resultant of the four given forces is denoted by R). As a special case it may happen that the force-polygon is closed, i.e., its first and last points coincide; the first and last sides of the funicular will then be parallel (unless they coincide), and the two uncompensated forces form a couple. If, however, the first and last sides of the funicular coincide, the two outstanding forces neutralize one another, and we have equilibrium. Hence the necessary and sufficient conditions of equilibrium are that the force-polygon and the funicular should both be closed.

This is illustrated by fig. 26 if we imagine the force R, reversed, to be included in the system of given forces. It is evident that a system of jointed bars having the shape of the funicular polygon would be in equilibrium under the action of the given forces, supposed applied to the joints; moreover any bar in which the stress is of the nature of a tension (as distinguished from a thrust) might be replaced by a string. This is the origin of the names “link-polygon” and “funicular” (cf. § 2).

If funiculars be drawn for two positions O, O′ of the pole in the force-diagram, their corresponding sides will intersect on a straight line parallel to OO′. This is essentially a theorem of projective geometry, but the following statistical proof is interesting. Let AB (fig. 27) be any side of the force-polygon, and construct the corresponding portions of the two diagrams, first with O and then with O′ as pole. The force corresponding to AB may be replaced by the two components marked x, y; and a force corresponding to BA may be represented by the two components marked x′, y′. Hence the forces x, y, x′, y′ are in equilibrium. Now x, x′ have a resultant through H, represented in magnitude and direction by OY′, whilst y and y′ have a resultant through K represented in magnitude and direction by O′Y. Hence HK must be parallel to O′O. This theorem enables us, when one funicular has been drawn, to construct any other without further reference to the force-diagram.

The complete figures obtained by drawing first the force-diagrams of a system of forces in equilibrium with two distinct poles O, O′ and secondly the corresponding funiculars, have various interesting relations. In the first place, each of these figures may be conceived as an orthogonal projection of a closed plane-faced polyhedron.

As regards the former figure this is evident at once; viz, the polyhedron consists of two pyramids with vertices represented by O, O′ and a common base whose perimeter is represented by the force-polygon (only one of these is shown in fig. 28). As regards the funicular figure, let LM be the line on which the pairs of corresponding sides of the two polygons meet, and through it draw any two planes ω, ω′. Through the vertices A, B, C, . . . and A′, B′, C′, . . . of the two funiculars draw normals to the plane of the diagram, to meet ω and ω′ respectively. The points thus obtained are evidently the vertices of a polyhedron with plane faces.
When the given forces are all parallel, the force-polygon consists of a series of segments of a straight line. This case has important practical applications; for instance we may use the method to find the pressures on the supports of a beam loaded in any given manner. Thus if AB, BC, CD represent the given loads, in the force-diagram, we construct the sides corresponding to OA, OB, OC, OD in the funicular; we then draw the closing line of the funicular polygon, and a parallel OE to it in the force diagram. The segments DE, EA then represent the upward pressures of the two supports on the beam, which pressures together with the given loads constitute a system of forces in equilibrium. The pressures of the beam on the supports are of course represented by ED, AE. The two diagrams are portions of reciprocal figures, so that Bow's notation is applicable.

The "centre" (§ 4) of a system of parallel forces of given magnitudes, acting at given points, is easily determined graphically. We have only to construct the line of action of the resultant for each of two arbitrary directions of the forces; the intersection of the two lines gives the point required. The construction is neatest if the two arbitrary directions are taken at right angles to one another.

§ 5. Theory of Frames.—A frame is a structure made up of pieces, or members, each of which has two joints connecting it with other members. In a two-dimensional frame, each joint may be conceived as consisting of a small cylindrical pin fitting accurately and smoothly into holes drilled through the members which it connects. This supposition is a somewhat ideal one, and is only often roughly approximated to in practice. We shall suppose, in the first instance, that extraneous forces act on the frame at the joints only, i.e. on the pins. On this assumption, the reactions on any member at its two joints must be equal and opposite. This combination of equal and opposite forces is called the stress in the member; it may be a tension or a thrust. For diagrammatic purposes each member is sufficiently represented by a straight line terminating at the two joints; these lines will be referred to as the bars of the frame.

In structural applications a frame must be stiff, or rigid, i.e. it must be incapable of deformation without alteration of length in at least one of its bars. It is said to be just rigid if it ceases to be rigid when any one of its bars is removed. A frame which has more bars than are essential for rigidity may be called over-rigid; such a frame is in general self-stressed, i.e. it is in a state of stress independently of the action of extraneous forces. A plane frame of $n$ joints which is just rigid (as regards deformation in its own plane) has $2n-3$ bars, for if one bar he held fixed the $2(n-2)$ co-ordinates of the remaining $n-2$ joints must just be determined by the lengths of the remaining bars. The total number of bars is therefore $2(n-2) + 1$. When a plane frame which is just rigid is subject to a given system of equilibrating extraneous forces (in its own plane) acting on the joints, the stresses in the bars are in general uniquely determinate. For the conditions of equilibrium of the forces on each pin furnish $2n$ equations, viz. two for each point, which are linear in respect of the stresses and the extraneous forces. This system of equations must involve the three conditions of equilibrium of the extraneous forces which are already identically satisfied, by hypothesis; there remain therefore $2n-3$ independent relations to determine the $2n-3$ unknown stresses. A frame of $n$ joints and $2n-3$ bars may of course fail to be rigid owing to some parts being over-stiff whilst others are deformable; in such a case it will be found that the statical equations, apart from the three identical relations imposed by the equilibration of the extraneous forces, are not all independent but are equivalent to less than $2n-3$ relations. Another exceptional case, known as the critical case, will be noticed later (§ 9).

A plane frame which can be built up from a single bar by successive steps, at each of which a new joint is introduced by two
new bars meeting there, is called a simple frame; it is obviously just rigid. The stresses produced by extraneous forces in a simple frame can be found by considering the equilibrium of the various joints in a proper succession; and if the graphical method be employed the various polygons of force can be combined into a single force-diagram. This procedure was introduced by W. J. M. Rankine and J. Clerk Maxwell (1864). It may be noticed that if we take an arbitrary pole in the force-diagram, and draw a corresponding funicular in the skeleton diagram which represents the frame together with the lines of action of the extraneous forces, we obtain two complete reciprocal figures, in Maxwell's sense. It is accordingly convenient to use Bow's notation (§ 5), and to distinguish the several compartments of the frame-diagram by letters. See fig. 33, where the successive triangles in the diagram of forces may be constructed in the order XYZ, ZXA, AZB. The class of "simple" frames includes many of the frameworks used in the construction of roofs, lattice girders and suspension bridges; a number of examples will be found in the article Bridges. By examining the senses in which the respective forces act at each joint we can ascertain which members are in tension and which are in thrust; in fig. 33 this is indicated by the directions of the arrowheads.

When a frame, though just rigid, is not "simple" in the above sense, the preceding method must be replaced, or supplemented, by one or other of various artifices. In some cases the method of sections is sufficient for the purpose. If an ideal section be drawn across the frame, the extraneous forces on either side must be in equilibrium with the forces in the bars cut across; and if the section can be drawn so as to cut only three bars, the forces in these can be found, since the problem reduces to that of resolving a given force into three components acting in three given lines (§ 4). The "critical case" where the directions of the three bars are concurrent is of course excluded. Another method, always available, will be explained under "Work" (§ 9).

When extraneous forces act on the bars themselves the stress in each bar no longer consists of a simple longitudinal tension or thrust. To find the reactions at the joints we may proceed as follows. Each extraneous force W acting on a bar may be replaced (in an infinite number of ways) by two components P, Q in lines through the centres of the pins at the extremities. In practice the forces W are usually vertical, and the components P, Q are then conveniently taken to be vertical also. We first alter the problem by transferring the forces P, Q to the pins. The stresses in the bars, in the problem as thus modified, may be supposed found by the preceding methods; it remains to infer from the results thus obtained the reactions in the original form of the problem. To find the pressure exerted by a bar AB on the pin A we compound with the force in AB given by the diagram a force equal to P. Conversely, to find the pressure of the pin A on the bar AB we must compound with the force given by the diagram a force equal and opposite to P. This question arises in practice in the theory of "three-jointed" structures; for the purpose in hand such a structure is sufficiently represented by two bars AB, BC. The right-hand figure represents a portion of the force-diagram; in particular ZX represents the pressure of AB on B in the modified problem where the loads W1 and W2 on the two bars are replaced by loads P1, Q1, and P2, Q2 respectively, acting on the pins. Compounding with this XV, which represents Q2, we get the actual pressure ZW exerted by AB on B. The directions and magnitudes of the reactions at A and C are then easily ascertained. On account of its practical importance several other graphical solutions of this problem have been devised.

§ 7. Three-dimensional Kinematics of a Rigid Body.—The position of a rigid body is determined when we know the positions of three points A, B, C of it which are not collinear, for the position of any other point P is then determined by the three distances PA, PB, PC. The nine co-ordinates (Cartesian or other) of A, B, C are subject to the three relations which express the invariability of the distances BC, CA, AB, and are therefore equivalent to six independent quantities. Hence a rigid body not constrained in any way is said to have six degrees of freedom. Conversely, any six geometrical relations restrict the body in general to one or other of a series of definite positions, none of which can be departed from without violating the conditions in question. For instance, the position of a theodolite is fixed by the fact that its rounded feet rest in contact with six given plane surfaces. Again, a rigid three-dimensional frame can be rigidly fixed relatively to the earth by means of six links.

The six independent quantities, or "co-ordinates," which serve to specify the position of a rigid body in space may of course be chosen in an endless variety of ways. We may, for instance, employ the three Cartesian co-ordinates of a particular point O of the body, and three angular co-ordinates which express the orientation of the body with respect to O. Thus in fig. 36, if OA, OB, OC be three mutually perpendicular lines in the solid, we may denote by θ the angle which OC makes with a fixed direction OZ, by ϕ the azimuth of the plane ZOC measured from some fixed plane through OZ, and by θ the inclination of the plane COA to the plane ZOC. In fig. 36 these various lines and planes are represented by their intersections with a unit sphere having O as centre. This very useful, although unsymmetrical, system of angular co-ordinates was introduced by L. Euler. It is exemplified in "Cardan's suspension," as used in connexion with a compass-bowl or a gyroscope. Thus in the gyroscope the "bywheel" (represented by the globe in fig. 37) can turn about a diameter OC of a ring which is itself free to turn about a diametral axis VX at right angles to the former; this axis is carried by a second ring which is free to turn about a fixed diameter OZ, which is at right angles to VX.

We proceed to sketch the theory of the finite displacements of a rigid body. It was shown by Euler (1776) that any displacement...
in which one point O of the body is fixed is equivalent to a pure rotation about some axis through O. Imagine two spheres of equal radius with O as their common centre, one fixed in the body and moving with it, the other fixed in space. In any displacement about O as a fixed point, the former sphere slides over the latter, as in a "hail-and-socket" joint. Suppose that as the result of the displacement a point of the moving sphere is brought from A to B, whilst the point which was at B is brought to C (cf. fig. 10).

Let J be the pole of the circle ABC (usually a "small circle" of the fixed sphere), and join JA, JB, JC, AB, BC by great-circle arcs. The spherical isosceles triangles AJB, BJC are congruent, and we see that AB can be brought into the position BC by a rotation about the axis OJ through an angle AJB.

It is convenient to distinguish the two senses in which a rotation may take place about an axis OA by opposite signs. We shall reckon a rotation as positive when it is related to the direction from O to A as the direction of rotation is related to that of translation in a right-handed screw. Thus a negative rotation about OA may be regarded as a positive rotation about OA', the prolongation of AO. Now suppose that a body receives first a positive rotation a about OA, and secondly a positive rotation b about OB; and let A, B be the intersections of these axes with a sphere described about O as centre. If we construct the spherical triangles ABC, ABC' (fig. 38), having in each case the angles at A and B equal to $\alpha$ and $\beta$ respectively, it is evident that the first rotation will bring a point from C to C'; and that the second will bring it back to C; the result is therefore equivalent to a rotation about OC. We note also that if the given rotations had been effected in the inverse order, the axis of the resultant rotation would have been OC', so that finite rotations do not obey the "commutative law." To find the angle of the equivalent rotation, in the actual case, suppose that the second rotation (about OB) brings a point from A to A'. The spherical triangles ABO, ABO' (fig. 39) are "symmetrically equal," and the angle of the resultant rotation, viz., $\angle ACA'$, is $\pi - 2\theta$. This is equivalent to a negative rotation $2\theta$ about OC, whence the theorem that the effect of three successive positive rotations $\alpha$, $\beta$, $\gamma$ about OA, OB, OC, respectively, is to leave the body in its original position, provided the circuit ABC is left-handed as seen from O. This theorem is due to O. Rodrigues (1840). The composition of finite rotations about parallel axes is a particular case of the preceding; the radius of the sphere is now infinite, and the triangles are plane.

In any continuous motion of a solid about a fixed point O, the limiting position of the axis of the rotation by which the body can be brought from any one of its positions to a consecutive one is called the instantaneous axis. This axis traces out a certain cone in the body, and a certain cone in space, and the continuous motion in question may be represented as consisting in a rolling of the former cone on the latter. The proof is similar to that of the corresponding theorem of plane kinematics (§ 3).

It follows from Euler's theorem that the most general displacement of a rigid body may be effected by a pure translation which brings any one point of it to its final position O, followed by a pure rotation about some axis through O. Those planes in the body which are perpendicular to this axis obviously remain parallel to their original positions. Hence, if $\alpha$, $\beta$, $\gamma$ denote the initial and final positions of any figure in one of these planes, the displacement could evidently have been effected by (1) a translation perpendicular to the planes in question, bringing $\alpha$ into some position $\alpha'$ in the plane of $\beta$, and (2) a rotation about a normal to the planes, bringing $\beta'$ into coincidence with $\beta$ (§ 8).

In other words, the most general displacement is equivalent to a translation and a rotation. If the rotation is about an axis which makes an angle with rotation about that axis; i.e. it may be described as a twist about a certain screw. In particular cases, of course, the translation, or the rotation, may vanish.

The preceding theorem, which is due to Michel Chasles (1839), may be proved in various other interesting ways. Thus if a point of the body be displaced from A to B, whilst the point which was at B is displaced to C, and that which was at C to D, the four points A, B, C, D lie on a helix whose axis is the common perpendicular to the bisectors of the angles ABC, BCD. This is the axis of the required screw; the amount of the translation is measured by the projection of AB or BC or CD on the axis; and the angle of rotation is given by the inclination of the aforesaid bisectors. This construction was given by M. W. Crofton. Again, H. Wiener and W. Burnside have employed the half-turn (i.e. a rotation through two right angles) as the fundamental operation. This has the advantage that it is completely specified by the axis of the rotation, the sense being immaterial. Successive half-turns about parallel axes $a, b$ are equivalent to a translation measured by double the distance between these axes in the direction from $a$ to $b$. Successive half-turns about intersecting axes $a, b$ are equivalent to a rotation about the common perpendicular to $a, b$, at their intersection, of amount equal to twice the acute angle between them, in the direction from $a$ to $b$. Successive half-turns about two skew axes $a, b$ are equivalent to a twist about a screw whose axis is the common perpendicular to $a, b$, the transverse distance being the shortest distance, and the angle of rotation being twice the acute angle between $a, b$, in the direction from $a$ to $b$. It is easily shown that any displacement whatever is equivalent to two half-turns and therefore to a screw.

In mechanics we are specially concerned with the theory of infinitesimal displacements. This is included in the preceding, but it is simpler in that the various operations are commutative. An infinitely small rotation about any axis is conveniently represented geometrically by a length AB measures along the axis and proportional to the angle of rotation, with the convention that the direction from A to B shall be related to the rotation as is the direction of translation to that of rotation in a right-handed screw. The consequent displacement of any point P will then be at right angles to the plane PAB, its amount will be represented by double the area of the triangle PAB, and its sense will depend on the cyclical order of the letters P, A, B. If AB, AC represent infinitesimal rotations about intersecting axes, the consequent displacements of any point O in the plane BAC will be at right angles to the plane, and will be represented by twice the sum of the areas OAB, OAC, taken with proper signs. It follows by analogy with the theory of moments (§ 4) that the resultant rotation will be represented by AD, the vector-sum of AB, AC (see fig. 16). It is easily inferred as a limiting case, or proved directly, that two infinitesimal rotations $\alpha, \beta$ about parallel axes are equivalent to a rotation $\alpha + \beta$ about a parallel axis in the same plane as the two former, and dividing a common perpendicular AB in a point C so that $AC/AB = \beta/\alpha$. If the rotations are equal and opposite, so that $\alpha + \beta = 0$, the point C is at infinity, and the effect is a translation perpendicular to the plane of the two given axes, of amount $\alpha$. AB. It thus appears that an infinitesimal rotation is of the nature of a "localized vector," and is subject in all respects to the same mathematical laws as a force, conceived as acting on a rigid body. Moreover, that an infinitesimal translation is analogous to a couple and follows the same laws. These results are due to Poinsot.

The analytical treatment of small displacements is as follows. We first suppose that one point O of the body is fixed, and take this as the origin of a "right-handed" system of rectangular
co-ordinates; i.e. the positive directions of the axes are assumed to be so arranged that a positive rotation of 90° about Oy would bring Oy into the position of Oe, and so on. The displacement will consist of an infinitesimal rotation $\varepsilon$ about some axis through O, whose direction-cosines are $i, j, k$. From the equivalence of a small rotation to a localized vector it follows that the rotation $\varepsilon$ will be equivalent to rotations $\xi, \eta, \zeta$ about Ox, Oy, Oz, respectively, provided
\[ \xi = \delta x, \eta = \delta y, \zeta = \delta z, \]
and we note that
\[ x^2 + y^2 + z^2 = c^2. \]
(1)
Thus in the case of fig. 36 it may be required to connect the infinitesimal rotations $\xi, \eta, \zeta$ about Ox, Oy, OZ with the variations of the angular co-ordinates $\theta, \psi, \phi$. The displacement of the point C of the body is made up of $dd$ tangential to the meridian ZC and $\theta$ by $\phi$ perpendicular to the plane of this meridian. Hence, resolving along the tangents to the arcs BC, CA, respectively, we have
\[ \xi = dd \sin \phi \sin \theta \cos \psi, \eta = dd \cos \phi, \zeta = dd \sin \theta \sin \phi. \]
(2)
Again, consider the point of the solid which was initially at $A'$ in the figure. This is displaced relatively to $A'$ through a space $ab$ perpendicular to the plane of the meridian, whilst $A''$ itself is displaced through a space $\cos \theta \phi$ in the same direction. Hence
\[ \xi = ab + \cos \theta \phi. \]
(4)
To find the component displacements of a point P of the body, whose co-ordinates are $x, y, z$, we draw PL normal to the plane $x'Ox$, and LH, LK perpendicular to Oy, Oz, respectively. The displacement of P parallel to Ox is the same as that of L, which is made up of $w$ and $-y$. In this way we obtain the formulae
\[ dx = yz - cy, dy = cx - ex, dz = ey - ox. \]
(5)
The most general case is derived from this by adding the component displacements $\lambda, \mu, \nu$ (say) of the point which was at O; thus
\[ dx = \lambda + nz - cy, dy = \mu + tx - ez, dz = \nu + uy - ox. \]
(6)
The displacement is thus expressed in terms of the six independent quantities $\xi, \eta, \zeta, \lambda, \mu, \nu$. The points whose displacements are in the direction of the resultant axis of rotation are determined by $dx, dy, dz = \xi, \eta, \zeta$, or
\[ (x + nz - cy)(x + t) = (y + tx - ez)(y + u) = (z + uy - ox)(z + v). \]
(7)
These are the equations of a straight line, and the displacement is in fact equivalent to a twist about a screw having this line as an axis. The translation parallel to this axis is
\[ dx + myz + nzs = (\lambda + ny + oz)/c. \]
(8)
The linear magnitude which measures the ratio of translation to a rotation in a screw is called the pitch. In the present case the pitch is
\[ (\lambda x + \mu y + \nu z)(t^2 + y^2 + z^2). \]
(9)
Since $t^2 + y^2 + z^2$, or $t^2$, is necessarily an absolute invariant for all transformations of the (rectangular) co-ordinate axes, we infer that $\lambda x + \mu y + \nu z$ is also an absolute invariant. When the latter invariant, but not the former, vanishes, the displacement is equivalent to a pure rotation.

If the small displacements of a rigid body are to be subject to one condition only, e.g. if a point of the body be restricted to lie on a given surface, the mathematical expression of this fact leads to a homogeneous linear equation between the infinitesimals $\xi, \eta, \zeta, \lambda, \mu, \nu$. We will briefly notice the case of two degrees, which involves an interesting generalization of the method (already explained) of compounding rotations about intersecting axes. We assume that the body receives arbitrary twists about two given screws, and it is required to determine the character of the resultant displacement. We examine first the case where the axes of the two screws are at right angles and intersect. We take these as axes of x and y; then if $\xi, \eta, \zeta$ be the component rotations about them, we have
\[ \lambda = h, \mu = k, r = 0, \]
where $h, k$, are the pitches of the two given screws. The equations (7) of the axis of the resultant screw then reduce to
\[ x\xi = y\eta, \xi(t^2 + y^2) = (k - h)\eta. \]
(10)
Hence, whatever the ratio $\xi : \eta$, the axis of the resultant screw lies on the conoidal surface
\[ x(t^2 + y^2) = cxy, \]
(11)
where $c = \frac{1}{2}(k - h)$. The co-ordinates of any point on (13) may be written
\[ x = r \cos \theta, y = r \sin \theta, z = c \sin 2\theta; \]
(12)
however, if we imagine a curve of sines to be traced on a circular cylinder so that the circumference just includes two complete undulations, a straight line cutting the axis of the cylinder at right angles and meeting this curve will generate the surface. This is called a cylinderoid. Again, the pitch of the resultant screw is
\[ p = (\lambda x + \mu y)(t^2 + y^2) = h \cos^2 \theta + k \sin^2 \theta. \]
(13)
The distribution of pitch among the various screws has therefore a simple relation to the pitch-conic
\[ h^2 \alpha^2 + k^2 \beta^2 = \text{const}; \]
(14)
viz. the pitch of any screw varies inversely as the square of that diameter of the conic which is parallel to its axis. It is to be noticed that the parameter $c$ of the cylinderoid is unaltered if the two pitches $h, k$ be increased by equal amounts; the only change is that all the pitches are increased by the same amount. It remains to show that a system of screws of the above type can be constructed so as to contain any two given screws whatever. In the first place, a cylinderoid can be constructed so as to have its axis coincident with the common perpendicular to the axes of the two given screws and to satisfy three other conditions, for the position of the centre, the parameter, and the orientation about the axis are still at our disposal. Hence we can adjust these so that the surface shall contain the axes of the two given screws as generators, and that the difference of the corresponding pitches shall have the proper value. It follows that when a body has two degrees of freedom it can twist about any one of a singly infinite system of screws whose axes lie on a certain cylinderoid. In particular cases the cylinderoid may degenerate into a plane, the pitches being then all equal.

§ 8. Three-dimensional Statics.—A system of parallel forces can be combined two and two until they are replaced by a single resultant equal to their sum, acting in a certain line. As special cases, the system may reduce to a couple, or it may be in equilibrium.

In general, however, a three-dimensional system of forces cannot be replaced by a single resultant force. But it may be reduced to simpler elements in a variety of ways. For example, it may be reduced to two forces in perpendicular skew lines. For consider any plane, and let each force, at its intersection with the plane, be resolved into two components, one (P) normal to the plane, the other (Q) in the plane. The assemblage of parallel forces P can be replaced in general by a single force, and the coplanar system of forces Q by another single force.
If the plane in question be chosen perpendicular to the direction of the vector-sum of the given forces, the vector-sum of the components Q is zero, and these components are therefore equivalent to a couple (§ 4). Hence any three-dimensional system can be reduced to a single force R acting in a certain line, together with a couple G in a plane perpendicular to the line.

This theorem was first given by L. Poinsot, and the line of action of R was called by him the central axis of the system. The combination of a force and a couple in a perpendicular plane is termed by Sir R. S. Ball a wrench. Its type, as distinguished from its absolute magnitude, may be specified by a screw whose axis is the line of action of R, and whose pitch is the ratio G/R.

The case of two forces may be specially noticed. Let AB be the shortest distance between the lines of action, and let AA', BB' (fig. 42) represent the forces. Let α, β be the angles which AA', BB' make with the direction of the vector-sum, on opposite sides. Divide AB in O, so that AA', cos α = AO, BB', cos β = OB, \( (1) \) and draw OC parallel to the vector-sum. Resolving AA', BB' each into two components parallel and perpendicular to OC, we see that the former components have a single resultant in OC, of amount \( R = AA' \cos α + BB' \cos β \), \( (2) \) whilst the latter components form a couple of moment \( G = AA' \sin α + BB' \sin β \).

Thus it is seen that any wrench can be replaced in an infinite number of ways by two forces, and that the line of action of one of these may be chosen quite arbitrarily. Also, we find from \( (2) \) and \( (3) \) that \( G \cdot R = AA' \cdot BB' \sin (α - β) \), \( (4) \).

The right-hand expression is six times the volume of the tetrahedron of which the lines AA', BB' representing the forces are opposite edges; and we infer that, whatever way the wrench be resolved into two forces, the volume of this tetrahedron is invariable.

To define the moment of a force about an axis HK, we project the force orthogonally on a plane perpendicular to HK and take the moment of the projection about the intersection of HK with the plane (see § 4). Some convention as to sign is necessary; we shall reckon the moment to be positive when the tendency of the force is right-handed as regards the direction from H to K. Since two-concurrent forces and their resultant obviously project into two concurrent forces and their resultant, we see that the sum of the moments of two concurrent forces about any axis HK is equal to the moment of their resultant. Parallel forces may be included in this statement as a limiting case. Hence, in whatever way one system of forces is by successive steps replaced by another, no change is made in the sum of the moments about any assigned axis. By means of this theorem we can show that the previous reduction of any system to a wrench is unique.

From the analogy of couples to translations which was pointed out in § 7, we may infer that a couple is sufficiently represented by a "free" (or non-localized) vector perpendicular to its plane. The length of the vector must be proportional to the moment of the couple, and its sense must be such that the sum of the moments of the two forces of the couple about it is positive. In particular, we infer that couples of the same moment in parallel planes are equivalent; and that couples in any two planes may be compounded by geometrical addition of the corresponding vectors. Independent statical proofs are of course easily given.

Thus, let the plane of the paper be perpendicular to the planes of two couples, and therefore perpendicular to the line of intersection of these planes. By § 4, each couple can be replaced by two forces \( = P \) (fig. 43) perpendicular to the plane of the paper, and so that one force of each couple is in the line of intersection (B); the arms \((AB, BC)\) will then be proportional to the respective moments. The two forces at B will cancel, and we are left with a couple of moment \( P \cdot AC \) in the plane \( AC \). If we draw three vectors to represent these three couples, they will be perpendicular and proportional to the respective sides of the triangle ABC; hence the third vector is the geometric sum of the other two. Since, in this proof the magnitude of \( P \) is arbitrary, it follows incidentally that couples of the same moment in parallel planes, \( e.g. \) planes parallel to \( AC \), are equivalent.

Hence a couple of moment \( G \), whose axis has the direction \((l, m, n)\) relative to a right-handed system of rectangular axes, is equivalent to three couples \( IG, mG, nG \) in the co-ordinate planes. The analytical reduction of a three-dimensional system can now be conducted as follows. Let \( (x_1, y_1, z_1) \) be the co-ordinates of a point \( P \) on the line of action of one of the forces, whose components are \((\text{say}) X_1, Y_1, Z_1 \). Draw \( PH \parallel \) normal to the plane \( xOy \), and \( HK \) perpendicular to \( Oz \). In \( KH \) introduce two equal and opposite forces \( = X_1 \). The force \( X_1 \) at \( P \), with \( -X_1 \) in \( KH \) forms a couple about \( Oz \), of moment \( -y_1X_1 \). Next, introduce along \( Ox \) two equal and opposite forces \( = X_2 \). The force \( X_2 \) in \( KH \) with \( -X_2 \) in \( Ox \) forms a couple about \( Oy \), of moment \( -x_1X_2 \). Hence the force \( X_1 \) can be transferred from \( P_1 \) to \( O \), provided we introduce couples of moments \( x_1X_1 \) about \( Oy \) and \(-y_1X_1 \) about \( Oz \). In this way we can bring the forces \( Y_1, Z_1 \) at \( P_1 \) and \( -Y_1, -Z_1 \) about \( Oy, sz \) respectively.

Thus we find that \( L_x, L_y, L_z \) are the moments of the original force \( P \) about the co-ordinate axes. Summing up for all the forces of the given system, we obtain a force \( R \) at \( O \), whose components are \( X = X_1(x_1), Y = Y_1(y_1), Z = Z_1(z_1) \), and a couple \( G \) whose components are \( L = L_x(x_1), M = L_y(y_1), N = L_z(z_1), \) \( (6) \), where \( r = 1, 2, 3 \ldots \) Since \( R^2 = X^2 + Y^2 + Z^2, G^2 = L^2 + M^2 + N^2 \), it is necessary and sufficient for equilibrium that the six quantities \( X, Y, Z, L, M, N \) all have the same sign. In words: the sum of the projections of the forces on each of the co-ordinate axes must vanish; and, the sum of the moments of the forces about each of these axes must vanish.

If any other point \( \delta' \) of \( \delta \) whose co-ordinates are \( x, y, z \) is chosen in place of \( O \), as the point to which the forces are transferred, we have to write \( x_1 - x, y_1 - y, z_1 - z \) for \( x_1, y_1, z_1 \), and so on, in the preceding process. The components of the resultant force \( R \) are unaltered, but the new components of force are found to be

\[
\begin{align*}
\left( L - \gamma Z + \xi Y \right) & = L - \gamma Z + \xi Y, \\
\left( M - \xi Z + \sigma X \right) & = M - \xi Z + \sigma X, \\
\left( N - \gamma X + \xi Y \right) & = N - \gamma X + \xi Y.
\end{align*}
\]

\( (8) \)

By properly choosing \( \delta' \) we can make the plane of the couple perpendicular to the resultant force. The conditions for this are \( L' \): \( M' \); \( N' \) = \( X : Y : Z \), or

\[
\begin{align*}
L - \gamma Z + \xi Y & = L - \gamma Z + \xi Y, \\
M - \xi Z + \sigma X & = M - \xi Z + \sigma X, \\
N - \gamma X + \xi Y & = N - \gamma X + \xi Y
\end{align*}
\]

\( (9) \)
These are the equations of the central axis. Since the moment of the resultant couple is now
\[ G' = \frac{X}{R}L' + \frac{Y}{R}M' + \frac{Z}{R}N' = LX + MY + NZ \]
the pitch of the equivalent wrench is
\[ (LX + MY + NZ)/(x^2 + y^2 + z^2). \]
It appears that \( X^2 + Y^2 + Z^2 \) and \( LX + MY + NZ \) are absolute invariants (cf. § 7). When the latter invariant, but not the former, vanishes, the system reduces to a single force.

The relationship between the mathematical relations of infinitely small displacements on the one hand and those of force-systems on the other enables us immediately to convert any theorem in the one subject into a theorem in the other. For example, we can assert without further proof that any infinitely small displacement may be resolved into two rotations, and that the axis of one of these can be chosen arbitrarily. Again, that wrenches of arbitrary amounts about two given screws compound into a wrench the locus of whose axis is a cylinder.

The mathematical properties of a twist or of a wrench have been studied by the line of invariance which are, however, of secondary importance from a physical point of view. In the "Null-System" of A. F. Möbius (1790-1868), a line such that the magnitude and sign of the couple, given \( J \), which acting at the point \( (x, y, z) \) is called a null-line. The triply infinite system of null-lines form what is called in line-geometry a "complex." As regards the configuration of this complex, consider a line whose shortest distance from the central and is named whose inclination to the central axis is \( \theta \). The moment of the resultant force \( R \) of the wrench about this line is \(-R \sin \theta\), and that of the couple \( G \) is \( G \cos \theta \). Hence the line will be a null-line provided
\[ \tan \theta = k/r, \]
where \( k \) is the pitch of the wrench. The null-lines which are at a given distance \( r \) from a point \( O \) of the central axis will therefore form one system of generators of a hyperboloid of revolution; and by varying \( r \) we get a series of such hyperboloids with a common centre and axis. By moving \( O \) along the central axis we obtain the whole complex of null-lines. It appears also from (11) that the distance of any point \( r \) from the central axis is \( r \) and that from the lines to a system of helices of slope \( \tan^{-1}(r/k) \); and it is to be noticed that these helices are left-handed if the given wrench is right-handed and vice versa.

Since the given wrench can be replaced by a force acting through any assigned point \( P \), and a couple, the locus of the null-lines through \( P \) is a plane, viz. a plane perpendicular to the vector which represents the couple. The complex is therefore of the type called "linear" (in relation to the degree of this locus). The plane in question is called the null-plane of \( P \). If the null-plane of \( P \) intersects the null-plane of \( Q \) in a straight line, then the null-plane of \( Q \) will pass through \( P \); and \( PQ \) is a null-line. Again, any plane \( \omega \) is the locus of a system of null-lines meeting in a point, called the null-point of \( \omega \). If a plane rotate about a fixed straight line \( R \) in it, its null-point describes another straight line \( R' \), which is called the conjugate line of \( R \).

We have seen that the wrench may be replaced by two forces, one of which may act in any arbitrary line \( R \). It is now evident that the second force must act in the conjugate line \( R' \), since every line meeting \( R \) is a null-line. Again, since the shortest distance between any two conjugate lines cuts the central axis at right angles, the orthogonal projections of two conjugate lines on a plane perpendicular to the central axis will be parallel (fig. 42). This property was employed by L. Cremona to prove the existence under certain conditions of "reciprocal figures" in a plane (§ 5). If we take any polyhedron with plane faces, the null-planes of its vertices with respect to any given wrench will form another polyhedron, and the edges of the latter will be conjugate (in the above sense) to those of the former. Projecting orthogonally on a plane parallel to the central axis we obtain two reciprocal figures.

In the analogous theory of infinitely small displacements of a solid, a "null-line" is a line such that the lengthwise displacement of any point on it is zero. Since a wrench is defined by six independent quantities, it can in general be replaced by any system of forces which involves six adjustable elements. For instance, it can in general be replaced by six forces acting in six given lines, e.g. in the six edges of a given tetrahedron. An exception to the general statement occurs when the six lines are such that they are lines of action of a system of six forces in equilibrium; they are then said to be in involution. The theory of systems of forces in involution has been studied by A. Cayley, J. J. Sylvester and others. We have seen that a rigid structure may in general be rigidly connected with the earth by six links, and that a system of forces acting on the structure can in general be balanced by six determine forces exerted on these links. If, however, the links are in involution, these forces become infinite or indeterminate. There is a corresponding kinematic peculiarity, in that the connection is now not strictly rigid, an infinitely small relative displacement being possible. See § 9.

When parallel forces of given magnitudes act at given points, the resultant acts through a definite point, or centre of parallel forces, which is independent of the special direction of the forces. If \( P \) be the force at \((x, y, z)\), acting in the direction \((l, m, n)\), the formulæ (6) and (7) reduce to
\[ X = \Sigma(P), \quad Y = \Sigma(P), \quad Z = \Sigma(P), \quad n, \]
and
\[ L = \Sigma(P), \quad (ny - mz), \quad M = \Sigma(P), \quad (lx - n), \quad N = \Sigma(P), \quad (mz - ly). \]

These are the same as if we had a single force \( \Sigma(P) \) acting at the point \((x, y, z)\), which is the same for all directions \((l, m, n)\).

An exceptional case occurs when \( \Sigma(P) = 0 \).

If we imagine a rigid body to be acted on at given points by forces of given magnitudes in directions (not all parallel) which are fixed in space, then as the body is turned about the resultant wrench will assume different configurations in the body, and will in certain positions reduce to a single force. The investigation of such questions forms the subject of "Astatics," which has been cultivated by Möbius, Minding, G. Darboux and others. As it has no physical bearing it is passed over here.

§ 9. Work.—The work done by a force acting on a particle, in any infinitely small displacement, is defined as the product of the force into the orthogonal projection of the displacement on the direction of the force, i.e. it is equal to \( F \cdot \delta \cdot \cos \theta \), where \( F \) is the force, \( \delta \) the displacement, and \( \theta \) is the angle between the directions of \( F \) and \( \delta \).

In the language of vector analysis \((q, r)\) it is the "scalar product" of the vector representing the force and the displacement. In the same way, the work done by a force acting on a rigid body in any infinitely small displacement of the body is the scalar product of the force into the displacement of any point on the line of action. This product is the same whatever point on the line of action be taken, since the lengthwise components of the displacements of any two points \( A, B \) on a line \( AB \) are equal, to the first order of small quantities.

To see this, let \( A', B' \) be the displaced positions of \( A, B \), and let \( \phi \) be the infinitely small angle between \( AB \) and \( A'B' \). Then if

\[ \text{Fig. 45.} \]

\[ a, \beta \text{ be the orthogonal projections of } A', B' \text{ on } AB, \]

\[ \text{we have } \alpha - \beta = AB - \alpha a = AB(1 - \cos \phi) = AAB \cdot e^\phi. \]

ultimately. Since this is of the second order, the products \( F \cdot a \) and \( F \cdot \beta \) are ultimately equal.

The total work done by two concurrent forces acting on a particle, or on a rigid body, in any infinitely small displacement, is equal to the work of their resultant. Let \( AB, AC \) (fig. 46) represent the forces, \( AD \) their resultant, and let \( AH \) be the direction of the displacement \( \delta \) of the point \( A \). The proposition follows at once from the fact that the sum of orthogonal projections of \( AB, AC \) on \( AH \) is equal to the projection of \( AD \).

It is to be noticed that \( AH \) need not be in the same plane with \( AB, AC \).

It follows from the preceding statements that any two systems
of forces which are statically equivalent, according to the principles of §§ 4, 8, will (to the first order of small quantities) do the same amount of work in any infinitely small displacement of a rigid body to which they may be applied. It is also evident that the total work done in two or more successive infinitely small displacements is equal to the work done in the resultant displacement.

The work of a couple in any infinitely small rotation of a rigid body about an axis perpendicular to the plane of the couple is equal to the product of the moment of the couple into the angle of rotation, proper conventions as to sign being observed. Let the couple consist of two forces \( \mathbf{P}, \mathbf{P} \) (fig. 47) in the plane of the paper, and let \( \mathbf{J} \) be the point where this plane is met by the axis of rotation. Draw \( \mathbf{JBA} \) perpendicular to the lines of action, and let \( \epsilon \) be the angle of rotation. The work of the couple is

\[
P \cdot A \mathbf{J} \sin \epsilon.
\]

The analytical calculation of the work done by a system of forces in any infinitesimal displacement is as follows. For a two-dimensional system we have, in the notation of §§ 3, 4,

\[
\Sigma (X X \epsilon + Y Y \epsilon) = 2 \Sigma (X \epsilon + Y \epsilon) + 2 \Sigma (X \epsilon + Y \epsilon) = \Sigma x \epsilon + \Sigma y \epsilon.
\]

Again, for a three-dimensional system, in the notation of §§ 7, 8,

\[
\Sigma (X X \epsilon + Y Y \epsilon + Z Z \epsilon) = 2 \Sigma (X \epsilon + Y \epsilon + Z \epsilon) + \Sigma (X \epsilon + Y \epsilon + Z \epsilon) = \Sigma x \epsilon + \Sigma y \epsilon + \Sigma z \epsilon.
\]

This expression gives the work done by a given wrench when the body receives a given infinitely small twist; it must of course be an absolute invariant for all transformations of rectangular axes. The first three terms express the work done by the components of a force \( X, Y, Z \) acting at \( O \), and the remaining three terms express the work of a couple \( L, M, N \).

The work done by a wrench about a given screw, when the body twists about a second given screw, may be calculated directly as follows. In fig. 48 let \( G \) be the force and couple of the wrench, \( \epsilon, \theta \) the rotation and translation in the twist. Let \( \mathbf{R} \) be the moment of the couple.

\[
\frac{dR}{d \epsilon} = \frac{G \cos \theta - \epsilon \sin \theta}{G \cos \theta - e \sin \theta}.
\]

The work is therefore

\[
R = \int_{\theta} \left( \frac{G \cos \theta - \epsilon \sin \theta}{G \cos \theta - e \sin \theta} \right) d \theta,
\]

where \( R \) is the work done by the wrench and the twist is inclined at an angle \( \theta \), and \( e \) is the shortest distance between them. The displacement of the point \( H \) in the figure, resolved in the direction of \( \mathbf{R} \), is \( \tau \) cos \( \theta - e \sin \theta \).

Two screws are reciprocal when a wrench about one does not work on a body which twists about the other. The condition for this is

\[
\lambda \mu + \mu \nu + \nu \lambda = 0,
\]

in the analytical investigations of line geometry, these six quantities, supposed subject to the relation (4), are used to specify a line, and are called the six "co-ordinates" of the line; they are of course equivalent to only four independent quantities. If a line is a null-line with respect to the wrench \( X, Y, Z, L, M, N \), the work done in an infinitely small rotation about it is zero, and its co-ordinates are accordingly subject to the further relation

\[
L + M + N + 2 \lambda \mu = 0,
\]

where the coefficients are constant. This is the equation of a "linear complex" (cf. § 8).

Two screws are said to be equal when a wrench about one does not work on a body which twists about the other. The condition for this is

\[
\lambda \mu = \mu \nu + \nu \lambda = 0,
\]

if the screws be defined by the ratios \( \epsilon : \eta : \lambda : \mu : \nu: \varepsilon, \gamma: \xi: \eta: \zeta: \mu: \nu, \).
the internal stresses, provided the hypothetical displacements be such that none of the connections of the system are violated.

If the system be subject to gravity, the corresponding part of the virtual work can be calculated from the displacement of the centre of gravity. If \( W_1, W_2, \ldots \) be the weights of a system of particles, whose depths below a fixed horizontal plane of reference are \( z_1, z_2, \ldots \), respectively, the virtual work of gravity is

\[
W_{2k} + W_{2k+1} + \ldots = 8(W_1 + W_2 + \ldots)
\]

where 8 is the depth of the centre of gravity (see § 8 (14) and § 11 (6)). This expression is the same as if the whole mass were concentrated at the centre of gravity, and displaced with this point. An important conclusion is that in any displacement of a system of bodies in equilibrium, such that the virtual work of all forces except gravity may be ignored, the depth of the centre of gravity is "stationary."

The question as to stability of equilibrium belongs essentially to kinetics; but we may state by anticipation that in cases where gravity is the only force which does work, the equilibrium of a body or system of bodies is stable only if the depth of the centre of gravity be a maximum.

Consider, for instance, the case of a bar resting with its ends on two smooth inclines (Fig. 6). If the bar may be displaced in a horizontal plane so that its ends slide on the two inclines, the instantaneous centre is at the point J. The displacement of G is at right angles to JG; this shows that for equilibrium JG must be vertical. Again, the locus of G is an arc of an ellipse centred in the intersection of the planes; since this arc is convex upwards the equilibrium is unstable. A general criterion for the case of a rigid body moveable in two dimensions, with one degree of freedom, can be obtained as follows. We have seen (§ 3) that the sequence of possible positions is obtained if we imagine the "body-centre" to roll on the "space-centre." For equilibrium, the altitude of the centre of gravity G must be stationary; hence G must lie in the same vertical line as the point of contact J of the two curves. Further, it is known from the theory of "rotteles" that the locus of G will be concave or convex upwards according as

\[
\phi = \frac{1}{\rho - \rho'} + \frac{1}{\rho''}
\]

where \( \rho, \rho' \) are the radii of curvature of the two curves at J, \( \phi \) is the inclination of the common tangent at J to the horizontal, and \( h \) is the height of G above J. The signs of \( \rho, \rho' \) are to be taken positive when the curves are as in the standard case shown in fig. 49. Hence for stability the upper sign must obtain in (8). The same criterion may be arrived at in a more intuitive manner as follows. If the body be supposed to roll (say to the right) until the curves touch at J, and then roll on the resultant projection of the lower curve on the vertical through which the upper figure rotates is \( \delta \rho + \delta \rho' \), and the horizontal displacement of G is equal to the product of this expression into \( h \). If this displacement be less than the horizontal projection of \( J' \), viz. \( \delta \rho \cos \phi \), the vertical through the new position of G will fall to the left of \( J' \) and gravity will tend to restore the body to its former position. It is here assumed that the remaining forces acting on the body in its displaced position have zero moment about \( J' \); this is evidently the case, for instance, in the problem of "rocking stones."

The principle of virtual work is specially convenient in the theory of frames (§ 6), since the reactions at smooth joints and the stresses in inextensible bars may be left out of account. In particular, in the case of a frame which is just rigid, the principle enables us to calculate the internal forces in the bar independently of the rest. If we imagine the bar in question to be removed, equilibrium will still persist if we introduce two equal and opposite forces \( S \), of suitable magnitude, at the joints which it connected. In any infinitely small deformation of the frame as thus modified, the virtual work of the forces \( S \), together with that of the original extraneous forces, must vanish; this determines \( S \).

As a simple example, take the case of a light frame, whose bars form the slides of a rhombus ABCD with the diagonal BD, suspended from A and carrying a weight W at C; and let it be required to find the stress in BD. If we remove the bar BD, and apply two equal and opposite forces \( S \) at B and D, the equation is

\[
W. \delta (2\cos \theta + 2S. \delta (\sin \theta) = 0
\]

where \( l \) is the length of a side of the rhombus, and \( \theta \) its inclination to the vertical. Hence

\[
S = W \tan \theta = \frac{W}{BD}.AC
\]

The method is specially appropriate when the frame, although just rigid, is not "simple" in the sense of § 6, and when accordingly the method of reciprocal figures is not immediately available. To avoid the intricate trigonometrical calculations which would often be necessary, graphical devices have been introduced by H. Müller-Breslau and others. For this purpose the infinitesimal displacements of the various joints are replaced by finite lengths proportional to them, and therefore proportional to the velocities of the joints in some imagined motion of the deformable frame through its actual configuration; this is really (it may be remarked) a reversion to the original notion of "virtual velocities." Let \( J \) be the instantaneous centre for any bar CD (fig. 12), and let \( s_1, s_2 \) represent the virtual velocities of \( C, D \). If these lines be turned through a right angle in the same sense, they take up positions such as C', D', where \( C', D' \) are on JC, JD, respectively, and C'D' is parallel to CD. Further, if FJ (fig. 51) be any force acting on the joint C, its virtual work will be equal to the moment of \( FJ \) about \( C' \); the equation of virtual work is thus transformed into an equation of moments.

Consider, for example, a frame whose sides form the six sides of a hexagon ABCDEF and the three diagonals AD, BE, CF; and suppose that it is required to find the stress in CF due to a given system of extraneous forces in equilibrium, acting on the joints. Imagine the bar CF to be removed, and consider a deformation in which AB is fixed. The instantaneous centre of CD will be at the intersection of AD, BC, and if C'D' will be drawn parallel to CD, the lines CC', DD' may be taken to represent the virtual velocities of C, D, C', D', respectively.

