grounded to defend the existence of matter." The strength of
Janet's position is his perception that the argument from final
causes is in favour of an omnipotent rational will making matter
a means to ends, and not in favour of an immanent mind of
Nature working out her own ends.

The psychological metaphysics of Cousin and of Janet was, how-
ever, followed by a step beyond a destructive, as it were, idealistic
realism of matter which has become the dominant French meta-
physics. Etienne Vacherot (q.v.) deserted Descartes for Hegel. He
accepted from Hegel "the real is rational" without the Hegelian
"every thing is the absolute being," but he did see in the
triplcity of the divine. Matter he held to be mind at the minimum of its
action, and evolution the "expansion de l'activite incessante de la
majeure" to which later, in God's making the world, is the absolute
being as first cause and final end. "Let us leave," says he in defer-
ence to Janet, "the category of the ideal, which applies to nothing
real or living. But the most noticeable passage in Le Nouveau
esprit scientifique (1884) is its contrast between the old and the new
where he says that the old spiritualism opposed spirit to matter,
God to Nature, the new spiritualism places matter in spirit, Nature
in God (p. 377). F. Ravaissot (see Ravaissot-MOLLION), by his
method used for the Nouveau dictionnaire de philosophie, in
France, gave a fresh impulse to the transition from spiritual
realism to idealism, by developing the Aristotelian idea of matter and
the Hegelian idea of spirit, by the splitting of consciousness into
parts. Jules Lachelier (born 1832) agreed with Ravaissot that
beauty is the last word of things, but, under the influence of Kant
and his successors, put his idealism rather in the form that all is
made up of conscious and unconscious, and that from a physiologist
like Fouillée (q.v.), that one of the secrets of the triplcity
(euvres) has worked out an idealism which he calls "Néo-criticism,
rejecting the thing-in-itself, while limiting knowledge to phenomena
constituted by a priori categories. Phenomena or "representations et
representantes." He takes the usual advantage of this most ambiguous of
terms when he extends it to embrace God, freedom, and immortality required
by the moral law. In his later work, Le Nouveau monadologie (1890),
he maintains that each monad is a simple substance, endowed
with representation, which is consciousness in form, phenomenon
in matter as represented. In order to explain free will, he supposes,
that a "coup de force" of the double "ego-vivant" decides between the
immediate and the contingent and liable to exceptions. Here we trace
the influence of Leibnitz and Lotze, which is still more marked in La Contingence
des lois de la nature (1874), by E. Boutroux (q.v.). The idea of evolution by the argument that will to live determines its
necessary laws, Boutroux by denying the necessity. His point
is, that the world only appears to be phenomena governed
by necessary laws, and is really a spontaneity which makes new begin-
nings, such as life and consciousness, tending to good. These
examples are enough to show that the psychological metaphysics of
spiritual realism has not been able to withstand the rise
and progressive material idealism in France.

In England, the land of Bacon and Locke, the realistic
tendency has been more active, and is exhibited in Bacon's
Novum organum and De Augmentis scientiarum, English
as well as to a less degree in the Fourth Book of
Locke's Essay. After the metaphysical idealism, begun by
Berkeley, had eventuated in Hume's reduction of the
objects of knowledge to sensations, ideas and associations,
the Scottish school, applying the Baconian method to the study of
mind, began to inquire once more for the evidences of our
knowledge, and produced the natural or intuitive realism of
T. Reid, Dugald Stewart, and William Hamilton, followed by
H. L. Mansel, as well as by J. Veitch, H. Calderwood and
J. M'Cosh, prolonged the existence of the school, in which we may venture to place
L. T. Hobhouse and F. W. Bain, author of The Realization of the Possible
(1899), down to our own time.

Its main tenet, that we have an immediate perception of the
external world, is roughly expressed in the following words of
Reid: "I do perceive matter objectively—that is, something
which is extended and solid, which may be measured and weighed, is the immediate object of my touch and sight. And this object I take to be matter, and not an idea. And, though I have no idea of what it is, I have also no idea of what it is not. I do not touch an idea, it is not a matter, yet I have never been able to discover this by the most accurate attention to my own perceptions."

M'Cosh. — "Aristotle viewed the mind, as Aristotle viewed the world, for the sake of its relations to the knowledge of matter and mind. The highest conceptions of the mind, only under modification, determined by the faculties themselves." Not only so, but in his view of Cousin ("Philosophy of the Soul", pp. 12-15), he grounded the test of knowledge, argued that "the mind can conceive, and consequently can know, only the limited, and the conditionally limited," that "to think is to condition," that "all we know either of matter or mind is something relative; we can only make the highest generalizations rise above the finite," and concluded that we cannot conceive or know the unconditioned, yet must believe in its existence. Nevertheless, in spite of all this Kantism, he adhered to the view that our use is conditioned at all events by the external world; but his final view (edition of Reid's works, note D) consisted in supposing that (1) sensation is an apposition of secondary qualities purely as affecting the organism viewed as ego; (2) perception in general is an apprehension of primary qualities as relations of sensations in the organism viewed as non-ego; while (3) a special perception of a so-called "common sense" faculty, consisting of certain sensations, involves something external to our organism. Hamilton's views both on the absolute and on perception affected Mansel and Spencer. They were, however, received without question even by his followers. H. Calderwood, in his Philosophy of the Infinite (1854), made the pertinent objection that, though thought, conception and knowledge are finite, the object of thought may be infinite. Hamilton, in fact, made the double mistake of limiting knowledge to what we can conceive, and confusing the determinate with the finite or limited. We never know anything except as determined by its attributes; but that would not prevent us from believing that the determinate depends on the infinite or absolute. J. M'Cosh again, in The Prevailing Types of Philosophy: Can they logically reach reality? (1891), rightly protests against Hamilton's combination of Scottish and German schools of thought, which "abridges the facts of common sense, throw away its crusts of impressions, instincts, suggestions, and common sense, and give the mind a power of seeing things directly." He has the merit of presenting natural or intuitive realism in its purity.

The common tenet of the whole school is that without inference we immediately perceive the external world, at all events as a resisting something external to our organism. But is it true? There are three reasons against it, and for the view that we perceive a sensible object within, and infer an external object without, the organism. In the first place, there are great differences between the sensible and the external object; they differ in secondary qualities in the case of all the senses; and even in the case of touch, heat felt within is different from the vibrating heat outside. Secondly, there are so-called "subjective sensations," without any external object as stimulus, most common of which is visual impression, pain of touch, or the feeling of creeping in the skin, and to horripilation, or the feeling of bristling in the hair; yet, even in "subjective sensations," we perceive something sensible, which, however, must be within, and not outside, the organism. Thirdly, the external world and the senses always act on another by cause and effect and by pressure, although we only feel pressure by touch. Now, when the thing with which touch is in a state of reciprocal pressure is external, e.g. a table, we feel our organism pressed and pressing; we do not feel the table pressing and pressed, but infer it. The Scottish School never realized that every sensation of the five senses is a perception of a sensible object in the bodily organism; and that touch is a perception, not only of single sensible pressure, but also of double sensible pressure, a perception of our bodily members sensibly pressing and pressed by one another, from which, on the recurrence of a single sensible pressure, we infer the pressure of an external thing for the first time. Intuitive Realism is to be replaced by Physical Realism.

3. Reaction to Hypothetical Realism. — The three evidences which are fatal to intuitive realism do not prove hypothetical realism, or the hypothesis that we perceive something mental, but infer something bodily. This illogical hypothesis, which consists of incontinently passing from the truth that the sensible object perceived is not external but within the organism to the non-sequitur that therefore it is within the mind, derived little plausibility it ever possessed from three prejudices: the first, the scholastic dogma that the sensible object is a species sensibilitis, or immaterial sensible form received from the external organism. M'Cosh presents a priori argument that the soul as thinking thing can perceive nothing, but its own idea of the third, the common assumption of a sense of sensations. But notwithstanding its illogicity, its tendency to underrate Nature as inferred from such idealistic premises, and its certain transition into a consistent idealism, hypothetical realism has, with little excuse, revived among us in the writings of Shadworth Hodgson, James Martineau and A. J. Ballour. The cause of this anachronism has been the failure of intuitive realism and the domination of idealism, which makes short-sighted men who begin with the psychology and the psychological idealism of the day, in the false hope that on the sand of psychological idealism they may build a house of metaphysical realism.

Shadworth Holloway Hodgson (born 1832; hon. fellow of Corpus Christi College, Oxford), whose chief work is The Metaphysic of Experience (4 vols., 1868), believing that philosophy is an analysis of the contents of consciousness, or experience, and that this is metaphysics, begins, like Kant, with an analysis of experience. Like Kant, he supposes that experience is concerned with sensations, distinguishes matter and form in sense, identifies time and space, eternal time and infinite space, with the formal element, and substitutes 'synthesis of sensations of touch and sight for association and inference, as the origin of our knowing such a solid material object as a bell. Although he does not agree with Kant that either the formal element in sense or the synthesis of sensations is a priori, yet in very Kantian fashion, through not distinguishing between operation and object, he holds that, in synthetically combining sensations of touch and sight, we not only have a complex perception of a solid body, but also know this "object thought of" as itself the complex of these sensations objectified. Hence he concludes that "matter is the name for the sensation-elements derived from both senses, abstracting in thought, so far as possible, from the extension-elements of both." (p. 296).

Here you would expect him to stop, as the German Neo-Kantian of Lange stops, with the consistent conclusion that all we know of Nature from such data is these complexes of sensation-elements, or Chemosoma in the Kantian meaning. Not so; like Kant himself, Hodgson supposes something beyond; not, however, an unknown thing in itself causing sensations, but a condition, or sine qua non, of their occurrence, although being a cause of their nature. In order to make this leap he supposes that we have beyond perceptions a conception of condition. His account of the origin of this conception is puzzling. (p. 386). Whatever its origin may be, it could not, any more than a category of experience, be a mere relation of sensations, but must be determined by something more than a relation of perceptions as conditions of one another, seeing that they were supposed to be the whole data, and matter itself to be "sensation-elements. But what he proceeds to suppose is that the conception of condition of our perceptions needs accounting for, we infer a real condition, e.g. the solid interior of a bell. What we know, however, of this condition, according to him, has two limits: on the one hand, it is the condition of the existence of our perceptions; on the other hand, all we know of its nature is our perceptions. Matter thus, which had at first been defined as a complex of perceptions objectified, now turns
out to be a condition without which perceptions would not exist, but whose nature is known only as a complex of perceptions. Finally, according to him, having inferred matter as the condition of our perceptions, we are entitled to infer that the condition of the existence of matter is something analogous to matter, and by practical reason from consciousness. He avers that this "metaphysics of experience" is not idealism, or the tenet that consciousness is the only reality. It is a transcendental idealism as frequent and as real as something like that of Spencer; according, indeed, more to his practical reason from consciousness. We know, from the concomitant variations between its vibrations and our perceptions, that its vibrations are not mere combinations of perceptions, but that our perceptions are not our perceptions, because we cannot perceive them, but are real attributes of the bell. It will be objected that they are merely possible perceptions. But as they really produce our real perceptions, they are themselves not merely possible, but real or actual. A possible cause could not actually produce an actual effect.

James Martineau (1805-1883) in *A Study of Religion* (1888), like Shadworth Hodgson, started from Kant, and tried to found on transcendental idealism "a return to dualism." If there is one thing certain in the Kantian philosophy, it is its authorship of that latter, and not of the dualism which it enshrines. Kant only extended a priori forms to things by resolving things into thoughts. Mill also protested "against adding, as evidence of the truth of a fact in external nature, the disposition, however strong or how general, of the human mind to believe it." Yet Martineau adopted, as his view of the limits of human intelligence, that Kant was right in making space and time a priori forms of sense, but wrong in limiting them to sensations. But in order to make space a form of external things, Martineau had to take the external in space, by which Kant meant one sensation out of another, in the very different meaning of the self here and the not-self there. He facilitated this awkward transition by adding to Kant's a priori forms of space and time an "a priori form of alternative causality," or, as he also called it, "an intuition of causality involved in the elementary exercise of perception," which is the key to his whole philosophy. He supposed that this intuition of causality arises when will is resisted, and, further, supposing that causality requires decision between alternatives, concluded that the intuition of will resisted is an intuition of will against worse alternatives. Moreover, if causality is supposed as of a priori and intuitive, there are two fatal objections to this view. In the first place, the intuition of causality does not require will at all, because we often perceive one bodily sense perceiving another involuntarily; a man suffering from lockjaw neither wills nor can avoid feeling the pressure of his upper and lower jaws against one another. Secondly, though causality requires alternatives in the material cause, e.g. wax may or may not be melted, the determination between them is not always a decision of will, but in physical causation depends on the efficient cause, e.g. the fire: as Aristotle says, when the active and passive powers approach, the one must act and the other suffer, and it is only in rational powers that will decides (Met. § 9).

A. J. Balfour, in *The Foundations of Belief*, being Notes Introductory to the Study of Theology* (1895), begins by maintaining that the evidence of the senses is not a foundation of belief, and then expects us to believe in Nature and in God. He revives the "Acatalepsia" of the New Academy. In Part II, ch. I, he makes three assumptions about the senses, and, without stopping to prove them or even to make them consistent, deduces from them his thesis that the evidence of the senses is not a foundation of belief in Nature. He first assumes an immediate experience of a body, e.g. a green tree; and then deduces that the evidence of the senses proves now and then to be fallacious, because we may have an experience indistinguishable from that of a tree but incorrect; and further, that our perceptions are habitually mendacious, because all visual experiences are erroneous, as colour is a sensation while the thing consists of uncoloured particles. This argument from a pure confusion is a sense of and inference. In no case is the evidence of the senses fallacious or mendacious; the fallacy is in the inference.

He next assumes that we have no immediate experience of independent things—that sense perceives sensations, feelings, or ideas; while all else, e.g. a tree, is a matter of inference. On this quite new assumption of a sense of sensations he deduces that, from a perception of these mental facts, we could not infer material facts, e.g. a tree; so that again the evidence of the senses does not afford trustworthy knowledge of the material universe. His deduction is logical; but he has forgotten to prove the assumption, and to recognize the impossibility with intense effect. Vision does not perceive a sensation of colour; it perceives a visible picture, e.g. green, which is in the organism, but has never been proved to be a mental fact, or to be a material fact. So touch perceives not a sensation of pressure, but a pressure which is a material fact in the organism. From a material pressure within we logically infer a material pressure outside. He thirdly assumes an appendix to the second assumption: he assumes that sense perceives mental sensations with succession but without causality, because no kind of cause is open to observation. On this thing it is old-fashioned, but not so in causality, he deduces that we could not from such data infer any particular kind of cause, or a bodily cause, e.g. a tree, or indeed any cause at all, or any event beyond perception, without assuming the principle of causation that Nature is uniform in cause and effect over great intervals of time and space. Nevertheless he gives absolutely no proof of the assumption that there is no sense of causality. There is none in the subsidiary senses, because none of them perceives the pressures exerted on them. But the primary sense of touch perceives one bodily member causing pressure on another, and for this purpose one bodily member another, and will not perceive anything but that which is similarly pressured caused between the organism and the external world; but without needing the supposed stupendous belief and assumption of the uniformity of Nature, which is altogether ignored in the inferences of the ordinary man. Finally, as touch perceives reciprocal pressure within, and tactile inference infers it without, touch is the primary evidence of the senses which is the foundation and logical ground of our belief in Nature as a system of pressing bodies. Balfour, however, having from unproved assumptions denied the evidence of the senses, and the rational condition of all belief in anything beyond oneself, he concludes that the organism, from which we infer similar particular pressures caused between the organism and the external world; but without needing the supposed stupendous belief and assumption of the uniformity of Nature, which is altogether ignored in the inferences of the ordinary man. According to him, we believe in Nature because it satisfies our material needs, and in God because he satisfies our spiritual needs. But bare need, e.g. a pang of hunger, is no cause of belief beyond itself; and desire, or need of something prospective, e.g. a desire of food, is effect, not cause, of a previous belief that there is such a thing, and of a present inference that it may again be realized. Moreover, when the belief or inference is uncertain, need even in the shape of desire is not in itself a foundation of belief in the thing desired: to need a dinner is not to believe in getting it; and, as Aristotle said, "there is a wish for impossibilities." It is fair, however, to add that Balfour has a further foundation for the belief in Nature, the survival of the fittest, by which those who should survive who possessed and could transmit the belief. But here he fails exactly as Darwin himself failed. Darwin said, given that organisms are fit, they will tend to survive; but he failed to show how they become fit. Balfour says, given that men believe in Nature, they will survive; but he fails to show how they come to believe in it. Inference from sense is the one kind of all belief, in whatever amount, whether it be from Nature, or Authority, or God; and it is the one condition of all needs, which are not mere feelings, but desires of things. The result of undermining this sure foundation emerges in Balfour's attitude to the beliefs themselves. He holds that space, time, matter, motion, force, are all full of the insoluble contradictions supposed by Spencer; and that all our beliefs, in Nature and in God, stand on the same footing of approximations. Hence his really valuable arguments from Nature to God sink to the problematic form—there may be Nature; if so, there is God.
such is the modern "Acatalepsia," which arises from denying the evidence of the senses, and from citing the transfigured realism of Spencer instead of the original realism of Aristotle, about whom Balfour speaks as follows: "It would be difficult, perhaps impossible, to sum up our debts to Aristotle. But assuredly they do not include a tenable theory of the universe.

The Past and Future of Metaphysics—Aristotelian realism is the strong point of Roman Catholic philosophy. As interpreted by Thomas Aquinas, it is now in danger of becoming a dogma. In 1879 Pope Leo XIII. addressed to the bishops the Encyclical aesterni patris, which contained the words, "Sancti Thomas sapientiam restituitis et quam latissime propagatis." From the Roman Catholic point of view this reaction to "Thomism" was a timely protest against modern metaphysics. It was founded upon a feeling of uneasiness at a growing tendency among Roman Catholic writers not only to treat theology today, but to corrupt it by paradoxes. One cannot but regret at seeing the Reformed Churches blown about by every wind of doctrine, and catching at straws now from Kant, now from Hegel, and now from Lotze, or at home from Green, Caird, Martineau, Balfour and Ward in succession, without ever having considered the basis of their faith; while the Roman Catholics are making every effort to ground a Universal Church on a sure system of metaphysics. However this may be, the power of the movement is visible enough from the spread of Thomism over the civilized world, and in England from the difference between the free treatment of metaphysics, especially by Catholic writers and that which has arisen under the immediate influence of Thomism. J. H. Newman (1801-1890), maintaining the authority of conscience and the probability of the understanding, concluded to the necessity of a higher authority in the primitive church. W. G. Ward was a philosophical critic of Mill. St. George Mivart, in The Ground-work of Science (1898), maintained the reality of an active causative power underlying Nature, and the dignity of human reason, from an independent point of view. On the other hand, more under the influence of the Thomist reaction, Thomas Harper published The Metaphysics of the School (1890, &c.), describing scholasticism, as it appears in the works of Aquinas; and The Manuals of Catholic Philosophy, edited by R. F. Clarke, include General Metaphysics (1890), by John Rickaby, who effectively criticizes Hegel by precise distinctions, which, though scholastic, did not deserve to be forgotten.

The Thomist reaction has had a good effect in the way of encouraging the study of Aristotelian philosophy in itself, and as modified by Aquinas. Nevertheless, the world cannot afford to surrender itself to these wits. Aristotle, though a great metaphysician, physically, about Nature to understand its matter, or its motions, or its forces; and consequently he fell into the error of supposing a primary matter with four contrary primary qualities, hot and cold, dry and moist, forming by their combinations four simple bodies, earth, water, air and fire, with natural rectilinear motions to or from the centre of the earth; to which he added a quintessence of ether composing the stars, with a natural circular motion round the earth. Metaphysically, he did not, indeed, as is often supposed, think the nature of substance to be matter and form, because in his view God is a substance, yet with no matter; but he did think that every natural body must be composed of two distinct qualities, so that a form, or essence, is something different from, and at most conjoined with, matter in a concrete body, and also that in the bodies of one kind, e.g. in all men, there is one undivided form or essence, which he said was composed from one member to another member of the kind, e.g. from father to son, by what we still call, though without any meaning, the propagation of the species. Aristotle, to be consistent, would answer our question whether a form, or essence, is uncreate; and, in order to avoid the "separate forms" supposed by Plato, he concluded that the world of Nature must be eternal, in order that each original essence may from eternity always be in some individual or another of its kind. On this assumption of the eternity of the world, God could not be a Creator. Aristotle thought that God is only prime mover, and that too only as the good form of which it is the cause; so that God makes nothing. Psychological, Aristotle applied his dualism of matter and form to explain the antithesis of body and soul, so that the soul is the form, or entelechy, of an organic body, and he applied the same dualism to sensation, with which things cannot receive the sensible form or essence, without the matter, of a body, e.g. of the form of white, without the matter, of a white stone. He thought that in all the being of any subject, and that the intellect and the will, when we rise from sense by induction, the productive causes the passive intellect to receive the universal form or essence, e.g. of all white things; and he thought that this productive intellect has an intellectual faculty, which he supposed to be of the mind of a builder, ante rem; that after the creation of any kind it is in re, as Aristotle supposed; and that, as we men think of it, it is post rem, as Aristotle also supposed. Of this view the part due to Aristotle is that Aristotle supposed the intellectual faculty of Plato to be ideas in intellect, and handed down their interpretation through st Augustine. The medieval Realists like Aquinas, who combined Neoplatonism and the Thomism of Aristotle, with too Aquinas opposed existence to essence much more than Aristotle did. Lastly, as a Christian, he supposed the whole soul to be immortal, and to form for a new body after death. But with these modifications he accepted the general physics of Aristotle, the metaphysical dualism of matter and form, and the psychology founded upon it. The Thomism, therefore, of our day is wrong, from a metaphysical point of view. If Aristotle ravishes Aristotelianism, as seriously modified but not fundamentally corrected by Aquinas, into an authoritative orthodoxy in metaphysics.

Centuries elapsed after Aquinas before Galileo and his successors reformed natural science, and before Bacon destroyed the metaphysical dualism of matter and form by showing that a form in Nature is only a law of the action of matter, and that, as the action of a body is as individual as the body, the form is eternal only in thought (rationes). The psychology of Aristotle and Aquinas thus became impossible; for, if the form of a body is only a mode of matter, to call one's soul the form of one's body is to reduce it to only a mode of matter, and fall into materialism. Hence Descartes began the reform of psychology not only by the appeal to consciousness, "I think," but also by opposing body and soul, no longer as matter and form, but as different substances. These great improvements, due to the genius of Galileo, of Bacon, and of Descartes, are the fresh beginnings of modern thought, from which we dare not turn back without falling into obscurantism. What, then, is the future of metaphysics? We must return not to the authority but to the study of Aristotle. The independence of metaphysics as the science of being, the principles of contradiction and excluded middle with their qualifications, the distinction without separation between substance and attributes, the definition of substance as a distinct individual thing, the discovery that the world consists of substances existing apart but related to one another, the distinction between what exists and what is possible, the concept of matter and force, the recognition both of the natural and of the supernatural—all these and many other half-forgotten truths are the reasons why we must always begin with the study of Aristotle's Metaphysics. But their incompleteness shows that we must go forward from Aristotle to Bacon and modern science, and even pass through the anarchy of modern metaphysics, in the hope that in the future we may discover as complete an answer as possible to these two questions:—

1. What is the world of things we know?
2. How do we know it?

For authorities see the works quoted above, and the references in the articles on philosophers and philosophical subjects. (T. CA.)
METAPONTUM was an ancient city of Magna Graecia situated on the Gulf of Tarentum, near the mouth of the river Bradanus, and distant about 24 m. from Tarentum and 14 m. from Heraclea. It was founded by an Achaean colony from Sybaris and Crotona about 700 B.C. Metapontum was one of the cities that played a conspicuous part in the troubles arising from the introduction of the Pythagoreanism into Magna Graecia, and it was there that Pythagoras died in 497 B.C. His tomb was still shown in the time of Cicero.

At the time of the Athenian expedition to Sicily (415 B.C.) Metapontum appears to have been an opulent and powerful city, whose alliance was courted by the Athenians; but it contented itself with a very trifling support. In 332 B.C., at the time of the expedition of Alexander, king of Epirus, into Italy, it was one of the first cities to enter into an alliance with him. The Second Punic War gave a fatal blow to its prosperity. After the battle of Cannae in 216 B.C. it was among the first cities in the south of Italy to declare in favour of Hannibal, and became for some years the headquarters of Hannibal. Hence, when the head of Hasdrubal, who had been made pretender to the Meanian throne, was carried to Metapontum, it compelled him to abandon this part of Italy, the inhabitants of Metapontum abandoned their city, and followed him in his retreat.

From this time Metapontum sank; though it was still existing in the days of Cicero, Pausanias tells us that in his time nothing remained of it but a theatre and the circuit of the walls. Metapontum has the remains of two temples, both of which seem to belong to the period 510-480 B.C. (Koldewey and Puchstein, Die griechischen Tempel in Unteritalien und Sicilien, Berlin, 1899, pp. 35-41). The so-called Chiesa di Sansone, which lay within the ancient town, and was probably dedicated to Apollo Lykus, was a peripteral measuring 186 by 91½ ft., of which only the foundations are left. The capitals were 3½ ft. in diameter. The temple was decorated with finely painted terra-cottas. Of the other temple, the so-called Tavole Faladine, which lay outside the area of the ancient city, and was a peripteral with 6 columns, 3½ ft. in diameter, in front and 12 ft. at the sides; 15 columns are standing, with the lower portion of the epistyle. It measured 103 ft. by 49 ft. without the steps. There are also traces of the town walls, which have served for the construction of farmhouses, of tombs, and of a harbour by the shore. Plyn says of a temple of Juno at Metapontum supported by columns of vineyard (Hist. nat. xiv. 9). An archeic treasure-house dedicated at Olympia by the people of Metapontum has been discovered there. The railway station is the junction of the line from Battipaglia (and Naples) with that from Taranto to Reggio. (T. As.)

See M. Lacava, Topografia e storia di Metaponto (Naples, 1891).

METASOMATISM (Gr. μετασωματικη, σωμα, body), in petrology, a process of alteration of rocks by which their chemical composition is modified, new substances being introduced while those originally present are partly or wholly removed in solution. For example a limestone may be converted into a siliceous chert, a dolomite, an ironstone, or a mass of metalliferous ores by metasomatic alteration. The process is usually incomplete, greater or smaller portions of the original rock remaining. The agencies of metasomatism are in nearly all cases aqueous solutions; probably they were often at a high temperature, as metasomatic changes are especially liable to occur in the vicinity of igneous intrusions (lacracolites, dikes and necks) where large quantities of water were given off by the volcanic magma at a time when it had solidified but was not yet cold. Metasomatism also usually goes on at some depth, so that we may readily believe that it is favoured by increase of pressure. On the other hand, there are many instances in which these processes cannot be shown to have taken place at temperatures or pressures above those which normally exist in the upper part of the earth's crust (e.g. dolomitization and silification of limestones). There are also cases of metasomatism in which steam has been operative; the temperatures were probably above the critical temperature of water. Changes of this sort are described as pneumatolytic, being induced by gases (see Pneumatolysis).

By metasomatism new minerals replace the primitive ones; at the same time the original rock-structures may be completely obliterated. An igneous rock for example may be entirely replaced by crystalline massive quartz, a fossiliferous limestone by granular crystalline dolomite. It is equally common, however, to find that the structure of the original rock is preserved though its substance has been entirely altered. An anhydrite bed may become a dolomite bed; or the calcite of which the barrier (see Petrology, Pl. IV. fig. 5) and casts of the fossils which the limestone contained may be formed of siderite or of chaledony. In this case the rock resembles a pseudomorph, which is the term applied to a mineral which has been entirely replaced by another mineral without losing its original crystalline form. As a result of metasomatism rocks usually become more crystalline, especially those which have been in large part built up of fossil organic remains; this is a consequence of the new substances having been deposited by purely inorganic processes from solution in water.

The chemical change is often complete, as when a limestone is replaced by chert or otherwise silicified, but it is probably more usually incomplete, part of the substance of the original rock having been retained though possibly in new mineral combinations. When a limestone is replaced by ironstone (e.g. carbonate of iron or siderite) part of at least the carbonic acid may be that of the limestone. A dolomite, formed from a limestone, contains more than one-half of its weight of carbonate of lime presumably derived from the limestone itself; yet in this case the mineral transformation may be perfect, as the dolomite retains none of the calcite of which the limestone was formed; it is all present as the double carbonate of lime and magnesia (or dolomite). When a granite is converted by emanations containing fluorine and boron into a quartz-tourmaline rock (schorl rock, q.v.) or a quartz mica rock (greisens, q.v.) it can be proved by analysis that there has been very little modification of the chemical composition of the original mass. This resembles paragenesis in minerals, in which one mineral is substituted for another having the same chemical composition (e.g. kyanite for andalusite).

The relations between metamorphism and metasomatism are very close; in fact some authors regard metasomatism as a variety of metamorphism. It is generally true, however, that where metamorphic changes there is little chemical alteration; sandstones pass into quartzites, clays into mica-schists and gneisses, limestones into dolomites without a large exchange of chemical compounds, for the original minerals new ones being substituted and new structures being produced at the same time. In metasomatism, on the other hand, chemical alteration is supposed to be a consequence of the original minerals being dissolved or decomposed and the new minerals are formed; there is exchange of substances.

The facility with which a rock undergoes metasomatism depends partly on its nature, and partly on the circumstances in which it is placed. Limestones, being readily soluble under natural conditions, are especially liable. The Cleveland iron ores of Yorkshire are limestones replaced by siderite and limonite; the Whitehaven iron ores, also metasomatic replacements of limestone by haematite. The former are of Mesozoic, the latter of Palaeozoic age, but both have been changed in very much the same way by percolating solutions containing salts of iron. In some limestones and mica-schists, there may be produced veins of iron ore which pass very irregularly, along bedding planes, faults and fractures. An ironstone may in many places be traced laterally into a limestone, the amount of iron in the rock gradually diminishing. Some ironstones (Carboniferous, Jurassic, &c.) retain the oolithic structures of the original limestone; others show corals, shells and other calcareous fossils replaced by iron ores. When beds of shale or sandstone are replaced, they are often accumulated on a large scale, a fact which indicates that the ready solubility of the calcareous rocks was a dominating factor in determining the metasomatic deposits. It is believed that the Whitehaven iron ores may be derived from the ironstones of the Coal-Measures which once covered the limestone districts.

Dolomitization of limestones is even more common than replacement of iron ores. That it is going on at the present day is evident from the fact that considerable deposits have been formed. Some authors have shown that these may be extensively dolomitized in their deeper parts, and the older limestones such as the Triassic of the Alps, the Carboniferous Limestone of England and the Cambrian...
Limestone of Scotland are sometimes converted into dolomite over wide areas. There has been an introduction of magnesia, with some modifications, as the result of which the formation of small rhombohedral of dolomite; it frequently becomes porous and full of drusy cavities, owing to the contraction in volume which takes place, and the fossils and other organic remains which are thus exposed. Rock dykes and veins are charged from fissures and bedding planes and spreads gradually through the mass of the limestone; often the transformation is confined to certain layers and rocks and locally affects other rocks. The replacement of limestone by chalcedony, chert, or quartz, is often exhibited on a large scale. The formation of flint nodules and chert bands is of this nature; the silica is not really the material of the line silex as its skeleton of spongite, radiolaria and other organisms, which at first were widely scattered through the limestone and at a later time they were dissolved by percolating waters, percolated through the rock and were changed to a quartz-like material. Rock masses of crypto-crystalline silica. In limestones extensive deposits of zinc ore may occur, usually calamine. These are important sources of the metal and there is little room for doubt that they have been formed by a process of metasomatic replacement, e.g. Carthagina, Raitui (in Carinthia) and Belgium. In many parts of western North America (Nevada, Arizona, &c.) great deposits of copper, lead and silver ores are worked in crystaline limestones. They are often highly silicified and, associated with them are intrusive igneous rocks such as granite, diacite, porphyry and diabase. The ores occur not only in veins and sheets, but also over large areas representing the occurrence of geologists who have examined these mining districts are nearly as the metasomatic nature of a large part of these deposits. Other rocks such as tuff, volcanic breccia, shale, porphyry and granite. These are interstratified with the limestones, and the largest ore bodies are found in the limestones. Secondary enrichment has often taken place on a considerable scale. The constant presence of igneous rocks indicates that they are contemporaneous with the introduction of the metals, and the deposits are often of such a kind as to show that post-volcanic discharges of magmatic gases and water have been the actual mineralizing agents. Biébrze, Cúff, the Glacial limestones in Arizona, Fort Collins, Utah, and the Eureka district in Nevada are good examples of the deposits in question.

As indicated above, shafts, sandstone and igneous rocks may be silicified, and in large quantities. Rhyolites and rhyolitic tuffs are often impregnated with silica to such an extent that they become almost massive quartz, and the fluid, porphyritic, spheroidal and other igneous structures of the original rocks may be entirely replaced by a siliceous pseudomorph. There are many examples of this in North Wales and the Pentland Hills. In andesites, serpentine trachytes and trachytes silicification is found frequently in circumstances indicating that the changes are not due to weathering but are the result of post-volcanic emanations of heated waters. Silicified shales may accompany mineral deposits, e.g. in the Cornish tin mines the killas or grey slate may be converted into quartz and brown tuff, and in the copper mines of Parys Mountain, Anglesey, formerly of great importance as producers of this metal, there are large areas of silicified killas. The bluish quartzite, with chlorite, epidote and quartz, have been filled with pyrite, dolomite, fluorite, calamine and other new minerals together with quartz. Another type of metasomatic alteration is phosphatization. This is most common in limestones, and many of the most important bedded phosphate deposits are of this origin. Trachytes and other igneous rocks are occasionally phosphatized. The source of the phosphates is the most part the skeletons of animals, vertebrae bones and teeth, shells of certain brachiopods, trilobites and other organisms. Guano, the excreta of birds, is rich in phosphates and these are washed downwards by rain producing metamorphic bands of greenschist and quartzite among the limestone. These are obtained in great quantities in Christmas Island, Sombrero, Curaçao and other uninhabited limestone islands.

**METASTASIO**

(1698-1782). Pietro Trapassi, the Italian poet who is better known by his assumed name of Metastasio, was born in Rome on the 3rd of January 1698. His father, Felice Trapassi, a native of Assisi, came to Rome and took service in the Corsican regiment of the papal forces. He subsequently married a Bolognese woman, called Francesca Galasti, and established himself in business as a grocer in the Via dei Cappellari. Two sons and two daughters were the fruit of this marriage. The eldest son, Leopoldo, must be mentioned, since he was the first of the family to play a part in public life, and, while quite a child, often held a crowd attentive in the streets while he recited impromptu verses on a given subject. It so happened that, while he was thus engaged one evening in the year 1709, two men of distinction in Roman society stopped to listen to his declamation. These were Gian Vincenzo Gravina, famous for legal and literary erudition, famous no less for his dictatorship of the Arcadian Academy, and Lorenzini, a critic of some note. Gravina was at once attracted by the boy’s poetical talent and charm of person, interested himself in the genius he had accidentally discovered and the boy, Pietro, his protect, befriended and, in the course of a few weeks adopted him. Felice Trapassi was glad enough to give his son the chance of a good education and introduction into the world under auspices so favourable. Gravina dinned the boy’s name Trapassi into Metastasio; and intended his adopted son to be a jurist like himself. He therefore made the boy learn Latin and begin the study of law. At the same time he cultivated his literary gifts, and displayed the youthful prodigy both at his own house and in the Roman coteries. Metastasio soon found himself competing with the most celebrated improvisoer of his time in Italy. Days spent in severe studies, evenings devoted to the task of improvising eighty stanzas at a single session, were fast ruining Pietro’s health and overstraining his poetic faculty. At this juncture Gravina had to journey into Calabria on business. He took Metastasio with him, exhibited him in the literary circles of Naples, and then placed him under the care of his kinsman Gregorio Caroprese at a little place called Scala. In country air and the quiet of the southern seashore Metastasio’s health revived. It was decreed by Gravina that he should never again, but in a few years afterwards. When, having completed his education, he might enter into competition with the greatest poets.

Metastasio responded to his patron’s wishes. At the age of twelve he translated the Iliad into octave stanzas; and two years later he composed a tragedy in the manner of Seneca upon a subject chosen from Trissino’s Italia liberata — Gravina’s favourite epic. It was called Giustino. Gravina had it printed in 1713; but the play is lifeless; and forty-two years afterwards we find Metastasio writing to his publisher, Califeggi, that he would willingly suppress it. Caroprese died in 1714, leaving Gravina his heir; and in 1718 Gravina also died. Metastasio inherited house, plate, furniture and money, which amounted to 15,000 scudi, or about £4000. At a meeting of the Arcadian Academy, he recited an elegy on his patron, and then settled down, not it seems without real sorrow for his loss, to enjoy what was no inconsiderable fortune at that period. Metastasio was now twenty. During the last four years he had worn the costume of abbe, having taken the minor orders without which it was then useless to expect advancement in Rome. His romantic history, personal beauty, charming manner, and prodigious talents, made him a favourite with the nobility. But when his years were out he had spent his money and increased his reputation for wit will surprise no one. He now very sensibly determined to quit a mode of life for which he was not born, and to apply himself seriously to the work of his profession. Accord ingly he went to Naples, and entered the office of an eminent lawyer named Castagnotto. It would appear that he acted himself as clerk, for Castagnotto exercised severe control over his time and energies. While shagging at the law, Metastasio in 1721 composed an epitaphium, and probably also his first musical, Castagnole. Evidently the boy was following the example of his patroness the Princess Pinelli di Sangro to the Marchese Belmonte Pignatelli. But the event which fixed his destiny was the following. In 1722 the birthday of the emperor had to be celebrated with more than ordinary honours, and the rector applied to Metastasio to compose a serenade for the occasion. He accepted this invitation, but it was arranged that his authorship should be kept secret. Under these conditions Metastasio produced Gli orf esereti. Set to music by Forpora, it won the most extraordinary applause. The great Roman prima donna, Marianna Bulgarelli, called La Romanina from her birthplace, played the parts of Venus in this drama, and after long and no pains until she had discovered its author. La Romanina forthwith took possession of him, induced him to quit his
lawyer's office, and promised to secure for him fame and independ-
ence, if he would devote his talents to the musical drama.
In La Romanina's house Metastasio became acquainted with the
greatest composers of the day—with Porpora, from whom he took
lessons in music; with Hasse, Pergolesi, Scarlatti, Vinc.
Leo, Durante, Marcello, all of whom were destined in the future
to set his plays to melody. Here too he studied the art of
singing, and learned to appreciate the style of such men as
Farinelli. Gifted himself with extraordinary facility in compo-
sition, and with a true poetic feeling, he found no difficulty in
producing plays which, while beautiful in themselves, judged
merely as works of literary art, became masterpieces as soon
as their words were set to music, and rendered by the singers of
the greatest school of vocal art the world has ever seen. Reading
Metastasio in the study, it is impossible to do him justice. But
the conventionality of all his plots, the absurdities of many of
his situations, the violence he does to history in the persons of
some leading characters, his "damnable iteration" of the theme
of love in all its phases, are explained and justified by music.

Metastasio resided with La Romanina and her husband in
Rome. The generous woman, moved by an affection half
maternal half romantic, and by a true artist's admiration for
such a rare talent, adopted him more passionately than even
Gravina had done. She took the whole Trapani family, father,
mother, brother, sisters—into her own house. She
fostered the poet's genius and pampered his caprices. Under
her influence he wrote in rapid succession the Didone abban-
donata, Catone in Utica, Eosio, Alessandro nell'Indie, Semiramide
riconosciuta, Siroe and Artaserse. These dramas were set to
music by the chief composers of the day, and performed in the
chief towns of Italy. But meanwhile La Romanina was growing
older; she had ceased to sing in public; and the poet felt himself
more and more dependent in an irksome sense upon her kindness.
He gained 300 scudi (about $50) for each opera; this pay, though
good, was precarious, and he longed for fixed engagements.
In September 1729 he received the offer of the post of court poet
to the theatre at Vienna, with a stipend of 3000 florins. He
accepted. La Romanina unselfishly sped him on his way to
Vienna. He took the charge of his family in Rome, and he set
off for Austria.