The equation of virtual work is then formed by taking moments about C', D', E', F' of the extraneous forces which act at C, D, E, F, respectively. Amongst these forces we must include the two equal and opposite forces \( S \) which take the place of the stress in the removed bar PC. The above method lends itself naturally to the investigation of the critical forms of a frame whose general structure is given. We have seen that the stresses produced by an equilibrating system of extraneous forces in a frame which is just rigid, according to the section of § 6, are in general uniquely determinate; in particular, when there are no extraneous forces the bars are in general free from stress. It may however happen that owing to some special relation between the lengths of the bars the frame admits of an infinitesimal deformation. The simplest case is that of a frame of three bars, when the three joints A, B, C fall into a straight line; a small displacement of the joints in any right angles to AC would involve changes in the lengths of AB, BC which are only of the second order of small quantities. Another example is shown in fig. 53. The graphical method leads at once to the detection of such cases. Thus in the hexagonal frame of fig. 52, an infinitesimal deformation is possible without removing the bar CF, the instantaneous centre of CF (when AB is fixed) will be at the intersection of AF and BC, and since CC', FF' represent the virtual velocities of the points C, F, turned each through a right angle, CC', FF' must be parallel to AF. Conversely, if this condition be satisfied, an infinitesimal deformation is possible. The result may be generalized into the statement that a frame has a critical form whenever a frame of the same structure can be designed.
MECHANICS

with corresponding bars parallel, but without complete geometric similarity. In the case of fig. 52 it may be shown that an equivalent condition is that the six points A, B, C, D, E, F should lie on a conic (M. W. Crofton). This is fulfilled when the opposite sides of the hexagon are parallel, and (as a still more special case) when the hexagon is regular.

When a frame has a critical form it may be in a state of stress independently of the action of extraneous forces; moreover, the stresses due to extraneous forces are indeterminate, and may be infinite. For suppose as before that one of the bars is removed. If there are no extraneous forces the equation of virtual work reduces to \( S \cdot \delta \beta = 0 \), where \( S \) is the stress in the removed bar, and \( \delta \beta \) is the change in the distance between the joints which it connected. In a critical form we have \( \delta \beta = 0 \), and the equation is satisfied by an arbitrary value of \( S \); a consistent system of stresses in the remaining bars can then be found by preceding rules. Again, when extraneous forces \( P \) act on the joints, the equation is

\[ \Sigma (P \cdot \delta P) + S \cdot \delta \beta = 0, \]

where \( \delta \beta \) is the displacement of any joint in the direction of the corresponding force \( P \). If \( \Sigma (P \cdot \delta P) = 0 \), the stresses are merely indeterminate as before; but if \( \Sigma (P \cdot \delta P) \) does not vanish, the equation cannot be satisfied by any finite value of \( S \), since \( \delta \beta = 0 \). This means that, if the material of the frame were absolutely unyielding, no finite stresses in the bars would enable it to withstand the extraneous forces. With actual materials, the frame would yield elastically, until its configuration is no longer "critical." The stresses in the bars would then be comparatively very great, although infinite; the use of frames which approximate to a critical form is of course to be avoided in practice.

A brief reference must suffice to the theory of three-dimensional frames. This is important from a technical point of view, since all structures are practically three-dimensional. We may note that a frame of \( n \) joints which is just rigid must have \( 3n - 6 \) bars; and that the stresses produced in such a frame by a given system of extraneous forces in equilibrium are statically determinate, subject to the exception of "critical forms."

§ 10. Statics of Inextensible Chains.—The theory of bodies or structures which are deformable in their smallest parts belongs properly to elasticity (q.v.). The case of inextensible strings or chains is, however, so simple that it is generally included in expositions of statics.

It is assumed that the form can be sufficiently represented by a plane curve, that the stress (tension) at any point of the curve, between the two portions which meet there, is in the direction of the tangent at \( P \), and that the forces on any linear element \( \delta \alpha \) must satisfy the conditions of equilibrium laid down in § 1. It follows that the forces on any finite portion will satisfy the conditions of equilibrium which apply to the case of a rigid body (§ 4).

We will suppose in the first instance that the curve is plane. It is often convenient to resolve the forces on an element \( PQ (= \delta \alpha) \) in the directions of the tangent and normal respectively.

If \( T, T + \delta T \) be the tensions at \( P, Q \), and \( \delta \psi \) be the angle between the directions of the curvatures at these points, the components of the tensions along the tangent at \( P \) give \( (T + \delta T) \cos \psi - T \), or \( \delta T \), ultimately; whilst for the component along the normal at \( P \) we have \( (T + \delta T) \sin \delta \psi \), or \( \delta T \).

\[ T = \text{const.}, \quad R = T/\rho. \]

The tension is constant, and the pressure per unit length varies as the curvature.

Next suppose that the curve is "rough"; and let \( F_x \) be the tangential force of friction on \( \delta \alpha \). We have \( \delta T = F_x \delta \alpha = 0 \), \( \delta T \psi = R \delta \alpha \), where the upper or lower sign is to be taken according to the sense in which \( F \) acts. We assume that in limiting equilibrium we have \( F = \mu R \), everywhere, where \( \mu \) is the coefficient of friction. If the string be on the point of slipping in the direction in which \( \psi \) increases, the lower sign is to be taken; hence \( \delta T = F \alpha = \mu T \psi \), whence

\[ T = T_{\text{max}}. \]

If \( T \) be the tension corresponding to \( \psi = 0 \). This illustrates the resistance to dragging of a rope coiled round a post; e.g. if we put \( \psi = -3 \), \( \psi = \pi \), we find for the change of tension in one turn \( T/T_{\text{max}} = 6.5 \). In two turns this ratio is squared, and so on.

Again, take the case of a string under gravity, in contact with a smooth curve in a vertical plane. Let \( \psi \) denote the inclination to the horizontal, and \( \psi \) the weight of an element \( \delta \alpha \). The tangential and normal components of \( \psi \) are \( -w \delta \sin \psi \) and \( -w \delta \cos \psi \). Hence

\[ \delta T = -w \delta \sin \psi, \quad \delta T \psi = -w \delta \cos \psi + R \delta \psi. \]

If we take rectangular axes \( O x, O y \), of which \( Oy \) is drawn vertically upwards, we have \( \delta y = \sin \delta \psi \), whence \( \delta T = w \delta y \).

If the string be uniform, \( w \) is constant, and

\[ T = w \delta y + \text{const.} = w(y - y_0), \]

say; hence the tension varies as the height above some fixed level \( y_0 \). The pressure is then given by the formula

\[ \frac{R}{T} = \frac{1}{w} \cos \psi. \]

In the case of a chain hanging freely under gravity it is usually convenient to formulate the conditions of equilibrium of a finite portion \( PQ \). The forces on this reduce to three, viz. the weight of \( PQ \) and the tensions at \( P, Q \). Hence these three forces will be concurrent, and their ratios will be given by a triangle of forces. In particular, if we consider a length \( AP \) beginning at the lowest point \( A \), then resolving horizontally and vertically we have

\[ T \cos \psi = T_0, \quad T \sin \psi = W, \]

where \( T_0 \) is the tension at \( A \), and \( W \) is the weight of \( PA \). The former equation expresses that the horizontal tension is constant.

If the chain be uniform we have \( W = w s \), where \( s \) is the arc \( AP \); hence \( w = T_0 \tan \psi \). If we write \( T_0 = w \delta \alpha \), so that \( \delta \alpha \) is the length of a portion of the chain whose weight would equal the horizontal tension, this becomes

\[ \delta \alpha = \tan \psi. \]

This is the "intrinsic" equation of the curve. If the axes of \( x \) and \( y \) be taken horizontal and vertical (upwards), we derive

\[ x = a \log (sec \psi + tan \psi), \quad y = a \sec \psi. \]

Eliminating \( \psi \) we obtain the Cartesian equation

\[ y = a \cosh \frac{x}{a}, \]

of the common catenary, as it is called (fig. 56). The omission of the additive arbitrary constants of integration in (8) is equivalent to a special choice of the origin \( O \) of co-ordinates; viz. \( O \) is at a distance \( a \) vertically below the lowest point \( (\psi = 0) \) of the curve. The horizontal line through \( O \) is called the directrix. The relations

\[ x = a \sinh \frac{s}{a}, \quad y = a \cosh \frac{s}{a}, \quad s = T_0 \sec \psi = w y, \]

where
which are involved in the preceding formulæ are also noteworthy. It is a classical problem in the calculus of variations to deduce the equation (9) from the condition that the depth of the centre of gravity of a chain of given length hanging between fixed points must be stationary (§ 9). The length $a$ is called the parameter of the catenary; it determines the scale of the curve, all catenaries being geometrically similar. If $\lambda$ is the mass per unit length of a hanging chain, the intervening portions will form arcs of equal catenaries, since the horizontal tension (ton) is the same for all. Again, if a chain pass over a perfectly smooth peg, the catenaries in which it hangs on the two sides, though usually of different parameters, will have the same directrix, since by (10) $y$ is the same for both at the peg.

As an example of the use of the formulæ we may determine the maximum span for a wire of given material. The condition is that the tension must not exceed the weight of a certain length $\lambda$ of the wire. At the ends we shall have $y = \lambda$, or

$$\lambda = a \cosh \frac{x}{a},$$

and the problem is to make $x$ a maximum for variations of $a$. Differentiating (11) we find that, if $\frac{dx}{da} = 0$,

$$\frac{x}{a} \tan \frac{x}{a} = 1.$$

It is easily seen graphically, or from a table of hyperbolic tangents, that the equation $a \tan h = 1$ has only one positive root ($a = 1 - 200$); the span is therefore

$$2 \lambda = 2au = 2\lambda / \sinh a = 1 - 132 \lambda,$$

and the length of wire is

$$22 = 2\lambda u = 1 - 667 \lambda.$$

The tangents at the ends meet on the directrix, and their inclination to the horizontal is $56^\circ 30^\prime$.

The relation between the sag, the tension, and the span of a wire (e.g. a telegraph wire) stretched nearly straight between two points $A$, $B$ at the same level is determined most simply from first principles. If $T$ be the tension, $W$ the total weight, $k$ the sag in the middle, and

$$\begin{align*}
\psi & \text{ the inclination to the horizontal at } A \text{ or } B, \text{ we have } 2T\psi = W, \\
AB & = 2au, \text{ approximately, where } \rho \text{ is the radius of curvature. Since } \\
2k = 3A, & \text{ or } A \text{ would be the sag, measured vertically, half way between } A \text{ and } B.
\end{align*}$$

The same formula applies if $A$, $B$ be at different levels, provided $k$ be the sag, measured horizontally, half way between $A$ and $B$.

In relation to the theory of suspension bridges the case where all or any portion of the chain varies as its horizontal projection is of interest. The vertical through the centre of gravity of the arc AP (see fig. 55) will then bisect its horizontal projection AN; hence if PS be the tangent at $P$ we shall have $AS = SN$. This property is characteristic of a parabola whose axis is vertical. If we take $A$ as origin and $AN$ as axis of $x$, the weight of AP may be denoted by $w$, where $w$ is the weight per unit length at $A$. Since $PNS$ is a triangle of forces for the portion AP of the chain, we have $w2T/\sin \theta = PNS$, or

$$y = w . x^2/2T_0,$$

which is the equation of the parabola in question. The result might of course have been inferred from the theory of the parabolic funicular in § 2.

Finally, we may refer to the catenary of uniform strength, where the cross-section of the wire (or cable) is supposed to vary as the tension. Hence $w$, the weight per foot, varies as $T$, and we may write $T = \lambda w$, where $\lambda$ is a constant length. Resolving along the normal the forces on an element $dx$, we find $T \psi = 2\rho w \cos \psi$, whence

$$\rho = \frac{dx}{d\psi} = \lambda \sec \psi.$$

From this we derive

$$x = \lambda \psi, \quad \psi = \lambda \log \sec \frac{x}{\lambda},$$

where the directions of $x$ and $y$ are horizontal and vertical, and the origin is taken at the lowest point. The curve (fig. 58) has two vertical asymptotes $x = \pi \lambda / 2$; this shows that however the thickness of a cable be adjusted there is a limit $\pi \lambda$ to the horizontal span, where $\lambda$ depends on the tensile strength of the material. For a uniform catenary the limit was found above to be $1 - 326 \lambda$.

![Fig. 58.](image-url)

For investigations relating to the equilibrium of a string in three dimensions we must refer to the textbooks. In the case of a string stretched over a smooth surface, but in other respects free from extraneous force, the tensions at the ends of a small element $dx$ must be balanced by the normal reaction of the surface. It follows that the osculating plane of the curve formed by the string must contain the normal to the surface, i.e. the curve must be a "geodesic," and that the normal pressure per unit length must vary as the principal curvature of the curve.

§ 11. Theory of Mass-Systems.—This is a purely geometrical subject. We consider a system of points $P_1, P_2, \ldots, P_n$, with which are associated certain co-efficients $m_1, m_2, \ldots, m_n$, respectively. In the application to mechanics these coefficients are the masses of particles situated at the respective points, and are therefore all positive. We shall make this supposition in what follows, but it should be remarked that hardly any difference is made in the theory if some of the coefficients have a different sign from the rest, except in the special case where $\Sigma(m) = 0$. This has a certain interest in magnetism.

In a given mass-system there exists one and only one point $G$ such that

$$\Sigma(mGP) = 0.$$  

For, take any point $O$, and construct the vector

$$\text{OG} = \frac{\Sigma(mOG)}{\Sigma(m)}.$$

Then

$$\Sigma(mGP) = \Sigma(m(OG + OP)) = \Sigma(m).OG + \Sigma(m).OP = 0.$$

Also there cannot be a distinct point $G'$ such that $\Sigma(m, GP') = 0$, for we should have, by subtraction,

$$\Sigma(m(GP - GP')) = 0, \quad \text{or } \Sigma(m).GG' = 0;$$

i.e. $G'$ must coincide with $G$. The point $G$ determined by (1) is called the mass-centre or centre of inertia of the given system. It is easily seen that, in the process of determining the mass-centre, any group of particles may be replaced by a single particle whose mass is equal to that of the group, situate at the mass-centre of the group.

If through $P_1, P_2, \ldots, P_n$ we draw any system of parallel planes meeting a straight line $OX$ in the points $M_1, M_2, \ldots, M_n$, the collinear vectors $OM_1, OM_2, \ldots, OM_n$ may be called the "projections" of $OP_1, OP_2, \ldots, OP_n$ on $OX$. Let these projections be denoted algebraically by $x_1, x_2, \ldots, x_n$, the sign being positive or negative according as the direction is that of $OX$ or the reverse. Since the projection of a vector-
sum is the sum of the projections of the several vectors, the equation (2) gives
\[ \mathbf{x} = \sum (\mathbf{m}_x) \mathbf{S}(m) \]  
(5)
for \( \mathbf{x} \) the projection of \( \mathbf{O} \). Hence if the Cartesian co-ordinates of \( P_1, P_2, \ldots, P_n \) relative to the axes, rectangular or oblique be \((x_1, y_1, z_1), (x_2, y_2, z_2), \ldots, (x_n, y_n, z_n)\), the mass-centre \((\bar{x}, \bar{y}, \bar{z})\) is determined by the formulae
\[ \bar{x} = \sum (m_x) \mathbf{S}(m) = \bar{y} = \sum (m_y) \mathbf{S}(m) = \bar{z} = \sum (m_z) \mathbf{S}(m) \]  
(6)
whence
\[ \Sigma(\mathbf{m}_x) = \bar{x} \]  
\[ \Sigma(\mathbf{m}_y) = \bar{y} \]  
\[ \Sigma(\mathbf{m}_z) = \bar{z} \]  
(7)
One or two special cases may be noticed. If three masses \( a, \beta, \gamma \) be situated at the vertices of a triangle ABC, the mass-centre of \( \beta \) and \( \gamma \) is at a point \( V \) in BC, such that \( \beta BV = \gamma VC \). The mass-centre \((G)\) of \( a, \beta, \gamma \) will then divide AA' so that \( AG = (\beta + \gamma) \mathbf{G} \mathbf{N} \). It is easily proved that
\[ \alpha + \beta + \gamma = \frac{ADG}{\Delta GCA} = \frac{\Delta GCA}{\Delta DAB} \]  
also, by giving suitable values (positive or negative) to the ratios \( a : \beta : \gamma \) we can make \( G \) assume any assigned position in the plane ABC. We have here the origin of the "barycentric co-ordinates" of Moebius, now usually known as "areal" co-ordinates. If \( a + \beta + \gamma = 0 \), \( G \) is at infinity; if \( a = 0 \), \( \gamma = 0 \), \( G \) is at the intersection of the median lines of the triangle; if \( \alpha = \beta \) \( = \gamma = 0 \), \( G \) is at the centre of the inscribed circle. Again, if \( G \) be the mass-centre of four particles \( a, \beta, \gamma, \delta \) situated at the vertices of a tetrahedron ABCD, we find
\[ \alpha + \beta + \gamma + \delta = \frac{ABG}{\Delta ABC} = \frac{\Delta ABC}{\Delta DAB} \]  
(8)
and by suitable determination of the ratios on the left hand we can make \( G \) assume any assigned position in space. If \( G \) be the mass-centre of \( n \) particles at the vertices of a n-sided, \( G \) denoted by \((7)\) Gibbs, \( G \) divides points of opposite edges of the tetrahedron ABCD; if \( a : \beta : \gamma = \frac{\Delta BCD}{\Delta ABC} = \frac{\Delta DAB}{\Delta ABC} \) at the centre of the inscribed sphere.

If we have a continuous distribution of matter, instead of a system of discrete particles, the summations in (6) are to be replaced by integrations. Examples will be found in textbooks of the calculus and of analytical statics. As particular cases; the mass-centre of a uniform thin triangular plate coincide with that of three equal particles at the corners; and that of a uniform solid tetrahedron coincides with that of four equal particles at the vertices. Again, the mass-centre of a uniform solid right circular cone divides the axis in the ratio \( 3 : 1 \); that of a uniform solid hemisphere divides the radial axis in the ratio \( 3 : 5 \).

It is easily seen from (6) that if the configuration of a system of particles be altered by "homogeneous strain" (see ELASTICITY) the new position of the mass-centre will be at that point of the strained figure which corresponds to the original mass-centre.

The formula (2) shows that a system of concurrent forces represented by \( m_1 \mathbf{O}P_1, m_2 \mathbf{O}P_2, \ldots, m_n \mathbf{O}P_n \), will have a resultant represented by \( \Sigma(m) \mathbf{O} \). If we imagine O to recede to infinity in any direction we learn that a system of parallel forces proportional to \( m_1, m_2, \ldots, m_n \), acting at \( P_1, P_2, \ldots, P_n \), have a resultant proportional to \( \Sigma(m) \) which acts always through a point \( G \) fixed relatively to the given mass-system. This contains the theory of the "centre of gravity" (§§ 4, 9). We may note also that if \( P_1, P_2, \ldots, P_n \), and \( P'_1, P'_2, \ldots, P'_n \), represent two configurations of the series of particles, then
\[ \Sigma(m) \mathbf{P} \mathbf{P'} = \Sigma(m) \mathbf{G} \mathbf{G'} \]  
(8)
where \( G, G' \) are the two positions of the mass-centre. The forces \( m_1 \mathbf{P} \mathbf{P'}_1, m_2 \mathbf{P} \mathbf{P'}_2, \ldots, m_n \mathbf{P} \mathbf{P'}_n \), considered as localized vectors, do not, however, as a rule reduce to a single resultant. We proceed to the theory of the plane, axial and polar quadratics, moments of the system. The numerical moments have alone a dynamical significance, but the others are useful as subsidiary conceptions. If \( h_1, h_2, \ldots, h_n \) be the perpendicular distances of the particles from any fixed plane, the sum \( \Sigma(mh) \) is the quadratic moment with respect to the plane. If \( p_1, p_2, \ldots, p_n \) be the perpendicular distances of any given axis, the sum \( \Sigma(mp) \) is the quadratic moment with respect to the axis; it is also called the moment of inertia about the axis. If \( r_1, r_2, \ldots, r_n \) be the distances from a fixed point, the sum \( \Sigma(mr^2) \) is the quadratic moment with respect to that point (or pole). If we divide any of the above quadratic moments by the total mass \( \Sigma(m) \), the result is called the mean square of the distances of the particles from the respective plane, axis or pole. In the case of an axial moment, the square root of the resulting mean square is called the radius of gyration of the system about the axis in question. If we take rectangular axes through any point \( O \), the quadratic moments with respect to the co-ordinate planes are
\[ I_x = \Sigma(m_{xy^2}), \quad I_y = \Sigma(m_{yz^2}), \quad I_z = \Sigma(m_{zx^2}) \]  
(9)
whilst the polar quadratic moment with respect to \( O \) is
\[ I = \Sigma(m_{xy^2} + m_{yz^2} + m_{zx^2}) \]  
(10)
We note that
\[ I_x = I_1 + I_2, \quad I_y = I_1 + I_2, \quad I_z = I_1 + I_2, \]  
(11)
and
\[ I = I_1 + I_2 + I_3, = (I_1 + I_2 + I_3) \]  
(12)
In the case of continuous distributions of matter the summations in (9), (10), (11) are of course to be replaced by integrations. For a uniform thin circular plate, we find, taking the origin at its centre, and the axis of \( z \) normal to its plane, \( I_z = \frac{1}{2} \mu^2 \), where \( \mu \) is the mass and \( a \) the radius. Since \( I_1 = 1, I_2 = 0 \), we deduce \( I_1 = \frac{1}{2} \mu^2 \), \( I_2 = \frac{1}{4} \mu^2 \); hence the value of the squared radius of gyration is for a diameter \( a^2 \), and for the axis of symmetry \( \frac{a^2}{2} \). Again, for a uniform solid sphere having its centre at the origin we find \( I_1 = \frac{1}{2} \mu^2 \), \( I_2 = I_3 = \frac{1}{3} \mu^2 \); hence, the square of the radius of gyration with respect to a diameter is \( \frac{a^2}{2} \). The method of homogeneous strain can be applied to produce the corresponding results for an ellipsoid of semi-axes \( a, b, c \). If the co-ordinate axes coincide with the principal axes, we find \( I_1 = \frac{1}{2} \mu^2 \), \( I_2 = \mu^2 \), \( I_3 = \frac{1}{2} \mu^2 \), whereas \( I_1 = \frac{1}{3} \mu^2 \), \( I_2 = \frac{1}{3} \mu^2 \), \( I_3 = \frac{1}{3} \mu^2 \), &c.

If \( (x, y, z) \) be any homogeneous quadratic function of \( x, y, z \), we have
\[ \Sigma(m \mathbf{x} \mathbf{y} \mathbf{z}) = \Sigma(m \mathbf{x} \mathbf{y} \mathbf{z}) \]  
\[ = 2 \mathbf{m} \mathbf{z} (x, y, z) \]  
(12)

and expresses that the mean square of the distances of the particles from \( O \) exceeds the square of the distance of \( O \) by the square of the distance of the particles from the centre of mass in terms of the masses and mutual distances. For instance, considering four equal particles at the vertices of a regular tetrahedron, we can infer that the radius \( R \) of the circumscribing sphere is given by \( R^2 = \frac{\sqrt{2}}{2} a^2 \), if \( \sqrt{2} \) be the length of an edge.

Another type of quadratic moment is supplied by the deviation-moments, or products of inertia of a distribution of matter. Thus the sum \( \Sigma(m \mathbf{y} \mathbf{z}) \) is called the "product of inertia" with respect to the planes \( y = o, z = o \). This may be expressed in terms of the product of inertia with respect to parallel planes through \( G \) by means of the formula (14); viz.:
\[ \Sigma(m \mathbf{y} \mathbf{z}) = \Sigma(m \mathbf{y} \mathbf{z}) \]  
(21)
The quadratic moments with respect to different planes through a fixed point O are related to one another as follows. The moment with respect to the plane

\[ \lambda x + \mu y + z = 0, \]

where \( \lambda, \mu, \nu \) are direction-cosines, is

\[ \Sigma(m(\lambda x + \mu y + z)) = \Sigma(m' z^2). \]

(22)

and therefore as the square of the perpendicular drawn from O to a tangent plane of a certain quadric surface, the tangent plane in question being parallel to (22). If the co-ordinate axes coincide with the principal axes of this quadric, we shall have

\[ \Sigma(mx^2) = 0, \quad \Sigma(zy^2) = 0, \quad \Sigma(zmxy) = 0; \]

(24)

and if we write

\[ M = \Sigma(m), \quad M_y = \Sigma(m'y), \quad M_{x} = \Sigma(mx'), \]

where \( M = \text{the moment of inertia about the origin.} \)

(25)

The ellipse (20) was first employed by J. Binet (1811), and may be called "Binet's Ellipsoid" for the point O. Evidently the quadratic moment for a variable plane through O will have a "stationary" value when, and only when, the plane coincides with a principal plane of (20). It may further be shown that if Binet's ellipsoid be referred to any system of conjugate diameters as co-ordinate axes, its equation will be

\[ \frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} = 1, \]

(26)

providing

\[ \Sigma(mx^2) = Ma^2, \quad \Sigma(my^2) = Mb^2, \quad \Sigma(mxz) = Mc^2; \]

also

\[ \Sigma(m'y^2) = 0, \quad \Sigma(mx'z') = 0, \quad \Sigma(mx'y') = 0. \]

(27)

Let us now take as co-ordinate axes the principal axes of inertia at the mass-centre G. If \( a, b, c \) be the semi-axes of the Binet's ellipsoid of G, the quadratic moment with respect to the plane \( \lambda x + \mu y + z = 0 \) will be \( M(a^2 x^2 + b^2 y^2 + c^2 z^2) \), and that with respect to a parallel plane

\[ \lambda x + \mu y + z = \rho \]

(28)

will be \( M(a^2 x^2 + b^2 y^2 + c^2 z^2) \), by (15). This will have a given value \( M \rho^2 \), provided

\[ \rho^2 = (k^2 + c^2)\lambda^2 + (k^2 + b^2)\mu^2 + (k^2 + a^2)\nu^2. \]

(29)

Hence the planes of constant quadratic moment \( M \rho^2 \) will envelop the quadric

\[ \frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} \rho^2 = 1, \]

(30)

and the quadrics corresponding to different values of \( \rho^2 \) will be confocal. If we write

\[ k^2 = a^2 + b^2 + c^2, \]

(31)

the equation (31) becomes

\[ \frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} \rho^2 = 1; \]

(32)

for different values of \( \rho^2 \) this represents a system of quadrics confocal with the ellipsoid

\[ \frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} = 1, \]

(33)

which we shall meet with presently as the "ellipsoid of gyration" at G. Now consider the tangent plane \( \omega \) at any point \( P \) of a confocal, the tangent plane \( \omega' \) at an adjacent point \( N \), and a plane \( \omega'' \) through \( P \) parallel to \( \omega' \). The distance between the planes \( \omega' \) and \( \omega'' \) will be of the second order of small quantities, and the quadratic moments with respect to \( \omega' \) and \( \omega'' \) will therefore be equal, to the first order. Since the quadratic moments with respect to \( \omega \) and \( \omega' \) are equal, it follows that \( \omega \) is a plane of stationary quadratic moment at \( P \), and therefore a principal plane of inertia at \( P \). In other words, the principal axes of inertia at \( P \) are the normals to the three confocal systems of the ellipsoid (33) which pass through \( P \). Moreover if \( x, y, z \) be the co-ordinates of \( P \), (33) is an equation to find the corresponding values of \( \theta; \) and if \( \theta_1, \theta_2, \theta_3 \) be the roots we find

\[ \theta_1 + \theta_2 + \theta_3 = \pi - \theta - \gamma, \]

(35)

where \( r^2 = x^2 + y^2 + z^2 \). The squares of the radii of gyration about the principal axes at \( P \) may be denoted by \( k^2 + k_1^2, \]

(36)

\( k^2 + k_3^2, k^2 + k_4^2 \); hence by (32) and (35) they are \( r^2 - \theta_1, \]

(37)

\( r^2 - \theta_2, r^2 - \theta_3 \), respectively.

To find the relations between the moments of inertia about different axes through any assigned point \( O \), we take \( O \) as origin.

(38)

The moment of inertia about any radius of the quadric (39) therefore varies inversely as the square of the length of this radius. When referred to its principal axes, the equation of the quadric takes the form

\[ A x^2 + B y^2 + C z^2 = M^2. \]

(39)

The directions of these axes are determined by the property (24), and therefore coincide with those of the principal axes of inertia at \( O \), as already defined in connexion with the theory of plane quadratic moments. The new \( A, B, C \) are called the principal moments of inertia at \( O \). Since they are essentially positive the quadric is an ellipsoid; it is called the momental ellipsoid at \( O \). Since, by (12), \( B + C = A, \) &c., the sum of the two lesser principal moments must exceed the greatest principal moment. A limitation is thus imposed on the possible forms of the momental ellipsoid; e.g. in the case of symmetry about an axis it appears that the ratio of the polar to the equatorial diameter of the ellipsoid cannot be less than \( 1/\sqrt{2} \).

If we write \( A = M a^2, \quad B = M b^2, \quad C = M c^2, \) the formula (37), when referred to the principal axes at \( O \), becomes

\[ I = M(a^2 x^2 + b^2 y^2 + c^2 z^2); \]

(32)

if \( \rho \) denotes the perpendicular drawn from \( O \) in the direction \( (\lambda, \mu, \nu) \) to a tangent plane of the ellipsoid

\[ \frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} = 1, \]

(34)

This is called the ellipsoid of gyration at \( O \); it was introduced into the theory by J. MacCullagh. The ellipsoids (41) and (43) are reciprocal polars with respect to a sphere having \( O \) as centre.

If \( A = B = C \), the momental ellipsoid becomes a sphere; all axes through \( O \) are then principal axes, and the moment of inertia is the same for each. The mass-system is then said to possess kinetic symmetry about \( O \).

If all the masses lie in a plane \( (z = 0) \) we have, in the notation of (25), \( c = 0 \), and therefore \( A = M a^2, \quad B = M b^2, \quad C = M(a^2 + b^2) \), so that the equation of the momental ellipsoid takes the form

\[ b^2 z^2 + a^2 x^2 + c^2 y^2 = c^2; \]

(42)

\[ b^2 x^2 + a^2 y^2 + c^2 z^2 = c^2. \]

(43)

The section of this by the plane \( z = 0 \) is similar to

\[ \frac{x^2}{a^2} + \frac{y^2}{b^2} = 1, \]

(44)

which may be called the momental ellipse at \( O \). It possesses the property that the radius of gyration about any diameter is half the distance between the two tangents which are parallel to that diameter. In the case of a uniform triangular plate it may be shown that the momental ellipse at \( G \) is concentric, similar and similarly situated.
MECHANICS

to the ellipse which touches the sides of the triangle at their middle points.

The graphical methods of determining the moment of inertia of a plane system of particles with respect to any line in its plane may be briefly noticed. It appears from § 5 (fig. 31) that the linear moment of each particle about the line may be found by means of a funicular polygon. If we replace the mass of each particle by its moment, as thus found, we can in like manner obtain the quadratic moment of the system with respect to the line. For if the line in question be the axis of \( y \), the first process gives us the values of \( mx \), and the second the value of \( \Sigma (mx^2) \) or \( \Sigma m^2 \).

The construction of a second funicular may be dispensed with by the employment of a planimeter, as follows. In fig. 59 \( p \) is the line with respect to which moments are to be taken, and the masses of the respective particles are indicated by the corresponding segments of a line in the force-diagram, drawn parallel to \( p \). The funicular \( ZABCD \) corresponding to any pole \( O \) is constructed for a system of forces acting parallel to \( p \) through the positions of the particles and proportional to the respective masses; and its successive sides are produced to meet \( p \) in the points \( H, K, L, M, \ldots \). As explained in § 5, the moment of the first particle is represented on a certain scale by \( HK \), that of the second by \( KL \), and so on. The momentary moment of the first particle will then be represented by twice the area \( AHK \), that of the second by twice the area \( BKL \), and so on. The quadratic moment of the whole system is therefore represented by twice the area \( AHEDCB \). Since a quadratic moment is essentially positive, the various areas are to be taken positive in all cases. If \( b \) be the radius of gyration about \( p \) we find

\[ b^2 = \sum x^2 \text{area } AHEDCB. \]

where \( a \) is the line in the force-diagram which represents the sum of the masses, and \( ON \) is the distance of the pole \( O \) from this line. If some of the particles lie on one side of \( p \) and some on the other, the quadratic moment of each set may be found, and the results added. This is illustrated in fig. 60, where the total quadratic moment is represented by the sum of the shaded areas. It is seen that for a given direction of \( p \) this moment is least when \( p \) passes through the intersection \( X \) of the first and last sides of the funicular; i.e. when \( p \) goes through the mass-centre of the given system; cf. equation (15).

PART II.—KINETICS

§ 12. Rectilinear Motion.—Let \( x \) denote the distance OP of a moving point \( P \) at time \( t \) from a fixed origin \( O \) on the line of motion, this distance being reckoned positive or negative according as it lies to one side or the other of \( O \). At time \( t + \delta t \) let the point be at \( Q \), and let \( OQ = x + \delta x \). The mean velocity of the point in the interval \( \delta t \) is \( \delta x / \delta t \). The limiting value of this when \( \delta t \) is indefinitely small, viz. \( dx/dt \), is adopted as the definition of the velocity at the instant \( t \). Again, let \( u \) be the velocity at time \( t, u + \delta u \) that at time \( t + \delta t \). The mean rate of increase of velocity, or the mean acceleration, in the interval \( \delta t \) is then \( \delta u / \delta t \).

The limiting value of this when \( \delta t \) is indefinitely small, viz. \( du/dt \), is adopted as the definition of the acceleration at the instant \( t \). Since \( u = dx/dt \), the acceleration is also denoted by \( d^2x/dt^2 \). It is often convenient to use the "fluxional" notation for differential coefficients with respect to the time; thus the velocity may be represented by \( \dot{x} \) and the acceleration by \( \ddot{x} \) or \( \dot{\dot{x}} \). There is another formula for the acceleration, in which \( u \) is regarded as a function of the position; thus \( \frac{d^2x}{dt^2} = \frac{du}{dx} \frac{dx}{dt} = \frac{du}{dx} \).

The relation between \( x \) and \( t \) in any particular case may be illustrated by means of a curve constructed with \( t \) as abscissa and \( x \) as ordinate. This is called the curve of positions or space-time curve; its gradient represents the velocity. Such curves are often traced mechanically in acoustical and other experiments. A curve with \( t \) as abscissa and \( u \) as ordinate is called the curve of velocities or velocity-time curve. Its gradient represents the acceleration, and the area \( \int u \, dt \) included between any two ordinates represents the space described in the interval between the corresponding instants (see fig. 62).

So far nothing has been said about the measurement of time. From the purely kinematic point of view, the \( t \) of our formulae may be any continuous independent variable, suggested (it may be) by some physical process. But from the dynamical standpoint it is obvious that equations which represent the facts correctly on one system of \( t \) might become seriously defective on another. It is found that for almost all purposes a system of measurement based ultimately on the rotation of the earth's axis is perfectly adequate. It is only when we come to consider such delicate questions as the influence of tidal friction that other standards become necessary.

The most important conception in kinetics is that of "inertia." It is a matter of ordinary observation that different bodies acted on by the same force, or what is judged to be the same force, undergo different changes of velocity in equal times. In our ideal representation of natural phenomena this is allowed for by endowing each material particle with a suitable mass or inertial coefficient \( m \). The product \( tu \) of the mass into the velocity is called the momentum or (in Newton's phrase) the quantity of motion. On the Newtonian system the motion of a particle entirely uninfluenced by other bodies, when referred to a suitable base, would be rectilinear, with constant velocity. If the velocity changes, this is attributed to the action of force; and if we agree to measure the force \( F \) by the rate of change of momentum which it produces, we have the equation

\[ \frac{du}{dt} (mu) = F. \]

From this point of view the equation is a mere truism, its real importance resting on the fact that by attributing suitable values to the masses \( m \), and by making simple assumptions as to the value of \( X \) in each case, we are able to frame adequate representations of whole classes of phenomena as they actually occur. The question remains, of course, as to how far the measurement of force here implied is practically consistent with the gravitational method usually adopted in statics; this will be referred to presently.

The practical unit or standard of mass must, from the nature of the case, be the mass of some particular body, e.g. the imperial pound, or the kilogramme. In the "C.G.S." system a subdivision of the latter, viz. the gramme, is adopted, and is associated with the centimetre as the unit of length, and the mean solar second as the unit of time. The unit of force implied in (1) is that which produces unit momentum in unit time. On the C.G.S. system it is that force which acting on one gramme for one second produces a velocity of one centimetre per second; this unit is known as the dyne. Units of this kind are called absolute on account of their fundamental and invariable character as contrasted with gravitational units, which (as we shall see presently) vary somewhat with the locality at which the measurements are supposed to be made.

If we integrate the equation (1) with respect to \( t \) between the limits \( t \), \( t' \) we obtain

\[ mu' - mu = \int_{t'}^t X \, dt. \]

The time-integral on the right-hand side is called the impulse of the force on the interval \( t' - t \). The statement that the increase of
momentum is equal to the impulse is (it may be remarked) equivalent to Newton's own formulation of his Second Law. The form (1) is deduced from it by putting \( t' = t = \beta t \), and taking \( \beta t \) to be infinitely small. In problems of impact we have to deal with cases of practically instantaneous impulse, where a very great and rapidly varying force produces an appreciable change of momentum in an exceedingly minute interval of time.

In the case of a constant force, the acceleration \( u \) or \( z \) is, according to (1), constant, and we have

\[
\frac{dx}{dt} = a,
\]

or the general solution of which is

\[
x = at + B.
\]

The "arbitrary constants" \( A, B \) enable us to represent the circumstances of any particular case; thus if the velocity \( x \) and the position \( z \) be given for any one value of \( f \), we have two conditions to determine \( A, B \). The curve of positions corresponding to (4) is a parabola, and that of velocities is a straight line. We may take it as an experimental result, although the best evidence is indirect, that a particle falling freely under gravity experiences a constant acceleration which at the same place is the same for all bodies. This acceleration is denoted by \( g \); its value at Greenwich is about 981 centimetre-second units, or 32.2 feet per second. It increases somewhat with the latitude, the extreme variation from the equator to the pole being about \( \frac{1}{14} \). We infer that on our reckoning the force of gravity on a mass is to be measured by \( mg \), the momentum produced per second when this force acts alone. Since this is proportional to the mass, the relative masses to be attributed to various bodies can be determined practically by means of the balance. We learn also that on account of the variation of \( g \) with the locality a gravitational system of force-measurement is inapplicable when more than a moderate degree of accuracy is desired.

We take next the case of a particle attracted towards a fixed point \( O \) in the line of motion with a force varying as the distance from that point. If \( f \) be the acceleration at unit distance, the equation of motion becomes

\[
\frac{dx}{dt^2} = -fz,
\]

the solution of which may be written in either of the forms

\[
x = A \cos (ct + B) \sin ct \quad \text{or} \quad x = a \cos (ct + \alpha),
\]

where \( a = \sqrt{\mu} \), and the two constants \( A, B \) or \( a, \alpha \) are arbitrary. The particle oscillates between the two positions \( x = \pm a, \) and the same point is passed through in the same direction with the same velocity at equal intervals of time \( 2\pi/t \). The type of motion represented by (6) is of fundamental importance in that the theory of vibrations (§ 23); it is called a simple-harmonic or (shortly) a simple vibration. If we imagine a point \( Q \) to describe a circle of radius \( a \) with the angular velocity \( \sigma \), its orthogonal projection \( P \) on a fixed diameter \( AA' \) will execute a vibration of this character. The angle \( \sigma t + \alpha \) (or AOQ) is called the phase; the arbitrary elements \( a, \alpha \) are called the amplitude and epoch (or initial phase), respectively. In the case of very rapid vibrations it is usual to specify, not the period \( 2\pi/\sigma \), but its reciprocal the frequency, i.e. the number of complete vibrations per unit time. Fig. 62 shows the curves of position and velocity; they both have the form of the "curve of sines." The numbers correspond to an amplitude of 10 centimetres and a period of two seconds.

The vertical oscillations of a weight which hangs from a fixed point by a spiral spring come under this case. If \( M \) be the mass, and \( x \) the vertical displacement from the position of equilibrium, the equation of motion is of the form

\[
M\frac{dx}{dt^2} = -Kx,
\]

provided the inertia of the spring itself be neglected. This becomes identical with (5) if we put \( \mu = K/M \); and the period is therefore \( 2\pi\sqrt{K/M} \), the same for all amplitudes. The period is increased by an increase of the mass \( M \), and diminished by an increase in the stiffness \( K \) of the spring. If \( c \) be the statical increase of length which is produced by the gravity of the mass \( M \), we have \( Kc = Mg \), and the period is \( 2\pi\sqrt{c/g} \).

The small oscillations of a simple pendulum in a vertical plane also come under equation (5). According to the principles of

\[
\text{Fig. 62.}
\]
be accepted as a representation of the initial stages of the forced oscillation. To obtain the complete solution of (11) we must of course superpose the free vibration (6) with its arbitrary constants in order to obtain a complete representation of the most general motion consequent on arbitrary initial conditions.

A simple mechanical illustration is afforded by the pendulum. If the point of suspension have an imposed simple vibration \( \xi = a \cos \omega t \) in a horizontal line, the equation of small motion of the bob is

\[
m \ddot{\xi} = -mg \frac{x - \xi}{l^2},
\]

or

\[
x + \xi = \frac{1}{2} \xi.
\]

This is the same as if the point of suspension were fixed, and a horizontal disturbing force \( mg \xi/l \) were to act on the bob. The difference of phase of the forced vibration in the two cases is illustrated and explained in the annexed fig. 63, where the pendulum virtually oscillates about \( C \) as a fixed point of suspension. This illustration was given by T. Young in connexion with the kinetic theory of the tides, where the same point arises.

We may notice also the case of an attractive force varying inversely as the square of the distance from the origin. If \( \mu \) be the acceleration at unit distance, we have

\[
u \frac{du}{dx} = -\frac{\mu}{x^2},
\]

whence

\[
u = \frac{2}{\mu} + C.
\]

In the case of a particle falling directly towards the earth from rest at a very great distance we have \( C = 0 \) and, by Newton's Law of Gravitation, \( u/d^2 = g \), where \( d \) is the earth's radius. The deviation of the earth's figure from sphericity, and the variation of \( g \) with latitude, are here ignored. We find that the velocity with which the particle would arrive at the earth's surface \( x = d \) is \( \sqrt{2gd} \). If we take as rough values \( a = 10 \times 10^8 \) feet, \( g = 32 \) foot-second units, we get a velocity of 35,500 feet, or about seven miles, per second. If the particles start from rest at a finite distance \( c \), we have in (16), \( C = -2\mu/c \), and therefore

\[
u \frac{du}{dx} = -\sqrt{\frac{2}{\mu} + \frac{c^2}{x^2}},
\]

the minus sign indicating motion towards the origin. If we put \( x = c \cos \theta \), we find

\[
\frac{dx}{dt} = \frac{c}{\sqrt{c^2 - x^2}} (c + \sin \phi),
\]

(18) no additive constant being necessary if \( t \) be reckoned from the instant of starting, when \( \phi = 0 \). The time \( t \) of reaching the origin (\( \phi = \pi \)) is

\[
t = \frac{\pi c}{\sqrt{2g}},
\]

(19) This may be compared with the period of revolution in a circular orbit of radius \( c \) about the same centre of force, viz. \( 2\pi \sqrt{c^3/\mu} \). We learn that if the orbital motion of a planet, or a satellite, were arrested, the body would fall into the sun, or into its primary, in the fraction of a-tenth of its actual periodic time. Thus the moon would reach the earth in about five days. It may be noticed that if the scales of \( c \) and \( t \) be properly adjusted, the curve of positions in the present problem is the portion of a cycloid extending from a vertex to a cusp.

In any case of rectilinear motion, if we integrate both sides of the equation

\[
\frac{dx}{dt} = X,
\]

which is equivalent to (1), with respect to \( x \) between the limits \( x_0, x_1 \), we obtain

\[
\frac{1}{2} m u^2 - \frac{1}{2} m u_0^2 = \int_{x_0}^{x_1} X dx.
\]

We recognize the right-hand member as the work done by the force \( X \) on the particle as the latter moves from the position \( x_0 \) to the position \( x_1 \). If we construct a curve with \( x \) as abscissa and \( x \) as ordinate, this work is represented, as in J. Watt's "indicator-diagram," by the area cut off by the ordinates \( x = x_0, x = x_1 \). The product \( \frac{1}{2} m u^2 \) is called the kinetic energy of the particle, and the equation (21) is therefore equivalent to the statement that the increment of the kinetic energy is equal to the work done on the particle. If the force \( X \) be always the same in the same position, the particle may be regarded as moving in a certain invariable "field of force." The work which would have to be supplied by other forces, extraneous to the field, in order to bring the particle from rest in some standard position \( P \) to rest in any assigned position \( P' \), will depend only on the position of \( P' \); it is called the statical or potential energy of the particle with respect to the field, in the position \( P \). Denoting this by \( V \), we have \( dV = -\frac{1}{2} k x^2 \), whence

\[
X = -\frac{dV}{dx}.
\]

The equation (21) may now be written

\[
\frac{1}{2} m u^2 + V = \frac{1}{2} m u_0^2 + V_0,
\]

which asserts that when no extraneous forces act the sum of the kinetic and potential energies is constant. Thus in the case of a weight hanging by a spiral spring the work required to increase the length \( x \) is \( V = k \int x dx = k/2 x^2 \), whence \( \frac{1}{2} m u^2 + k/2 x^2 + \text{const} \), as is easily verified from preceding results. It is easily seen that the effect of extraneous forces will be to increase the sum of the kinetic and potential energies by an amount equal to the work done by them. If this amount be negative the sum in question is diminished by a corresponding amount. It appears then that this sum is a measure of the total capacity for doing work against extraneous resistances which the particle possesses in virtue of its motion and its position; this is in fact the origin of the term "energy." The product \( m u^2 \) had been called by G. W. Leibnitz the "vis viva"; the name "actual energy" was appropriated to the expression \( \frac{1}{2} m u^2 \) by W. J. Rankine.

The laws which regulate the resistance of a medium such as air to the motion of bodies through it are only imperfectly known. We may briefly notice the case of resistance varying as the square of the velocity, which is mathematically simple. If the positive direction of \( x \) be downwards, the equation of motion of a falling particle will be of the form

\[
u \frac{du}{dx} = -g - ku^2,
\]

this shows that the velocity \( u \) will send asymptotically to a certain limit \( V \) (called the terminal velocity) such that \( kV^2 = g \). The solution is

\[
u = \sqrt{\frac{c}{\mu}} \log (\phi + \sin \phi),
\]

(18) if the particle start from rest in the position \( x = 0 \) at the instant \( t = 0 \). In the case of a particle projected vertically upwards we have

\[
u \frac{du}{dx} = -g - ku^2,
\]

the positive direction being now upwards. This leads to

\[
u = \sqrt{\frac{c}{\mu}} \log (\phi + \sin \phi),
\]

where \( u_0 \) is the velocity of projection. The particle comes to rest when

\[
u = \sqrt{\frac{c}{\mu}} \log (\phi + \sin \phi),
\]

(18).

For small velocities the resistance of the air is nearly proportional to the first power of the velocity. The effect of forces of this type on small vibratory motions may be investigated as follows. The equation (5) when modified by the introduction of a frictional term becomes

\[
\ddot{x} = -\mu \dot{x} - k x,
\]

(29) if \( k < 4 \mu \). The solution is

\[
x = a e^{-\tau t} \cos (\omega t + \phi),
\]

where \( \tau = \sqrt{k/\mu} \), \( \omega = \sqrt{(\mu - k^2)/\mu} \), (30) and the constants \( a, \phi \) are arbitrary. This may be given as a simple harmonic oscillation whose amplitude diminishes asymptotically to zero according to the law \( c^{-\tau} \). The constant \( \tau \) is called the modulus of decay of the oscillations; if it is large compared with \( 2\pi/\omega \) the effect of friction is limited to the second order of small quantities and may in general be neglected. We have seen that
MECHANICS

a true simple-harmonic vibration may be regarded as the orthogonal projection of uniform circular motion; it was pointed out by P. G. Tait that a similar representation of the type (30) is obtained if we replace the circle by an equiangular spiral described, with a constant angular velocity about the pole, in the direction of diminishing radius vector. When \( k^2 > \mu \), the solution of (29) is, in real form,

\[
x = A e^{\gamma t} + B e^{\alpha t},
\]

where \( \gamma, \alpha = \pm \sqrt{\mu - k^2} \).

(32)

The body now passes once (at most) through its equilibrium position, and the vibration is therefore styled aneroidic.

To find the forced oscillation due to a periodic force we have

\[
x + k \ddot{x} + \omega^2 x = f \cos(\omega t + \phi).
\]

(34)

The solution is

\[
x = \frac{f}{k \omega^2 - \omega^2} \cos(\omega t + \phi) + \frac{1}{k} \int_k \frac{-k \omega^2 - \omega^2}{\sin(\beta t + \phi)} dt.
\]

(35)

provided

\[
R = \left| \frac{(1-\omega^2) - k^2 \omega^2}{\sin(\beta t + \phi)} \right|, \tan \beta = \frac{k}{\sqrt{1-k^2}}.
\]

(36)

Hence the phase of the vibration lags behind that of the force by the amount \( \xi \), which lies between 0 and \( T \) or between \( 0 \) and \( \pi \), according as \( \mu > \pi \). If the friction be comparatively slight the amplitude is greatest when the imposed period coincides with the free period, being then equal to \( f / \mu \omega^2 \) and therefore very great compared with that due to a slowly varying force of the same average intensity. We have here, in principle, the explanation of the phenomenon of "resonance" in acoustics. The abnormal amplitude is greater, and is restricted to a narrower range of frequency, the smaller the friction.

For a complete solution of (34) we must of course superpose the free vibration (30); but owing to the factor \( e^{\gamma t} \) the influence of the initial conditions gradually disappears.

For purposes of mathematical treatment a force which produces a finite change of velocity in a time too short to be appreciated is regarded as infinitely great, and the time of action as infinitely short. The whole effect is summed up in the value of the instantaneous impulse, which is the time-integral of the force. Thus if an instantaneous impulse \( \xi \) changes the velocity of a mass \( m \) from \( u \) to \( u' \) we have

\[
w' - w = \xi.
\]

(37)

The effect of ordinary finite forces during the infinitely short duration of this impulse is of course ignored.

We may apply this to the theory of impact. If we have two bodies, \( m_1, m_2 \) moving in the same straight line impinge, with the result that the velocities are changed from \( u_1, u_2 \) to \( u_1', u_2' \), then, since the impulses on the two bodies must be equal and opposite, the total momentum is unchanged, i.e.

\[
m_1 u_1 + m_2 u_2 = m_1 u_1' + m_2 u_2'.
\]

(38)

The complete determination of the result of a collision under given circumstances is not a matter of abstract dynamics alone, but requires some auxiliary assumption. If we assume that there is no loss of apparent kinetic energy we have also

\[
m_1 u_1'^2 + m_2 u_2'^2 = m_1 u_1'^2 + m_2 u_2'^2.
\]

(39)

Hence, and from (38),

\[
u_1' - u_1 = - (u_2 - u_2'),
\]

(40)

(i.e. the relative velocity of the two bodies is reversed in direction, but unaltered in magnitude. This appears to be the case very approximately with steel or glass balls; generally, however, there is some appreciable loss of apparent energy; this is accounted for by vibrations produced in the balls and imperfect elasticity of the materials. The usual empirical assumption is that

\[
u_1' - u_1 = - c (u_2 - u_2'),
\]

(41)

where \( c \) is a proper fraction which is constant for the same two bodies. It follows from the formula \( \sin c \) (10) for the internal kinetic energy of a system of particles as a result of the impact this energy is diminished by the amount

\[
\frac{1}{2} (1 - c^2) \frac{m_1 m_2}{m_1 + m_2} (u_1 - u_2)'^2.
\]

(42)

The further theoretical discussion of the subject belongs to ELASTICITY.

This is perhaps the most suitable place for a few remarks on the theory of "dimensions." (See also UNITS, DIMENSIONS OR.) In any absolute system of dynamical measurement the fundamental units are those of mass, length and time; we may denote them by the symbols \( M, L, T \), respectively.

They may be chosen quite arbitrarily, e.g. on the C.G.S. system they are the gramme, centimetre and second. All other units are derived from these. Thus the unit of velocity is that of a point describing the unit of length in the unit of time; it may be denoted by \( \text{LT}^{-1} \), this symbol indicating that the magnitude of the unit in question varies directly as the unit of length and inversely as the unit of time. The unit of acceleration is the acceleration of a point which gains unit velocity in unit time; it is accordingly denoted by \( \text{LT}^{-2} \). The unit of momentum is \( \text{MLT}^{-1} \); the unit force generates unit momentum in unit time and is therefore denoted by \( \text{MLT}^{-2} \). The unit of work on the same principles is \( \text{MLT}^{-2} \), and it is to be noticed that this is identical with the unit of kinetic energy. Some of these derivates have special names assigned to them; thus on the C.G.S. system the unit of force is called the dyne, and the unit of work or energy the erg. The number which expresses a physical quantity of any particular kind will of course vary inversely as the magnitude of the corresponding unit. In any general dynamical equation the dimensions of each term in the fundamental units must be the same, for a change of units would otherwise alter the various terms in different ratios. This principle is often useful as a check on the accuracy of an equation.

The theory of dimensions often enables us to forecast, to some extent, the manner in which the magnitudes involved in any particular problem will enter into the result. Thus, assuming that the period of a small oscillation of a given pendulum at a given place is a definite quantity, we see that it must vary as \( \sqrt{l/g} \). For it can only depend on the mass of the bob, the length of the string, and the value of \( g \) at the place in question; and the above expression is the only combination of these symbols whose dimensions are those of a time, simply. Again, the time of falling from a distance \( x \) into a given centre of force varying inversely as the square of the distance will depend only on \( x \) and on the constant \( \mu \) of equation (15). The dimensions of \( \mu \) are \( \text{LT}^{-2} \). Assuming that the time in question varies as \( a \omega^2 \), whose dimensions are \( \text{L} \times \text{T}^{-2} \), we must have \( x + y = 0 \), or \( \mu x = 1 \), that is, the time of falling will vary as \( dx^2 / \mu \), in agreement with (19).

The argument appears in a more demonstrative form in the theory of "similar" systems, or (more precisely) of the similar motion of similar systems. Thus, considering the equations

\[
\frac{dx}{dt} = - \mu x, \frac{dx'}{dt'} = - \mu' x',
\]

(43)

which refer to two particles falling independently into two distinct centres of force, it is obvious that it is possible to have \( x, x' \) in a constant ratio to \( x, x' \), and \( t, t' \) in a constant ratio to \( t, t' \), provided that

\[
x : x' = \mu : \mu', \quad t : t' = \mu : \mu'.
\]

(44)

and that there is a suitable correspondence between the initial conditions. The relation (44) is equivalent to

\[
t = \frac{t'}{t} \mu = \mu',
\]

(45)

where \( x, x' \) are any two corresponding distances, e.g. they may be the initial distances, both particles being supposed to start from rest. The consideration of dimensions was introduced by J. B. Fourier (1822) in connexion with the conduct of heat.

§ 13. General Motion of a Particle.—Let \( P, Q \) be the positions of a moving point at times \( t, t + \delta t \) respectively. A vector \( \overrightarrow{OQ} \) drawn parallel to \( PQ \), of length proportional to \( PQ/\delta t \) on any convenient scale, will represent the mean velocity in the interval \( \delta t \), i.e. a point moving with a constant velocity having the magnitude and direction indicated by this vector would experience the same resultant displacement \( \overrightarrow{PO} \) in the same time. As \( \delta t \) is indefinitely diminished, the vector \( \overrightarrow{OU} \) will tend to a definite limit \( \overrightarrow{OV} \); this is adopted as the definition

FIG. 64.
of the velocity of the moving point at the instant $t$. Obviously, $\vec{O}V$ is parallel to the tangent to the path at $P$, and its magnitude is $ds/dt$, where $s$ is the arc. If we project $OV$ on the co-ordinate axes (rectangular or oblique) in the usual manner, the projections $u$, $v$, $w$ are called the component velocities parallel to the axes. If $x, y, z$ be the co-ordinates of $P$ it is easily proved that

$$u = \frac{dx}{dt}, \quad v = \frac{dy}{dt}, \quad w = \frac{dz}{dt}. \tag{1}$$

The momentum of a particle is the vector obtained by multiplying the velocity by the mass $m$. The impulse of a force in any infinitesimal short interval of time $dt$ is the product of the force into $dt$; it is to be regarded as a vector. The total impulse in any finite interval of time is the integral of the impulses corresponding to the infinitesimal elements $dt$ into which the interval may be subdivided; the summation of which the integral is the limit of course to be understood in the vectorial sense.

Newton's Second Law asserts that change of momentum is equal to the impulse; this is a statement as to equality of vectors and so implies identity of direction as well as of magnitude. If $X, Y, Z$ are the components of force, then considering the changes in an infinitesimally short time $dt$ we have, by projection on the co-ordinate axes, $\delta (mu) = \frac{X}{dt}$, and so on, or

$$\frac{du}{dt} = X, \quad \frac{dv}{dt} = Y, \quad \frac{dw}{dt} = Z. \tag{2}$$

For example, the path of a particle projected anywhere under gravity will obviously be confined to the vertical plane through the initial direction of motion. Taking this as the plane $xy$, with the axis of $x$ drawn horizontally, and that of $y$ vertically upwards, we have $X = 0, Y = -mg$; so that

$$\frac{dx}{dt} = 0, \quad \frac{dy}{dt} = -g. \tag{3}$$

The solution is

$$x = at + b, \quad y = -\frac{1}{2}gt^2 + c. \tag{4}$$

If the initial values of $x, y, \dot{x}, \dot{y}$ are given, we have four conditions to determine the four arbitrary constants $a, b, c, d$. Thus if the particle start at time $t = 0$ from the origin, with the component velocities $u_0, v_0, w_0$ we have

$$\dot{x} = u_0, \quad \dot{y} = -\frac{1}{2}gt. \tag{5}$$

Eliminating $t$ we have the equation of the path, viz.

$$\frac{3}{2}x - y = c. \tag{6}$$

This is a parabola with vertical axis, of latus-rectum $2u_0/\dot{g}$. The range on a horizontal plane through $O$ is got by putting $y = 0$, viz. it is $2u_0\dot{g}/g$. If we determine the resultant velocity at any instant by $\ddot{x}$ we have

$$\ddot{x} = \ddot{x} + \ddot{y} = \ddot{x} - 2gy. \tag{7}$$

Another important example is that of a particle subject to an acceleration which is directed always towards a fixed point $O$ and is proportional to the distance from $O$. The motion will evidently be in one plane, which we take as the plane $xyz$. If $\mu$ be the acceleration at unit distance, the component accelerations parallel to axes of $x$ and $y$ through $O$ as origin will be $-\mu x, -\mu y$, whence

$$\frac{d^2x}{dt^2} = -\mu x, \quad \frac{d^2y}{dt^2} = -\mu y. \tag{8}$$

The solution is

$$x = A \cos nt + B \sin nt, \quad y = C \cos nt + D \sin nt, \tag{9}$$

where $n = \mu$. If $P$ be the initial position of the particle, we may conveniently take $O$ as axis of $x$, and draw $Oy$ parallel to the direction of motion at $P$. If $O = a$, and $\delta O$ be the velocity at $P$, we have, initially, $x = a, y = 0, \dot{x} = 0, \dot{y} = \delta p$; whence

$$x = a \cos nt + b \sin nt, \tag{10}$$

if $b = \delta p/n$. The path is therefore an ellipse of which $a, b$ are conjugate semi-diameters, and is described in the period $2\pi/\mu$; moreover, the velocity at any point $P$ is equal to $\mu/a$ OD, where OD is the semi-diameter conjugate to OP. This type of motion is called elliptic harmonic.

If the co-ordinate axes are the principal axes of the ellipse, the angle $nt$ in (10) is identical with the "eccentric angle." The motion of the bob of a "spherical pendulum," i.e. a simple pendulum whose oscillations are not confined to one vertical plane, is of this character, provided the extreme inclination of the string to the vertical be small. The acceleration is towards the vertical through the point of suspension, and is equal to $g/r$, approximately, if $r$ denote distance from this vertical. Hence the path is approximately an ellipse, and the period is $2\pi/\sqrt{g/r}$.

The above problem is identical with that of the oscillation of a particle in a smooth spherical bowl, in the neighbourhood of the lowest point. If the bowl has any other shape, the axes $Ox, Oy$ may be taken tangential to the lines for curvature at the lowest point $O$; the equations of small motion then are

$$\frac{dx}{dt} = -p, \quad \frac{dy}{dt} = -q. \tag{11}$$

where $p$, $q$, are the principal radii of curvature at $O$. The motion is therefore the resultant of two simple vibrations in perpendicular directions, of periods $2\pi\sqrt{g/p}$, $2\pi\sqrt{g/q}$. The circumstances are realized in "Blackburn's pendulum," which consists of a weight $P$ hanging from a point $C$ of a string $ACB$ whose ends $A, B$ are fixed. If $E$ be the point in which the line of the string meets $AB$, we have $p = AC, q = EP$. Many contrivances for actually drawing the resulting curves have been devised.

It is sometimes convenient to resolve the accelerations in directions having a more intricate relation to the path. Thus, in a plane path, let $P, Q$ be two consecutive positions, corresponding to the times $t, t + \delta t$; and let the normals at $P, Q$ meet in $C$, making an angle $\delta \phi$. Let $v = \psi$ be the velocity at $P$, $v + \delta v$ that at $Q$. In the time $\delta t$ the velocity parallel to the tangent at $P$ changes from $v$ to $v + \delta v$, ultimately, and the tangential acceleration at $P$ is therefore $\delta v/\delta t$ or $\delta$. Again, the velocity parallel to the normal at $P$ changes from $\psi$ to $\psi + dx/\delta t$, ultimately, so that the normal acceleration is $xv/\delta t$.

$$\frac{dx}{dt} = \frac{x}{P}, \quad \frac{dy}{dt} = \frac{y}{P}, \tag{12}$$

where $P$ is the radius of curvature of the path at $P$, the tangential and normal accelerations are also expressed by $xv/\delta t$ and $v^2/\delta t$, respectively. Take, for example, the case of a particle moving on a smooth curve in a vertical plane, under the action of gravity and the pressure $R$ of the curve. If the axes of $x$ and $y$ be drawn horizontal and vertical (upwards), and if $v$ be the inclination of the tangent to the horizontal, we have

$$\frac{dx}{dt} = -mg \sin v = -mg \cos \psi \frac{dv}{dt}, \quad \frac{dy}{dt} = -mg \cos \psi + R. \tag{13}$$

The former equation gives

$$v = C - \Delta y, \tag{14}$$

and the latter then determines $R$.

In the case of the pendulum the tension of the string takes the place of the pressure of the curve. If $\Delta$ is inclination to the downward vertical, we have $\Delta = \delta \phi$, so that $v = dv/\delta t$. The tangential resolution then gives

$$\frac{dv}{dt} = -g \sin \phi. \tag{15}$$

If we multiply by $2\delta v/\delta t$ and integrate, we obtain

$$\frac{dv}{dt} = \frac{2\Delta}{R} \cos \psi - \text{const.}, \tag{16}$$

which is seen to be equivalent to (14). If the pendulum oscillate between the limits $\psi = \Delta$, we have

$$\frac{dv}{dt} = \frac{2\Delta}{R} \cos \psi - \psi - \sin \Delta - \sin \Delta, \tag{17}$$

and, putting $\psi = \sin \Delta$, we find, for the period $t$ of a complete oscillation

$$t = 4 \int_0^{\Delta} \frac{dv}{2\Delta} = 4 \int_0^{\Delta} \frac{dt}{1 - (\sin^2 \frac{1}{2} \sin \Delta)}, \tag{18}$$

which is probably true to the first approximation.
in the notation of elliptic integrals. The function $F_1 (\sin \beta)$ was tabulated by A. M. Legendre for values of $\beta$ ranging from $0^\circ$ to $90^\circ$. The following table gives the period, for various amplitudes $a$, in terms of that of oscillation in an infinitely small arc [viz. $2\sqrt{x^2}$] as unit.

The value of $\tau$ can also be obtained as an infinite series, by expanding the integrand in (18) by the binomial theorem, and integrating term by term. Thus

$$\tau = 2\pi \sqrt{\frac{1}{2} \left( 1 + \frac{\pi^2}{3} \sin^2 \psi + \frac{\pi^4}{30} \sin^4 \psi + \ldots \right)}.$$  \hspace{1cm} (19)

If $a$ be small, an approximate (usually sufficient) is

$$\tau = 2\pi \sqrt{\frac{1}{2} \left( 1 + \frac{\pi}{\sqrt{2}} \right)}.$$  \hspace{1cm} (20)

This becomes infinite for $a = \pi$, showing that the pendulum only tends asymptotically to the highest position.

The variation of period with amplitude was at one time a hindrance to the accurate performance of pendulum clocks, since the errors produced are cumulative. It was therefore sought to replace the circular pendulum by some other contrivance free from this defect. The equation of motion of a particle in any smooth path is

$$\frac{d^2 s}{dt^2} = -g \sin \psi,$$  \hspace{1cm} (21)

where $\psi$ is the inclination of the tangent to the horizontal. If $\sin \psi$ were accurately and not merely approximately proportional to the arc $s$, say

$$s = \delta \sin \psi,$$  \hspace{1cm} (22)

the equation (21) would assume the same form as $\S 12$ (5). The motion along the arc would then be accurately simple-harmonic, and the period $2\pi \sqrt{k/\delta}$ would be the same for all amplitudes. Now equation (22) is the intrinsic equation of a cycloid; viz. the curve is that traced by a point on the circumference of a circle of radius $\delta$ which rolls on the under side of a horizontal straight line. Since the evolute of a cycloid is an equal cycloid the object is attained by means of two metal cheeks, having the form of the evolute near the cusp, on which the string wraps itself alternately as the pendulum swings. The device has long been abandoned, the difficulty being met in other ways, but the problem, originally investigated by C. Huygens, is important in the history of mathematics.

The component accelerations of a point describing a tortuous curve, in the directions of the tangent, the principal normal, and the binormal, respectively, are found as follows. If $OV$, $OV'$ be vectors representing the velocities at two consecutive points $P$, $P'$ of the path, the plane $VOV'$ is ultimately parallel to the osculating plane of the path at $P$; the resultant acceleration is therefore in the osculating plane. Also, the projections of $VV'$ on $OV$ and on a perpendicular to $OV$ in the plane $VOV'$ are $\delta \omega$ and $\omega \delta v$, where $\delta v$ is the angle between the directions of the tangents at $P$, $P'$. Since $\delta v = \delta s/p$, where $\delta s = PP' = \omega t \delta t$ and $p$ is the radius of principal curvature at $P$, the component accelerations along the tangent and principal normal are $\delta v/dt$ and $\omega v dt$, respectively, or $\delta v/dt$ and $\omega v$. For example, if a particle moves on a smooth surface, under no forces except the reaction of the surface, $v$ is constant, and the principal normal to the path will coincide with the normal to the surface. Hence the path is a "geodesic" on the surface.

If we resolve along the tangent to the path (whether plane or tortuous), the equation of motion of a particle may be written

$$m \frac{d^2 s}{dt^2} = \mathbf{T},$$  \hspace{1cm} (23)

where $\mathbf{T}$ is the tangential component of the force. Integrating with respect to $s$ we find

$$\frac{1}{2} m v^2 - \frac{1}{2} m v_0^2 = \int s^2 \mathbf{T} ds,$$  \hspace{1cm} (24)

i.e. the increase of kinetic energy between any two positions is equal to the work done by the forces. The result follows also from the Cartesian equations (2); viz. we have

$$m(\dot{x}^2 + \dot{y}^2 + \dot{z}^2) = X^2 + Y^2 + Z^2,$$  \hspace{1cm} (25)

whence, on integration with respect to $t$,

$$\int (\dot{x}^2 + \dot{y}^2 + \dot{z}^2) = \int (X^2 + Y^2 + Z^2) dt + \text{const.}$$  \hspace{1cm} (26)

If the axes be rectangular, this has the same interpretation as (24).

Suppose now that we have a constant field of force; i.e. the force acting on the particle is always the same at the same place. The work which must be done by forces extraneous to the field in order to bring the particle from rest in some standard position $A$ to rest in any other position $P$ will not necessarily be the same for all paths between $A$ and $P$. If it is different for different paths, then by bringing the particle from $A$ to $P$ by one path, and back again from $P$ to $A$ by another, we might secure a gain of work, and the process could be repeated indefinitely. If the work required is the same for all paths between $A$ and $P$, and therefore for a closed circuit, the field is said to be conservative. In this case the work required to bring the particle from rest at $A$ to rest at $P$ is called the potential energy of the particle in the position $P$; we denote it by $V$. If $PP'$ be a linear element $\delta s$ drawn in any direction from $P$, and $s$ the force due to the field, resolved in the direction $PP'$, we have $\delta V = -s \delta s$ or

$$s = -\frac{\delta V}{\delta s}.$$  \hspace{1cm} (27)

In particular, by taking $PP'$ parallel to each of the (rectangular) co-ordinate axes in succession, we find

$$X = -\frac{\partial V}{\partial x}, \quad Y = -\frac{\partial V}{\partial y}, \quad Z = -\frac{\partial V}{\partial z}.$$  \hspace{1cm} (28)

The equation (24) or (26) now gives

$$\frac{1}{2} m v^2 + V = \frac{1}{2} m v_0^2 + V_0;$$  \hspace{1cm} (29)

i.e. the sum of the kinetic and potential energies is constant when no work is done by extraneous forces. For example, if the field be that due to gravity we have $V = g m x y z = m g x y z$, if the axis of $y$ be drawn vertically upwards; hence

$$\frac{1}{2} m v^2 + m g x y z = \text{const.}$$  \hspace{1cm} (30)

This applies to motion on a smooth curve, as well as to the free motion of a projectile; cf. (7), (14). Again, in the case of a force $K$ tending towards $O$, where $r$ denotes distance from $O$ we have $V = K r^2 = K r^2 + \text{const.}$, whence

$$\frac{1}{2} m v^2 + K r^2 = \text{const.}$$  \hspace{1cm} (31)

It has been seen that the orbit in this case is an ellipse; also that if we put $u = K/m$ the velocity at any point $P$ is $v = \sqrt{u^2 - v^2}$, where $OD$ is the semi-diameter conjugate to OP. Hence (31) is consistent with the known property of the ellipse that $OP^2 + OD^2$ is constant.

The forms assumed by the dynamical equations when the axes of reference are themselves in motion will be considered in $\S 21$. At present we take only the case where the rectangular axes Ox, Oy rotate in their own plane, with angular velocity $\omega$ about Oz, which is fixed. In the interval $dt$ the line joining the origin to any point $(x, y, z)$ on the directions of the co-ordinate axes at time $t$ are changed from $x$, $y$, $z$ to $(x + \delta x)$, $\cos \omega (y + \delta y)$, $\sin \omega (z + \delta z)$, $(x + \delta x)$, $\sin \omega (z + \delta z)$, $\cos \omega (y + \delta y)$, respectively. Hence the component velocities parallel to the instantaneous positions of the co-ordinate axes at time $t$ are

$$u = \dot{x} = -\omega y, \quad v = \dot{y} = + \omega z, \quad w = \dot{z} = \omega x.$$  \hspace{1cm} (32)

In the same way we find that the component $a$ of $\mathbf{a}$, the acceleration, are

$$\dot{x} = -\omega y, \quad \dot{y} = + \omega z, \quad \dot{z} = \omega x.$$  \hspace{1cm} (33)

Hence if $\omega$ is constant the equations of motion take the forms

$$m(\ddot{x} - 2\omega \dot{y} + \omega^2 x) = X, \quad m(\ddot{y} + 2\omega \dot{z} + \omega^2 y) = Y, \quad m(\ddot{z} - \omega^2 z) = Z.$$  \hspace{1cm} (34)

These become identical with the equations of motion relative to fixed axes provided we introduce a fictitious force $m \mathbf{a}_0$ acting outwards from the axis of $z$, where $r = (s^2 + y^2)$, and a second fictitious force $m \mathbf{a}_0$ at right angles to the path, where $\mathbf{a}$ is the component of the relative velocity parallel to the plane $x y$. The former force is called by French writers the force centrifuge ordinaire, and the latter the force centrifuge composée, or force de Coriolis. As an application of (34) we may take the case of a symmetrical Blackburn's pendulum hanging from a horizontal bar which is made to rotate.
about a vertical axis half-way between the points of attachment of the upper string. The equations of small motion are then of the type

\[ -2\omega y + a^2 x = -p_x x + 2a \omega - a^2 y = -p_y y. \]  
This is satisfied by

\[ a = A \cos (a t + \epsilon), \quad y = B \sin (a t + \epsilon), \]  
provided

\[ \left( a^2 + p^2 - \rho^2 \right) A^2 + 2a \omega B = 0, \]  
and

\[ 2a A = (a^2 + p^2 - \rho^2) B = 0. \]  
Eliminating the ratio \( A : B \) we have

\[ \left( a^2 + p^2 - \rho^2 \right) (a^2 + p^2 - \sigma^2) - 4a^2 \sigma = 0. \]  
It is easily proved that the roots of this quadratic in \( \sigma \) are always real, and that they are moreover both positive unless \( a^2 \) lies between \( p^2 \) and \( a^2 \). The ratio \( B/A \) is determined in each case by either of the equations (37); hence each root of the quadratic gives a solution of the type (36), with two arbitrary constants \( A, \epsilon \). Since the equations (35) are linear, these two solutions are to be superposed. If the quadratic (38) has a negative root, the trigonometrical functions in (36) are to be replaced by real exponentials, and the position \( x = 0, y = 0 \) is unstable. This occurs only when the period \( (2 \pi / \omega) \) of revolution of the arm lies between the two periods \( (2 \pi / p, 2 \pi / q) \) of oscillation when the arm is fixed.

**Central Forces.** The motion of a particle subject to a force which passes always through a fixed point \( O \) is necessarily in a plane orbit. For its investigation we require two equations; these may be obtained in a variety of forms.

Since the impulse of the force in any element of time \( dt \) has zero moment about \( O \), the same will be true of the additional momentum generated. Hence the moment of the momentum (considered as a localized vector) about \( O \) will be constant. In symbols, if \( p = \) the velocity and \( \ell \) the perpendicular from \( O \) to the tangent to the path,

\[ p_\ell = h, \]  
where \( h \) is a constant. If \( ds \) be an element of the path, \( pds \) is twice the area enclosed by \( ds \) and the radii drawn to its extremities from \( O \). Hence, if \( ds \) be this area, we have

\[ dA = \frac{1}{2} h ds, \]  
where equal areas are swept over by the radius vector in equal times.

If \( P \) be the acceleration towards \( O \), we have

\[ \frac{d^2 A}{dt^2} = -1 \frac{d^2 H}{d\ell^2} ds, \]  
where \( d\ell/ds \) is the cosine of the angle between the directions of \( r \) and \( ds \). We will suppose that \( P \) is a function of \( r \) only; then integrating (3) we find

\[ \frac{1}{2} \frac{d^2 \ell}{dt^2} = - \int P d\ell + \text{const}, \]  
which is recognized as the equation of energy. Combining this with (1) we have

\[ \frac{1}{2} \frac{d^2 \ell}{dt^2} = C - 2J P d\ell, \]  
which completely determines the path except as to its orientation with respect to \( O \).

If the law of attraction be that of the inverse square of the distance, we have \( P = \mu/r^2 \), and

\[ \frac{1}{2} \frac{d^2 \ell}{dt^2} = C - 2J \frac{\mu}{r^2} \]  
Now in a conic whose focus is at \( O \) we have

\[ \frac{1}{2} \frac{d^2 \ell}{dt^2} = C - \frac{\mu}{r^2}, \]  
where \( \ell \) is half the latus-rectum, \( a \) is half the major axis, and the upper or lower sign is to be taken according as the conic is an ellipse or hyperbola. In the intermediate case of the parabola we have \( a = \infty \) and the last term disappears. The equations (6) and (7) are identified by putting

\[ l = h^2/\mu, \quad a = \infty = \mu/C. \]  
Since

\[ \frac{d^2 \ell}{dt^2} = h^2/\mu (2 - 1/\ell^2), \]  
it appears that the orbit is an ellipse, parabola or hyperbola, according as \( \ell^2 \) is less than, equal to, or greater than \( 2h^2/\mu \). Now it appears from (6) that \( 2h^2/\mu \) is the square of the velocity which would be acquired by a particle falling from rest at infinity to the distance \( r \). Hence the character of the orbit depends on whether the velocity at any point is less than, equal to, or greater than the velocity from infinity, as it is called. In an elliptic orbit the area \( \text{area} \) is swept over in the time

\[ \tau = \frac{\text{area}}{\pi}, \]  
hence

\[ \mu = \frac{h^2}{\ell} = \mu_0 = \ell^2 \]  
by (6).

The converse problem, to determine the law of force under which a given orbit can be described about a given pole, is solved by differentiating (5) with respect to \( r \); thus

\[ P = \frac{\mu h^2}{r^3}, \]  
and the components of the force at \( P \) along and perpendicular to \( OP \) (direction of \( \theta \) increasing), we have

\[ \frac{d\theta}{dt} = \frac{d\ell}{dt} = \frac{d\ell}{dt} = \frac{d\ell}{dt}, \]  
respectively.

In the case of a central force, with \( O \) as pole, the transverse acceleration vanishes, so that

\[ r \frac{d\theta}{dt} = \frac{d\ell}{dt} = \frac{d\ell}{dt}, \]  
where \( k = \) constant; this shows (again) that the radius vector sweeps over equal areas in equal times. The radial resolution gives

\[ \frac{d^2 \ell}{dt^2} = \frac{d\ell}{dt} - \frac{d\ell}{dt} \]  
and

\[ \frac{d^2 \ell}{dt^2} = - \frac{d\ell}{dt} + \frac{d\ell}{dt} \]  
Finally, it appears when \( P \) is as before, that the acceleration towards \( O \). If in this \( P \) is \( 1/r^2 \), and \( t \) be means of the mean, we obtain the general differential equation of central orbits, viz.

\[ \frac{d^2 \ell}{dt^2} = \frac{d\ell}{dt} - \frac{d\ell}{dt} \]  
where, \( \epsilon, \) are arbitrary constants. This is recognized as the polar equation of a conic referred to the focus, the half latus-rectum being \( h^2/\mu \).
MECHANICS

The law of the inverse cube $P = \mu u^2$ is interesting by way of contrast. The orbits may be divided into two classes according as $\mu^2 u^2$, i.e. according as the transverse velocity $4u^2$ is greater or less than the velocity $\sqrt{\mu}$ appropriate to a circular orbit at the same distance. In the former case the equation (17) takes the form

$$\frac{d\theta}{dr}m^2 = \theta,$$

the solution of which is

$$a = \sin m (\theta - \alpha).$$

The orbit has therefore two asymptotes, inclined at an angle $\pi/m$. In the latter case the differential equation is of the form

$$\frac{d\theta}{dr}m^2 = \theta,$$

so that

$$a = \cos m \theta,$$

if the orbit of $\theta$ be suitably adjusted; hence $r$ has a maximum value $a$, and the particle ultimately approaches the pole asymptotically by an infinite number of convolutions. If $A$, $B$ 

or its

have opposite signs the form is

$$a = \sinh m \theta,$$

This has an asymptote parallel to $\theta = 0$, but the path near the origin has the same general form as in the case of $(23)$. If $A$ or $B$ vanish we have an equiangular spiral, and the velocity at infinity is zero. In the critical case of $k^2 = m^2$, we have $\frac{d\theta}{dr}m^2 = 0$, and

$$A = B + \theta;$$

the orbit is therefore a "reciprocal spiral," except in the special case of $A = 0$, when it is a circle. It will be seen that unless the conditions be exactly adjusted for a circular orbit the particle will either never arrive at infinity or approach the pole asymptotically. This problem was investigated by R. Cotes (1682–1716), and the various curves obtained are known as Cotes's spirals.

A point on a central orbit where the radial velocity $(d\theta/dr)$ vanishes is called an *apex*, and the corresponding radius is called an *apslide*. If the force is always the same at the same distance any apse-line will divide the orbit symmetrically, as is seen by imagining the velocity at the apse to be reversed. It follows that the angle between successive apse-lines is constant; it is called the *apsidal angle of the orbit*. If in a central orbit the velocity is equal to the velocity from infinity, we have, from $(\mathcal{E})$,

$$\frac{k^2}{r} = 2\int_0^r \frac{P}{r}dr;$$

this determines the form of the *critical orbit*, as it is called. If $P = \mu/m$, its polar equation is

$$r = \cos m \theta = a^m,$$

(27)

where $m = (3 - n)$, except in the case $n = 3$, when the orbit is an equiangular spiral. The case $n = 2$ gives the parabola as before.

If we eliminate $d\theta/dr$ between $(19)$ and $(16)$ we obtain

$$\frac{d^2\alpha}{dr^2} + \frac{\alpha}{r} = \frac{f(a)}{r^{3/2}},$$

say. We may apply this to the investigation of the stability of a circular orbit. Assuming that $r = a + x$, where $x$ is small, we have, approximately,

$$\frac{d^2x}{dr^2} + \frac{f(a)}{r^{3/2}} \approx 0.$$

Hence if $h$ and $a$ be connected by the relation $h^2 = a^3 f(a)$ proper to a circular orbit, we have

$$\frac{d^2x}{dr^2} + \left\{ f(a) + \frac{3}{2} \left( f'(a) \right) \right\} x = 0.$$

If the coefficient of $x$ be positive the variations of $x$ are simple-harmonic, and $x$ can remain permanently small; the circular orbit is then said to be stable. The condition for this may be written

$$\frac{d}{dr} \left( a^3 f(a) \right) > 0,$$

(29)

i.e. the intensity of the force in the region for which $r = a$, nearly must diminish with increasing distance less rapidly than according to the law of the inverse cube. Again, the half-period of $x$ is $\pi \sqrt{f(a)^3 x^2} / (a^3 f(a))$, and since the angular velocity in the orbit is $h/a^2$, approximately, the apsidal angle is, ultimately,

$$x \approx \sqrt{\left\{ a/f(a) + 3/(a^3 f(a)) \right\}},$$

(30)

or, in the case of $f(a) = \mu/m$, $\pi/m (3 - n)$. This is in agreement with the known results for $n = 2, \infty$.

We have seen that under the law of the inverse square all finite orbits are elliptical. The question presents itself whether there

then is any other law of force, giving a finite velocity from infinity, under which all finite orbits are necessarily closed curves. If this is the case, the apsidal angle must evidently be commensurable with $\pi$, and since it cannot vary discontinuously the apsidal angle in a nearly circular orbit must be constant. Equating the expression $(30)$ to $\pi/m$, we find that $f(a) = C/a^n$, where $n = 3 - m$. The force must therefore vary as a power of the distance, and $m$ must be less than 3. Moreover, the case $n = 2$ is the only one in which the critical orbit $(27)$ can be regarded as the limiting form of a closed curve. Hence the only law of force which satisfies the conditions is that of the inverse square.

At the beginning of § 13 the velocity of a moving point $P$ was represented by a vector $OV$ drawn from a fixed origin $O$. The locus of the point $V$ is called the *hodograph* (q.v.); and it appears that the velocity of the point $V$ along the hodograph represents in magnitude and in direction the acceleration in the original orbit. Thus in the case of a plane orbit, if $v$ be the velocity of $P$, $\psi$ the inclination of the direction of motion to some fixed direction, the polar co-ordinates of $V$ may be taken to be $r, \psi$; hence the velocities of $V$ along and perpendicular to $OV$ will be $dv/dt$ and $d\psi/dt$. These expressions therefore give the tangential and normal accelerations of $P$; cf. § 13 (12).

In the motion of a projectile under gravity the hodograph is a vertical line described with constant velocity. In elliptic harmonic motion the velocity of $P$ is parallel and proportional to the semi-diameter $CD$ which is conjugate to the radius $CP$; the hodograph is therefore an ellipse similar to the actual orbit. In the case of a central orbit described under the law of the inverse square we have $v = h/SY = h \frac{SZ}{S^2}$, where $S$ is the centre of $S$ and $Z$ is the point where $YS$ meets the auxiliary circle again. Hence the hodograph is similar and similarly situated to the locus of $Z$ (the auxiliary circle) turned about $S$ through a right angle. This applies to an elliptic or hyperbolic orbit; the case of the parabolic orbit may be examined separately or treated as a limiting case. The annexed fig. 70 exhibits the various cases, with the hodograph in its proper orientation. The pole $O$ of the hodograph is inside on or outside the circle, according as the orbit is an ellipse, parabola or hyperbola. In any case of a central orbit the hodograph (when turned through a right angle) is similar and similarly situated to the "reciprocal polar" of the orbit with respect to the centre of force.

Thus for a circular orbit with the centre of force at an eccentric point, the hodograph is a conic with the pole as focus. In the case of a particle oscillating under gravity on a smooth cycloid from rest at the cusp the hodograph is a circle through the pole, described with constant velocity.

13. Kinetics of a System of Discrete Particles. — The momenta of the several particles constitute a system of localized vectors which, for purposes of resolving and taking moments, may be reduced like a system of forces in statics (§ 8). Thus taking any point $O$ as base, we have first a linear *momentum* whose components refer to rectangular axes through $O$ are

$$\Sigma(m\mathbf{x}), \Sigma(m\mathbf{y}), \Sigma(m\mathbf{z})$$

its representative vector is the same whatever point $O$ be chosen. Secondly, we have an angular *momentum* whose components are

$$\Sigma(m\mathbf{r}), \Sigma(m\mathbf{\theta}), \Sigma(m\mathbf{\phi}), \Sigma(m\mathbf{\phi})$$

(1)

these being the sums of the moments of the momenta of the several particles about the respective axes. This is subject to the same relations as a couple in statics; it may be represented by a vector which will, however, in general vary with the position of $O$.

The linear momentum is the same as if the whole mass were concentrated at the centre of mass $G$, and endowed with the velocity of this point. This follows at once from equation $(8)$ of § 11, if we imagine the two configurations of the system there referred to be those corresponding to the instant $t, t+\delta t$. Thus

$$\Sigma \left( m \frac{\mathbf{P}}{\delta t} \right) = \Sigma(m) \frac{\mathbf{G}}{\delta t}.\quad (3)$$

Analytically we have

$$\Sigma(m \mathbf{x}) \frac{d}{dt} = \Sigma(m \delta x) = \Sigma(m \mathbf{x}) \frac{d}{dt}$$

(4)

with two similar formulae.
Again, if the instantaneous position of $G$ be taken as base, the angular momentum of the absolute motion is the same as the angular momentum of the motion relative to $G$. For the velocity of a particle $m$ at $P$ may be replaced by two components one of which (0) is identical in magnitude and direction with the velocity of $G$, whilst the other ($\phi$) is the velocity relative to $G$.

For let $G'$ be a consecutive position of $G$. At the instant $t+\delta t$ the momenta of the system are equivalent to a linear momentum represented by a localized vector $\Sigma(m)(\vec{y}+\vec{u})$ in a line through $G'$ tangential to the path of $G'$, together with a certain angular momentum. Now the moment of this localized vector with respect to any axis through $G$ is zero, to the first order of $\delta t$, since the perpendicular distance of $G$ from the tangent line at $G'$ is of the order of $(\delta t)^2$. Analytically we have from (3),

$$\frac{d}{dt}[m(z^2-x^2)] = \Sigma(m) \left( \frac{d}{dt}x^2 - \frac{d}{dt}y^2 \right) + \Sigma(m)[(x^2-\frac{\partial}{\partial t}t^2)].$$

(6)

If we put $x, y, z = 0$, the theorem is proved as regards axes parallel to $Ox$.

Next consider the kinetic energy of the system. If from a fixed point $O$ we draw vectors $\overrightarrow{OV_i}, \overrightarrow{OV_2}, \ldots$ to represent the velocities of the several particles $m_1, m_2, \ldots$, and if we construct the vector

$$\overrightarrow{OK} = \sqrt{\Sigma(m \overrightarrow{OV})},$$

(7)

this will represent the velocity of the mass-centre, by (3). We find, exactly as in the proof of Lagrange's First Theorem (§ 11), that

$$\Sigma(m \overrightarrow{OV}) = \Sigma(m \overrightarrow{OV}) = \Sigma(m \overrightarrow{KV});$$

(8)

i.e., the total kinetic energy is equal to the kinetic energy of the whole mass supposed concentrated at $G$ and moving with this point, together with the kinetic energy of the motion relative to $G$. The latter may be called the internal kinetic energy of the system. Analytically we have

$$\Sigma(m \overrightarrow{OV}) = \Sigma(m \overrightarrow{OV}) = \Sigma(m \overrightarrow{KV}) + \Sigma(m \overrightarrow{KV});$$

(9)

which expresses the internal kinetic energy in terms of the relative velocities of the several pairs of particles. This formula is due to Möbius.

The preceding theorems are purely kinematical. We have now to consider the effect of the forces acting on the particles. These may be divided into two categories; we have first, the extraneous forces exerted on the various particles from without, and, secondly, the mutual or internal forces between the various pairs of particles. It is assumed that these latter are subject to the law of equality of action and reaction. If the equations of motion of each particle be formed separately, each such internal force will appear twice, with opposite signs for its components, viz., as affecting the motion of each of the two particles between which it acts. The full working out is in general difficult, the comparatively simple problem of "three bodies," for instance, in gravitational astronomy being still unsolved, but some general theorems can be formulated.

The first of these may be called the Principle of Linear Momentum. If there are no extraneous forces, the resultant linear momentum is constant in every respect. For consider any two particles at $P$ and $Q$, acting on one another with equal and opposite forces in the line $PQ$. In the time $\delta t$ a certain impulse is given to the first particle in the direction $(say)$ from $P$ to $Q$, whilst an equal and opposite impulse is given to the second in the direction from $Q$ to $P$. Since these impulses produce equal and opposite momenta in the two particles, the resultant linear momentum of the system is unaltered. If extraneous forces act, it is seen in like manner that the resultant linear momentum of the system is in any given time modified by the geometric addition of the total impulse of the extraneous forces. It follows, by the preceding kinematical theory, that the mass-centre of the system will move exactly as if the whole mass were concentrated there and were acted on by the extraneous forces applied parallel to their original directions. For example, the mass-centre of a system free from extraneous force will describe a straight line with constant velocity. Again, the mass-centre of a chain

**Fig. 70.**

The aggregate of the components $m\vec{v}$ of momentum is equivalent to a single localized vector $\Sigma(m)\vec{v}$ in a line through $G$, and has therefore zero moment about any axis through $G$; hence in taking moments about such an axis we need only regard the velocities relative to $G$. In symbols, we have

$$\Sigma[m(z^2-x^2)] = \Sigma(m) \left( \frac{d}{dt}x^2 - \frac{d}{dt}y^2 \right) + \Sigma[m(x^2-\frac{\partial}{\partial t}t^2)].$$

(5)

since $\Sigma(m\vec{v}) = 0, \Sigma(m\vec{v}) = 0$, and so on, the notation being as in § 11. This expresses that the moment of momentum about any fixed axis (e.g. $Ox$) is equal to the moment of momentum of the motion relative to $G$ about a parallel axis through $G$, together with the moment of momentum of the whole mass supposed concentrated at $G$ and moving with this point. If in (5) we make $O$ coincide with the instantaneous position of $G$, we have $x, y, z = 0$, and the theorem follows.

Finally, the rates of change of the components of the angular momentum of the motion relative to $G$ referred to $G$ as a moving base, are equal to the rates of change of the corresponding components of angular momentum relative to a fixed base coincident with the instantaneous position of $G$.

**Fig. 71.**
particles connected by strings, projected anyhow under gravity, will describe a parabola.

The second general result is the Principle of Angular Momentum. If there are no extraneous forces, the moment of momentum about any fixed axis is constant. For in time $\delta t$ the mutual action between two particles at $P$ and $Q$ produces equal and opposite momenta in the line $PQ$, and these will have equal and opposite momenta about the fixed axis. If extraneous forces act, the total angular momentum about any fixed axis is in time $\delta t$ increased by the total extraneous impulse about that axis. The kinematic relations above explained now lead to the conclusion that in calculating the effect of extraneous forces in an infinitely short time $\delta t$ we may take moments about an axis passing through the instantaneous position of G exactly as if G were fixed; moreover, the result will be the same whether in this process we employ the true velocities of the particles or merely their velocities relative to G. If there are no extraneous forces, or if the extraneous forces have zero moment about any axis through G, the vector which represents the resultant angular momentum relative to G is constant in every respect. A plane through G perpendicular to this vector has a fixed direction in space, and is called the invariant plane; it may sometimes be conveniently used as a plane of reference.

For example, if we have two particles connected by a string, the invariant plane passes through the string, and if $v$ be the angular velocity in this plane, the angular momentum relative to G is

$$m_1 v_1 r_1 + m_2 v_2 r_2 = (m_1 r_1 + m_2 r_2) v,$$

where $r_1$, $r_2$ are the distances of $m_1$, $m_2$ from their mass-centre G. Hence if the extraneous forces (e.g. gravity) have zero moment about G, $v$ will be constant. Again, the tension $T$ of the string is given by

$$R = m_1 v_1 r_1 + m_2 v_2 r_2,$$

where $a = r_1 + r_2$. Also by (10) the internal kinetic energy is

$$\frac{1}{2} m_1 v_1^2 + \frac{1}{2} m_2 v_2^2,$$

when the summation includes every pair of particles, and each integral is to be taken between the proper limits. If we write

$$V = \sum m p v,$$

when $p_v$ ranges from its value in some standard configuration $A$ of the system to its value in any other configuration $P$, it is plain that $V$ represents the work which would have to be done in order to bring the system from rest in the configuration $A$ to rest in the configuration $P$. Hence $V$ is a definite function of the configuration $P$; it is called the internal potential energy. If $T$ denote the kinetic energy, we may say then that the sum $T + V$ is in any interval of time increased by an amount equal to the work done by the extraneous forces. In particular, if there are no extraneous forces $T + V$ is constant. Again, if some of the extraneous forces are due to a conservative field of force, the work which they do may be reckoned as a diminution of the potential energy relative to the field as in § 13.