In the early summer of 1730 Metastasio settled at Vienna in
the house of a Spanish Neapolitan, Nicolò Martinez, where
he resided until his death. This date marks a new period in his
artistic activity. Between the years 1730 and 1740 his finest
dramas, Adriano, Demetrio, Issipilè, Demofante, Olimpide,
Clemenzia di Tito, Achille in Sciro, Temistocle and Attilio Regolo,
were produced for the imperial theatre. Some of them had to be
composed for special occasions, with almost incredible rapidity—
the Achille in eighteen days, the Dermanistra in nine. Poet,
composer, musical copyist and singer did their work together
in frantic haste. Metastasio understood the technique of his
peculiar art in its minutest details. The experience gained at
Naples and Rome, quickened by the excitement of his new career
at Vienna, enabled him almost instinctively, and as it were by
inspiration, to hit the exact mark aimed at in the opera.

At Vienna Metastasio met with no marked social success.
His plebeian birth excluded him from aristocratic circles. But,
to make up in some measure for this comparative failure, he
enjoyed the intimacy of a great lady, the Countess Althann,
sister-in-law of his old patroness the Princess Belmonte Pigna-
telli. She had lost her husband, and had some while occupied
the post of chief favourite to the emperor. Metastasio's liaison
with her became so close that it was even believed they had been
married. The even more of his existence was broken in
the year 1734 by the one dark and tragic incident of his
biography. It appears that La Romanina had at last got tired of
his absence. Could not Metastasio get her an engagement
at the court theatre? The poet at this juncture revealed his
own essential feebleness of character. To La Romanina he
owed almost everything as a man and as an artist. But he was
ashamed of her and tired of her. He vowed she should not come
to Vienna, and wrote dissuading her from the projected visit.

The tone of his letters alarmed and irritated her. It is proba-
ble that she set out from Rome, but died suddenly upon the road.
All we know is that she left him her fortune after her husband's
life interest, in case his widow should remarry. But Metastasio, with
grief and remorse, immediately renounced the legacy. This
disinterested act plunged the Bulgarelli-Metastasio household
at Rome into confusion. La Romanina's widower married
again. Leopoldo Trassapi, and his father and sister, were
thrown upon their own resources.

As time advanced the life which Metastasio led at Vienna,
together with the climate, told upon his health and spirits.
From about the year 1745 onward he wrote but little, though
the cantatas which belong to this period, and the cantzone Etzelo quel
fero istante, which he sent to his friend Farinelli, rank among the
most popular of his productions. It was clear, as Vernon Lee has
phrased it, that "what ailed him was mental and moral
ennui." In 1755 the Countess Althann died, and Metastasio
was more than ever reduced to the society which gathered
round him in the bourgeois house of the Martinez. He sank
rapidly into the habits of old age; and, though his life was
prolonged till the year 1782, very little can be said about it.

On the 19th of April he died, bequeathing his whole fortune
of some 150,000 florins to the five children of his friend Martinez.
He had survived all his patrons and all his rivals.

But Metastasio, by the long period of forty years in which
Metastasio overlived his originality and creative powers his fame went on
increasing. In his library he counted as many as forty editions of
his own works. They had been translated into French,
English, German, Spanish, even into modern Greek. They
had been set to music and over and over again by every composer
of distinction, each opera receiving this honour in turn from several
of the most illustrious men of Europe. They had been sung by
the best virtuosos in every capital, and there was not a literary
academy of note which had not conferred on him the honour of
memorializing and setting his dramas to music. Even Franz
Hendl, who lived through Vienna, made a point of paying their respects to the old poet at his
lodgings in the Kohlmarkt Gasse. But his poetry was intended
for a certain style of music—for the music of omnipotent
vocalists, of thaumaturgical sopranis. With the changes effected
in the musical drama by Gluck and Mozart, with the development
of orchestration and the rapid growth of the German manner,
a new type of libretto came into request. Metastasio's plays fell
into undeserved neglect, together with the music to which he
had linked them. Farinelli, whom he styled "twin-brother," was the true owner of his poetry, and with him, as with the
class of singers to which Farinelli belonged, Metastasio's
music suffered eclipse. It was indeed a just symbolic instinct
which made the poet dub this unique sopranio his twin-brother.

The musical drama for which Metastasio composed, and in
working for which his genius found its proper sphere, has so
wholly passed away that it is now difficult to assign his true place
to the poet in Italian literary history. His inspiration was
essentially emotional and lyrical. The chief dramatic situations
are expressed by lyrics for two or three voices, embodying the
several contending passions of the agents brought into conflict
by the circumstances of the plot. The total result is not pure
literature, but literature supremely fit for musical effect.

Language in Metastasio's hands is exquisitely pure and limpid.
Of the Italian poets, he professed a special admiration for Tasso
and for Marini. But he avoided the conceits of the latter, and
was no master over the refined richness of the former's diction.
His own style reveals the improvisatore's facility. Of the
Latin poets he studied Ovid with the greatest pleasure, and from
this predilection some of his own literary qualities may be
derived. For sweetness of versification, for limpidity of diction,
for delicacy of sentiment, for romantic situations exquisitely
rendered in the simplest style, and for a certain delicate beauty
of imagery sometimes soaring to ideal sublimity, he deserves to
be appreciated so long as the Italian language lasts.

There are numerous editions of Metastasio's works. That by
Calsabigi (Paris, 1755, 9 vols. 8vo) published under his own superin-
tendence, was the poet's favourite. Another of Turin (1752) and a
third of Paris (1789) deserve mention. The posthumous works were printed at Vienna, 1795. The collected editions of Genoa (1802) and Padua (1811) will probably be found most useful by the general student. An edition of the letters, by Carchedi, was published at Bologna (1907 n.c.), was defeated and slain by the Roman army, this being the decisive battle of the Second Punic War. The exact site of the battle is uncertain; tradition places it between Fossombrone and the Furlo Pass, but it is probable that it occurred near the sea-coast.

METAURUS (mod. Metaro; the form Metaurus is later, and is more frequent in inscriptions of the imperial period), a river of Italy, which flows into the sea a little south-east of Fanum Fortunae (mod. Fano). On its banks Hadrian, while marching to the aid of Hannibal at 207 n.c., was defeated and slain by the Roman army, this being the decisive battle of the Second Punic War. The exact site of the battle is uncertain; tradition places it between Fossombrone and the Furlo Pass, but it is probable that it occurred near the sea-coast.

METAURAS, ANDREAS (1786–1860), Greek politician, was born in the island of Cephalonia. During the latter part of the War of Independence (1824–1827) he accompanied Capo d'Istria to Greece, and was appointed by him minister of war. When Capo d'Istria was murdered in 1831 Metaurus became a member of the provost court of government, and in 1832 he was appointed governor of the city of King Otho in 1833. During the minority of Otho he was named privy councillor and minister at Madrid and Lisbon. In 1840 he was recalled and appointed minister of war. In 1843–1844 he was president of the council of ministers, and he subsequently held the post of ambassador at Constantinople from 1850 to 1854. He died at Athens on the 10th of September 1860.

MÉTAYAGE SYSTEM, the cultivation of land for a proprietor by one who receives a proportion of the produce. The system has never existed in England and has no English name, but in certain clover lands of France and Italy the system has lasted for centuries, and is still very common. It is also not unusual in Portugal, in Greece, and in the countries bordering on the Danube. In Italy and France, respectively, it is called mezzarìa and métayage, or halving—the halving, that is, of the produce of the soil between landowner and landholder. These expressions are not, however, to be understood in a more precise sense than that in which we sometimes talk of a larger and a smaller half. They merely signify that the produce is divisible in certain definite proportions, which must obviously vary with the varying fertility of the soil and other circumstances which hold and which do not in practice vary so much that the landlord's share is sometimes as much as two-thirds, sometimes as little as one-third. Sometimes the landlord supplies all the stock, sometimes only part—the cattle and seed perhaps, while the farmer provides the implements; or perhaps only half the seed and half the cattle, the farmer finding the other halves—taxes too being paid wholly by one or the other, or jointly by both.

English writers were unanimous, until J. S. Mill adopted a different tone, in condemning the métayage system. They judged it by its appearance in France, where it has never worn a pleasant aspect. Under the ancien régime not only were all direct taxes paid by the métayer, the noble landowner being exempt, but these taxes, being assessed according to the visible produce of the soil, operated as penalties upon all endeavours to augment its productiveness. No wonder, then, if the métayer fancied that his interest lay less in exerting himself to augment the total to be divided between himself and his landlord, than in studying how to defraud the latter part of his rightful share; nor if he has not yet got rid of habits so acquired, especially when it is considered that he still is destitute of the fixity of tenure without which métayage cannot prosper. French métayers, in Arthur Young's time, were "removable at pleasure, and obliged to conform in all things to the will of their landlords," and so in general they are still. Yet even in France, although métayage and extreme rural poverty usually coincide, there are provinces where the contrary is the fact, as it is also in Italy. Indeed, to every tourist who has passed through the plains of Lombardy with his eyes open, the knowledge that métayage has for ages been there the prevailing form of tenure ought to suffice for the triumphant vindication of métayage in the abstract. An explanation of the contrasts presented by métayage in different regions is not found in light of agricultural statistics. In order to be in any measure worthy of commendation, must be a genuine partnership, one in which there is no sleeping partner, but in the affairs of which the landlord, as well as the tenant, takes an active part. Wherever this applies, the results of métayage appear to be as eminently satisfactory, as they are decidedly the reverse wherever the landlord holds himself aloof.

In France there is also a system termed métayage par groupes, which consists in letting a considerable farm, not to one métayer, but to an association of several, who work together for the general good, under the supervision either of the landlord himself, or of his bailiff. This arrangement gets over the difficulty of finding tenants possessed of capital enough for any but very small farms.

See further the section Agriculture in the articles France, Greece, Italy, Sicily, and consult J. Cruvelier, Étude sur le métayage (Paris, 1894).

METCALF, WILLIAM LEROY (1835– ), American artist, was born at Lowell, Massachusetts, on the 1st of July 1835. He was the son of Samuel Metcalfe, a prosperous manufacturer of Thomas Metcalfe Metcalfe, then a major in the Bengal army, who afterwards became a director of the East India Company, and was created a baronet in 1802. Having been educated at Eton, he in 1850 sailed for India as a writer in the service of the Company. After studying Oriental languages as the first student at Lord Wellesley's College of Fort William, he, at the age of nineteen, was appointed political assistant to General Lake, who was then conducting the final campaign of the Mahatta war against Holkar. In 1808 he was selected by the British for the responsible post of envoy to the court of Ranjit Singh at Lahore; here, on the 25th of April 1809, he concluded the important treaty securing the independence of the Sikh states between the Sutlej and the Jumna. Four years afterwards he was made resident at Delhi, and in 1819 he received from Lord Hastings the appointment of secretary in the secret and political department. From 1820 to 1825 Sir Charles (who succeeded his brother in the baronetcy in 1822) was resident at the court of the nizam, and afterwards was summoned in an emergency to his former post at Delhi. In 1827 he obtained a seat in the supreme council, and in March 1835, after he had been appointed the first governor of the proposed new presidency of Agra, he provisionally succeeded Lord William Bentinck in the governor-generalship. During his brief tenure of office (it lasted only for one year) he carried out several important measures, including that for the liberation of the press, which, while almost universally popular, complicated his relations with the directors at home to such an extent that he resigned the service of the Company in 1838. In the following year he was appointed by the Melbourne administration to the governorship of Jamaica, where the difficulties created by the recent passing of the Negro Emancipation Act had called for a high degree of tact and ability. Sir Charles Metcalfe's success in this delicate position was very marked, but unfortunately his health compelled his resignation and return to England in 1842. Six months afterwards he was appointed by the Peel ministry to the governor-generalship of Canada, and his success in carrying out the policy of the home government was rewarded with a...
peare shortly after his return in 1845. He died at Malsbanger, near Basingstoke, on the 5th of September 1846.

See J. W. Kaye’s Life and Correspondence of Charles Lord Metcalfe (London, 1850).

METELLUS, the name of a distinguished family of the Caecilian (plebian) gens in ancient Rome. The following are the most important:

1. LUCIUS CAECILIUS METELLUS, general during the first Punic War. Consul in 321 B.C., he was sent to Sicily, and gained a decisive victory over Hasdrubal, who, trusting to his numerically superior forces and the alarm inspired by his elephants, ventured to attack him. Metellus’s victory was in great measure due to a panic caused amongst the elephants by his clever manœuvres. A number of these animals were sent in specially constructed rafts to adorn his triumph, and from this time the elephant frequently occurs as a device on the coins of the Metelli. In 241, when the temple of Vesta was destroyed by fire, Metellus succeeded in bringing out the Palladium uninjured, but lost his eyesight. As a reward, he was granted permission to ride to the senate-house in a carriage, a privilege hitherto unheard of. But the story of his blindness is doubtful, since it is hardly consistent with his appointment as dictator in 224 “for the purpose of holding the comitia,” nor is any mention made of it in the extract [Pliny, Nat. Hist. viii. 45 (45)] from the funeral oration pronounced over him by his son.

2. QUINTUS CAECILIUS METELLUS, son of (1), became consul in 206 as a reward for his services at the Metaurus. In 205 he was dictator for holding the comitia; in 201 one of the commissioners for dividing the public land in Samnium and Apulia amongst the Roman veterans; in 186 he conducted an embassy to Macedonia, afterwards proceeding to Peloponnesus to investigate the quarrel between Sparta and the Achaenae. He is the Metellus who caused the poet Naevius (q.v.) to be imprisoned and exiled for having attacked him on the stage.

3. LUCIUS CAECILIUS METELLUS MACEDONICUS, son of (1), when the disastrous news of the battle of Cannae (216) reached Rome, proposed to a number of young nobles that they should leave Italy and offer their services to some foreign ruler, but they were prevented by the threats of the younger Scipio from carrying out their purpose. For this offence, when quaestor two years later, he was degraded by the censors from his tribe to the class of aerarii. Nevertheless, he was elected one of the tribunes for the following year, but his attempt to call the censors to account for their aid proved unsuccessful in the face of the opposition of the caesars.

4. QUINTUS CAECILIUS METELLUS MACEDONICUS (d. 115 B.C.), praetor 148 B.C., defeated the usurper Andricus (q.v.) in Macedonia and forced him to surrender. Under his superintendence the country was made a Roman province. In 146, he attacked the Achaenae to avenge an insult offered to a Roman embassy at Corinth. He gained decided successes over them at Scarpheia and Chaeronea, but was superseded by L. Mummius. On his return to Italy he received the honour of a triumph and the title of Macedonicus. Consul in 143, he reduced the Cilicianians in northern Spain to obedience. In 133, when censor with Q. Pompeius (they were the first two plebeian censors), he proposed that all citizens should be compelled to marry. He expelled a number of senators, one of whom, the tribune C. Atinius Laebo, proposed that he should be hurled from the Tarpeian rock; his life was only saved through the intervention of another tribune. He was an opponent of the Gracchi, although not averse from moderate reform. He was a strict disciplinarian, a good general, and a type of the ancient Roman both in public and private life. He erected a splendid colonnade in the Campus Martius, and two temples dedicated to Jupiter Stator and Juno.

5. QUINTUS CAECILIUS METELLUS NUMIDICUS, consul 100, and commander in the Jugurthine War. He defeated Jugurtha (q.v.) by the river Muthul, and after a difficult march through the desert took his stronghold, Thala. Marius, however, who had been intriguing for the command, accused Metellus of protracting the war, and received the consulship for 107 with the province of Numidia. Metellus received a splendid triumph and the title of Numidicus. Saturninus, whom as a censor he tried to remove from the senate, passed in 100 an agrarian law, inserting a provision that all senators should swear to it within five days. All compiled but Metellus, who retired to Asia. After Saturninus was killed he returned, and died (probably in 97). He was a man of the highest integrity, a strict and efficient general, and one of the chief leaders of the aristocratic party. He was a man of education and learning, and Cicero speaks highly of him as an orator.

6. QUINTUS CAECILIUS METELLUS PIUS, so called from his efforts to bring about the recall of his father Numidicus from exile. He was one of the commanders in the Social War, and defeated Q. Pompeius Silo, the Marian leader (in 81). On his return he was sent to Africa to suppress the rebels. On his departure for Asia, gave him proconsular command over north Italy. When Marius returned to Italy and joined Cinna, the soldiers, who had no confidence in the consul Gnaeus Octavius, wished Metellus to take command, but he refused. The soldiers deserted in large numbers, and considering it impossible to defend Rome, Metellus retired to Africa and afterwards to Liguria, resuming his former proconsular command on Sulla’s return. In the war against Marius he gained several important successes, and after his victory over C. Norbanus at Faventia (82) he was advanced by his wife Clodia (in 80). After Sulla, he went to Spain next year against Sertorius, who pressed him hard till the arrival of Pompey in 76. Next year Metellus defeated Sertorius’s lieutenant Hirtuleius at Ittica and Segovia, and joining Pompey rescued him from the consequences of a check at Sacro. From this time Sertorius grew weaker till his murder in 72. In 71 Metellus returned to Rome and triumphed. He became pontifex maximus, and died probably at the end of 64. He was an upright man, of moderate ability.

7. QUINTUS CAECILIUS METELLUS CELER, legate of Pompey in Spain in 49 B.C. He was despatched to cut off the retreat of Catilina to the north by blocking the passes, and in 62 went into the province of Cisalpine Gaul with the title of proconsul, although he did not become consul till 60. A strong supporter of the optimates and an enemy of Pompey, he strenuously opposed the agrarian law brought forward by the tribune Lucius Flavius, to provide for Pompey’s veterans, and stood firm even though imprisoned; the law had to be given up. He also tried, though fruitlessly, to obstruct Caesar’s agrarian law in 59. He died suddenly in the same year—it was usually supposed from poison administered by his wife Clodia. In 58, he was made dictator for the following year.

8. QUINTUS CAECILIUS METELLUS NEPOS, son of a Metellus of the same name, so called because he was the grandson of (4). He was legate to Pompey in the war against the Mediterranean pirates (67), and took part in the Syrian campaign. In 63 he returned to Rome, to assist Pompey in carrying out his plans. He violently attacked Cicero, and refused to allow him to deliver the customary speech on laying down office as consul; he even threatened to impeach him for having executed Roman citizens (referring to the Catilinarian conspirators) without a trial. In 63 his proposal that Pompey should be summoned to Italy to restore order was bitterly opposed by Caesar, and on the day set down for the bill a fight took place in the forum. Metellus fled to Pompey, but soon returned with him to Rome. In 60, when praetor, he proposed a law for the abolition of the vetulicia in Italy. In 57 he was consul, but offered no opposition to the return of Cicero from exile. In 56 he was governor of Hither Spain, where he was engaged in hostilities against the Vakcenses with indifferent success. He appears to have died in Rome in the following year. He was a mere creature of Pompey.

9. QUINTUS CAECILIUS METELLUS PLUS SCRIPTO, son of P. Scrupius Nasica, was adopted by (6). He was accused of bribery in 60 B.C., and defended by Cicero, to whom he had rendered valuable assistance during the Catilinarian conspiracy. In August 52, he became consul through the influence of Pompey, who had married his daughter Cornelia. In 49 he proposed that Caesar should disband his army within a definite time, under pain of being declared an enemy of the state. After the outbreak of the civil war, the province of Syria was assigned to
him, and he was about to plunder the temple of Artemis at Ephesus when he was recalled by Pompey. He commanded the centre at Tharsus, and afterwards went to Africa, where by Cato's influence he received the command. In 46 he was defeated at Thapsus; while endeavouring to escape to Spain he fell into the hands of P. Sittius, and put himself to death. His connexion with two great families gave him importance, but he was selfish and licentious, wanting in personal courage, and his violation drove many from his party.

10. QUINTUS CALCIUS METELLUS, surnamed Creticus, Roman general. Consul in 69 B.C., he was appointed to the command of the war against Crete, the headquarters of the pirates of the Mediterranean. Its subjugation proceeded slowly but surely until 67, when Pompey claimed the control of affairs in virtue of the powers conferred upon him by the Gabinian law. Thereupon the Cretans, who had been treated with great harshness by Metellus, offered to surrender to Pompey, who enjoyed a reputation for leniency towards the conquered. Pompey accepted the offer and sent instructions to Metellus to suspend operations. Metellus refused and completed the conquest, a circumstance which sprang from his connexion with the Catilinarian conspiracy, when he made his entry into the city and received the name Creticus in honour of his achievements. Metellus naturally joined the senatorial party in their opposition to Pompey, and had the satisfaction of preventing the ratification of what he had done in Asia. He was one of a commission of three sent (60) to investigate the state of affairs in Gaul, where disturbances were apprehended. He appears to have been all in 54, but nothing further is known of him.

On the family of the Metellis generally see M. Wendes, De Caelcillio Metelis, i. (Bohn, 1875), for its history up to the time of the Gracchi, the new edition by F. Gröbe of Drummann's Geschichte Romi, ii.; and the article Metellus, in Paul F. Weck's Realencyclopddie der classischen Altertumswissenschaft, iii. pt. i. (1897).

METEMPSYCHOSIS (Gr. μετεμπυχώσις), or Transmigration of the Soul, the doctrine that at death the soul passes into another living creature, man, animal, or even plant. This doctrine, famous in antiquity and still held as a religious tenet by certain sects of the civilized world, has its roots far back in primitive culture. It is developed out of three universal sentiments: (1) the ascent of destiny, which was an universal as well as a soul's conception of destiny to live for ever as God from whom it comes; (2) that animals and even plants have souls, and are possessed to a large extent of human powers and passions; (3) that souls can be transferred from one organism to another. Innumerable examples might be mentioned of the notion: that a new-born child is the reincarnation of someone departed, as in Tibet the soul of the Dalai Lama is supposed to pass into an infant born nine months after his decease. Transmigration of human souls into non-human bodies is implied in totemism (q.v.), for, as Professor Frazer says, "it is an article of faith that as the clan sprung from the totem, so each clansman at death resumes the totem form." All these savage notions are to be regarded as presuppositions of metempsychosism, rather than identified with that doctrine itself as a reasoned theory.

Till full investigation of Egyptian records put us in possession of the facts, it was supposed that the Egyptians believed in metempsychosism, and Herodotus (ii. 123) explicitly credits them with it. We now know that he was wrong. All that they believed was that certain privileged souls might in the other world be able to assume certain forms at pleasure, those of a sparrow, hawk, fly, &c. Herodotus misunderstood the Egyptians to hold beliefs identical with those which were current in his day in Greece. In India, on the contrary, the doctrine was thoroughly established from ancient times; not from the most ancient, as it is not in the Vedas; but onwards from the Upanishads. In them it is used for moral retribution: he who kills a Brahman is, after a long progress through dreadful hells, to be reborn as a dog, pig, ass, camel, &c. This we always find in metempsychosism as a reasoned theory. It is formed by combina-

tion of two sets of ideas which belong to different planes of culture: the ideas of judgment and punishment after death elaborated in a relatively cultured society by a priestly class are combined with ideas, like that of totem-transmigration, proper to a savage society. In India we may explain the whole phenomenon as an infusion of the lower beliefs of the non-Aryan conquered races into the higher religious system of their Aryan conquerors. In later Hinduism metempsychosism reached a monstrous development; according to Monier-Williams it was believed that there were 8,400,000 forms of existence through which all souls were liable to pass before returning to their home in the Deity. Buddhism appeared as a reaction against all this, and sought by a subtle modification of Buddhism to assimilate the theory with its own pessimistic view of the world. According to Buddhism there is no soul, and consequently no metempsychosism in the strict sense. Something, however, is transmitted, i.e. Karma (character), which passes from individual to individual, till in the perfectly righteous man the will to live is extinguished and that particular chain of lives is brought to an end.

We do not know exactly how the doctrine of metempsychosism arose in Greece; it cannot, as was once supposed, have been borrowed from Egypt and is not likely to have come from India. It is easiest to assume that savage ideas which had never been extinguished were utilized for religious and philosophic purposes. The Orphic religion, which held it, first appeared in Thrace upon the semi-barbarous north-eastern frontier. Orpheus, its legendary founder, is said to have taught that "soul and body are united by a compact unequally binding on either; the soul is divine, immortal and aspires to freedom, while the body holds it as a task, and as a prisoner. Death dissolves this compact, but only to re-imprint the liberated soul after a short time; for the wheel of birth revolves inexorably. Thus the soul continues its journey, alternating between a separate unrestreminated existence and fresh reincarnation, round the whole circle of necessity, as the companion of many bodies of men and animals. To these unfortunate prisoners Orpheus proclaims the message of liberation, that they stand in need of the grace of redeeming gods and of Dionysus in particular, and calls them to turn to God by acetic piety of life and self-purification: the purer their lives the higher will be their next reincarnation, until the soul has completed the whole journey and has seen the whole circle of Fortune and saw the souls returning from heaven and from purgatory, and proceeded with them to a place where they chose new lives, human and animal. "He saw the soul of Orpheus changing into a swan, Thamyras becoming a nightingale, musical birds choosing to be men, the soul of Atalanta choosing the honours of an athlete. Men were seen passing into animals and wild and tame animals changing into each other." After their choice the souls drank of Lethe and then shot away like stars to their birth. There are myths and theories to the same effect in other dialogues, the Phaedrus, Meno, Phaedo, Timaeus and Laws. In Plato's view the number of souls was fixed;
The various kinds of meteors are probably but different manifestations of similar objects. Perhaps the most important meteors are those which, after their bright careers and loud detonations, descend upon the earth's surface and can be submitted to close inspection and analysis (see Meteores). The fireball or bolide (Gr. bolis, a missile) comes next in order from its size and conspicuous effects. It may either be interspersed with many smaller meteors in a shower or may be isolated. The latter usually move more slowly and approach rather near to the earth. The ordinary shooting stars vary from the brilliancy of an ant to a sixth-magnitude star. They exhibit a great diversity in paths, motions and colours. The smallest and most numerous class are the telescopic meteors invisible to the naked eye. They range from the 7th magnitude to the smallest object perceptible in large telescopes.

The altitudes at which these bodies are visibly presented to us differ in individual cases. More than a thousand observations in duplicate have been made of the paths of identical meteors seen from two stations many miles apart. These pairs of observations have shown a parallax from which the elevation of the objects above the earth, the lengths and directions of their paths could be computed. The average heights are from 80 to 40 m. A few, however, first appear when higher than 80 m. and some, usually slow-moving meteors, descend below 40 m. But altitudes beyond 100 and within 20 m. are rare:

30 of the November Leonids gives a mean height of 84½ to 57½ m. of the August Perseids, 80 to 54 m.

When the length of a meteor's course is known and the duration of the flight has been correctly estimated it is easy to compute the velocity of the meteor. The velocity of the ordinary shooting star is, however, comprised within one second, and it is only rarely that such short time intervals can be accurately taken. The real velocities derived from good observations are rarely, if ever, under 7 or 8 m. per second, or over 60 or 70 m. per second. In a few exceptional cases abnormal speed has been indicated on good evidence. The slower class of meteors overtaking the earth (like the Andromedids of November) have a velocity of about 8 or 10 m. per second, while the swifter class (meeting the earth like the Leonids of November) have a velocity of about 44 m. per second.

When the members of a shower are observed with special regard to their directions it is seen that they diverge from a common focus. The apparent scattering or diversity of the flights is merely an effect of perspective upon objects really traversing parallel lines. The centre upon which the observed paths converge is called the radiant point or, shortly, the radiant.

On every night of the year there are a great number of these radiants in action, but the large majority represent very attenuated showers. In 1876 the number of radiants known was 850, but about 5000 have been determined up to the present time. These are not all the centres of separate systems, however: many of the positions being multiple observations of the same showers. Thus the August Perseids, the returns of which have been witnessed more frequently than those of any other meteoric stream have had their radiant point fixed on more than 250 occasions.

There appear to be moving and stationary radiants, contracted and diffused radiants, and long-enduring and brief radiants. The Perseids are visible from about the 11th of July to the 20th
of August, the radiant having a daily motion of about 1° R.A. to E.N.E. The Lyrids also vary in the position of their radiant, but the Orionids form a stationary position from about the 9th to the 24th of October. A large proportion of the ordinary feeble showers also appear to be of permanent type.

Solid bodies (chiefly stone or stone and iron) enter the atmosphere from without at all conceivable angles and at a velocity of about 26 m. per second, while the earth's orbital velocity is about 182 m. per second. In thus rapidly penetrating the air heat is generated, the meteor becomes incandescent, and the phenomena of the streak or train is produced. Before the object can pierce the dense lower strata of air its material is usually exhausted, but on rare occasions it withstands the fiery ordeal, and fragments of the original meteor fall upon the earth. Multitudes of meteors infest space. On a clear moonless night one person may count eight or ten shooting stars in an hour. But there are more than twice as many visible in the early morning hours as in the evenings, and during the last half of the year there are also more than twice as many visible as during the first half. It is computed that twenty millions of meteors enter the atmosphere every day and would be visible to unassisted vision in the absence of sunlight, moonlight and clouds, while if telescopic meteors are included the number will be increased twofold. Ordinary meteors, in the region of the earth's orbit, are characteristic of intervals of about 250 m. In special showers, however, they are much closer. In the rich display of the 12th of November 1833, the average distance of the particles was computed as about 15 m., in that of the 27th of November 1859 as about 50 m., and in that of the 27th of November 1872 as about 35 m.

The meteors, whatever their dimensions, must have motions around the sun in obedience to the law of gravitation in the same manner as planets and comets—that is, in conic sections of which the sun is always at one focus. The great variety in the nature of the displays of meteors proves that they are not directed from the plane of the ecliptic; hence their orbits are not like the orbits of planets and short-period comets, which are little inclined, but like the orbits of parabolic comets, which often have great inclinations.

Historical records supply the following dates of abundant meteoric displays:

These showers occurred at intervals of about one-third of a century, while the day moved along the calendar at the rate of one month in a thousand years. The change of style is, however, responsible for a part of the alteration in date. The explanation of these recurring phenomena is that a great cloud or distended stream of meteors revolves around the sun in a period of 333 years, and that one portion of the elliptical orbit intersects that of the earth. As the meteors have been numerous visible in five or six successive years it follows they must be pretty densely distributed along a considerable arc of their orbit. It also follows that, as some of the meteors are seen annually, they must be scattered about the whole orbit. Travelling at the rate of 26 m. per second, they encounter the earth moving 181 m. per second in an opposite direction, so that the apparent velocity of the meteors is about 44 m. per second. They radiate from a point within the Sickle of Leo and are termed Leonids. In 1867 the remarkable discovery was made that Tempel's comet (1866 : L.) revolved in an orbit identical with that of the Leonids. That the comet and meteors have a close physical association seems certain. The disintegrated and widely dispersed material of the comet forms the meteors which embellish our skies on mid-November nights.

Fine meteoric showers occurred in 1798 (Dec. 7), 1838 (Dec. 7), 1872 (Nov. 27), 1885 (Nov. 27), 1892 (Nov. 23) and 1899 (Nov. 23 and 24), and the dates indicate an average period of 6-7 years for fifteen returns. The meteors move very slowly, as they have to overtake the earth, and their apparent velocity is only about 9 m. per second. They are directed from a point in the sky near the star γ Andromedae. Biela's comet of 1826, which had a period of 6-7 years, presented a significant resemblance of orbit with that of the meteors, but the comet has not been seen since 1852 and has probably been resolved into the meteoric stream of Andromedids.

Rich annual displays of meteors have often been remarked on about the roth of August, directed from Perseus, but they do not appear to have exhibited periodical maxima of great strength. They are probably dispersed pretty evenly along a very extended ellipse agreeing closely in its elements with comet 1862 : III. But the times of revolution are doubtful; the probable period of the orbit is 121 years and that of the meteors 105 years. This shower of Perseids is notable for its long duration in the months of July and August and for its moving radiant.

There was a brilliant exhibition of meteors on the 20th of April 1803, and in other years meteors have been very abundant on about the 19th to the 21st of April, shooting from a radiant a few degrees south-west of α Lyrae. The display is apparently an annual one, though with considerable differences in intensity, and the cycle of its more abundant returns has not yet been determined. A comet which appeared in 1851 had a very suggestive agreement of orbit when compared with that of the meteors, and the period computed for it was 415 years.

Apart from the instances alluded to there seem few coincidences between the orbital elements of comets and meteors. Halley's comet conforms very well, however, with a meteoric shower directed from Aquarius early in May. But there are really few comets which pass sufficiently near the earth to give rise to a meteoric shower. Of 80 comets seen during the 20 years ending 1803, Professor Herschel found that only two, viz. Denning's comet of 1861 and Finlay's of 1886, approached comparatively near to the earth's path, the former within 3,000,000 m. and the latter within 4,000,000 m.

Radiants of Principal Showers.—The following is a list of the chief radiant points visible during the year:

Many meteors exhibit the green line of magnesium as a principal constituent. Professor N. von Konkoly remarked in the fireball of 1873 (July 26) the lines of magnesium and sodium. Other lines in the red and green have been detected and found by comparison with the lines of marsh gas. Bright meteors often emit the bluish-white light suggestive of burning magnesium. In addition to magnesium and sodium the lines of potassium, lithium and also the carbon flutings exhibited in cometary spectra, has been seen.

Meteoric observation has depended upon rough and hurried eye estimates in past years, but the importance of attaining greater accuracy by means of photography has been recognized. At several American observatories, and at Vienna, fairly successful attempts were made in November 1898 to photograph a sufficient number of meteor-trails to derive the Leonid radiant, and the mean position was at R.A. 151° 33' Dec. +22° 12'. But the materials obtained were few, the shower having proved inconspicuous. The photographic method appears to have practically failed during recent years, since there has
METEORA—METEORITE

been no brilliant display upon which to test its capacity. Really large meteors can be satisfactorily photographed, but small ones leave no impression on the plates.

Meteors look larger than they are, from the glare and flaming effect due to ground momentum combustion. The finer meteors on entering the air only weigh a few hundred or, at most, a few thousand pounds, while the smallest shooting stars visible to the eye may probably be equal in size to coarse grains of sand, and still be large enough to evolve the light presented by them (W. F. D.).

**METEORA**, a group of monasteries in Thessaly, in the northern side of the Peneus valley, not quite 20 m. W. of Trikkala, and near the village of Kalabaka (the ancient Aeginium, medieval stage or Stagio). From the Cambunian chain two masses of rock are thrust southward into the plain, surmounted by isolated columns from 85 to 300 ft. high, "some like gigantic tusks, some like sugar-loaves, and some like vast stalagmites," but all consisting of iron-red or reddish-brown conglomerate of gneiss, mica-slate, syenite and greenstone. The monasteries stand on the summit of these pillars; they are accessible only by aid of rope and net worked by a windlass from the top, or by a series of almost perpendicular ladders climbing the cliff. In the time of St Stephen’s, the peak on which it is built does not rise higher than the ground behind, from which it is separated by a deep, narrow chasm, spanned by a drawbridge. Owing to the confined area, the buildings are closely packed together; but each monastery contains beside the monks’ cells and water-cisterns, at least one church and a refectory, and some also a library. At one time they were fourteen in number, but now not more than four (the Great Monastery, Holy Trinity, St Barlaam’s and St Stephen’s) are inhabited by more than two or three monks. The present church of the Great Monastery was erected, according to Leake’s recording of the local inscription, in 1388 (Björnsthål, the Swedish traveller, had given 1321), and it is one of the largest and handsomest in Greece. A number of the manuscripts from these monasteries have now been brought to the National Library at Athens. Aeginium is described by Livy as a strong place, and is frequently mentioned during the Roman wars; and Stagus appears from time to time in Byzantine writers.

**METEORITE**, a mass of mineral matter which has reached the earth’s surface from outer space. Observation teaches that the fall of a meteorite is often preceded by the flight of a fireball (see METEOR) through the sky, and by one or more loud detonations. It was inferred by Chladni (1794) that the fireball and the detonations result from the quick passage of the meteorite through the earth’s atmosphere.

The fall of stones from the sky, though not credited by scientific men till the end of the 18th century, had been again and again placed on record. One of the most famous of meteorites fell in Phrygia and was worshipped there for many generations under the name of Cybele, the mother of the gods. After an oracle had declared that possession of the stone would secure to the Romans a continual increase of prosperity, it was demanded by them from King Attalus about the year 204 B.C., and taken with great ceremony to Rome. It is described by the historian as "a black stone, in the figure of a cone, circular below and ending in an apex above." Plutarch relates the fall of a stone in Thrace about 470 B.C., during the time of Pindar, and according to Pliny the stone was still preserved in his day, 500 years afterwards. Both Diana of the Ephesians "which fell down from Jupiter," and the image of Venus at Cyprus, appear to have been conical or pyramidal stones. One of the holiest relics of the Moslems is preserved at Mecca, built into a corner of the Kaaba; its history goes back far beyond the 7th century; the description of it given to Dr Parthey suggests that the stone had fallen from the sky. The oldest existing meteorite of which the fall is known to have been observed is that which fell at Ensisheim in Elsass on the 10th of November 1492. It was seen to strike the ground and was immediately dug out; it had penetrated to a depth of 5 ft. and was found to weigh 260 lb. It was long suspended by a chain from the roof of the parish church, and is now kept in the Rathhaus of the town.

It was not till scientific men gave credence to the reports of the fall of heavy bodies from the sky that steps were taken for the formation of meteorite collections. The British Museum (Natural History) at South Kensington now contains specimens belonging to 56 distinct falls; of these falls 325 have been actually observed; the remaining specimens are inferred to have come from outer space, because their characters are similar to those of the masses which have been seen to fall. Of these meteorites the following twelve have fallen within the British Isles:

Meteoric falls are independent of thunderstorms and all other terrestrial circumstances; they occur at all hours of the day and night, and at all seasons of the year; they favour no particular latitudes. The number of stones which reach the earth’s surface from one fireball is very variable. In each of the two Yorkshire falls only one stone was found; the Guernsey County meteor yielded 50; at Toulouse, as many as 350 are estimated to have fallen; at Hesse, over 500; at Knyahinya, more than 1000; at L’Aigle, from 1000 to 2000; at both Pultusk and Mocs no fewer than 100,000 are estimated to have reached the earth’s surface. The largest single mass seen to fall is one of those which came down at Knyahinya, Hungary, in 1866, and weighed 347 lb; but far larger masses, inferred from their characters to be meteorites, have been mentioned in the British Museum (Natural History), before rusting weighed 33 tons; the largest of the masses brought by Liut. Peary from western Greenland weighs 364 tons. A mass found at Bacubiritú in Mexico is 13 ft. long, 6 ft. wide and 5 ft. thick, and is estimated to weigh 50 tons.

From observations of the path and time of flight of the luminous meteor it is calculated that meteorites enter the earth’s atmosphere with absolute velocities ranging from 10 to 45 m. a second; but the speed of a meteorite after the whole of the resisting atmosphere has been traversed is extremely small and comparable with that of an ordinary falling body. According to Professor A. S. Herschel’s experiments, the meteorite which fell at Middlesbrough must have struck the ground with a velocity of only 42 ft. a second. In the case of the Hesse fall, several stones fell on the ice, which was only a few inches thick, and rebounded without breaking the ice or being broken themselves. The depth to which a meteorite penetrates depends on the speed, form, weight and density of the meteorite and on the nature of the ground. At Stannerv a meteoric stone weighing 2 lb entered to a depth of only 4 in. The largest Knyahinya stone already mentioned made a hole 11 ft. deep.

The area of the earth’s surface occupied by towns and villages being comparatively small, the probability of a shower of stones falling within a town is extremely minute; the likelihood of a living creature being struck is still more remote. The first Yorkshire stone, that of Wold Cottage, struck the ground only 70 yds. from a labourer; the second, that of Middlesbrough, fell on the railroad only 40 yds. away from some platelayers at
work; a stone completely buried itself in the highway at Kaba; one fell between two carters on the road at Charscville, throwing the ground up to a height of 6 ft.; the Tourniase-la-Grosse meteorite broke the pavement, and was broken itself; the Ktelhenberg stone fell within a few paces of a little girl; the Angers stone fell close to a lady standing in her garden; the Brauna mass went through the roof of a cottage; at Macao, in Brazil, where there was a shower of stones, some oxen are said to have been killed; at Nedagolla, in India, a man was so near that he was stunned by the shock; while at Mhow, also in India, a man was killed in 1827 by a stone which is a true meteorite, and is represented by fragments in museum collections.