§ 15. An alternative procedure is to adopt the principle first formally enunciated by J. Le R. d'Alembert and since known by his name. If $x$, $y$, $z$ be the rectangular co-ordinates of a mass-element $m$, the expressions $m x$, $m y$, $m z$ must be equal to the components of the total force on $m$, these forces being partly extraneous and partly forces exerted on $m$ by other mass elements of the system. Hence $(m x, m y, m z)$ is called the actual or effective force on $m$. According to d'Alembert's formulation, the extraneous forces together with the effective forces reversed fulfd the statistical conditions of equilibrium. In other words, the whole assemblage of effective forces is statistically equivalent to the extraneous forces. This leads, by the principles of § 8, to the equations

$$\Sigma (m z) = X, \Sigma (m y) = Y, \Sigma (m x) = Z,$$

$$\Sigma (m y z - x z) = L, \Sigma (m x z - y z) = M, \Sigma (m y x - z x) = N,$$

where $(X, Y, Z)$ and $(L, M, N)$ are the force—and couple—constituents of the system of extraneous forces, referred to $O$ as base, and the summations extend over all the mass-elements of the system. These equations may be written

$$d \frac{d}{dt} (m z) = X, d \frac{d}{dt} (m y) = Y, d \frac{d}{dt} (m x) = Z,$$

$$d \frac{d}{dt} (m y z - x z) = L, d \frac{d}{dt} (m x z - y z) = M, d \frac{d}{dt} (m y x - z x) = N,$$

and so express the rate of change of the linear momentum in any fixed direction (e.g. of $O x$) is equal to the total extraneous force in that direction, and that the rate of change of the angular momentum about any fixed axis is equal to the moment of the extraneous forces about that axis. If we integrate with respect to $t$ between fixed limits, we obtain the principles of linear and angular momentum in the form previously given. Hence, whichever form of postulate we adopt, we are led to the principles of linear and angular momentum, which form in fact the basis of all our subsequent work. It is to be noticed that the preceding statements are not intended to be restricted to rigid bodies; they are assumed to hold for all material systems whatever. The peculiar status of rigid bodies is that the principles in question are in most cases sufficient for the complete determination of the motion, the dynamical equations (1 or 2) being equal in number to the degrees of freedom (six) of a rigid solid, whereas in cases where the freedom is greater we have to invoke the aid of other supplementary physical hypotheses (cf. Elasticity; Hydromechanics).

The increase of the kinetic energy of a rigid body in any interval of time is equal to the work done by the extraneous forces acting on the body. This is an immediate consequence of the fundamental postulate, in either of the forms above stated, since the internal forces do on the whole no work. The statement may be extended to a system of rigid bodies, provided the mutual reactions consist of the stresses in inextensible links, or the pressures between smooth surfaces, or the reactions at rolling contacts (§ 9).

§ 17. Two-dimensional Problems. In the case of rotation about a fixed axis, the principles take a very simple form. The position of the body is specified by a single co-ordinate, viz. the angle $\theta$ through which some plane passing through the axis and fixed in the body has turned from a standard position in space. Then $d \theta / dt = \omega$, say, is the angular velocity of the body. The angular momentum of a particle $m$ at a distance $r$ from the axis is $m r \omega$, and the total angular momentum is $\Sigma (m r^2 \omega)$. If we denote the moment of inertia (§ 11) about the axis. Hence if $N$ be the moment of the extraneous forces about the axis, we have

$$\frac{d}{dt} (m \omega) = N.$$

This may be compared with the equation of rectilinear motion of a particle, viz. $d^2 \ell / dt^2 = F$; it shows that I measures the inertia of the body as regards rotation, just as $M$ measures its inertia as regards translation. If $N = 0$, $\omega$ is constant.
As a first example, suppose we have a flywheel free to rotate about a horizontal axis, and that a weight $m$ hangs by a vertical string of a suspending wire, or to a "bifilar" suspension. In the latter case, the body hangs by two vertical threads of equal length $l$ in a plane through $G$. The motion being assumed to be small, the tensions of the two strings may be taken as their statical values $Mgh(a+b), Mg(a+b), Mg(a+b), Mg(a+b)$. We shall assume that each string is free from two threads. When the body is twisted through an angle $\theta$ the threads make angles $ab/l, ab/l$ with the vertical, and the moment of the tensions about the vertical through $G$ is accordingly $-K\theta$, where $K = M g ab/l$.

For the determination of the motion it has only been necessary to use two of the dynamical equations. The remaining equations serve to determine the reactions of the rotating body on its bearings. Suppose, for example, that there are no extraneous forces. Take rectangular axes, of which $Oz$ coincides with the axis of rotation. The angular velocity being constant, the effective force on a particle $m$ at a distance $r$ from $Oz$ is $m\omega^2 r$ towards this axis, and its components are accordingly $-\omega^2 x, -\omega^2 y, -\omega^2 z$. Since the reactions on the bearings must be statically equivalent to the whole system of effective forces, they will reduce to a force $(X,Y,Z)$ at $O$ and a couple $(L,M,N)$ given by

$$X = -\omega^2 (mx), Y = -\omega^2 (my), Z = 0,$$

$$L = \omega^2 (my), M = -\omega^2 (mx), N = 0,$$

where $x, y$ refer to the mass-centre $G$. The reactions do not therefore reduce to a single force at $O$ unless $\omega^2 (mx) = 0, \omega^2 (my) = 0$, i.e., unless the axis of rotation be a principal axis of inertia $(\S 11)$ at $O$. In order that the force may vanish we must also have $x, y = 0$, i.e., the mass-centre must lie in the axis of rotation. These considerations are important in the "balancing" of machinery. We note further that if a body be free to turn about a fixed point $O$, there are three mutually perpendicular linear cylindrical lines through this point about which it can rotate steadily, without further constraint. The theory of principal or "permanent" axes was first investigated from this point of view by J. A. Segner (1755). The origin of the name "deviation moment" sometimes applied to a product of inertia is also now apparent.

Proceeding to the general motion of a rigid body in two dimensions we may take as the three co-ordinates of the body the rectangular Cartesian co-ordinates $x, y$ of the mass-centre $G$ and the angle $\theta$ through which the body has turned from some standard position. The components of linear momentum are then $Mx, My, Mz$, and the angular momentum relative to $G$ as base is $I\theta$, where $I$ is the mass and $\theta$ the moment of inertia about $G$. If the extraneous forces be reduced to a force $(X, Y)$ at $G$ and a couple $N$, we have

$$Mx = X, My = Y, I\theta = N.$$  

If the extraneous forces have zero moment about $G$ the angular velocity $\theta$ is constant. Thus a circular disk projected under gravity in a vertical plane spins with constant angular velocity, whilst its centre describes a parabola.

We may apply the equations (9) to the case of a solid of revolution rolling with its axis horizontal on a plane of inclination $\alpha$. If the axis of $x$ be taken parallel to the slope of the plane, with $x$ increasing downwards, we have

$$Mg = M g \sin \alpha - F = 0, M g \cos \alpha - R, M g \tan \alpha = F_0,$$

where $\alpha$ is the radius of gyration about the axis of symmetry, $\alpha$ is the constant distance of $G$ from the plane, and $R, F$ are the normal and tangential components of the reaction of the plane, as shown in Fig. 74. We have also the kinematic relation $\dot{x} = \dot{\theta}$. Hence

$$\ddot{x} - \alpha^2 \dot{x} - \alpha^2 g \sin \alpha, R = M g \cos \alpha, F = \frac{\alpha^2}{\alpha^2} M g \sin \alpha.$$  

The acceleration of $G$ is therefore less than in the case of frictionless sliding in the ratio $\alpha^2/(\alpha^2 + \alpha^2)$. For a homogeneous sphere this ratio is $\frac{4}{3}$, for a uniform circular cylinder or disk $\frac{1}{3}$, for a circular hoop or a thin cylindrical shell $\frac{2}{3}$.

The equation of energy for a rigid body has already been stated (in effect) as a corollary from fundamental assumptions.
It may also be deduced from the principles of linear and angular momentum as embodied in the equations (q). We have
\[ M(\dot{x} + \ddot{y}) + 100 + x + y + 3N = 0, \]
whence, integrating with respect to \( t \),
\[ \frac{1}{2}M(\dot{x}^2 + \dot{y}^2) + \frac{1}{2}J\dot{\theta}^2 = \int (x\dot{x} + y\dot{y} + \dot{N}t) + \text{const}. \]
(13)
The left-hand side is the kinetic energy of the whole mass, supposed concentrated at \( G \) and moving with this point, together with the kinetic energy of the motion relative to \( G \) (§ 15); and the right-hand member represents the integral work done by the extraneous forces in the successive infinitesimal displacements into which the motion may be resolved.

The formula (13) may be easily verified in the case of the compound pendulum, or of the solid rolling down an incline. As another example, suppose we have a circular cylinder whose masscentre is at an eccentric point, rolling on a horizontal plane. This includes the case of a compound pendulum in which the knife-edge is replaced by a cylindrical pin. If \( a \) be the radius of the cylinder, \( k \) the distance of \( G \) from its axis (O), \( \epsilon \) the radius of gyration about a longitudinal axis through \( G \), and \( \theta \) the inclination of \( OG \) to the vertical, the kinetic energy is \( \frac{1}{2}Ma^2\dot{\theta}^2 + \frac{1}{2}Mc\epsilon^2\dot{\theta}^2 \), by § 3, since the cylinder is a rigid body, and the potential energy is \(-Mgh\cos\theta\). The equation of energy is therefore
\[ \frac{1}{2}M(a^2 + \epsilon^2 + h^2 - 2ah\cos\theta)\dot{\theta}^2 - Mgh\cos\theta = \text{const}. \]
(14)
Whenever, as in the preceding examples, a body or a system of bodies, is subject to constraints which leave it virtually only one degree of freedom, the equation of energy is sufficient for the complete determination of the motion. If \( q \) be any variable co-ordinate defining the position or (in the case of a system of bodies) the configuration, the velocity of each particle at any instant will be proportional to \( \dot{q} \), and the total kinetic energy may be expressed in the form \( \frac{1}{2}A\dot{q}^2 \), where \( A \) is in general a function of \( q \) (cf. equation (14)). This coefficient \( A \) is called the coefficient of inertia, or the reduced inertia of the system, referred to the co-ordinate \( q \).

Thus in the case of a railway truck travelling with velocity \( u \) the kinetic energy is \( \frac{1}{2}(M + me^2)\dot{u}^2 \), where \( M \) is the total mass of the truck and the wheels, \( m \) the sum of the masses of the wheels; the reduced inertia is therefore \( M + me^2 \). Again, take the system composed of the flywheel, connecting rod, and piston of a steam-engine. We have here a limiting case of three-
The special case where both cones are right circular and \( \omega \) is constant is important in astronomy and also in mechanism (theory of bevel wheels). The "precession of the equinoxes" is due to the fact that the earth performs a motion of this kind about its centre, and the whole class of such motions has therefore been termed precessional. In fig. 78, which shows the various cases, \( OZ \) is the axis of the fixed and \( OC \) that of the rolling cone, and \( j \) is the point of contact of the polhode and the perihelode, which are of course both circles. If \( a \) be the semi-angle of the rolling cone, \( \beta \) the constant inclination of \( OC \) to \( OZ \), and \( \psi \) the angular velocity with which the plane ZOC revolves about \( OZ \), then, considering the velocity of a point in \( OZ \) at unit distance from \( O \), we have

\[
\omega \sin a = \psi \sin \beta, \tag{3}
\]

where the lower sign belongs to the third case. The earth's precessional motion is of this latter type, the angles being \( a = 0^\circ 07^\prime 7 \), \( \beta = 23^\circ 26^\prime \).

If \( m \) be the mass of a particle at \( P \), and \( PN \) the perpendicular to the instantaneous axis, the kinetic energy \( T \) is given by

\[
2T = \sum m(\omega \cdot PN)^2 = \omega^2, \quad \sum (m \cdot PN^2) = I_0, \tag{4}
\]

where \( I_0 \) is the moment of inertia about the instantaneous axis. With the same notation for moments and products of inertia as in § 11 (38), we have

\[
1 = AP + bm^2 + Cn^2 - 2Fmn - 2Gml - 2Him, \tag{5}
\]

and therefore by (1),

\[
2T = AP^2 + Bq^2 + Cr^2 - 2Fg - 2Gr - 2Hq. \tag{6}
\]

Again, if \( x, y, z \) be the co-ordinates of \( P \), the component velocities of \( m \) are

\[
q = -\tau y, \quad r = -\tau x, \quad \omega = -\tau z, \tag{7}
\]

by § 7 (6); hence, if \( \lambda, \mu, \nu \) be now used to denote the component angular moments about the co-axial axes, we have

\[
Cm(\omega y - g) = \lambda, \quad Bm(\omega z - r) = \mu, \quad Crm(\omega x - q) = \nu. \tag{8}
\]

If the co-ordinate axes be taken to coincide with the principal axes of inertia at \( O \), at the instant under consideration, we have the simpler formulae

\[
2T = Ap^2 + Bq^2 + Cr^2, \tag{9}
\]

\[
\lambda = Ap, \quad \mu = Bq, \quad \nu = Cr. \tag{10}
\]

It is to be carefully noticed that the axis of resultant angular momentum about \( O \) does not in general coincide with the instantaneous axis of rotation. The relation between these axes may be expressed by means of the momental ellipsoid at \( O \). The equation of the latter, referred to its principal axes, being as in § 11 (41), the co-ordinates of the point \( J \) where it is met by the instantaneous axis are proportional to \( p, q, r \), and the direction-cosines of the normal at \( j \) are therefore proportional to \( Ap, Bq, Cr \), or \( \lambda, \mu, \nu \). The axis of resultant angular momentum is therefore normal to the tangent plane at \( J \), and does not coincide with \( OJ \) unless the latter be a principal axis. Again, if \( \Gamma \) be the resultant angular momentum, so that

\[
\lambda^2 + \mu^2 + \nu^2 = \Gamma^2, \tag{11}
\]

the length of the perpendicular OH on the tangent plane at \( J \)

\[
OH = \frac{\lambda p + \mu q + \nu r}{\tau p + \tau q + \tau r} = \frac{2T - \omega^2}{T}, \tag{12}
\]

where \( \rho = OJ \). This relation will be of use to us presently (§ 19).

The components \( \xi, \eta, \zeta \) of linear momentum are

\[
\xi = M\omega + \frac{\partial T}{\partial y}, \quad \eta = M\omega + \frac{\partial T}{\partial z}, \quad \zeta = M\omega + \frac{\partial T}{\partial x}. \tag{13}
\]

by § 7 (6). It is usually convenient to take as our base-point the mass-centre of the body. In this case the kinetic energy is given by

\[
2T = M_0(\omega y + \omega z + \omega x) + Ap'q^2 + Bq'r^2 + Cr'p^2 - 2Gr' - 2Gr' - 2Hq', \tag{14}
\]

where \( M_0 \) is the mass, and \( A, B, C, F, G, H \) are the moments and products of inertia with respect to the mass-centre; cf. § 15 (9).

The components \( \xi, \eta, \zeta \) of linear momentum are

\[
\xi = M\omega + \frac{\partial T}{\partial y}, \quad \eta = M\omega + \frac{\partial T}{\partial z}, \quad \zeta = M\omega + \frac{\partial T}{\partial x}. \tag{15}
\]

whilst those of the relative angular momentum are given by (7).

The preceding formulae are sufficient for the treatment of instantaneous impulses. Thus if an impulse \( (\xi, \eta, \zeta) \) be imparted to the motion from \( (u, v, w, q, r) \) to \( (u', v', w', q', r') \), we have

\[
M(u' - u) = \xi, \quad M(v' - v) = \eta, \quad M(w' - w) = \zeta. \tag{16}
\]

and, for simplicity, the co-ordinate axes are supposed to coincide with the principal axes at the mass-centre. Hence the change of kinetic energy is

\[
T' - T = \xi \cdot (u + u') + \eta \cdot (v + v') + \zeta \cdot (w + w') + \lambda \cdot (q + q') + \mu \cdot (g + g') + \nu \cdot (r + r'). \tag{17}
\]

The factors of \( \xi, \eta, \zeta, \lambda, \mu, \nu \) on the right-hand side are proportional to the constituents of a possible infinitesimal displacement of the solid, and the whole expression is proportional (on the same scale) to the work done by the given system of impulsive forces in such a displacement. As in § 8 this must be equal to the total work done in such a displacement by the several forces, whatever they are, which make up the impulse. We are thus led to the following statement: the change of kinetic energy due to any system of impulsive forces is equal to the sum of the products of the several forces into the semi-quantity of the initial and final velocities of their respective points of application, resolved in the directions of the forces. Thus in the problem of fig. 77 the kinetic energy generated is

\[
\frac{1}{2}M(\xi^2 + \eta^2 + \zeta^2), \tag{18}
\]

where \( C, F, G, L, M, N \) denote the system of extraneous forces referred to the mass-centre as base, the co-ordinate axes being of course fixed in direction. The resulting equations are not as a rule easy of application, owing to the fact that the moments and products of inertia \( A, B, C, F, G, H \) are not constants but vary in consequence of the changing orientation of the body with respect to the co-ordinate axes.

An exception occurs, however, in the case of a solid which is kinetically symmetrical (§ 11) about the mass-centre, e.g. a uniform sphere. The equations then take the forms

\[
\begin{align*}
\frac{d\xi}{dt} &= X, & \frac{d\eta}{dt} &= Y, & \frac{d\zeta}{dt} &= Z, \\
\frac{d\lambda}{dt} &= L, & \frac{d\mu}{dt} &= M, & \frac{d\nu}{dt} &= N,
\end{align*}
\]

where \( X, Y, Z, L, M, N \) denote the system of extraneous forces referred (like the momenta) to the mass-centre as base, the co-ordinate axes being of course fixed in direction. The resulting equations are not as a rule easy of application, owing to the fact that the moments and products of inertia \( A, B, C, F, G, H \) are not constants but vary in consequence of the changing orientation of the body with respect to the co-ordinate axes.

An exception occurs, however, in the case of a solid which is kinetically symmetrical (§ 11) about the mass-centre, e.g. a uniform sphere. The equations then take the forms

\[
\begin{align*}
\frac{d\xi}{dt} &= X, & \frac{d\eta}{dt} &= Y, & \frac{d\zeta}{dt} &= Z, \\
\frac{d\lambda}{dt} &= L, & \frac{d\mu}{dt} &= M, & \frac{d\nu}{dt} &= N,
\end{align*}
\]

where \( C, F, G, L, M, N \) denote the system of extraneous forces referred to the mass-centre as base, the co-ordinate axes being of course fixed in direction. The resulting equations are not as a rule easy of application, owing to the fact that the moments and products of inertia \( A, B, C, F, G, H \) are not constants but vary in consequence of the changing orientation of the body with respect to the co-ordinate axes.
MECHANICS

This has two solutions of the type \( x + iy = ae^{(p+ip)t} \), where \( a \), \( e \), and \( p \) are arbitrary, and \( \sigma \) is a root of the quadratic

\[
(C + Ma^2)z^2 - (Cna + Mga)z + c = 0,
\]

both roots are real, and have the same sign as \( n \). The motion of \( G \) then consists of two superposed circular vibrations of the type

\[
x = a \cos(\sigma t + e), \quad y = a \sin(\sigma t + e),
\]

in each of which the direction of revolution is the same as that of the initial spin of the sphere. It follows therefore that the original position is stable provided the spin \( n \) exceed the limit defined by (35). The case of a sphere spinning about a vertical axis at the lowest point of a spherical bowl is obtained by reversing the signs of \( a \) and \( e \). It appears that this position is always stable.

It is to be remarked, however, that in the first form of the problem the stability above investigated is practically of a limited or temporary kind. The slightest frictional forces—such as the resistance of the air—even if they act in lines through the centre of the rolling sphere, and so do not directly affect its angular momentum, will cause the centre gradually to descend in an ever-widening spiral path.

§ 19. Free Motion of a Solid.—Before proceeding to further problems of motion under extraneous forces it is convenient to investigate the free motion of a solid relative to its mass-centre, for the most general case. This is the same as the motion about a fixed point under the action of extraneous forces which have zero moment about that point. The question was first discussed by Euler (1750); the geometrical representation to be given is due to Poinsot (1851).

The kinetic energy \( T \) of the motion relative to \( O \) will be constant.

\[
T = \frac{1}{2}J\dot{\omega}^2,
\]

where \( \omega \) is the angular velocity and \( I \) is the moment of inertia about the instantaneous axis. If \( p \) be the radius-vector \( OJ \) of the momental ellipsoid

\[
A^2x^2 + B^2y^2 + C^2z^2 = M^4
\]

drawn in the direction of the instantaneous axis, we have

\[
I = \mathbf{M}^2\rho(\rho + 1);
\]

hence \( \omega \) varies as \( \rho \). The locus of \( J \) may therefore be taken as the "polhode" (§ 18). Again, the vector which represents the angular momentum with respect to \( O \) will be constant in every respect. We have seen (§ 18) that this vector coincides in direction with the perpendicular OH to the tangent plane of the momental ellipsoid at \( J \); also that

\[
OH = \frac{2T}{\dot{T}} \cdot \dot{\omega}
\]

where \( J \) is the resultant angular momentum about \( O \). Since \( \omega \) varies as \( \rho \), it follows that \( OH \) is constant, and the tangent plane at \( J \) is therefore fixed in space. The motion of the body relative to \( O \) is therefore completely represented if we imagine the momental ellipsoid at \( O \) to roll without sliding on a plane fixed in space, with an angular velocity proportional to each instant at the radius-vector of the point of contact. The fixed plane is parallel to the invariable plane at \( O \), and the line \( OH \) is called the invariable line. The trace of the point of contact on the fixed plane is the "perpolid." If \( \rho, \dot{\rho}, \dot{t} \) be the component angular velocities about the principal axes at \( O \), we have

\[
(A^2\rho + B^2\dot{\rho} + C^2\dot{t}) = I\dot{\rho}^2 + (A^2\dot{\rho} + B^2\dot{\rho} + C^2\dot{t})\dot{t},
\]

each side being in fact equal to unity. At a point on the polhode cone \( x = \frac{P_1}{2\Delta}, y = \frac{P_2}{2\Delta}, z = \frac{P_3}{2\Delta} \), and the equation of this cone is therefore

\[
A^2(1 - \frac{P_1}{2\Delta})x^2 + B^2(1 - \frac{P_2}{2\Delta})y^2 + C^2(1 - \frac{P_3}{2\Delta})z^2 = \frac{O^2}{4}\Delta.
\]

Since \( 2\Delta - I\Theta = (A - B)\rho^2 + C(A - C)^2 \), it appears that if \( A > B > C \) the coefficient of \( x^2 \) is \( 4 \) is positive, that of \( y^2 \) is negative, whilst that of \( z^2 \) is positive or negative according to \( 2B \gtrless 2^2 \). Hence the polhode cone surrounds the axis of greatest or least moment according as \( 2B \gtrless 2^2 \). In the critical case of \( 2B = 2^2 \) it breaks up into two planes through the axis of mean moment (\( O \)). The perpolid curve in the fixed plane is obviously confined between two concentric circles which it alternately touches; it is not in general a re-entrant curve. It has been shown by De Sparre that, owing to the limitation imposed on the possible forms of the momental ellipsoid by the relation \( B + C \gtrless A \), the curve has no points of inflexion. The invariable line \( OH \) describes another cone in the
body, called the invariable cone. At any point of this we have
\[ x : y : z = A p : B q : C r, \text{ and the equation is therefore} \]
\[ \left(1 - \frac{r^2}{2A^2}\right) x^2 + \left(1 - \frac{r^2}{2B^2}\right) y^2 + \left(1 - \frac{r^2}{2C^2}\right) z^2 = 0. \]  
(5)

The signs of the coefficients follow the same rule as in the case of (4). The possible forms of the invariable cone are indicated in fig. 80 by means of the intersections with a concentric spherical surface. In the critical case of \(2B^2 = l^2\) the cone degenerates into two planes. It appears that if the body be slightly disturbed from a state of rotation about the principal axis of greatest or least moment, the invariable cone will closely surround this axis, which will therefore never deviate far from the invariable line. If, on the other hand, the body be slightly disturbed from a state of rotation about the mean axis a wide deviation will take place.

Hence a rotation about the axis of greatest or least moment is reckoned as stable, a rotation about the mean axis as unstable. The question is greatly simplified when two of the principal moments are equal, say \(A = B\). The polhode and herpolhode cones are then right circular, and the motion is "precessional" according to the definition of \(\delta u\). If \(\delta\) be the inclination of the instantaneous axis to the axis of symmetry, \(\beta\) the inclination of the latter axis to the invariable line, we have
\[ \Gamma \cos \beta = C \omega \cos a, \]
\[ \Gamma \sin \beta = A \omega \sin a, \]
whence
\[ \tan \beta = \frac{A}{C} \tan a. \]  
(6)
(7)

Hence \(\beta > a\), and the circumstances are therefore those of the first or second case in fig. 78, according as \(A > C\). If \(\psi\) be the rate at which the plane \(HOM\) revolves about \(OH\), we have
\[ \psi = \frac{\cos a - A \cos \psi}{\sin a}. \]  
(8)
by \(\delta u\) (3). Also if \(\chi\) be the rate at which \(J\) describes the polhode, we have
\[ \psi = \frac{\sin (\beta - a) - \chi \sin \beta}{\sin a}. \]  
(9)
If the instantaneous axis only deviates slightly from the axis of symmetry the angles \(a\), \(\beta\), small, then \(\chi = (A - C) A \cdot \omega\); the instantaneous axis therefore completes its revolution in the body in the period
\[ 2\pi \frac{A - C}{A \cdot \omega}. \]  
(10)

In the case of the earth it is inferred from the independent phenomenon of lunisolar precession that \((C - A)A = -00313\). Hence if the earth's axis of rotation deviates slightly from the axis of figure, it should describe a cone about the latter in 320 sidereal days. This would cause a periodic variation in the latitude of any place on the earth's surface, as determined by astronomical methods. There appears to be evidence of a slight periodic variation of latitude, but the period would seem to be about fourteen months. The discrepancy is attributed to a defect of rigidity in the earth. The phenomenon is known as the Eulerian nutation, since it is supposed to come under the free rotations first discussed by Euler.

§ 20. Motion of a Solid of Revolution.—In the case of a solid of revolution, or (more generally) whenever there is kinetic symmetry about an axis through the mass-centre, or through a fixed point \(O\), a number of interesting problems can be treated almost directly from first principles. It frequently happens that the extraneous forces have zero moment about the axis of symmetry, as e.g. in the case of the flywheel of a gyroscopic if we neglect the friction at the bearings. The angular velocity \(r\) about this axis is then constant. For we have seen that \(r\) is constant when there are no extraneous forces; and \(r\) is evidently not affected by an instantaneous impulse which leaves the angular momentum \(Cr\), about the axis of symmetry, unaltered. And a continuous force may be regarded as the limit of a succession of infinitesimal instantaneous impulses.

Suppose, for example, that a flywheel is rotating with angular velocity \(a\) about its axis, which is (more) horizontal, and that this axis is made to rotate with the angular velocity \(\psi\) in the horizontal plane. The components of angular momentum about the axis of the flywheel and about the vertical will be \(Cr\) and \(A\psi\) respectively, where \(A\) is the moment of inertia about any axis through the mass-centre (or through the fixed point \(O\)) perpendicular to that of symmetry. If \(OK\) be the vector representing the former component at time \(t\), the vector which represents it at time \(t + \delta t\) will be \(\vec{OK}'\), equal to \(\vec{OK}\) in magnitude and making with it an angle \(\delta \theta\). Hence
\[ K^\kappa = K - C \omega \psi \]  
represents the change in this component due to the extraneous forces. Hence, so far as this component is concerned, the extraneous forces must supply a couple of moment \(C\omega\psi\) in a vertical plane through the axis of the flywheel. If this couple be absent, the axis will be tilted out of the horizontal plane, and \(\phi\) will be the angle which the direction of the spin \(\pi\) approximates to that of the azimuthal rotation \(\psi\). The remaining constituent of the extraneous forces is a couple \(A\psi\) about the vertical; this vanishes if \(\psi\) is constant. If the axis of the flywheel make an angle \(\theta\) with the vertical, it is seen in like manner that the required couple in the vertical plane through the axis is \(Cn\sin \theta\psi\). This matter can be strikingly illustrated by an ordinary gyroscopic, e.g. by making the larger movable ring in fig. 37 rotate about its vertical diameter.

If the direction of the axis of kinetic symmetry be specified by means of the angular co-ordinates \(\theta, \psi\) of § 7, then considering the component velocities of the point in fig. 83, which are \(\theta\) and \(\psi\) along and perpendicular to the meridian \(ZC\), we see that the component angular velocities about the lines \(OA', OB'\) are \(-\sin \theta \psi\) and \(\psi\) respectively. Hence if the principal moments of inertia at \(O\) be \(A, C, \psi\), and if \(n\) be the constant angular velocity about the axis \(OC\), the kinetic energy is given by
\[ \frac{1}{2}T = \theta \cdot (\psi + \sin \theta \psi) + Cn^2. \]  
(11)
Again, the components of angular momentum about \(OC\), \(OA'\) are \(Cn\cdot \sin \theta \psi\), and therefore the angular momentum \(\mu\), say about \(OZ\) is
\[ \mu = A \sin \theta \psi + Cn \cos \theta. \]  
(12)

We can hence deduce the condition of steady precessional motion in a top. A solid of revolution is supposed to be free to turn about a fixed point \(O\) on its axis of symmetry, its mass-centre \(G\) being in this at a distance \(b\) from \(O\). In fig. 83 \(OZ\) is supposed to be vertical, and \(OC\) is the axis of the solid drawn in the direction \(OG\). If \(\theta\) is constant the points \(C, A'\) will in time \(t\) come to positions \(C', A''\) such that \(CC'' = \sin \theta \psi\) and \(AA'' = Cn\cos \theta\); and the angular momentum about \(OB'\) will become \(Cn\cdot \psi + A \sin \theta \psi\) and \(\psi\) respectively. Equating this to \(Mg\sin \theta \delta t\), and dividing out by \(\sin \theta\), we obtain
\[ A \cos \theta \cdot \psi = -Cn^2 \psi + Mgh = 0. \]  
(13)

as the condition in question. For given values of \(n\) and \(\theta\) we have two possible values of \(\psi\) provided \(n\) exceed a certain limit. With a very rapid spin, or (more precisely) with \(Cp\) large in comparison with \((4AMgh \cos \theta)\), one value of \(\psi\) is small and the other large, viz. the two values are \(Mgh/Cn\) and \(Cn/A \cos \theta\) approximately. The absence of \(g\) from the latter expression indicates that the circumstances of the rapid precession are very
nearly those of a free Eulerian rotation (§ 19), gravity playing only a subordinate part.

Again, take the case of a circular disk rolling in steady motion on a horizontal plane. The centre $O$ of the disk is supposed to describe a horizontal circle of radius $c$ with the constant angular velocity $\psi$, whilst its plane preserves a constant inclination $\theta$ to the horizontal. The components of the reaction of the horizontal lane will be $\text{Me}_{\theta}$ at right angles to the tangent line at the point of contact and $\text{Mg}$ vertically upwards, and the moment of these about the horizontal diameter of the disk, which corresponds to an impulse on lines $\theta$, where $\theta$ is the radius of the disk. Equating this to the rate of increase of the angular momentum about $\text{O'\theta}$, investigated as above, we find

$$\frac{d}{dt} (c+\text{Me}_{\theta}+\lambda_{\theta} \cos \theta) \theta^2 = \text{Mg} \frac{c}{2} \cot \theta$$,

where $\text{Mg}$ has been made of the obvious relation $\text{Me}_{\theta} = \text{cf}_\theta$. If $\phi$ and $\theta$ be given this formula determines the value of $\psi$ for which the motion will be steady.

In the case of the top, the equation of energy and the condition of constant angular momentum ($\mu$) about the vertical OZ is sufficient to determine the motion of the axis. Thus, we have

$$\frac{d}{dt} \lambda_{\theta} - (\mu - p \cos \theta)(\mu \cos \theta - \nu) - \text{Mg} \sin \theta = 0$$,

where $\psi$ is written for $Cn$. From these $\psi$ may be eliminated, and on differentiating the resulting equation with respect to $t$ we obtain

$$\Lambda \frac{d}{dt} \phi - (\mu - p \cos \theta)(\mu \cos \theta - \nu) - \text{Mg} \sin \theta = 0$$,

where

$$\sigma = (\mu - p \cos \theta) + 2(\mu - \nu \cos \theta)(\mu \cos \theta - \nu)$$

$$+ (\mu \cos \theta - \nu) \lambda_{\theta}^2 \sin \alpha$$.

When $\nu$ is large we have, for the "slow" precession $\sigma = \mu A$, and for the "rapid" precession $\sigma = \mu A \theta$, approximately. Further, on examining the small variation in $\psi$, it appears that in a slightly disturbed slow precession the motion of any point of the axis consists of a rapid circular vibration superposed on the steady precession, so that the resultant path has a trochoidal character. This is a type of motion commonly observed in a top spun in the ordinary way, although the successive rotations of the trochoid may be too small to be easily observed. In a slightly disturbed rapid precession the superposed vibration is elliptic-harmonic, with a period equal to that of the precession itself. The ratio of the axes of the ellipse is sec $\alpha$, the longer axis being in the plane of $\theta$. The result is that the axis of the top describes a circular cone about a fixed line making a small angle with the vertical. This is, in fact, the "invariable plane" of the free Eulerian rotation with which (as already remarked) we are here virtually concerned. For the more general discussion of the motion of a top see Gyroscope.

§ 21. Moving Axes of Reference.—For the more general treatment of the kinetics of a rigid body it is usually convenient to adopt a system of moving axes. In order that the moments and products of inertia with respect to these axes may be constant, it is in general necessary to suppose them fixed in the solid.

We will assume for the present that the origin $O$ is fixed. The moving axes $Ox$, $Oy$, $Oz$ form a rigid frame of reference whose motion at time $t$ may be specified by the three component angular velocities $p, q, r$. The components of angular momentum about $Ox$, $Oy$, $Oz$ will be denoted as usual by $P, Q, R$. We consider a system of fixed axes $Ox', Oy', Oz'$ chosen so as to coincide at the instant $t$ with the moving system $Ox$, $Oy$, $Oz$. At the instant $t + \delta t$, $Ox$, $Oy$, $Oz$ will no longer coincide with $Ox'$, $Oy'$, $Oz'$; in particular they will make with $Ox'$ angles whose cosines are, to the first order, $1, -p\delta t, q\delta t$, respectively. Hence the altered angular momentum about $Ox'$ will be $\lambda + \delta \lambda = (\mu + p\delta t)(-r\delta t) + (q + q\delta t)\delta t$. If $L$, $M$, $N$ be the moments of the extraneous forces about $Ox$, $Oy$, $Oz$ this must be equal to $L + \delta L$, $M + \delta M$, $N + \delta N$.

These equations are applicable to any dynamical system whatever. If we now apply them to the case of a rigid body moving about a fixed point $O$, and make $Ox$, $Oy$, $Oz$ coincide with the principal axes of inertia at $O$, we have $L = \lambda$, $M = \mu$, $N = \nu$, whence

$$A \frac{d}{dt} (A - B) = (B - C) \theta$$

$$B \frac{d}{dt} (B - C) = (C - A) \theta$$

$$C \frac{d}{dt} (A - B) = (A - C) \theta$$,

which is (virtually) the equation of energy.

As a first application of the equations (2) take the case of a solid constrained to rotate with constant angular velocity $\omega$ about a fixed axis (\(\hat{t}, m, n\)). Since $p$, $q$, $r$ are then constant, the requisite coupling constant is

$$L = (C - B) \omega^2, M = (C - A) \omega^2, N = (B - A) \omega^2$$.

If we reverse the signs, we get the "centrifugal couple" exerted by the solid on its bearings. This couple vanishes when the axis of rotation is a principal axis at $O$, and in no other case (cf. § 17).

If in (2) we put, $L$, $M$, $N = 0$ we get the case of free rotation; thus

$$A \frac{d}{dt} (A - B) = (B - C) \theta$$

$$B \frac{d}{dt} (B - C) = (C - A) \theta$$

$$C \frac{d}{dt} (A - B) = (A - C) \theta$$,

These equations are due to Euler, with whom the conception of moving axes, and the application to the problem of free rotation, originated. If we multiply them by $p$, $q$, $r$, respectively, or again by $A$, $B$, $C$, respectively, and add, we verify that the expressions $A \omega^2 = B \omega^2 + C \omega^2$ and $A \omega^2 + B \omega^2 + C \omega^2$ are both constant. The former is, in fact, equal to $\dot{\omega}$, and the latter to $\dot{T}$, where $T$ is the kinetic energy and $\Gamma$ the resultant angular momentum.

To complete the solution of (2) a third integral is required; this involves in general the use of elliptic functions. The problem has been the subject of numerous memoirs; we will here notice only the form of solution given by Rude (1834), and at a later period by G. Kirchhoff (1875). If we write

$$u = \frac{\dot{\phi} \dot{\theta} \dot{\alpha}}{\sin \theta}, \quad \Delta \dot{\phi} = 1 - k^2 \sin^2 \phi$$,

we have, in the notation of elliptic functions, $\phi = \alpha \theta$. If we assume $\rho = \rho_0 \cos \alpha (\alpha + \epsilon), \quad q = \rho_0 \sin \alpha (\alpha + \epsilon), \quad r = \rho_0 \alpha (\alpha + \epsilon)$, we find

$$\dot{\beta} = \frac{\sigma p_0 q_0}{\rho_0^3} \theta, \quad \dot{q} = \frac{\sigma p_0 q_0}{\rho_0^3} \rho_0 \beta$$.

Hence (5) will be satisfied, provided

$$\frac{\sigma p_0 q_0}{\rho_0^3} = 1, \quad \frac{\sigma p_0 q_0}{\rho_0^3} = 1, \quad \frac{\sigma p_0 q_0}{\rho_0^3} = 1$$.

These equations, together with the arbitrary initial values of $p, q, r$, determine the six constants which we have denoted by $p_0, q_0, r_0, k^2, \epsilon$. We will suppose that $A > B > C$. From the form of the trochode curves referred to in § 10 it appears that the angular velocity $\theta$ about the axis of mean motion must vanish periodically. If we adopt one of these epochs as the origin of $t$, we have $\theta = 0$ and $\rho_0 = 0$, $\rho_0$, $\beta$ will become identical with the initial values of $p, q, r$. The conditions (9) then lead to

$$\frac{\lambda (A - C)}{AB} \rho_0^3, \quad \dot{\theta} = \frac{(A - C)(B - C)}{AB} \rho_0^3, \quad \dot{\theta} = \frac{(A - B)\rho_0^3}{(B - C)\rho_0^3}$$.
For a real solution we must have $k^2 < 1$, which is equivalent to $2BT > 1^2$. If the initial conditions are such as to make $2BT < 1^2$, we must interchange the forms of $\varphi$ and $r$ in (8). In the present case the instantaneous axis returns to its initial position in the body whenever $\phi$ increases by $2\pi$, i.e. whenever $t$ increases by $4K/\varphi$, when $K$ is the complete elliptic integral of the first kind with respect to the modulus $k$.

The elliptic functions degenerate into simpler forms when $k^2 = 0$ or $k^2 = 1$. The former case arises when two of the principal moments are equal, this has been sufficiently dealt with in (9). If $k^2 = 1$, we must have $2BT = 1^2$. We have seen that the alternative $2BT < 1^2$ determines whether the pole of the cone surrounds the principal axis of least or greatest moment. The case of $2BT = 1^2$, exactly, is therefore a critical case; it may be shown that the instantaneous axis either coincides permanently with the axis of mean moment or approaches it asymptotically.

When the origin of the moving axes is also in motion with a velocity whose components are $u$, $v$, $w$, the dynamical equations are

\[
\begin{align*}
\frac{dz}{dt} &= r - rt + q = X, \quad \frac{dz}{dt} = \frac{dz}{dt} + q = Y, \quad \frac{dz}{dt} - q + q = Z, \\
\frac{dz}{dt} &= r - rt + q = X, \quad \frac{dz}{dt} = \frac{dz}{dt} + q = Y, \quad \frac{dz}{dt} - q + q = Z.
\end{align*}
\]

(11)

To prove these, we may take fixed axes $O'x'$, $O'y'$, $O'z'$ coincident with the moving axes at time $t$, and compare the linear and angular momenta $\xi^2 + \xi = \eta^{2} + \eta = \lambda^{2} + \lambda = \mu^{2} + \mu = v + v$ relative to the new position of the axes, $O, O, O$, at time $t + dt$ with the original momenta $\xi, \eta, \lambda, \mu, v, v$ relative to $O'x', O'y', O'z'$ at time $t$. As in the case of (2), the equations are applicable to any dynamical system whatever. If the moving origin coincides always with the mass-centre, we have $q = \xi = \eta = \lambda = \mu = v = 0$, therefore $M = 0$, where $M$ is the total mass, and the equations simplify.

When, in any problem, the values of $u, v, w, p, q, r$ have been determined as functions of $t$, it still remains to connect the moving axes with some fixed frame of reference. It will be sufficient to take the case of motion about a fixed point $O$; the angular co-ordinates $\theta$, $\phi$, $\psi$ of Euler may then be used for the purpose. Referring to fig. 36 we see that the angular velocities $p, q, r$ of the moving lines, OA, OB, OC about their instantaneous positions are

\[
\begin{align*}
p &= \sin \phi \cos \theta, \quad q = \cos \phi, \quad r = -\sin \theta \sin \phi, \\
\phi &= \sin \theta \cos \phi, \quad \psi = \cos \theta, \quad \psi = \phi.
\end{align*}
\]

(13)

by § 7 (4). If OA, OB, OC be principal axes of inertia of a solid, and if $A, B, C$ denote the corresponding moments of inertia, the kinetic energy is given by

\[
2T = \frac{1}{2} \left( \frac{dx}{dt} \right)^2 + \frac{1}{2} \left( \frac{dy}{dt} \right)^2 + \frac{1}{2} \left( \frac{dz}{dt} \right)^2 + \frac{1}{2} \left( \frac{d\theta}{dt} \right)^2 + \frac{1}{2} \left( \frac{d\phi}{dt} \right)^2 + \frac{1}{2} \left( \frac{d\psi}{dt} \right)^2
\]

(14)

If $A = B$ this reduces to

\[
2T = \frac{1}{2} \left( \frac{dx}{dt} \right)^2 + \frac{1}{2} \left( \frac{dy}{dt} \right)^2 + C \left( \frac{d\psi}{dt} \right)^2
\]

(15)

cf. § 20 (1).

§ 22. Equations of Motion in Generalized Co-ordinates.—Suppose we have a dynamical system composed of a finite number of material particles or rigid bodies, whether free or constrained in any way, which are subject to multiple forces and also to the action of any given extraneous forces. The configuration of such a system can be completely specified by means of a certain number $(n)$ of independent quantities, called the generalized co-ordinates of the system. These co-ordinates may be chosen in an endless variety of ways, but their number is determinate, and expresses the number of degrees of freedom of the system. We denote these co-ordinates by $q_1, q_2, \ldots, q_n$. It is implied in the above description of the system that the Cartesian co-ordinates $x, y, z$ of any particle of the system are known functions of the $q_i$'s, varying in form (of course) from particle to particle. Hence the kinetic energy $T$ is given by

\[
2T = \frac{1}{2} \left[ \sum \left( \frac{\partial q_i}{\partial t} \right)^2 + \left( \frac{\partial q_j}{\partial t} \right)^2 + \ldots + \left( \frac{\partial q_n}{\partial t} \right)^2 \right]
\]

(1)

where $a_{nn} = \frac{1}{2} \left( \frac{\partial q_i}{\partial q_j} \right)^2 + \left( \frac{\partial q_j}{\partial q_j} \right)^2 + \ldots + \left( \frac{\partial q_n}{\partial q_n} \right)^2$.

Thus $T$ is expressed as a homogenous quadratic function of the quantities $q_1, q_2, \ldots, q_n$, which are called the generalized components of velocity. The coefficients $a_{ij}, a_{ji}$ are called the coefficients of inertia; they are not in general constants, being functions of the $q_i$'s and so variable with the configuration. Again, if $(X, Y, Z)$ be the force on $m$, the work done in an infinitesimal change of configuration is

\[
\Sigma (Xq_1 + Yq_2 + Zq_n) = \Sigma q_i a_{ii} + \Sigma q_j a_{ij} + \Sigma q_n a_{nj}
\]

(3)

where

\[
Q_i = \Sigma (Xq_i + Yq_j + Zq_n)
\]

(4)

The quantities $Q_i$ are called the generalized components of force.

The equations of motion of $m$ being

\[
m\frac{dx}{dt} = X, \quad m\frac{dy}{dt} = Y, \quad m\frac{dz}{dt} = Z
\]

(5)

we have

\[
\Sigma \left\{ \frac{d^2 q_i}{dt^2} \right\} + \Sigma \left( \frac{\partial x}{\partial q_j} \right) \frac{dq_j}{dt} = 0
\]

(6)

whence

\[
\frac{d^2 q_i}{dt^2} = \frac{\partial x}{\partial q_i}
\]

(7)

Also

\[
\frac{d^2 q_i}{dt^2} = \frac{\partial x}{\partial q_j} = \frac{\partial y}{\partial q_j} = \frac{\partial z}{\partial q_j}
\]

(8)

Hence

\[
\frac{d^2 q_i}{dt^2} - \frac{d^2 q_i}{dt^2} = \frac{d^2 q_i}{dt^2} - \frac{d^2 q_i}{dt^2}
\]

(9)

By these and the similar transformations relating to $y$ and $z$ the equation (6) takes the form

\[
\frac{d^2 q_i}{dt^2} = \frac{\partial x}{\partial q_i}
\]

(10)

If we put $r = 1, 2, \ldots, n$ in succession, we get the $n$ independent equations of motion of the system. These equations are due to Lagrange, with whom indeed the first conception, as well as the establishment, of a general dynamical method applicable to all systems whatever appears to have originated. The above proof was given by Sir W. R. Hamilton (1835). Lagrange's own proof will be found under Dynamics, § Analytical. In a conservative system free from extraneous force we have

\[
\Sigma (Xq_1 + Yq_2 + Zq_n) = -\frac{dV}{dt}
\]

(12)

where $V$ is the potential energy. Hence

\[
Q_i = -\frac{\partial V}{\partial q_i}
\]

and

\[
\frac{d^2 q_i}{dt^2} = \frac{\partial x}{\partial q_i} = \frac{\partial y}{\partial q_i} = \frac{\partial z}{\partial q_i}
\]

(13)

If we imagine any given state of the system as a configuration through the configuration $(q_1, q_2, \ldots, q_n)$ to be generated instantaneously from rest by the action of suitable impulsive forces, we find on integrating (11) with respect to $t$ over the infinitely short duration of the impulse

\[
\frac{d^2 q_i}{dt^2} = Q_i
\]

(15)

where $Q_i$ is the time integral of $Q_i$ and so represents a generalized component of impulse. By an obvious analogy, the expressions $\frac{d^2 q_i}{dt^2}$ may be called the generalized components of momentum; they are usually denoted by $p_i$, thus

\[
p_i = \frac{d^2 q_i}{dt^2} = a_{ii} q_i + a_{ij} q_j + \ldots + a_{ni} q_n
\]

(16)

Since $T$ is a homogenous quadratic function of the velocities $q_1, q_2, \ldots, q_n$, we have

\[
2T = \frac{d^2 q_i}{dt^2} + \frac{d^2 q_j}{dt^2} + \ldots + \frac{d^2 q_n}{dt^2} = p_i q_i + p_j q_j + \ldots + p_n q_n
\]

(17)

Hence

\[
\frac{d^2 q_i}{dt^2} = p_i q_i + p_j q_j + \ldots + p_n q_n
\]

(18)

or

\[
\frac{d^2 q_i}{dt^2} = Q_i q_i + Q_j q_j + \ldots + Q_n q_n
\]

(19)
This equation expresses that the kinetic energy is increasing at a rate equal to that at which work is being done by the forces. In the case of a conservative system free from extraneous force it becomes the equation of energy
\[
\frac{d}{dt}(T+V) = 0, \text{ or } T+V = \text{const.},
\]
in virtue of (13).