Though the surface of a meteoric stone becomes very hot during the fall, yet it cools again during the later and slower part of the flight. Meteorites are generally found to be warm to the touch if immediately dug out; at the moment of their impact they are not hot enough to char woody fibre on which they chance to fall, nor is the surface then soft, for terrestrial matter with which the surface comes into contact makes no impression upon the meteorite. Where many stones fall at the same time they are generally distributed over a large area elongated in the direction of the flight of the luminous meteor, and the largest stones generally travel farthest. At Hesse, for instance, the stones were distributed over an area of 500,000 square miles.

Meteorites are almost invariably found to be completely covered with a thin crust such as would be caused by intense heating of the material for a short time; its thinness shows the slight depth to which the heat has had time to penetrate. They are presumably cold and invisible when they enter the earth's atmosphere, and become heated and visible during their passage through the air; doubtless the greater part of the superficial material ficks off as the result of the sudden heating and is left behind heating in the air as the trail of the meteor. The crust varies in aspect with the mineral composition of the meteorite; it is generally black; it is in most cases dull but is sometimes lustrous; more rarely it is dark-grey in colour. Each stone of a shower is in general completely covered with crust; but occasionally, as in the case of the Butsura fall, stones found some miles apart fit each other closely and the fitting surfaces are uncruited, showing that a meteorite may break up during a late and cool stage of the flight through the atmosphere. A meteorite is generally covered with pittings which have been compared in size and form to thumbmarks; the pittings are probably caused by carbonaceous matter in the meteorite, and are found on the superficial material. As picked up, complete and covered with crust, meteorites are always irregularly-shaped fragments, such as would be obtained on breaking up a rock presenting no regularity of structure.

About one-third, and those the most common, of the chemical elements at present recognized as constituents of the earth's crust have been met with in meteorites; no new chemical element has been discovered. The most frequent or plentiful in their occurrence are: aluminium, calcium, carbon, iron, magnesium, nickel, oxygen, phosphorus, silicon and sulphur; while less frequently or in smaller quantities are found antimony, arsenic, chlorine, chromium, cobalt, copper, hydrogen, lithium, manganese, nitrogen, potassium, sodium, strontium, tin, titanium, vanadium. The existence of minute traces of several other elements has been announced; of these special mention may be made of gallium, gold, iridium, lead, platinum and silver. Iron occurs chiefly in combination with nickel, and phosphorus almost always in combination with both nickel and iron (schreibersite); carbon occurs both as indistinctly crystalized diamond and as graphitic carbon, the latter generally being amorphous, but occasionally having the forms of cubic crystals (cliftonite); free phosphorus has been found in one meteorite; free sulphur has also been observed, but may have resulted from the decomposition of a sulphide since the fall of the stone.

Of the mineral constituents of meteorites, the following are by many mineralogists regarded as still unrepresented among native terrestrial products: cliftonite, a cubic form of graphitic carbon; phosphorus; various alloys of nickel and iron; moissanite, silicide of carbon; enechite, carbide of iron and nickel (corresponding to cementite, carbide of iron, found in artificial iron); schreibersite, phosphide of iron and nickel; trinitite, protoporphyrin of iron; oldhamite, sulphide of calcium; esborinite, oxyxalpohide of calcium and titanium or zirconium; daubréelite, sulphide of iron and chromium; lawrencite, protophosphate of iron; asmanite, a species of silica; maskelynite, a single refractive mineral from the meteorite; taubolite, a silicate intermediate in chemical composition to pyroxene and nepheline.

Trollite is perhaps identical with some varieties of terrestrial pyrrhotite; asmanite has characters which approach very closely to those of terrestrial tridymite; maskelynite, according to one view, is the result of fusion of labradorite, according to another, is an independent species chemically related to leucoxene. Other compounds are present corresponding to the following terrestrial minerals: olivine and forsterite; enstatite and bronzite; diopside and augite; anorthite, labradorite and olivine; magnetite and chromite; pyrites; pyrrhotite; breunnerite. Quartz (silica), the most common of terrestrial minerals, is absent from the stony meteorites; but from the Toloca meteoric iron microscopic crystals have been obtained of which some have certain resemblances to quartz, and others to zircon. Free silica is present in the Breitenbach meteorite but as asmanite. In addition to the above there are several compounds or mixtures of which the nature has not yet been satisfactorily ascertained.

Meteorites are conveniently distributed into three classes, which pass more or less gradually into each other: the first (siderolites or meteoric iron) is mainly of metallic iron alloyed with nickel; only nine of them have been actually seen to fall; the second (siderolites) includes those in which metallic iron ( alloyed with nickel) and stony matter are present in large proportion; few of them have been seen to fall; those of the third class (aerolites or meteoric stones) consist almost entirely of stony matter; nearly all have been seen to fall.

In the meteoric irons the iron generally varies from 80 to 95% and the nickel from 6 to 10%; the latter is generally alloyed with carbon, and several also contain a chemical component of iron (plessite) distinguished by special names (kamacite, taenite, plessite). Trollite is frequently present as plates, veins or large nodules, sometimes surrounded by graphite; schreibersite is almost always present, and occasionally also daubréelite. The compositeness and the structure of meteoric iron are well shown by the figures generally called into existence when a polished surface is etched by means of acids or bromine-water; they are due to the inequality of the etching action on thick and thin plates of various constituents, the plates being composed chiefly of two nickel-iron compounds: kamacite (octahedral) and taenite (cubic). A meteoric iron (plessite) fills up the spaces formed by the intersection of the joint plates of kamacite and taenite; it is probably not an independent substance but an intertimate intergrowth of kamacite and taenite. The figures were first observed in 1808 and are generally termed "Widmanstätten figures" in honour of their discoverer; the plates which give rise to them are parallel to the faces of the regular octahedron, and such masses have therefore an octahedral structure. A small number of the remaining masses have cubic cleavage; instead of Widmanstätten figures they yield fine linear furrows when etched; the furrows (ternite, etc.) and several also have directions such as would result from twinning of the cube about an octahedral face; they are known as "Neumann lines." For meteoric irons of cubic structure the percentage of nickel is lower than 6 or 7; for those of octahedral structure it is higher than 0 or 7; the plates of kamacite are thinner, and the structure therefore finer the higher the percentage of that metal. A considerable number of meteoric irons, however, show no crystalline structure at all, and have percentages of nickel both below and above 7; it has been suggested that each of these masses may once have had crystalline structure and that it has disappeared as a result of prolonged heating about the mass while the meteorite has been passing near a star.

An investigation of the changes of the magnetic permeability of the Sacramento meteoric iron with changing temperature led Dr S. W. J. Smith to infer that the magnetic behaviour can only be explained by imagining the meteorite to consist
largely of plates of nickel-iron containing about 7% of nickel (kamacite), separated from each other by thin plates of a nickel-iron constituent (taenite), containing about 37% of nickel and having different thermomagnetic characters from those of kamagate; he suggests, however, that taenite is not a definite chemical compound but a eutectic mixture of kamagate and a nickel-iron compound containing not less than 37% of nickel. About eleven out of every twelve of the known meteoric stones belong to a division to which Rosé gave the name "chondritic" (χόνδρος, a grain); they present a very fine-grained but crystalline matrix or paste, consisting of olivine and enstatite or bronzite, with more or less nickel-iron, troilitie, chromite, augite and troilitie lepidol; through this paste are disseminated round chondrules of various sizes and generally with the same mineral composition as the matrix; in some cases the chondrules consist wholly or in great part of glass. Some meteorites consist almost solely of chondrules; others contain only few; in some cases the chondrules are easily separable from the surrounding material. In mineral composition chondritic meteorites approximate more or less to terrestrial lherzolites.

A few meteorites belonging to the chondritic division are remarkable as containing carbon in combination with hydrogen and oxygen; those of Alais and Cold Bokkeveld are good examples.

The remaining meteoric stones are without chondrules and contain little or no nickel-iron; of these the following may be mentioned as illustrative of the varieties of mineral composition: Juvinias, consisting essentially of anorhite and augite; Petersburg, of anorhite, augite and olivine, with little chromite and nickel-iron; Busetras, of enstatite and a little triclinic lepidol, with some nickel-iron, olivine and bronzite; Bishopville, of enstatite and triclinic lepidol, with occasional augite, nickel-iron, troilitie and chromite; Randol, of olivine and bronzite; and Chatanary, consisting of olivine with enclosed chromite, and thus mineralogically identical with terrestrial dunite.

Almost all meteoric stones appear to be made up of irregular angular fragments, and some of them bear a close resemblance to volcanic tuffs. In the large group of chondritic stones, chondrules or spherules, some of which can only be seen under the microscope while others reach the size of a walnut, are embedded in a matrix apparently made up of minute splinters such as might be produced by the fracture of a rock or the violence of a volcanic explosion. In fact, until recently it was thought by some mineralogists that the chondrules owe their form, not to crystallization, but to friction, and that the matrix was actually produced by the wearing down of the chondrules through frequent collision with each other as oscillating components of a comet or during repeated ejection from a volcanic vent of some small celestial body. Chondrules have been observed, however, presenting forms and crystalline surfaces incompatible with such a mode of formation, and others have been described which exhibit features resulting from mutual interference during their growth. The chondritic structure is different from anything which has yet been observed in terrestrial rocks, and the chondrules are distinct in character from those observed in peridot and obsidian.

It is now generally believed that the structural features of meteoric stones are the result of hurried crystallization. No organized matter has been found in meteorites and they have brought us, therefore, no evidence of the existence of living beings outside our own world.

AUTHORITIES.—The literature consists chiefly of memoirs dispersed among the official records of some of the meteoric societies. The following separate works may be consulted: A. Brezina, Die Meteoriten, Sammlung der k.k. min. Hofkabinetes in Wien (Vienna, 1886); A. Brezina u. E. Cohen, Die Struktur und die Zusammensetzung der Meteoriten (Stuttgart, 1886-1889); P. S. Bigot de Montaigne, Memorie historique et physique sur les chutes des pierres (Orléans, 1812); Chladni, Über den Ursprung der von Pallas gefundenen und anderer fürwahrten Eitemassen (Riga, 1794), and Uber die mineralischen Körner und über die mit denselben heraufgekommenen Massen (Vienna, 1819); E. Cohen, Meteoritenkunde (Stuttgart, 1864-1909); L. Fletcher, An Introduction to the Study of Meteorites, 10th ed. (London, 1968); E. King, Remarks concerning Stones said to have fallen from the Clouds both in these and in Ancient Times (London, 1796); S. Meunier, Météorites (Paris, 1884); C. Rammelsberg, Die chemische Natur der Meteoriten (Berlin, 1870-1879); G. Rosé, Beschreibung und Eintheilung der Meteoriten (Berlin, 1609); T. Schmerk, Die meteorologische Beschaffenheit der Meteoriten (Stuttgart, 1883-1885); E. A. Völling, Die Meteoriten in Sammlungen und ihre Literatur (Thiebarg, 1897).
was compiled in facsimile by George C. Symons in 1891. Doubtless many similar monastic diaries have been lost to us. In 1853 Ferdinand H. of Tuscany organized a local system of stations and daily records which extended over and beyond Tuscany, and the transparency of the instrument and the transmission of various meteorological systems in Europe. The records kept during the years 1855-1870 at the Cloister Angelus near Florence were reduced by Libri, professor of mathematics at Pisa, and published in 1870. The history of meteorology is marked by the production of comprehensive treatises embodying the current state of our knowledge. Such were Louis Cotte's Traité de météorologie (Paris, 1774) and his Mémoires sur la météorologie, supplément au traité (1788); Ludwig Kämtz's Lehrbuch der Meteorologie (Halle, 1831-1836) and his Vorlesungen (1840; French, 1842, English, 1843, Italian, 1845); Sir John Herschel's Meteorology (London, 1840; the splendid series of memoirs by H. W. Brandes in Gehler's Physikalisches Wörterbuch (Leipzig, 1820-1840); E. E. F. W. Schmid's Grundriss der Meteorologie (Leipzig, 1862); Ferrel's Recent Advances in Meteorology (Washington, 1885); the great works of Julius Hann, as summarized in his Handbuch der Klimatologie (1883, 2nd ed., Stuttgart, 1897; vol. I, English 1903) and his Lehrbuch der Meteorologie (Leipzig, 1901, 2nd ed. 1909); the extensive studies of J. E. Woeikoff (Voeikof), as presented in his Klima der Erde (Russian, 1893, German 1894) and his Meteorology (Russian 1904). The development of this science has been greatly stimulated by the regular publication of special periodicals such as the Zeitschrift of the Austrian Meteorological Society, 1866-1885, vol. 21 appearing with vol. 3 of the Meteorologische Zeitschrift of the German Meteorological Society in 1886, and since that date this journal has been jointly maintained by the two societies. The analogous journals of the Royal Meteorological Society, London, 1830 to date, the Scottish Meteorological Society, 1860 to date, the Meteorological Society of France, 1838 to date, the Italian Meteorological Society, and the American Meteorological Society, have all played important parts in the history of meteorology. On the other hand, the Annals of the Central Meteorological Office at Paris, the Archive of the Deutsche Seewarte at Hamburg, the Annals and the Report of the Central Physical Observatory at St Petersburg, the Annals of the Central Meteorological Office at Rome, Bulletin of International Simultaneous Mt. Obs. and the Monthly Weather Review of the Weather Bureau at Washington, the Abhandlungen of the Royal Prussian Meteorological Institute at Berlin, the Meteorological Papers of the Meteorological Office at St Petersburg, and numerous journals of meteorological societies, have represented the important official contributions of the respective national governments to technical meteorology. The recent international union for aerial exploration by kites and balloons has given rise to two important publications, i.e. the Veröffentlichungen of the International Commission for Scientific Aerostatics (Strassburg, 1905, etc.), devoted to records of observations, and the Beiträge zur Physik der freien Atmosphäre (Strassburg, 1904, etc.), devoted to research. The necessity of studying the atmosphere as a unit and of securing uniform accuracy in the observations has led to the formation of the International Meteorological Committee (of which in 1900 the secretary was Professor Dr G. Hellmann of Berlin, and the president Dr W. N. Shaw of London). Under its directions conferences and general congresses have been held, beginning with that of 1872 at Leipzig. Its International Tables, Atlas of Clouds, Codex of Instructions, and Forms for Climatological Publications illustrate the activity and usefulness of this committee. Modern meteorology has been developed along two lines of study, based respectively on maps of monthly and annual averages and on daily weather maps. The latter study seems to have been begun by H. W. Brandes in Leipzig, who first, about 1820, compiled maps for 1783 from the data collected in the Ephemerides manheimensis, and subsequently published maps of the European storms of 1820 and 1821. Simultaneously with Brandes we find William C. Redfield in New York compiling a chart of the hurricane of 1821, which was published in 1834, and was the first of many memoirs by him on hurricanes that completely established their rotary and progressive motion. Soon after this Fiddington and Sir William Reid began their great work on the storms of the continent. About 1825 James Pollard Esqy, in Philadelphia, began the publication of his maps as to the motive power of thunderstorms and tornadoes, and in 1842 was appointed "meteorologist to the U.S. government" and assigned to work in the office of the surgeon-general of the army, where he prepared daily weather maps that were published in his four successive "Reports." In 1848 the three American leaders united in letters to Professor Joseph Henry, secretary of the Smithsonian Institution, urging that the telegraph be used for collecting data for daily maps and that action was taken in 1840, the Smithsonian maps began to be compiled for the southern states and were displayed in public from 1853 onwards. Meanwhile in England James Glaisher, with the help of the daily press, carried out similar work, publishing his first map in 1851 as soon as daily weather maps of sufficient extent could be promptly prepared by the help of the telegraph. The destructive storm of the 14th of November 1854, in the Crimea gave U. J. J. Le Verrier, at Paris, an opportunity to propose the proper action, and his proposals were immediately adopted by the secretaries of the British and French scientific societies, and on the 17th of January 1855 the emperor ordered the director-general of government telegraphs to co-operate completely with Le Verrier in the organization of a bureau of telegraphic meteorology. The international daily bulletin of the Paris Observatory began to be printed in regular form on the 1st of January 1858, and the daily map of isobars was added to the text in the autumn of 1863. The further development of this bulletin, the inclusion of British and ocean reports in 1861, the addition of special storm warnings in 1863, the publication of the Atlas des mouvements généraux de l'atmosphère in 1865, the study of local thunderstorms by Stommel of Munich and the Marquis de la Faye in France, and the work of Fitzroy, Buys-Ballot, Buchan, Glaisher and Thomson in Great Britain, parallel the analogous works of the American students of meteorology and form the beginnings of our modern dynamic meteorology.

The details of the historical development of this subject are well given by Hugo Hildebrand-Hildebrandsson and Léon Tissier de Bort in their joint work, Les Bases de la météorologie dynamique (1903); The first meteogram has been collected by Hann in his Lehrbuch. Many of the original maps have been reproduced by Brillouin in his Mémoires originaux (Paris, 1900), and in Cleveland Abbe's Mechanics of the Earth's Atmosphere (vol. i., 1897; vol. ii., 1909). The publication of daily weather charts and forecasts is now carried on by all civilized nations. The list of government bureaux and their publications is given in Bartholomew's Atlas (vol. iii., London, 1893). Special establishments for the study of upper atmospheric conditions are maintained at Paris, Berlin, Copenhagen, St Petersburgh, Washington and Strassburg. The general problems of climatology (1900) are best presented in the Handbook of Dr Julius Hann (2nd ed., Stuttgart, 1897). The general distribution of temperature, winds and pressure over the whole globe was first given by Buchan in charts published by the Royal Society of Edinburgh in 1866, and again greatly revised in the volume of the Challenger reports devoted to meteorology. The most complete atlas of meteorology is Buchan and Herbertson's vol. iii. of Bartholomew's Atlas (London, 1899). Extensive works of a more special character have been published by the London Meteorological Office, and the Deutsche Seewarte for the Atlantic, Pacific and Indian Oceans. Daily charts of atmospheric conditions of the whole northern hemisphere were published by the U.S. Weather Bureau from 1875 to 1883 inclusive, with monthly charts, the latter were continued through 1889. The physical problems of meteorology were discussed in Ferrel's Recent Advances of Aeronautics (Washington, 1889).Mathematically important works have been made by Brillouin (Paris, 1898), entitled Vents contiguës et nuages. A general summary of our knowledge of the mechanics and physics of the atmosphere is contained in the Report on the International Cloud Work, by F. H. Bigelow (Washington, 1900). The extensive Lehrbuch (Leipzig, 1901: 2nd ed., 1906) by Dr Julius Hann is an authoritative work. The optical
METEOROLOGY

I. FUNDAMENTAL PHYSICAL DATA

There can be no proper study of meteorology without a consideration of the various physical properties of the atmospheric gases and vapours, each of which plays an independent part, and yet also reacts upon its neighbours.

Atmospheric air is a mixture of nitrogen, oxygen, aqueous vapour, carbonic acid gas (carbon dioxide), argon, neon, helium, with slight traces of free hydrogen and hydro-carbons. The proportions in which these gases are present are quite constant, except that the percentage of aqueous vapour is subject to large variations. In an atmosphere that is saturated with water vapour, the temperature of 0°C, as may occur in such a climate as that of Calcutta, the water may be 23% of the whole weight of any given volume of air. When this aqueous vapour is entirely abstracted, the remaining dry gas is found to have a very uniform constitution in all regions and at all altitudes where examination has been carried out. In this so-called dry atmosphere the relative weights are about as follows: Oxygen, 23.16; nitrogen and argon, 76.77; carbonic acid, 0.04; ammonia and all other gases, less than 0.01 in the lower half of the atmosphere, but probably not very much less in the great altitudes. Of the elements of light, the very highly volatile gases, argon (g.v.), neon, krypton and helium (g.v.).

Other Limit.—These exceedingly volatile components of the atmosphere cannot apparently be held down to the earth by the attraction of gravitation, but are continually diffusing through the atmosphere outwards into interstellar space, and possibly also from that region back into the atmosphere. There are doubtless other volatile gases filling interstellar space and occasionally entering into the atmosphere of the various planets as well as of the sun itself; possibly the hydro-carbons and hydro-carbons that escape from the earth into the lower atmosphere ascend to regions inaccessible to man and slowly diffuse into the outer space. The laws of diffusion show that for each gas there is an altitude at which as many molecules diffuse inward as outwards in a unit of time. This condition defines the outer limit of each particular gaseous atmosphere, so that we must not imagine the atmosphere of the earth to have any general boundary. The only indication we have to this point lies far above the clouds, where the light, the moon, and the stars of the planets shines upon us as if it resulted from what we call our atmosphere. (See C. C. Trowbridge, On Luminous Meteor Trains and "On Movements of the Atmosphere at Very Great Heights," Monthly Weather Review, Sept. 1907.)

Such observations are supposed to show that there is an appreciable quantity of gas at the height of 100 m. above it, where may have a density of a millionth part of that which prevails at the earth's surface. Such matter is not a gas in the ordinary use of that term, but is a collection of particles moving independently of each other under those influences that emanate from sun and earth, which we call radiant energy. According to Störmer this radiant energy is that of electrons, that is, as may occur that the beautiful region of the globe come from the phenomena of the Aurora, the refraction of light, the morning and evening-twilight, and especially from the shadow of the earth suddenly being thrown outwards by what we call its weather, into what we call our atmosphere. (See C. C. Trowbridge, On Luminous Meteor Trains and "On Movements of the Atmosphere at Very Great Heights," Monthly Weather Review, Sept. 1907.)

In addition to the gases and vapours in the atmosphere, the motes of dust and the aqueous particles that constitute cloud, fog and haze are also important. As all these float in the air, slowly descending, but resisted by the viscosity of the atmosphere, their whole weight is added to the atmosphere and becomes a part of the barometric record. When the air is cooled to the dew-point and condensation of the vapours begins, it takes place first upon the atoms of dust as nuclei; consequently, air that is free from dust is scarcely affected except with low temperature.

Mass.—According to a calculation published in the U.S. Monthly Weather Review for February 1899, the total mass of the atmosphere is 1.1,25,000,000 of the mass of the earth itself but, according to Professor R. W. Ferrel, the weight is by an order of magnitude, and this by a factor of seven. The dynamical theory shows that there may possibly be a gaseous envelope whose weight is not felt at the earth's surface, since it is held in dynamic equilibrium above the atmosphere; the mass of this outer atmosphere cannot exceed 1/900th of the mass of the earth, and is probably far less, if indeed it be at all appreciable.

Conductivity.—Dry air is a poor conductor of heat, its coefficient of conduction being expressed by the formula: 0-000 0568 (1-o-o019t) where the temperature (t) is expressed in centigrade degrees. This formula states the fact that a plate of air 1 centimetre thick can conduct through its substance for every square centimetre of its area one second of time, when the difference of temperature between two faces of the plate is 1° C., enough heat to warm 1 gram of water 0-000 0568° C., or 1 gram of air 0-000 239° C., or a mass of air 0-000 239° C. This is the coefficient of air for the altitude of 750 millimetres of pressure and 6° C. The figure 0-0589° C. is the thermometric coefficient as distinguished from the first or calorimetric coefficient (0-000 0568° C.), and shows what great effect on the air has the effect of poor heat and thus the general coefficient of transmission for the thickness of one atmosphere is usually estimated at about 60%. Of course when the rays are more oblique, or when haze, dust or cloud interfere, the transmission
is still further diminished. In general one half of the heat received from the sun by the illuminated terrestrial hemisphere is absorbed by the clearest atmosphere, leaving the other half to reach the surface of the ground, provided there be no intercepting clouds. The thermal condition observed at the immediate surface of the globe during hazy and cloudy weather are therefore of minor importance in the mechanism of the whole atmosphere, as compared with the influence of that which is retained within its limits.

The transmission of solar radiation through the earth's atmosphere is the fundamental problem of meteorology, and has been the subject of many studies, beginning with J. H. Lambert and P. Bouguer. The pyrheliometer of C. S. M. Pouillet gave us our first idea of the thermal equivalent of solar radiation outside of our atmosphere or the so-called "solar constant," the value of which has been variously placed at from 2 to 4 calories per sq. cm. per minute. At present the weight of the argument is in favour of 2.4, with a fair presumption that both the intensity and the quality of the solar radiation as it strikes the upper layers of our atmosphere are slightly variable. It is also likely that this "layering" does not represent the sun proper, but the remaining energy after the sunbeam has slanted through layers of matter between the sun and our upper atmosphere, so that it may thus come to have appreciable variations.

The coefficients of absorption for specific wave-lengths were first determined by L. E. Jewell, of Johns Hopkins University, for numerous vapour lines in 1892 (see W. B. Bulletin, No. 16). In 1904 C. G. Abbot published a table based on bolograph work at Washington, showing the coefficients of atmospheric transmission for solar rays passing through a unit mass of air—namely, from the zenith to the ground. He showed that this coefficient increased with the wave-length; hence any change in the quality of the solar radiation will affect the general coefficient of transmission. The following table gives his averages for the respective wave-lengths, as deduced from ten clear days in 1901-1902 and nine clear days in 1903:

Any variation in the energy that the atmosphere receives from the sun will have a corresponding influence on meteorological phenomena. Such variations were simultaneously announced in 1903 by Charles F. Brooks and H. H. Knall in Washington (Monthly Weather Review, May 1903); the latter was then conducting a series of observations with Angström's electric compensation pyrheliometer, and his conclusions have been confirmed by the work of L. Goryevas at Pogrestchik (1901-1906)and C. G. Abbot at Washington. Kimball's pyrheliometric work on this problem is still being continued; but meanwhile Abbot and Fowle from their bolometric observations at the Smithsonian Astrophysical Observatory have deduced preliminary values of the observed total energy, or the solar constant, for numerous dates when the sky was very clear, as follows (see Smithsonian Misc. Coll., xlvii. 78 and xlviii. 403, 1905):

If the relative accuracy of these figures is 1%, as estimated by Abbot, then they demonstrate irregular fluctuations of 5%. But different observers and localities vary so much that Abbot estimates the reliability of the mean value, 2.12, to be about 10%. The causes of such variation appear to be the result of local conditions, which move slowly eastward from day to day, and as the variability is comparable with that of other atmospheric data, therefore considerable in an explanation of terrestrial phenomena under the assumption of a constant solar radiation. The large local changes of weather and climate are not due to changes in the sun, but to the mechanical conditions of the earth and atmosphere. Illustrations of this point are found in the studies of Blanford, Eliot and Walker on the monsoons of India, of Sieger (1892) on the contrasts of temperature between Europe and North America and between the atmosphere and the ice of the antarctic seas. Excellent illustrations of this principle are found in the studies of Meinardus (1906) on periodical variations of the icecord near Iceland.

The absorption of solar radiation by the atmosphere is apparently explained by the laws of diffuse reflection, selective diffusion and fluorescence in accordance with which each atom and molecule and particle becomes a new centre for the diffusion in all directions of the energy represented by some specific wave-length. The specific influences of carbon dioxide and water vapour are less than those of the liquid particles (and of cloud and rain) and of the great mass of the air and nitrogen, as deduced from the density of the 1 atmosphere.

Specific Heat.—The capacity of dry air for heat varies according as the heat increases the volume of the air expanding under constant pressure, or the pressure of the air confined in constant volume. The ratio of the specific heat under slight pressure to its specific heat under constant volume. The numerical value of the specific heat under constant pressure is about 1.25, that is, to say, that one gram-calorie, or units of heat, is required to change the condition of 1 gram of air by 1° centigrade. The latter is determined in the condensation of this moisture is a matter of great importance in the formation of cloud and rain.

Radiating Power.—The radiating power of clear dry air is so small that it cannot be measured quantitatively, but the spectroscope and bolometer demonstrate its existence. The coefficient of radiation of the moisture diffused in the atmosphere is combined with that of the particles of dust and cloud, and is near equal to that of an equal surface of lamp-black. From the common diurnal change in temperature at high and low stations, it should be possible to determine the general coefficient of atmospheric radiation for the average condition of the air in so far as this is influenced by the condition of the winds. This was first done by J. Mairer in 1885, who obtained a result in calories that may be expressed as follows: the total radiation in twenty-four hours per unit mass of air towards an enclosure whose temperature is 1° lower is sufficient to lower the temperature of the radiating air by 3.1 °C. in twenty-four hours. This very small quantity was confirmed by observations of Trabut at 1859, who found that the radiation of air at 278° absolute temperature radiates 0.1675 calories per minute toward a black surface at the absolute zero. The direct observations of C. C. Hutchins on dry dusty air, as published in 1890, gave a larger value, namely, 0.25 calories per minute. Slight changes in water, vapour and carbon dioxide affect the radiation greatly. The investigation of this subject prosecuted by Professor F. W. Very at the Allegheny Observatory, and published as "Bulletin G" of the U.S. Weather Bureau, shows the character and amount of the radiation of several gases, and especially the details of the process going on under normal conditions in the atmosphere.

The absorbed or massed amount of a cubic centimetre of dry air at the standard pressure, 760 millimetres, and temperature 0°C., is 0.001 29335 grams; that of a cubic metre is 1.29335 kilograms; that of a cubic foot is 0.08071 lb avoirdupois. The variations between the pressure with the temperature of the atmosphere are given in the Smithsonian meteorological tables, and give rise to all the movements of the atmosphere; they are, therefore, of fundamental importance to dynamic meteorology.

Elasticity.—The air is compressed nearly in proportion to the pressure it exerts, that is, temperature and volume of the ideal gas are connected by the equation \( pV = RT \), where \( T \) is the absolute temperature or 273 ° plus the centigrade temperature \( p \) is the barometric pressure in millimetres and \( V \) the volume of a unit mass of air, and \( R \) is the constant in -272 for dry atmospheric air when the centimetre,
METEOROLOGY

There is a certain condition of the atmosphere which has been adopted for many purposes as a standard. This condition is known as the 'sea-level' condition, and it is a condition in which the pressure of the atmosphere is 1013 millibars, the temperature is 15°C, and the relative humidity is 80%. This condition is useful for comparing weather data from different locations and times.

The movement of air and the transfer of heat are fundamental processes in the atmosphere. These movements are driven by differences in temperature and pressure, which in turn are influenced by the Earth's rotation, the uneven heating of the Earth's surface by the sun, and the interaction of the oceans and atmosphere.

The energy transfer in the atmosphere is a complex process that involves the conversion of solar energy into kinetic energy of wind. This energy conversion is influenced by the Earth's geography, the Earth's orbit around the sun, and the orientation of the Earth's axis.

The Earth's atmosphere is composed of various gases, with the most abundant being nitrogen (78%) and oxygen (21%). The remaining 1% consists of argon, carbon dioxide, and other trace gases. The composition of the atmosphere is crucial for understanding weather patterns and climate change.

In summary, the atmosphere is subject to various forces and processes that shape weather patterns and climate. These include the rotation of the Earth, the uneven heating of the Earth's surface, and the interaction of the oceans and atmosphere.

[Physical Data]

**Data on Pressure, Temperature, and Humidity**

- **Pressure:**
  - Sea level: 1013 millibars
  - Mountain tops: 700 to 800 millibars
  - Enclosed vessels: 760 millibars

- **Temperature:**
  - Equatorial regions: 25°C to 30°C
  - Arctic regions: -10°C to -20°C

- **Humidity:**
  - Equatorial regions: 80% to 90%
  - Arctic regions: 10% to 20%

Average: 7 1/2

It is evident that the annual average vertical gradient of temperature over Paris is 16° in June and 6° in January. The 1000 feet losses of ascent in the free air, agreeing closely with the value 5° per 1000 feet, which has come into extensive use since the year 1890, on the recommendation and authority of Hann, for the reduction of land observations to sea-level; the winter gradients are less than those for summer, possibly owing to the influence of the condensation into cloud and rain during the winter season in France; the same value may not result from observations in the United States, where the clouds and precipitation of winter do not so greatly exceed those of summer. The work at Trappes is therefore not necessarily representatative of the general average of the northern hemisphere, but belongs to a coastal region in which during the summer time, at great heights, the air is cooler than in the winter time, since during the latter season there is an extensive flow of warm moist winds from the ocean over the cold east winds from the land. Sounding balloons have also been used with great success. The greatest heights attained by them have been 25,989 metres at Uccle, Belgium, on the 5th of September 1907, and 25,800 metres at Strassburg, August 1905.

The most extensive meteorological explorations of the free atmosphere have been those accomplished in Germany by Richard Assmann and Arthur Berson, beginning (1887) in co-operation with the German Verein for the Promotion of Aeronautics and the Aeronautical Section of the German Army, afterwards under the auspices of the Prussian Meteorological Office, but later as a wholly independent institution at Lindenburg. The details of their work during 1887-1889 and the scientific results of seventy balloon voyages were published in three large volumes, *Wissenschaftliche Lautlichtfahrten* (Berlin, 1900). The work done at Tegel at the Aeronautical Office of the Berlin Metropolitan Office, from the 1st of October 1899 to April 1905, was published in three volumes of *Ergebnisse*. But the location at Tegel had to be given up and

In this table the second column gives the altitude of the ground at the reel on which the kite wire was wound. The third column shows the average gradient in degrees Fahrenheit per 1000 feet between the reel at the respective stations, and a uniform altitude of 3200 feet above sea-level. The fourth column shows the total reduction to be applied to the temperature at the reel in order to obtain the temperature at the 1 m. level. The two columns show the readings and reductions are based upon observations made during the six warm months from May to October 1898.

The great work of L. Teisserenc de Bort began with 1897, when he founded his private observatory at Trappes near Paris devoted to the problems of dynamical meteorology, and which was published in full in the Memoirs of the Central Meteorological Bureau of France for 1897 and subsequent years. Beginning with the soundings given by Hermann the subsequently added kite work as supplementary to these. In the *Comptes rendus* (1904), he gives the mean temperatures as they result from five years of work, 1899-1903, at Trappes. Out of 858 ascensions of sounding balloons there were 141 that attained 14 km., or more, and the following table gives the average temperatures recorded in these ascensions. It will be seen that there is a slow decrease in temperature up to 2 km., a rapid decrease thence up to 10 km., and a slow decrease, almost a stationary temperature, between

Holland and Russia, amounting in all to 2000, enabled Assmann to compute the monthly and annual means of temperature and wind velocity for each altitude; the German results are given in table at foot of page 269.

The results of these numerous ascents, during these six years, have also been grouped into monthly means that have a reliability proportionate to the number of days on which observations were obtained at a given level, and we are now able to speak of the annual and even of the diurnal periodicity of temperature at different altitudes in the free air with considerable confidence.

Some of the most important conclusions to be drawn from the best recent work were published by Hann either in special memoirs or in his Lehrbuch, from which we take the following table. The actual temperatures given in this table have only local importance, but the differences or the vertical gradients doubtless hold good over a large portion of Europe if not of the world.

The differences of temperature between any layer and those above it and below it, or the vertical gradients at each level go through annual periodical changes quite analogous to those derived from mountain observations; the most rapid falls of temperature, or the largest vertical gradients in the free air occur on the 1st Moving days over Europe:

The values above given as deduced from 141 high ascents at Trappes show that between 11 and 14 km, there was no appreciable diminution of temperature, in other words, the air is warmer than could be expected and therefore has a higher potential temperature. This fact was first confirmed by the Berlin ascensions, and is now recognized as well-nigh universal. The altitude of the base of this warm stratum is about 12 km, in areas of high pressure and 10 km, in areas of low pressure. It is higher as we approach the tropics and above ordinary balloon work near the equator if indeed it exists there. At first this unexpected warmth was considered as possibly a matter of error in the meteorographs, but this idea is now abandoned. Assmann suggested that the altitude is that of the highest cirrus, from which Clevland and Able inferred that it had something to do with the absorption of the solar and terrestrial heat by dissolving cirrus. But the most plausible explanation that published simultaneously in September 1908 by W. J. Humphreys of Washington, and Ernest Gold of London.

The daily diagrams in Day Better show that both the irregular and the periodic and the geographic variations of temperature in the upper strata are unexpectedly large, almost as large as at the earth's surface, so that the uniform temperature of space that was formerly supposed to prevail in the upper air must be looked for, if at all, far above the level to which sounding balloons have as yet attained. It is evident that both horizontal and vertical convection currents of great importance really occur at these great altitudes. These upper currents cannot be due to any very local influence at the earth's surface, but only to the interchange of the air over the oceans and continents or between the polar and equatorial regions. They constitute the important feature of the so-called general circulation of the atmosphere, which have hitherto mistakenly thought of as confined to lower levels; their general direction is from west to east over all parts of the globe as far as yet known, showing that they are controlled by the rotation of the earth. It is likely that masses of air having special temperature conditions or clouds of vapour dust such as came from Krakatoa, may be carried in these high currents around the globe perhaps several times before being dissipated.

The average eastward movement of the west wind at 3 km above Germany is 10-7 m per sec. or 18° of longitude (at 45° latitude) in 424 minutes; or such as to describe the whole circumference of this small circle in 10-5 days. At the equator above the calm belt the velocity eastward or the east wind as given by Krakatoa volcanic-dust phenomena was 34-5 m per sec., on 30° of a great circle daily, or around the equator in 1° 37' 37". while its poleward movement was only 1.88° per day or 1.3 metre per second. The average motion of the storm centres moving westward in northern and equatorial regions but eastward in the north temperate zone is at the rate of one circumference or a small circle or latitude 45° in 19 days. Observations of the cloud movements gave Professor Bigelow the following results for the United States:

### Total Fall of Temperature from Ground upward.

Evidently, therefore, the great west wind (that James H. Coffin deduced from his work on the winds of the northern hemisphere and that William Ferrel deduced from his theoretical studies) represents with its gentle movement poleward a factor of fundamental importance. We must consider all our meteorological phenomena except at the equator as existing beneath and controlled, if not
caused, by this general deep swift upward current of air that began as an ascending east wind above the calm equatorial air but speedily overflowed the best wind settling down to the sea-level in the temperate and polar regions as great areas of high pressure and dry clear cool weather containing air on its return passage to the equator. This west wind currents towards some great low areas, and flooding the warm equatorial wind flows in beneath it, but when it descends we have blizzards and dry clear weather. It is a covering for the lower strata of air, it flows over them in standing waves and gives easterly winds, like a gale in the gulf stream. The latitude of the area to which it is believed to be associated, is that of the geographical pole, which is in latitude 72° N. But the sense of its motion is from west to east.

The topographic figures result from the use of Assmann's ventilated psychrometer and are therefore very reliable.

The vapour pressure in mm. in free air over Europe is best given by Süring's formula

$$\log e_v = e_0 + \frac{h}{9} \left[ \frac{1 + \frac{h}{20}}{A/6517} \right]$$

where the altitude is expressed in kilometres. From this formula we derive the "specific moisture" or the mass of vapour contained in a kilogram of moist air as given in the following table whose numbers do not appreciably differ from "the mixing ratio," or quantity of moisture associated with a kilogram of dry air.

The relative humidities vary irregularly depending on convection currents but in clear weather when descending waves prevail they have been observed in America and during Berlin of the third and fourth columns of the following table:

**Observed Specific Moisture and Relative Humidity.**

The total amount of vapour in the atmosphere, according to Hann's formula, is between one-fourth and one-fifth of the amount represented by the Dalton formula. The data are presented as a table taken from an article by Cleveland Abbe in the Smithsonian Report for 1888.

A heavy rainfall results from the precipitation of only a small percentage of the water contained in the fresh supplies of air brought by the wind; if all moisture were abstracted from the atmosphere, it could only affect the barometer throughout the equatorial regions by 2-8/136 inches, or about two-tenths of an inch, while at the polar regions the diminution would be much less than one-tenth. Evidently, therefore, it is idle to argue that the fall of pressure in an extensive storm is to be considered as the simple result of the condensation of the vapour into rain.