As a first application of Lagrange's formula (11) we may form the equations of motion of a particle in spherical polar co-ordinates. Let \( r \) be the distance of a point \( P \) from a fixed origin \( O \), \( \theta \) the angle which \( OP \) makes with a fixed direction \( OZ \), \( \phi \) the azimuth of the plane \( ZOP \) relative to some fixed plane through \( OZ \). The displacements of \( P \) due to small variations of these co-ordinates are \( dr, r\theta \), perpendicular to \( OP \) in the plane \( ZOP \), and \( r \sin \theta \phi \), perpendicular to this plane. The components of velocities in these directions are therefore \( r \dot{r}, r \dot{\theta} \sin \theta \phi \), and if \( r \) be the mass of a moving particle at \( P \) we have

\[
2T = m(r^2 \dot{r}^2 + r^2 \dot{\theta}^2 + r^2 \dot{\phi}^2 \sin^2 \theta \phi^2),
\]

Hence the formula (11) gives

\[
\frac{d}{dt}(mr^2 \dot{r} - r \sin \theta \dot{\theta} \phi^2) = 0,
\]

\[
\frac{d}{dt}(m r^2 \dot{\theta} \sin \theta \phi - r \sin \theta \dot{\phi}^2) = 0.
\]

The quantities \( r, \theta, \phi \) are the coefficients in the expression \( r\theta + \theta \phi + \phi \psi \) for the work done in an infinitely small displacement, viz \( r \) is the radial component of force, \( \theta \) is the moment about a line through \( O \) perpendicular to the plane \( ZOP \), and \( \phi \) is the moment about \( OZ \). In the case of the spherical pendulum we have \( r = a, \theta = e, \phi = \phi \), if \( OZ \) be drawn vertically downwards, and therefore

\[
\frac{d}{dt}(m r^2 \dot{\theta} \sin \theta \phi - r \sin \theta \dot{\phi}^2) = 0,
\]

\[
\sin \theta \phi \dot{\phi}^2 = \sin \theta \phi \dot{\phi}^2.
\]

If the particle describes a horizontal circle of angular radius \( a \) with constant angular velocity \( \Omega \), we have \( \dot{\theta} = 0, \phi = 2\pi t \in \in \), and therefore

\[
\dddot{\theta} + \frac{h}{a \sin \theta} \ddot{\phi} \theta = \frac{h}{a \sin \theta} \dot{\phi}.
\]

As is otherwise evident from the elementary theory of uniform circular motion. To investigate the small oscillations about this state of steady motion we write \( \theta = \alpha + \dot{\theta} t \) in (24) and neglect terms of the second order in \( \dot{\theta} \). We find, after some reductions,

\[
\dot{\theta} \dddot{\theta} + \frac{h}{a \sin \theta} \ddot{\theta} \theta = 0;
\]

this shows that the variation of \( \dot{\theta} \) is simple-harmonic, with the period

\[
2\pi \sqrt{\frac{a \sin \theta}{(1 + \cos^2 a)}} \Omega.
\]

As regards the most general motion of a spherical pendulum, it is obvious that a particle moving under gravity on a smooth sphere cannot pass through the highest or lowest point unless it describes a vertical circle. In all other cases there must be an upper and a lower limit to the altitude. Again, a vertical plane passing through \( O \) and a point where the motion is horizontal is evidently a plane of symmetry as regards the path. Hence the path will be confined between two horizontal circles which it touches alternately, and the direction of motion is never horizontal except at these circles. In the case of disturbed steady motion, just considered, these circles are nearly coincident. When both are near the lowest point the horizontal projection of the path is approximately an ellipse, as shown in Fig 13; a closer investigation shows that the ellipse is to be regarded as revolving about its centre with the angular velocity \( \sqrt{\frac{a \sin \theta}{(1 + \cos^2 a)} \Omega} \), where \( a, b \) are the semi-axes.

To apply the equations (11) to the case of the top we start with the expression (15) of § 21 for the kinetic energy, the simplified form (1) of § 20 being for the present purpose inadmissible, since it is essential that the generalized co-ordinates employed should be competent to specify the position of every particle. If \( \lambda, \mu, \nu \) be the components of momentum, we have

\[
\lambda = \frac{\partial A}{\partial \theta}, \quad \mu = \frac{\partial A}{\partial \phi}, \quad \nu = \frac{\partial A}{\partial \phi}.
\]

The meaning of these quantities is easily recognized; thus \( \lambda \) is the angular momentum about a horizontal axis normal to the plane of \( \theta, \mu \) is the angular momentum about the vertical \( OZ \), and \( \nu \) is

the angular momentum about the axis of symmetry. If \( M \) be the total mass of the body, \( V \) the volume of \( OZ \) if \( OZ \) be drawn vertically upwards. Hence the equations (11) become

\[
\begin{align*}
\frac{d}{dt} \left( A \sin \theta \cos \theta \dot{\phi}^2 + C \left( \dot{\phi} + \cos \theta \dot{\phi} \right) \cos \theta \right) & = 0, \\
\frac{d}{dt} \left( A \sin \theta \dot{\phi}^2 + C \left( \dot{\phi} + \cos \theta \dot{\phi} \right) \cos \theta \right) & = 0.
\end{align*}
\]

(28)

in which the last two steps establish the constancy of the momenta \( \mu, \nu \).

Hence

\[
\begin{align*}
\frac{d}{dt} \left( A \sin \theta \cos \theta \dot{\phi}^2 + \sin \phi \dot{\phi} + M g h \sin \theta \right) & = 0, \\
\frac{d}{dt} \left( A \sin \theta \dot{\phi}^2 + \sin \phi \dot{\phi} + M g h \sin \theta \right) & = 0.
\end{align*}
\]

(29)

If we eliminate \( \psi \) we obtain the equation (7) of § 20. The theory of disturbed precessional motion there outlined does not give a convenient view of the oscillations of the axis about the vertical position. If \( \theta \) be small the equations (29) may be written

\[
\delta \ddot{\theta} - \delta q = -2a \frac{a M g h}{A^2},
\]

\[
\theta = \omega = \omega = \Omega = \frac{2a}{A^2},
\]

where

\[
\omega = \psi = \frac{x}{2A}.
\]

(30)

Since \( \theta, \phi \) are the polar co-ordinates (in a horizontal plane) of a point on the axis of symmetry, relative to an initial line which revolves with constant angular velocity \( \omega \), we see by comparison with § 14 (15) (16) that the motion of such a point will be elliptic-harmonic superposed on a uniform rotation \( \omega \), provided \( \frac{\dot{a}}{a} \gt \frac{M g h}{A} \). This gives (in essentials) the theory of the "gyroscopic pendulum."
Elminating the $n-1$ ratios $A_i:A_2: \ldots : A_n$ we obtain the
determinantal equation

$$
\Delta(\sigma) = 0,
$$

(6)

where

$$
\Delta(\sigma) = c_{11} - \sigma c_{12} - \sigma^2 c_{13} - \ldots - c_{1n} \sigma^{n-1},
$$

$$
- \sigma c_{21} + c_{22} - \sigma^2 c_{23} - \ldots - c_{2n} \sigma^{n-1},
$$

$$
\ldots
$$

(7)

The quadraphic expression for $T$ is essentially positive, and the
same holds with regard to $V$ in virtue of the assumed stability.
It may be shown algebraically that under these conditions the
$n$ roots of the above equation in $\sigma$ are all real and positive.
For any particular root, the equations (5) determine the ratios of
the quantities $A_1, A_2, \ldots A_n$, the absolute values being alone
arbitrary; these quantities are in fact proportional to the minors of
any one row in the determinant $\Delta(\sigma)$. By combining the
solutions corresponding to a pair of equal and opposite values of
$\sigma$ we obtain a solution in real form:

$$
g_0 = C_0 \cos(\alpha t + \phi),
$$

(8)

where $a_1, a_2, \ldots a_n$ are a determinate series of quantities having
to one another the above-mentioned ratios, whilst the constants
C, $\epsilon$ are arbitrary. This solution, taken by itself, represents a
motion in which each particle of the system (since its
placements parallel to Cartesian co-ordinate axes are linear functions of the $q$'s) executes a simple vertical
motion of period $\pi \sqrt{M/g}$. The amplitudes of oscillation of
the various particles have definite ratios to one another, and the phases
are in agreement, the absolute amplitude (depending on $C$ and the
phase constant $\epsilon$) being alone arbitrary. A vibration of
this character is called a normal mode

of vibration of the system; the number $n$ of such modes is equal to that of the degrees of freedom
possessed by the system. These statements require some modification when two or more of the roots
of the equation (6) are equal. In the case of
multiple root the minors of $\Delta(\sigma)$ all vanish, and the basis for the determination of the quantities $a_i$
disappears. Two or more normal modes then
to some extent indeterminate, and
elliptic vibrations of the individual particles are possible. An
example is furnished by the spherical pendulum (§ 13).

As an example of the method of determination of the normal modes
we may take the "double pendulum." A mass $M$ hangs from a
fixed point by a string of length $a$, and a second mass $m$ hangs from
$M$ by a string of length $b$. For simplicity we will suppose that
the motion is confined to one vertical plane. If $\theta, \phi$ be the inclinations of the two strings to the vertical, we have, approximately,

$$
t = Ma^2 \theta + mb^2 \phi + \frac{1}{2} (ad + \theta) \theta^2 + 2 \theta \phi + \frac{1}{2} (gb + \phi) \phi^2,
$$

(9)

The equations (3) take the forms

$$
a \theta + b \phi = 0,
$$

$$
a b + \theta + gb = 0,
$$

where $\mu = m/(M + m)$.

Hence

$$
\langle a^2 - g/a - \mu \theta \phi^2 + \phi a \theta \phi^2\rangle = 0,
$$

(10)

The frequency equation is therefore

$$
\sigma^2 - g/a \sigma^2 - \mu \sigma^2 = 0.
$$

(12)

The roots of this quadratic in $\sigma^2$ are easily seen to be real and
positive. If $M$ be large compared with $m$, $\mu$ is small, and the roots
are $g/a$ and $g/b$, approximately. In the normal mode corresponding to the
former root, $M$ swings almost like the bob of a simple pendulum
of length $a$, being comparatively uninfluenced by the presence of $m,
whilst $m$ executes a "forced" vibration (§ 12) of the corresponding
period. In the second mode, $M$ is nearly at rest [as appears from the
second of equations (11)], whilst $m$ swings almost like the bob of
a simple pendulum of length $b$. Whatever the ratio $M/m$, the
two values of $\sigma^2$ can never be exactly equal, but they are approximately
equal if $a, b$ are nearly equal and $\mu$ is very small. A curious
phenomenon is then to be observed; the motion of each particle, being
made up in general of two superposed simple vibrations of nearly
equal period, is seen to fluctuate greatly in extent, and if the amplitudes
be equal we have periods of approximate rest, as in the case of
"beats" in acoustics. The vibration then appears to be transferred
alternately from $m$ to $M$ at regular intervals. If, on the other hand,
$M$ is small compared with $m$, $\mu$ is nearly equal to unity, and the roots of
(12) are $\sigma^2 = g/(a-b)$ and $\sigma^2 = mgM/(a+b)ab$, approximately.

The former root makes $\theta = \omega t$, nearly; in the corresponding normal
mode $m$ oscillates like the bob of a simple pendulum of length $a-b$.
In the second mode $a \theta + b \phi = 0$, nearly, so that $m$ is approximately
at rest. The oscillation of $M$ then resembles that of a particle at
a distance $\alpha$ from one end of a string of length $a+b$ fixed at the ends
and subject to a tension $mg$.

The motion of the system consequent on arbitrary initial
conditions may be obtained by superposition of the $n$ normal modes
with suitable amplitudes and phases. We have then

$$
g = a_1 \phi + a_2 \theta^2 + a_3 \phi^3 + \ldots,
$$

(13)

where

$$
\theta = C \cos(\alpha t + \phi), \quad \phi = C' \cos(\alpha' t + \phi'), \quad \phi'' = C'' \cos(\alpha'' t + \phi''),
$$

(14)

provided $\sigma_1, \sigma_2, \sigma_3$, are the $n$ roots of (6). The coefficients
of $\theta, \phi, \theta', \phi', \ldots$ in (13) satisfy the conjugate or orthogonal
relations

$$
a_{11} a_1 + a_{12} a_2 + a_{13} a_3 + \ldots + a_{1n} a_n = 0,
$$

(15)

$$
a_{11} a_1' + a_{12} a_2' + a_{13} a_3' + \ldots + a_{1n} a_n' = 0,
$$

(16)

provided the symbols $a_1, a_2, \ldots a_n$ refer to two distinct roots
$\sigma_1, \sigma_2, \ldots$ of (6). To prove these relations, we replace the symbols
$A_1, A_2, \ldots A_n$ in (5) by $a_1, a_2, \ldots a_n$, respectively, multiply
the resulting equations by $a_1, a_2, \ldots a_n$, in order and add.
The result, owing to its symmetry, must still hold if we interchange
certified and unaccented Greek letters, and by comparison we deduce (15) and (16), provided $\sigma_2$ and $\sigma_2'$ are unequal.

The actual determination of $C, C', C''$, and $\epsilon, \epsilon', \epsilon''$, in terms of the initial conditions is as follows. If we write

$$
C \cos \epsilon = H - C \sin \epsilon = K,
$$

(17)

we must have

$$
a_{11} a_1' + a_{12} a_2' + a_{13} a_3' + \ldots + a_{1n} a_n' = [0, \ldots, 0],
$$

(18)

and

$$
a_{11} a_1 + a_{12} a_2 + a_{13} a_3 + \ldots + a_{1n} a_n = [0, \ldots, 0],
$$

(19)

The new co-ordinates $\theta, \theta', \theta''$ are called the normal co-ordinates
of the system; in a normal mode of vibration one of these varies alone.

The physical characteristics of a normal mode are

that an impulse of a particular normal type generates an initial
velocity of that type only, and that a constant extraneous force
of a particular normal type maintains a displacement of that type
only. The normal modes are further distinguished by an important
"stationary" property, as regards the frequency. If we
imagine the system reduced by frictionless constraints to one
degree of freedom, so that the co-ordinates $\theta, \theta', \theta''$ have
prescribed ratios to one another, we have, from (19),

$$
a_{11} \sigma_1 + a_{12} \sigma_2 + a_{13} \sigma_3 + \ldots + a_{1n} \sigma_n = [0, \ldots, 0],
$$

(20)

This shows that the value of $\sigma^2$ for the constrained mode is
intermediate to the greatest and least of the values $c_1 \sigma^2, c_1' \sigma^2,
\ldots \quad \ldots \quad \ldots$ proper to the several normal modes. Also that if the constrained
mode differs little from a normal mode of free vibration (e.g. if
$\theta', \theta'', \ldots$ are small compared with $\theta$), the change in the frequency
is of the second order. This property can often be utilized to
estimate the frequency of the gravest normal mode of a system,
by means of an assumed approximate type, when the exact
determination would be difficult. It also appears that an estimate
thus obtained is necessarily too high.

From another point of view it is easily recognized that the
equations (3) are exactly those to which we are led in the ordinary
process of finding the stationary values of the function

$$
V(q_0, q_1, \ldots q_n) / T(q_0, q_1, \ldots q_n)
$$

where the denominator stands for the same homogeneous
quadratic function of the $q$'s that $T$ is for the $q$'s. It is easy to
construct in this connexion a proof that the $n$ values of $\sigma^2$ are
all real and positive.
The case of three degrees of freedom is instructive on account of the geometrical analogies. With a view to these we may write

\[ 2T = a x^2 + b y^2 + c z^2 + 2f xy + 2g xz + 2h yz, \]

\[ 2V = A x^4 + B y^4 + C z^4 + 2F x^2 + 2G xz + 2H yz. \]

It is obvious that the ratio

\[ V(x,y,z) \]

\[ T(x,y,z) \]

must have a least value, which is moreover positive, since the numerator and denominator are both essentially positive. Denoting this value by \( \sigma^2 \), we have

\[ A x^2 + B y^2 + C z^2 = \sigma^2 (A x^2 + B y^2 + C z^2), \]

\[ A x^2 + B y^2 + C z^2 = \sigma^2 (A x^2 + B y^2 + C z^2), \]

\[ G x^2 + F y^2 + C z^2 = \sigma^2 (G x^2 + F y^2 + C z^2), \]

providing \( x, y, z \) be the corresponding values of the ratios \( x:y:z \). Again, the expression \( T \) will also have a least value when the ratios \( x:y:z \) are subject to the condition

\[ \frac{\partial V}{\partial x} + \frac{\partial V}{\partial y} + \frac{\partial V}{\partial z} = 0. \]

and if this be denoted by \( \sigma^{2*} \) we have a second system of equations similar to \( (21) \). The remaining value \( \sigma^{2*} \) is the value of \( \sigma \) when \( x, y, z \) are chosen so as to satisfy \( (24) \) and

\[ \frac{\partial V}{\partial x} + \frac{\partial V}{\partial y} + \frac{\partial V}{\partial z} = 0. \]

The problem is identical with that of finding the common conjugate diameters of the ellipsoids \( T, V, x, y, z = \text{const.} \), \( V, x, y, z = \text{const.} \). If in \( (21) \) we imagine that \( x, y, z \) denote infinitesimal rotations of a solid free to turn about a fixed point in a given field of force, it appears that the three angular modes consist each of a rotation about one of the three diameters aforesaid, and that the values of \( \sigma \) are proportional to the ratios of the lengths of corresponding diameters of the two quadrics.

We proceed to the forced vibrations of the system. The typical case is where the extraneous forces are of the simple-harmonic type \( \cos (a t + \phi) \); the most general law of variation with time can be derived from this by superposition, in virtue of Fourier's theorem. Analytically, it is convenient to put \( Q \) equal to \( e^{i \phi} \) multiplied by a complex coefficient; owing to the linearity of the equations the factor \( e^{i \phi} \) will run through them all, and need not always be exhibited. For a system of one degree of freedom we have

\[ aq_0 + z = Q, \]

and therefore on the present supposition as to the nature of \( Q \)

\[ \frac{Q}{a - e^{i \phi}}. \]

This solution has been discussed to some extent in \( \S 12 \), in connection with the forced oscillations of a pendulum. We may note further that when \( a \) is small the displacement \( q \) has the "equilibrium value \( Q/e \), the same as would be produced by a steady force equal to the instantaneous value of the actual force, the inertia of the system being negligible. On the other hand, when \( \sigma \) is great \( q \) tends to the value \( Q/\sigma \), the same as if the potential energy were ignored. When there are \( n \) degrees of freedom we have from \( (3) \)

\[ (e^{i \phi} - e^{-i \phi}) q_1 + (e^{i \phi} - e^{-i \phi}) q_2 + \ldots + (e^{i \phi} - e^{-i \phi}) q_n = Q, \]

and therefore

\[ \Delta (\phi), q_0 = a_0 q_0 + a_{01} q_1 + \ldots + a_{0n} q_n, \]

where \( a_{01}, \ldots, a_{0n} \) are the minors of the \( r \)th row of the determinant \( \Delta \). Every particle of the system executes in general a simple vibration of the imposed period \( 2\pi/\phi \), and all the particles pass simultaneously through their equilibrium positions. The amplitude becomes very great when \( \phi \) approximates to a root of \( (6) \), i.e. when the imposed period nearly coincides with one of the free periods. Since \( a_{01} = a_{0n} \), the coefficient of \( Q \) in the expression for \( q_0 \) is identical with that of \( Q \) in the expression for \( q \). Various important "reciprocal theories" formulated by H. Helmholtz and Lord Rayleigh are founded on this relation. Free vibrations must of course be superposed on the forced vibrations given by \( (29) \) in order to obtain the complete solution of the dynamical equations.

In practice the vibrations of a system are more or less affected by dissipative forces. In order to obtain at all events a qualitative representation of these it is usual to introduce into the equations frictional terms proportional to the velocities. Thus in the case of one degree of freedom we have, in place of \( (26) \),

\[ aq_0 + bq + cq = Q. \]
by a transcendental equation corresponding to the determinantal equation (5).

Numerous examples of this procedure, and of the corresponding treatment of forced oscillations, present themselves in theoretical acoustics. It may be shown here that the small oscillations of a chain hanging vertically from a fixed extremity. If x be measured upwards from the lower end, the horizontal component of the tension P at any point will be P\partial y/\partial x, approximately, if y denote the lateral displacement. Forming the equation of motion of a masslement, p\delta x, we have

\[ p\delta x = (P\partial y/\partial x). \]

Neglecting the vertical acceleration we have P = g\rho x, whence

\[ \frac{\partial y}{\partial t} = \frac{\partial}{\partial x} \left( \frac{g\rho}{\partial x} \right) \]

Assuming that y varies as \( e^\xi \), we have

\[ y = C (1 - \frac{k}{\xi}) e^\xi \]

in the notation of Bossel's functions, if \( \xi = \omega x \). Since y must vanish at the upper end (\( x = l \)), the admissible values of \( \omega \) are determined by

\[ \frac{\partial^2 y}{\partial x^2} = \frac{g\rho}{\partial x} (1 - \frac{k}{\xi}) e^\xi \]

provided \( k = g\rho/l \). The solution of (6) which is finite for \( x = 0 \) is readily obtained in the form of a series, thus

\[ y = \frac{C}{1 - \frac{k}{\xi}} \sum_{n=0}^\infty \frac{g\rho}{\partial x} (1 - \frac{k}{\xi}) e^\xi \]

approximately, where the numbers tend to the limit \( s = 1 \). The frequency of the gravest mode is to that of a uniform bar in the ratio \( \sqrt{g\rho/k} \). This should be compared with the theory of "constrained types" already given. In the higher normal modes there are nodes or points of rest (\( y = 0 \)); thus in the second mode, which is a node at a distance \( l/2 \) from the lower end.

AUTHORITIES.—For indications as to the earlier history of the subject see W. W. R. Ball, Short Account of the History of Mathematics; M. Cantor, Geschichte der Mathematik (Leipzig, 1880 . . .); J. Cox (Cambridge, 1904); E. Mach, Die Mechanik in ihrer Entwicklung (4th ed., Leipzig, 1901; Eng. trans.). Of the classical treatises which have had a notable influence on the development of the subject, and which may still be consulted with advantage, we may note particularly, Sir I. Newton, Philosophiae naturalis Principia Mathematica (1st ed., London, 1687); J. L. Lagrange, Mécanique analytique (2nd ed., Paris, 1811-1815); P. S. Laplace, Mécanique céleste (Paris, 1900-1825); A. F. Möbus, Lehrbuch der Statik (Leipzig, 1837); and Mechanik des Himmels; L. Poinset, Éléments de statique (Paris, 1804), and Théorie nouvelle de la rotation des corps (Paris, 1834).

The literature of graphical statics and its technical applications is very extensive. We may mention K. Kulmann, Graphische Statik (2nd ed., Zürich, 1895); A. Föppel, Technische Mechanik, vol. ii. (Leipzig, 1900); L. Henneberg, Statik der starren Systeme (Darmstadt, 1886); M. Lévy, La statique graphique (2nd ed., Paris, 1886-1888); H. Müller-Breslau, Graphische Statik (3rd ed., Berlin, 1901). Sir R. S. Ball's highly original investigations in kinematics and dynamics were published in collected form under the title Theory of Screws (Cambridge, 1878).

Detailed accounts of the developments of the various branches of the subject from the beginning of the 19th century to the present time, with full bibliographical references, are given in the fourth volume (edited by Professor F. Klein) of the Encyclopédie der mathematischen Wissenschaften (Leipzig). There is a French translation of this work. (See also Dynamics.) (H. LB.)

II.—APPLIED MECHANICS

§ 1. The practical application of mechanics may be divided into two classes, according as the assemblages of material objects to which they relate are intended to remain fixed or to move relatively to each other—the former class being comprehended under the term "Theory of Structures" and the latter under the term "Theory of Machines."

PART I.—OUTLINE OF THE THEORY OF STRUCTURES

§ 2. Support of Structures.—Every structure, as a whole, is maintained in equilibrium by the joint action of its own weight, of the external load or pressure applied to it from without and tending to disrupt the stability of the whole, and of the resistances of the parts.

A structure is supported either by resting on the solid crust of the earth, as buildings do, or by floating in a fluid, as ships do in water and icebergs in air. The principles of the support of a structure resting on the earth are so far identical with those which regulate the equilibrium and stability of the earth itself, that there is no fundamental difference. The one principle which seems to require special mention here is one which comprehends in one statement the power both of liquids and of the earth to support structures. This was first demonstrated in a paper "On the Stability of Loose Earth," read to the Royal Society on the 19th of June 1856 (Phil. Trans., 1856), as follows:—

Let E represent the weight of the portion of a horizontal stratum of thickness z, of which is the distance of the middle of the stratum from the end of the layer, and let E be the utmost weight of that structure consistently with the power of the earth to resist displacement, φ the angle of repose of the earth; then

\[ S = \frac{1 + \sin \phi}{2 - \sin \phi} E \]

Apply this to liquids φ must be made zero, and then S/E = 1, as is seen from the last of this expression see Rankine's Applied Mechanics, 17th ed., p. 219.

§ 3. Composition of a Structure, and Connection of its Pieces.—The composition of structures is usually divided into two kinds, pieces, such as the stones of a building in masonry, the beams of a timber frame-work, the bars, plates, and bolts of an iron bridge. Those pieces are connected at their joints or surfaces of mutual contact, either by simple pressure and friction (as in masonry with moist mortar), or by pressure and adhesion (as in masonry with cement or with hardened mortar, and timber with glue), or by the resistance of fastenings of different kinds, whether made by means of the form of the joint (as by nuts and bolts, notched iron bars), or by means of the pieces (as tenails, pins, spikes, nails, holdfasts, screws, bolts, rivets, hoops, straps and sockets).

§ 4. Stability, Stiffness and Strength.—A structure may be damaged or destroyed in three ways:—first, by displacement of its pieces from their proper positions relatively to each other or to the earth; secondly by disfigurement of one or more of those pieces, owing to their being unable to preserve their proper shapes under the pressures to which they are subjected; thirdly, by breaking of one or more of those pieces. The power of resisting displacement conditions the power of each piece to resist disfigurement its stiffness; and its power to resist breaking, its strength.

§ 5. Conditions of Stability.—The principles of the stability of a structure can be to a certain extent investigated independently of stiffness and strength. For the first instance, that each piece has strength sufficient to be safe against being broken, and stiffness sufficient to prevent its being disfigured to an extent inconsistent with the purposes of the structure, by the greatest forces which it is required to resist, the structure is to be maintained in equilibrium by having its gross load, consisting of its own weight and of the external pressure applied to it, balanced by the resistances or pressures exerted between it and the contiguous pieces, furnishes the means of determining the magnitude, position and direction of the resistances required at each joint in order to produce equilibrium; and the conditions of stability are, first, that the direction of the resistance required at each joint shall, under all the variations to which the load is subject, be such as the joint is capable of exerting—conditions which are the same as those for the positions and the joints, and the ratios of the gross loads of the pieces. As for the magnitude of the resistance, it is limited by conditions, not of stability, but of strength and stiffness.

§ 6. Principle of Least Resistance.—The principle of least resistance is of more than one system of resistances are all capable of balancing the same system of loads applied to a given structure, the smallest those alternative systems, and was demonstrated by the Rev. Henry Moseley in his Mechanics of Engineering and Architecture, is that which will actually be exerted.
because the resistances to displacement are the effect of a strained state, the pieces, which strained state is the effect of the load, and when the load is applied the strained state and the resistances produced by it increase until the resistances acquire just those magnitudes which are sufficient to balance the load, after which they increase no further.

This principle of least resistance renders determinate many problems in the statics of structures which were formerly considered indeterminate.

§ 7. Relations between Polygons of Loads and of Resistances.—In a structure in which each piece is supported at two joints only, the well-known laws of statics show that the directions of the gross load on each piece is represented by the diagonal sides of a parallelogram; the moments about any one side of the parallelogram must lie in one plane, must either be parallel or meet in one point, and must bear to each other, if not parallel, the proportions of the sides of a triangle respectively parallel to their directions, and, if parallel, such proportions will be as the distances between the points of application of the loads, to the distance of the two other,—all the three distances being measured along one direction.

Considering, in the first place, the case in which the load and the two resistances by which each piece is balanced meet in one point, which may be called the centre of load, there will be as many such points of intersection, or centres of load, as there are pieces in the structure; and the directions and positions of the resistances or mutual pressures exerted between the pieces will be represented by the sides of a polygon joining those points, as in fig. 86, where PL, PR, PS represent the centres of load in a structure of four pieces, and the sides of the polygon of resistances PL, PR, PS represent the directions and positions of the resistances exerted as stated above.

Further, at any one of the centres of load let PL represent the magnitude and direction of the gross load, and PR, PS the two resistances by which the piece to which that load is applied is supported; then will those three lines be respectively the diagonal and sides of a parallelogram; or, what is the same thing, they will be equal to the three sides of a triangle; and they must be in the same plane, although the sides of the polygon of resistances may be in different planes.

According to a well-known principle of statics, because the loads or external pressures PL, PR, PS, balance each other, they must be proportional to the sides of a closed polygon drawn respectively parallel to their directions. In fig. 87 construct such a polygon of loads by drawing the lines L1, L2, etc., parallel and proportional to, and joined end to end, the sides of, of the gross loads on the piece of the structure. Then from the proportionality and parallelism of the load and the two resistances applied to each piece of the structure, at the three sides of a triangle, there results the following theorem (originally due to Rankine):—

If from the angles of the polygon of loads there be drawn lines (R1, R2, etc.), each of which is parallel to the resistance (at PL, PR, PS) exerted at the joint between the pieces to which the two loads represented by the contiguous sides of the polygon of loads (such as L1, L2, etc.) are applied; then will all those lines meet in one point (O), and their lengths, measured from that point to the angles of the polygon, will represent the magnitudes of the resistances to which they are respectively parallel.

When the load on one of the pieces is parallel to the resistance which balances it, the polygon of resistances ceases to be closed, two of its sides becoming coincident with the external, and the question, and extending indefinitely. In the polygon of loads the direction of a load sustained by parallel resistances traverses the point O.1

1 Since the relation discussed in § 7 was enunciated by Rankine, an enormous development has taken place in the subject of Graphic Statics, the first systematic textbook on the subject, "Die Graphische Statik" by K. Culmann, published at Zürich in 1866. Many of the graphical methods therein given have now passed into the textbooks usually employed by engineers. One has the task of describing the beautiful graphical constructions regularly used by engineers and known as "the method of reciprocal figures." This is for finding the loads supported by the several members of a braced structure, having given a system of external loads. The original conception was given by Clerk Maxwell, and the complete theory is discussed and exemplified in a paper "On Reciprocal Figures, Frames and Diagrams of Forces," Trans. Roy. Soc. Ed., vol. xxvi. (1870). Professor M. W. Crofton read a paper on "Stress-Diagrams in Warren and Lattice Girders" at the meeting of the Mathematical Society (April 13, 1871), and Professor O. Henrici illustrated the subject by a simple and ingenious notation. The application of the method of reciprocal figures was facilitated by a system of notation published in "Economics of Construction in relation to Framed Structures," by Robert H. Bow (London, 1883). Of the work on the general subject is that of Luigi Cremona, translated from the Italian by Professor T. H. Beare (Oxford, 1890), and a discussion of the subject of reciprocal figures from the special point of view of the engineering student is given in "Vectors and Rotors" by Henrici and Turner (London, 1903). See also above under "Theoretical Mechanics," Part I. § 5.
by turning or by sliding. Safety against displacement by turning is called stability of position; safety against displacement by sliding, stability of friction.

§ 13. Condition of Stability of Position.—If the materials of a structure were infinitely stiff and strong, stability of position at any joint would be insured simply by making the resistance fall within the joint under all possible variations of load. In order to allow for the finite stiffness and strength of materials, the least distance of the centre of resistance inward from the nearest edge of the joint is made to bear a definite proportion to the depth of the joint measured in the same direction, which proportion is fixed, sometimes empirically, sometimes by theoretical deduction from the laws of the strength of materials. That least distance, Moseley the modulus of stability. The following are some of the ratios of the modulus of stability to the depth of the joint which occur in practice:

Retaining walls, as designed by British engineers

1:8

Retaining walls, as designed by French engineers

1:5

Rectangular piers of bridges and other buildings, and arch-stones

1:3

Rectangular foundations, firm ground

1:3

Rectangular foundations, very soft ground

1:2

Rectangular foundations, intermediate kinds of ground 1:3 to 1:2

Thin hollow towers (such as furnace chimneys exposed to high winds), semi-circular

1:6

Thin, hollow towers, circular

1:4

Frames of timber or metal, under their ordinary or average distribution of load

1:3

Frames of timber or metal, under the greatest irregularities of load

1:1

In the case of the towers, the depth of the joint is to be understood as the diameter of the tower.

§ 14. Condition of Stability of Friction.—If the resistance to be exerted at a joint is always perpendicular to the surfaces which abut at and form that joint, there is no tendency of the pieces to be displaced by sliding. If the resistance be oblique, let JK (fig. 89) be the joint, C its centre of resistance, CR a line representing the resistance, CN a perpendicular to the joint at the centre of resistance. The angle NCR is the obliquity of the resistance. From C draw RP parallel and RQ perpendicular to the joint; then, by the principles of statics, the component of the resistance normal to the joint is

\[ CP = CR \cos \phi; \]

and the component tangential to the joint is

\[ CQ = CR \sin \phi = CP \tan \phi. \]

If the joint be provided either with projections and recesses, such as mortises and tenons, or with fastenings, such as pins or bolts, as to resist displacement by sliding, the question of the utmost amount of the tangential resistance CQ which it is capable of exerting depends on the strength of such projections, recesses, or fastenings; and belongs to the study of strength of materials. That least distance is called the modulus of stability. In other cases the safety of the joint against displacement by sliding depends on its power of exerting friction, and that power depends on the law, known by experiment, that the friction between two surfaces bears a constant ratio, depending on the nature of the surfaces, to the force by which they are pressed together. In order that the surfaces which abut at the joint JK may be pressed together, the resistance required by the conditions of equilibrium CR, must be a thrust and not a pull; and in that case the force by which the surfaces are pressed together is equal and opposite to the normal component CP of the resistance. The condition of stability of friction is that the tangential component CQ of the resistance required shall not exceed the friction due to the normal component; that is, that

\[ CQ \leq f \cdot CP, \]

where \( f \) denotes the coefficient of friction for the surfaces in question. The angle whose tangent is the coefficient of friction is called the angle of repose, and is expressed symbolically by

\[ \phi = \tan^{-1} f. \]

Now \( CQ = CP \tan \phi \); consequently the condition of stability of friction is fulfilled if the angle PCR is not greater than \( \phi \); that is to say, if the obliquity of the resistance required at the joint does not exceed the angle of repose; and this condition ought to be fulfilled under all possible variations of the load.

It is chiefly in masonry and earthwork that stability of friction is relied on.

§ 15. Stability of Friction in Earth.—The grains of a mass of loose earth are to be regarded as so many separate pieces abutting against one another, each with all possible forces depending on its stability on friction. To determine whether a mass of earth is stable at a given point, conceivably that point to be traversed by planes in all possible positions, and determine which position gives the greatest obliquity to the total pressure exerted between the portions of earth on either side of the plane. The condition of stability is that this obliquity shall not exceed the angle of repose of the earth. The consequences of this principle are developed in a paper, "On the Stability of Loose Earth," already cited by Moseley.

§ 16. Parallel Projections of Figures.—If any figure be referred to a system of co-ordinates, rectangular or oblique, and if a second figure be constructed by means of a second system of co-ordinates, rectangular or oblique, and either agreeing with or differing from the first system in rectangularity or obliquity, but so related to the co-ordinates of the first figure that for each point in the first figure there shall be a corresponding point in the second figure, the lengths of the projections of the first are the measures of the corresponding projections of the second figure. Also the product of the corresponding projections of each other. The properties of parallel projections of most importance to the subject of the present article are the following:

(1) A parallel projection of a straight line is a straight line.

(2) A parallel projection of a plane is a plane.

(3) A parallel projection of a straight line or a plane surface divided in a given ratio is a straight line or a plane surface divided in the same ratio.

(4) A parallel projection of a pair of equal and parallel straight lines, or plain surfaces, is a pair of equal and parallel straight lines, or plane surfaces; whence it follows

(5) That a parallel projection of a parallelogram is a parallelogram,

(6) That a parallel projection of a parallelepiped is a parallelepiped,

(7) A parallel projection of a pair of solids having a given ratio is a pair of solids having the same ratio.

Though not essential for the purposes of the present article, the following theorem will serve to illustrate the principle of parallel projections:

(8) A parallel projection of a curve, or of a surface of a given angle, is a curve or a surface of the same order.

For example, all ellipsoids referred to co-ordinates parallel to any three conjugate diameters are parallel projections of each other and of a sphere referred to rectangular co-ordinates.

§ 17. Parallel Systems of Forces.—If a balanced system of forces be represented by a system of lines, then will every parallel projection of that system of lines represent a balanced system of forces.

For the condition of equilibrium of forces not parallel is that they shall be represented in direction and magnitude by the sides and diagonals of certain parallelograms, and of parallel forces that they shall divide certain, straight lines in certain ratios; and the parallel projection of a parallelogram is a parallelogram, and that of a straight line divided in a given ratio is a straight line divided in the same ratio.

The resultant of a parallel projection of any system of forces is the projection of their resultant; and the centre of gravity of a parallel projection of a solid is the projection of the centre of gravity of the solid.

§ 18. Principle of the Transformation of Structures.—Here we have the following theorem: If a structure of a given figure have stability of position under a system of forces represented by a given system of lines, then will any structure whose figure is a parallel projection of that of the first structure have stability of position under a system of forces represented by the corresponding projection of the first system of lines.

For in the second structure the weights, external pressures, and resistances will balance each other as in the first structure; the weights of the pieces and all other parallel systems of forces will have the same ratios as in the first structure; and the several centres of resistance will divide the depths of the joints in the same proportions as in the first structure.

If the first structure have stability of friction, the second structure will have stability of friction also, so long as the effect of the projection is not to increase the obliquity of the resistance at any joint beyond the angle of repose.

The lines representing the forces in the second figure show their relative positions and magnitudes. To find their absolute directions and magnitudes, a vertical line is to be drawn in the first figure, of such a length as to represent the weight of a particular portion of the structure. The horizontal lines of projection in the second figure indicate the vertical direction, and represent the weight of the part of the second structure corresponding to the before-mentioned portion of the first structure.

The following "principle of the transformation of structures" was first announced, though in a somewhat less comprehensive form, to the Royal Society on the 6th of March 1856. It is useful for the purpose of determining forces and resistances in plan, and for the deduction of the conditions of equilibrium and stability of structures of complex and unsymmetrical forms from those of structures of simple and symmetrical forms. By its aid, for example, the whole of the properties of
elliptic arches, whether square or skew, whether level or sloping in the space, are at once deduced by projection from those of symmetrical circular arches, and the properties of elliptic and elliptic-
conoidal domes from those of hemispherical and circular-conoidal domes; and the figures of the pieces are so cast that the thrusts horizontally or vertically in a certain given ratio, can be deduced by a projection from those of arches fitted to resist the thrust of a liquid, which is of equal intensity, horizontally and vertically.

§ 19. Conditions of Stiffness and Strength.—After the arrangement of the pieces of a structure and the size and figure of their joints or surfaces of contact have been determined so as to fulfill the conditions of the structural theory on the position and direction of the resultant or total load on each piece, and the relative magnitude of the loads on the different pieces—the dimensions of each piece and its strength determined, by fulfilling the law of stiffness and strength—conditions which depend not only on the absolute magnitude of the load on each piece, and of the resistances by which it is balanced, but also on the mode of distribution of the load over the piece, and of the resistances over the points.

The effect of the pressures applied to a piece, consisting of the load and the supporting resistances, is to force the piece into a state of strain or disarrangement, which increases until the elasticity, or resistance of the material causes it to exert a stress, or effort to recover its figure, equal and opposite to the system of applied pressures. The condition of stiffness is that the strain or disarrangement of the pieces shall be greater than consistent with the purposes of the structure; and the condition of strength is that the stress shall be within the limits of that which the material can bear with safety against breaking. The ratio in which the stresses borne before breaking are in excess of those which give it stiffness, or are safe for the factor of safety, and is determined empirically. It varies from three to twelve for various materials and structures (See STRENGTH OF MATERIALS).

PART II. THEORY OF MACHINES

§ 20. Parts of a Machine: Frame and Mechanism.—The parts of a machine may be distinguished into two principal divisions,—the frame, or fixed parts, and the mechanism, or moving parts. The frame is the skeleton of the mechanism, and to a certain extent determines the nature of their motions.

The form and arrangement of the pieces of the frame, or the mechanism, the dimensions of the pieces, and the stress or resistance given to the parts, constitutes the strength of the machine. It appears therefore that in general the mechanism is to be designed first and the frame afterwards, and that the designing of the frame is regulated by the principles of the stability of structures and of the strength and stiffness of materials, care being taken to adapt the frame to the most severe load which can be thrown upon it at any period of the action of the mechanism.

Each independent piece of the mechanism also is a structure, and its dimensions are to be adapted, according to the principles of the strength and stiffness of materials, to the most severe load to which it is to be subjected in the action of the machine.

§ 21. Definition and Division of the Theory of Machines.—From what has been said in the last section it appears that the department of the theory of machines is that branch of the science of applied mechanics which teaches the design and construction of machines, and the principles of their operation. The stability of the frame and to the stiffness and strength of the frame and mechanism is a branch of the art of construction. It is therefore to be separated from the theory of machines, properly speaking, which has reference to the action of machines considered as moving. In the action of a machine the following three things take place:

Firstly, Some natural source of energy communicates motion and force to a piece or pieces of the mechanism, called the receiver of power or prime mover.

Secondly, The motion and force are transmitted from the prime mover through the train of mechanism to the working piece or pieces, and during that transmission the motion and force are diminished in amount and direction, so as to be rendered suitable for the purpose to which they are to be applied.

Thirdly, The working piece or pieces by their motion, or by their motion and force combined, produces useful effect.

Such are the phenomena of the action of a machine, arranged in the order of causation. But in studying or treating of the theory of machines, the order of causation is reversed; the first branch of the subject is the modification of motion and force by the train of mechanism; the next is the effect or purpose of the machine; and the last, or most complex, is the action of the prime mover.

The modification of motion and the modification of force take place together, and are connected by certain laws; but in the study of machines, as well as in the study of the pure sciences, much advantage has been gained in point of clarity of simplicity by first considering alone the principles of the modification of motion, which are founded upon what is now known as Kinematics, and afterwards the principles of the modification of forces, which are founded on geometry and on the laws of dynamics. The separation of kinematics from dynamics is due mainly to G. Monge, Ampère and R. W.}

The theory of machines in the present article will be considered under the following heads:—

1. Pure MECHANICS, or APPLIED KINEMATICS; being the theory of machines considered simply as modifying motion.

11. APPLIED DYNAMICS; being the theory of machines considered as modifying force and doing work.

CHAP. I. ON PURE MECHANISM

§ 22. Division of the Subject.—Proceeding in the order of simplicity, the subject of Pure Mechanics, or Applied Kinematics, may be thus divided:

Division 1. Motion of a point.

Division 2. Motion of the surface of a fluid.

Division 3. Motion of a solid.

Division 4. Motions of a pair of connected pieces, or of an "elementary combination" in mechanism.

Division 5. Motions of pieces of mechanism.

Division 6. Motions of sets of more than two connected pieces, or of "aggregate combinations."

A point is the boundary of a line, which is the boundary of a surface, and the boundary of a volume. Points, lines and surfaces have no independent existence, and consequently those divisions of this chapter which relate to their motions are only preliminary to the subsequent divisions, which relate to the motions of bodies.

Division 1. Motion of a Point.

§ 23. Comparative Motion. The comparative motion of two points is the relation which exists between their motions, without having regard to their absolute amounts. It consists of two elements, which are the ratio, which compares the magnitudes of the two points at a given instant, and the directional relation, which is the relation borne to each other by the respective directions of the motions of the two points at the same given instant.

It is obvious that the motions of a pair of points may be varied in any manner, whether by direct or by lateral deviation, and yet the comparative motion remains the same. The comparative motion of a pair of points may be expressed by one of Sir William Hamilton's Quaternions, the "tensor" expressing the velocity ratio, and the "versor" the directional relation.

Graphical methods of analysis founded on this way of representing velocity and acceleration were developed by R. H. Smith in a paper communicated to the Royal Society of Edinburgh in 1885, and illustrations of the method will be found below.

§ 24. General Principle.—A mass of fluid is used in mechanism to transmit motion and force between two or more movable parts (called pistons or plungers) of the solid envelope or vessel in which the fluid is contained; and, when such transmission is the sole function of the mechanism, the only applicable term is "hydraulic", its principle is the like absolute constant, by reason of its temperature and pressure being maintained constant, or not sensibly varied.

Let a represent the area of the section of a piston made by a plane perpendicular to its direction of motion, and w its velocity, which is to be considered as positive when outward, and negative when inward. Then the variation of the cubic contents of the vessel in a unit of time by reason of the motion of one piston is w. Let represent the velocity of the other piston, and so on, the area of the pump-plunger is less than the area of the presser.

(See HYDRAULICS.)

In the pneumatic power-transmitter the motion of one piston is
transmitted to another at a distance by means of a mass of air contained in two cylinders and an intervening tube. When the pressure and temperature of the air can be maintained constant, this machine fulfils equation (2), like the hydraulic press. The amount and effect of the variations of pressure and temperature undergone by the air depend on the friction of the mechanism, the internal heat, or THERMODYNAMICS (especially), and are foreign to the subject of pure mechanism.

\[ \text{Equation (2)} \]

Division 3. Motion of a Rigid Solid.

§ 27. Motions Classed.—In problems of mechanism, each solid piece of the machine is supposed to be so stiff and strong as not to undergo any sensible change of figure or dimensions when the forces applied to it—a supposition which is realized in practice if the machine is skillfully designed.

For the case of the various possible motions of a rigid solid body may all be classed under the following heads: (1) Shifting or Translation; (2) Turning or Rotation; (3) Motions compounded of Shifting and Turning.

The most common forms for the paths of the points of a piece of mechanism, whose motion is simple shifting, are the straight line and the circle.

Shifting in a straight line is regulated either by straight fixed guides, in contact with which the moving piece slides, or by combinations of link-work, called parallel motions, which will be described in the sequel. Shifting in a straight line is usually reciprocating; that is to say, the piece, after shifting through a certain distance, returns to its original position by reversing its motion.

Circular shifting is regulated by attaching two or more points of the shifting piece to ends of equal and parallel rotating cranks, or by combinations of wheels which can be described as follows. An example of circular shifting may be cited the motion of the coupling rod, by which the parallel and equal cranks upon two or more axles of an engine are connected and made to rotate simultaneously. The coupling rod remains always parallel to itself, and all its points describe equal and similar circles relatively to the frame of the engine, and move in parallel directions with equal velocities at the same instant.

§ 28. Rotation about a Fixed Axis: Lever, Wheel and Axle.—The fixed axis of a turning body is a line fixed relatively to the body and relatively to the fixed space in which the body turns. In mechanism it is usually the central line either of a rotating shaft or axle having journals, gudgeons, or pivots turning in fixed bearings, or of a fixed spindle or dead centre round which a rotating bush turns; but it may sometimes be entirely beyond the limits of the turning body. For example, if a sliding piece moves in circular fixed guides, that piece rotates about an ideal fixed axis traversing the centre of those guides.

Let the angular velocity of the rotation be denoted by \( \alpha = \text{d} \theta / \text{d} t \), then the linear velocity of any point \( A \) at the distance \( r \) from the axis is \( \alpha r \); and the path of that point is a circle of the radius \( r \) described about the axis.

This is the principle of the modification of motion by the lever, which consists of a rigid body turning about a fixed axis called a fulcrum, and having two points at the same or different distances from the axis, which are the same or different, or which receives motion and the other transmits motion, modified in direction and velocity according to the above law.

A wheel and axle, motion is received and transmitted by two cylinders of different radii described about their common fixed axis of turning, their velocity-ratio being that of their radii.

Velocity Ratio of Components of Motion.—As the distance between any two points in a rigid body is invariable, the projections of their velocities upon the line joining them must be equal. Hence it follows that, if \( A \) in fig. 90 be a point in a rigid body CD, rotating round the fixed axis \( F \), the component of the velocity of \( A \) in any direction \( AP \) parallel to the plane of rotation is equal to the total velocity of the point \( m \), found by letting fall \( FM \) perpendicular to \( AP \); that is to say, is equal to \( \alpha \cdot FM \).

Hence also the ratio of the components of the velocities of two points A and B in the directions AP and BW respectively, both in the plane of rotation, is equal to the ratio of the perpendiculars \( FM \) and \( BO \).

§ 30. Instantaneous Axis of a Cylinder rolling on a Cylinder.—Let a cylinder \( bbb \), whose axis of figure is \( B \) and angular velocity \( \gamma \), roll on a fixed cylinder \( aaa \), whose axis of figure is \( A \), either outside (as in fig. 92), when the rolling will be towards the same side as the rotation, or inside (as in fig. 92), when the rolling will be towards the opposite side; and at a given instant let \( T \) be the line of contact of the two cylindrical surfaces, which is at their common intersection with the plane AB traversing the two axes of figure.

The line \( T \) on the surface \( bbb \) has for the instant no velocity in a direction perpendicular to \( AB \); because for the instant it touches, without sliding, the line \( T \) on the fixed surface \( aaa \).

The line \( T \) on the surface \( bbb \) has also for the instant no velocity in the plane \( AB \); for it has just ceased to move towards the fixed surface \( aaa \), and is just about to begin to move away from that surface.

The line of contact \( T \), therefore, on the surface of the cylinder \( bbb \), is for the instant at rest, and is the "instantaneous axis" about which the cylinder \( bbb \) turns, together with any body rigidly attached to that cylinder.

To find, then, the direction and velocity at the given instant of any point \( P \), either in or rigidly attached to the rolling cylinder \( T \), draw the plane \( PT \); the direction of motion of \( P \) will be perpendicular to that plane, and towards the right or left hand according to the direction of the rotation of \( bbb \); and the velocity of \( P \) will be

\[ v_P = \gamma \cdot PT \]

(3)

PT denoting the perpendicular distance of \( P \) from \( T \). The path of \( P \) is a curve of the kind epicycloid. If \( P \) is in the circumference of \( bbb \), that path becomes an epicycloid.

The velocity of any point in the axis of figure \( B \) is

\[ v_B = \gamma \cdot TB \]

(4)

and the path of such a point is a circle described about \( A \) with the radius \( AB \), being for outside rolling the sum, and for inside rolling the difference, of the radii of the cylinders.

Let \( a \) denote the angular velocity with which the plane of axes \( AB \) rotates about the fixed axis \( A' \). Then it is evident that

\[ a = \alpha \cdot TB \]

(5)

and consequently that \( a = \gamma \cdot TB/AB \).

(6)

For internal rolling, as in fig. 92, \( AB \) is to be treated as negative, which will give a negative value to \( a \), indicating that in this case the rotation of \( AB \) round \( A \) is contrary to that of the cylinder \( bbb \).

The angular velocity of the rolling cylinder, relatively to the plane of axes \( AB \), is obviously given by the equation

\[ \beta = \gamma - a \]

(7)

where \( \beta = \gamma \cdot TA/AB \). \( \gamma \) care being taken to attend to the sign of \( a \), so that when that is negative the arithmetical values of \( \gamma \) and \( a \) are to be added in order to give that of \( \beta \).

The whole of the foregoing reasonings are applicable, not merely when \( bbb \) and \( aaa \) are actual cylinders, but also when they are the osculating cylinders of a pair of cylindrical surfaces of varying curvature, \( A \) and \( B \) being the axes of curvature of the parts of those surfaces which are in contact for the instant under consideration.

§ 31. Instantaneous Axis of a Cone rolling on a Cone.—Let \( OAA \) (fig. 93) be a fixed cone, \( OA \) its axis, \( OBB \) a cone rolling on it, \( OB \) the axis of the rolling cone, \( OT \) the line of contact of the two cones at the instant under consideration. By reasoning similar to that of § 30, it appears that \( OT \) is the instantaneous axis of rotation of the rolling cone.

Let \( \gamma \) denote the total angular velocity of the rotation of the cone \( B \) about the instantaneous axis, \( \beta \) its angular velocity about the axis \( OB \) relatively to the plane \( AOB \), and \( a \) the angular velocity with which the plane \( AOB \) turns round the axis \( OA \). It is required to find the ratios of those angular velocities.

Solution.—In OT take any point \( E \), from which draw EC parallel to \( OA \), and ED parallel to \( OB \), so as to construct the parallogram OCD. Then

\[ OD : OC : OE : a : \beta : \gamma \]

(8)

Or because of the proportionality of the sides of triangles to the sines of the opposite angles,

\[ \sin TOB : \sin TOA : \sin AOB : \sin: \beta : \gamma \]

(8 a)
that is to say, the angular velocity about each axis is proportional to the sine of the angle between the other two.

**Demonstration.**—From C draw CF perpendicular to OA, and CG perpendicular to OE.

Then \( CF = 2xy \cdot \frac{\text{area ECO}}{CE} \)

and \( CG = 2xy \cdot \frac{\text{area ECO}}{OE} \).

\[ \therefore \] \( CG : CF :: CE : OD : OE \).

Let \( \gamma \) denote the linear velocity of the point C. Then

\[ \gamma = a \cdot \text{EK} \cdot \text{AO} \cdot \text{BO} \cdot \text{CE} \cdot \text{OF} \cdot \text{OA} \cdot \text{OE}. \]

which is one part of the solution above stated. From E draw EH perpendicular to OB, and EK to OA. Then it can be shown as before that

\( \text{EK} :: \text{EH} :: \text{OC} :: \text{OD} \).

Let \( v_2 \) be the linear velocity of the point E fixed in the plane of axes AOB. Then

\[ v_2 = a \cdot \text{EK} \].

Now, as the line of contact OT is for the instant at rest on the rolling cone as well as on the fixed cone, the linear velocity of the point E fixed to the plane AOB relatively to the rolling cone is the same with its velocity relatively to the fixed cone. That is to say,

\[ a \cdot \beta \cdot \text{EH} = a \cdot \text{EK} \cdot \text{OE} \];

therefore

\[ a \cdot \beta :: \text{EH} :: \text{EK} :: \text{OD} :: \text{OC} \],

which is the remainder of the solution.

The path of a point P in or attached to the rolling cone is a spherical epicycloid traced on the surface of a sphere of the radius OP. From P draw PQ perpendicular to the instantaneous axis. Then the motion of P is perpendicular to the plane OPQ, and its velocity is

\[ v_1 = \gamma \cdot \text{PQ} \].

The whole of the foregoing reasonings are applicable, not merely when A and B are actual regular cones, but also when they are the osculating regular cones of a pair of irregular conical surfaces, having a common apex at O.

**§ 32. Screw-like or Helical Motion.**—Since any displacement in a plane can be represented in general by a rotation, it follows that the only combination of translation and rotation, in which a complex movement which is not a mere rotation is produced, occurs when there is a translation perpendicular to the plane and parallel to the axis of rotation.

Such a complex motion is called screw-like or helical motion; for each point in the body describes a helix or screw round the axis of rotation, fixed or instantaneous as the case may be. To cause a body to move in this manner, it is usually made of a helical or screw-like figure, and moved in a guide of a corresponding figure. Helical motion and screws adapted to it are said to be right- or left-handed according to the appearance presented by the rotation to an observer looking towards the direction of the translation. Thus the screw G in fig. 94 is right-handed.

The translation of a body in helical motion is called its *advance*. Let \( v_2 \) denote the velocity of advance at a given instant, which of course is common to all the particles of the body; \( \alpha \) the angular velocity of the rotation at the same instant; \( \omega = 6.2832 \) nearly, the circumference of a circle of the radius unity. Then

\[ T = 2\pi a \] (10)

is the time of one turn at the rate \( \alpha \); and

\[ \beta = v_2 = \frac{2\pi a}{T} \] (11)

is the *pitch* or *advance per turn*—a length which expresses the *comparative motion* of the translation to the rotation. The pitch of a screw is the distance, measured parallel to its axis, between two successive turns of the same thread or helical projection.

Let \( r \) denote the perpendicular distance of a point in a body moving helically from the axis. Then

\[ \gamma = \alpha \cdot r \] (12)

is the component of the velocity of that point in a plane perpendicular to the axis, and its total velocity is

\[ \omega = \sqrt{\frac{r^2 + \gamma^2}{T}} \] (13)

The ratio of the two components of that velocity is

\[ \frac{\beta}{\gamma} = \frac{2\pi}{\alpha} \] (14)

where \( \beta \) denotes the angle made by the helical path of the point with a plane perpendicular to the axis.

**Division IV. Elementary Combinations in Mechanism**

**§ 33. Definitions.**—An *elementary combination* in mechanism consists of two pieces whose kinds of motion are determined by their connexion with the frame, and their comparative motion by their connexion with each other—that connexion being effected either by direct contact of the pieces, or by a connecting piece, which is not connected with the frame, and whose motion depends entirely on the motions of the pieces which it connects.

The piece whose motion is the cause is called the *driver*; the piece whose motion is the effect, the *follower*.

The connexion of each of those two pieces with the frame is in general such as to determine the path of every point in it. In the investigation, therefore, of the comparative motion of the driver and follower of an elementary combination, it is unnecessary to consider relations of angular direction, which are already fixed by the connexion of each piece with the frame; so that the enquiry is confined to the determination of the velocity ratio, and of the directional relation, so far only as it expresses the connexion between forward and backward movements of the driver and follower. When a continuous motion of the driver produces a continuous motion of the follower, forward or backward, and a reciprocating motion a motion reciprocating at the same instant, the directional relation is said to be constant. When a continuous motion produces a reciprocating motion, or vice versa, or when a reciprocating motion produces a motion not reciprocating at the same instant, the directional relation is said to be variable.

The *line of action* or of connexion of the driver and follower is a line traversing a pair of points in the driver and follower respectively, which are so connected that the component of their velocity relatively to each other, resolved along the line of connexion, is null.

There may be several or an indefinite number of lines of connexion, or there may be but one, and a line of connexion may connect either the same pair of points or a succession of different pairs.

**§ 34. General Principles.**—From the definition of a line of connexion it follows that the components of the velocities of a pair of connected points along their line of connexion are equal. And from this, and from the property of a rigid body, already stated in \( \S 29 \), it follows, that the components of a line of connexion of all the points traversed by that line, whether in the driver or in the follower, must be equal; consequently, that the velocities of any pair of points traversed by a line of connexion are to each other inversely as the cosines, or directly as the sines, of the angles made by the paths of those points with the line of connexion.

The general principle stated above in different forms serves to solve every problem in which—the mode of connexion of a pair of pieces being given—it is required to find their comparative motion at a given instant, or vice versa.

**§ 35. Application to a Pair of Shifting Pieces.**—In fig. 95, let \( P_1' \) be the line of connexion of a pair of pieces, each of which has a motion of translation or shifting.

Through any point \( T \) in that line draw \( TV_1, TV_2 \), respectively parallel to the simultaneous direction of motion of the pieces; through any other point \( A \) in the line of connexion draw a plane perpendicular to \( TV_1, TV_2 \); then, cutting \( TV_1, TV_2 \) in \( V_1, V_2 \); then, velocity of piece 1: velocity of piece 2 : \( TV_1 : TV_2 \). Also \( TA \) represents the equal components of the velocities of the velocities of the pieces parallel to their line of connexion, and the line \( TV_1 \) represents their velocity relatively to each other.

**§ 36. Application to a Pair of Turning Pieces.**—Let \( a, a' \) be the angular velocities of a pair of turning pieces; \( \theta, \theta' \) the angles which their line of connexion makes with their respective planes of rotation; \( r, r' \) the common perpendiculars let fall from the line of connexion upon the respective axes of rotation of the pieces.

Then the equal components, along the line of connexion, of the velocities of the points where those perpendiculars meet that line are

\[ a_r \cdot \cos \theta = a_r' \cdot \cos \theta' \] (15)

consequently, the comparative motion of the pieces is given by the equation

\[ a_r = \gamma \cdot \cos \theta \]

\[ a_r' = \gamma \cdot \cos \theta' \] (16)

which equation expresses the comparative motion of the two pieces. 

**§ 38. Classification of Elementary Combinations in Mechanism.**—The *elementary combination* of mechanism was founded by Monge, and fully developed by Lanz and Bé tacourt, which has been generally received, and has been adopted in most treatises on applied mechanics. But that classification is founded on the absolute instead of the comparative...
motions of the pieces, and is, for that reason, defective, as Willis pointed out in his admirable treatise *On the Principles of Mechanism*. Section III of § 39 appears that the angular velocity ratio of a pair of wheels is the inverse ratio of the distances of the point of contact from the centres respectively.

For outside gearing, because the wheels turn contrary ways; for inside gearing it is positive, because they turn the same way.

If the velocity ratio is to be constant, as in Willis's Class A, the wheels must be circular; and this is the most common form for wheels.

If the velocity ratio is to be variable, as in Willis's Class B, the wheels are of the following of rolling curves, subject to the condition that the distance between their poles (which are therefore vectors of rotation) shall be constant.

The following is the geometrical relation which must exist between such a pair of curves:

$$\text{Let } C, C \text{ (fig. 96) be the poles of a pair of rolling curves; } T_1, T_2 \text{ any pair of points of contact}; U_1, U_2 \text{ any other pair of points of contact. Then, for every possible pair of points of contact, the following two equations must be satisfied:}$$

$$\frac{\text{Sum of radii, } C_i U_i + C_2 U_2 = C_1 T_1 + C_2 T_2}{\text{arc, } T_1 U_2 = T_2 U_1.}$$

A condition equivalent to the above, and necessarily connected with it, is, that at each pair of points of contact the inclinations of the curves to their radii-vectors shall be equal and contrary; or, denoting by $\tau_1, \tau_2$ the radii-vectors at any given pair of points of contact, the following relations must be satisfied:

$$\text{The equal axes measured from a certain fixed pair of points of contact:}$$

$$d_{\tau_1}/ds = -d_{\tau_2}/ds;$$

$$\text{which is the differential equation of a pair of rolling curves whose poles are at a constant distance apart. For full details as to rolling curves, see Willis's work, already mentioned, and Clerk Maxwell's paper on Rolling Curves, *Trans. R. Soc. Edin.*, 1849.}$$

A rack, to work with a circular wheel, must be straight. To work with a wheel of any other figure, its section must be a rolling curve, subject to the condition that the perpendicular distance from the line of contact to the line of axes remains equal, both parallel to the direction of the motion of the rack shall be constant. Let $n_1$ be the radius-vector of a point of contact on the wheel, $x$ the ordinate from the straight line before mentioned to the corresponding point of contact on the rack. Then

$$\text{is the differential equation of the pair of rolling curves.}$$

To illustrate this subject, it is evident that an ellipse rotating about one focus rolls completely round in outside gearing with an equal and similar ellipse also rotating about one focus, the distance between the axes of rotation being equal to the major axis of the ellipse, and the velocity ratio varying from $1 + \text{eccentricity}$ to $1 - \text{eccentricity}$.

A hyperbola rotating about its further focus rolls in inside gearing, through a limited arc, with an equal and similar hyperbola also rotating about one of its foci, the distance between the axes of rotation being equal to the hyperbola, and the velocity ratio varying between $1 + \text{eccentricity}$ and $1 - \text{eccentricity}$. And a parabola rotating about its focus rolls with an equal and similar parabola, shifting parallel to its directrix.

§ 41. Conical or Bevel and Disk Wheels.—From Principles III and VI. of § 39 it appears that the angular velocities of a pair of wheels whose axes meet in a point are to each other inversely as the sines of the angles which the axes of the wheels make with the line of contact. Hence we have the following construction (figs. 97 and 98).—Let $O$ be the apex or point of intersection of the two axes of the wheels. The line joining $O$ to the point of contact being given, it is required to find the line of contact. On $OC_1, OC_2$ take lengths $OA_1, OA_2$, respectively proportional to the angles which the lines from the points on whose axes they are taken. Complete the parallelogram $A_1OA_2EC_1EC_2$; the diagonal $CT$ will be the line of contact required.

When the velocity ratio is variable, the line of contact will shift its position as the plane $C_1C_2$ rotates; and the axes will be cones, with eccentric or irregular bases. In every case which occurs in practice, however, the line of contact is constant; the line of contact is constant in position, and the rolling surfaces of the wheels are regular circular cones (when they are called bevel wheels); or one of a pair of wheels may have a flat disk
for its rolling surface, as \( W_1 \) in fig. 98, in which case it is a disk wheel. The rolling surfaces of actual wheels consist of frustums or zones of the complete cones or disks, as shown by \( W_1, W_2 \) in figs. 97 and 98.

### 42. Sliding Contact (lateral); Skew-Bewel Wheels

An hyperboloid of revolution is a surface resembling a sheaf or a dice box, generated by the rotation of a straight line round an axis from which it is a constant distance and to which it is inclined at a constant angle. If two such hyperboloids \( E, F \), equal and unequal, be placed in the closest possible contact, as in fig. 99, they will touch each other at one or two tangential straight lines of each which will form their line of contact, and will be inclined to the axes \( A_E, B_H \) in opposite directions. The axes will not be parallel, nor will they intersect each other.

The motion of two such hyperboloids, turning in contact with each other, has hitherto been classed amongst cases of rolling contact; but that classification is not strictly correct, for, although the component velocities of a pair of points of contact, between an axis at right angles to the line of contact are equal, still, as the axes are parallel neither to each other nor to the line of contact, the velocities of a pair of points of contact have components along the line of contact which are unequal, and their difference constitutes a lateral sliding.

The directions and positions of the axes being given, and the required angular velocity ratio, the following construction serves to determine the line of contact, by whose rotation round the two axes respectively the hyperboloids are generated:

In fig. 100, let \( B_C, B_D \) be the two axes; \( B_B \) their common perpendicular. Through any point \( O \) in this common perpendicular draw \( OA, \parallel \) to \( B_C, \) and \( OB, \parallel \) to \( B_D; \) make those lines proportional to the angular velocities about the axes to which they are respectively directed, complete the parallelogram \( O_AE_A, \) and draw the diagonal \( OE; \) divide \( B_B \) in \( D \) into two parts, inversely proportional to the angular velocities about the axes which they respectively adjoin; through \( D \) parallel to \( OE \) draw \( DT; \) this will be the line of contact.

A pair of thin frusta of a pair of hyperboloids are used in practice to communicate motion between a pair of axes which are not parallel or perpendicular, and are called skew-bevel wheels.

In skew-bevel wheels the properties of a line of connexion are not preserved in the line of contact, but only by every line traversing the line of contact at right angles.

If the velocities to be communicated were variable, the point \( D \) would alter its position, and the line \( DT \) its direction, at different periods of the motion, and the wheels would be hyperboloids of an eccentric or irregular cross-section; but forms of this kind are not used in practice.

### 43. Sliding Contact (circular); Grooved Wheels

As the adhesion or friction between a pair of smooth wheels is seldom sufficient to prevent their slipping on each other, contrivances are used to increase their mutual hold. One of the simplest consists in cutting a rim of each wheel into a series of alternate ridges and grooves parallel to the plane of rotation; it is applicable to cylindrical and bevel wheels, but not to skew-bevel wheels. The comparison of motion of a pair of wheels so ridged and grooved is the same as that of a pair of smooth wheels in rolling contact, whose cylindrical or conical surfaces lie midway between the tops of the ridges and bottoms of the grooves, and those ideal smooth surfaces are called the pitch surfaces of the wheels.

The relative motion of the faces of contact of the ridges and grooves is a rotary sliding or gridding motion, about the line of contact of the pitch-surfaces as an instantaneous axis.

Grooved wheels have hitherto been little used.

### 44. Sliding Contact (direct); Teeth of Wheels, Their Number and Pitch

The ordinary method of connecting wheels in shafts is by the teeth of spur-wheels, or by the teeth of a rack. The pitch is the distance between two teeth parallel to the axes of the wheel, or to the case of an axis perpendicular to the direction of motion of a pair of spur-wheels, and to the case of a line parallel to the face of a rack, or to the pitch-point.

#### 44.1. Teeth of Wheels

Wheels, their numbers, and pitch, are always designated in principles by the numbers of teeth of which the smaller wheel is supposed to consist, and the pitch, or the distance between two teeth parallel to the axes of the wheel. The number of teeth used on wheels is for the most part not greater than 100, and for the smaller wheels generally not greater than 30. The pitch is usually stated in inches, being, for large wheels, the distance between two teeth parallel to the axes of the wheel, or to the case of an axis perpendicular to the direction of motion of a pair of spur-wheels, or to the case of a line parallel to the face of a rack, or to the pitch-point.

#### 44.2. Teeth, Their Numbers, and Pitch, in Practice

The driver pushes those of the follower before them, and in so doing sliding takes place between them in a direction along their lines of contact.

The pitch-surfaces of a pair of toothed wheels are the ideal smooth surfaces which would hold in the sliding contact that the actual wheels have by the sliding contact of their teeth. The pitch-circles of a pair of toothed wheels are sections of their pitch-surfaces, made for spur-wheels (that is, for wheels with a plane right angle to the axes, and for bevel wheels by a sphere described about the common apex. For a pair of skew-bevel wheels the pitch-circles are a pair of circles whose radii, or pitch-surfaces, have the pitch-point as their point of contact.

The pitch-surfaces of a wheel line intermediate between the points of the teeth and the bottoms of the hollows between them. That part of the wheel moving in the opposite direction of the pitch-surface is called the face; that part which lies within the pitch-surface, the flank.

Teeth, when not otherwise specified, are understood to be made in one piece with the wheel, the material being generally cast-iron, brass or bronze. Separate teeth, fixed into mortises in the rim of the wheel, are called cogs. A pinion is a small toothed wheel; a turbine is a pinion with cylindrical teeth for teeth.

The radius of the pitch-circle of a wheel is called the geometrical radius; a circle touching the ends of the teeth is called the addendum circle, and its radius the real radius; the difference between these radii, that part of the projection of the teeth beyond the pitch-surface, is called the addendum.

The distance, measured along the pitch-circle, from the face of one tooth to the face of the next, or the distance of one pitch of tooth and the number of teeth in wheels are regulated by the following principles:

1. In wheels which rotate continuously for one revolution or more, it is evidently necessary that the pitch should be an exact multiple of the circumference.

2. In wheels which reciprocate without performing a complete revolution this condition is not necessary. Such wheels are called sector wheels.

3. In order that a pair of wheels, or a wheel and a rack, may work correctly together, it is in all cases essential that the pitch should be the same in both.

4. Hence, in any pair of circular wheels which work together, the numbers of teeth in a complete circumference are directly as the radii and inversely as the angular velocities.

5. For commensurate gearwheels which rotate continuously for one revolution or more, the ratio of the numbers of teeth and its reciprocal the angular velocity ratio must be expressible in whole numbers.

From this principle arises problems of a kind which will be referred to in treating of Trains of Mechanism.

#### 44.3. Teeth, Their Numbers, and Pitch, in Practice

Let \( n, N \) be the respective numbers of teeth in a pair of wheels; \( n = N \) is called the equal or unidirectional.

Let \( e = \) the pitch in each wheel.

If the velocity to be communicated were variable, the point \( D \) would alter its position, and the line \( DT \) its direction, at different periods of the motion, and the wheels would be hyperboloids of an eccentric or irregular cross-section; but forms of this kind are not used in practice.

#### 44.4. Sliding Contact; Forms of the Teeth of Spur-wheels and Racks

A line of connexion of two pieces in sliding contact is a line in which the velocity at any point is parallel to it.

Bearing this in mind, the principle of the comparative motion of a pair of teeth belonging to a pair of spur-wheels, or to a spur-wheel and a rack, is found by applying the principles stated generally in \( \text{sec. } 44 \), that is, by the transformation of the pitch SURFACES of spur-wheels, and to the case of an axis perpendicular to the direction of motion of a pair of spur-wheels, and to the case of a line parallel to the face of a rack, or to the pitch-point.

#### 44.5. Toothed wheels, Teeth, Their Numbers, and Pitch, in Practice

Let \( C, C' \) be the centres of a pair of spur-wheels; \( B_B, B_B' \) portions of their pitch-circles, touching at \( I, \) the pitch-point. Let the wheel 1 be the driver, and the wheel 2 the follower.
Let \( D_1 B_A \), \( D_T B_A \) be the positions, at a given instant, of the teeth in the driver and follower respectively, now touch \( C_1 P_1 \) and \( C_2 P_2 \) at \( T \); the line of connexion of those teeth is \( P_1 P_2 \), perpendicular to \( P_1 B_2 \), and with those lines as radii describe about the centres of the wheels the circles \( D_1 D_2 \), \( D_T D_2 \), called base-circles. It is evident that the radii of the base-circle surface to each other the same proportions as the radii of the pitch-circles, and also that

\[
\frac{C_1 P_1}{C_2 P_2} = \cos \theta
\]

The obliquity which is found to answer best in practice is about \( 1 \) in 10, its cosine is about \( 1/\sqrt{10} \), and its sine about \( 1/\sqrt{10} \). These values though not absolutely exact, are near enough to the truth for practical purposes.

Suppose the base-circles to be a pair of circular pulleys connected by means of a cord whose course from pulley to pulley is \( P_1 P_2 \). The line of connexion of these pulleys is the same as that of the proposed teeth, they will rotate with the required velocity ratio. Now, suppose a tracing point \( T \) to be fixed to the cord, so as to be carried along the path of contact \( P_1 P_2 \), that point describes on a plane rotating along with the wheel 1 part of the involute of the circle \( D_1 D_2 \), and on a plane rotating along with the wheel 2 part of the involute of the base-circle \( D_T D_2 \); and the two curves so described will always coincide with each other in the required point of contact \( T \), and will therefore fulfil the condition required by Principle I. of § 45.

Consequently, one of the forms suitable for the teeth of wheels is the involute of a circle; and the obliquity of the action of such teeth is the angle whose cosine is the radius of their base-circle to that of the pitch-circle of the wheel.

All the teeth of the same pitch work smoothly together.

To find the length of the path of contact on either side of the pitch-point 1, it is to be observed that the distance between the fronts of two successive teeth, as measured along \( P_1 P_2 \), is less than the difference of the radii of the two base-circles, so as to make the pitch-circle \( P_1 P_2 \) a little shorter than the circle to which the teeth are connected.

A circle of rolling velocity will pass through the contact point, and with this length of path, and the obliquity already mentioned of 143°, the addendum is about 3/1 of the pitch. The teeth of a rack, to work correctly with wheels having involute teeth, should have plane surfaces perpendicular to the line of connexion at the base-circle, and consequently the action of the rack angles equal to the complement of the obliquity of action.

§ 47. Teeth for a given Path of Contact: Sang's Method.—In the previous section, the form of the teeth is found by assuming a figure for the path of contact, viz., the straight line. Any other convenient figure may be assumed for the path of contact, and the corresponding forms of the teeth found by determining what curves a point moving along the assumed path of contact, will trace on two disks rotating round the centres of the wheels with angular velocities bearing that relation to the component velocity of \( T \) along \( T \), which is given by Principle II. of § 45, and by equation (25). This method of finding the forms of the teeth of wheels forms the subject of an elaborate and most interesting treatise by Edward Sang.

If a wheel has teeth of the same pitch, traced from the same path of contact, work correctly together, and are said to belong to the same set.

§ 48. Teeth traced by Rolling Curves.—If any curve R (fig. 103) be applied on the inside of the pitch-circle BB of a wheel, it appears, from § 30, that the instantaneous axis of the rolling curve at any instant will be at the point I, where it touches the pitch-circle for the moment, and that consequently the line IT traced by a tracing-point T, fixed to the rolling curve upon the place of the wheel, will be everywhere perpendicular to the straight line IT; so that the traced curve AT will be suitable for the flank of a tooth, in which T is the point of contact corresponding to the position I of the pitch-point. If the
same rolling curve R, with the same tracing-point T, be rolled on the outside of any other pitch-circle, it will have the face of a tooth suitable to work with the flank AT.

In like manner, if either the same or any other rolling curve R' be rolled the opposite way, on the outside of the pitch-circle BB', so that the tracing point T' shall start from A, it will trace the face AT' of a tooth suitable to work with a flank traced by rolling the same curve R' with the same tracing-point T' inside any other pitch-circle.

The figure of the path of contact is that traced on a fixed plane by the faces and the flanks of the teeth of a number of wheels of different sizes but of the same pitch, all those wheels will work correctly together, and will form a set. The teeth of a rack, of the same set, are traced by rolling the rolling curve on both sides of a straight line.

The teeth of wheels of any figure, as well as of circular wheels, may be traced by rolling curves on their pitch-surfaces; and all teeth of the same pitch, traced by the same rolling curve with the same tracing-point, will work together correctly if their pitch-surfaces are in rolling contact.

§ 49. Epicycloidal Teeth.—The most convenient rolling curve is the pitch-circle. The path of contact with the rolling circles is identical with itself; and the flanks of the teeth are internal and their faces external, for the flanks for wheels, and both flanks and faces are cycloids for a rack.

For a pitch-circle of twice the radius of the rolling or describing circle (as it is called) the internal epicycloid is a straight line, being, in fact, a diameter of the pitch-circle so that the flanks of the teeth for such a pitch-circle are planes radiating from the axis. For a smaller pitch-circle the flanks would be convex and incurved or under-cut, which would be inconvenient; therefore the smallest wheel of a set should have its pitch-circle of twice the radius of the describing circle, so that the flanks may be either straight or concave.

In fig. 104 let BB' be part of the pitch-circle of a wheel with epicycloidal teeth; CIC' the line of centres; I the pitch-point; EIE' a straight tangent to the pitch-circle at that point; R the internal and R' the equal external describing circles, so placed as to touch the pitch-circle and each other at I. Let DlID' be the path of contact, consisting of the arc of approach DI and the arc of recess ID'. If in order that there may always be a pair of teeth in action, each of those arcs should be equal to the pitch.

The obliquity of the action in passing the line of centres is nothing; the maximum obliquity is the angle EID' = E1D'; and the mean obliquity is one-half of that angle.

It appears from experience that the mean obliquity should not exceed 15°; therefore the maximum obliquity should be about 30°; therefore the equal arcs DI and ID' should each be one-sixth of a circumference; therefore the circumference of the describing circle should be six times the pitch.

It follows that the smallest pinion of a set in which the pinion the flanks are straight should have its pitch-circle of six times the pitch.

§ 50. Nearly Epicycloidal Teeth; Willis's Method.—To facilitate the drawing of epicycloidal teeth in practice, Willis showed how to approximate to their figure by means of two circular arcs—one concave, for the flank, and the other convex, for the face—and each having for its radius the mean radius of curvature of the epicycloidal arc. Willis's formulae are founded on the following properties of epicycloids.

Let R be the radius of the pitch-circle; r that of the describing circle; θ the angle made by the normal TI to the epicycloid at a given point T, with a tangent to the circle at I—that is, the obliquity of the action at T.

Then the radius of curvature of the epicycloid at T is:

For an internal epicycloid, \( \rho + 4r \sin \theta \)

For an external epicycloid, \( \rho - 4r \sin \theta \)

Also, to find the position of the centres of curvature relatively to the pitch-circle, we have, denoting the chord of the describing circle TI by c, \( c = 2r \sin \theta \); and therefore

For the flank, \( \rho - c = 2r \sin \theta \)

For the face, \( \rho - c = 2r \sin \theta \)

For the proportions approved of by Willis, \( \sin \theta = \frac{1}{2} \) nearly; \( r = \frac{p}{2} \) (the pitch) nearly; \( c = \frac{p}{2} \) nearly; and, if N be the number of teeth in the wheel, \( \pi R/6N \) nearly; therefore, approximately,

\[
\rho - c = \frac{N}{12} \quad \rho - c' = \frac{N}{2} \quad \rho' - c = \frac{N}{12}
\]

Hence the following construction (fig. 105). Let BB' be part of the pitch-circle, and a the point where a tooth is to cross it. Set off \( ak = \frac{p}{2} \). Draw radii BD, BC, making angles of 75° with those radii. Make \( \angle b = c \). \( \angle acp = c \). From a, with the radius fa, draw the circular arc ak. From a, with the radius ga, draw the circular arc ak. Then ak is the face and ak the flank of the tooth required.

To facilitate the application of this rule, Willis published tables of \( \rho - c \) and \( \rho' - c \), and invented an instrument called the 'odontograph.'

§ 51. Trundles and Pin-Wheels.—If a wheel or trundle have cylindrical pins or staves for teeth, the faces of the teeth of a wheel should be such that the corresponding teeth of a pin-wheel tracing epicycloids, by rolling the pitch-circle of the pin-wheel or trundle on the pitch-circle of the driving-wheel, with the centre of a stave for a tracing-point, and then drawing curves parallel to, and within the epicycloids, at a distance from them equal to the radius of a stave. Trundles having only six staves will work with large wheels.

§ 52. Backs of Teeth and Spaces.—Toothed wheels being in general intended to rotate either way, the backs of the teeth are made similar to the fronts. The space between two teeth, measured on the pitch-circle, is made about \( \frac{1}{4} \)th part wider than the thickness of the tooth on the pitch-circle, so as to say,

Thickness of tooth = \( \frac{1}{4} \) pitch;

Width of space = \( \frac{3}{10} \) pitch.

The difference of \( \frac{1}{4} \) of the pitch is called the back-lash. The clearance allowed between the points of teeth and the bottoms of spaces between the teeth of the other wheel is about one-tenth of the pitch.

§ 53. Stepped and Helical Teeth.—R. J. Hooke invented the making of the points of teeth in a series of steps with a view to increase the smoothness of action. A wheel thus formed resembles in shape a series of equal and similar toothed disks placed side by side, with the teeth of each a little behind those of the preceding disk.

He also invented, with the same object, teeth whose fronts, instead of being parallel to the line of contact of the pitch-circles, cross it obliquely, so as to be a screw-like or helical form. In wheel-screws he gave the contact the kind of each pair of teeth commences at the foremost end of the engagement, and terminates at the aftermost; and the helix is of such a pitch that the contact of one pair of teeth shall not terminate until that of the next pair has commenced.

Stepped and helical teeth have the desired effect of increasing the smoothness of motion, but they require more difficult and expensive workmanship than common teeth; and helical teeth are, besides, open to the objection that they exert a laterally oblique pressure, which tends to increase resistance, and unduly strain the machinery.

§ 54. Teeth of Bevel-Wheels.—The acting surfaces of the teeth of bevel-wheels are conical, and generated by the motion of a line passing through the common apex of the cone, while its extremity is carried round the outlines of the cross section of the teeth made by a sphere described about that apex.

The operations of describing the exact figures of the teeth of bevel-wheels, whether by involutes or by rolling curves, are in every respect analogous to those for describing the figures of the teeth of spur-wheels, except that in the case of bevel-wheels all those operations are to be performed on the surface of a sphere described about the apex instead of on a plane, substituting poles for centres, and great circles for straight lines.

In consideration of the practical difficulty, especially in the case of large wheels, of obtaining an accurate spherical surface, and of drawing upon it when obtained, the following approximate methods are generally used.

Let \( O \) (fig. 106) be the common apex of a pair of bevel-wheels. Ob1, Ob2 their pitch cones; Oa1, Oa2 their axes; Ol their line of contact. Perpendicular to Ol draw A1A0, cutting the axes in A1, A0; make the outer rims of the patterns and of the wheels.
III. The angular velocities of the screws are inversely as their numbers of threads.

Hooke's wheels with oblique or helical teeth are in fact screws of many threads, and of large diameters as compared with their heads.

The ordinary position of a pair of endless screws is with their axes at right angles to each other. When one is of considerably greater diameter than the other, the larger is commonly called in practice a wheel, the name of the smaller being applied to the smaller only; but they are nevertheless both screws in fact.

To make the teeth of a pair of endless screws fit correctly and work smoothly, a hardened steel screw is made of the figure of the smaller screw, with a helix of the threads so made that, when the teeth at a given pitch-circle are similar to those of the teeth of a bevel-whe else its pitch surface is a cone touching the hyperboloidal surface at the pitch-circle.

§ 58. Cams.—A cam is a single tooth, either rotating continuously or oscillating, and driving a sliding or turning piece either constantly or at intervals. All the principles which have been stated in § 45 as being applicable to teeth are applicable to cams; but in designing cams it is not usual to determine or take into consideration the form of the ideal pitch-surface, which would give the same comparative motion by rolling contact that the cam gives by sliding contact.

§ 56. Teeth of Skew-Bevel Wheels.—The cones of a skew-wheels are parallel to the generating straight line of the hyperboloidal pitch surface of one wheel, and the corresponding sections of the teeth at a given pitch circle are similar to those of the teeth of a bevel-wheel whose pitch surface is a cone touching the hyperboloidal surface at the pitch circle.

The relation between the advance and the rotation, which compose the motion of a wheel rolling in a fixed screw or helical guide, has already been demonstrated in § 32; and the same relation exists between the magnitudes of the rotation of a screw about a fixed axis, and its obliquity, in which it rotates.

The advance of the nut takes place in the opposite direction to that of the advance of the screw in the case in which the nut is fixed.

The pitch or axial pitch of a screw has the meaning assigned to it in that section, viz., the distance, measured parallel to the axis, between the corresponding points in two successive turns of the same thread.

If, therefore, the screw has several equidistant threads, the true pitch is equal to the divided axial pitch, as measured between two adjacent threads, multiplied by the number of threads.

If a helix be described round the screw, crossing each turn of the thread at right angles, the distance between corresponding points on two successive turns of the same thread, measured along this normal helix, may be called the normal pitch; and when the screw has more than one thread the normal pitch from thread to thread may be called the normal divided pitch.

The distance from thread to thread, measured on a circle described about the axis of the screw, called the pitch-circle, may be called the circumferential pitch; for a screw of one thread it is one circumference; for a screw of n threads, n circumferences.

Let r denote the radius of the pitch circle; n the number of threads; θ the obliquity of the threads to the pitch circle, and of the normal helix to the axis.

\[
\begin{align*}
\rho_a &= \rho_n \cot \theta = \rho_n \cos \theta = \frac{2\pi}{n} \\
\rho_d &= \rho_n \sec \theta = \rho_n \tan \theta = \frac{2\pi \tan \theta}{n} \\
\rho_c &= \rho_n \sin \theta = \rho_n \cos \theta = \frac{2\pi \sin \theta}{n}
\end{align*}
\]

If a screw rotates, the number of threads which pass a fixed point in one revolution is the number of threads in the screw.

A pair of convex screws, each rotating about its axis, are used as an elementary combination to transmit motion by the sliding contact of their threads. Such screws are commonly called endless screws, and in the same point of contact of the two screws the threads must be parallel; and their line of connexion is the constant perpendicular to the acting surfaces of the threads at their point of contact.

Hence the following principles:

I. If the screws are both right-handed or both left-handed, the angle between the directions of their axes is the sum of their obliquities; if one is right-handed and the other left-handed, that angle is the difference of their obliquities.

II. The normal pitch for a screw of one thread, and the normal divided pitch for a screw of more than one thread, must be the same in each screw.

The circular pitch of a screw is defined as the distance traversed by the centre of the thread of a screw in one revolution of the screw.

If the given screw is a right-handed one, the circular pitch is a directed quantity, measured along the direction of the axis of the screw, and directed towards the right.

FIG. 107.

If the given screw is a left-handed one, the circular pitch is measured along the direction of the axis of the screw, and directed towards the left.

The effective radius of the pitch-circle, or radius of the pitch-circle of a circular pulley or drum, is equal to the real radius added to half the thickness of the wrapping.
angular velocities of a pair of connected circular pulleys or drums are effectively the same as the effective radii.

A crossed belt, as in fig. 108, A, reverses the direction of the rotation communicated; an uncrossed belt, as in fig. 108, B, preserves that direction.

The length \( L \) of an endless belt connecting a pair of pulleys whose effective radii are \( r_1, r_2 \), with parallel axes whose distance apart is \( c \), is given by the following formulas, each of which the belt-term, containing the radius, expresses the length of the straight parts of the belt, and the remainder of the formula the length of the curved parts.

For a crossed belt:

\[
L = 2\sqrt{r_1^2 + (r_2 - c)^2} + 2 \left( r_1 + r_2 \right) \frac{\sin^{-1}(r_1/c)}{c}; \quad (32 \text{ A})
\]

and for an uncrossed belt:

\[
L = 2\sqrt{r_1^2 + (r_2 - c)^2} + \pi (r_1 + r_2 + 2 (r_1 - r_2) \sin^{-1}(r_1/c)) \quad (32 \text{ B})
\]

in which \( r_1 \) is the greater radius, and \( r_2 \) the less.

Fig. 109. A pair of speed-cones (fig. 109) is a contrivance for varying and adjusting the velocity ratio communicated between a pair of parallel shafts by means of a belt. The speed-cones are either connected continuously, or as A, B, whose velocity ratio can be varied gradually, while they are in motion by shifting their stationary sets or sets of pulleys whose radii vary by steps, as \( C, D \), in which case, the velocity ratio can be changed by shifting the belt from one pair of the speed-cones to another.

In order that the belt may fit accurately in every possible position, on a pair of speed-cones, the quantity \( L \) must be constant, in equations (32 A) or (32 B), according to whether the belt is crossed or uncrossed.

For a crossed belt, as in A and C, fig. 109, \( L \) depends solely on \( c \) and on \( r_1 + r_2 \). Now \( c \) is constant because the axes are parallel; therefore the sum of the radii of the pitch-triangles connected in every position of the belt is to be constant.

This condition is fulfilled by a pair of continuous cones generated by the revolution of two straight lines inclined opposite ways to their respective axes at equal angles.

For an uncrossed belt, the quantity \( L \) in equation (32 B) is to be made constant. The exact fulfilment of this condition requires the solution of a transcendental equation; but it may be fulfilled with accuracy sufficient for practical purposes by using, instead of (32 B) the following equation:

\[ L \text{ nearly} = 2c + (r_1 + r_2 + (r_1 - r_2)/c). \] 

(33)

The following is the most convenient practical rule for the application of this equation:

Let the speed-cones be equal and similar conoids, as in B, fig. 109, but with their large and small ends turned opposite ways. Let \( r_1 \) be the radius of the large end of each, \( r_2 \) that of the small end, \( r_3 \) that of the middle; and let \( s \) be the sagitta, measured perpendicular to the axes, of the arc by whose revolution each of the conoids is generated, or, in other words, the budding of the conoids in the middle of their length. Then

\[ s = \frac{(r_1 + r_2) - 2}{2(1 + (r_1 - r_2)/c)}. \] 

(34)

In which case the angular velocity ratio at any instant is the reciprocal of the ratio of the common perpendiculars let fall from the line of connexion upon the respective axes of rotation.

If the instant that the direction of one of the crank-arms coincides with the line of connexion, the common perpendicular of the line of connexion and the axis of that crank-arm vanishes, and the directional relation of the motions becomes indeterminate. The position of the other axis is arbitrary, for from the connexion of an arm in question, such an instant is called a dead-point. The velocity of the other connected point at such an instant is null, unless it also reaches a dead-point at the same time: this is true in the plane of the two axes of rotation, in which case the velocity ratio is indeterminate. Examples of dead-points, and of the means of preventing the inconvenience which they tend to occasion, will appear in the sequel.

§ 62. Coupling of Parallel Axes.—Two or more parallel shafts (such as those of a locomotive engine, with two or more pairs of driving-wheels) are made to rotate with constantly equal angular velocities by having their shafts, which are maintained parallel by a coupling-rod of such a length that the line of connexion is equal to the distance between the axes. The cranks pass their dead-points simultaneously. To obviate the unsightliness of motion which this tends to cause, the shafts are provided with a second set of cranks at right angles to the first, connected by means of a similar coupling-rod, so that one set of cranks pass their dead points at the instant when the other set reaches its furthest from them.

§ 63. Comparative Motion of Connected Points.—As the link is a rigid body, it is obvious that its action in communicating motion must be determined by the relative motion of the connected points, and this is often the most convenient method of proceeding.

If a connected point belongs to a turning piece, the direction of its motion at a given instant is perpendicular to the plane containing the axis and crank-arm of the piece. If a connected point belongs to a shifting piece, the direction of its motion at any instant is given, and it can be determined perpendicular to that direction.

The line of intersection of the planes perpendicular to the paths of the two connected points at a given instant is the instantaneous axis of the link at that instant; and the velocities of the connected points are directly as their distances from that axis.

In drawing on a plane surface, the two planes perpendicular to the paths of the connected points are represented by two lines (being their sections by a plane normal to them), and the instantaneous axis by a point (fig. 110); and, should the length of the two lines render it impracticable to produce them until they actually intersect, the velocity ratio of the connected points may be found by the principle that it is equal to the ratio of the segments which a line parallel to the line of connexion cuts off upon the two lines drawn from a given point, perpendicular respectively to the paths of the connected points.

To illustrate this by one example. Let \( C_1 \) be the axis, and \( T_1 \) the connected point of the beam of a steam-engine; \( T_1 T_1 \) the connecting or crank-rod; \( T_2 \) the other connected point, and \( C_2 \) the connected point of the beam of some other engine. \( C_2 \) is the axis of the crank and its shaft. Let \( T_2 \) be the axis of the crank at any given instant; \( T_1 \) that of \( T_1 \). To find the ratio of these velocities, produce \( C_1 T_1 \) and \( C_1 T_2 \), till they intersect in \( K \); \( K \) is the instantaneous axis of the connecting rod, and the velocity ratio is

\[ \text{K} : \text{K}_1 : \text{K}_1. \] 

(35)

Should \( K \) be inconveniently far off, draw any triangle with its sides respectively parallel to \( C_1 T_1 \), \( C_1 T_2 \) and \( T_1 T_2 \); the ratio of the two sides first mentioned will be the velocity ratio required. For example, draw \( C_1 T_1 \), parallel to \( C_1 T_2 \), cutting \( T_1 T_2 \) in \( A \); then

\[ \angle C_1 A T_1 = 90^\circ. \] 

(36)

§ 64. Eccentric.—An eccentric or crankpin of a shaft, and used to give a reciprocating motion to a rod, is in effect a crank-pin of sufficiently large diameter to surround the shaft, and so avoid the swinging of the driven wheel, which would result from making it so as to form an ordinary crank. The centre of the eccentric is its connected point; and its eccentricity, or the distance from that centre to the axis of the shaft, is its crank-arm.