**Barometric Pressure.**—The horizontal distribution of barometric pressure over the earth is shown by the isobars, or lines of equal pressure at sea-level; it can also be expressed by a system of complex spherical harmonics. As the indications of the mercurial barometer must vary with the variation of apparent gravity, whereas those of the aneroid barometer do not, it has been agreed by the International Meteorological Conventions that for scientific purposes all atmospheric pressures, when expressed as barometric heights, must be reduced to one standard value of gravity, namely, its value at sea-level and at 45° of latitude. In this locality its value is such as to give in one second an acceleration of 980-8 centimetres, or 32-2 English ft. per second. The effect of the variation of apparent gravity with latitude is therefore to make the mercurial barometer read too high, between 0° and 23°, and between 45° and the pole. The gravity-correction to be applied to any mercurial barometric-reading at or near sea-level, in order to get the atmospheric pressure in

METEOROLOGY

standard units, should be given on the edge of a meteorological chart, unless the isolars shown thereon already contain this correction. The local standard barometric pressure at sea-level is by no means uniform over the earth's surface, and daily weather charts show very great fluctuations in this respect, the lowest pressures being found in the equatorial regions, the highest over the polar regions. These, however, vary considerably from day to day. But even the normal average charts show high pressures over the continents in the winter and low pressures over the oceans, these conditions being the result of the direct influence of the sun in its summer and winter declinations. The earth's atmosphere, which we mentioned in the last section, is composed of gases, and the most abundant of these is the nitrogen, which makes up over 78% of the atmosphere. The rest is mostly oxygen, with smaller amounts of argon, carbon dioxide, and other trace gases.

Clouds.—It is evident that the clouds (q.v.) are formed from that portion of the atmosphere which is saturated with moisture, and from which the invisible moisture therein is condensed into visible particles. Under certain conditions, these particles coalesce into larger masses, the result being a cloud. The size of a cloud is determined by the amount of moisture it contains, and the height at which it is formed. Clouds can be classified into several types based on their characteristics, such as altitude, density, and the type of aerosol that formed them.

Clouds are important in the Earth's climate system as they play a role in the radiation budget. They reflect incoming solar radiation and absorb outgoing infrared radiation, which helps regulate the Earth's temperature. Clouds also act as a barrier to the propagation of sound waves, and can influence the local climate by modifying the flow of air.

The study of clouds and their properties is essential in understanding the Earth's climate and weather patterns. Clouds can be observed using various techniques, such as satellite imagery, ground-based observations, and aircraft-based measurements. The data collected from these observations are used to improve weather forecasting models and to better understand the Earth's climate system.
The average annual speed of the winds increases from the northern latitudes towards the equator, and the speed of the winds in the northern latitudes is much greater than in the southern latitudes. The average annual speed of the winds in the northern latitudes is much greater than in the southern latitudes. The average annual speed of the winds in the northern latitudes is much greater than in the southern latitudes.

The movements of the upper clouds are more rapid in winter than in summer, and the movement of the clouds is much greater in the winter than in the summer. The movement of the clouds in the winter is much greater than in the summer. The movement of the clouds in the winter is much greater than in the summer. The movement of the clouds in the winter is much greater than in the summer.

### II. Meteorological Apparatus and Methods

The observational basis of meteorology is the frequent and, if possible, continuous record of the temperature, moisture and barometric pressure at different altitudes in the free atmosphere, the direction and velocity of the wind, the rain and snow, and the kind, amount and motion of the clouds. For Europe these data have been furnished with more or less accuracy and continuity by thousands of observers ever since 1653, when Ferdinand II, grand duke of Tuscany, organized a system of daily observations in Italy under the general supervision of Luigi Antinori. During the 18th century great efforts were made to obtain equally full records from all parts of the land and ocean, and thousands of navigators were added to the great corps of observers. Other matters have also been investigated, the most important being the intensity of radiation from the earth at night-time and from the sun by day-time, the optical phenomena of the sky, the amount of dust in the air, the electrical condition and the chemical constitution of the atmosphere. Although all the instruments used belong to the category of physical apparatus, yet certain points must be considered as peculiar to their use in connexion with meteorology.

**Thermometer.**—In using the thermometer to determine the temperature of the free air it is necessary to consider not merely its intrinsic accuracy as compared with the standard gas thermometer of the International Bureau of Weights and Measures at Paris, but especially its sluggishness, the influence of noxious radiations, the gradual change of its zero point with time, and the influence of atmospheric pressure.

1. We have here inserted the Washington data as interpolated from the figures given by Hann, Lehrbuch, 1906, p. 262.
in a fixed louver shelter, but by means of a ventilating apparatus drew currents of fresh air from below into the shelter, where they circulated rapidly and passed out. In Germany, since 1855, Dr. Assmann has developed a shield, the draught of which being known as the ‘dronus,’ is supposed to be an effective protection against the draught of a hurricane. The draught of a hurricane is raised, if the chimney is large, to about one-tenth of an inch in a 50-m. wind, and to nearly four-tenths in a 100-m. wind. The expression ‘dronus’ is used to describe the draught of a chimney. The maximum effect of the wind in raising the pressure is given by the formula, \( P = \frac{938 \times 3}{V^2} \), where the pressure is given in inches and the velocity in miles per hour. This amounts to about one-tenth of an inch in a 50-m. wind, and to nearly four-tenths in a 100-m. wind.

The draught of the chimney is usually less than this amount. This alteration in pressure, due to the local effect of wind, does not belong to the free atmosphere but to the method of exposure of the chimney, and is described by Abbe in 1852: it is a very different matter from the general diminution of pressure in the atmosphere produced by the movement of the wind or the barometric effect of a vortex. The latter is an atmospheric phenomenon, independent of instruments and locality, which in hurricanes and tornadoes may amount to several inches of the mercurial column. It is, however, quite possible to have a barometer showing a sudden diminution of pressure during a hurricane evidence of the fact that the low pressure due to the hurricane and the special diminution due to the exposure of the barometer are combined together, so that when the calm center of a hurricane is passed, the pressure rises by the amount due to the sudden stoppage of the wind and the local exposure effect.

The other sources of error that give rise to discrepancies in meteorological work in the instrument, or the sluggishness of the movement of the mercury, and the inevitable large secular changes in the correction for capillarity, due principally to the changes in the condition of the surfaces of the glass and the mercury, especially those that are exposed to the open air. The international comparisons of barometers show that discrepancies exist between the best normals or standards, and that ordinary barometers would move in two different directions that have not yet been determined, one movement being too fast and the other too slow, and the result is that the barometers would remain permanently depressed to an amount nearly proportional to the heating. The normal method of treatment consists in determining the average of the two, and, after allowing for the rise, determining the freezing-point. If this method is uniformly followed, the two fiducial points will stay in permanent relation to each other. A thermometer that has been used for many years by a faithful meteorological observer has almost inevitably been going through a steady series of changes; in the course of ten years its freezing-point may have risen by 2° or 3° F., and, moreover, it changes by fully a tenth of a degree between summer and winter.

Any motion of the air will have an influence upon the reading quite independently of the prevailing elastic pressures. The pressure within a mass of gas at any point is the summation of the effects due to the motions of the myriad molecules of the gas at that point; it is the kinetic energy of the molecules striking against one another and the sides of the enclosure, which in this case is the surface of the mercury in the cistern of the instrument. If the barometer moves with respect to the general mass of the gas there will be a change in the average kinetic energy of the molecules, whether there be none in the general mass of the free gas, and a barometer giving correctly the pressure of the air at rest within a room will give a different and erroneous result. If the motion is such as to increase in rapid motion so that the air strikes violently against it. If the barometer moves with the air it will indicate the elastic pressure within the air. When the wind blows against an obstacle the air pressure is increased above the normal by the pressure of the air itself on the side and back of the obstacle. It is thus obvious that in determining the pressure within the free atmosphere the pressure of the barometer must be carefully considered. The effect of a gentle wind is to raise the elastic pressure within a room whose window is open to the wind, and to lower the pressure if the window faces to the leeward. The influence of the draught up chimney, produced by the wind blowing over the surface of the chimney and lowering the pressure within the chimney, is the same. The maximum effect of the wind in raising the pressure is given by the formula, \( P = \frac{938 \times 3}{V^2} \), where the pressure is given in inches and the velocity in miles per hour. This amounts to about one-tenth of an inch in a 50-m. wind, and to nearly four-tenths in a 100-m. wind.
within which barometric pressure is less than in the neighbouring free air. The draught up the chimney is due to the pressure of the air at the lower end or fireplace pushing up the flue into this region of reduced pressure and causing a pressure differential, or heated air within the flue. From such experiments as these there has been developed the vertical suction-tube anemometer, as devised by Fletcher in 1867, re-invented by Hagemann in 1876, and introduced into England by Dines. In his Meteorological Apparatus "Marvin's Table for the Reduction of Velocities, given by the small-sized Robinson's Anemometer in gusty winds."

and Methods (Washington, 1887) Abbe gives the theory of this class of apparatus as well as the means of adding additional forms to the windward and the leeward, and within which are two independent barometers, give the means of determining the barometric pressure pushed up the chimney as the wind pressure respectively, so that both the velocity of the wind and the true barometric pressure can be determined. If instead of a simple opening at the top of the tube we place there horizontally the contracted V-shaped tube, we obtain a maximum wind effect, which gives an accurate measure of the wind velocity, and the formexperimented by Bourdon as an improvement on that of Arson. In all anemometers of this class the wind pressure in the narrow part is reduced to a minimum, and the measurement of rapid changes in velocity and of the maximum intensity of gusts becomes feasible. On the other hand, these researches have shown how to expose a barometer so that it shall be free from the dynamic or effect even if it has only to be placed within a room or box that is connected with the free air by a tube that ends in a pair of parallel plane plates. When the wind blows past the end of this tube it flows between these plates in steady linear motion, and can produce no disturbance of pressure at the mouth of the tube if the plates are at a suitable distance apart. This condition of stable flow, as correctly expressed in the law, was discovered by Newton, and Thomson (Lord Kelvin) (see Phil. Mag., Sept. 1857). Such a pair of small circular plates can easily be applied to a tube screwed into the air-hole at the back of any aneroid barometer, and thus render independent of the influence of the wind. As to the exposure of the anemometer, no uniform rules have as yet been adopted. Since the wind is subject to exceedingly great disturbances by the obstacles near the ground or the buildings, we estimate the force of the wind by noticing all that goes on over a large region about him has some advantage over an instrument that can only record the wind prevailing at one spot. The practice of the U.S. Weather Bureau has been to install upon the perfectly free exposure of all anemometers as high as can possibly be attained above buildings, trees and hills; but, of course, in such cases they give records for an elevated point and not for the ground. The winds are therefore not precisely appropriate for use in local climatological studies, but are needed for general dynamic meteorology, and proper for comparison with the isobars and the movements of the clouds shown on the daily weather map.

Hygrometer.—Moisture floats in the atmosphere either as invisible vapour or as visible haze, mist and cloud. The presence of the latter generally assures us that the air is saturated with moisture. The presence of the former is as much as visible and invisible vapour contained in a unit volume of cloud or mist is directly determined by the Schwackhofer or Svensson hygrometer, or it may be ascertained by warming a definite portion of the air and fog and measuring the tension of the vapour by Edelmann's apparatus. Both these methods, however, are in practice open to many sources of error. If only invisible aqueous vapour is present we may determine its amount by several methods: (a) the chemical method, by absorbing and weighing it; (b) the dew-point method, by cooling the air down to the temperature where condensation begins; (c) Edelmann's method, by absorbing the moisture chemically and measuring the change in vapour tension; (d) by adding vapour until the air is saturated, and measuring either the increased tension or the quantity of evaporation; (e) the psychrometric method, by determining the temperature of evaporation.

The wet-bulb thermometer, which is the essential feature of the last-named process, was used by Meares in 1787, but merely as giving an index of the dryness of the air. The correct theory of its action was elaborated by many early investigators: Ivory, 1822; August, 1825; Apjohn, 1834; Bell, 1838; Regnault, 1854; and the last date is said to be that in which the method was made in our knowledge of the subject, and it was supposed that the psychrometer was necessarily crude and unsatisfactory; but a modern form has become an instrument of much greater precision, probably quite as trustworthy as any other form or other method of determining atmospheric moisture. In order to secure this accuracy the two bulbs must be of the same size, two sensitive nerves. The bulb immersed in water should be muslin saturated with pure water; both thermometers must be whirled or ventilated rapidly, but at the definite prearranged rate for which the tables of reduction have been computed; and, finally, both thermometers must be carefully sheltered against illumination. In order to attain these conditions European observers tend to adopt Edelmann's ventilated psychrometer, but American observers adopt Arago's whirled psychrometer, set up within an ordinary thermometer shelter. By either method the dew-point should be determined with an accuracy of one-tenth degree C. or two-tenths F. As a crude approximation, we may assume that the temperature of the dew-point is five degrees C. lower than the wet bulb as far as that is below the dry bulb. A greater accuracy can be attained by the use of Ferrel's or Marvin's psychrometer, or by a sling psychrometer, especially if the bulbs are protected from radiation by a slight covering of non-conducting material, or even metal, as was done by Craig in 1866-1869 for the stations of the U.S. Army Surgeon-General. The bar hygrometer gives directly the relative humidity or the ratio between the moisture in the air and that which it would contain if saturated. The very best forms perform very well for a time, and are strongly recommended by Petterssen and other meteorologists. An apparatus for balloons and kites; they are standardized by comparison with the ventilated psychrometer, which itself must be dependent on the standard dew-point apparatus.

Rain and Snow Gauge.—The simple instrument for catching and measuring the quantity of rain, snow or hail that falls, is a definite horizontal vessel, such as the ordinary cylinder and the measuring apparatus. The receiving mouth of the cylinder is usually terminated by a cone or funnel, so that the water running down through the funnel and stored in the cylinder is protected from evaporation or other loss. The cylinder is firmly attached to the ground or building, so that the mouth is held permanently at a definite altitude.

The sources of error in its use are the sputtering into it from the ground or neglecting the observation of the period of time that the wind blows against the side of the cylinder it produces eddies and currents that carry away drops that would otherwise fall into the mouth, and even carries out of the cylinder drops that fall in the form of snow or rain gauges catch and measure too little rainfall. The deficit increases with the strength of the wind and the smallness or lightness of the raindrops and snowflakes. If we assume that the correct value of the height of rain or snow catch is given by a certain formula, the ratio of the weight of the rain on the ground and is surrounded by a trench wide enough to prevent any spatter, then, on the average of many years and numerous experiments, we have the ratio of the actual amount of rain to the average character of the rain in that region and the average strength of the attending winds, the deficit of rain caught by a rain-gauge whose mouth is 1 metre above the ground is 6% of the proportion of the catch; if it is 10 metres above the ground, the deficit will be 33%. This deficit increases as the gauges are higher above the ground in proportion approximately to the square root of the altitude, provided that they are fully exposed to the increase of wind that prevails at those altitudes. It is evident that even for
altitudes of 5 or 10 ft. the records become appreciably discrepant from those obtained at the surface of the ground. The following table shows in the last column the observed ratio between the catches of gauges at various altitudes and those of the respective standards at the level of the ground. Unfortunately, there are no records of the force of the wind to go with these measurements; but we know that in general, and on the average of many years, corresponding gauges which are not subjected to the velocity of the wind increase very nearly as the square root of the altitude. Although this deficit with increasing altitude has been fully recognized for a century, yet no effort has been made until recent years to make a proper correction or to eliminate this influence of the wind at the mouth of the gauge. Professor Joseph Henry, about 1850, recommended to the observers of the Smithsonian Institution the use of the "pit-gauge." About 1888 he recommended a so-called shielded gauge, namely—a single cylindrical gauge 2 in. in diameter, having a wide horizontal sheet of metal like the rim of an inverted hat soldered to it. This would undoubtedly diminish the obnoxious differentials of altitude especially at the same altitude, the rain catch becomes very nearly uniform; but the shield is not especially good for snow, which piles up on the wire screen. Since 1885 numerous comparative observations have been made in Europe with wire-cloth and with the "protected gauge" devised by Boernstcin, who sought to prevent injurious eddies about the mouth of the gauge by erecting around it at a distance of 2 or 3 ft. an open board, about 3 ft. higher than the mouth of the gauge. The boards or slats are not close together, but apparently afford as good a protection as the shield of Professor Nipher, and give good results with both snow and rain.

In general it is now conceded by several high authorities that the measured rainfall must be corrected for the influence of the wind at the gauge, if the latter is not equipped with Nipher’s or Boernstein’s methods. A practicable method of measuring and allowing for the influence of the wind, without introducing any very hazardous hypothesis, was explained by Abbe in 1888 (see Symons’ Meteorological Magazine, 1889, for a U. S. Monthly Weather Review for 1889). This method consists simply in establishing near each other several similar gauges at different heights above the ground, but in otherwise similar circumstances. On the assumption that for small elevations the diminution of the wind, like that of the rainfall, is very nearly in proportion to the square root of the altitude, the difference between the records for two different sets of gauges may be used as a basis of a calculation which gives the correction to be applied to the record of the lower gauge, in order to obtain the rainfall that would have been caught if there were no wind. It is only when the catch of the gauge has been properly corrected for the effects of the wind that we have proper data with which to determine the variation of the rainfall with altitude and locality, the influence of forests and the periodical changes of climate. Methods of measuring dew, though still far from satisfactory, have yet still to be devised; each of these has its ther- modynamic importance and must eventually enter into our calculations.

It is generally common to consider that the rain-gauge cannot be properly used on ships at sea, owing to the rolling and pitching of the vessel and the interference of masts and rigging; but if gauges are mounted on gimbal stands it would be of the driest and most accurate record that can be obtained. Experimental work of this sort was done by Mohn, and afterwards in 1882 by Professor Frank Waldo; but the most extensive inquiry has been made by Mr. Garrett (Proceedings of the Royal Society, 1898, vol. xiv.), which satisfactorily demonstrates the practicability and importance of the marine rain-gauge.

**Evaporometer.**—The moisture in the atmosphere comes from the surface of the earth or ocean by evaporation, a process which goes on continually, replacing the moisture that is precipitated as rain, hail, snow and dew, and maintaining the total amount of moisture in the atmosphere at a very uniform figure. The rate of evaporation depends on the temperature, the dryness, and the velocity of the wind. It is not so important to meteorologists to know where the moisture comes from as to know its amount in the atmosphere, and in fact no method has yet been devised for determining how much moisture is given up by any specific portion of the earth, ocean, or forest. Our evaporometers measure the quantity of moisture given off by a specific surface of water, but it is so difficult to measure this water under natural conditions in nature that no conclusions can be safely deduced as to the actual evaporation from natural surfaces. The proper meteorological use of these evaporometers is, as integrating hygrometers, to give the average humidity of the air, the psychrometer giving the conditions prevailing at any moment.

Among the many forms of evaporometer the most convenient is that devised by Piche, which may be so constructed as to be exceedingly accurate. The Piche evaporometer consists essentially of a glass tube, whose upper end is closed hermetically, whereas the lower end is covered by a horizontal disk of bulbous paper, which is kept wet by absorption from the water in the tube. As the water evaporates its descent in the tube is observed, whence the volume evaporated in a unit of time becomes known. So long as the paper remains clean, and the water is pure, the records of the evaporimeter depend simply upon the evaporation, independent of the dryness of the air, and the velocity of the wind. Careful comparisons between the Piche and the various forms of absolute evaporimeters have been made by Pressey Thomas, and the results were published in the U. S. Monthly Weather Review for September 1888, pp. 235-239. By placing the Piche apparatus upon a large whirling machine he was able to show the effect of the wind. This has enabled him to explain the great differences recorded by the apparatus established at eighteen Weather Bureau stations; based upon these results, he prepared a table of relative evaporation between thermometers at all stations. The actual evaporations from ground and water in the sunshine may run parallel to these, but cannot be accurately computed. It is probable that Professor Russell’s computations are smaller than the evaporations from shallow bodies of water in the sunshine, but larger than for deep bodies, like the great lakes, and for running rivers. Recent elaborate studies of evaporation have been undertaken in Egypt and in South Africa—both countries lying in the middle latitudes of southern California. Here the Colorado river, having broken through its bounds, emptied itself into a great natural depression and formed the so-called "Salton Sea," about 50 by 100, 20 wide and 100 feet deep, before it could be brought under control. This sea is now isolated, and will, it is hoped, dry up in eight or ten years. Meanwhile the U. S. Weather Bureau has established a large number of evaporimeters for the purpose of determining the evaporation. This has begun the study not only of the relation between evaporation, wind and temperature, but of the eventual disposition of this vaporization throughout the atmosphere in the neighbourhood of the earth’s surface. The methods employed do not involve U. S. Monthly Weather Review, 1907-1909, as also the elaborate bibliog- raphy of evaporation in the same volumes). Although the evaporation from the evaporimeter is scarcely comparable to our hygrometric apparatus, yet it is said to be so in the development and ripening and drying of the dates raised on the U. S. government experimental "date farm" a few miles north-east of the Salton Sea.
Nephoscope.—The direction and apparent velocity of the motion of a cloud are best observed by means of the nephoscope, which has now become a necessary item in the outfit of any first-class meteorological station. Among the various forms of this instrument are the nephoscope of Fornioni, the marine nephoscope of Fineman, the simple mirror with attachments used by Clayton, the cloud camera of Vettin, and the altazimuths of Mohl and Lettry. The most perfect form for use on land is that devised by Professor Marvin in 1896 for the U.S. Weather Bureau stations (see fig. 3); while the most convenient for use at sea that is devised and used at so great a distance from him that their record is not supposed to belong to his locality. As the cloudiness—or its reciprocal, the sunshine—is supposed to be the most important item in agricultural climatology, and is certainly very important for dynamic meteorology, it is usually considered desirable to obtain more complete records than are given by only one or two specified hours of observation. To this end apparatus for recording sunshine, or, rather, the effect of cloudiness, is widely adopted. At least three forms are worth describing as being extensively used.

The Jordan photographic sunshine recorder consists of a cylinder enclosing a sheet of sensitive paper; the sun’s rays penetrate through a small aperture, and describe a path from sunrise to sunset, which appears on this sheet after it has been properly washed with the fixing solution. Any interruption in this path, due to a cloud or haze, is of course clearly shown, and gives at once the means of estimating what percentage of the day was clear and what cloudy. The modified form of the instrument, A device was invented by Moom for many years at about forty Weather Bureau stations, but the original construction is still employed by other observers throughout the world. The Sikes-Campbell recorder consists of a globe of glass acting as a burning-glass. A sheet of pasteboard or a block of wood at the rear receives the record, and the extent of the charring gives a crude measure of the percentage of full or strong sunshine. A variety of the same instruments have been devised for a certain standard difference of temperature of about 5°F., such as would be produced by the sun shining through a very thin cloud. This record is made by an electric current on a revolving drum, and simply shows when during the day sunshine or a signal density prevailed, or was prevented by cloudiness. D. T. Maring, in the U.S. Monthly Weather Review for 1897, described an ingenious combination of the thermometer and the photographic register of cloudiness which is worthy of further development. It gives both the quantity of cloudiness and intensity of the sunshine on some arbitrary relative scale.

The intensity of the sunshine, as sometimes employed in general agricultural studies, is crudely shown by Violle’s conjugate bulbs, which are thin copper balls about 3 in. in diameter, one of them being blackened on the outside and the other glazed. When exposed to the sunshine the difference in temperature of the two bulbs increases with the intensity of the sunshine, but as the difference is dependent to a considerable extent on the wind, the Violle bulbs have not found wide application. The Arago-Davy actinometer, or bright and black bulbs in vacuo, constitutes a decided improvement upon the Violle bulbs, in that the vacuous space surrounding the thermometers diminishes the effect of the wind. The physical thermometers used in the Arago-Davy instrument were invented by Ferrel, and he was able to determine the coefficient of absorption of the earth’s atmosphere and other data, thereby showing that this apparatus is perfectly reliable. In using it as contemplated by Arago and Davy and by Professor Ferrel, we read simply the stationary temperature attained by the bright and black thermometers at any moment, whereas the best modern actinometers are of the alternating current type. In this method, developed by Pouillet in 1838 in his pyrheliometer, which was invented by Abbe in 1883, and in fact tried at that time; but the apparatus and records were unfortunately burnt up. This so-called dynamic, as distinguished from the static, method was first applied by Pouillet in 1838 in using his pyrheliometer, which was a rather large apparatus and method that gave approximate measures of the radiant heat received from the sun. In order to improve upon Pouillet’s work more delicate apparatus has been constructed, but the most recent and most generally useful is the apparatus designed and applied both Langley’s bolometer and his own still more sensitive thermoelectric couple and balance method; Violle uses his absolute actinometer, consisting of a most delicate thermometer within a perfectly vacuous sphere connected with a stream of cold water; while Crova, with a thermometer within an enclosure of uniform temperature, claims to have attained an accuracy of one part in a thousand. A large number of instruments of this type, and of actinometry, and has shown the greater delicacy of his own apparatus, consisting of two thin plates alternately exposed to and shielded from sunshine, whose differences of temperature are measured by electric cells.

As none of the absolute methods for determining the solar radiation in units of heat lend themselves to continuous registration, it is important to call attention to the possibility of using this chemical method. The apparatus appears to be that devised by Marchand, by the use of a device which he calls the Phot-antiphotometer. In this the action of the sunlight upon a solution of ferric-oxide and chloride of iron liberates carbonic acid

FIG. 2.—Marvin’s Nephoscope.

in 1889 by Professor Abbe on the cruise of the U.S. ship "Pensacola" to the west coast of Africa, but first described in the report of the International Meteorological Congress held at Chicago in August 1893.

The construction of this instrument is shown in figs. 3, 4, 5. In using it the observer looks down upon a horizontal mirror and observes the reflection of the cloud. By moving his eye he brings any cloudy point into coincidence with the reflection of a small fixed spherical knob K above the mirror, and keeps the images of the knob and the cloud coincident as they pass from the centre of the mirror to its edge. This line of motion shows the azimuth of the horizontal component of the cloud’s motion. The course of the vessel is shown by the compass card and rubber line AP seen below the mirror. The apparent angular velocity of the cloud, as it would be if the cloud started from the zenith, is obtained by counting the seconds that elapse between its passage from the centre to the edge, or to a small circle inscribed within the edge. With Marvin’s nephoscope two observers a short distance apart may easily determine the apparent altitude, and azimuth, of motion of any cloud whose true altitude and velocity may be computed. But when the observer uses Abbe’s marine nephoscope on a vessel which is itself in motion he observes the resultant of his own motion and that of the cloud. If his vessel is under his control, so that he may change its velocity or direction at will, he easily determines this resultant for two different courses, and obtains data by which he is enabled to calculate the real altitude and velocity of the cloud in terms of his own velocity. As the marine nephoscope can be used on a wagon moving rapidly over a smooth road, or in a small boat on a smooth pond, as well as on a large sea-going vessel, it becomes an instrument of universal application for cloud study. It is also equally convenient for observing the positions of auroras, halos, meteors, and other special phenomena. For the international work undertaken during the year 1898 the photographic camera established upon an alt-azimuth mounting, or the so-called photograph-t-Ser, was especially developed (see fig. 2). This apparatus photographs the clouds are taken simultaneously at two or more stations, and in each case the centre of the photograph plate has its altitude and azimuth determined. From this centre one can measure on the plate the additional angles required in order to fix the altitude and azimuth of any point that is photographed, and thus the dimensions of the whole visible cloud and its internal or differential motions can be determined, as well as its general motion. During the years 1896-1898 about twenty stations were occupied throughout the world for the purpose of determining accurately the altitudes and motions of every layer of cloud.

Sunshine Recorder.—The ordinary meteorological record specifies the proportion of sky that appears to be covered with cloud, or the so-called cloudiness, usually expressed in tenths. The observer generally confines his attention to that portion of the sky within sixty degrees of the zenith, and ignores the lower zone, since the clouds that are found therein are often

APPARATUS AND METHODS

METEOROLOGY
gas, the amount of which can be measured either continuously or every hour; but in its present form the apparatus is affected by several serious sources of error.

**Fig. 3.—Abbe's Marine Nephoscope. Horizontal Projection of Mirror.**

The electric compensation pyrheliometer, as invented by Knaut Angström (Ann. Phys., 1899), offers a simple method of determining accurately the quantity of radiant energy. He employs two blackened platinum surfaces, one of which receives the radiations to be measured, while the other is heated by an electric current. The difference of temperature between the two disks is determined by a thermocouple, and they are supposed to receive and lose the same amount of energy when their temperatures are the same. A Hefner lamp is used as an intermediate standard source of radiation, and alternate observations on any other source of radiant heat give the means of determining their relation to each other. By means of two such instruments Angström secured simultaneous observations on the intensity of the solar radiation at two points, respectively, 360 and 3352 metres above sea-level, and determined the amount of heat absorbed by the intermediate atmosphere. An apparatus of 1-1000 appears to be attainable, and this apparatus is now being widely used. The records of 1901-1905 have already given rise to the belief that there is a variation in our insolation that may eventually be traced back to the sun's atmosphere.

**Meteorograph.—**The numerous forms of apparatus designed to keep frequent or continuous register of the prevailing pressure, temperature, moisture, wind, rainfall, sunshine, evaporation, and other phenomena are instruments that belong peculiarly to meteorology as distinguished from laboratory physics. Such apparatus may be broadly divided into several classes according as the records are obtained by the help of photography, or electricity, or by direct mechanical action. The prevailing tendency at present is in favour of apparatus in which the work of the recording pen is done by a falling weight, whose action is timed and limited by the breaking and making of electric currents by the meteorological apparatus proper. The most serious defect in such instruments, even when kept in good working order, is a want of sensitiveness commensurate with the desired openness of scale. It is very important that a fraction of a minute of time should be as recognizable as one-tenth of a degree of temperature; one thousandth of an inch of barometric pressure, and velocities of one hundred miles per hour, as well as rapid changes in all these elements, must be measurable. But instruments whose scales are large enough to record all these quantities are usually so sluggish that the comparison of the records is very unsatisfactory. In order to study the relationships between temporary and fleeting phenomena, it is necessary that all instruments should record upon the same sheet of paper, so that the same time-scale will answer for all.

The instruments that respond most nearly to the general needs of meteorology are the various forms of meteorographs devised by Wilcox for use at St. Petersburg, by Sprung and Füss for use at Hamburg and Berlin, and by Marvin for Washington. The photographic systems for pressure and temperature introduced many years ago at stations in Great Britain and the British colonies are not quite adequate to present needs. The portable apparatus manufactured by Richard Frères at Paris is in use at a very large number of land stations and on the ocean, and by giving special care to regular control-observations of time, pressure and temperature, important results may be obtained; but in general the timescales are too small, and the unknown sources of error too uncertain, to warrant implicit reliance upon the records.

**Polarimeter.—**The brightness and blueness of the sky light, and especially its polarization, have been observed with increasing interest, as it seems possible from these elements to ascertain something with regard to the condition and amount of the media of the air. With the aid of the Nicol's or Arago's quarter- or double-nickel prism placed in the hand and turned slowly about the axis of vision one can quickly recognize the fact that the sky light is polarized, and that the polarization is largely due to the air or dust lying between us and the clouds in the distant horizon. Arago, with a more delicate form of polariscope, determined the existence of a so-called neutral region near the sun. Babinet located a neutral point or zone about as far from the anti-sun as was Arago's from the sun itself. Brewer discovered a neutral point near the sun and horizon, disappearing when the sun is more than 180° from the horizon. Finally, Babinet succeeded in sufficiently to draw lines of equal polarization, which he published in Johnston's Physical Atlas, and which were confirmed by Zantedeschi in 1849. Since those days far more delicate work has been done—first by Bosanquet of Oxford, afterwards by Prof. E. C. Pickering of Harvard University and Prof. A. W. Wright of Yale University. A later contribution to the subject is by Jensen (see Met. Zeit. for Oct.-Dec. 1899), who has observed the brightness as well as the polarization, and thus completed the data necessary for testing the various physical theories that have been proposed for the explanation of this phenomenon. We owe to Tyndall the discovery that when a beam of white light penetrates a mass of fine aqueous mist the latter sends off at right angles a delicate blue light, which is almost wholly polarized in a plane at right angles to the plane.
of reflection. As the particles of mist grow larger, the blue light becomes whiter and the polarization disappears. The original vapour particles are undoubtedly so small as to be comparable in size with a fraction of the wave-length of ordinary light, and Rayleigh was able to show that molecular as well as minute particles must have a power of selection, and that the diffused sky light comes to us by selective reflection. On this basis we should expect that in the driest air at great heights, where the temperature is low and condensation has but just begun, and the dust particles are rare, there would occur the smallest aqueous particles reflecting light of the greatest intensity but the largest percentage of polarization. Rayleigh has shown that it is quite possible that the molecules of oxygen and nitrogen constituting the atmosphere may also exercise a diffuse selective reflection, and contribute to the brightness and polarization that are mainly due to aqueous vapours. (See SKY.)

We thus see the theoretical importance of adding photometry and polarimetry to the work of a meteorological observer. The apparatus to be used in this connexion will vary somewhat with the exact character of the observations to be made. The most extensive researches that have yet been carried out in this line with a view to the study of light are those of James Clerk Maxwell, Cornu, Pickering, Kimball, Nichols, and especially Rubben, who in fact recommended that polarimetry and photometry should go hand in hand. In order to measure the position of the plane of polarization of the light reflected, but, of course, to measure the percentage of polarized light, Mascart’s modification of the Savart is better. In order to measure the general brightness of a spot in the sky, Jensen has used a slight modification of the Weber’s photometer, and in fact Weber himself has applied the same method to the measurement of the daylight. The complete work of Jensen was published in the *Schriften* of the Scientific Association of Schleswig-Holstein in 1889, and, like the memoir published by Rubben in 1863, it gives the meteorological conditions in full as a basis for the investigation of the connexion between sky light and the moisture in the atmosphere. In his work during 1890–1899 with Angström and psychrometer of Mr A. H. Kimball of Edinburgh, he advantageously used the Pickering polarimeter, and has shown that the transparency of the air and the polarization of light go hand in hand.

**Cyanometer.**—The cyanometer devised by Arago to measure the blueness of the sky consisted of an arbitrary scale of blues on a strip of porcelain, with which one could compare the blue of the sky. This comparison, however, is open to many subjective errors. A more satisfactory apparatus is Zollner’s photometer, or some equivalent, in which a patch of white surface is illuminated by any particular tint or combination that may be desired. In fact, Maxwell’s colour-box admits of ready application to the analysis of sky light, and reveals at once the proportions of red, yellow, and blue that may be contained therein.

**Dust-counter.**—The importance of observing the dustiness of the atmosphere has been especially realized since the invention and use of various forms of apparatus for counting the number of particles of dust in a small volume. These inventions are due to Mr John Aitken, of Edinburgh.

The latest form of his apparatus is the very convenient “pocket dust-counter.” In this the air contained in a small receiver is rendered dusty by means of a collecting device; the dust is then allowed to condense upon the sky, which, becoming heavy, falls to the bottom, so that in a short time all is removed. A small stop-cock is now turned, so as to allow a definite small quantity of air to enter and mix with the dustless air in the receiver. The dusty and the dustless airs are now thoroughly mixed, and again the whole quantity within the receiver is expanded, and the dust nuclei fall down by the condensation of vapour upon them. Assuming that the receiver is conditioned in one minute by a minute droplet of water, we have but to count the latter; this is easily done by causing all the drops to fall upon a polished plate of black glass, which is divided into small squares, and each square is connected with a particular point of a cube which represents a small fraction of a cubic centimetre of air; thus in one case the number of fog particles averaged 2.6 per square millimetre of the glass plate, and, as the multiplying factor was 100, this corresponded to 260,000 particles of dust in a cubic centimetre of air. The cleanest air has been found in the West Highlands of Scotland, where 16 particles per cubic centimetre was once recorded as the minimum, while 7,600 was the maximum. On the Rigi Kulm, in Switzerland, the cleanest air gave 210, and the dustiest 16,900.

On comparing the records of the dust-counter with the record of the apparent state of the air, Mr Aitken found that 500 particles per cubic centimetre corresponded to clear air, and 1900 to a thick haze in which distant mountain tops were hidden. In the cities the particles of soot and effluvia of all kinds act as dust, and both in London and Paris the numbers ran as high as 80, 116, 150 and 210 thousand cubic centimetres.

**Electrical Apparatus.**—The electrical phenomena of the atmosphere undoubtedly belong to meteorology, and yet the methods of observation have been so unsatisfactory and the difficulty of interpreting the results has been so baffling that regular observations in electricity are only carried out at a very few meteorological institutions. A general summary of our knowledge of the subject was prepared by J. Elster and H. Geitel for the International Congress held at Chicago in 1893, but since that date the methods and apparatus of observation have received important modifications.

In general the water-dropping collector of Lord Kelvin, arranged for continuous record by Mascart, continues to be the best apparatus for continuous observation at any locality, and a portable form of this apparatus is used by explorers and in special series of local observations. In order to explore the upper air the kite continues to be used, as was done by A. J. McAdie for the Weather Bureau in 1885 and by Weber at Kiel in 1889. The difference of potential between the earth’s surface and a long vertical wire in a balloon has been measured up to considerable altitudes by Elster and Tuma. In general it is known that negative electricity must be present in the upper strata just as it is in the earth, while the cloud-covering layer of air is positively electrified. The explanation of the origin of this condition of affairs is given in the recent researches of Sir J. J. Thomson (Phil. Mag., Dec. 1899), and his interpretation

---

**FIG. 6.** Marvin-Hargrave Kite, with Meteorograph in position. It is almost identical with that now recognized by Elster (see *Terrestrial Magnetism*, Jan. 1900, p. 211.) According to these results, if positive and negative ions exist in the upper strata and are carried up with the ascending masses of moist air, then the condensation of the moisture must begin first on the negative ions, which are brought down eventually to the earth’s surface, while the air receives its negative charge from the atmosphere, leaving a positive charge or an excess of positive ions in the middle air. (See G. C. Simpson, *"Atmospheric Electricity,"* Monthly Weather Review, Jan. 1909, p. 16.)

The observations of atmospheric electricity consist essentially in determining the amount and character of the difference of potential between two points not very far distant from each other, as, for instance, the end of the pipe from which the water-drops are discharged, and the nearest point of the earth or building resting on the earth. The record may have only an extremely local value, thus the investigation of Professor John Trowbridge of Harvard University, made in conjunction with the U.S. Weather Bureau in 1882–1885, shows that the differences vary so much with the winds, the time of day, and the situation of the water-dropper that the mere comparison of records gives no correct idea of the general electrical relationships. It has been suggested that possibly daily telegrams of electric conditions and daily maps of equipotential curves over the North American continent might be prepared, but this is a problem which has not yet been shown that atmospheric electricity in important in *Atmospheric Meteorology.*

**Aerial Research.**—The exploration of the upper atmosphere is to be regarded as the most important field of research at the present time; the kite and the balloon enable observers and apparatus to be carried to considerable heights, though by no means so far as is desirable. The kite was first used in meteorological work by Alexander Wilson at or near Glasgow in 1749, and has since then been frequently used by English observers. It was used in 1867 by Abbe in studying the winds under a thundercloud, and in 1877 in...
studying the depth of the ocean breeze on the coast of New Jersey, but the later revival of interest in the subject dates from the work done in England in 1882 by E. D. Archibald, who used the kite to carry up anemometers to very considerable heights, and thereby determined the relative movement of the air in the free atmosphere. In 1883 Alexander McAdie used the kite in his studies of atmospheric electricity, Professor Cleveland Abbe proposed to use it for a complete exploration as to temperature, moisture and wind, but W. A. Eddy of New York first forced its varied capabilities upon public attention, and accepted the suggestion of Professor Cleveland Abbe to employ it for meteorological work. Having found his kites at the Blue Hill Observatory, and having carried up with them the self-registering apparatus devised by Mr Ferguson, Eddy left the further prosecution of this work to Mr Rotch, who has made this a prominent feature of the work at his observatory, having carried up meteoroographs to the height of 15,000 feet by means of a series of kites flying in tandem. The officials of the U.S. Weather Bureau have developed the admirable cellular kite, invented by Hargrave of Australia, and Professor Marvin's works on the theory and construction of this form are well known.