A reciprocating motion is being capable of having its eccentricity altered by means of an adjusting screw, so as to vary the extent of the reciprocating motion which it communicates.

§ 65. Reciprocating Stroke—Stroke.—The distance between the extreme positions of the path of the connected point in a reciprocating piece (such as the piston of a steam-engine) is called the stroke or length of stroke of that piece. When it is connected with a reciprocating piece, such as the crank of a steam-engine, the ends of the stroke of the reciprocating piece correspond to the
dead-points of the path of the connected point of the turning piece, where the line of connexion is continuous with or coincides with the crank-arm.

Let $S$ be the length of stroke of the reciprocating piece, $L$ the length of the crank, and $\theta$ the angle of the continuous turning piece. Then, if the two ends of the stroke be in one straight line with the axis of the crank,

$$S = 2R;$$

and if these ends be not in one straight line with that axis, then $S = 2L - R$, and $L - R$ are the three sides of a triangle, having the angle opposite $S$ at that axis; so that, if $\theta$ be the supplement of the arc between the dead-points,

$$S^2 = 2(L^2 - R^2) - 2L^2 \cos \theta.$$ \hspace{1cm} (38)

§ 66. Coupling of Interesting Axes—Hooke’s Universal Joint.—

Interssed axisses are coupled by a contrivance of Hooke’s, known as the “universal joint,” which belongs to the class of linkwork (see fig. 111). Let $O$ be the point of intersection of the axes $OC_1, OC_2,$ and $\theta$ their angle of inclination to each other. The pair of shafts $C_1, C_2$ terminate in a pair of forks $F_1, F_2$ in bearings at the extremities of which are the gudgeons at the ends of the arms of a rectangular cross; having its centre at $O$. The cross is the link; the connected points are the centres of the bearings $F_1, F_2$. At each instant, each of those points moves at right angles to the central plane of its shaft and fork, therefore the line of intersection of the central planes of the two forks at any instant is the instantaneous axis of the cross, and the velocity ratio of the points $F_1, F_2$ (which, as the forks are equal, is also the angular velocity ratio of the shafts) is equal to the ratio of the distances of those points from that instantaneous axis. The mean value of that velocity ratio is that of equality, for each successive quarter-turn made by both shafts in the same time; but its actual value fluctuates between the limits:

$$\frac{a_1}{a_2} = \frac{\cos \theta}{\cos \theta}$$ \hspace{1cm} (39)

and $a_3 = \cos \theta$ when $F_1$ is in that plane.

Its value at intermediate instants is given by the following equations: let $\phi_1, \phi_2$ be the angles respectively made by the central planes of the forks and shafts with the plane $OC_1$, at a given instant; then

$$\cos \theta = \tan \phi_1 \tan \phi_2$$ \hspace{1cm} (40)

§ 67. Intermittent Linkwork—Click and Ratchet.—A click acting upon a ratchet-wheel or rack, which it pushes or pulls through a certain arc at each forward stroke and returns to rest at each backward stroke, is an example of intermittent linkwork. During the forward stroke the action of the click is governed by the principles of linkwork; during the backward stroke that action ceases, or pulls, turning on a fixed axis, prevents the ratchet-wheel or rack from reversing its motion.

Division 5.—Trains of Mechanism.

§ 68. General Principles.—A train of mechanism consists of a series of pieces each of which is follower to that which drives it and driver to that which follows it.

The comparative motion of the first driver and last follower is obtained by combining the properties of their terms, the velocity ratios and by their signs the directional relations of the several elementary combinations of which the train consists.

§ 69. Trains of Wheelwork.—Let $A_1, A_2, A_3, \ldots, A_n$ denote a series of axes, and $a_1, a_2, a_3, \ldots, a_n$ their angular velocities. Let the axis $A_1$ carry a wheel of $N_1$ teeth, driving a wheel of $N_2$ teeth on the axis $A_2$, which carries also a wheel of $N_2$ teeth, driving a wheel of $N_3$ teeth on axis $A_3$, and so on, that the numbers of teeth in the drivers being denoted by $N_1$, and in followers by $N_2$, and the axes to which the wheels are fixed being denoted by $a_1, a_2, a_3, \ldots$, then

$$a_1 = a_2 a_3 a_4 \ldots a_n$$ \hspace{1cm} (41)

that is, to say, the velocity ratio of the last and first axes is the ratio of the product of all the coefficients of the drivers to the product of the numbers of teeth in the followers.

Supposing all the wheels to be in outside gearing, then, as each elementary combination reverses the direction of rotation, and as the number of elementary combinations $m - 1$ is one less than the number of axes $m$, it is evident that if $m$ is odd the direction of rotation is preserved, and if even reversed.

It is often a question of importance to determine the number of teeth in a train of wheels for giving a determined velocity. It was shown by Young that, to do this with the least total number of teeth, the velocity ratio of each elementary combination should approximate as nearly as possible to $3.59$. This being the case in many cases gives an advantage, for smoother motion, not to go below fifteen; and for involute teeth the smallest number is about twenty-four.

If the velocity ratio required, reduced to its least terms, and let $B$ be greater than $C$. If $B/C$ is not greater than 6, and $C$ lies between the prescribed minimum number of teeth (which may be called $l$ and its double $2l$), then one pair of wheels will answer the purpose, and the number of teeth for driving, multiplied by $2l$, be at once inconveniently large and prime, then, instead of the exact ratio $B/C$ some ratio approximating to that ratio, and capable of resolution into convenient factors, is to be found by the method of continued fractions, which is to be substituted for $B/C$ as before.

So far as the resultant velocity ratio is concerned, the order of the drivers $N$ and of the followers $n$ is immaterial; but to secure equal tooth wear of the teeth, as explained in § 44, the wheels ought to be so arranged that, for each elementary combination, the greatest common divisor of the numbers of teeth of the followers of a given combination, found by the method of continued fractions, is to be substituted for $B/C$ as before.

§ 70. Double Hooke’s Coupling.—It has been shown in § 66 that the velocity ratio of a pair of shafts coupled by a universal joint fluctuates between the limits $\cos \theta$ and $\cos \theta$; hence that shafts must have vibrating and unsteady motion, injurious to the mechanism and framework. To obviate this evil a short intermediate shaft is introduced, making equal angles with the first and last shaft, coupled with each of them by a Hooke’s joint, and having its own two forks in the same plane. Let $a_1, a_2, a_3$ be the angular velocities of the first, intermediate, and last shaft in this train of two Hooke’s couplings. Then, from the principles of § 65 it is evident that at each instant $\frac{a_1}{a_3} = \frac{a_1}{a_2} \frac{a_2}{a_3}$; so that the fluctuations of angular velocity caused by the first coupling are exactly neutralized by the second, and the first and last angular velocities are equal to each other at each instant.

Converging and Diverging Trains of Mechanism.—Two or more trains of mechanism may converge into one—as when the two pistons of a pair of steam-engines, each through its own connecting-rod, carries one cranking shaft, or change into two or more—as when a single shaft, driven by a prime mover, carries several pulleys, each of which drives a different machine. The principles of comparative motion in each converging and diverging trains are the same as in simple trains.

Division 6.—Aggregate Combinations.

§ 71. General Principles.—Willis designated as “aggregate combinations" those assemblages of pieces of mechanism in which the motion of one follower is the resultant of component motions impressed on it by more than one driver. Two classes of aggregate combinations may be distinguished, which, though not different in their conception, appear at first to be divided from each other, one comprising those cases in which a piece A is carried directly by the frame C, but by another piece B, relatively to which the motion of A is given—the motion of the piece B relatively to the frame C being also given. Then the motion of A relatively to B is the same as the motion of A relatively to C, and that resultant is to be found by the principles already explained in Division 3 of this Chapter §§ 27–32. The other class comprises those cases in which the motion of A does not affect the motion of B, which in this three points in one follower are determined by their connexions with two or with three different drivers.

This classification is founded on the kinds of problems arising from aggregate combinations. Willis adopts another classification founded on the objects of the combinations, which objects he divides into two classes, viz. (1) to produce aggregate velocity, or a velocity which is the resultant of $n$ or more components in the same path, and (2) to produce an aggregate path—that is, to make a given point
in a rigid body move in an assigned path by communicating certain motions to that body. It is seldom that one of these effects is produced without at the same time producing the other; but the classification of Willis depends upon which of those two effects, even supposed them to occur together, is the practical object of consideration.

§ 73. Differential Windlass.—The axis C (fig. 112) carries a larger barrel AE and a smaller barrel DB, rotating as one piece with the angular velocity \( \omega_1 \) in the direction AE. The pulley or sheave FG has a weight W hung to its centre. A cord has one end fast made to and wrapped round the barrel AE; it passes from A under the sheave FG, and has the other end wrapped round and made fast to the barrel BD. Required the relation between the velocity of translation \( v_t \) of W and the angular velocity \( \omega_2 \) of the differential barrel.

In this case \( v_t \) is an aggregate velocity, produced by the joint action of the two drivers AE and BD, translating the point A of the sheave FG, and the aggregate curve, combined by that sheave so as to act on the follower W, whose motion is the same as that of the centre of FG.

The velocity of the point F is \( a_1 \), upword motion being considered positive. Hence the instantaneous axis of the sheave FG is in the direction FG, the distance

\[
\frac{FG}{2} = AC - BC
\]

and, consequently, the velocity of its centre is

\[
v = a_1 = \frac{FG}{2} = \frac{AC - BC}{2}
\]

or the mean between the velocities of the two vertical parts of the cord.

If the cord be fixed to the framework at the point B, instead of being wound on a barrel, the velocity of W is half that of FG.

A case containing several sheaves is called a block. A full-block is attached to a fixed point; a running-block is movable to and from a full-block, with which it is connected by two or more piles of a rope. The whole composition constitutes a rope or cable winch. (See Pulleys for practical applications of these principles.)

§ 74. Differential Screw.—On the same axis let there be two screws of the respective pitches \( p_1 \) and \( p_2 \), made in one piece, and rotating with the angular velocity \( \omega_1 \). Let this piece be called B. Let the first screw turn in a fixed nut C, and the second in a sliding nut A. The velocity of advance of B relatively to C is (according to § 22)

\[
\omega_1 p_1
\]

and of A relatively to C (according to § 57) \(-\omega_1 p_2\); hence the velocity of A relatively to C is

\[
\omega_1 (p_1 - p_2)
\]

being the same with the velocity of advance of a screw of the pitch \( p_1 - p_2 \). This combination, called a combination screw, combines the strength of a large thread with the looseness of motion due to a small one.

§ 75. Epicyclic Trains.—The term epicyclic train is used by Willis to denote a train of wheels carried by an arm, and having certain rotations relatively to that arm, which itself rotates. The arm may either be driven by the wheels or assist in driving them. The comparative motions of the wheels and of the arm, and the epicyclic paths traced by points in the wheels, are determined by the principles of the composition of rotations, and of the description of rolling curves, explained in §§ 30, 31.

§ 76. Link Motion.—A slide valve operated by a link motion receives an aggregate motion from the mechanism driving it. (See Steam-engine for a description of this and other types of mechanism of this class.)

§ 77. Parallel Motions.—A parallel motion is a combination of turning pieces in mechanism designed to guide the motion of a reciprocating piece either exactly or approximately in a straight line, so as to avoid the friction which arises from the use of straight guides for that purpose.

§ 78. *The Reuleaux System of Analysis.*—If two pieces, A and B, (fig. 118) are jointed together by a pin, the pin being fixed, say, to A, the only relative motion possible between the pieces is one of turning about the axis of the pin. Whatever motion the pair of pieces may have as a whole each separate piece shares in common, and this common motion may be in any way affected the relative motion of A and B. The motion of one piece is said to be completely constrained relatively to the other piece. Again, the pieces A and B (fig. 119) are paired together as a light line by only hinges (London possible) between them now is that of sliding, and therefore the motion of one relatively to the other is completely constrained. The pieces may be paired to P. L. Tchebichev of St Petersburg. The links AB and CD are equal in length and are centred respectively at A and C. The ends of the link BC and CD, if the respective lengths are made in the proportions AC:CD:DB = 1:1:3:9, the middle point P of DB will describe an approximately straight line parallel to AC within limits of length about equal to AC. C. N. Peaucellier, a French engineer officer, first, in 1864, to invent a line mechanism with which an exact straight line could be drawn. The linkwork is shown in fig. 115, from which it will be seen that it consists of a rhombus and four equal half circles, CD, joined at opposite ends of two equal bars BE and DE. The seventh link AF is equal in length to half the distance EA when the mechanism is in its central position. The points E and F are fixed. It can be proved that the point C always moves in a straight line to the line EF. The more general property of the mechanism corresponding to proportions between the lengths FA and EF other than that of equality is that the curve described by the point C is the inverse of the curve described by A. No way affects the relative motion of A and B, straight-line motions, and these arrangements together with the general principles of mechanisms of this kind are discussed in How to Draw a Straight Line, by Professor J. J. Sylvester discovered that this property of the parallellogram is not confined to points lying in one line with the fixed point. Thus if b (fig. 117) be any point on the link CD, and if a point c be taken on the link DE such that the triangles CED and DAE are similar and similarly situated with regard to their respective links, then the ratio of the distances ab and ac is constant, and the angle abc is constant for all positions of the mechanism; so that, if b is guided in any curve, the point c will describe a similar curve turned through an angle abc, the scales of the curves being in the ratio ab : ac. Sylvester called an instrument based on this property a plagiographic or a skew pantograph.

The combination of the parallellogram with a straight-line motion, for guiding one of the points in a straight line, is illustrated in Watt's parallel motion for steam-engines. (See Steam-engine.

§ 80. *The Reuleaux System of Analysis.* —If two pieces, A and B, (fig. 118) are jointed together by a pin, the pin being fixed, say, to A, the only relative motion possible between the pieces is one of turning about the axis of the pin. Whatever motion the pair of pieces may have as a whole each separate piece shares in common, and this common motion may be in any way affected the relative motion of A and B. The motion of one piece is said to be completely constrained relatively to the other piece. Again, the pieces A and B (fig. 119) are paired together as a light line by only hinges (London possible) between them now is that of sliding, and therefore the motion of one relatively to the other is completely constrained. The pieces may be paired
together as a screw and nut, in which case the relative motion is
compounded of turning with sliding.

These combinations of pieces are known individually as kinematic
pairs of elements, or briefly kinematic pairs. The three pairs men-
tioned above have each the peculiarity that contact between the two
pieces forming the pair is distributed over a surface. Kinematic
pairs which have surface contact are classified as lower pairs. Kine-
matic pairs in which contact takes place along a line only are classified
as higher pairs. A pair of spur wheels in gear is an example of a
higher pair, because the wheels have contact between their teeth
along lines only.

A kinematic link of the simplest form is made by joining up the
halves of two kinematic pairs by means of a rigid link AB. This
AB forms a turning pair, and AB a second turning pair, the
rigid link formed by joining B1 to B2 is a kinematic link. Four
links of this kind are shown in fig. 120 joined up to form a closed
kinematic chain.

In order that a kinematic chain may be made the basis of a
mechanism, every point in any link of it must be completely con-
strained with regard to every other link. Thus in fig. 120 the motion
of a point a in the link A1A2 is completely con-
strained with regard to the link B1B2 by the turning
pair A1B1 and it can be proved that the motion of
point a is in turn completely constrained, and there-
fore the four-bar chain, as it is called, can be and is used as the
basis of many mechanisms. Another way of considering the question of
constraint is to imagine any one link of the chain fixed; then, however
the chain be moved, the path of a point, as a, will always
remain the same. In a five-bar chain, if a is a point in a link non-
adjacent to a fixed link, its path is indeterminate. Still another
way of stating the matter is to say that, if an entire chain can be
fixed, any point in the chain must have only one degree of
freedom. In a five-bar chain a point, as a, in a link non-adjacent
to the fixed link has two degrees of freedom and the chain cannot
therefore be used for a mechanism. These principles may be
applied to examine any possible combination of links forming a
kinematic chain in order to test its suitability for use as a
mechanism. Compound chains are formed by the super-position
of two or more simple chains, and in these more complex chains
links will be found carrying three, or even more, halves of kine-
matic pairs. The Joy valve gear mechanism is a good example of
a compound kinematic chain.

A chain built up of three turning pairs and one sliding pair,
and known as the slider crank chain, is shown in fig. 121. It will be seen
that the piece A1 can only slide relative to the piece B1, and
these two pieces have therefore formed a sliding pair. The piece
A1 carries the pin B1, which is one half of the turning
pair A1 B1. The piece A1 together
with the pin B1, therefore form a kinematic link A1 B1. The other
links of the chain are B1 B2, B2 B3, A1 B1. In order to
form a chain into a mechanism it is necessary to fix one link in it. Any
one of the links may be fixed. It follows therefore that there are
as many possible mechanisms as there are links in the chain. For
example, there is a well-known mechanism corresponding to the
fixing of three of the four links of the slider crank chain (fig. 121).
If the link d is fixed the chain at once becomes the mechanism of
the ordinary steam engine; if the link e is fixed the mechanism obtained
is that of the oscillating cylinder steam engine; if the link f is fixed the
mechanism becomes either the Whitworth quick-return motion
or the slot-bar motion, depending upon the proportion between the
lengths of the links c and e. These different mechanisms are called
inversions of the slider crank chain. What was the fixed frame-
work of the mechanism in one case becomes a moving link in an
inversion.

The Reuleaux system, therefore, consists essentially of the analysis
of every mechanism into a kinematic chain, and since each link in
the chain may be the fixed point in one inversion and the moving
mechanisms are found to be merely inversions of the same kinematic
chain. Franz Reuleaux’s Kinematics of Machinery, translated by
Sir A. B. W. Kennedy (London, 1876), is the book in which the sys-
tem is set forth in all its completeness. An earlier work by Reuleaux,
by Sir A. B. W. Kennedy (London, 1886), the system was used
for the first time in an English textbook, and now it has found
its way into most modern textbooks relating to the subject of
mechanics.

§ 81. Centrodes, Instantaneous Centres, Velocity Image, Velocity
Diagram. Problems concerning the relative motion of the several
pairs of elements (kinematic chains) are studied then by means of
the way hitherto used in this article and based on the principle of
§ 34. The first is by the method of instantaneous centres, already
exemplified in § 65, and rolling centroids, developed by Reuleaux
in connexion with his method of analysis.

Method 1.—By reference to fig. 91 it will be seen that the motion
of a cylinder rolling on a fixed cylinder is instantaneous with the
instantaneous axis T, and that the velocity both as regards direction
and magnitude is the same as if the rolling piece B were for the
instant turning about a fixed axis coincident with the instantaneous
axis T. If the cylinder rolls and its path is such that it is to receive a
common plane motion, what was before the velocity of the point
P becomes the velocity of P relatively to the cylinder A, since the
motion of B relatively to A still takes place about the instantaneous axis T. But the rolling cylinder will continue to move as though they were parts of a rigid body. Notice
that the shape of either rolling curve (fig. 91 or 92) may be found by
considering each fixed link in turn and then of the chain about the
instantaneous axis. These rolling cylinders are sometimes called
axodes, and a section of an axode in a plane parallel to the plane
of motion is called a centrodre. The centrodre is therefore the locus
of the instantaneously moving body in any one plane parallel to the
plane of motion. There is no restriction on the shape of these rolling axodes; they may have
any shape consistent with rolling (that is, no slipping is permitted),
and the relative velocity of a point P is still found by considering it
with regard to the instantaneous centre.

Reuleaux has shown that the relative motion of any pair of non-
adjacent links of a kinematic chain is determined by the two
instantaneous centres corresponding to the fixed link, or, considering
a plane of motion only, the locus of the instantaneous centre is
corresponding to the fixed link.

To find the instantaneous centre for a particular link corresponding
to any given configuration of the kinematic chain, it is only necessary
to know the direction of motion of any two points in the link, since
all the other points in the chain are determined by application to their
directions of motion intersect in the instantaneous centre.

To illustrate this principle, consider the four-bar chain shown in
fig. 122 made up of the four links, a, b, c, d. Let a be the fixed link,
and consider the link c. Its extremities are moving respectively in
directions at right angles to the links b and d; hence produce
the straight lines a c and c d so that they meet in the point Oc.
This point is the in-
stantaneous centre of the point a of the link c relatively to the fixed
link a, a fact indicated by the suffix c placed
thereon; this process is being repeated for different values of
the angle θ the curve through the several positions of the
centroid which may be imagined as formed by an extension of the
material of the link a. To find the corresponding centroid for the
link c, fix c and repeat the process. Again, imagine
the fixed link d, then the instantaneous centre of the link d is found by producing the lines c a to intersect in Odb,
and the shapes of the centroids belonging respectively to the
links b and d can be found as before. The axis about which a pair
of adjacent links turn is a permanent axis, and is of course the
axis...
of the pin which forms the point. Adding the centres corresponding to these several axes to the figure, it will be seen that there are six centres in connexion with the four-bar chain of which four are permanent and one is virtual. The position of the permanent centres is fixed; and, further, that whatever be the configuration of the chain these centres group themselves into three sets of three, each set lying on a straight line. This peculiarity is not an accident or a special property of the four-bar chain, but is generally true regarding the subject discovered by Aronhold and Sir A. B. W. Kennedy independently, which may be thus stated: If any three bodies, \(a, b, c\), have planes of virtual contact, and \(O_a, O_b, O_c\), are three points on one straight line. A proof of this will be found in The Mechanics of Machinery quoted above. Having obtained the set of instantaneous centres for a chain, suppose \(c\) is the fixed link of the chain and \(c\) any other link; then \(O_c\) is the instantaneous centre of the two links and may be considered for the instant as the trace of an axis fixed to an extension of the link \(a\) about which \(c\) is turning, and \(O_a\) the instantaneous centre of the two links as solved though the link \(c\) were merely rotating for the instant about a fixed axis coincident with the instantaneous axis.

**Method 2.** The second method is based upon the vector representation of velocity, and may be illustrated by applying it to the four-bar chain. Let \(AD\) (fig. 123) be the fixed link. Consider the link \(BC\), and let it be required to find the velocity of the point \(B\) having given the velocity of the point \(C\). The principle upon which the solution is based is that the only motion which \(B\) can have relative to an axis through \(C\) fixed to the link \(CD\) is one of turning about \(C\), called a virtual motion (figs. 123 and 124). Fig. 124 then represents the velocity of the point \(C\). The direction of this must be at right angles to the line \(CD\), because this is the only direction possible to the point \(C\) if \(AB\) be the fixed link. \(O_c\) will also represent the velocity of the point \(B\); but, if the link is turning, \(B\) can only move about the axis \(C\), and its direction of motion is therefore at right angles to the line \(CB\). Hence set out the possible direction of \(B\)'s motion in the velocity diagram, namely \(Ob\), at right angles to \(CB\). But the point \(B\) must also move at right angles to \(AI\) in the case under consideration. Hence draw a line through \(O\) in the velocity diagram at right angles to \(AB\) to cut \(Ob\) in \(b\). Then \(Ob\) is the velocity of the point \(b\) in magnitude and direction, and is the tangential velocity of \(B\) relatively to \(C\). Moreover, whatever be the actual magnitudes of the velocities, the instantaneous velocity ratio of the points \(C\) and \(b\) is given by the ratio \(O_c:Ob\).

A most important property of the diagram (figs. 123 and 124) is the following: If points \(X\) and \(Y\) are taken dividing the link \(BC\) and the tangential velocity \(Ob\) so that \(cX:Ob=CB:XB\), then \(Ox\) represents the velocity of the point \(X\) in magnitude and direction.

The line \(Ob\) has been called the velocity image of the rod, since it may be looked upon as a scale drawing of the rod turned through 90° from the actual rod. Or, put in another way, if the link \(CB\) is drawn to scale on the new length \(Ob\) in the velocity diagram (fig. 124), then a vector drawn from \(O\) to any point on the new drawing of the rod will represent the velocity of that point of the actual rod in magnitude and direction. It will be understood that there is a new velocity diagram for every new configuration of the mechanism, and that in each new diagram the image of the rod will be different in scale.

Following the method indicated above, the various links of the mechanism have been given a velocity diagram similar to that of fig. 124 for each configuration of the mechanism, a diagram in which the velocity of the several points in the chain utilized for drawing the mechanism is set out in the same magnitude and direction for the instant of drawing it. The lines joining the ends of these several velocities are the several tangential velocities, each being the velocity image of a link in the chain. These several images are not to the same scale, so that although the images may be regarded as forming collectively an image of the chain itself, the several members of this chain-image are to different scales in any one velocity diagram, and thus the chain-image is derived from the actual proportions of the mechanism which it represents.

**§ 82. Acceleration Diagram. Acceleration Image.**—Although it is possible to obtain the acceleration of points in a kinematic chain with one link fixed by methods which utilize the instantaneous centres of the chain, the vector method more readily lends itself to this purpose. It should be understood that the instantaneous centre considered in the preceding paragraphs is available only for estimating relative velocities; it cannot be used in a similar manner for questions regarding acceleration. That is to say, although the instantaneous centre is a centre of no velocity for the instant, it is not a centre of no acceleration, and in fact the centre of no acceleration is a virtual point—this general theorem on which the method of drawing an acceleration diagram depends is that if a link \(CB\) (fig. 125) have plane motion and the acceleration of a point \(c\) be given, the tangential acceleration of any other point \(B\) is the vector sum of the acceleration of the point \(C\), the radial acceleration of the point \(c\), and the tangential acceleration of \(C\) about \(B\). Let \(A\) be any origin, and let \(Ac\) represent the acceleration of the point \(C\), \(\alpha\) the radial acceleration of \(C\), and \(\tau\) the tangential acceleration of \(C\) about \(B\), which must be in a direction parallel to \(CB\), and \(\beta\) the tangential acceleration of \(B\). Then, that is the vector sum of these three magnitudes is \(Ab\), and this vector represents the acceleration of the point \(B\). The directions of the radial and tangential accelerations of the point \(B\) are always known when the position of the link is assigned, since these are to be drawn respectively parallel to and at right angles to the link itself.

The magnitude of the radial acceleration is given by the expression \(\mathbf{v}/\mathbf{CB}\), \(v\) being the velocity of the point \(B\) about the point \(C\). This velocity can always be found from the velocity diagram of the chain or of the link forming the particular part. \(\alpha d\theta/dt\) is the angular acceleration of the link, \(\alpha d\theta/dt\times\mathbf{CB}\) is the tangential acceleration of the point \(B\) about the point \(C\). Generally this tangential acceleration is unknown in magnitude, and it becomes part of the problem to find it. An important point in the vector method is that it points \(X\) and \(Y\) are taken dividing the link \(CB\) and the whole acceleration of \(B\) about \(C\), namely, \(\beta\), in the same ratio, then \(\alpha x\) represents the acceleration of the point \(X\) in magnitude and direction; \(\beta\) is called the acceleration image of the rod. In applying this principle to the drawing of an acceleration diagram for a mechanism, the velocity diagram of the mechanism must be first drawn in order to afford the means of obtaining the several tangential accelerations of the links in question. Then assuming that the acceleration of one point of a particular link of the mechanism is known together with the corresponding configuration of the mechanism, \(\alpha x\) and \(\beta\) can be obtained.

The direction of \(\mathbf{b}\), the third vector in the diagram, is also known, so that the problem is reduced to the condition that \(b\) is somewhere on the line \(\mathbf{b}\). Then other conditions consequent upon the fact that the link forms part of a mechanism to operate enable \(b\) to be fixed. These methods are set forth and exemplified in the book, Graphical Dynamics, by R. H. Smith (London, 1889). Examples, completely worked out, of velocity and acceleration diagrams for the slider crank chain, the four-bar chain, and the mechanism of the Joy valve gear will be found in ch. ix. of Valves and Valve Gear Mechanism, by W. E. Dalby (London, 1906).

**Chapter II. On Applied Dynamics**

**§ 83. Laws of Motion.—**The action of a machine in transmitting force and motion simultaneously, or performing work, is governed, in common with the phenomena of moving bodies in general, by two "laws of motion."

**Division 1. Balanced Forces in Machines of Uniform Velocity.**

**§ 84. Application of Force to Mechanism.—**Forces are applied in units of weight; and the unit most commonly employed in Britain is the pound avoirdupois. The action of a force applied to a body is always in reality distributed over some definite space, either a volume of three dimensions or a surface of two. An example of a force distributed throughout a volume is the weight of the body itself, which acts on every particle, however small. The pressure exerted between two bodies at their surface of contact, or between the bodies and the surface of an ideal body contained in a vessel, is an example of a force distributed over a surface. The mode of distribution of a force applied to a solid body requires to be considered, and its stiffness, or its "springiness," may be considered as the acting upon a rigid body considered as a whole, the resultant of the distributed force, determined according to the principles of statics, and considered as acting in a single direction applied at a point, may be considered as the acting upon a rigid body, or the "static" of pressure of the surface to which the pressure is really applied.

**§ 85. Forces Applied to Mechanism Classified.—**If \(\mathbf{F}\) be the obliquity of the force \(\mathbf{F}\) applied to a mechanism—that is, the angle made by the direction of the force with the direction of motion of its point of application—then by the principles of statics, \(\mathbf{F}\) may be resolved into two rectangular components, viz.:

- Along the direction of motion, \(\mathbf{P}=\mathbf{F}\cos \theta\)
- Across the direction of motion, \(\mathbf{Q}=\mathbf{F}\sin \theta\)
If the component along the direction of motion acts with the motion, it is called an effort; if against the motion, a resistance. The component across the direction of motion is a lateral pressure; the unbalanced lateral pressure on any piece, or part of a piece, is defined by multiplying its area by the velocity; the resultant, causing friction; the friction so caused acts against the motion, and is a resistance, but the lateral pressure causing it is not a resistance. Resistances are distinguished into useful and prejudicial, according as they arise from the useful effect produced by the machine or from other causes.

§ 86. Work.—Work consists in moving against resistance. The work done against resistance is performed, and work is measured by the product of the resistance into the distance through which its point of application is moved. The unit of work commonly used in Britain is a resistance of one pound overcome through a distance of one foot called the foot-pound, and the unit of work, as thus there are obtained the components P cos \( \theta \) and \( R \cos \phi \). Let the mechanism have a small motion; then, for the instant, the link \( b \) is turning about its instantaneous centre \( O_{db} \), and therefore, \( P \cos \theta X \omega = R \cos \phi X \omega \). Hence, the direction of the instantaneous angular velocity of the point \( y \) is the same as the direction of the point \( q \).

The general problem may then be thus stated: Given a mechanism of which \( r \) is the fixed link, and \( s \) and \( t \) any other two links, given also a method of applying \( f \), so as to find the force \( f \), acting in a given direction on the link \( t \), which will keep the mechanism in static equilibrium.

Another general solution of the problem is given in the Proc. Lond. Math. Soc. (1875-1879), by the same author. An example of the method of solution stated above, and taken from the Mechanics of Machinery, is illustrated by the mechanism fig. 127, which is an epicyclic train of three wheels with the first wheel \( v \) fixed. Let it be required to find the vertical force which must act at the pitch radius of the last wheel \( t \), in such a manner that \( f \), acting as a force, will keeping the mechanism in equilibrium, be a point of which the last wheel \( t \) is the arm, and the wheel \( s \) being the fixed link of the mechanism.

The virtual centres \( O_s, O_t \) are at the respective axes of the wheels and \( f \), and the centre \( d \), divides the line through these two points externally in the ratio of the train of wheels. The figure sufficiently indicates the various steps of the solution.

The relation between the effort and the resistance in a machine to include the effect of friction at the joints has been investigated in a paper by Professor Fleeming Jenkin, "On the application of graphic methods to the determination of the efficiency of machinery."
(Trans. Roy. Soc. Ed., vol. 28). It is shown that a machine may at any instant be represented by a frame of links the stresses in which are identical with the stresses at the joints of the mechanism. The driving and resisting forces are represented by elastic links in the dynamic frame, and when the frame with its elastic links is drawn the stresses in the several members of it may be determined by the new method. Incidentally the method gives the pressures at every joint of the mechanism.

§ 91. Efficiency.—The efficiency of a machine is the ratio of the useful work to the total work—that is, to the energy exerted—and is represented by

$$\eta = \frac{\sum \text{units of work done}}{\sum \text{units of work put in}}.$$ 

(53)

ρ being taken to represent useful and μ prejudicial resistances. The more nearly the efficiency of a machine approaches to unity the better is the machine.

§ 92. Power and Effect.—The power of a machine is the energy exerted, and the effect the useful work performed, in some interval of time of definite length, such as a second, an hour, or a day.

The unit of power, called conventionally a horse-power, is 550 foot-pounds per second, or 33,000 foot-pounds per minute, or 1,080,000 foot-pounds per hour.

§ 93. Modulus of a Machine.—In the investigation of the properties of a mechanism it is convenient to determine the resistances to be overcome and the useful work to be performed are usually given. The prejudicial resistances are generally functions of the useful resistances of the machine, of the materials, and of the arrangement; and, having been determined, they serve for the determination of the lost work, which, being added to the useful work, gives the expenditure of energy required. The result of this investigation, expressed in the form of an equation of which this energy or useful work, is called by Moseley the modulus of the machine. The general form of the modulus may be expressed thus

$$E = U + \phi(U, A) + \phi(A),$$

(54)

where A denotes some quantity or set of quantities depending on the form, arrangement, and weight of the mechanism. Moseley, however, has pointed out that in this case the equation takes the much more simple form of

$$E = (1 + A)U + B,$$

(55)

where A and B are constants, depending on the form, arrangement, and weight of the mechanism. The efficiency corresponding to the last equation is

$$\eta = \frac{1}{U + A + B/U}.$$ 

(56)

§ 94. Trains of Mechanism.—In applying the preceding principles to a train of mechanism, it may either be treated as a whole, or it may be considered in sections consisting of single pieces, or of any convenient portion of the train—each section being treated as a machine driven by the effort applied to it and energy exerted upon it through its line of connexion with the preceding section, permitting the use of the preceding section of the train as a work by overcoming its own prejudicial resistances. It is evident that the efficiency of the whole train is the product of the efficiencies of its parts.

§ 95. Rotating Pieces: Couples of Forces.—It is often convenient to express the energy exerted upon the work performed by a turning piece in a machine in terms of the moment of the couples of forces acting on it and of the angular velocity. The ordinary British unit of moment is a foot-pound; but it is to be remembered that this is a foot-pound of a different sort from the unit of energy and work.

If a force be applied to a turning piece in a line not passing through its axis, the axis will press against its bearings with an equal and parallel force, and the equal and opposite reaction of the bearings will constitute, together with the first-mentioned force, a couple whose arm is the perpendicular distance from the axis to the line of action of the first force.

A couple is said to be right or left handed with reference to the observer, according to the direction in which it tends to turn the body, and is a driving couple or a resisting couple according as its tendency is with or against that of the actual rotation.

In the following time dτ the tangential velocity of the piece; then \(\alpha = v\) is the angle through which it turns in the interval dτ, and

$$d\alpha = v dt = r \dot{\theta} dt = r d\theta$$

is the distance through which the point of application of the force moves. Let \(P\) represent an effort, so that \(P\) is a driving couple, then

$$P ds = P d\alpha = P r d\theta = M d\alpha$$

is the energy exerted by the couple M in the interval dα; and a similar equation gives the work performed in overcoming a resisting couple. Hence, if \(M\) be the couple, the moment of the piece, \(P\) the moment of the effort, and \(P\) the moment of the resistance, they are multiplied by the common angular velocity of the whole piece.

§ 96. Reduction of Forces to a Given Point, and of Couples to the Axis of a Given Piece.—In computations regarding machines it is often convenient to substitute for a force applied to a given point, or a couple applied to a given piece, the equivalent force or couple applied to some other point or piece; that is to say, the force or couple, which, if applied to the other point or piece, would exert equal energy or employ equal work. The principle of this reduction are that the ratio of the given to the equivalent force is the reciprocal of the ratio of the distance of the point of the couple to the point of the force of couple, and the ratio of the given to the equivalent couple is the reciprocal of the ratio of the angular velocities of the pieces to which they are applied.

These velocity ratios are known by the construction of the relevant forces and couples, and are given by

$$R = \frac{\text{speed of point}}{\text{speed of couple}}$$

and

$$R = \frac{\text{angular speed of point}}{\text{angular speed of couple}}.$$ 

$\eta 97. Balanced Lateral Pressure of Guides and Bearings.—The most important part of the lateral pressure on a piece of mechanism is the reaction of its guides, if it is a sliding piece, or of the bearings of its shafts, if it is a revolving piece; and the normal portion of this reaction is equal and opposite to the resultant of all the other forces applied to the piece, its own weight included. There may be or may be more than one angle which may be considered in this process due to the deviated motion. Its laws will be considered in the sequel.

§ 98. Friction. Unguents.—The most important kind of resistance in machines is the friction or rubbing resistance of surfaces which slide over each other. The direction of the resistance of friction is opposite to that in which the sliding takes place. Its magnitude is the product of the normal pressure or force which presses the rubbing surfaces, either in a direction perpendicular to themselves to a specific constant already mentioned in § 14, as the coefficient of friction, which depends on the nature and condition of the surfaces of the unguent, if any, with which they are covered. The total frictional resistance of the friction surfaces, or the friction of the piece, is the resultant of the friction of the bearings of the shafts of the piece, and of the friction of the guides. Thus the total friction of the piece, together with the friction of its bearings and guides, is the product of the normal pressure, the friction coefficient of the piece, and the angle of repose; or,

$$R = \tan \phi \tag{58}$$

Experiments on friction have been made by Coulomb, Samuel Vinc, John Rennie, James Wood, D. Rankine and others. The most complete and elaborate experiments are those of Roy. Moseley, published in the British Journal of Mechanics and Mathematics, and republished in the works of Moseley and Gordon.

The experiments of Beauchamp Tower ("Report of Friction Experiments," Proc. Inst. Mech. Eng., 1881) showed that the frictional resistance is supplied to a journal by means of oil and that the coefficient of friction varies nearly inversely as the load on the bearing, thus making the product of the load on the bearing and the coefficient of friction constant, or constant within experimental error, when the load is a nearly constant temperature. The more recent experiments of Lasche (Zeitsch. Verein. Deutsche Ingen., 1902, 46, 1881) show that the coefficient of friction of a bearing varies with the condition of the surface and the temperature of the oil, and that the temperature of the oil is approximately constant. For further reference see this on this point and on Osborne Reynolds' theory of lubrication see BEARINGS and LUBRICATION.

§ 99. Work of Friction: Moment of Friction.—The work performed in a unit of time in overcoming the friction of a pair of surfaces is the product of the friction by the velocity of sliding of the surfaces over each other, if that is the same throughout the whole extent of the sliding surfaces. When the friction is due to the relative motion of the rubbing surfaces, the velocity of each portion is to be multiplied by the friction of that portion, and the results summed or integrated. When the relative motion of the rubbing surfaces is one of rotation, the work of friction in a unit of time, for a portion of the rubbing surfaces at a given distance from the axis of rotation, may be found by multiplying together the friction of that portion, its distance from the axis, and the angular velocity. The product of the force of friction by the distance at which it acts from the axis of rotation is called the moment of friction. The total moment of friction of a pair of rotating rubbing surfaces is the sum or integral of the moments of friction of their several portions.

To express this symbolically, let \(a\) represent the area of a portion of a rubbing surface at a given distance from the axis of rotation; \(\lambda\) the intensity of the friction; \(\rho\) the intensity of the normal pressure at \(a\) per unit area; and \(f\) the coefficient of friction. Then the moment of friction of \(a\) is

$$f \lambda \rho a$$

and the work performed in a unit of time in overcoming friction, when the angular velocity is \(a\), is

$$f \lambda \rho \frac{da}{dt}$$

It is evident that the friction and the work lost by being performed in overcoming friction, are less in a rotating piece as the angular velocity increases; and this is the reasoning which led to the diminution of the radii of journals and pivots by the conditions of durability and of proper lubrication, and also by conditions of speed of rotation.

§ 100. Total Pressure between Journal and Bearing.—A single piece rotating with a uniform velocity has four mutually balanced forces applied to it: (1) the effort exerted on it by the piece which resists the force; (2) the force which resists the effort which may be considered for the purposes of the present question as useful resistance; (3) its weight; and (4) the reaction of its own cylindrical bearings. There are given the following data—
The direction of the effort.

The weight of the piece of resistance.

The magnitude of the useful resistance.

The angle of the force, corresponding to the friction of the journal on the bearing.

And there are required the following:

The direction of the friction of the bearing.

The magnitude of that reaction.

The magnitude of the effort.

Let the useful resistance, the weight and the weight of the piece be compounded by the principles of Statics into one force, and let this be called the given force.

The directions of the effort and of the given force are either parallel or perpendicular. If they are parallel, the direction of the reaction of the bearing is also parallel to them; if they meet in a point, the direction of the reaction traverses the same point. Also, let AAA, fig. 128, be a section of the bearing, and C its axis; then the direction of the reaction, at the point where it intersects the circle AAA, must make the angle \( \phi \) with the radius of that circle; that is to say, it must be a line such as PT touching the smaller circle BB, whose radius is \( r \), or \( \sin \phi \) the side on which it touches that circle is determined by the fact that the obliquity of the reaction is such as to oppose the rotation.

Thus is determined the direction of the reaction of the bearing; and the magnitude of that reaction and of the effort are then found by the principles of the equilibrium of three forces already stated in § 7.

The work lost in overcoming the friction of the bearing is the same as that which would be performed in overcoming at the circumference of the small circle BB a resistance equal to the whole pressure between the journal and bearing.

In order to diminish that pressure to the smallest possible amount, the effort, and the resultant of the useful resistance, and the weight of the piece (called above the ‘given force’) ought to be opposed to each other as directly as is practicable consistently with the purposes of the machine.

An investigation of the forces acting on a bearing and journal lubricated by oil will be found in a paper by Osborn Reynolds in the Phil. Trans., pt. 1. (1866). See also BEARINGS.

§ 101. Friction of Pins and Collars.—When a shaft is acted upon by a force tending to shift it lengthways, that force must be balanced by the reaction of a bearing against a pin at the end of the shaft; or, if that be impossible, against one or more collars, or rings projecting from the body of the shaft. The bearing of the pin is called a step or footstep. Pins require great hardness, and are usually made of steel. The flat pivot is a cylinder of steel having a plane circular end as a rubbing surface. Let N be the total pressure sustained by a flat pivot of the radius \( r \); if that pressure be uniformly distributed, which is the case where the rubbing surface of the pivot and its step are both plane plates, the intensity of the pressure is

\[
p = \frac{N}{\pi r^2};
\]

and, introducing this value into equation 59, the moment of friction of the flat pivot is found to be

\[
\frac{N}{\pi r^2} r^3 = \frac{N}{\pi} r^3
\]

or two-thirds of that of a cylindrical journal of the same radius under the same normal pressure.

The friction of a conical pivot exceeds that of a flat pivot of the same radius, and under the same pressure, in the proportion of the side of the cone to the side of the flat pivot.

The moment of friction of a collar is given by the formula

\[
\frac{N}{\pi} r^3 \frac{(r')^2 - r^2}{r'}
\]

where \( r \) is the external and \( r' \) the internal radius.

In the case of a flat pivot the end of the shaft and the step present two recesses facing each other, into which are fitted two shallow cups of steel or hard bronze. Between the concave spherical surfaces of those cups is placed a steel ball, being either a complete sphere or a lens having convex surfaces of a somewhat less radius than the convexive surfaces of the cups. The moment of friction of this pivot is at first almost inappreciable from the extreme smallness of the radius of the circles of contact of the ball and cups, but, as they wear, that radius and the moment of friction increase.

It appears that the rapidity with which a rubbing surface wears away is proportional to the friction and to the velocity; to wear so.

Hence the pivots already mentioned wear unequally at different points, and tend to alter their figures. Schiefe has invented a pivot which preserves its original figure by wearing equally at all points in a direction parallel to its axis. The following are the principles on which this equality of wear depends—

The rapidity of wear of a surface measured in an oblique direction is to the rapidity of wear measured normally as the secant of the obliquity is to unity. Let P be the axis of a pivot, and let RPC be a portion of a curve such that at any point \( P \) the secant of the obliquity to the normal of the curve of a line parallel to the axis is inversely proportional to the ordinate \( y \), to which the velocity of \( P \) is proportional. The rotation of that curve round \( P \) will generate the form of pivot required. Now let \( PT \) be tangent to the curve at \( P \), cutting \( OX \) in \( T \); then, \( PT = PY \times \text{secant obliquity} \).

This curve is described by having a fixed straight edge parallel to \( OX \), along which slides a slider carrying a pin whose centre is \( T \). On that pin turns an arm, carrying at a point \( P \) a tracing-point, pencil or pen. Should the pen have a nib of two jaws, like those of an ordinary drawing-pen, the plane of the jaws must pass through \( PT \). Then, while \( T \) is slid along the axis from \( O \) towards \( X \), \( P \) will be drawn after it from \( R \) towards \( L \) along the trajectory. This curve, being an asymptote to its axis, is capable of being indefinitely prolonged towards \( X \); but in designing pivots it should stop before the angle \( PTV \) becomes less than the angle of repose of the rubbing surfaces, otherwise the pivot will be liable to stick in its bearing. The moment of friction of "Schiefe's anti-friction pivot," as it is called, is equal to that of a cylindrical journal of the radius \( OR = PT \) the constant tangent, under the same pressure.

Records of experiments on the friction of a pivot bearing will be found in the Proc. Inst. Mech. Eng. (1891), and on the friction of a collar bearing ib. May 1888.}

\[
f_N = \frac{N}{\pi} r^3
\]

is the work lost in unity of time by friction of the teeth. The sliding \( s \) is composed of two parts, which take place during the approach and recess respectively. Let those be denoted by \( s_a \) and \( s_r \), so that \( s = s_a + s_r \). In § 45 the velocity of sliding at any instant has been given, viz. \( w = \varepsilon (a_1 + a_2) \), where \( \varepsilon \) is the velocity, \( c \) the distance between the point of contact of the teeth to the pitch-point, and \( a_1 \), \( a_2 \) the respective angular velocities of the wheels.

Let \( \theta \) be the common velocity of the two pitch-circles, \( r_1 \), \( r_2 \), their radii; then the above equation becomes

\[
u = r_1 \frac{1}{r_1} \frac{1}{r_2}
\]

To apply this to involute teeth, let \( \alpha_1 \) be the length of the approach, \( \alpha_2 \) that of the recess, \( s_a \), the mean velocity of sliding during the approach, \( s_a \) that during the recess; then

\[
u_a = \frac{c_2}{2} \frac{(1 + \frac{1}{r_1})}{r_1} \quad \text{and} \quad \nu_r = \frac{c_2}{2} \frac{(1 + \frac{1}{r_2})}{r_2}
\]

also, let \( \theta \) be the obliquity of the action; then the times occupied by the approach and recess are respectively

\[
\frac{1}{s_a} \quad \frac{1}{\cos \theta} \quad \frac{1}{s_r} \quad \frac{1}{\cos \theta}
\]

giving, finally, for the length of sliding between each pair of teeth,

\[
\frac{1}{s_a} = \frac{1}{s_r} = \frac{1}{\cos \theta}
\]

which, substituted in equation (63), gives the work lost in a unit of time by the friction of involute teeth. This result, which is exact for involute teeth, is approximately true for teeth of any figure.

For inside gearing, if \( r_1 \) be the lesser radius and \( r_2 \) the greater,

\[
\frac{1}{s_1} = \frac{1}{s_2} = \frac{1}{\cos \theta}
\]

Also, let \( T \) be the tension of the free part of the band at that side towards which it tends to draw the pulley, or from which the pulley tends to be drawn, and \( s_1 \), \( s_2 \) the tangential force between the band and the pulley; \( \theta \) the ratio of the length of that arc to the radius of the pulley; \( \phi \) the ratio of an indefinitely small element \( ds \) of arc to the radius; \( f \) the coefficient of friction between the materials of the band and pulley.

Then, according to a well-known principle in statics, the normal pressure at the elementary arc \( d \theta \) is \( \frac{\phi f}{T} d \theta \), being the mean tension of the band at that elementary arc; consequently the friction on that arc is \( dF = \phi f \frac{d \theta}{T} \). Now that friction is also the difference
between the tensions of the band at the two ends of the elementary arc, or \( dT = -\frac{dF}{r} \); which equation, being integrated throughout the entire arc of contact, gives the following formula:—

\[
\text{hyp log. } \frac{T}{T_0} = \beta
\]

\[
T = T_0 \left(1 - e^{-\beta}\right) = T_0 \left(1 - e^{-\frac{d}{2}}\right)
\]

When a belt connecting a pair of pulleys has the tensions of its two ends equal, the belt is in a state of rest; and when the pulleys are next set in motion, so that one of them drives the other by means of the belt, it is found that the advancing side of the belt is exactly as much tightened as the returning side is slackened, so that the tension remains unchanged. Its value is given by this formula:

\[
T_1 + T_2 = e^{\beta} - 1
\]

which is useful in determining the original tension required to enable a belt to transmit a given force between two pulleys.

The equations 65 and 66 are applicable to a kind of brake called a friction-strap, used to stop or moderate the velocity of machines by being tightly rounded a pulley. The strap is usually of iron, and the pulley of hard wood.

Let a denote the arc of contact expressed in turns and fractions of a turn; then

\[
\theta = \frac{\pi \times 2.532a}{2} \]

where \( a \) is the number whose common logarithm is \( 2.288a \).

See also DYNAMOMETER for illustrations of the use of what are essentially friction-strap devices for the measurement of the brake horse-power of an engine or motor.

§ 101. Stiffness of Ropes.—Ropes offer a resistance to being bent, and when bent, to being straightened again, which arises from the mutual friction of the fibres. It increases with the sectional area of the rope, and is inversely proportional to the radius of the curve into which it is bent.

The work lost in pulling a given length of rope over a pulley is found by multiplying the length of the rope in feet by its stiffness in pounds, that stiffness being the excess of the tension at the leading edge of a rib of rope, or the excess of that force which is necessary to bend it into a curve fitting the pulley, and then to straighten it again.

The following empirical formulae for the stiffness of hempen ropes have been deduced by Morin from the experiments of Coulomb:

Let \( F \) be the stiffness in pounds avoirdupois; \( d \) the diameter of the rope in inches; \( n = \frac{462}{d} \) for white ropes and \( \frac{350}{d} \) for tarred ropes; \( r \) the effective radius of the pulley in inches; \( T \) the tension in pounds. Then

For white ropes, \( F = \frac{7}{r} \left(0.00112 + 0.000126n + 0.001T\right) \)

For tarred ropes, \( F = \frac{7}{r} \left(0.006 + 0.001392n + 0.00168T\right) \)

§ 105. Friction-Couplings.—Friction is useful as a means of communicating motion when sudden changes either of force or velocity take place, because, being limited in amount, it may be so adjusted as to limit the speed at which the pieces of the mechanism within the bounds of safety. Amongst contrivances for effecting this object are friction-cones. A rotating shaft carries upon a cylindrical portion of its figure a wedge or pulley turning loosely on it, and consequently capable of remaining at rest when the shaft is in motion. This pulley has fixed to one side, and concentric with it, a short frustum of a hollow cone. At a small distance from the pulley the shaft carries a short frustum of a solid cone accurately turned to fit the hollow cone. This frustum is made always to turn along with the shaft by being fitted on a square portion of it, or by means of a rib or screw, or otherwise, but is capable of a slight longitudinal motion, so as to be pressed into, or withdrawn from, the hollow cone by means of a lever. When the cones are pressed together or engaged, their friction causes the pulley to rotate along with the shaft; and if they are disengaged, they remain free to stand still. The angle made by the sides of the cones with the axis should not be less than the angle of repose. In the friction-clutch, a pulley looped on the shaft has a hoop or gland made to embrace it more or less tightly by means of a screw; this hoop has short projecting arms or ears. A fork or clutch rotates along with the shaft, and is capable of being moved longitudinally by a handle. When the clutch is moved, the arms of its arched ribbon catch those of the hoop, and cause the hoop to rotate and to communicate its rotation to the pulley by friction. There are many other contrivances of the same class, but the two just mentioned may serve for examples.

§ 106. Friction-Belt: The Work Lost in Friction is Employed in Producing Heat. This fact is very obvious, and has been known from a remote period; but the exact determination of the proportion of the work lost to that which is produced, and the experimental proof that that proportion is the same under all circumstances and with all materials, solid, liquid and gaseous, are comparatively recent achievements of J. P. Joule. The quantity of work which produces a British unit of heat (for so much heat as elevates the temperature of one pound of pure water, at or near ordinary atmospheric temperatures, by 1° F.) is 772 foot-pounds. This constant, now designated as "Joule's equivalent," is the principal experimental result of the science of friction.

A more recent determination (Phil. Trans., 1897), by Osborne Reynolds and W. M. Moorby, gives 778 as the mean value of Joule's constant, determined through the range of force, 2,900 to 270 lbs. of Rowland in the Proc. Amer. Acad. (1879), and Griffiths, Phil. Trans. (1893).

The heat produced by friction, when moderate in amount, is useful in many directions, for example in the heating of the bearing surface of a cog wheel. But when excessive, it is prejudicial, by decomposing the unguents, and sometimes even by softening the metal of the bearings, and raising their temperature so high as to set fire to neighboring combustible matters. The mechanical heating of machines is constant and copious supply of a good unguent. The elevation of temperature produced by the friction of a journal is sometimes used as an experimental test of the quality of unguents. For modern methods of forced lubrication see BEARINGS.

§ 107. Rolling Resistance.—By the rolling of two surfaces over each other without sliding a resistance is caused which is called sometimes "rolling friction," but more correctly rolling resistance. It is of the nature of a couple, resisting rotation. Its moment is found by multiplying the normal pressure between the rolling surfaces by the friction loss at the contact and the radius of the rolling surfaces, and the work lost in a unit of time in overcoming it is the product of its moment by the angular velocity of the rolling surfaces relatively to each other. The following are approximate values of the moment in decimals of a foot-

- Oak upon oak: 0.006 (Coulomb).
- Lignum vitae on oak: 0.004.
- Cast iron on cast iron: 0.002 (Tredgold).

§ 108. Reciprocating Forces: Stored and Restored Energy.—When a force acts on a machine alternately as an effort and as a resistance, it may be called a reciprocating force. Of this kind is the weight of any piece in the mechanism whose centre of gravity alternately rises and falls; for during the rise of the centre of gravity that weight acts as a resistance, and energy is employed in lifting it to an amount expressed by the product of the weight into the vertical height of its rise; and during the fall of the centre of gravity the weight acts as an effort, and exerts in assisting to perform the work of the machine an amount of energy which may not have previously been employed in lifting it. Thus that amount of energy is not lost, but has its operation deferred; and it is said to be stored when the weight is lifted, and restored when it falls.

In a machine of which each piece is to move with a uniform velocity, if the effort and the resistance be constant, the weight of each piece must be balanced on its axis, so that it may produce lateral pressure only, and not act as a reciprocating force. But if the forces be reciprocating, then gravity may be used as a compensating force for storing and restoring energy—for example, the elasticity of a spring or of a mass of air.

One of the inventions of machines commonly called "perpetual motions," of which so many are patented each year, and which are expected by their inventors to perform work without receiving energy, the fundamental fallacy consists in an expectation that some reciprocating force shall restore more energy than it has been the means of storing.

Division 2. Deflecting Forces.

§ 109. Deflecting Force for Translation in a Curved Path.—In machinery, a deflecting force is supplied by the tenacity of some piece, such as a crank, which guides the deflected body in its curved path, and which is under the same principle employed in producing deflexion, and not in balancing another force.

§ 110. Centrifugal Force of a Rotating Body.—The centrifugal force exerted by a rotating body on its axis of rotation is the same in magnitude as if the mass of the body were concentrated at its central point of gravity, and acts in a plane passing through the axis of rotation and the centre of gravity of the body.

Those forces of a revolving body exert centrifugal forces on each other, which strain the body, and tend to tear it asunder, but these forces balance each other, and do not affect the resultant centrifugal force exerted on the axis of rotation.

§ 111. The Axis of Centrifugal Force: The axis of the centre of gravity of the body, the centrifugal force exerted on that axis is nothing. Hence, unless there be some reason to the contrary, each piece of a machine should be balanced on its axis of rotation; otherwise the
centrifugal force will cause strains, vibration and increased friction, and a tendency of the shafts to jump their bearings.

§ 111. Centrifugal Couples of a Rotating Body.—Besides the tendency (if any) of the combined centrifugal forces of the particles of a rotating body to shift the axis of rotation, they may combined produce a force, the line of action of which is the axis, and the direction and tendency is called a centrifugal couple, and vanishes for rotation about a principal axis. It is essential to the steady motion of every rapidly rotating piece in a machine that its axis of rotation might not merely travel in its centre of gravity, but should be a permanent axis; for otherwise the centrifugal couples will increase friction, produce oscillation of the shaft and tend to make it leave its bearings.

The principles of this action are those which regulate the adjustment of the weight and position of the counterpoises which are placed between the spokes of the driving-wheels of locomotive engines.

§ 112. Method of computing the position and magnitudes of weights which must be added to a given system of arbitrarily chosen rotating masses in order to make the common axis of rotation a permanent axis. —Let the weight (fig. 130), attached to a truly round disk, be rotated by the shaft $O X$.

(From Balancing of Engines, by permission of Edward Arnold.)

FIG. 130.

We must conceive that the shaft is held in a bearing at one point, $O$. The force required to constrain the weight to move in a plane $O Y$, tending to jump out of the plane of the mass centre of the weight, and $a$ is its angular velocity in radians per second. By substituting the value of $O$, it is equivalent to, (1) a force at $O$ equal and parallel to $F$, and (2) a centrifugal couple of $F$ about $O$.

In order that $OX$ may be a permanent axis it is necessary that there should be a sufficient number of weights attached to the shaft and so distributed that when each is referred to the point $O$

$$\begin{align*}
(1) \quad & W_1 + W_2 + W_3 + \ldots + W_n = 0 \\
(2) \quad & F = \frac{\alpha}{g}
\end{align*}$$

The plane through $O$ to which the shaft is perpendicular is called the reference plane, because all the transferred forces act in that plane at the point $O$. The square of the radius of the weight containing the axis $O X$ is called the axial plane because it contains the forces.
supported on two bearings to carry a disk of weight W at its centre, and let the centre of gravity of the disk be at a distance e from the axis of rotation, this small distance being due to imperfections of material or faults in construction. Neglecting the mass of the shaft itself, when the shaft rotates with angular velocity ω its centrifugal force 3We/g will act upon the shaft and cause its axis to deflect from the axis of rotation a distance, y say. The elastic resistance of the shaft is in proportion to the deflection y, and the deflection e is a constant depending upon the form, material and method of support of the shaft, the following equality must hold if the shaft is to rotate stably at the stated speed—

\[ N = (y + e)w = ec, \]

from which \( y = \frac{We}{gc} \).

This expression shows that as \( a \) increases \( y \) increases until when \( w = gc \), \( y \) becomes infinite, in this case the corresponding value of \( a \), namely \( \sqrt{gc/w} \), is called the critical velocity of the shaft, and is the speed at which the shaft ceases to rotate stably and at which centripetal or centrifugal whirl begins. The general problem is to find the value of \( a \) corresponding to all kinds of loadings on shafts supported in any manner. The question was investigated by Rankine in an article in the Engineer (April 9, 1869). Professor A. G. Greenhill treated the problem of the critical velocity of an unloaded shaft with different supporting conditions in a paper entitled "On the Shifting exposed both to torsion and to thrust," Proc. Inst. Mech. Eng. (1868). Professor S. Dunkerley ("On the Whirling and Transverse Vibrations of Rotating Shafts," Proc. Phys. Soc. Lon., vol. 19 (1904); also Phil. Mag., vol. 7 (1904),) the question is investigated from a new mathematical point of view, and expressions for the whirling of loaded shafts are obtained without the necessity of any assumption of the kind stated above. An elementary presentation of the problem from a practical point of view will be found in Steam Turbines, by Dr. A. Stodola (London, 1905).

§ 114. Revolving Pendulum, Governors.—In fig. 131 AO represents an upright axis or spindle; B a weight called a bob, suspended by rod OB from a horizontal axis at O, carried by the vertical axis. When the spindle is at rest the bob hangs close to it; when the spindle rotates, the bob, being made to revolve round it, diverges from the resultant of the centrifugal force and the weight of the bob being a force acting at O in the direction OB, and then it revolves steadily in a circle. This combination is called a revolving centrifugal, or conical pendulum. Revolving pendulums are usually constructed with parallel rods and bobs, as OB, hung at some distance from the spindle, so the centrifugal forces exerted at the point O may balance each other.

In finding the position in which the bob will revolve with a given angular velocity \( \omega \), for most practical cases connected with machinery the mass of the rod may be considered as insensible compared with that of the bob. Let the bob be a sphere, and from the centre of that sphere draw a straight line perpendicular to OA. Let OH = \( z \); let \( W \) be the weight of the bob, F its centrifugal force. The condition of its steady rotation is \( W : F = z : \omega^2 \); that is to say, \( \omega^2 = \frac{w}{z} \); consequently

\[ z = \frac{w}{\omega^2}. \]

Or, if \( n \omega^2 = 2\pi \) be the number of turns or fractions of a turn in a second,

\[ z = \frac{4\pi^2}{n^2} = \frac{6155}{n^2}. \]

\[ \omega = 9.7777 \text{ in. sec.} \]

\[ z \] is called the altitude of the pendulum.

If the rod of a revolving pendulum be jointed, as in fig. 132, not to a point in the vertical axis, but to the end of a projecting arm AC, the position in which the bob will revolve will be the same as if the rod were jointed to the centre O, where its prolongation cuts the vertical axis.

A revolving pendulum is an essential part of most of the contrivances called governors, for regulating the speed of a machine, and for further particulars of which see steam engine.

Division 3. Working of Machines of Varying Velocity.

§ 115. General Principles.—In order that the velocity of every piece of a machine may be uniform, it is necessary that the forces acting on each piece should be always exactly balanced. Also, in order that the forces acting on every piece of a machine may be always exactly balanced, it is necessary that the velocity of that piece should be uniform.

An excess of the effort exerted on any piece, above that which is necessary to balance the resistance, is accompanied with acceleration; a deficiency of the effort, with retardation.

When a machine is being started from a state of rest, and brought by degrees up to its proper speed, the effort must be in excess; when it is being retarded for the purpose of stopping it, the resistance must be in excess.

The excess of effort above resistance involves an excess of energy exerted above work performed; that excess of energy is employed in producing acceleration.

An excess of resistance above effort involves an excess of work performed above energy exerted; that excess of energy is produced by means of the retardation of the machinery.

When a machine undergoes alternate acceleration and retardation, so that the certain instants of time, occurring at the end of intervals called periods or cycles, an excess of force, and therefore of speed, is carried over to the next period or cycle, and in the course of the interval of time \( \Delta t \), let its velocity be increased at a uniform rate of acceleration from \( t \) to \( t + \Delta t \). The rate of acceleration will be

\[ \frac{dv}{dt} = \text{const.} = \frac{(v_t - v_0)}{\Delta t}; \]

and to produce this acceleration a uniform effort will be required, expressed by

\[ P = \frac{w}{(v_t - v_0)} \Delta t \]

(71)

(The product \( \frac{w}{g} \) of the mass of a body by its velocity is called its momentum; so that the effort required is found by dividing the change of momentum by the rate of time (which it is produced).)

To find the energy which has to be exerted to produce the acceleration from \( v_0 \) to \( v_t \), it is to be observed that the distance through which the effort \( F \) acts during the acceleration is \( \Delta s = \frac{(v_t^2 - v_0^2)}{2a} \); consequently, the energy of acceleration is

\[ \text{Pas} = \frac{(v_t^2 - v_0^2)}{2a} = \frac{w}{(n^2 - n)} \Delta t \]

(72)

being proportional to the increase in the square of the velocity, and independent of the time.

In order to produce a retardation from the greater velocity \( v_t \) to the less velocity \( v_0 \), it is necessary to apply to the body a resistance continually equal to the momentum, the equation identical in every respect with equation (71), except by the substitution of a resistance for an effort; and in overcoming that resistance the body must do work to an amount determined by equation (72), putting \( Fds \) for \( \text{Pas} \).

§ 116. Energy Stored and Restored by Variations of Velocity.—Thus a body alternately accelerated and retarded, so as to be brought back to its original speed, performs work during its retardation exactly equal in amount to the energy exerted upon it during its acceleration; so that energy may be considered as stored during the acceleration, and restored during the retardation, in a manner analogous to the operation of a reciprocating force (§ 102).

Let there be given the mean velocity \( v = \frac{1}{2} (v_t + v_0) \) of a body whose weight is \( w \), and let it be required to determine the frictional resistance \( n \), the initial resistances \( n_0 \), which body must have, in order alternately to store and restore an amount of energy \( E \). By equation (72) we have

\[ E = \frac{(v_t^2 - v_0^2)}{2a} \]

which, being divided by \( v = \frac{1}{2} (v_t + v_0) \), gives

\[ E/V = \frac{w}{(n - n_0)} \Delta t; \]

and consequently

\[ n - n_0 = \frac{2E}{Vw} \]

(73)
The ratio of this fluctuation to the mean velocity, sometimes called the unsteadiness of the motion of the flywheel, is

$$\frac{(a-a)}{a}$$

§ 118. Actual Energy of a Shifting Body.—The energy which must be exerted on a body of the weight \( w \), to accelerate it from a state of rest up to a given velocity of translation \( v \), and the equal amount of work which that body is capable of performing by overcoming resistance while being retarded from the same velocity of translation \( v \) to a state of rest, is

$$\frac{w v^2}{2}$$

This is called the actual energy of the motion of the body, and is half the quantity which in some treatises is called vis viva.

The energy stored or restored, as the case may be, by the deviations of velocity of a body or a system of bodies, is the amount by which the actual energy of the body is increased or diminished by overcoming resistance while being retarded from the same velocity of translation \( v \) to a state of rest, is

$$\frac{w v^2}{2} = \frac{w v^2}{2}$$

By this comparison with the expression for the centrifugal force \( w \sqrt{v^2} \), it appears that the actual energy of a revolving body is equal to the potential energy \( E_p/2 \) due to the action of the deflecting force along one-half of the radius of curvature of the path of the body.

The product \( w \sqrt{v^2} \), by which the half-square of the angular velocity is multiplied, is called the moment of inertia of the revolving body.

§ 119. Principle of the Conservation of Energy in Machines.—The following principle, expressing the general law of the action of machines with a velocity uniform or varying, includes the law of the equality of energy and work stated in § 89 for systems of uniform speed.

In any given interval during the working of a machine, the energy exerted added to the energy stored is equal to the energy stored added to the work performed.

§ 120. Actual Energy of Circular Translation.—Moment of Inertia.—Let a small body of the weight \( w \) undergo a translation in a circular path of radius \( R \) with the angular velocity of deflection \( a \), so that the common linear velocity of all its particles is \( v = a \). Then the actual energy of that body is

$$\frac{w v^2}{2} = \frac{w v^2}{2}$$

Let \( W \) be the weight of a flywheel, \( R \) its radius of gyration, \( a \) its maximum, \( a_1 \) its minimum, and \( A = (a + a_1) \) its mean angular velocity. Let

$$1/S = (a_1 - a)/A$$

denote the unsteadiness of the motion of the flywheel; the denominator \( S \) of this fraction is called the steadiness. Let \( e \) denote the quantity by which the energy exerted in each cycle of the work of the machine alternately exceeds and falls short of the work performed for the same duration; the consequent energy to be alternately stored by acceleration and restored by retardation of the flywheel. The value of this periodical excess is

$$e = RW\pi (a_1^2 - a^2)$$

from which, dividing both sides by \( A^2 \), we obtain the following equations:

$$e = RW\pi (a_1^2 - a^2)$$

The latter of these equations may be thus expressed in words: The actual energy due to the rotation of the flywheel, with its mean angular velocity, is equal to one-half of the periodical excess of energy multiplied by the steadiness.

In ordinary machinery \( S \) is about 32; in machinery for fine purposes \( S \) is from 50 to 60; and when greatest steadiness is required \( S \) is from 100 to 150.

The periodical excess \( e \) may arise either from variations in the effort exerted by the prime mover, or from variations in the resistance of the work, or from both these causes combined; but if one flywheel is used, it should be placed in as direct connexion as possible with that part of the mechanism where the greatest amount of the periodical excess originates; but when it originates at two or more points, it is best to have a flywheel in connexion with each of these points. For example, in a machine-work, the steam-engine, which is the prime mover of the various tools, has a flywheel on the crank-shaft to store and restore the periodical excess of energy arising from the variations in the effort exerted by the connecting-rod upon the crank; and each of the slotting machines, punching machines, riveting machines, and other tools has a flywheel of its own to store and restore energy, so as to enable the very different resistances opposed to those tools at different times to be overcome without too great unsteadiness of motion. For tools performing a useful work at intervals, and having only their own friction to overcome during the intermediate intervals, \( e \) should be assumed equal to the whole work performed at each separate operation.

§ 122. Brakes.—A brake is an apparatus for stopping and diminishing the velocity of a machine by friction, such as the friction-strap already referred to in § 103. To find the distance \( s \) through which a brake, exerting the friction \( F \), must run in order to stop a machine having the total actual energy \( E \) at the moment when the brake begins its action, reduces the equation of the problem to find the energy and other resistances of the machine which act at the same time with the friction of the brake to the rubbing surface of the brake, and let \( R \) be their resultant—positive if resistance, negative if effort preponderates. Then

$$s = E/(F + R)$$

§ 123. Energy distributed between two Bodies: Projection and Propulsion.—Hitherto the effort by which a machine is moved has been treated as a couple between a movable body and a fixed body, so that the whole energy exerted by it is employed upon the movable body, and none upon the fixed body. This conception is sensibly realized in practice when one of the two bodies between which the effort acts is either so heavy as compared with the other, or has so great a resistance opposed to its motion, that it may, without sensible error, be treated as fixed. But there are cases in which the motions of both bodies are appreciable, and must be taken into account—such as the projection of projectiles, where the velocity of the recoil or backward motion of the gun bears an appreciable proportion to the forward motion of the projectile; and such as the propulsion of vessels, where the velocity of the water thrown backward by the paddle, screw or other propeller bears a very considerable proportion to the velocity of the water moved forwards and sideways by the ship. In such kinematics, the energy exerted by the effort is distributed between the two bodies between which the effort is exerted in shares proportional to the velocities of the two bodies during the action of the effort; and those velocities are to each other as the moment of the effort directly acting on one body, or the mutual resistance of that body to the action of the effort, to the moment of the effort on the other body, or the mutual resistance of the other body to the action of the effort.

If \( R_1 = R_2 \), which is the case when the resistance, as well as the effort, arises from the mutual actions of the two bodies, the above becomes,

$$s = E/(R_1 + R_2)$$

that is to say, the energy is exerted on the bodies in shares inversely proportional to their weights; and they receive accelerations inversely proportional to their weights, according to the principle of dynamics already quoted. In a case in which \( R_1 \) is the mutual resistance of a system of bodies do not affect the motion of their common centre of gravity.

For example, if the weight of a gun be 160 times that of its ball \( W \), all the energy exerted by the recoiling body in expelling it will be employed in propelling the ball, and \( 151 \) in producing the recoil of the gun, provided the gun up to the instant of the ball's quitting the muzzle meets with no resistance to its recoil except the friction of the ball.

§ 124. Centre of Percussion.—It is obviously desirable that the deviations or changes of motion of oscillating pieces in machinery should, as far as possible, be effected by forces applied at their centres of percussion.

If the deviation be a translation—that is, an equal change of motion of all the particles of the body—the centre of percussion is obviously the centre of gravity itself; and, according to the second law of motion, if \( dv \) be the deviation of velocity to be produced in the interval \( dt \), and \( W \) the weight of the body, then

$$P = W \frac{dv}{dt}$$

is the unbalanced effort required.

If the deviation be a rotation about an axis traversing the centre of gravity, there is no centre of percussion; for such a deviation can only be produced by a couple of forces, and not by any single force. Let \( dv \) be the deviation of angular velocity to be produced in the interval \( dt \), and \( M \) the moment of the inertia of the body about an axis through its centre of gravity. If \( dG \) be the moment of the unbalanced couple required to produce the deviation; then by equation § 104, the energy exerted by this couple in the interval \( dt \) is \( M dG \), which, being equated to the variation of energy, gives

$$M = \frac{P^2}{W} \frac{R_2}{R_1} - E\frac{dG}{dt}$$

If \( R \) is called the radius of gyration of the body with regard to an axis through its centre of gravity.

Now (fig. 153) let the required deviation be a rotation of the body BB about an axis \( O \), not traversing the centre of gravity \( G \), \( dG \)
being, as before, the deviation of angular velocity to be produced in the interval $dt$. A rotation with the angular velocity $\omega$ about an axis $O$ may be considered as compounded of a rotation about some axis angular to an axis drawn through $O$ parallel to $\omega$ and a translation with the velocity $a$. $O$, $G$ being the centres of the respective circular disturbances of the two axes. Hence the required deviation may be regarded as compounded of a deviation of translation $d\theta = \omega G$, $da$, to produce which $V$ would be equal to $W$, and according to equation (82), a force applied at $G$ perpendicular to the plane $OG$—

$$P = \frac{W}{g} \cdot OG \cdot \frac{da}{dt}$$

and a deviation of $\omega$ about an axis drawn through $O$ parallel to $G$. $P$, $G$ parallel to $O$ through the centre of gravity when any $P$, $G$ parallel to $O$ and produce which would be required a couple of the moment $M$ given by equation (83). According to the principles of statics, the resultant of the force $P$, applied at $G$ perpendicular to the plane OG, and the couple $M$ is a force equal and parallel to $P$, but applied at a distance $GC$ from $G$, in the prolongation of the perpendicular OG, whose value is

$$GC = M/P = R/OG.$$  

(85)

Thus is determined the position of the centre of percussion $C$, corresponding to the axis of rotation $O$. It is obvious from this equation that, for an axis of rotation parallel to $O$ traversing $C$, the centre of percussion is at the point where the perpendicular OG meets $O$.

§ 125. *To find the moment of inertia of a body about an axis through its centre of gravity experimentally.* Through any conveniently selected axis $O$ (fig. 148) and hang near it a small plumb bob. Adjust the length of the plumb-line until it and the body oscillate together in unison. The length of the plumb-line, measured from its point of suspension to the midpoint of the plumb bob, is equal to the length of axis parallel to the axis of body, which will give the moment of inertia of the body about the axis of body parallel to the axis of body.

§ 126. *To find the force competent to produce the instantaneous acceleration of any link of a mechanism.*—In many practical problems it is necessary to know the magnitude and position of the forces acting to produce the accelerations of the several links of a mechanism. For a given link, this force is the resultant of all the accelerating forces distributed through the substance of the material of the link itself, and of the forces acting on the link, and the determination of this force depends upon the principles of the two preceding sections. The investigation of the distribution of the forces through the material and consequently produced belong to the subject of the STRENGTH OF MATERIALS (q.v.).

Let BK (fig. 134) be any link moving in any manner in a plane, and let $G$ be its centre of gravity.

The angular motion may be resolved into (1) a translation of its centre of gravity; and (2) a rotation about an axis through the centre of gravity perpendicular to the plane of motion. Let $a$ be the acceleration of the centre of gravity and let $\alpha$ be the angular acceleration about the axis through the centre of gravity; then the force required to produce the translation of the centre of gravity is $F = W/a$, and the force required to produce the angular acceleration about the centre of gravity is $M = Ia/\alpha$. $\alpha$ is the angular velocity and $I$ is the moment of inertia of the link about the axis through the centre of gravity of the link. Hence the force required at any point $B$ (fig. 49) is $\frac{W}{g} \times OB$, and set out $OB$ equal to the acceleration of $B$ and $OB$ equal to the acceleration of $K$.

Join $bk$ and take the point $g$ so that $KG$

$GB = k_{g}gb$. $G$ is then the acceleration of the centre of gravity and the force $F$ can therefore be immediately calculated. To find the angular acceleration $A$, draw $bl$, $bl$ respectively parallel to and at right angles to the link $KB$. Then $bl$ represents the angular acceleration of the point $B$ relatively to the point $K$ and hence $bl/KB$ is the value of $A$, the angular acceleration of the link. Its moment of inertia about the point $K$ can be found experimentally by the method explained in § 125, and then the value of the couple $M$ can be computed. The value of $x$ is found immediately from the quotient $M/F$. Hence the magnitude $F$ and the position of $F$ relatively to the centre of gravity of the link, necessary to give rise to the couple $M$, are known, and this force is therefore the resultant force required.

127. *Alternative construction for finding the position of $F$ relatively to the centre of gravity of the link.*—Let $B$ and $K$ be any two points in the link which for greater generality are taken in fig. 135, so that the centre of gravity of the link is described by them. First find the value of $R$ experimentally. Then produce the given directions of acceleration of $B$ and $K$ to meet in $O$; draw a circle through the three points $B$, $K$, and $O$; produce the line joining $O$ and $G$ to cut the circle in $Y$; and take a point $Z$ on the line $OY$ so that $YG \times GX = R^2$. Then $Z$ is a point in the line of action of the force $F$. This useful theorem is due to G. T. Bennett, of Emmanuel College, Cambridge. A proof of it and three corollaries are given in appendix 4 of the second edition of Dalby's *Balancing of Engines* (London, 1906). It is to be noticed that only the directions of the accelerations of two points are required to find the position of the force, but for practical purposes the accelerations of eight points may be used for the purpose of finding the position of the force for eight different positions of the connecting rod in the crank.

For an example of the application of the principles of the two preceding sections to a practical problem see *Valve and Valve Gear for Steam-engines*, by W. K. & W. D. Bennett, (London, 1896), p. 125.* The connecting rod Problem.*—A particular problem of practical importance is the determination of the force producing the motion of the connecting rod of a steam-engine mechanism of the usual type. The methods of the two preceding sections may be applied to the determination of the acceleration of the connecting rod in the crank.

In this problem it is usually assumed that the crank pin $K$ (fig. 136) moves with uniform velocity, so that if $a$ is its angular velocity and $r$ radius, the acceleration along the crank arm from the crank pin to the centre of the shaft is therefore the acceleration of one point $K$ known completely. The acceleration of a second point, usually taken at the centre of the crosshead pin, can be found by the principles of § 82, but several special geometrical constructions have been devised for this purpose, notably the construction of Klein,* discovered also independently by Kirsch.† But probably the most convenient is the construction due to G. T. Bennett‡ which is as follows: Let $OK$ be the crank and $KB$ the connecting rod. On the connecting rod take a point $L$ such that $KL \times KB = KO$. Then, the crank standing at any angle with the line of stroke, draw $L^1$ at right angles to the connecting rod, $PN$ at right angles to the line of stroke $NO$ and $NA$ at right angles to the connecting rod; then $AO$ is the acceleration of the point $B$ to the scale on which $KO$ represents the acceleration of the connecting rod. The proof of this construction is given in the *Balancing of Engines*.

The finding of $F$ may be continued thus: join $AK$, then $AK$ is the acceleration image of the rod, $OKA$ being the acceleration diagram. Through $G$, the centre of gravity of the rod, draw $GQ$ parallel to the line of stroke, thus dividing the image at $g$ in the proportion that the connecting rod is divided by $G$. Hence $Oq$ represents the acceleration of the centre of gravity and the weight of the connecting rod.
rod being ascertainment, F can be immediately calculated. To find a 2-dimensional flow, take point Q on the rod such that \[ \text{KG} \times \text{GQ} = R \times R \] having been determined experimentally by the method of section 125; join G with O and through G draw a line parallel to BO to cut GO in Z. Z is a point in the line of action of the resultant force F; hence through Z draw a line parallel to OG. The force F acts in this line, and thus the problem is completely solved. The above construction for Z is a corollary of the general theorem given in section 125.

### 129. Impact

Impact or collision is a pressure of short duration exerted between two bodies. The effects of impact are sometimes an alteration of the distribution of the actual energy between the two bodies, and always a loss of a portion of that energy, depending on the imperfection of the elasticity of the bodies, in permanently altering their figures, and producing heat. The determination of the distribution of the actual energy after collision and the loss of energy is effected by means of the following principles:

I. The motion of the common centre of gravity of the two bodies is unchanged by the collision.

II. The loss of energy consists of a certain proportion of that part of the actual energy of the bodies which is due to their motion relatively to their common centre of gravity.

Unless there is some special reason for using impact in machines, it ought to be avoided, on account not only of the waste of energy which it causes, but from the damage which it occasions to the frame and mechanism.

(W. J. M. R.; W. E. D.)

### MECHANICVILLE—MECKLENBURG

MECHANICVILLE, a village of Saratoga county, New York, U.S.A., on the west bank of the Hudson River, about 20 m. N. of Albany; on the New York and Berkshire railroad. Pop. (1900), 4695 (702 foreign-born); (1905, state census), 5877; (1910) 6364. It lies partly within Stillwater and partly within Half-Moon townships, in the bottom-lands at the mouth of the Anthony Kill, about 1/2 m. S. of the mouth of the Hoosick River. On the north and south are hills reaching a maximum height of 200 ft. There is ample water power, and there are manufactures of paper, sash and blinds, fibre, &c. From a dam here power is derived for the General Electric Company at Schenectady. The first settlement in the neighborhood was in what is now Half-Moon township about 1680. Mechanicville (originally called Burrow) was chartered by the county court in 1850, and incorporated as a village in 1870. It was the birthplace of Colonel Ephraim Elmer Ellsworth (1837–1861), the first Federal officer to lose his life in the Civil War.

MECHITARISTS, a congregation of Armenian monks in communion with the Church of Rome. The founder, Mechitar, was born at Sebaste in Armenia, 1676. He entered a monastery, but under the influence of Western missionaries he became possessed with the idea of uniting the Western Pime and Armenian culture in Armenia, and of converting the Armenian Church from its monophysitism and uniting it to the Latin Church. Mechitar set out for Rome in 1695 to make his ecclesiastical studies there, but he was compelled by illness to abandon the journey and return to Armenia. In 1696 he was ordained priest and for four years worked among his people. In 1700 he went to Constantinople and began to gather disciples around him. Mechitar formally joined the Latin Church, and in 1701, with sixteen companions, he formed a definitely religious institute of which he became the superior. Their Uniat propaganda encountered the opposition of the Armenians and they were compelled to move to the Morea, at that time Venetian territory, and there built a monastery, 1706. On the outbreak of hostilities between the Turks and Venetians they migrated to Venice, and the island of St Lazzaro was bestowed on them, 1717. This has since been the headquarters of the congregation, and here Mechitar died in 1749, leaving his institute firmly established. The rule followed at first was that attributed to St Anthony of Egypt, but when they settled in the West modifications from the Benedictine rule were introduced, and the Mechitarists are numbered among the lesser orders affiliated to the Benedictines. They have ever been faithful to their founder's programme. Their work has been fourfold: (1) they have brought out editions of important patriotic works, some Armenian, others translated into Armenian from Greek and Syriac originals no longer extant; (2) they print and circulate Armenian literature among the Armenians, and thereby exercise a powerful educational influence; (3) they carry on schools both in Europe and Asia, in which Uniat Armenian boys receive a good secondary education; (4) they work as Uniat missionaries in Armenia. The congregation is divided into two branches, the head house being in Venice. They have missions in various places in Asia Minor and Europe. There are some 150 monks, all Armenians; they use the Armenian language and rite in the liturgy.

Kongregationen (1905); Elmer von Wettin, Kirchenlexikon (ed. 2) and Herzog, Realeencyclopadie (ed. 5), also articles by Sargisian, a Mechitarian, in Rivista storica benedettina (1906), "La Congregazione Mechitartista." (E. C. B.)

MECKLENBURG, a territory in northern Germany, on the Baltic Sea, extending from 53° 4' to 54° 24' N. and from 10° 35' to 13° 57' E., unequally divided into the two grand duchies of Mecklenburg-Schwerin and Mecklenburg-Strelitz.

Mecklenburg-Schwerin is bounded N. by the Baltic Sea, W. by the principality of Ratzeburg and Schleswig-Holstein, S. by Brandenburg and Hanover, and E. by Pomerania and Mecklenburg-Strelitz. It embraces the duchies of Schwerin and Güstrow, the district of Rostock, the principality of Schwerin, and the barony of Wismar, besides several small enclaves (Ahrensberg, Rosson, Tretzeband, &c.) in the adjacent territories. Its area is 5080 sq. m. Pop. (1905) 625,045.

Mecklenburg-Strelitz consists of two detached parts, the duchy of Strelitz on the E. of Mecklenburg-Schwerin, the principality of Strelitz, and the principality of Pomerania and Brandenburg, the second by Mecklenburg-Schwerin, Lauenburg, and the territory of the free town of Lübeck. Their joint area is 1130 sq. m. Pop. (1905) 103,451.

Mecklenburg lies wholly within the great North-European plain, and its flat surface is interrupted only by one range of low hills, intersecting the country from south-east to north-west, and forming the watershed between the Baltic Sea and the Elbe. Its highest point, the Helper Berg, is 887 ft. above sea-level. The coast-line runs for 65 m. along the Baltic (without including indentations), for the most part in flat sandy stretches covered with dunes. The chief inlets are Wismar Bay, the Salzhaff, and the roads of Warnemünde. The rivers are numerous though small; most of them are affluents of the Elbe, which traverses a small portion of Mecklenburg. In the north are navigable and the facilities for inland water traffic on canals, foundries, wool-spinning mills, carriage and machine factories, dye-works, tanneries, brick-fields, soap-works, breweries, distilleries, paper-mills and similar works, and besides these are foundaries and numerous mills of various kinds. Mining is insignificant, though a fair variety of minerals is represented in the district. Amber is found on and near the Baltic coast. Rostock, Warnemünde and Wismar are the principal commercial centres. The chief exports are grain and other agricultural produce, live stock, spirits, wood and wool; the chief imports are colonial produce, iron, coal, salt, sugar, cotton, tobacco, and wine. Mecklenburg is largely attended by buyers from various parts of Germany. Fishing is carried on extensively in the numerous inland lakes.

In 1607 the grand dukes of both duchies promised a constitution to each of their subjects. The dukes were of the same family, the grand duchy having the executive entirely in their hands (though acting through ministers), while the duchy of Strelitz was a separate state. The grand dukes were represented at other times by a committee, and consisting of the proprietors of their estates (Rittergüter), known as the Ritterhaus, and the Landschaft or burgomasters of certain towns.
MECKLENBURG

1019

Mecklenburg-Schwerin returns six members to the Reichstag and Mecklenburg-Strelitz one member.

The Medical and the chief towns are Rostock (with a university), Schwerin, and Wismar the capital. The capital of Mecklenburg-Strelitz is Neu-Strelitz. The peasantry of Mecklenburg retain traces of their Slavonic origin, especially in speech, but their particularities have been much modified by immigration from Teutonic colonists. The townspeople and nobility are almost wholly of Saxon strain. The slowness of the increase in population is chiefly accounted for by the state's careful settlement of its territory.

History.—The Teutonic peoples, who in the time of Tacitus occupied the region now known as Mecklenburg, were succeeded in the 6th century by some Slavonic tribes, one of these being the Oborites, whose chief fortress was Mecklenburg, the modern Mecklenburg, near Wismar; hence the name of the country. Though partly subdued by Charlemagne towards the close of the 8th century, they soon regained their independence, and until the 10th century no serious effort was made by their Christian neighbours to subject them. Then the German king, Henry the Fowler, reduced the Slavs of Mecklenburg to obedience and introduced Christianity among them. During the period of weakness through which the German kingdom passed under the later Ottos, however, they wrenched themselves free from this bondage; the 11th and the early part of the 12th century saw the ebb and flow of the tide of conquest, and then came the effective subjugation of Mecklenburg by Henry the Lion, duke of Saxony. The Oboite prince Niklot was killed in battle in 1180 whilst resisting the Saxons, but his son Pribislaus (d. 1178) submitted to Henry the Lion, married his daughter, and received from him the title and throne of the Slavonic duchy of Mecklenburg, which he ruled as an ally of Saxony.

About 1170 a division of the land between his sons, Pribislaus and Gerhard, took place, and the former retained Mecklenburg. The Slavonic duchy of Mecklenburg was thus divided between two princes, grandsons of duke Henry Borwin, who had died two years previously. But in less than a century the families of two of these princes became extinct, and after dividing into three branches a third family suffered the same fate in 1436. There then remained only the line ruling in Mecklenburg proper, and the princes of this family, in addition to inheriting the lands of their dead kinsmen, made many additions to their territory, including the counties of Schwerin and of Strelitz. In 1535 the two princes of this family made a division of the duchy, regarded by them as Christian, and divided from the rest of the country to form Mecklenburg. The division of Mecklenburg for the whole country was abolished in 1523. About the same time the teaching of Luther and the reformers was welcomed in Mecklenburg, although Duke Albert (d. 1547) soon reverted to the Catholic faith; in 1549 Lutheranism was recognized as the state religion; a little later the churches and schools were reformed and most of the monasteries were suppressed. A division of the land which took place in 1555 was of short duration, but a more important one was effected in 1611, when the Duke John Albert I. (d. 1616) had inherited the principle of primogeniture and had forbidden all further divisions of territory. By this partition John Albert's grandson Adolphus Frederick I. (d. 1658) received Schwerin, and another grandson John Albert II. (d. 1630) received Güstrow. The town of Rostock "with its university and high court of justice" was declared to be common property, while the Diet or Landtag also retained its joint character, its meetings being held alternately at Sternberg and at Malchin.

During the early part of the Thirty Years' War the dukes of Mecklenburg-Schwerin and Mecklenburg-Güstrow were on the Protestant side, but about 1627 they submitted to the emperor Ferdinand II. This did not prevent Ferdinand and his successor from the Protestant side, and but for the policies of the House of Wettin, they would have been suppressed. During the Thirty Years' War were not exceeded by those of their class in any other part of Germany; most of them were reduced for a time to the same. The Landtag of the country was continued to be ravaged by both sides until the conclusion of the war. In 1648 by the Treaty of Westphalia, Wismar and some other parts of Mecklenburg were surrendered to Sweden, the recompense assigned to the duchies including the secularized bishoprics of Schwerin and of Rostock. The sufferings of the peasants in Mecklenburg during the Thirty Years' War were not exceeded by those of their class in any other part of Germany; most of them were reduced to a state of servitude and in some cases whole villages vanished. Christian Louis who ruled Mecklenburg-Schwerin from 1658 until his death in 1692, was like his father Adolphus Frederick, frequently at variance with the estates of the land and with members of his family. He was a Roman Catholic and a supporter of Louis XIV., and his country suffered severely during the wars waged by France and her allies in VI. In 1701, Christian II. died without issue, and his brother, Christian Louis, became ruler. The colonists were suppressed, and the rights of the peasants were restored. The duchy was divided between the two claimants, the shares given to each being represented by the existing duchies of Mecklenburg-Schwerin, the part which fell to Frederick William, and Mecklenburg-Strelitz, the share of Adolphus Frederick. At the same time the principle of primogeniture was again asserted, and the right of summoning the joint Landtag was reserved to the ruler of Mecklenburg-Schwerin.

Mecklenburg-Schwerin began its existence by a series of constitutional struggles between the duke and the nobles. The heavy debt incurred by Duke Charles Leopold (d. 1747), who had joined Russia in a war against Sweden, brought matters to a crisis; the emperor Frederick II. of Prussia, who was an imperial court of justice declared the duke incapable of governing and his brother Christian Louis was appointed administrator of the duchy. Under this prince, who became ruler de jure in 1747, there was signed in April 1755 the convention of Rostock by which a new constitution was framed for the duchy. By this instrument all power was in the hands of the duke, the nobles and the upper classes generally, the lower classes being entirely unrepresented. During the Seven Years' War Duke Christian II. (1755) was driven from his duchies by Frederick the Great, and in consequence Mecklenburg was occupied by Prussian troops, but in other ways his rule was beneficial to the country. In the early years of the French revolutionary wars Duke Frederick Francis I. (1756–1837) remained neutral, and in 1803 he regained Wismar from Sweden, but in 1806 his land was overrun by the French and in 1808 he joined the Confederation of the Rhine. He was the first member of the confederation to abandon Napoleon, to whose armies he had sent a contingent, and in 1813-1814 he fought against France. In 1815 he joined the Germanic Confederation (Bund) and took the title of grand duke. In 1830 Stettin was abolished in his dominions. During the movement of 1848 the duchy witnessed a considerable agitation in favour of a more liberal constitution, but in the subsequent reaction all the concessions which had been
made to the democracy were withdrawn and further restrictive measures were introduced in 1851 and 1852.

Mecklenburg-Strelitz adopted the constitution of the sister duchy by an act of September 1755. In 1806 it was spared the infliction of a French occupation through the good offices of the king of Bavaria; in 1808 its duke, Charles (d. 1816), joined the confederation of the Rhine, but in 1813 he withdrew therefrom. Having been a member of the alliance against Napoleon he joined the Germanic confederation in 1815 and assumed the title of grand duke.

In 1866 both the grand dukes of Mecklenburg joined the North German confederation and the Zollverein, and began to pass more and more under the influence of Prussia, who in the war with Austria had been aided by the soldiers of Mecklenburg-Schwerin. In the Franco-German War also Prussia received valuable assistance from Mecklenburg, Duke Frederick Francis II. (1823–1853), an ardent advocate of German unity, holding a high command in her armies. In 1871 the two grand duchies became states of the German Empire. There was now a renewal of the agitation for a more democratic constitution, and the German Reichstag gave some countenance to this movement. In 1897 Frederick Francis IV. (b. 1882) succeeded his father Frederick Francis III. (1851–1897) as grand duke of Mecklenburg-Schwerin, and in 1904 Adolphus Frederick (b. 1848) a son of the grand duke Frederick William (1819–1904) and his wife Augusta Carolina, daughter of Adolphus Frederick, duke of Cambridge, became grand duke of Mecklenburg-Strelitz. The grand dukes still style themselves princes of the Wends.