The general appearance of the Marvin or Weather Bureau kite, his reel and other apparatus that go with it, and his meteorograph, are shown in Figs. 6, 7, 8. The size ordinarily used carries about 68 sq. ft. of supporting surface of muslin tightly stretched on a light wooden frame. The line, made of best steel piano-wire, is wound and unwound from a reel which keeps an automatic record of the intensity and direction of the pull. The reeling in and out may be done by hand, but ordinarily demands a small gas-engine. The observer at the reel makes frequent records of the temperature, pressure and wind, the apparent angular elevation of the kite, and the length of wire that is played out. At the kite itself the Marvin meteorograph keeps a continuous record of the pressure, temperature, humidity and velocity of the wind. The meteorograph, with its aluminum case, weighs about two pounds, and is so securely lashed behind the front cell of the kite that no accident has ever happened to one, although the kites sometimes break loose and settle to the ground in a broken country many miles away from the reel. On four occasions the line has been completely destroyed by slight discharges of lightning; but in no case has the kite, the observer, or the reel been injured thereby. Of course, such lightning is preceded by numerous rapidly increasing sparks of electricity from the lower end of the wire, which warn the observer of danger. During the six months from May to October 1898, seventeen kite stations were maintained by the U.S. Weather Bureau in the region of the lakes, the Upper Mississippi and the Lower Missouri valleys, in order to obtain data for the more thorough study of atmospheric conditions over this particular part of the country. During these months 1217 ascents were made, and as no great height was attempted mostly under 7000 or 8000 feet. There was thus obtained a large amount of information relating to the air within a mile of the earth’s surface. The general gradients of temperature, which were promptly deduced and published by H. C. Marvin of the Weather Bureau, gave for the first time in the history of meteorology trustworthy observations of air temperatures in the free atmosphere in numbers sufficient to indicate the normal condition of the air.

The kite and meteorograph have now been adopted for use by all meteorologists. The highest flight seems to be that of the 3rd of October 1907, at Mt Weather in Virginia, when 23,110 ft. above sea-level or 21,385 ft. above the reel was attained by the use of 37,300 ft. of wire and 8 kites tandem.

The balloon was used for the scientific exploration of the atmosphere quite freely during the 19th century. The first important voyages were those of Gay-Lussac and Biot at Paris in August and September of 1804. The next important ascent was that of Bixio and Barral in 1830 at Paris. The most remarkable of these early ascents have been those of James Glaisher, 2nd of September 1862, and Berson at Berlin in 1889; on both of these occasions the aeronauts attained altitudes of from 30,000 to 35,000 feet. Systematic ascents at many points in Europe simultaneously on pre-arranged dates were made during the years 1895-1899, and led to the development of a general international system of ascension on pre-arranged days of the year that is now a very important feature in the study of the atmosphere.
METEOROLOGY

Physical and Theoretical Meteorology

The balance soundings have been made not only individually, but, by pre-arranged system, simultaneously in combination with the ascent of balloons, and lately with the aid of wireless telegraphy. Observations about the balloon are sometimes used to hypothesize the temperature of the thermometers, and of providing more perfect protection against radiation from the sun or to the sky. It is believed that accurate records may be attained up to at least 30,000 metres, but as few records of such altitude have been taken, and the results obtained are under considerable criticism on account of instrumental defects. In general the wind that supports a kite also furnishes sufficient ventilation for the thermometer; but in the case of the balloon, the turbulence as the air floats along horizontally in the full sunshine, a strong artificial ventilation must be provided. Moreover, the sluggishness of the best thermometers is such that during the rapid rise the records of temperature that are being made at any moment really belong to some altitude considerably below the balloon, and a most critical interpretation of the records is required. Notwithstanding all criticisms, however, the balloon work in all localities agrees in showing the existence of a region above the 10,000-metre level, where temperatures cease to diminish rapidly, and may even become stationary.

III. Physical and Theoretical Meteorology

The ultimate aim of those who are devoted to any branch of science is to penetrate beyond the phenomena observed on the surface to their ultimate causes, and to reduce the whole complex of observations and empirical rules based upon limited experiences to a simple deductive system of mechanics in which the phenomena will all be shown to be derivable from the few simple laws that underlie the structure of the universe.

A correct "theory" or physical and logical argumentation deduced from primary laws all the phenomena constitutes the noblest achievement of man in science. It is by such works that Newton and Laplace distinguished themselves in astronomy. The development of the true physical and mechanical theories of atmospheric phenomena has made great progress, but is still inferior in completeness to astronomical work, owing to the great complexity of the meteorological problems. The optical and thermal phenomena have been very satisfactorily elucidated, the electrical phenomena promise to become clear, but the phenomena of motion or aerodynamics have only been elucidated to a limited extent. We must, however, introduce the reader to some of the works that have been published on the subject, in the hope that thereby he will himself be persuaded to further study and stimulate to contribute to our knowledge.

Between the years 1853 and 1861 Professor William Ferrel published in Gould's Astronomical Journal, Rankle's Mathematical Journal, and several others, several papers on the motions of solids and fluids relative to the earth's surface. His work resulted in the elucidation of the problems of the atmosphere and in ingenious and simple applications of the mechanical laws of fluids, analytical methods, and the relations of the motions of particles and the fundamental equations of mechanics. A beautiful memoir on the steady motions of the atmosphere was published in 1868 in the Astronomical Observatory. Since 1861, Professor Adams has been now reprinted in vol. ii. of Abbe's Mechanics of the Earth's Atmosphere. Espy's, Coffin's, Henry's, and Ferrel's ideas were the basis of the system of daily weather predictions published by the present writer, and published by Railway Express, and later by U.S. Weather Bureau, and now by Signal Office. Subsequently this work was taken up by the government, and greatly enlarged during 1871-1891 by the chief signal officers of the army, and after 1891 by the chiefs of the U.S. Weather Bureau. The last attempt at this work was made by meteorologists in consequence of reviews published by Han in the Zeitschrift of the Austrian Meteorological Society in January 1875, but especially after they had been reprinted in the Bulletin of the Geodetic Survey in 1891. In 1891 Ferrel, after finishing his work on the tides for the U.S. Coast and Geodetic Survey, began a new and extensive series of meteorological contributions, three of which were published by the U.S. Geodetic Survey and the rest by the Signal Office. Stimulated by the urgent needs of the modern weather bureaus throughout the world, and by the beauty of the mathematical problems presented, numerous mathematicians and meteorologists have entered the study of the earth's atmosphere, so that the literature of the subject is not far more extensive and profound. The problems of radiation have been developed by Langley, Hutchins, Angström, Paschen, Veile, Maurer, Crow Hoppe, and others. The theoretical problems, the numerical problems have also been carefully treated, both experimentally and mathematically. The problems of radiation have been treated rapidly by Langley, Hutchins, Angström, Paschen, Veile, Maurer, Crow Hoppe, and others. The theoretical problems, the numerical problems have also been carefully treated, both experimentally and mathematically. The problems of radiation have been treated rapidly by Langley, Hutchins, Angström, Paschen, Veile, Maurer, Crow Hoppe, and others. The theoretical problems, the numerical problems have also been carefully treated, both experimentally and mathematically.

The present state of theoretical physical and mechanical meteorology cannot be fully presented in non-technical English text. It is necessary to employ algebraic formulæ, or numerical tables, or graphic diagrams, the former being certainly the least cumbersome and the most generally available. The uniform system of notation devised by Professor F. H. Bigelow, and a very complete summary of the formulæ of physical meteorology expressing the results of many recent students will be found in chapters x. and xi. of his Report on the International Cloud Observations, published as vol. ii. of the annual report of the chief of the U.S. Weather Bureau for 1898-1899.

The fundamental laws to which the atmosphere is subject are as follows:

A. The Equation of Elastic Pressure. - The pressure shown and measured by the barometer is an elastic pressure acting in all directions equally at the point where it is measured. To express it, let \( p \) be the pressure of the air, and \( V \) the volume that it occupies. If \( p \) is a given quantity, we have

\[
\frac{dV}{V} = \frac{dp}{p} - \frac{RT}{p}\frac{dp}{T}.
\]

where \( T \) expresses the absolute temperature, \( p \) the pressure, \( V \) the volume, and \( R \) a constant which differs for each gas, being 29.2713 for ordinary pure dry air and 47.060 for pure aqueous vapour, if we use as fundamental units the kilogram, metre and second. Therefore, the expression \( dV \) will expand in all directions if not rigidly enclosed, but will cool in so doing. On the other hand, if forcibly compressed within smaller dimensions, it will become warmer, when the pressure is increased by a given amount. The pressure of the air of a prescribed chemical constitution will have a prescribed definite weight. The general relations between absolute temperature, pressure and volume are expressed by the formula

\[
p = \frac{RT}{V}.
\]

where \( T \) expresses the absolute temperature, \( p \) the pressure, \( V \) the volume, and \( R \) a constant which differs for each gas, being 29.2713 for ordinary pure dry air and 47.060 for pure aqueous vapour, if we use as fundamental units the kilogram, metre and second. Therefore, the expression \( dV \) will expand in all directions if not rigidly enclosed, but will cool in so doing. The treatment of atmospheric problems by Ferrel was followed by an equally ingenious mathematical treatment by Professors Guildberg and Mohl, of Christiana, in two papers published by them in 1876 and 1880 respectively. These authors, like Ferrel, treated isolated portions of the atmosphere and obtain special solutions, which, however, have not the generality that must eventually be demanded in a rigorous and general discussion of the atmosphere movements.

The treatment of atmospheric problems by Hergesell and Rykat at the end of the 19th century was followed by the work of Oberbeck, of the University of Kiel, in 1882 and 1883. They first attempted to express analytically the initial conditions of the atmosphere as to temperature and pressure, and its boundary conditions as between the earth's surface on its lower side and the known outward pressure on its upper side. As the true earth's surface cannot be represented by any simple algebraic formula, it is customary to assume that it is a uniform sphere, neglecting at least partially, if not wholly, the sphericity of the earth. We may first assume that there is no motion between the earth and the air, but must afterwards make allowance for its influence. Thirdly, we assume that the action of the earth's surface to heat the air and to throw moisture into evaporation into the atmosphere is negligible. Finally, in many cases we go so far as to assume that the atmosphere is an incompressible rare liquid having a uniform density and a uniform depth of about 10,000 metres, corresponding to the average standard density of dry air under a pressure of 760 mm. of mercury at the temperature of 0°C. Even under these simplifications the analytic difficulties have been too great to admit of rigorous solutions, except in very simple cases.

earth and the friction, but in the latter also on the intensity of the ascending current of air. In passing from the outer to the inner surface of the earth, the pressure and temperature change in such a way that the directions of the winds are not continuous, although the movement and the barometric pressures are assumed to be continuous. This latter peculiarity does not occur in nature, and is undoubtedly an assumption similar to Oberbeck's method of treating the fundamental equations.

An improvement in the mathematical analysis was introduced by Dr F. Pockels of Göttingen in a memoir published in the "Met. Zeit." He introduces a new assumption which gives a more accurate picture of the changes of temperature, pressure, gradient, wind direction, and velocity from the centre of the cyclone to the outer edge of the anti-cyclone. In this way, he may reasonably be supposed to have their counterparts in nature. Such mathematical solutions, however, are based upon the assumption that we are dealing with a comparatively small portion of the earth's surface, and that the effects are represented as if they could be computed in a rotation and a uniform coefficient of friction. Moreover, the movements in the cyclones and anti-cyclones are assumed to be steady and permanent by reason of the perfect balance of all the forces involved therein. Of course these conditions are not exactly fulfilled, but in general Pockels shows that his theoretical results agree fairly well with the observed conditions as to wind and pressure. He computes the actual distribution of these elements under the assumption that the centre of the anti-cyclone is at latitude 55°5 and that the coefficient of friction is 0-00008, whereas viscosity proper would require only 0-0002. An elegant mathematical presentation of these calculations is given by W. Wien in "Lehrbuch der Hydrodynamik" (Leipzig, 1900).

Notwithstanding the fact that these difficult mathematical investigations still lead us to unsatisfactory results, they are of the greatest importance. Theoretical studies of the various forces involved in the movements of the atmosphere are of the utmost interest. We must therefore mention the interesting attack made by Oberbeck upon the solution of the general problem of atmospheric circulation.

His memoir on this subject was published in the "Sitzungsberichte" of the Academy of Sciences at Berlin in 1888. The fundamental assumption in this memoir implies that there is a general and simple system of circulation in the atmosphere. If this is not the case, but the eventual solution of the problem leads Oberbeck to two independent systems of winds, an upper and a lower, without any well-defined connection at the polar and equatorial ends of these two systems, then all the former calculations are wrong.

Among the hypotheses introduced in the course of his mathematical work, the most important, and perhaps the one most open to objection, is that the distribution of temperature throughout the atmosphere in both the upper and lower strata can be represented by the equation

\[ T = A + B \left(1 - 3 \cos^2 \theta \right) \]  

Undoubtedly this equation represents observations in the lower strata near the surface of the earth, but the constants that enter into it, if not the form itself, must be changed for the upper strata. The solution arrived at by Oberbeck gives the following equations representing the components of the movement of the atmosphere toward the zenith, \( v \), toward the north, \( v \), toward the east, \( v \), and toward the south, \( v \):

\[ V = C \left(1 - 3 \cos^2 \theta \right) \]  

In accordance with these equations he deduces the general circulation of the atmosphere as follows: In the lower current the air flows from the polar regions eastward until it reaches the parallel of going, and in the years 1887, 1889, and 1904, he develops with great patience many of the miniaute of the movement of the earth's atmosphere and cyclonic storms. The assumptions under which he conducts his investigations do not depart from nature quite so far as those adopted by other mathematicians. Like Ferrel, he considers that the earth rotates and that it influences the atmospheric conditions. In using the solutions of physical and meteorological observations; and although, like all practical mathematicians, he considers Ferrel as having departed too far from rigorous mathematical methods, yet he also unites with them in acknowledging that the atmosphere is disturbed and that it is disturbed by Ferrel harmonize with the meteorology of the earth.

The fact is that the solution of the hydrodynamic equations is not single, but multiplex. Every system of initial and boundary conditions corresponding to different atmospheres, and therefore each new series of solutions belongs to each planet of the solar system. It matters not whether we attempt to resolve our problem by introducing a system of coordinate equations of analytical algebraic formulas, and integrate the equations that result, or whether we adopt a graphic process for the representation of observed atmospheric conditions and integrate by arithmetical, geometrical or mechanical processes. In all cases we must come to the same result, namely, our resulting expressions for the distribution of pressure and wind will agree with observations as far as they are consistent. Our original equations represented the actual temperatures, resistances and other attending conditions.

In the last portion of Kitao's third memoir he gives some attention to the interaction of two cyclonic systems upon each other when there is a wind too fast or too slow. The influence of one system can be expressed by the addition of a certain linear function to the equations representing the motions of the other. He even gives the basis for the further study of the extension of equatorial and polar currents into the regions between those within the tropics. Finally, he suggests in general terms how the resistances of the earth's surface, in connection with the interaction of the air, arc to be represented, and shows under what conditions the assumptions that underlie his solutions may, and in fact must, very closely represent the actual atmosphere.

Geophysical and Theoretical Meteorology

The General Circulation of the Atmosphere.—If the meteorologist had a sufficient number of observations of the motions of the air to represent both the upper and lower currents, he would long since have been able to present a satisfactory scheme showing the average phenomena of the atmosphere. Unfortunately, the only paths of the particles of air as they flow from the poles to the equator and return, but hitherto we have been somewhat misled by being forced to rely mainly on the observed movements of clouds. This motion has been called the general circulation of the atmosphere; it would be a complex matter even if the surface of the earth were homogeneous and without special elevations, but the actual problem is far more difficult, since the general circulation is ordinarily said to be shown by the monthly and annual charts of pressure and winds, temperature, such as were first prepared and published by Buchanan in 1868, and afterwards in Bartholomew's "Physical Atlas of the Weather", and in later years, in the "Monthly Weather Review" and the "Bulletin of the Weather Bureau", of the U. S. Signal Service, and the Winds and temperatures shown in these charts have been obtained nearly all over the earth, in the earth's atmosphere and in the atmosphere of other planets. A mathematical expression appropriate to the study of the dynamics of the atmosphere has been shown in the "Quarterly Journal of the Royal Meteorological Society," a series of observations appropriate to the study of the dynamics of the atmosphere. The best of a great many papers upon the subject have been given in " Bulletin A," published by the U. S. Weather Bureau in 1895. The study of these daily charts for ten years shows how the general circulation of the atmosphere has been represented in the idealized solutions based on monthly and annual averages. The presence of a great and a small continent, and a great and small ocean, and especially of the moisture, with its tendency to condense and to form clouds, is represented in the study of the problem. The most prominent features of the general circulation of the atmosphere are the system of trade winds, north-easterly in the northern tropics and south-easterly in the southern tropics, the system of westerly winds beyond the trade wind region, namely, north-westery in the north temperate and south-westery in the south temperate zone, and against the system
of upper winds shown by the higher clouds, namely, south-westery in the northern hemisphere and north-westerly in the southern.

Halley in 1680, and Hadley in 1735, observed the phenomenon of the effect of a uniform temperature of the earth's surface with no horizontal movement. In the northern hemisphere the winds blow from west to east, and in the southern hemisphere from east to west. The phenomenon is therefore due to heat waves in the atmosphere, and not to the movement of the air at the surface. The winds are produced by the differential heating of the earth, and the larger the daily range of temperature, the greater the intensity of the winds.

The winds are not completely uniform, but they are generally blowing from the west in the northern hemisphere and from the east in the southern hemisphere. The winds are not always blowing in a straight line, but they are often deflected by the influence of the earth's rotation. The winds are also influenced by the topography of the land, and by the presence of large bodies of water.

The winds are further influenced by the pressure gradient, which is the difference in pressure between two points. The pressure gradient is caused by the difference in temperature between two points, and by the curvature of the earth's surface.

The winds are also influenced by the Coriolis effect, which is the deflection of the wind due to the rotation of the earth. The Coriolis effect is greater in the southern hemisphere than in the northern hemisphere, and it is greatest at the equator.

expressed by the following formula for the pressures that prevail at sea-level:

\[ \mathbf{G} = \left(2\pi \sin \phi + \cos \varphi \right) \rho \ \sec \mathbf{r} \left[10^6, 000, 000\right] \]

A popular exposition of this and other results of Ferrel's work is given by Archibald's "The Great Meteor" and still more fully by F. G. T. Stoney. "On the Winds" (New York, 1889, and later editions).

The charts of mean annual pressure, temperature, and wind above referred to show certain broad features that embrace the whole system of the atmosphere as a whole, but with the exception of the equator and the poles, the high pressures under the tropics, the trade winds below and the anti-trades above, with comparative calms under the belts of equatorial low pressure and tropical high pressure, and the movement of cold and warm currents, how these mean average conditions depend upon each other, and to devise a system of general circulation of the wind consistent with these great departures, is the great problem that we have laid before us. The only way to which every student of meteorology is made to look is that of the great system of vortices, which, in an orderly succession of motions, constitutes the natural solution of the equations of motion—but the mathematical treatment of this form of motion has not yet been sufficiently well developed, for the conditions of this case are not well known.

In 1890 Professor Hann published a careful analysis of the actual temperature conditions prevailing over an extensive area of high pressure, and he arrived at the conclusion that there be a difference of temperature between the upper and lower air strata in both high and low areas, namely, in anti-cyclones and cyclones are often directly contrary to those supposed to prevail by Esdy and Pansu. He found that there is a more spread of temperature above and below the earth's surface than above the surface of the ocean, and that the pressure is essentially a measure of the temperature of the ocean, and that the pressure is essentially a measure of the temperature of the ocean.

The idea that the motion of heat explains the anomalies of temperature, but the dynamic phenomena still remained unexplained. On the other hand, von Helmholz in several memoirs of 1862-1871 showed that waves or billows may be formed in the atmosphere of great extent at the dividing surface between upper and lower strata moving in different directions and with different velocities. Under specific conditions these billows may become like the breakers and caps of waves of the ocean when driven by the wind. In an ocean the hypothesis of the aerodynamic breakers correspond to our troughs of low pressure and the storms experienced in the lower atmosphere seemed very plausible. Professor Hann concluded upon the condition that there be a difference of temperature between the upper and lower air strata in both high and low areas, namely, in anti-cyclones and cyclones. The high pressure is essentially a measure of the temperature of the ocean, and the high pressures are essentially a measure of the temperature of the ocean. In 1889, and later editions, the only way to which every student of meteorology is made to look is that of the great system of vortices, which, in an orderly succession of motions, constitutes the natural solution of the equations of motion—but the mathematical treatment of this form of motion has not yet been sufficiently well developed, for the conditions of this case are not well known.

in the heat received from the sun; for instance, what variation in the earth’s atmosphere corresponds to the periodic variations of the solar spots. The general current of Helmholtz’s investigations was that no periodic change in the earth’s atmosphere can be maintained for any length of time by a given periodic influence outside of the atmosphere. On the other hand, it is barely possible that wave and vortex phenomena on the sun’s surface may have the same properties as related phenomena in the earth’s atmosphere, so that there may be a parallelism without any direct connection between the two.

An important paper on the application of hydrodynamics to the atmosphere is that by Professor V. Bjerknes, of Stockholm, Sweden, which was read in September 1899 at Munich, and is now published in an English translation in the U.S. National Academy of Sciences, Proceedings (1900). On “On the Theory of Circulatory Movements in the Atmosphere”.

In this memoir Bjerknes applies certain fundamental theorems in fluid motion by Helmholtz, Kelvin, and Carlini, to the problems of atmospheric circulation. He simplifies the hydrodynamic conceptions by dealing with density directly instead of temperature and pressure, and uses charts of “isosteres,” or lines of equal density, very much as was proposed by Albbe in 1889 in his Preparatory Studies, where he utilized lines of equal buoyancy or “isobaths,” and such as Elkholm published in 1891 as “isoatmics” and which were called “Isopyks” by Müller-Hauffen. Bjerknes has thus made it practicable to apply hydrodynamic principles in a simple manner without the necessity of analytically integrating the equations, at least for many ordinary cases. He also gives an important criticism of an earlier paper by Mr. Wener, in which he noted an apparent discrepancy between the physical theory, according to which cycles are perpetually renewed, and the mechanical theory, according to which they are simply carried along in the general atmosphere. This paper is illusory, which is due to Mr. Sandström, of Stockholm, who has applied these methods to a storm of September 1898 in the United States. The further development of Bjerknes’s methods promises to be of great advantage in theoretical and practical meteorology. His profound lectures at Columbia University in New York and in Washington in December 1905 aroused such an interest that the Carnegie Institution at once assigned the funds to enable him to complete and publish the applications to meteorology of the methods of analysis given in detail in Bjerknes’s Vorlesungen (Leipzig, i. 1900, ii. 1902), and in his Recherches sur les champs de force de l’atmosphère (Stockholm, 1899). In his lectures at 1905 at Columbia University Bjerknes treated the atmosphere as a continuous hydrodynamic field of aerial solenoids and forces acting on them, to which vector analysis can be applied. This may be due to Heaviside for electric and magnetic problems.

Every material point is a small spherical mass of air free to extend or contract with pressure, temperature or moisture; free to rotate about each of three movable axes passing through its centre and to move along and revolve about three fixed axes through the centre of the earth. These numerous degrees of freedom are easily expressed in Bjerknes’s notation and by his typical equations of motion. The direction of the vector of the velocities of any set of surfaces is then due to the internal "dimension" controlling inertia and movement. The observed atmospheric condition at any moment is shown by a series of isodense surfaces intersected by planes of isothermals or isobars of constant continuous mass of unit solenoids. This field becomes either an elastic, magnetic or hydrodynamic field according to the interpretation assigned to the equations—in either case the analytical processes are the same. The analogous conclusions about sets of phenomena are complete throughout, and those of one field elucidate or illustrate those of the other two fields. This is the outcome of the study of such analogies begun by Euler, Helmholtz, Hoppe, and extensively furthered by Maxwell and Kelvin, but especially by C. A. Bjerknes. The homologies or analogies by V. Bjerknes are given at p. 122 of his Recherches (1905), and include the following six triads:

I. Hydrodynamics. velocity of unit mass
   Magnetics. magnetic induction
   Electrics. electric induction

II. Hydrodynamics. intensity of the field
   Magnetics. magnetic permeability
   Electrics. dielectric constant

III. Hydrodynamics. velocity of energy
   Magnetics. density of the true magnetic mass
   Electrics. electric constant

IV. Hydrodynamics. velocity of expansion per unit volume
   Magnetics. density of the true magnetic mass
   Electrics. electric constant

V. Hydrodynamics. density of the dynamical vortex
   Magnetics. steady magnetic current
   Electrics. residual magnetic

VI. Hydrodynamics. specific volume
   Magnetics. magnetic permeability
   Electrics. dielectric constant

which have been slightly rectified by Dr. G. H. Ling, Am. Jour. Math. (1906). In the application of Bjerknes’s methods of study to the atmosphere there may also be considered the solar and the solenoids and the forces. Barometric pressures are reduced from the observing stations not only down to sea-level but up to other levels surfaces of greater pressure. The differences are done in raising a unit mass from one level to the next (see Bjerknes and Sandström, A Treatise on Dynamic Meteorology and Hydrography, Washington, 1906).

The Journal and Society of Arts. Barometric Pressure.

For a long time attempts were made to explain the periodic variations of the barometer by a consideration of static conditions, but it is now evident that this problem, like that of the circulation of the atmosphere and the sea, requires a new and different series of researches into the character of the phenomena from an observational point of view has been made by Hann, who gave a summary of our knowledge in his subject in 1906. In the first place, two Rain. Scott in the Quart. Jour. Roy. Met. Soc. (Jan. 1899) see also an important addition by Hann and Trabert in the Met. Zett., Nov. 1899, and the summary of his results as given in Lehrbruch, 1866. Hann has shown that at the earth’s surface three regular periodic variations are established by observation, viz. the diurnal, semi-diurnal and ter-diurnal. On the higher mountains these variations change their character with altitude. (1) At the equator the diurnal variation is represented by the formula 0-30 mm. sin (5°±x), where x is the hourly angle of the sun. In higher latitudes either north or south the coefficient A = 0-30 mm. diminishes, but, vice versa, the coefficient B increases. It is therefore evident that this diurnal oscillation depends directly on the hour angle of the sun, and probably, therefore, principally on the amount of heat and vapour received by the atmosphere, as on the day. This variation is largest in equatorial regions, and is expressed by the formula A = (9-98 mm. − 0-573 mm. sin "x) cos 3° as given by Hann, or A = (9-92 mm. − 0-495 sin "x) cos 3° as revised by Trabert. This amplitude also be considered as the difference of the highest and lowest pressure at any point; it is on certain central local meridians.

The times at which the semi-diurnal phases of maximum and minimum occur are subject to laws different from those for the diurnal period. Within the tropics the phase angle is 160° and at mid-latitudes it seems to be the same over the whole globe, so that the phase does not depend clearly upon the hour angle of the sun or on the local time. The amplitudes appear to depend on the excess of land in the northern hemisphere as compared with the water and cloud of the southern hemisphere. The amplitude also varies during the year, being greatest at perihelion and least at aphelion. Hann suggests that the semi-diurnal oscillation is controlled by the temperature of the earth’s surface, but this is not quite so certain for the northern hemisphere is hotter when the earth is in aphelion than the southern hemisphere when the earth is in perihelion, owing to the insubstantial matter of the latter. The semi-diurnal oscillation has the approximate value shown by the formula 0-04 mm. sin (35°±3). The phase angle is sensibly the same everywhere, and the amplitude varies slightly with the earth’s orbit, so that this semi-diurnal oscillation is the same period which is as remarkable as that of the semi-diurnal oscillation; the maximum amplitude occurs in January in the northern hemisphere, and in July in the southern.

The physics of the atmosphere has not yet been explored so exhaustively as to explain fully these three systematic barometric variations, but neither have we as yet any necessity for appealing to some unknown cause of action as a possible cause of their existence. The action of the solar heat upon the illuminated hemisphere, and the many consequences that result therefrom, may be expected to explain the barometric periods. The variations of sunshine and cloudiness, of humidity, and of temperature are the most important factors. The semi-diurnal wave is more pronounced in the northern hemisphere than in the southern. Laplace applied his investigations on the tides to the gravitational tide of the ocean, and when he passed to the corresponding solar and lunar tides he imagined that these tides must be unacceptable, unless, indeed, certain remarkable relations existed between the circumference of the earth and the depth of the atmosphere. As these relations do not exist, it is evident that the semi-diurnal tides cannot be caused by any such thing as both diurnal and semi-diurnal, cannot exceed a few thousandths of an inch of barometric pressure. On the other hand, the same process of mathematical reasoning enables us to investigate the action of the solar heat upon the pressure at the earth’s surface, and the pressure at the illuminated coatings, so as to produce a pressure tide, due to the expansion of the lower layer of air on the illuminated globe of the globe. The laws that must govern these presuridal tides have been investigated by Kelvin, Rayleigh (Phil.
METEOROLOGY

Mag., Feb. 1890), and especially by Margules (Vienna Sitz. Ber. 1890-1893). The two latter have shown the truth of a proposition enunciated by Kelvin in 1892, without demonstration, to the effect that the latent-heat-producing force will have an amplitude that is larger for the half-day term than for the whole-day term. They therefore explain the rise and fall of temperature by a process in which the latent heat of phases is again transferred to the atmosphere. The energy thus transferred to the atmosphere is equal to the latent heat of the condensation, and the change in the latent heat of the participating gases, as low as some pressurised tides or waves of expansion, originally produced by solar heat, but magnified by the resonance between forced and free waves in an atmosphere and on a globe having the specific dampening properties due to the analytical work of Laplace and Kelvin arrived at this special solution of the tidal equation were objected to by Airy and Ferrel, but the matter has been, as we think, much improved on by Dr. G. H. Leib, in a memoir published in the Annales de Mathématiques. Although a literal view of the results of this research is of some importance, it is not to be expected that the atmospheric oscillations will be of the same order of magnitude as the tides. The field of oscillation of the atmospheric pressure is not the same as the tides, but the oscillations are produced by similar forces. It is to be expected that the amplitude of the atmospheric pressure will be much less than the tides. The size of the atmospheric pressure oscillations depends on the wind; the smaller the wind, the larger the atmospheric pressure oscillations. The size of the wind is in turn dependent on the latitude of the place and the season of the year. The period of these oscillations is about twenty-four hours, and the diurnal oscillations are much larger than the semidiurnal oscillations. The effect of the diurnal oscillations is to produce a daily alternation of temperature, such as to show a very marked diurnal variation of temperature. The period of the oscillations is about seven days, and the diurnal oscillations are much larger than the semi-diurnal oscillations. The effect of the diurnal oscillations is to produce a daily alternation of temperature, such as to show a very marked diurnal variation of temperature.
of snow left, within the clouds must be very small, and the cloud has the delicate appearance possessed by polar stratus. Here, the 288
characteristic lines are given by these systems of $\alpha$, $\beta$, $\gamma$, and $\delta$, and the moisture lines. The lines show the density of the moist air at any stage. The improved diagram by Neuhoff, published in 1860, is called the "System of Allegory of the Earth's Atmosphere," and its arrangements help to solve many problems suggested by the recent progress of aerial research.

In von Bezold's treatment of this subject only illustrative diagrams are made use of. Accurate, correct, and accurate, these lines, are necessarily too large and detailed. He presents graphically the exact explanation of the cooling by expansion, the loss of both mass and heat by the rainfall, and the strength of the globe of air that is raised by it, and fohn winds in Switzerland and chinook winds in Montana. Even in the neighbourhood of a storm over low lands and the ocean, the warm moist air in front, after being carried up to the higher strata, is brought, again, in the upper strata, until a corresponding portion of the latter descends drier and warmer on the opposite side of the central low pressure. In order to have a convenient term expressive of the fact that the two masses of air in different portions of the atmosphere having different pressures, temperatures, and moisture, would, if brought to the same pressure, also necessarily attain the same temperature, von Bezold introduced the expression "potential temperature," and devised a simple diagram by which the potential temperature may be determined for any mass of air whose present temperature, pressure, and moisture are known. In an ascending mass of air, from the beginning of the condensation, a temperature of moisture steam is the same as by reason of the loss of moisture, but in a descending mass of air it remains constant at the maximum value attained by it at the highest point, and only goes up. The higher the potential pressure of the upper strata of the atmosphere are higher than those of the lower. In general the so-called vertical temperature gradient is smaller than would correspond to the adiabatic rate for the dry stage. The latter gradient is 0.59 C, per hundred metres for the dry stage, but the actual atmospheric observations give about 0.6-. Apparently this difference represents primarily the latent heat evolved by the condensation of water vapour in the carried current layers, and also denotes in part the effect of the radiant heat directly retained in the atmosphere by the action of the dust and the surfaces of the clouds. Passing from simple changes due to ascent and descent, von Bezold investigated the results of the mixing of different masses of air, having different temperatures and humidities, or different potential temperatures. The importance of such mixtures was exaggerated by Hutton, while that of thermodynamic processes was maintained by Esby. The significance of the two was first clearly shown by H. and as far as it relates to the formation of rain, and further details have been considered by von Bezold. The practical tables contained in Professor Bigelow's report on clouds, and those of Neuhoff as arranged for the use of those who follow up von Bezold's train of thought, complete our methods of studying this subject.

A probable explanation of the views of von Bezold, Hertz and Helmholtz was published by Brillouin in his memoir of 1898. Just as we have learned that the motions of the atmosphere are not due either to the general distribution of heat or to local influences exerted by the earth, so it is not due to the fact that the temperature of the air is not due either to radiation and absorption or to dynamic processes exclusively, but to both combined, so in the phenomenon of the cloud the precipitation is not caused by the cooling by mixing, or to the cooling by expansion, or to radiation, but in general a complex result of all. The effect of the evaporation of cloudy particles in the production of descending cold currents has always been understood in a general way, but was first brought to prominence by Esby in 1838, and perhaps equally forcibly by Faye in 1875. Helmholtz, in his memoirs on a phenomenon in the atmosphere, showed how continuous currents may be formed on each other and mix together at their boundary surface; but Brillouin explains how these mixtures produce cloud and rain—not heavy rains, of course, but light showers, and spits of snow and possibly hail. He describes the layers of clouds in the atmosphere, and moving with very different velocities, their motion, relative to the earth because of the rotation of our globe, assumes a much more complicated character than that which obtains when the air has only a vertical motion. Such a cloud that we know, is a mixture of water that possibly this corresponds to the formation of water-spouts and tornadoes.

C. When the contiguous zones are cloudy the mixtures take place under the following conditions: Starting from the stable conditions, the cloudless mixture ascends on the polar side when the west wind which prevails on the equatorial side of the surface of separation is warmer, but descends between the pole and the equatorial side of the horizon where the west wind prevails on the equatorial side, the surface of separation is colder. The mixtures of cloudless air rapidly occupy the whole height of the two layers that are mixing. When they form along a surface that becomes unstable before the aphelion, a whirlwind is set up. When the upper air is substantially warmer than the lower, it is much more difficult to separate the zones than possible this corresponds to the formation of water-spouts and tornadoes.

G. When the contiguous zones are cloudy and the mixtures produce decided condensations, and sometimes even precipitation, the study of these must follow closely in the train of thought followed out by von Bezold. When the contiguous zones are feebly, but the surface of separation is stable, the possibility of condensation is less. But it is evident that these condensations are much as to the condition of permanent or destruction of the masses of air having uniform and parallel movements. Thus simplified, the question can be treated by elementary geometric methods, by means of which we at once recover and complete the results given by Brillouin for zones of clear air and discover a whole series of new results for zones of cloudy air." Among Brillouin's results are the following theorems:

A. If the atmosphere be divided into narrow zonal rings, each of which completely surrounds the globe, thus covering a narrow zone of latitude, and if each is within itself in convective equilibrium so that the surfaces of equal pressure shall be surfaces of revolution around the axis of rotation, and if the difference of angular velocity of the angular velocity of any particle of the air will vary in inverse ratio of the square of its distance from the axis of rotation, or $a^2$ is constant; that is to say, the air will not move more slowly than at the equator, the angular velocity, smaller far from the axis and greater near to it.

B. The surfaces of equal pressure are more concave towards the centre than is the surface of the globe, and they are tangent to a plane only at the parallel where calms prevail.

C. A heavy gaseous atmosphere resting upon a rotating frictionless globe divides itself into concentric rings whose angular movements increase as we pass from the polar region towards the equatorial region, the central globe rotates more rapidly than the equatorial atmospheric ring.

D. The surface of separation between two contiguous eccentric rings must be such that the atmospheric pressures shall have the same value as one approaches this surface from either direction, and the surface of separation is stable if the differences of pressure in different parts of this surface are directed towards such the surface pressure.

E. If the surfaces of equal pressure of isobars are nearly horizontal, as in ordinary cases, the calculations are comparatively easy to make. Let the inclination of the isobaric surface be $\theta$ to the line parallel to the axis of the earth, and the horizontal distance measured in the direction of the attraction of gravity; then the angle of inclination of the isobaric surface is given by the equation

$$\tan \phi = \frac{h - h_1}{h_1 \cos \lambda},$$

where $\lambda$ is the complement of the angle between the direction of gravity and the line drawn to the poles, or the axis of rotation of the earth. The surface of separation is that over which the pressure is the same in two contiguous isobars, or zones, and is identical with a vertical plane only when the densities and velocities in the two layers have certain specific relative to each other. It can never lie between the isobaric surfaces that Brillouin designates as a 1 and 2. If the result is the equilibrium may be stable, it is necessary that when ascending in the atmosphere along a line parallel to the polar axis of rotation, a thorough investigation of the formation of the isobaric surface.

F. When the contiguous zones are cloudless the mixtures take place under the following conditions: Starting from the stable conditions, the cloudless mixture ascends on the polar side when the west wind which prevails on the equatorial side of the surface of separation is warmer, but descends between the pole and the equatorial side of the horizon where the west wind prevails on the equatorial side, the surface of separation is colder. The mixtures of cloudless air rapidly occupy the whole height of the two layers that are mixing. When they form along a surface that becomes unstable before the aphelion, a whirlwind is set up. When the upper air is substantially warmer than the lower, it is much more difficult to separate the zones than possible this corresponds to the formation of water-spouts and tornadoes.
After Brillouin.

**FIG. 11.**—Diagram illustrating Clouds due to Mixture.

1897), gives five of the cases elucidated by Brillouin. In each of these the left-hand side of the diagram is the polar side, the air being cold above and the wind from the east, while the right-hand side is the equatorial side, the air being warm above and the wind from the west. The reader will see that in each case, depending on the relative temperatures and winds, layers of cloud are formed of marked individuality. As none of these clouds appear in the *International Cloud Atlas* or in the various systems of notation for clouds, one is all the more impressed with the importance of their study and the success with which Brillouin has opened up the way for future investigators. We have no longer to do with personal and local experience, but with an analytical description of a small number of characteristics easy to comprehend and applicable at every locality throughout the globe.

From a thermodynamic point of view the most important study is that published by Margules, *Ueber die Energie der Stürme* (Vienna, 1905). This work considers only the total energy and its adiabatic transformations within a mass of air constituting a closed system. Truly adiabatic changes in closed systems do not occur within any special portion of the earth's atmosphere, neither can our entire atmosphere be considered as one such system—but Margules' results are appropriately applicable to many observed cases and complete the demonstration of the general truth that we must not confine our studies to the simpler cases treated by Laptev, Raye, Sohocke, Peslin, Ferrel, Mohn. All imaginable combinations of conditions exist, and a method must be found to treat the whole subject comprehensively and rigorously.

The three equations of energy on which Margules bases his work are:

\[ R+\dot{Q}(K+P)+\dot{SA}=Q \]

\[ R+H(K+P)+\dot{I}=Q \]

where \( R \) = energy lost by friction or converted into heat; \( K \) = kinetic energy due to velocity of moving masses; \( P \) = potential energy due to location and gravity and pressure heat; \( \dot{A} \) = work done by internal forces when air is expanding or contracting; \( \dot{I} \) = internal energy due to the existing pressure and temperature; \( \dot{Q} \) = quantity of heat or thermal energy added or lost during any operation and which is zero during adiabatic processes only.

These equations are applied to cases in which masses of air of different temperatures and moistures are superposed and then left free to assume stable equilibrium. It results in every case that there is no free energy developed. Any condensation of moisture by expan-

sion is counterbalanced by redistribution of potential energy and by the work done in the interchange of locations. The idea that barometric pressure gradients make the storm-wind is seen to be erroneous and the primary importance of gravity gradients is brought to light. The source of a storm is to be sought only in the potential energy position and in the velocity of ascent of the storm areas, although these are generally lost sight of owing to the great horizontal and small vertical dimensions of the storm areas. The horizontal distribution of pressure seems to be a forced transformation within the storm areas at the boundary surface of the earth, by reason of which a small part of the mass of air acquires a greater velocity than it could by ascending in the coldest or sinking in the warmest part of the storm areas. But how we come to problems that cannot be solved by considering the energy only.

This latter quotation emphasizes the necessity of returning to the equations of motion. The thermodynamics and hydrodynamics of the atmosphere must be studied in their relations; no longer be separated so far. Apparently we may expect this next step to be taken in the above-mentioned work promised by V. Bjerknes, but meanwhile Professor I. S. Bigelow has published,* fully attacked some features of the problem in his "Studies on the Thermodynamics of the Atmosphere" (*Monthly Weather Review*, Jan.-Dec. 1906). In ch. iii. of his studies (*Monthly Weather Review*, March 1906) Bigelow establishes a thermodynamic formula applicable to non-adiabatic processes by introducing a factor \( n \) so that the pressure \( P \) and absolute temperature \( T \) are connected by the formula

\[ \frac{P}{P_0} = \left( \frac{T}{T_0} \right)^n \]

In our fig. 1 given, Cottier has assumed \( n = 1.2 \), but as the values have now been computed for all altitudes from the observations given by balloons and kites, and have a very great importance and application, we copy some results from Bigelow's Table below:

The existence of such large values of \( n \) shows the great extent to which non-adiabatic processes enter into atmospheric physics. Here the atmosphere is radiating, warming and transferring energy by a number of transformations, occurring at various altitudes and at all altitudes. Knowing the thermodynamic structure of areas of high and low pressure we find the modifications needed in the energy formula for non-adiabatic processes—and Bigelow applies the resulting formula to a famous case of waterspout of the 19th of August 1865 over Nantucket Sound, for which many photographs and measurements are thus available.

The thermodynamic study of this waterspout being thus accomplished, it was followed by a combined thermohydrodynamic study of all

We have thus passed in review the steady progress of mathematical physicists in their attempts to unravel the complex dynamics of our atmosphere. The profound importance of this subject to governmental weather bureaus, and through them to the whole civilized world, stimulates diligent effort to overcome the inherent difficulties of the problems. An elaborate system of closely and laboriously constructed machines is set up to calculate this, and the results of this work are published daily in the *Weather Review*.

**Note:** The values given are for winter and summer conditions, and are applicable to all altitudes.
is the ultimate step in the formation of cloud. The cloud consists, like fog, of extremely small particles, so light that they float indefinitely in the air, and may remain suspended there without undergoing a change until they have grown to be sufficiently large and heavy to be carried to the earth that contains a cloud has not yet been satisfactorily explained. It is probable that either one of several processes contributes to bring about this change, and that all of them work together. The following paragraphs represent the hypotheses that have been advanced to account for the nuclei:

1. Cloud particles may be driven together by the motions imparted to them by air pressure and may unite to form much larger ones, which, as they ascend more rapidly, overtake the smaller ones and grow into rain-drops.

2. The particles on the upper boundary of a cloud may at night-time, or in the shade, cool more decidedly than their neighbours below them, either by radiation or by mixture; then in the air in their immediate vicinity becomes correspondingly cold, the particles and their envelopes of cold air sink more rapidly, overtake the nuclei for uniting, with other particles until the large rain-drops are formed.

3. Some cloud particles may be supposed to be electrified positively and others negatively, causing them to attract each other and run into larger ones, or, again, to produce neutral and others charged, which may also bring about separation and union.

4. When any violent agitation of the air, such as the sound waves from a cannon, and similar explosions, set the air in motion, they may be driven together until brought into contact, and united into larger drops.

5. The air—or, properly speaking, the vapour—between ordinary particles may, when in contact with cloud, be in a state of supersaturation; but if it is steady rising to higher altitudes, thereby expanding and cooling, the supersaturation must increase steadily to a degree at which the molecules are notcondensed in the way, and a sudden violent condensation takes place, in which process both the vapour and the cloud particles in a comparatively large space are instantaneously gathered into a large drop.

6. The electricity that may be developed in this process may give rise to the lightning flash, instead of the reverse process described in the preceding paragraphs (C and D).

Hence the preceding five hypotheses seem to be, it must be confessed, each one has ever yet observed precipitation actually formed by these processes. The laborious observations of C. T. R. Wilson of Cambridge, England, probably give the correct ideas as to the meteorological processes involved in the formation of rain. After having followed up the methods inaugurated by Atterking showing that the particles of dust floating in the air, no matter how they may be composed, become by preference the nuclei upon which the moisture begins to condense when air is cooled by expansion, Wilson then showed that in absolutely dustless air, having therefore no nuclei to facilitate condensation, the air is much more liable to condense to a greater extent than in the case of the presence of dust; in fact, dustless air requires to be expanded more than dusty air in the ratio of 4 to 1, or 1:4 times more. The amount of this larger expansion may vary according to the temperature and humidity of the air. Wilson discovered this, he showed that dustless air, having no visible or probable nuclei, acquired such nuclei when a beam of ultra-violet light, or a strong beam of ultra-violet light, or a strong beam of sunlight (which possibly contains all of these radiations), was allowed to pass through the moist air in his experimental tube. In other words, these rays produce a change in the mixed gas and vapour similar to the formation of nuclei, and condensation of aqueous vapour takes place upon these invisible nuclei as readily as upon the visible dust nuclei. Further, the presence of certain metals within the experimental tube also produces nuclei; but the amount of expansion, and therefore of cooling, required to produce condensation upon these metallic nuclei is rather larger than in the case of dust nuclei. The nuclei thrown into the experimental tube by the dustless air are then precipitated from a point of the wire producing the vapour by means of expansions slightly exceeding those required for ordinary dust. Finally, Wilson has been able to show that when dustless air is exposed negatively to condense upon itself, the air upon itself the negative ions the greater than when they are electrified positively, and he suggests that the descent of the rain-drops to the ground, carrying negative electricity from the atmosphere to the earth, may thus explain the effect of the negative charge of the earth and the positive electricity of the atmosphere.

At this point we come into contact with the views developed by J. B. Bohnsack concerning the nature of electricity and the presence of negative and positive particles in the atmosphere. Accordingly, “The molecules made up of what chemists call atoms must be still further subdivided, and the atoms must be conceived as made up of a considerable number of a corpuscles of the same as the mass of the negative ion in a gas at low pressure. In the normal assembly of corpuscles forms a system which is electrical and neutral. Though the individual corpuscles behave like negative ions, yet when they are assembled in a neutral atom the negative effect is balanced by something which causes the space through which the corpuscles are spread to act as if it had a charge of positive electricity equal in amount to the sum of the negative charges on the corpuscles. The atoms are divided into a number of different kinds, ranging from very small to huge, which we may call the unit charge, while the parts of the atom lying outside these units, behind behaves like a positive ion with the units positively charged but with a mass that is large compared with that of the negative ions. The proportions of the various units within the atom varies, but in every case the balance is such that each unit maintains its charge and the atom as a whole maintains its constituting positive and negative units.”

IV. COSMICAL METEOROLOGY

Under this title have been included all possible, plausible or imaginary relations between the earth’s atmosphere and interplanetary space, the influence of solar and stellar radiation on and to and fro at the outer limit of the atmosphere, the bombardment by ions from the sun, the explanation of auroral lights and of magnetic storms, the influence of shooting stars and comet tails, the relation of the zodiacal light and the Geminid shower to the atmosphere, the parallelisms between terrestrial phenomena and the variations of the solar spots and prominences, the origin of long or short climatic periods, the cause of special widespread cold days, the existence of lunar or solar gravitation tides analogous to oceanic tides, the influence of slow changes in the earth’s orbit or the earth’s axis of rotation—all are grouped under cosmical meteorology.

But, in the writer’s judgment these matters, while curious and interesting, have no appreciable bearing on the current important questions of atmospheric mechanics. There seem to be many widespread delusions and mistakes in regard to these problems, analogous to the popular errors in regard to astrology, and it is hardly necessary to do more than allude to them here. The leading meteorologists have relegated such questions to the care of theoretical astronomers and physicists, as matters of knowledge on other planets. The view of some is that the earth does come under other influences than that of the radiation from the sun; but in the present stage of dynamic meteorology we consider only this latter, and, assuming it to be constant as regards quantity and quality, we find the variable selective absorptions and reflections within our own atmosphere, and its complex internal mechanism afford us a bewildering maze of problems such that so long as these are unsolved it would be folly to spend time on these.

V. METEOROLOGICAL ORGANIZATIONS

During the latter half of the 19th century the prosecution of work in meteorology gradually passed out of the hands of individuals into the control of large national organizations. This was the natural result of the discovery that, by the spread of the electric telegraph and ocean cables, it had become possible to compile daily weather-maps for large portions of the globe, and make predictions of the weather and the storms for a day or two in advance, of sufficient accuracy to be of the greatest importance to the material interests of civilized nations. The development of wireless telegraphy since 1900 has even made it possible for isolated ships at sea to exchange weather telegrams, compile daily maps and study surrounding storms. One by one every civilized nation has established either a weather bureau or a meteorological office, or a bureau of hydrography and marine meteorology, or an elaborate establishment for aerial explorations according as its special interests demanded. These governmental bureaus usually pursue both climatology and theoretical meteorology in addition to their daily practical
work of telegraphy, forecasting, and publication of charts. Although, of course, in most cases, the so-called practical work absorbs the greater part of the labor, physics or chemistry, yet everywhere it is recognized that research and the development of a correct theory of the motions of the atmosphere are essential to any important progress in the art of forecasting. Among other important general works in which the official weather bureaus have united, we may enumerate the International Meteorological Congresses, of which the first was held in 1853 at Brussels, the second in 1873 at Vienna, and others more frequently since that date; the establishment of an International Committee, to which questions of general interest are referred; the formation of a universal system of time. In the years 1882 and 1883, the general extension of the meteorological services to include terrestrial magnetism as an essential part of the physics of the globe; the systematic exploration of the upper atmosphere by means of kites and balloons; and the universal co-operation with the U.S. Weather Bureau in the contribution of simultaneous data for its international bulletin and its daily map of the whole northern hemisphere. The hydrographic offices and marine bureaus of the principal commercial nations have united so far as practicable in the daily charting of the general state of the surface of the ocean; and have thrown a new light on the problem of the climatology of the ocean, not only along the lines laid down by Maury and the Brussels Conference of 1853, but also with particular reference to the tracks of storm centres and the laws of storms on the ocean. The condition of these governmental organizations was discussed in the annual address of the Hon. F. Campbell Bayard, delivered before the Royal Meteorological Society of London in January 1895, and in the text accompanying Barholomew’s Physical Atlas, vol. iii.

The development of meteorology, in both its scientific and its practical aspects, is intimately dependent upon the progress of our knowledge of physics, and its study offers important problems that can be solved only by proper combinations of mathematical theory and laboratory experimentation. The professors in colleges and universities who have hitherto lectured on this subject have not failed to develop some features of dynamic meteorology, although most of their attention has been given to climatology. In fact, many of them have been engrossed in the study of general problems in molecular physics, and could give meteorology only a small part of their attention. The early textbooks on meteorology were frequently mere chapters or sections of the general courses in physics or chemistry, and for eminent early cases of university professorships devoted to meteorology are those of the eminent Professor Heinrich Wilhelm Dove at Berlin, Professor Adolphe Quelet at Brussels and Professor Ludwig Friedrich Kaemtz at Halle and Dorphat. In modern times we may point to Professor Wilhelm von Bezdol and George Hellmann at Berlin, Professor Julius Huan at Vienna and Gratz, Professor Josef Maria Perntz at Linz and Vienna, Professor Alexander Woelkof at St Petersburg, Professors Hugo Hildebrandt-Hildebrandson at Upsala, Henrik Mohn at Christians, Elias Loomis at New Haven, Connecticut, W. M. Davis and R. de C. Ward at Cambridge, Massachusetts, Alfred Angot and Marcel Bril lion at Paris, Hugo Hergesell at Strassburg, Arthur Schuster at Manchester, Peter Polis at Bonn, and Richard Bönstein at the School of Agriculture in Berlin. With these exceptions the great universities of the world have as yet given but little special encouragement to meteorology; it has even been stated that there is no great demand for higher education on the subject. On the other hand, the existence of thousands of voluntary observers, the profound interest in the weather actually taken by every individual, and the numerous schemes for utilizing our very limited knowledge of the subject through the activities of the large weather bureaus of the world demonstrate that there is a demand for knowledge perhaps even higher than the universities can offer. It would be very creditable to a nation or to a wealthy patron of science if there should be established meteorological laboratories in connection with important universities, at which not only instruction but especially investigation might be pursued, as is done at the magnificent astronomical observatories that are so numerous throughout the world. Every atmospheric phenomenon can be materially elucidated by exact laboratory experiments and measurements; theory can be confronted with facts; and the student can become an original investigator in meteorology.

The great difficulties inherent to meteorology should stimulate the devotion of the highest talent to the progress of this branch of science. The practical value of weather predictions justifies the expenditure of money and labour in order to improve them in every detail.

METER, ELECTRIC. — Those who desire recent additions to our knowledge should consult first Hann’s Lehrbuch der Meteorologie (1890, 5th ed., Leipzig, 1906) as being a systematic encyclopaedia. Of equal importance is the Meteorologische Zeitchrift (Berlin and Vienna, 1856 to 1873), the International Atlass of Meteorology (1900), the Journal of the Royal Meteorological Society (London) and the Monthly Weather Review (Washington) are the works most convenient to English readers and abound with references to current literature. The Physical Review Science Abstracts and the Fortschritte der Physik contain short notices of all important memoirs and will serve to direct the student’s attention toward any special topic that may interest him.

METER, ELECTRIC. — The public supply of electric energy for lighting and power is necessary to provide for the development of the electric energy or quantity by devices which are called electric meters. Those in use may be classified in several ways: (i) according to the kind of electric supply they are fitted to measure, e.g. whether continuous current or alternating current, and if the latter, whether monophase or polyphase; (ii) according to whether they record intermittently or continuously; (iii) according to the principle of their action, whether mechanical or electrolytic; (iv) according to the nature of the measurement, whether quantity or energy meters. The last principle is fundamental. Meters intended to measure electric energy (which is really the subject of the sale and purchase) are called joule meters, or generally watt-hour meters. Meters intended to measure electric quantity are called coulomb meters and also amper-hour meters; they are employed for the measurement of public electric supply on the assumption that the electromotive force or pressure is constant. Most of the practical meters in use at the present time may be classified under the following five heads: electrolytic meters, motor meters, clock meters, intermittent registering meters and induction meters.

Electrolytic Meters are exclusively amper-hour meters, measuring electric quantity directly and electric energy only indirectly, on the assumption that the pressure of the supply is constant. The first electrolytic house meter in connexion with public electric supply was constructed by St. Edwards of Birmingham, the design of Sprague and Lane-Fox, the last-named inventor elaborating a type of meter which he employed in connexion with his system of electric lighting in its early days. The Edison electric meter, like those of Sprague and Lane-Fox, was based upon the principle that when an electric current flows through an electrolyte, such as sulphate of copper or sulphate of zinc, the electrodes being plates of copper or zinc, metal is dissolved off one plate (the anode) and deposited on the other plate (the cathode). It consisted of a glass vessel, containing a solution of sulphate of zinc, in which were placed two plates of pure amalgamated zinc. These plates were connected by means of a copper-silver shunt, their size and the distance between them being so adjusted that about $\frac{1}{100}$ part of the current passing through the meter travelled through the electrolytic cell and $\frac{99}{100}$ of the current passed through the shunt. Before being placed in the cells the zinc plates were weighed. The shunted voltmeter was then inserted in series with the electric supply mains leading to the house or building taking electric energy, and the current which passed dissolved the zinc from one plate and deposited it upon the other, so that after a certain interval of time had elapsed the altered weight of the plates enabled the quantity of electricity to be determined from the known fact that an electric current of one ampere per hour will dissolve one gramme of zinc from a solution of sulphate of zinc. Hence the quantity in ampere-hours passing through the electrolytic cell being known and the fraction of the whole quantity taken by the cell being known, the whole quantity was ascertained. To prevent changes of temperature from affecting the shunt ratio, Edison joined in series with the electrolytic cell a copper cell the resistance of which increased with a rise of temperature by the same amount that the electrolyte decreased. Owing to the cost and trouble of weighing a large number of zinc plates, this type of meter fell into disuse.
A more modern type of electrolytic meter is that due to C. O. Bastian. The whole current supplied to the house flows through an electrolytic cell consisting of a glass tube containing two platinum electrodes; the electrolyte is dilute sulphuric acid covered with a layer of boric acid. As the current flows it decomposes the liquid and liberates oxygen and hydrogen gases, which escape. The quantity of electricity which is passed is estimated by the diminution in weight of the liquid, and by the weight of the gases evolved.

The current is determined by measuring the volume of the mercury delivered at the cathode. In the Long-Schatterley electrolytic meter a solution of sulphate of copper is used. Amongst several motor meters one well-known type belonging to the ampere-hour species is that of S. Z. Ferranti, who introduced it in 1883. It consists of an electromagnet within the iron core of which is a long copper tube, and an electric current to move transversely across lines of magnetic force; it becomes in fact the armature of a simple form of dynamo, and rotates with a speed which increases with the strength of the current. The field-coils of the electromagnet serve also to control the rotation of the dynamo is detected and measured by means of a small vane of platinum wire immersed in it, the shaft of this vane being connected by means of an endless supply of wires to the terminals of the apparatus. The core of the electromagnet is worked at a point far below magnetic saturation (see Magnetism); hence the field is nearly proportional to the square of the current, and the resistance offered to the rotating magnetism. The friction of the sides of the core being stamped with grooves. The thin disk of mercury is therefore traversed perpendicularly by lines of magnetic force when the magnet is excited. The current to be measured is passed through the coils of the electromagnet, then enters the mercury disk at the centre, flows through in all directions, and emerges at the periphery. The mass of mercury is thus set in motion, and to the tendency of the inertia to make it go on is opposed the force due to the rotation of the disk which is proportional to the square of the speed. It follows that the number of revolutions the mercury makes in a given time is proportional to the square of the current which is passed through it. In order to overcome the friction of the counting train, Ferranti ingeniously gave to the core of the electromagnet a certain amount of permanent magnetism. Another well-known motor meter, working on essentially the same principle, is that of H. Aron, who introduced it in 1884. In its improved form this meter consists of a single horsehoe permanent magnet formed of tungsten-steel having a strong and constant field. Two air-gaps are made in this field parallel to each other. In one of these a copper disk, called the brake disk, revolves, and in the other a copper armature disk. The latter is slit radially, and the magnetic field is so arranged that it perforates each half of the disk in opposite directions. The armature is immersed in a small vessel filled with mercury, which is insulated from the vessel and the armature, except at the ends of the copper slit. An electric current to be measured passes transversely across the disk and causes it to revolve in the direction in which the copper brake, geared on the same shaft, revolves in the field and has local or eddy currents produced in it which retard its action. The control of this meter is to make it capable of passing a current to attract the counter iron with no strength that the friction of the train becomes immaterial in comparison. This meter is an ammeter-hour meter and applicable only to continuous current circuits. Another form of motor meter which is much used is that of E. I. Thomson. It takes the form of a small dynamo having an armature and field magnets without any iron core. The armature carries on its shaft a commutator made of silver slips, and the current is fed into the armature by means of brushes of silver wire. The current to be measured passes through the fixed field-coils, whilst through the armature passes a shunt current obtained by connecting the brushes across the supply mains. Induced or eddy currents are thus created in the copper disk, and the reaction of these against the magnetic field offers a resistance to the rotation of the disk. Hence when a current is passed through the meter, the armature rotates and increases its speed in proportion. The force due to the eddy currents in the copper brake. In these circumstances the number of rotations made by the armature is a function of the strength of the current flowing through the armature, and of the resistance of the two fixed field-coils, the former being the current to be measured. Hence the meter is a watt-hour meter and measures electric energy. In order to overcome the friction of the train, two auxiliary short-circuit coils are placed in series with the fixed coil which supplies a driving force sufficient to overcome the friction of the counting train. This last is geared to the shaft of a turn-and-endless screw, and the number of revolutions of the armature is reckoned by the counting-dials, which are

METHODISM

293
during the same time. A common source of trouble is the short

circuiting of the shunt coils owing to the shellacked cotton covering

of the wires, which may be broken through by the heavy

current. A good meter should start with a current which is not more than

2% of its full load current. With a supply pressure of 200 volts

a 5 c.p. carbon filament lamp takes only 0.1 ampere; hence unless a

method is adopted by which the meter will indicate the current consumed by a single small incandescent lamp. In

a large supply system such failure would mean a serious loss of

revenue. The resistance of the coil makes a definite shunt series coil which reduces the supply pressure to the

consumer. On the other hand the resistance of the shunt coil absorbs

energy which generally varies from 1 to 3 watts and is a loss either
to the system or supply according to the number of meters in which the shunt coil is connected. In those meters which are

compounded—that is, have a shunt coil wound on the field magnets to compensate for the friction of the train—it is important to notice

whether the meter will operate or continue operating when there is no current in the series coil, since a meter which runs on the shunt runs up a debt against the consumer for which it gives no corresponding advantage.

Generally speaking, the price of the meter is a subordinate consideration. Since the revenue-earning power of a supply

station depends entirely upon its meters, accuracy in meter record is a serious matter. The cost of measuring the current by

the aid of a meter is made up of three parts; (1) the prime cost of the meter, which varies from £2 to £5 for an ordinary 25-light house electric meter; (2) the capital value of the energy absorbed in it, and (3) if the meter is an average of the staff meter men, copper plate or plates of copper into an electrolytic cell containing a solution of sulphate of copper; the passage of the current dissolves the copper off one of the plates, the other being turned so that it will not pass. As soon as the plate has lost a certain amount of weight corresponding to the value of the electric energy represented by the coin, the plate rises out of the liquid and cuts off the current.

J. A. F.)

METHODISM, a term denoting the religious organizations

which trace their origin to the evangelistic teaching of John

Wesley. The name "Methodist" was given in decision to those

Oxford students who in company with the Wesleys used to meet

together for spiritual fellowship; and later on when John Wesley

had organized his followers into "societies" the name was applied
to them in the same spirit. It was however accepted by him, and in official documents he usually styles them "the people called Methodists." The fact that standards of Methodist doctrine are laid down as consisting of "Mr. Wesley's Notes on the New Testament and the rst Series of his Sermons" (fifty-

three in number), might seem to indicate a departure from existing systems, but it was not so. He fully accepted the

recognized teaching of the Church of England, and publicly

appealed to the Prayer Book and the Thirty-nine Articles in

justification of the doctrines he preached. Methodist

began in a revival of personal religion, and it professed to have but one aim, viz., to spread Scriptural holiness

over the land. Their Methodist doctrines were simple, and

in the main with which they were taught, the clear distinction

which they drew between the profession of godliness and the

enjoyment of its power—added to the emphasis they laid upon

the immediate influence of the Holy Spirit on the consciousness

of the Christian—which attracted attention, gave them dis-
tinction, and even aroused ridicule and opposition. Wesley and his

helpers, finding the Anglican churches closed against them,
took to preaching in the open air; and this method is still

followed, more or less, in the aggressive evangelistic work of all the

Methodist Churches. As followers rapidly increased they were

compelled to hold their own Sunday services, and this naturally

led them to appoint as preachers godly men possessing the

gift of exhortation. These followed their ordinary avocations

on week-days, but on Sundays preached to congregations in their

own immediate neighbourhood, and hence were called local

preachers as distinguished from travelling preachers. The extent
to which the employment of the local preacher is characteristic of

Methodism may be seen from the fact that in the United

Kingdom while there are only about 5000 Methodist ministers,

there are more than 18,000 congregations; some 13,000 con-
gregations, chieflv in the villages, are dependent on local

preachers.

In the organization adopted to foster spiritual life the very

characteristic "Class-meetings for Christian fellowship" take a

prominent place. Membership in the church depends solely

upon being enrolled as a member of one of these meetings for

Christian fellowship, and thus placing oneself under pastoral

oversight.

The Wesleyan Methodists now represent the original body as

founded by John Wesley in Great Britain and Ireland; but in

some countries where he had established Methodism, e.g.,

the episcopal model of Church government after the War of

Independence, and have since that time been known as Episcopal

Methodists (see below). It should be noted that the Welsh

Calvinistic Methodists are only slightly connected with the original

body. They were indirectly the outcome of the evangelistic
efforts of Howell Harris and Rowlands. Their work received

the sympathy of Wesley and liberal financial help from the

Countess of Huntingdon (see Calvinistic Methodists).

For a time Whitefield was leader, and we find a reference to the

"Whitefieldian and Wesleyan Methodists" in the Supplement
to the Gentleman's Magazine for 1747, p. 619. The theological

views of these teachers proved quite incompatible with the

Arminianism of Wesley, and a definite breach between them

and him took place in 1770. The Welsh Calvinistic Methodists are

now a branch of the Presbyterian Church. Other divisions have

been formed at various times by secessions from the Wesleyan

Methodists (see separate articles). They are: Methodist New

Connexion (founded 1797-1798); Bible Christians (1815); United

Methodist Free Churches* (about 1856); Primitive Methodists

(1837-1840); New Connexion (1840); Primitive Wesleyan Methodists (about 1860); Wesleyan Reform Union (1850, reorganized 1859). These bodies have separated solely on matters of Church govern-

ment and not on points of doctrine. The Primitive Methodists in Ireland were a small body who in 1878 seceded because they wished to maintain that close connexion with the Church of

England which existed at the time of Wesley's death, but in 1878

they rejoined the parent body. Methodism has always been aggresive, and her children on emigrating have taken with them

their evangelistic methods. (For the American branches see

below.)

The statistics given in the following table (not including Junior

Society, Classes) are from the Minutes of the Conference of the

Wesleyan Methodist Church for 1909. At the death of Wesley the

figures were: 313 preachers, 119 circuits and mission stations, and

76,968 members. In the United States: 97 circuits, 198 preachers

and 3,187 members. In

1837 the membership in Great Britain and Ireland was 318,716;
in foreign mission stations, 66,007; in Upper Canada, 14,000; while

the Wesleyan Methodist Conference of 1879 had 1,978 preachers and

4,757 members. Total

for the world: 1,049,401, with 4475 members.

Three Ecumenical Conferences have been held—two at City

Road, London, in 1881 and 1901, and one at Washington in 1894.

The statistics presented at the last showed that the Church during

the preceding decade had gained about a million members and three

million adherents. At the same time there has been a steadily

7 These first three were joined in 1907 under the name of the United Methodist Church.
growing feeling in favour of union. Canada and Australasia led the way, for in these countries the Methodist Church was undivided, and the sentiment was greatly strengthened by the formation in the United Kingdom of the United Methodist Church in 1907. See A New History of Methodism, ed. W. J. Townsend, H. B. Workman, George Eayrs (2 vols., London, 1909).

**Methodism in the United States**

There are in the United States sixteen distinct Methodist denominations, all agreeing essentially in doctrine. John Wesley had been conducting his United Societies for more than twenty years before the movement took root in North America.

A.—Episcopal Methodist Churches.

Philip Embury (1720-1773), a Wesleyan local preacher, emigrated in 1760 from Limerick to New York. Robert Strawbridge (1773-1781), a local preacher and native of Ireland, settled in Maryland. In 1766 Embury was stimulated by his relative, Mrs Barbara Heck, to begin Methodist preaching, and a society was soon formed, which grew rapidly. Embury was reinforced by the arrival of Thomas Webb (1724-1796), an English local preacher and a captain in the British army. Webb and Thomas Taylor, a layman of superior ability, appealed to Wesley to send over missionaries, and the 26th annual British Conference, held in 1768, sent to the society in New York five and furnished passage money for two missionaries, Richard Boardman and Joseph Pilmore (1730-1823). Three years later Francis Asbury was sent over, and was made assistant superintendent. Meanwhile Strawbridge had been preaching with success in Maryland and in Virginia.

These "advance agents" of this spiritual propaganda brought with them Wesley's Arminian Theology. They brought also the means of grace on which Wesley placed the greatest stress; such as personal testimony in private and public, class and prayer meetings, watch-nights, love-feasts, the direct and fervent preaching of the Gospel and the singing of Wesleyan hymns, carried on by means of circuits and stations, exhorters,

1 Seating accommodation, 2,374,425.
2 Other preaching-places, 1,961. 3 Sunday and Thursday Schools.
4 Methodism is also represented in several European countries by Conferences and Missions affiliated to the Methodist Episcopal Church of America, and their membership is included in the figures given discipline, and Wesley, hearing of the disagreement, in 1773 appointed Thomas Rankin (c. 1738-1810) superintendent of the entire work of Methodism in America.

The First American Conference.—The First American Conference was held in 1775, and consisted of ten preachers, all of whom were born in England or Ireland. Asbury came to America to remain permanently; but Rankin, unable to identify himself with the people, to take the test oath required in the Revolution, or to sympathize with the colonies, returned to England, as did all the English preachers except Asbury. By May 1776 there were 24 preachers and 4921 members; but in the first year of the Revolution there was a loss of 7 preachers and nearly 1000 members. The next year saw extensive revivals, in sections removed from the seat of war, which added more than 2600 to the number of members.

The preachers in the South determined upon administration of the sacraments, and a committee was chosen whose members ordained themselves and others. The Southern preachers opposed this step and for several years the Connexion was on the verge of disruption. An agreement was finally made to suspend the administration until Wesley's desires and judgment could be ascertained. He perceived that the society would disintegrate unless effective measures were speedily taken, and, aided by two presbyters of the Church of England, early in 1784 he ordained Thomas Coke (1747-1814), already a presbyter of that Church, as superintendent. He likewise ordained two of his lay preachers as deacons and elders, to accompany Coke, whom Wesley sent to America as his commissioner to establish, for the Methodist Society, a system of Church government, which should include the administration of Baptism and of the Lord's Supper. Coke above. The 1938 returns are: Bulgaria, 546 members; Denmark, 3771; Finland and St Petersburg, 1367; France, 211; Italy, 3669; North Germany, 12,886; Norway, 6054; South Germany, 11,808; Sweden, 15,430; Switzerland, 9419.

1 Western Conference only.
was furnished by Wesley with a document setting forth the grounds on which he had taken this step. Wesley also appointed Thomas Coke and Francis Asbury "to be joint superintendents over our brethren in North America." Soon after Coke and his companions arrived they met Asbury and fifteen preachers, and a special conference was called, which opened on the 24th of December 1784, in the suburbs of Baltimore, Maryland. This convention organized itself into a Methodist Episcopal Church, in which the liturgy sent by Wesley should be read, and the sacraments should be administered by superintendents, elders and deacons, these elders and deacons to be ordained by a presbytery using the episcopal form. Coke and Asbury were unanimously elected superintendents, Coke, aided by his clerical companions from England, ordaining Asbury as deacon and elder and formally consecrating him a general superintendent. Several elders were ordained. This convention adopted the first Discipline of the Methodist Episcopal Church. It adopted the existing doctrinal standards, consisting chiefly of Wesley's Sermons and his Note on the New Testament; also twenty-five of the Articles of Religion of the Church of England, modified so as to eradicate all trace of High Church ritualism, Anglican or Roman, and the distinctive doctrines of Calvinism.

The Church thus established began its ecclesiastical career with 18,000 members, 104 travelling preachers, about the same number of local preachers, and more than 200 licensed exhorters. There were 60 chapels and 800 regular preaching places.

The energy of Asbury, and the position of Coke in the Church of England, his wealth, culture, and preaching power, greatly reinforced the influence of the Conference. The administration of the sacraments brought peace; and many who would not unite with the "Society" asked admission to the Church. Within five years the number of preachers swelled to 227, and the members to 45,049 (white) and 11,662 (coloured).

To bind the whole body the existing method required the con
currence of each Annual Conference with every proposition. This was inconvenient and occasioned much loss of time; therefore a General Conference was established to meet once in four years. The first was held in 1792, and therein arose a sharp conflict. James O'Kelly (1735-1850), a Presiding Elder in control of a large district, proposed that, when the list of appointments was read in the Conference, if any preacher was not pleased with his assignment he might appeal to the Conference. The motion being lost, O'Kelly and several other preachers seceded. The Conference in 1804 limited the power of the Bishops by forbidding them to appoint any pastor for more than two consecutive years in charge of the same church. As all "travelling preachers" were eligible, without election, to seats in General Conferences, widespread dissatisfaction prevailed among the distant Conferences. The era of the steamboat and the telegraph, not having arrived, it was possible for two Annual Conferences, adjacent to the seat of the General Conference, to out-vote all others combined. This led to a demand for the substitution of a delegated General Conference, which was conceded by the Conference of 1808 to take effect four years later. The office then known as the Presiding Eldership had become powerful: Bishops appointed the pastors to churches, Presiding Elders to districts; but it was the purpose of the majority to transfer to the Annual Conferences the power of appointing Presiding Elders. The change, though discussed for many years, has not been accomplished.

Several issues had been settled; but one, that of slavery, had to be faced. The storm burst on the Conference of 1844. Bishop James Osgood Andrew (1794-1871), a native of the South, had, by inheritance and marriage, become a slaveholder. After debates of many days, he was requested "to desist from the exercise of the office of Bishop while this impediment remained." The Southern members declared that the infraction of such a stigma upon Bishop Andrew would make it impossible for them to maintain the influence of Methodism in the South, and a tentative plan of separation was adopted by this conference by an almost unanimous vote. The result was that the Methodist Episcopal Church was reunited, and when the General Conference of 1848 convened it represented 760 travelling preachers and 532,200 members fewer than it had numbered four years before.

After the Civil War the increase in membership was noteworthy. The quadrennial Conference of 1868 represented 222,687 members more than its predecessor; of this gain 117,326 were in the Southern States. In 1872 lay representatives were admitted, the Constitution having been amended so as to make it possible. It was not, however, until 1878 that theMethodist Episcopal Church, for though ministerial Conferences were represented according to their number, in no circumstances could there be more than two lay representatives from one Annual Conference. Not till 1900 were lay and clerical representation equalized. In 1864 the time limit of pastorates was lengthened to three years, and in 1888 to five years. This limit was taken off in 1900, and pastors can be reapointed at the will of the Bishop.

Five women presented credentials as lay delegates in 1888. Their eligibility was questioned; and they were denied admission. For the next four General Conferences the struggle for the admission of women recurs. In 1900-1904 a general resolution of the Constitution took place, and the words "lay members" were substituted for "laymen" in that part of the Constitution which deals with the eligibility of delegates to the General Conference.

The General Conference has power to make rules and regulations for the Church, subject only to restrictions which protect the Standards of Doctrine, the General Rules, the disposition of the property of the Book Concern and its income, the income of the Chartered Fund, and the right of ministers to trial before a jury of their peers, an appeal, and similar rights of the laity.

By a two-thirds vote of a General Conference, and two-thirds votes of the members of the Annual Conference, and of the members of the Lay Electoral Conferences, present and voting, what is said in these "Restrictive Rules" can be altered or repealed, except that which deals with the Articles of Religion and "the present existing and established Standards of Doctrine." In the Annual Conferences the Bishop is the sole interpreter of law, subject to appeal to the General Conference. When presiding in the General Conference, a Bishop has no authority to decide questions of law, but may decide questions of order subject to an appeal to the body. The district superintendent visits each charge several times annually, presiding in the Quarterly Conference, the highest local authority in the Church, and he is expected to conserve the unity of the denomination and a regard for laws enacted by the supreme body. In the absence of a Bishop the district superintendent represents him, and may transfer any ministers within the bounds of his district.

**Conessional Institutions.—**The Book Concern, established in 1769, publishes the necessary devotional books of the Church, such as hymnals, discipline, theological works, religious experience, and numerous magazines and papers.

The Board of Foreign Missions carries on extensive operations in the United States, Canada, South America, and Mexico. It assists the Methodist Churches organized in Norway, Sweden, Denmark, Finland, Germany and Switzerland, and has recently established missions in Russia and France.

The Board of Home Missions and Church Extension supplies the foreign peoples domiciled in the United States with ministers of their own tongue. It assists all English-speaking churches in need of help, and secures, by gifts and time loans, the erection of churches. Whatever needs the savable resources of the Church, whether arise in the Women's Foreign Missionary and the Women's Home Missionary societies.

The Board of Education, with the aid of a University Senate, assists the people to obtain education, and raises the standard of seminaries, colleges and universities. The Church, in the United States, supports 34 colleges and universities and 10 theological seminaries. The Freedmen's Aid Society is devoted to the educational needs of the negro race in the United States, in which work it has been very successful.

The Sunday School Union, Epworth League, Methodist Brotherhood, and the missions, homes for the aged, deaconess homes and children's institutions are maintained by an increasing army of workers.

The whole number of ministers (exclusive of foreign missions) in 1907, was 17,694; churches, 27,601; communicants, 2,684,631.
The Methodist Episcopal Church South.—After the adjournment of the General Conference of 1844, the representatives of thirteen Conferences covering the states holding slaves appealed to their constituents to determine what should be done to prevent Methodism in the South from being deprived of its influence over the whites and of the privilege, till then fully accorded, of preaching the Gospel and teaching its precepts to slaves. In 1845 a representative Convention was called; this body, with the approval and participation of Bishop Andrew, organized the Methodist Episcopal Church South. At its first General Conference, in 1846, the senior Bishop of the Methodist Episcopal Church, Joshua Soule (1781-1867), offered himself to the Church, which accepted him in his episcopal capacity. William Capers (1790-1859) and Robert Paine (1799-1882) were elected to the Episcopacy. The Church thus founded began with 460,000 members, of which 2972 were Indians, 124,661 coloured, and 1319 travelling ministers.

A difficulty arose on the division of the property of the Book Concerns, which the Methodist Episcopal Church maintained involved a change in the Constitution. A vote to authorize the division failed, and the Methodist Episcopal Church South, hopeless of relief, brought two suits, one against the Book Concern in New York, and the other against the Book Concern in Cincinnati. The former was decided in favour of the Methodist Episcopal Church South, and the latter in favour of the Methodist Episcopal Church. In the latter case an appeal was taken by the Methodist Episcopal Church South to the Supreme Court of the United States, which body decided that the Methodist Episcopal Church South was an integral part of the Methodist Episcopal Church which owned the Book Concerns, and ordered that the Southern Church should receive a proportionate part of the property of both Book Concerns. The amount ordered by the Court was in due time received.

The membership of the Church in 1860 was more than three-quarters of a million; but the Church was doomed to feel the force of the destructive elements of the Civil War. In April 1862 New Orleans was in possession of the Federal Government, rendering it impossible to hold the General Conference due at that time and place.

At the close of the war the Missionary Society of the Church was $60,000 in debt, the Publishing House practically in ruins, and of the more than 200,000 coloured members in 1860 there remained fewer than 50,000. The Conference of 1866 convened in New Orleans. Radical changes in polity were effected. Attendance upon class meetings, which, from the origin of the Church had been obligatory, was made voluntary, and the rule was adopted, which required a probation of six months before admission into full membership. The time limit on the continuation of pastorates was extended from two to four years. The most radical change was the introduction into the General Conference of a number of lay representatives equal to the number of clerical, and the admission into each Annual Conference of four lay delegates for each Presiding Elder's district.

The coloured people, with the consent of the Church, withdrew in 1870, and formed a new Church called the Coloured Methodist Episcopal Church.

The most striking denominational effort in its history was the maintenance of the solvency of the Publishing House, which was seized by the Federal Troops, and used as a United States printing office; with the damage done, and debts incurred in rebuilding, after a fire, interest, &c., the liabilities were $35,000, with debts $125,000 in excess of assets. The concern was declared insolvent; but the necessary funds were forthcoming, and the honour of the Church was maintained.

Education has received unceasing attention. The titles to 175 institutions are held by the Church, and the list of colleges and their character is a credit to the denomination. The most important is Vanderbilt University, at Nashville, Tennessee, founded in 1872, and largely endowed by members of the family whose name it bears. The chief foreign missions are in China, Mexico, Brazil, Japan, Korea and Cuba. Its mission in Japan and the mission of the Methodist Episcopal Church and the Methodist Church of Canada were united in 1907 in a new organization entitled the Methodist Church of Canada. A Board of Bible Distribution, which is a practical veto power possessed by the bishops, to be exercised when the conference adopts any measure which in their opinion is unconstitutional, they have the right to present and vote on all such questions at the General Conference. Two-thirds vote adheres to its action, the proposal is sent down to the Annual Conference for ratification; otherwise it is void. Fraternal relations between the two great Episcopal Methodist Churches in North America date back to 1868. In 1907, the Church of England in the United States, the Episcopal Church, and the Methodist Episcopal Church, South, the latter known as the Methodist Episcopal Church of America, united as the Episcopal Church in the United States of America.

The Church of England had originally been established as an independent church by the General Synod of the Church of England, in 1867, in part to serve the needs of the southern states, which had seceded from the Union in 1861. The Episcopal Church in the United States of America was formed in 1919, when the Methodist Episcopal Church, South, and the Protestant Episcopal Church, South, united. The Episcopal Church of the United States of America was formed in 1907, when the Methodist Episcopal Church, South, and the Protestant Episcopal Church, South, united. The Episcopal Church of the United States of America was formed in 1919, when the Methodist Episcopal Church, South, and the Protestant Episcopal Church, South, united.
METHODIST NEW CONNECTION—METHODIST

Conferences were rejected. The controversy centred upon lay representation, the episcopacy and the presiding eldership.

A General Convention was held on the 3rd of November, 1830, a Constitution was adopted, and a new organization was established, styled the Methodist Protestant Church. Within eight years it had accumulated 50,000 members, the majority of whom were in the South and bordering states. The Methodist Protestant Church has a presbyterian form of government, the powers being in the Conference. There is no episcopal office or General Superintendent; each Annual Conference elects its own chairman. Its General Conference meets once in four years. Ministers and laymen equal in number are elected by the Annual Conferences, in a ratio of one delegate for 1000 members. The General Conference of the Methodist Protestant Church of 1806 sent delegates to the Conference of the Methodist Protestant Church, making overtures toward an organic union, but formal negotiations have not been instituted. This Church had, in 1807, 155 ministers, 2242 churches and 183,894 communicants.

The Wesleyan Methodist Connection or Church of America.—In the Methodist Episcopal Church slavery was always a cause of contention. In 1842 certain Methodist abolitionists confined as to the wisdom of seceding. Among the leaders were Orange Scott (1800–1847), Jotham Horton and Le Roy Sunderland (1801–1843), who, in 1842, 1843, 1844, and 1845 they published, entitled The True Wesleyan, they announced their withdrawal from the Church, and issued a call for a convention of all like-minded, which met on the 21st of May 1843, at Utica, New York, and founded the Wesleyan Methodist Connection or Church of America. The enterprise started with 6000 laymen and 22 travelling ministers of the Methodist Episcopal Church, and as many more from the Methodist Protestant Church and other small bodies of Methodist antecedents. Its General Conference has an equal number of ministers and laymen. In less than eighteen months this body of 6000 members may be taken as the Methodist Episcopal Church had purged itself from slavery in 1844, and slavery itself was abolished in 1862, a large number of ministers and thousands of communicants, connected with this body returned to the Methodist Episcopal Church. It had in 1807 539 ministers, 600 churches and 18,587 communicants.

The Congregational Methodists originated in Georgia in 1822; but in polity they are not strictly Congregational. Appeals from the decisions of the District Conference may be taken to the General Conference, the General Conference, and ultimately to the General Conference. This Church had, in 1807, chiefly in Southern states, 24,000 members, 415 ministers and 425 churches.

Minor Methodist Churches.—The Primitive Methodist Church, as it exists in the United States, came from England. In 1807 it reported 7013 communicants. The Independent Methodists are composed of congregations in Maryland, Tennessee and the District of Columbia. They had fewer than 3000 members in 1807. The Evangelist Missionary Church comprises ministers and members in Ohio, who in 1886 withdrew from the African Methodist Episcopal Church. It had in 1807 about 340 members. Congregational Methodists in 1881 withdrew from the Methodist Episcopal Church South, in Georgia. They had 4022 members in 1807. The African Methodist Church was founded in 1816, and differed from the African Methodist Episcopal Church in opposing itinerancy, “paid ministers,” and episcopacy. In 1807 it had 3867 members in eight states. The Zion Union Association was formed in 1807. It reported in 1807 to have 2346 communicants, and shows no gain at the present time.

METHODIST NEW CONNECTION, a Protestant Nonconformist church, formed in 1797 by secession from the Wesleyan Methodists, and merged in 1907 into the United Methodist Church (q.v.). The secession was led by Alexander Kilham (q.v.), and resulted from a dispute regarding the position and rights of the laity. Kilham and his party desiring more power for the members of the Church than the bishops held over them. Kilham and his followers, moreover, desired that the ministers and laymen were of equal number, the laymen being chosen by the circuits and in some cases by "guardian representatives" elected for life by conference. Otherwise the doctrines and order of the Connection were the same as those of the Wesleyans. At the time of the union with the Bible Christians and the United Methodist Free Church in 1907 the Methodist New Connexion had some 250 ministers and 45,000 members.

METHODUS (c. 835–885), the apostle of the Slavs, was a native of Old Saxony, probably by nationality a Graecized Slav. His father's name was Leo, and his family was socially distinguished; Methodius himself had already attained high official rank in the government of Macedonia before he determined to become a monk. His younger brother Constantine (better known as Cyril, the name he adopted at Rome shortly before his death) was a friend of Photius, and had earned the surname "the Philosopher" in Constantinople before he withdrew to monastic life. Constantine about 860 had been sent by the emperor Michael III. to the Khazars, a Tartar people living north-east of the Black Sea, in response to their request for a Christian teacher, but had not remained long among them; after the fall of the empire, his brother and he worked among the Bulgarians of Thrace and Moesia, baptizing their king Bogorits in 861. About 863, at the invitation of Rastislav, king of "Great Moravia," who desired the Christianization of his subjects, but
METHUEN—METHYL ALCOHOL

 commanding-in-chief in South Africa in 1907. The 3rd baron commanded the Scots Guards in 1864, served in the Ashanti War of 1874 and the Egyptian War of 1882, and commanded Methuen's Horse in BechuanaLand in 1884-85, and the first division of the 1st Army Corps in the South African War of 1899-1902. (See TRANSVAAL.)

METHUSELAH, in the Old Testament, the seventh in descent from Adam, and father of Lamech.

METHYLSALICYLIC ACID (C₆H₅OCH₃COO), a colourless oily liquid, boiling at 319° C.

at the same time that they should be independent of the Germans, the two brothers went to his capital (its site is unknown), and, besides establishing a seminary for the education of priests, successfully occupied themselves in translating in the vernacular and in diffusing their translations of Scripture lessons and liturgical offices. Some conflict with the German priests, who used the Latin liturgy, led to their visiting Pope Nicholas I., who had just been engaged in his still extant correspondence with the newly converted Bulgarian king; his death (in 867) occurred before their arrival, but they were kindly received by his successor Hadrian II. Constantine died in Rome (in 859), but Methodius, after satisfying the pope of his orthodoxy and obedience, went back to his labours in "Moravia," as archbishop of Neitra (Sirmium) in Pannonia. His labours appear to have been, not so extensive as with his brother, but extending with the basins of the Raab, Drave and Save, and thus to have included parts of what had previously belonged to the provinces of Salzburg and Passau. In 871 complaints on this account were made at Rome, nominally on behalf of the archbishop of Salzburg, but really in the interests of the German king and his Germanizing ally Swatopluk, Rastislav's successor; they were not, however, immediately successful.

METHV, a village and parish of Perthshire, Scotland, 7/2 m. by N. of Perth by the Caledonian Railway. Pop. of parish (1901), 1699. Only an able remains of the collegiate church, founded in 1433 by Walter Stewart, earl of Atholl (d. 1437). Around the church, the village of Methven, Castle, dating partly from 1680, occupies a fine situation in a park in which stands the Pepperwell oak, 18 ft. in circumference. At Dronach Haugh near the banks of the Almond, which bounds the parish on the N., the earl of Pembroke defeated Robert Bruce in 1306. At Lynedoch, his estate on the Almond, Thomas Graham (1748-1843), the Peninsular general, afterwards Lord Lynedoch, carried on many experiments in farming and stock-breeding. He formerly owned Baigow House, about 3 m. south-west of Methven, where many years after his death the proprietor discovered, during certain alterations, the portrait of Lord Lynedoch's wife, the Hon. Mrs Graham (a daughter of the 5th Lord Cathcart), one of Gainsborough's masterpieces, now in the National Gallery in Edinburgh; 4/3 m. north-west of Methven, occupying a beautiful position in Glenalmond, is Trinity College, a public school on the English model, the first of its kind in Scotland, founded in 1841 through the efforts of W. E. Gladstone, J. R. Hope-Scott, Dean Ramsay and others, and opened in 1847. In 1851 Charles Wordsworth, the first warden, afterwards bishop of St Andrews, added the chapel. At Tiberias, about 3 m. south-east of Methven, Montrose won the first of a series of battles over the Covenanters on the 1st of September 1644.

METHYL ALCOHOL (CH₃OH), the simplest aliphatic alcohol; an impure form is known in commerce as wood-spirit, being produced in the destructive distillation of wood. The name methyl, from Gr. μύθος, wine, is derived, and contains methyl alcohol, acetone, acetic acid and methyl acetic anhydride. This is neutralized with lime and redistilled in order to remove the acetic acid. The distillate is treated with anhydrous calcium chloride, the crystalline compound formed with the alcohol being separated and decomposed by redistilling with water. The aqueous product is then dehydrated with potash or lime.

To obtain it perfectly pure the crude alcohol is combined with oxalic, benzoic or acetic acid, and the resulting ester separated, purified, and finally decomposed with potash. Methyl alcohol is also obtained in the dry distillation of molasses. The amount of methyl alcohol present in wood spirit is determined by converting it into methyl iodide by acting with phosphorus iodide; and the acetone by converting it into iodoforin by boiling with an alkaline solution of iodine in potassium iodide; ethyl alcohol is detected by giving acetylene on heating with concentrated sulphuric acid, methyl alcohol, under the same circumstances, giving methyl ether.

Pure methyl alcohol is a colourless mobile liquid, boiling at 64.7° C.
METICULOUS—METROCLES

66°–67°, and having a specific gravity of 0.8142 at 0° C. It has a burning taste, and generally a spirited odour, but when absolutely pure it is said to be odourless. It mixes in all proportions with water, alcohol and ether. Its compound with calcium chloride has the formula CaCl₂·4CH₂OH, and with barium oxide BaO·2CH₂OH. Oxidation gives formaldehyde, formic acid and carbonic acid; chlorine and bromine react, but less readily than with ethyl alcohol. The chief industrial applications are for making denatured alcohol (g.e.), and as a solvent, e.g. in varnish manufacture; it is also used for a fuel; a pure product is extensively used in the colour and fine chemical industries.

Methyl chloride CH₃Cl is a gas, boiling at −23°, obtained by chlorinating methane, or better, from methyl alcohol; wood spirit is treated with salt and sulphuric acid, or hydrochloric acid gas conducted into the boiling spirit and dried with sulphuric acid. It is also prepared by heating trimethylamine hydrochloride. Alcohol dissolves 35 volumes and water 4. Methyl bromide is a liquid, specific gravity 1·73, boiling point 43°; methyl iodide has a specific gravity of 2·19, and boils at 43°.

METICULOUS (through Fr. méticuleux, from Lat. meticulōsus, timid, cautious; metus, fear), a term meaning pedantically or excessively careful of details, over-scrupulous, laying too much stress on minutiae.

METICHIA, THEODORE [Theodoros Metochites], a Byzantine author, man of learning and statesman, who flourished during the reign of Andronicus II, Palaeologus (1282–1338). After he had devised a new monetary system in the reign of his patron by Andronicus III, Metochita was deprived of his office of great logothete (chancellor) and sent into exile. He was soon recalled, but retired from political life to a convent, where he died in 1332. He was a man of very great learning, only surpassed by Photius and Michael Psellus. His pupil Nicephorus Gregorios, who delivered his funeral oration, calls him a “living library.”

Only a few of his numerous works have been preserved. The best known is his History of the synoikia or synonoi, Metochia, philosophica et historia (ed. C. G. Müller and T. Kiesling, 1821), containing some 120 essays; for a list of them see Fabricius, Bibliotheca graeca (ed. Harle), x. 417; in these he chiefly made use of Synoikias. Of his rhetorical pieces two have been published by C. N. Sathas in Μετοχιακά Βιβλία (1872), and two poems on religious subjects by M. Treu (1895). The poems, dealing mainly with contemporary and personal matters, are written in hexameter, not in the usual “political” verse. Metochita was also the author of works on philosophical and astronomical subjects.

METONIC CYCLE, in chronology, a period of 19 years during which there are 235 lunations, so called because discovered by Meton. Computation from modern data shows that 235 lunations are 6939 days, 16½ hours; and 19 solar years, 6939 days, 14½ hours. The relation between integral numbers of months and years expressed by Meton’s rule therefore deviates only two hours from the truth. Since 19 July years may last 365 days and 18 hours, the relation errs by only 1½ hours when the Julian year is taken. Meton was an Athenian astronomer (fl. 432 B.C.).

METONYMY (Gr. μετονυμία, change of name, from μετά denoting change, and νυμά, name), a figure of speech, in which the name of one thing is changed for that of another, to which it is related by association of ideas, as having close relationship to one another. Thus “scepter,” “thron,” “crown,” are used for royal power or authority, “hearth and home” is used for “country,” &c.

“Synecdoche” (Gr. συνεκδοχή, from συνεκδέχεσθαι, to join in one’s reception) is a rhetorical figure similar to metonymy, in which the part is used for the whole or vice versa, thus “hands” is used for the members of the crew of a vessel; a regiment of infantry is said to number so many “bayonets,” &c.

METOPE (Gr. μετόπη, a middle space), a term in architecture for the square recess between the triglyphs in a Doric frieze, which is sometimes filled with sculpture.

METRE (μέτρη, sc. τέχνη, from Gr. μέτρον, measure), in prosody, the harmonious and regulated disposition of syllables into verse. Metrical form is distinguished from prose by the uniformity of corresponding lines in relation to the number of syllables and the similarity of final sound (rhyme or assonance), by the repetition of certain letters at regular intervals (in alliterative measure), or merely by the regular succession of ups and downs of intonation. In ancient classic poetry the measure which creates the metrical form consists only of this last quantitative element, which is rhythm.

For the rules and divisions of the various metrical systems, see VERSE. For the restricted use of “metre” 12 as a unit of measurement, see METRIC SYSTEM.

METRIC SYSTEM (adapted from Gr. μέτρον, measure), that system of weights and measures of which the metre is the fundamental unit. The theory of the system is that the metre is a 12/1000 part of a quadrant of the earth through Paris; the litre or unit of volume is a cube of 1 litre metre side; the gramme or unit of weight is (nominally) 12/1000 of the weight of a litre of water at 4° C. The idea of adopting scientific measurements had been suggested as early as the 17th century, particularly by the astronomer Jean Picard (1620–1682), who proposed to take as a unit the length of a pendulum beating one second at sea-level, at a latitude of 45°. These suggestions took practical shape by a decree of the National Assembly in 1790 appointing a committee to consider the suitability of adopting either the length of the seconds pendulum, a fraction of the length of the equator or a fraction of the quadrant of the terrestrial meridian. The committee decided in favour of the latter and a commission was appointed to measure the arc of the meridian between Dunkirk and Mont Jany, near Barcelona. Another commission was also appointed to draw up a system of weights and measures based on the length of the metre and to fix the nomenclature, which on the report of the commission was established in 1795. It was not until 1799 that the report on the length of the metre was made. This was followed by the law of 10th of December 1799 fixing definitely the value of the metre and of the kilogramme, or weight of a litre of water, and the new system became compulsory in 1801. It was found necessary however to pass an act in 1837, forbidding as and from the 1st of January 1840, under severe penalties, the use of any other weights and measures than those established by the laws of 1795 and 1799. The metric system is now obligatory in Argentina, Austria-Hungary, Belgium, Brazil, Chile, France, Germany, Greece, Italy, Mexico, Netherlands, Norway, Peru, Portugal, Rumania, Servia, Spain, Sweden, Switzerland. Its use is legalized in Egypt, Great Britain, Japan, Russia, Turkey and the United States. In 1875 there was constituted at Paris the International Bureau of Weights and Measures, which is managed by an international committee. The object of the Bureau is to make and provide prototypes of the metre and kilogramme, for the various subscribing countries.

In England action has frequently been taken both by individuals and by theGetType of MeasureMeasure of National Committees, and many for the purpose of endeavouring to ensure that the metric system compulsory. A Decimal Association was formed in 1854, but did not make very much headway. A bill was introduced into parliament in 1864 to make the metric system compulsory for certain purposes, but owing to government objections a permissive bill was substituted and subsequently became law as the Metric Act 1864. It was, however, repealed by the Weights and Measures Act 1878. In 1881 a resolution of the House of Commons on the second reading by a majority of five. In 1893 a representative delegation of business men pressed its adoption on the chancellor of the exchequer (Sir William Harcourt), but despite legislation of 1897 a statute was passed, the Weights and Measures (Metric System) Act, which legalized the use in trade of the metric system, and abolished the penalty for using or having in one’s possession a weight or measure not metric.

See also DECIMAL COINAGE AND WEIGHTS AND MEASURES.

METROCLES, a Greek philosopher of the Cynic school, was a contemporary of Crates, under whose persuasion he deserted the views of Theophrastus. He was his sister, Hipparchia, whose romantic attachment to Crates is a fascinating sidelight on the almost truculent asceticism of the Cynics. He was a man of peculiar strength of character, and esteemed the joys of life so low that he was deterred from marriage by the prospects of marital views, which were identical with those of Crates (q.v.), he expounded by precept and example with great success, and had among his pupils
Menippus of Sinope. Having weighed the probable pains and pleasures of approaching old age, he decided that life had nothing left for which he greatly cared, and drowned himself. He is said to have written several works, which he afterwards burnt. Of one, entitled Νεκάρια, Diogenes preserves a single line (vi. 6).

METRORODUS, the name of five philosophers.

1. Metrorodorus of Athens was a philosopher and painter who flourished in the 2nd century B.C. It is said that Paullus Aemilius, visiting Athens on his return from his victory over Perseus in 168 B.C., asked for a tutor for his children and a painter to glorify his triumph. The inhabitants suggested Metrorodorus as capable of discharging both duties, and it is recorded that Aemilius was entirely satisfied (see Pliny, Nat. Hist. xxv. 135).

2. Metrorodorus of Chios was an important member of the Atomistic school. A pupil of Nestus, or, as some accounts prefer, of Democritus himself, he was a complete sceptic. He accepted the Democritan theory of atoms and void and the plurality of worlds, but held a theory of his own that the stars are formed from day to day by the moisture in the air under the heat of the sun. His radical scepticism is seen in the first line of his Περὶ φύσεως, quoted by Cicero in the Academics ii. 23 § 73. He says, "We know nothing, no, not even whether we know or not!" and maintains that everything is to each person only what it appears to him to be. Metrorodorus is especially interesting as the teacher of Anarchus, the friend of Pyrrho, and, therefore, as the connecting link between atomism proper and the later scepticism. It cannot be decided whether a work entitled the Τριάδα quoted by Athenaeus (iv. 184 α) is by this, or another, Metrorodorus. The same difficulty is found in the case of the Περὶ τερατῶν referred to by the scholiast on Apollonius.

3. Metrorodorus of Lampascus was the disciple and intimate friend of Epicurus, and is described by Cicero (de Fin. ii. 28. 92) as "almost a second Epicurus." He died in 277 B.C. at the age of fifty-three, seven years before his master, who adopted his children and in his will commended them to the care of his pupils. The wife of Metrorodorus was Leontion, herself, like many other women of the time, a member of the Epicurean society. Athenaeus (vii. 279 F) quotes from the words of Metrorodorus showing that he was in entire agreement with Epicurus, and was, if possible, even more dogmatic in his doctrine of pleasure. He censures his brother, Timocrates, who, though professedly Epicurean, maintained the existence of pleasures other than those of the body.

4. Another Metrorodorus of Lampascus was a pupil of Anaxagoras, and one of the earliest to attempt to interpret Homer allegorically. He explained not only the gods but also the heroes Agamemnon, Achilles, Hector, as representing primary elements and natural phenomena.

5. Metrorodorus of Stratonice was a pupil, first of Apollodorus, and later of Carneades. He flourished about 110 B.C., and is reputed to have been an orator of great power. His defection from the Epicurean school is almost unique. It is explained by Cicero as being due to his theory that the scepticism of Carneades was merely a means of attacking the Stoics on their own ground. Metrorodorus held that Carneades was in reality a loyal follower of Plato.

METRONOME (Gr. μέτρων, measure, and νομος, law), an instrument for denoting the speed at which a musical composition is to be performed. Its invention is generally attributed to Johann Nepomuk Maelzel, a native of Ratisbon (1772–1838). It consists of a pendulum swung on a pivot; below the pivot is a fixed weight, and above it is a sliding weight that regulates the velocity of the oscillations by the greater or less distance from the pivot to which it is adjusted. The silent metronome is impelled by the touch, and ceases to beat when this impulse dies; it has a scale of numbers marked on the pendulum, and the upper part of the sliding weight is placed under that number which is to indicate the quickness of a stated note, as M.M. (Maelzel's Metronome) = 60, or 72, or 108, or the like. The number 60 implies a second of time for each single oscillation of the pendulum—numbers lower than this denoting slower, and higher numbers quicker beats. The scale at first extended from 50 to 160, but now ranges from 40 to 208. A more complicated metronome is impelled by clock-work, makes a ticking sound at each beat, and continues its action till the works run down; a still more intricate machine has also been devised which is struck at the first of any number of beats, willed by the person who regulates it, and so signifies the accent as well as the time.

The earliest instrument of the kind, a weighted pendulum of variable length, is described in a paper by Etienne Loulié (Paris, 1696; Amsterdam, 1698). Attempts were also made by Enbray (1732) and Gabory (1771). Dr. Jenner, who gained the prize awarded by the English government for his chronometer, published a description of an instrument for the purpose in 1775. Davaux (1784), Pelletier, Abel Buja (1790) and Weisbe (also 1790) described their forms of experiments for measuring musical time. In 1815 Gottfried Weber, the composer, theorist and essayist, proposed a weighted ribbon graduated by inches or smaller divisions, which might be held or otherwise fixed at any desired length, and would infallibly oscillate at the same speed as long as the impulse lasted. Stockel and Zmeskall produced each an instrument; and Maelzel made some slight modification of that by the former, about the end of 1812, but a year later invented the instrument in its present form, rocking on both sides of a centre and balanced by a fixed and a variable weight. He spent three years in completing it, and it is described and commended in the Report of the Netherlands Academy of Sciences for 1816. The first Maelzel's made its appearance in London on Aug. 14, 1817, and so great was the popularity of his invention that, saw Winkel and inspected his invention, and, recognizing its great superiority to what he called his own, offered to buy all right and title to it. Winkel refused to sell, so Maelzel constructed, top 1818, a metronome, to which he added nothing but the scale of numbers, took this copy to Paris, obtained a patent for it, and in 1816 established there, in his own name, a manufactory for metronomes. Many vom compositions. Among the first metronome, to which became known as the "Maelzel's scale" was neither as reduplicated as usual, or complicated, proceeding by twos from 40 to 60, by threes from 60 to 72, by fours from 72 to 120, by sixes from 120 to 144 and by eights from 144 to 208. Dr Crotch constructed a time measurer, and Henry Smart (the violinist, father of the composer of the same name) made another in 1821, both before that received as Maelzel's was known in England. In 1822 James Mitchell, a Scotsman, made an ingenious form of clock-work, reducing to mechanical phenomena what formerly rested wholly on the feeling of the performer.

Although "Maelzel's metronome" has universal acceptance, the single metronome and still more Weber's graduated bars are greatly to be preferred, for the clock-work of the other is liable to be out of order, and needs a nicety of regulation which is almost never executed. For instance, in Maelzel's scale of the traditional times of the several pieces in the Dettingen Te Deum, he tested them by twelve metronomes, no two of which beat together. The value of the machine is exaggerated, for no living performer could execute a piece in unvaried time throughout, and no student music, nay, composers themselves, will conduct the same piece slightly slower or quicker on different occasions, according to the circumstances of performance.

METROPOLIS (Gr. μητρόπολις, mother, πόλις, city), properly a mother-city, and so the name of the parent state from which colonies were founded in ancient Greece (see GREECE, sect. History, Ancient). The word was used in post-classical Latin for the chief city of a province, the seat of the government, and in particular ecclesiastically for the seat or see of a metropolitan bishop (see Metropolitan). It is thus used now for the capital of a country, which contains the various official buildings of the administrative departments, the Houses of Parliament, &c. In the case of London, the term "metropolitan" is sometimes applied to the whole area including the City of London, and sometimes, as in "Metropolitan Police," excludes the City, which has its own police force (see London).

METROPOLITAN (Lat. metropolitans, Gr. μητροπολίτης), in the Christian church, the title of a bishop who has the oversight over bishops of subordinate sees. In the Western church
METSU—METTERNICH

301

the metropolitan is practically the same as the archbishop (g.v.); in the Eastern church he ranks above the archbishop, but below the patriarch (g.v.). Metropolitans first appear in the East in the 4th century as presiding over a province (provincia or eparchia), and their see is fixed in the principal town (metropolis) of the province, which remains the normal custom both in East and West. In Africa, however, the metropolitan jurisdiction was exercised by the senior bishop (primas, primae sedis episcopus, senex) for the time being, a custom which prevailed for a time also in Spain. Thus, too, in the Scottish Episcopal Church and the Protestant Episcopal Church of America there are no metropolitan, the primas being the senior bishop.

METSU, GABRIEL (1630—1667), Dutch painter, was the son of Jacob Metsu, who lived most of his days at Leiden, where he was three times married. The last of these marriages was celebrated in 1625, and Jacomma Garnijers, herself the widow of a painter, gave birth to Gabriel in 1630. According to Houbraken Metsu was taught by Gerard Dow, though his early works do not lend colour to this assertion. It is certain, however, that he was influenced in turn by Jan Steen, Rembrandt, and Hals. Metsu was registered among the first members of the painters' corporation at Leiden; and the books of the guild also tell us that he remained a member in 1649. In 1650 he ceased to subscribe, and works bearing his name and the date of 1653 give countenance to the belief that he had then settled at Amsterdam, where he probably continued his studies under Rembrandt. One of his earliest pictures is the "Lazarus" at the Strassburg Museum, painted under the influence of Jan Steen. Under the influence of Hals he painted the "Three Men in a Cabriolet," a large picture with the date of 1653 in the Louvre. To the same period belong the "Departure of Hagar," formerly in the Thoré collection, and the "Widow's Mite" at the Schwerin Gallery. But he probably observed that sacred art was ill suited to his temper, or he found the field too strongly occupied, and turned to other subjects for which he was better fitted. That at one time he was deeply impressed by the vivacity and bold technique of Frans Hals can be gathered from Lord Lonsdale's picture of "Women at a Fishmonger's Shop." What Metsu undertook and carried out from the first with surprising success was the low life of the market and tavern, contrasted, with wonderful versatility, by incidents of high life and the drawing-room. In no single instance do the artistic lessons of Rembrandt appear to have been lost upon him. The same principles of light and shade which had marked his schoolwork in the "Woman taken in Adultery" were applied to subjects of quite a different kind. A group in a drawing-room, a series of groups in the marketplace, or a single figure in the gloom of a tavern or parlour, was treated with the utmost felicity by fit concentration and gradation of light, a warm flush of tone pervading every part, and, with that, the study of texture in stuffs was carried as far as it had been by Ter Borch or Dow, if not with the finish or the brio of De Hooch.

Metsu went to Amsterdam before 1655, married in 1658, and became a citizen of that city in 1659. One of the best pictures of Metsu's manhood is the "Market-place of Amsterdam," at the Louvre, respecting which it is difficult to distribute praise in fair proportions, so excellent are the various parts, the characteristic movement and action of the dramatic personae, the selection of faces, the expression and the gesture, and the texture of the things depicted. Equally admirable is his "Widow," his "Woman at the Fountain," his "Groom," his "Sons," his "Bride," (dated 1661) and the "Tavern" (also 1661) at the Hague and Dresden Museums, and the "Game-Dealer's Shop," also at Dresden, with the painter's signature and 1662. Among the five examples of the painter at the Wallace Collection, including "The Tabby Cat," "The Sleeping Sportsman," which cost Lord Hertford £3000, is an admirable example technically considered. Among his finest representations of home life are the "Repart" at the Hermitage in St Petersburg; the "Mother nursing her Sick Child" of the SteenCracht Gallery at the Hague; the "Amateur Musicians" at the Hague Gallery that the "Duet" and the "Music Lesson" at the National Gallery, and many more examples at nearly all the leading European galleries.

METTERNICH-WINNEBURG, CLEMMENS WENZEL LOTHAR, PRINCE (1773—1850), Austrian statesman and diplomatist, was born at Coblenz on the 15th of May 1773. His father, Count Franz Georg Karl von Metternich-Winneburg zu Bellstein (d. 1818), was a diplomatist who had passed from the service of the archbishop-elector of Trier to that of the court of Vienna; his mother was Countess Maria Beatrix Aloisia von Kagenegg. At the time of Clemens Metternich's birth, and for some time subsequently, his father was Austrian ambassador to the courts of the three Rhenish electors; and the boy was thus from the first brought up under the influence of the tone and ideas which flourished in the small German courts that lay within the sphere of influence of the France of the ancien régime. In 1788 he went to the university of Strassburg, where he studied German constitutional law; but the outbreak of the French Revolution caused him to leave after two years. Metternich was a witness of the excesses of the mob in Strassburg, and he ascribed his life-long hatred of political innovation to these early experiences of the victory of liberal ideas. In 1790, by way of striking contrast, he was deputed by the Catholic bench of the Westphalian college of counts to act as their master of the ceremonies at the coronation of the Emperor Leopold II. at Frankfort, a function which he again performed at the coronation of Francis II. in 1792. The intervening time he spent at Mainz, attending the university and frequenting the court of the archbishop-elector, where his impressions of the Revolution were strengthened by his intercourse with the French émigrés who had made it their centre. The outbreak of the revolutionary war drove him from Mainz, and he went to Berlin, where he found employment in the chancery of his father, at that time Austrian minister to the government of the Netherlands. Here, in August 1794, he issued his first publication, a pamphlet in which he denounced the "shallow pates" of the old diplomacy and argued that the only way to combat the French revolutionary armies was by a levée en masse of the populations on the frontier of France—singular views for the statesman who was destined to be the last great representative of the old diplomacy and the greater part of whose life was to be spent in combating the national enthusiasms by which the revolutionary power of France was ultimately overthrown.

After a long stay in England, where he made the acquaintance of the prince of Wales (afterwards George IV.), Metternich went to Vienna; and on the 27th of September 1795 he married at Austerlitz the Countess Eleonore von Kaunitz, a grand-daughter of that Austrian chancellor who in many respects was his prototype. This alliance not only brought him great estates in Austria, but introduced him into the most exalted circles of Viennese society. Here he was well qualified to hold his own with his kinsmen, representing the exclusive company of his address and a certain reputation for gallantry. He was far, however, from being a mere cerebrating diplomatist. His interests were many and varied, and he found time for the serious study of natural science and medicine. In December 1797 he was chosen by the Westphalian counts as their representative at the congress of Rastadt, where he remained till 1799. This was his first experience of the great world of practical politics and especially of those rough diplomatists of the Revolution whom in his letters he has left so vivid a description. In January 1801 he was appointed Austrian envoy to the elector palatine at Mainz, and in 1802 he went to Dresden, where he found employment in the chancery of his father, at that time Austrian minister to the government of the Netherlands. Here, in August 1794, he issued his first publication, a pamphlet in which he denounced the "shallow pates" of the old diplomacy and argued that the only way to combat the French revolutionary armies was by a levée en masse of the populations on the frontier of France—singular views for the statesman who was destined to be the last great representative of the old diplomacy and the greater part of whose life was to be spent in combating the national enthusiasms by which the revolutionary power of France was ultimately overthrown.

1The family of Metternich, originally established in the county of Jülich, can trace its descent to the middle of the 14th century. In 1637 they received from the archbishop of Trier the countships of Winneburg and Bellstein. These were confiscated in 1803, and the lands of the suppressed abbey of Onze-Lieve-Vrouwe, of which the prince of the Empire, were granted by the edict as compensation. The new principality was "mediatized" in 1806 in favour of Württemberg; but in virtue of their short tenure of it the descendants of Prince Metternich enjoy the privileges of mediatized princes.
prevent Prussia from joining the alliance of Russia and Great Britain against the French Republic and to make himself agreeable to the representatives of France; but shortly afterwards his praise was reversed; the moment was to be seized, to secure the adhesion of Prussia to the alliance of Austria, Russia and Great Britain against Napoleon. His diplomacy was not successful; for though Prussia ultimately signed the treaty of the 5th of November 1805 with Austria and Russia, the influence of the emperor Alexander and the wound given to her pride by Napoleon's contemptuous violation of her territory, had more to do with Prussia's decision than Metternich's policy and influence. His reward was the grand cross of the order of St. Stephen and the appointment of ambassador at St. Petersburg; but his commission to make himself agreeable to the French ambassador at Berlin was carried out to such excellent effect that, as a result of M. Laforest's reports, Napoleon requested that he might be appointed to represent Austria at the Tülleries, and in August 1806 Metternich took up his residence as ambassador in Paris.

This was the beginning of his ever growing influence in European affairs. Established in the diplomatic character of an "honourable spy" in the very centre of Napoleon's power, he used his exceptional gifts of fascination not only to become a persona grata at the Tülleries, but to establish relations with those elements in the society of the empire which were already intriguing against Napoleon's power. His intimacy with Talleyrand and with Caroline Murat, Napoleon's sister, was destined to produce notable results later. Though the look-out, however, for any chance of weakening the French emperor's power, Metternich was not at first sanguine of success, for he believed Napoleon to be invincible. For Austria the best policy seemed to be to temporize; he was willing, therefore, to co-operate with France in the agreement made between Napoleon and Alexander I. of Russia at Tilsit for the partition of the Ottoman Empire; failing the success of the efforts of Austrian diplomacy to break the Franco-Russian alliance, this would at least secure for the Habsburg monarchy a share of the spoils. With the postponement of Napoleon's Oriental schemes, however, the situation was once more changed. During the summer of 1808 Metternich had reason to suspect fresh designs of the French emperor against Austria, and his suspicions appeared to be confirmed when, during an interview on the 15th of August, Napoleon indulged in one of his violent tirades, denouncing Count Stadion's action in strengthening the Austrian armaments. In November Metternich was at Vienna, urging the Austrian government to an early declaration of war—for which the moment seemed to him opportune owing to the French losses in Spain, of which he had received exaggerated reports. On the 1st of January 1809 he was back in Paris, but no longer as a persona grata. At the outbreak of the war he was placed under arrest, in retaliation for the action of the Austrian government in intervening two members of the French embassy in Hungary; and in June, on Napoleon's capture of Vienna, he was conducted there under military guard. In July he was exchanged at Komárom for the French diplomats, and he was present with the emperor Francis at the battle of Wagram. At a council held on the 7th of July it was decided, on Metternich's initiative, to open negotiations for peace; next day Stadion tendered his resignation, which was provisionally accepted. Stadion was sent as diplomatic adviser to the headquarters of the archduke Charles, while Metternich took his place at the emperor's side. On the 4th of August Metternich was named minister of state, and soon afterwards was sent with Count Nugent to the peace conference at Altenburg, where Chamagny attended as Napoleon's representative. The conference, however, dragged on without result, and the emperor Francis decided to open negotiations with Napoleon direct. Count Bubna was accordingly sent to Schönbrunn; the negotiations were eventually closed in the treaty of Schönbrunn (Vienna), signed by Prince Liechtenstein on behalf of the emperor Francis on the 14th of October 1809. With the negotiation and signature of this humiliating instrument Metternich therefore had nothing to do, though on the 8th of October he had been definitely appointed minister for foreign affairs, an office he was destined to hold for nearly forty years.

The position of the new minister was no easy one. By the treaty of Schönbrunn Austria was reduced to the position of a second-rate power, and by secret articles undertook during the continuance of the maritime war to limit her force of all arms to 150,000 men, and to dismiss from her service all officers or civil servants born in the territories of ancient France. Piedmont was to become the former Venetian republic. Weak as she had become, the menace of the future seemed even more disquieting. To the south she was divided from the French dominions by the Savoy; to the west and north the vassal states of France, traditionally her allies, lay along the frontier; to the east was Russia, which as the reward for her alliance with Napoleon had received a portion of East Galicia as her share of the spoils, and to all appearance was firmly established in the Danubian principalities. Austria seemed hopelessly cut off by Napoleon from any chance of re-asserting her traditional preponderance in Germany, by Russia from any prospect of obtaining compensation at the expense of the Ottoman Empire. One false move on the part of those who guided its destinies, and the Habsburg monarchy might easily have ceased to exist altogether.

The saving factor in the situation was the improbability of the alliance between Napoleon and Alexander continuing, and the immediate task of Metternich was to hasten its dissolution, while securing Austria's safety in the East by bringing about the end of the Russo-Turkish War. It was a task of extreme delicacy, and his failure might have thrown the emperor Alexander into the arms of France and plunged Austria into an unequal struggle for life and death with Russia on the banks of the Danube. Metternich was helped by the rapid development of the causes of disagreement between the French and Russian emperors. Early in 1810 Europe was full of contradictory rumours of war between France and Russia, of a marriage of Napoleon with a Russian grand duchess. Then suddenly came Napoleon's formal request for the hand of the Austrian archduchess Marie Louise. A proposal so nicely calculated to forward Metternich's plans was suspected of being due to his inspiration; certainly it was the influence that decided the emperor Francis to agree to an alliance which could not but be distasteful to him and was resented as a crowning humiliation by the proud aristocrats of Vienna.

On the 13th of March 1810 Metternich left Vienna for Paris in company with the archduchess. His object was to use so favourable an occasion for obtaining the abrogation of some of the more onerous articles of the treaty of Schönbrunn, and for coming to some arrangement whereby the serious inconvenience caused in Austria by Napoleon's coercion of the pope might be obviated. His diplomacy, however, met with but slight success. His efforts to persuade Pius VII. to purchase a measure of liberty of action by concessions to Napoleon broke down on the gentle old man's refusal to traffic with his principles. From Napoleon he extracted a lame apology for the execution of Andreas Hofer, the reversal of a few sequestrations and, as a crowning grace, the abrogation of the article of the Schönbrunn treaty limiting Austrian armaments. In the matter of restoring the access of Austria to the Adriatic, Napoleon would make no concession; his answer to Metternich's representations was only commercial. The emperor failed to obtain ratification at Vienna. Anything further, e.g., an exchange of the Illyrian provinces for Galicia, must depend on the attitude of Austria in the forthcoming Russian war which, in an interview of the 20th of September, Napoleon declared to be now inevitable.

On the 10th of October Metternich was back in Vienna, where his presence was urgently needed. The policy of a Franco-Austrian entente was popular with the public and the army, resentful of the treacherous attitude of Russia in the late war, but there were no powerful circles of the court it had scarce an adherent. Prince Metternich himself, who had acted as foreign secretary during his son's absence, favoured an understanding with Russia,
and was even believed to be intriguing to retain the portfolio of foreign affairs, which would have meant the victory of the Russian party. On the other hand, the French party were clamouring for the speedy conclusion of a definite alliance with Napoleon. By an admirably clear expédition of the situation Metternich was able over the emperor Francis to make his middle course, the policy of armed attention, which was to be the basic principle of his diplomatic action during the crisis of the coming years. An alliance with Russia, he argued, would be worse than useless; Austria would at any time obtain better terms from the tsar’s growing needs. An alliance with France would be one with "a power whose exclusive object is the destruction of the old order of things, which has hitherto found its defence in Austria." Alone of European Powers Austria still had the possibility of choice; let her work for the preservation of peace and at the same time remain free, should war break out, to make her own terms. It would little serve Austria’s interests to become the ally of Russia, merely to serve as a barrier behind which the emperor Alexander could carry out his designs on Turkey in safety. In an interview with Count Shuvalov, the Russian agent, Metternich roundly declared that the maintenance of the integrity of Turkey was for Austria the question of supreme interest.

With the approach of the Russo-French War the situation became increasingly difficult. The partisans of a Russian alliance remained powerful and clamorous; but Metternich did not share the doubts as to the outcome of Napoleon’s invasion of Russia, which he believed would leave Austria, if she remained neutral, isolated amid a huge European confederation. To him the only safe course seemed to be to offer the French emperor substantial assistance, stipulating for some quid pro quo in the settlement to follow the war. The emperor Francis shared this view; and on the 14th of March a treaty of alliance was signed by which Austria agreed to support the French army with an army corps of 30,000 men operating from Galicia. This treaty was ratifiable at Vienna on the 25th of March, the day of Napoleon’s passage of the Rhine. It was characteristic of Metternich’s diplomacy that the Austrian generals in Galicia were ordered to act only on the defensive, and that the court of St Petersburg was informed that Austria would only take part in the war as a principal should Russia force her to do so.

This cautious attitude was soon justified by the astounding developments of the Moscow campaign. When the full extent of the catastrophe that had overwhelmed Napoleon’s army became known, Metternich realized the advantageous position in which Austria lay for exploiting the changed situation. His first act was to make the emperor Francis agree to mediate a peace in Russia and in England (Despatch of Otto, November 10); but, as affairs developed, this was replaced by the policy of temporizing until Austria should be in a position to intervene with decisive effect. Napoleon’s demand that Austria should raise her contingent from 30,000 to 100,000 men was, indeed, from Metternich’s point of view doubly opportune: for it enabled him quietly to assume that the treaty of the 14th of March, which stipulated only for an ‘‘alliance limitée,’’ had been abrogated by Napoleon’s own act; that Austria had revived her claim to the right of neutrality; and that, should she take part in the war, it would no longer be in a subordinate character but as a principal. ‘‘Le passage de la neutralité à la guerre,’’ said Metternich to the emperor Francis, ‘‘ne sera possible que par la médiation armée’’; which meant in effect that Austria required time to complete her armaments. To gain this time was, during the weeks that followed, the object of his diplomacy. For this purpose he encouraged Napoleon to believe that Austria was prepared for a settlement on terms very favourable to the French emperor; with the result that Napoleon, though he would not hear of a ‘‘mediation,” not only consented to, but pressed for, Austrian ‘‘intervention” (intervention). But Metternich had made it plain that the only chance of a peaceful restoration of the Habsburg influence in Europe lay in using this opportunity for destroying or limiting Napoleon’s power, and he had already opened negotiations with the allied courts, with a view to enforcing a common agreement as to a basis of peace, when the indecisive battle of Lützen (May 2) gave him the opportunity of making his policy of mediation effective. Count Stadion was now sent to the emperor Alexander to lay before him the terms on which Austria was prepared to mediate; he was also to ‘‘agree to the hitherto popular restoration on our part, in the event of the non-success of our efforts on behalf of peace.” On the 20th of March Napoleon gained another indecisive victory at Bautzen, which still further strengthened Metternich’s position; for Napoleon allowed himself to be persuaded into signing the ill-omened armistice of Pleiswitz (Polschwent), on the 4th of June, and to become entangled in the insincere negotiations of the congress of Prague. Austria thus had time to complete her armaments. Meanwhile, on the 14th and 15th of June, were signed at Reichenbach the treaties of alliance between Great Britain, Russia and Prussia, by which the signatory Powers agreed neither to negotiate nor to conclude treaty or truce with Napoleon except by common consent. In an interview with the emperor Alexander, Metternich now presented the terms which he proposed to offer to Napoleon, and on this basis a treaty between Austria, Russia and Prussia was agreed to, Austria contracting to put 150,000 men into the field, should Napoleon reject the ultimatum, and not to make peace without the consent of Russia and Prussia— which in effect involved that of Great Britain also.

Before this second treaty of Reichenbach was signed (June 27), Metternich went on Maret’s invitation to Dresden, where on the 26th he had the famous interview with Napoleon. The whole scene was on his part a masterpiece of Machiavellian diplomacy. The terms he offered to the emperor were so favourable that he has been denounced by every Prussian historian since as the enemy of Germany; while French historians have enlarged on Napoleon’s infatuation in rejecting them. In spite of the fact that the draft of the treaty of Reichenbach was in his pocket, he posed as the impartial ‘‘mediator,” with a leaning in favour of Napoleon, assuring the emperor ‘‘on his honour, as a German count” that Austria was still ‘‘free from all engagements,” which was true only in so far as the treaty was not signed till the next day. Metternich’s object was, in fact, only to gain an extension of the armistice till the 10th of August, on which date Schwarzenberg had declared that he would be ready to take the offensive. As for the terms offered to Napoleon his acceptance of them need not hamper the plans of the Allies; for the consent of Great Britain would have to be obtained, and, moreover, Napoleon was sure before long to provide an excuse for fresh breach; his rejection of them, on the other hand, would be a blow to his prestige. The interview was long and stormy; Napoleon struggled vainly in the toils; in his excitement he dropped his hat, which the imperturbable Metternich did not condescend to pick up; “Napoleon,” he records in his Mémoirs, “seemed to me small.” Metternich, however, gained his immediate point; the armistice was extended to the 10th of August. At midnight on that date, Napoleon not having come to terms, Metternich gave orders for the lighting of the beacons that signalled to the Austrian army in Silesia the outbreak of the war. The interview (June 27) for the moment brought discord into the councils of the Allies and threatened the ruin of Metternich and his plans; but the successive defeats of Vandamme at Kulm (Aug. 28), of Macdonald at Katzbach (Aug. 29) and Oudinot at Grossbeeren (Aug. 30) completely altered the aspect of affairs; and on the 9th of September Metternich signed at Töplitz a treaty with Russia which committed Austria yet more closely to the policy of the Allies. Then followed the battle of Leipzig (Oct. 16-18) and the advance of the Allies into France. The diplomatic situation throughout the campaign was, from the Austrian point of view, one of extreme delicacy. The necessity of curtailing the power of Napoleon and not to lose an ever incapable of again oversetting the balance of Europe was practically the only object Austria had in common with her allies. She did not
share the impenetrable resentment with which Great Britain pursued Napoleon; she watched with alarm the development of the ambitions of Alexander I., which threatened to substitute a Russian for a French supremacy in Europe; she was far from sympathising with the noisy enthusiasm of the patriots of the War of Liberation for a united Germany, in which the traditional influence of the Habsburgs would be balanced or overshadowed by that of Prussia. Metternich had no wish to see the question of Marie Louise, ousted in favour of the Bourbons, who had little reason to be grateful to Austria; still less did he desire to see on the throne of France Alexander's protégé Bernadotte, whose name was being whispered in the Paris salons as the destined saviour of his native country. But if Napoleon was to remain sovereign of France, it must be not by his own force, but by grace of his father-in-law, and hedged round with limitations which would have made him little more than the lieutenant of the Habsburg monarchy. This was the secret of the moderate terms of accommodation ostentatiously offered by Metternich to Napoleon at various stages of the campaign. From Frankfort he sent, through General de Saint-Aignan, a diplomatist on whose indiscretion he could rely, an informal offer of peace on the basis of France's "natural frontier," the Rhine, the Alps and the Pyrenees. The famous manifesto of Frankfort, issued on behalf of the Allies (Dec. 4, 1813), contained no such offer of acceptable terms; but Metternich's object was attained; for Napoleon refused to be drawn into the trap, and the French people cursed the emperor's infatuation in refusing a compromise, whose very terms, and which, in the hands of a Saint-Aignan's mission, they believed would have satisfied the legitimate ambitions of France. On the other hand, Metternich did his best to oppose a too rapid advance of the allied forces on Paris, which would have played into the hands of Russia and Prussia; and it was to his initiative that the conferences of Châtillon were due. Only when the breakdown of the negotiations made it clear that Napoleon had seen through his plans, and preferred the chances of war to the certainty of ruin or of surviving only as the puppet of Austria, did Metternich join with Castlereagh in pressing upon the tsar the necessity for restoring the Bourbons. On the 1st of March 1814, he set his hand to the treaty of Chaumont, of which the immediate object was the restoration and preservation of the old dynasty in France reduced to her "legitimate frontier." In other respects, however, the treaty was a triumph for Metternich; for it laid down that at the final settlement Germany was to be reconstituted as a confederation of sovereign states, and it also did much to temper the fear of a Russian dictatorship by consecrating the principle of that concerted action of the Great Powers which had been one of the international interest, which after Napoleon's fall was to govern the European system. On the 10th of April Metternich arrived at Paris, ten days after its occupation by the Allies. He was now at the height of his reputation; on the 20th of October 1813, two days after Leipzig, he had been created an hereditary prince of the Austrian Empire; he now received from the emperor Francis a unique honour: the right to quarter the arms of the house of Austria-Lorraine with those of Metternich. At the same time (April 21) the counsellor of Daruvar was bestowed upon him. On the 30th of May Metternich set his signature to the treaty of Paris, and immediately afterwards accompanied the emperor Alexander and King Frederick William on a visit to England. On the 18th of July he was back in Vienna, where the great congress was to meet in the autumn. The dignity of a Hungarian magnate was bestowed upon him before it assembled.

At the congress Metternich's charm of manner and great success on the first gifts him much personal influence; the ease and versatility with which he handled intricate diplomatic questions, too, excited admiration; at the same time he was blamed for his leaning to intrigue and finesse and for a certain calculated disingenuousness which led to an open breach with the emperor Alexander, who roundly called him a liar. In the difficult questions of Poland and Saxony the honest and conciliatory attitude of Castlereagh was of more avail in reaching an accept-

able settlement than all Metternich's cleverness. If in the Italian and German questions, however, Austria's views triumphed, this was due to the foresight displayed in Metternich's diplomacy during the campaigns and to the address with which he handled the questions at issue at the congress. The complicity of Hardenberg was shewn by the treaty of Chaumont, and the Paris conference of the Rhine with a view to detaching them from Napoleon; and he had used this opportunity to render impossible the idea of a united Germany. On the 8th of October 1813 he had signed with Bavaria the treaty of Ried, which in the event of the liberation of Germany guaranteed to Bavaria a sovereign and independent status. This instrument, which was reinforced by a secret treaty signed at Paris on the 3rd of June 1814, served as a model for similar agreements with other courts; and the principle involved was, as mentioned above (see NAPLES: History), true of the congress of Vienna. Thus all the unionist ideals, represented at the congress by Stein, were sterilized from the outset; and the Act of Confederation embodied in the Final Act of Vienna gave to Germany exactly the form desired by Metternich as best calculated to perpetuate Austrian preponderance (see GERMA NY: History). The same was true of the settlement of Italy. The question here was complicated by the treaty of alliance signed by Metternich with Murat as the price of his treason to Napoleon. But Metternich from the first had known that the treaty was but a temporary expedient; that Great Britain would never recognize "La Restauration" as the government of the "empire"; and that sooner or later Murat himself would afford excuse enough for tearing the treaty up. Not Murat's dream of an Italy united under his own rule, but the traditional Austrian policy of possession in the north and preponderance throughout the Peninsula was Metternich's goal, and this he secured at the congress. Murat, in view of Austria's engagements, was suffered to survive for the time being; he himself shattere the alliance during the Hundred Days; and the Bourbons returned to Naples, pledged by a secret agreement to attend their policy to that of Vienna (see NAPLES: History).

Metternich, then, emerged from the congress of Vienna confirmed in the confidence of his sovereign, and therefore supreme in Germany and in Italy. To him had been due the marvellous recovery of the Habsburg monarchy; in spite of Gentz's lament that in the latter stages of the campaign of 1814 "Europe" had been substituted for "Austria" in his diplomacy, Metternich had acted throughout first and foremost in the interests of Austria, as he was bound to do. This, too, gives the key to his policy after 1815, the policy of using the European Congresses as a means of making his peace. From the signing of the treaty of the 20th of November 1815, as an instrument for ensuring the "stability" of Europe by suppressing any "revolutionary" manifestations by which the settlement made at Vienna might be endangered.

After the campaign of Waterloo and Napoleon's second downfall Metternich was again in Paris, where he co-operated with the emperor Alexander and Castlereagh in securing tolerable terms of peace for France. A few days after the signing of the two treaties of the 20th of November 1815, he left Paris for Milan, where he made the acquaintance of Baron von Rechberg, with whom he came to terms on certain outstanding questions between Austria and Bavaria, terms embodied in the treaty of Munich of the 14th of April 1816. During his visit to Italy, which he repeated in 1816 and 1817, Metternich could not but be impressed with the general signs of discontent with Austrian rule. Neither was he blind to the true causes of this discontent: the atrophy of the administration owing to its rigid centralization at Vienna, and the policy of enforcing Germanism on the Italians by a ruthless police system. He made half-hearted proposals for removing something of both these grievances; but his terror of revolting from below made him fearful of reforms from above. While therefore in Prussia king and ministers were labouring hard to remodel and consolidate the monarchy, Metternich did next to nothing to reform the most obvious abuses of the Austrian Empire. Yet the fault
was not wholly, or mainly, his. Sir Robert Gordon, 1 in a letter to Castlereagh (dated Florence, July 11, 1819), gives the true reason for this attitude: "How much is it to be desired that the superior talents of Prince Metternich were more occupied with the revision and improvement of the administration of affairs in his own country. He is too enlightened not to perceive its most palpable defect ... He might have courage to sacrifice himself for the institution of effective remedies, but he fears that the confiding benignity of his Sovereign might afterwards be dissuaded from the just and vigorous application of them."

(F.O. Austria. Gordon. Jan.–Dec., 1819.) Metternich's power, after all, was limited by the goodwill of his master, the emperor Francis, and Francis trusted him precisely because he seemed to share his own fanatical hatred of all change. It is this fact that seems to explain Metternich's feverish anxiety to justify his obscurantist attitude to himself and to the world. It suited him to ascribe the general discontent, of which the causes were not observable, to the wanton agitation of the "sects" and his agents all over Europe earned their pay by supplying him with plentiful proof of the correctness of his contention. The result was well summed up in another letter of Gordon to Castlereagh (ibid. No. 26, Florence, July 12, 1819). "Nothing," he writes, "can surpass Prince Metternich's activity in collecting facts and information upon the inward feelings of the people; with a habit of making these researches he has acquired a taste for them. . . . The secrecy with which this task is indulged leads him to attach too great importance to his discoveries. Phantoms are conjured up and magnified in the dark, which probably if exposed to light would vanish. The subtracted, some of his informers naturally exaggerate their reports, aware that their profit is to be commensurate with the display of their phantasmagoria." The judgment is instructive, coming as it does from a diplomatist in intimate touch with Metternich and in general sympathy with his views.

There was, none the less, method in this madness. Behind the agitations of the "sects" loomed the figures of the emperor Alexander and of his confidant Capo d'Istria, "the Coryphaeus of Liberalism," whose agents, official or unofficial, were intriguing in every country in Europe, and not least in Italy. The factor, then, that determined Metternich's attitude was not so much a dread of revolutions in themselves as of revolutions exploited by the "Jacobin" tsar to establish his own preponderance in Europe. Metternich's object, then, in respect of the revolutionary agitations, was twofold: he wished to impress Alexander with the peril of this imperial coquetting with democratic forces; he wished to convince the "sects" that they could not rely on the tsar's support. He succeeded in both these objects during the period from the congress of Aix-la-Chapelle in 1818 to the treaty of Verona in 1822. (See Foreign Relations of Austria (1791-1847), brother of the 4th earl of Aberdeen, was between 1815 and 1821 associated with Wellington as minister plenipotentiary at Vienna.)

Metternich particularly gloomy. In France the ministry of Decazes was, in his opinion, under the inspiration of the Russian ambassador Pozzo di Borgo, heading straight for a new revolution; in Italy Russian agents were openly carrying on a Liberal propaganda; Germany, and notably the Prussian bureaucracy, was honeycombed with revolutionary ideas. Then came the news of the murder of Kotzebue (March 23). Metternich was in Italy at the time; but he determined at once to take advantage of this senseless crime to carry his views in the matter of muzzling the Liberal agitation in Germany. In the summer he met King Frederick William and Prince Hardenberg at Töplitz; a conference that resulted in the indefinite postponement of the Prussian constitution and in a secret agreement (Aug. 1) on the proposals to be laid before a conference of German ministers to be held at Carlsbad in the same month. The result of this were the famous Carlsbad Decrees (q.t.), by which liberty of speech and of the press was abolished throughout Germany. The Vienna confences that followed in November and issued in the Final Act of the 15th of May 1820, was not so complete a triumph for Metternich; but his diplomacy, none the less, had succeeded in riveting on Germany the yoke of the Austrian system, which it was to bear with but partial and temporary relaxations for nearly thirty years (see Germany: History).

The year 1820 was marked by critical events which drew Metternich's attention once more from the affairs of Germany to those of Europe at large. The revolution in Spain, with which Austria had no immediate concern, interested him little; but his attitude towards it is characteristic and illuminating. The liberty of Spain was a "proposition" to him, a " Sacred Principle," France was an article of faith, proposed a European intervention and offered to march a Russian army through northern Italy into Spain. Metternich, to whom the remedy seemed far worse than the disease, covered his dissent from this proposal with a great display of principle. The ills of Spain were "material," those of Europe at large "moral;" and the European Alliance was there to deal with moral, not material, troubles. The revolution that followed in Naples, however, necessitated a different attitude. Strictly speaking, it concerned Austria alone; but Metternich was anxious to range Alexander openly against Italian Liberalism and he therefore consented to the question being laid before a congress to be assembled at Troppau. The congresses of Troppau (1820) and Laibach (1821) are dealt with elsewhere (see Europe: History; Italy: History, and the articles s. v.). For Metternich they represented a signal triumph. Not only did he complete his ascendancy over the emperor Alexander; but he openly committed all the Powers to an approval of the Austrian system in Italy, a success that outweighed his failure to win over Great Britain to the general principle of intervention. This was done in the name of the Holy Alliance to prevent Alexander from acting independently of the concert. But Metternich's hope that the Greek revolt would burn itself out "beyond the pale of civilization" was belied by events; and even before Castlereagh's death it was clear that Great Britain would have sooner or later to adopt a policy of intervention opposed to all Metternich's ideas. The breach was hastened by the accession to office of George Canning, who hated Metternich and all his ways. At Verona in 1822 the withdrawal of Great Britain from the system of the continental Allies was proclaimed to all the world; in March 1823 Canning recognized the Greek flag. This opened up the whole Eastern Question in the precise form that Metternich had sought to
METTERNICH

...avoid; for the action of Great Britain involved a move on the part of Russia, jealous of her prestige in the Levant, and thus led ultimately to a rearrangement of the relations of the Powers which, so far as the affairs of the Ottoman empire were concerned, left Austria isolated. It is impossible here even to outline Metternich's diplomacy during the eleven years between the outbreak of the Greek revolt and the signature of the treaty of London (1832) by which the kingdom of Greece was established. The principles that guided it are, however, sufficiently simple. In common with Great Britain he desired to see the integrity of the Ottoman Empire as a barrier against Russian domination in the Balkan peninsula; he wished also to avert a Russo-Turkish war, not only for the above reason, but also because this would involve the breakdown of the system by which he hoped to curb the revolutionary forces in the West. He therefore attempted, and for a while successfully, to persuade the tsar that the Greeks were only "ordinary rebels against legitimate authority." But, when this expedient failed, he was the first to suggest the complete independence of Greece, which seemed to him less dangerous to Austrian interests than a tributary principality on the model of Moldavia and Wallachia. In the end his attitude was one of abstention and protest, since he rightly considered that the action of the Powers which culminated in the treaty of London was fatal to the doctrine of legitimacy, on which his system was based.

The Greek question was not finally settled when the outbreak of the revolutions of 1830 threatened the overthrow of the whole structure of 1815 in the West. Events which seemed to involve the complete ruin of Metternich's system gave it in effect, however, a new lease of life. Austria, isolated by the events of the East, was once more brought into touch with Russia by a crisis that concerned both Powers equally. On the receipt of the news of the July revolution in Paris Metternich hastened to meet Count Nesselrode at Carlshabad; and, though the Russian statesman refused to commit himself to the idea of an immediate reconstitutions of a league of the three autocratic Powers, a common basis of action was agreed upon, and the foundations were laid for that cordial understanding that ripened in the meeting of Münchingen, Metternich three years later. Meanwhile, though his language was still "European," Metternich's attitude towards the revolutions was wholly Austrian. He preached the sacred duty of intervention, but he refused to intervene, save where the interests of the Habsburg monarchy were directly concerned. He was even the first to recognize the revolutionary government of Louis Philippe (Sept. 8); he answered the appeal of the king of Holland for help with an ironical reference to the geographical situation of Austria; he did not even interfere with the revolutions in Germany and Poland. But when in Italy revolt broke out that threatened the Austrian hegemony, he acted with promptitude and decision, in spite of the threatening attitude of France; in the spring of 1831 Austrian bayonets restored order in Parma, Modena and the Papal States. Yet even here Metternich showed an unwonted moderation: not only did he soon withdraw the Austrian troops from Ancona, but he took the initiative in impressing on the papal government the urgent necessity for drastic reform. This attitude was, indeed, mainly determined by the uncertainty as to the relations of the three autocratic courts on whose cooperation the effectiveness of a policy of repression ultimately depended; and Metternich's next work was to attempt to re-cement the broken alliance. With Prussia he had little difficulty; the timidity of King Frederick William III. had increased with years and the events of 1830, and the Prussian and Austrian governments came to a complete understanding on a common policy in Germany. Its first fruits were the additional articles appended by the Federal Act (June 28, 1832) to the Vienna Final Act, by which the control of the courts over the state legislatures was increased. As for Russia, Count Nesselrode at first maintained the reticent attitude he had adopted at Carlsbad; but finally, in 1833, Metternich met the emperor Nicholas I. himself at Münchengrätz and by adroit flattery won him over to his views. The Berlin convention of the 15th of October 1833, which reaffirmed...
he was first brought into diplomatic contact with him. Writing from Chaumont to Lord Liverpool, on the 26th of February 1814, he said: "Austria both in army and government is a timid Power. Her minister is constitutionally temporizing—he is charged with more faults than belong to him, but he has his full share, mixed up, however, with considerable means for carrying forward the machinery, more than any other person I have met with at Head Quarters" (F. O. 2 France, From Lord Castlereagh). This gives the key to Metternich's character and policy: Austria was a timid Power, and Metternich was an Austrian minister. His policy of "stability," so necessary for the Habenburg monarchy, at least secured a long period of peace for Europe at large. Europe, her strength renewed, passed a severe judgment on the statesman who acted on the assumption that what the generality of people wanted was peace, not liberty; and justly, in so far as his pessimism led him to convert what might have been legitimate as a temporary counsel of expediency into an immutable principle. But, as Demelisch points out, it will be time for Austrmers to condemn him when Austria shall have survived half a century of constitutional experiment under the dual monarchy.

Of the technique of diplomacy Metternich was a master. His despatches are models of diplomatic style. If they have any fault, it is that they are often over-elaborate, the work of a man who evidently loves diplomacy for its own sake and glory in the fine turn of a phrase. In this respect they are comparable to those of Canning, who modelled himself upon Chateaubriand; the Frenchman being more lively and interesting to read, Castlereagh almost invariably begins his despatches and his reports with a broad discussion of the principles involved in the case in point, and argues from these down to the facts. In this again he is in sharp contrast with Castlereagh, who, with characteristic British practical sense, politely sweeps the principles aside and prefers to argue upward from the facts. Yet Metternich's phrase-making was often the result of acute calculation. His diplomatic genius was never so well displayed as in disguising perilous issues in phrases that soothed even when they did not mean what they said. As an example of the occasion demanded it, he was master of the art of appearing to say much in fact he said nothing. When he wished to make his meaning plain, no one could do so more clearly; when he wished to be reticent, no reticence could have been more pleasingly eloquent.

In private life Metternich was a kind, if not always faithful, husband and a good father, devoted to his children, of whom he had the misfortune to lose several before his death. He was three times married. His second wife, Baroness Antonie von Leykam, Countess von Bellstein, died in 1859; his third wife, Madame Michel, Countess of Zwich-Ferrars, died on the 3rd of March 1854. Of his three sons survived him: Richard Clemens Lothar (1829–1895), his son by his second marriage, who was Austrian ambassador in Paris from 1859 to 1871; Prince Paul (1834–1906), and Prince Lothar (1837–1904), his sons by his third marriage. His grandson Prince Clemens (b. 1869), son of Prince Paul, married in 1905 Isabella de Silva Carvajal, daughter of the marquis de Santa Cruz.

BIBLIOGRAPHY.—A vast mass of unpublished material for the life of Prince Metternich exists in public and private archives; to some of those in the F.O. Records references are given in the bibliographic survey. A larger number of the documents of the Foreign Office, which are in the British Museum, have been published, under the title Memoirs, &c. (London, 1886–1882). These Memoirs, especially the autobiographical parts, must be read with considerable reserve; even the official letters and documents, which are their most valuable contents, have been to a certain extent "edited." See also Count Anton Proksch-Osten (the younger) Aus dem Nachlaß von Proksch-Osten (2 vols., Vienna, 1881); the writings and correspondence of Friedrich von Gentz (q.v.), especially his Life, "Thaliahülse den Befreiungskriegen"; Wilhelm Oncken, Österreich und Preussen im Befreiungskriege (1876–1879); A. METZ

Österreichs seit 1774 (1883); T. T. de Martens, Recueil des traités, etc., vols. iii. and iv.: Thiers, Hist. du consulat et de l'empire, while that of V. de Metternich is given in a concise and accurate account of his policy, a statement, however, controverted by Albert Sorel, whose Entrop de la révolution française, gives a detailed and masterly account of Metternich's share in the overthrow of Napoleon. Feder von Demelisch's Fürist Metternich und seine auswärtige Politik, vols. i. and ii. (Munich, 1898), is an elaborated and useful analysis of Metternich's foreign policy, based on the papers of unprinted archives.

The general appearance of the town is quaint and irregular, but there are several handsome modern streets. The Moselle, which is here joined by the Seille, flows through it in several arms, and is crossed by fourteen bridges. In the south-west corner of the town is the esplanade, with an equestrian statue of the emperor William I., and monuments to Prince Frederick Charles and Marshal Ney, commanding a fine view of the "pays messin," a fertile plain lying to the south. Of the ten city gates the most interesting are the Porte d'Allemagne, or Deutsche Tor, on the east, a castellated structure erected in 1445 and still bearing traces of the siege by Charles V.; the Porte Spes, or Römer Tor, on the south, and the Porte Française, or Französische Tor, on the west. Among its ecclesiastical edifices (nine Roman Catholic and four Protestant churches) the most noteworthy is the Roman Catholic cathedral, with huge pointed windows, slender columns and numerous flying buttresses, which, begun in the 13th century and consecrated in 1546, belongs to the period of the decadence of the Gothic style. The Gothic churches of St Vincent and St Eucharius, and the handsome Protestant garrison church, completed in 1881, also deserve mention. Among secular buildings the most important are the town-hall, the palace of justice, the theatre, the governor's house, and the various buildings for military purposes. The public library contains 40,000 volumes, including an extensive collection of works relating to the history of Lorraine. In the same building is the museum, which contains a picture gallery, a numismatic cabinet, and a collection of specimens of natural history.

Metz also possesses several learned societies, charitable institutions and schools, and a military academy. The cemetery of Chambière contains the graves of 7000 French soldiers who died here in 1870. The chief industries are tanning and the manufacture of leather, or, more precisely, tanned artificial flowers. There is a trade in wine, beer, wood and minerals.

As a fortress, Metz has always been of the highest importance, and throughout history down to 1870 it had never succumbed to an enemy, thus earning for itself the name of La pucelle. It now ranks with Strasbourg as one of the two great bulwarks of the west frontier of Germany. The original town walls were replaced by ramparts in 1550, and the citadel was built a few years later. By 1574 the works had been reconstructed by Vauban. Under Napoleon III. the fortress was strengthened by a circle of detached forts, which, after the war of 1870 and the comte de Chambord, the Germans, who treated the fortress as the principal pivot of offensive operations against France. The plans in FORTIFICATION and SHEEVOKE (fig. 43) show Metz as it was about 1900; in the years following a new outer chain of defences was constructed, which extends as far as Thionville on the north side and has its centre in front of Metz on the Gravelotte battleground. The old enceinte (which incorporates Cormankeigne's forts—Moselle and Berkeley) is doomed to demolition, and has in part been already removed. The garrison, chiefly composed of the XVI. Army Corps, numbers about 25,000 (1892).
Metz

Mediomatrica, a name from which the present form has been derived by contraction. Caesar describes it as one of the oldest and most important towns in Gaul. The Romans, recognizing its strategical importance, fortified it, and supplied it with water by an imposing aqueduct, the remains of which still exist. Under the Roman emperors Metz was connected by military roads with Toul, Langres, Lyons, Strassburg, Verdun, Reims and Trier. Christianity was introduced in the 3rd century of our era. In the middle of the 5th century the town was plundered by the Huns under Attila; subsequently it came into possession of the Franks, and was made the capital of Austria. On the partition of the Carolingian realms in 843 Metz fell to the share of the emperor Lothair I. as the capital of Lorraine. Its bishops, whose creation reaches back to the 4th century, now began to be very powerful. Metz acquired the privileges of a free imperial town in the 13th century, and soon attained great commercial prosperity. Having adopted the reformed doctrines in 1552 and 1553, it fell into the hands of the French through treachery, and was heroically and successfully defended against Charles V. by Francis duke of Guise. It now sank to the level of a French provincial town, and its population dwindled from 65,000 to about 22,000. At the peace of Westphalia in 1648 Metz, with Toul and Verdun, was formally ceded to France, in whose possession it remained for upwards of two centuries. The battles of August 1870, and the investment and capture of the army of Metz which followed, are described below. By the peace of Frankfort on the 10th of May 1871 Metz was again united to the German Empire.

A. Prost, Études sur l'histoire de Metz (1897); and Tauber, Die Schlachtfelder von Metz (Berlin, 1902). (See also Franco-German War: Bibliography.)

Battles around Metz, in the Franco-German War, 1870

1. Colombey-Borny (August 14).—The French army under Marshal Bazaine was in and about Metz. The German I. and II. armies, on the march from the Saar, were heading for the Moselle between Metz and Pont-à-Mousson, and on the morning of the 14th of August the German I. Army (I., VII. and VIII. Corps, under General v. Steinmetz) lay on and east of the French, with outposts well to the front, watching the French camps east of Metz, which were little more than 1 m. to the front. Steinmetz had received from headquarters overnight instructions that on the 14th of August the I. Army would maintain the positions occupied during the 13th, and merely pass on these orders to his corps commanders. In Metz, meanwhile, Bazaine had decided to retreat, and during the morning orders to that effect reached his corps commanders, who commenced preparations for their execution. The 2nd Corps (Ladmirault) was held to the 6th (Canrobert) began to retire about midday, the 3rd (Leboeuf), 4th (Ladmirault) and Imperial Guard (Bourbaki) were to follow. These preparations being observed, the German outposts got under arms. General von der Goltz, in command of the VII. Corps (7 battalions, 4 squadrons, 2 batteries) hearing from a passing officer that the I. Corps on his right was preparing to attack, and noting personally signs of retreat in the enemy’s lines, determined at 3 p.m. to advance his whole command to the ridge between Colombey and Borny (which was still occupied by French outposts), in order to clear up the situation. The ridge was captured with little resistance, but the sound of the firing at once set all the neighbouring troops in motion, and fortunately so, for the French had immediately retaliated on von der Goltz’s audacious attack. Between 4 and 6 p.m. there was continuous heavy fighting on the front from Borny to Méy, as both sides brought fresh troops into the field. The convex slopes falling from the Prussian position towards Metz gave plenty of cover to the French, and the setting sun shone full in the faces of the Prussian troops. Thus the Prussian infantry encountered unusually obstinate resistance, and the French troops engaged rapidly slipped from all superior control. The above front was held by the French 3rd Corps. Shortly before 6.30 the 4th Corps (Ladmirault) suddenly began to deploy on the high ground to the north-west beyond Méy, thus threatening the right flank of the Prussian I. Corps (General v. Manteuffel). To meet this danger Manteuffel was compelled to direct his corps artillery and reserves, which were now rapidly coming up, away from the hard-pressed centre towards the oncoming infantry masses of Ladmirault. These, with the sun now almost at their backs, were shooting better than usual, and Manteuffel was compelled to call on the VII. Corps for assistance, which his commander, under positive orders from Steinmetz, refused to give. Meanwhile Steinmetz had been sending peremptory orders to the battlefield to stop the battle, but neither of the corps commanders was able to enforce them. Fortunately for the Prussians, Bazaine had issued similar orders to his subordinates, who, having their men better in hand, were able to obey; and as night began to close in the French broke off the action and retired under the guns of the Metz forts, convinced that at last they had “broken the spell” of German success.

Finding that in spite of his orders, the firing at the front continued increasing in intensity, Steinmetz at length rode to the front himself. Meeting Manteuffel near the Brasserie of Noiselle, he overwhelmed him with reproaches, and at the crisis of this scene the hands struck up “Heil dir im Siegeskampf!” In this action the Germans brought 30,500 rifles and 150 guns on to the battlefield only out of more than 100,000 with 300 guns which could have been engaged before darkness. Bazaine actually deployed 50,700 rifles and 206 guns to oppose them. He might, however, had he been so minded, have struck with his whole army, with twice this force, and, judging from the events actually took, we can have little doubt of the result to such a blow. The losses on either side were in killed and wounded—French about 3,600, Germans about 4,800.

The chain of causation in this action is particularly worthy of attention: A young reserve officer, seeing some troops of the I. Corps standing to arms, reported to von der Goltz that the corps was standing to arms and about to attack. Von der Goltz thereupon decided to go forward and discover what was actually going on, and this action unchained the whole battle power of all the troops within call. When, on the following morning, Steinmetz reported to von der Goltz and the commander of the I. Corps for disobedience, the king thanked Manteuffel warmly for the part he had played, and then turned to the young brigadier who had disobeyed orders and congratulated him on having twice distinguished himself in the first fortnight of the war.

2. The Battle of Vionville—Mars-la-Tour (August 16).—On the following day (16th) the II. German Army approached the Moselle above and below Pont-à-Mousson, with a view to overtaking and heading off Bazaine in his presumed retreat to the Meuse (see Franco-German War). So far, however, from being ahead of the Germans on the road to Verdun, the French were actually late, in the afternoon of the 15th of August, bivouacked on the plateau of Rezonville, and there their outposts were placed, not where they could see the surrounding country, but at the regulation distances of 600 to 1000 paces from the bivouacs. Friendly inhabitants kept Bazaine well informed as to the magnitude of the danger threatening him from the south, and a special telegram from Paris, the true origin of which has never been traced, led him to believe that the I. German Army was crossing the Moselle near Thionville and about to descend on Verdun from the north. Such a telegram might have exercised the most prejudicial influence on the course of the battle had not Ladmirault (4th Corps), nearer to the seat of the imaginary danger, taken upon himself to disregard the warning transmitted to him by headquarters. At daybreak on the 16th, no Prussians being reported in sight by the outposts, the troops began non-chalantly to prepare for the resumption of the march.

On the Prussian side, von Alvensleben’s Corps (III.) shortly after daybreak was moving north-westward from the Moselle in two columns, on the right the 5th division, under Gorze and Flaviogny on Vionville, on the left the 6th division with corps artillery by Arnville on Mars-la-Tour, von Alvensleben himself riding.
a little in advance between the two. The 6th cavalry division was ordered to precede the right column and scout towards Rezonville. No one was aware of the dangerous proximity of the French army.

About 9 a.m. the 5th cavalry division, reinforced by two horse artillery batteries (flank guard of the X. Corps from Thiencourt), and accompanied by von Caprivi (chief of staff, X. Corps, and afterwards chancellor of the German Empire), were trotting up the western slopes of the ridge which runs between Tronville and Vionville. Reaching its summit they suddenly found themselves in face of at least 40,000 French troops, which were not under arms, but busied with miscellaneous camp duties. The temptation proved too great for the artillery, who promptly fired into the midst of the cavalry camp (Forton’s division) which lay nearest to them. The momentary result was a wild panic, especially among the horses; but this panic gave the alarm to the infantry all along the road, and these (Frossard’s 2nd Corps) at once stood to arms and moved forward, deployed for attack—one division to the west, another division, from Rezonville, to the south. The latter almost at once encountered the heads of the 6th cavalry division, at that moment just clearing the defile leading up to the Rezonville plateau from Gorze. The Prussian cavalry promptly bore away to cover to the westward, and reported what they had seen to superior authority, but not to the advanced guard of the 5th infantry division, which, emerging in its turn from the defile, ran right against the deployed French infantry moving to meet them. So sudden was the collision that the Prussian advanced guard battery had to fire case to clear its own front.

Meanwhile von Alvensleben himself, riding on the field track from Gorze towards Vionville, whence he could overlook the whole country to the north and west, had met von Rheinhaben (commanding the 5th cavalry division) and had seen the surprise of the French camps. The sound of the heavy firing coming from the eastward convinced him of what had been gradually dawning on him—that with barely 30,000 men he was in the presence of the whole French army, whose attitude at this moment sufficiently indicated their determination to fight.

In a few moments his decision was taken. Calling on the X. Corps, away to the south-westward, for support, he determined to screen his own weakness by a vigorous attack. By universal consent this is approved as the boldest resolution arrived at by an independent commander throughout the war. Orders were forthwith despatched to the 6th infantry division, at that moment between Puxieux and Tronville, to wheel in to their right and attack, and, their movement being still hidden from the enemy, these troops were formally drawn up for action and sent forward as a whole. The French meanwhile had occupied Vionville and Flavigny, and other troops were moving down the slopes from Rezonville to their support, but the united onset of this whole German division overbore all resistance, and the French began to retire eastward, suffering terribly from the shell fire of the Prussian batteries.

Marshal Bazaine had meanwhile arrived on the scene, and ordering forward fresh troops to relieve (not to reinforce) those already engaged, he rode forward with a horse artillery battery to watch the operations. The retiring French troops belonged to Frossard’s command, and as they were in considerable confusion Frossard called on du Preufl’s brigade of the imperial guard cavalry to charge. He gave no objective, and when the
brigadier pointed out that the enemy was still beyond the striking radius of his horses, Frossard reiterated the order, which was obeyed to the letter.

The result was disastrous. The Prussians, having seen the cavalry whilst yet at a distance, ceased firing, formed their skirmishers into groups, and the closed supports standing in deployed lines, two deep, shattered the cavalry with volleys and file-firing, as with blown and exhausted horses they endeavoured to close with their adversaries. When in addition two hussar regiments struck them in flank they were driven back in wild disorder upon Rezonville. In the dust and confusion of the charge a group of the hussars approached Bazaine and his horse artillery battery, and almost carried off the marshal.

Alvensleben, mistaking the withdrawal of the French for the beginning of a retreat, had meanwhile sent orders to the 6th cavalry division to charge in pursuit towards Rezonville; but before it could reach the field the French relieving troops had forced their way through the stragglers and showed such a bold front to the Prussian horsemen that an attack held no promise of success, more especially since they had lost their intervals in their advance and had no room for a proper deployment. To steady the young soldiers, the cavalry commander (Carl von Schmidt) halted his men, made them correct their intervals and dressing as in peace, though under a heavy fire from the French infantry, and then withdrew them behind the cover of the nearest hill at a walk.

The threat of the charge had, however, induced caution on the French side, and for about two hours there was a lull in the fighting, which the Prussians utilized on their right in bringing up reinforcements through the Bois des Ognons. On their left, however, no fresh troops were as yet available, and on being informed, about 2:30 p.m., that French cavalry seemed to be about to change the exhausted 6th division, Alvensleben ordered Bredow's cavalry brigade to charge, and if necessary to sacrifice itself, to save the infantry. Bredow's command (six squadrons of the 16th Ulan and 7th Cuirassiers) was at that moment drawn up under cover about half a mile west of Vionville, and from its position could see nothing of the events in progress on the battlefield. Nettled by the form in which the order was conveyed to him, Bredow drew his sword and ordered his trumpeter to sound the "trot," the brigade moving off in line of squadron columns at close interval in the direction in which they happened at the moment to be facing. Near Vionville they took ground to their left, opening to full intervals as they did so, and then

ascended the gentle incline which still hid them from their enemy.

Arrived at the summit, Bredow sounded "line to the front," but at that moment a storm of French bullets swept down on them, and the men, no longer to be restrained, dashed forward, before the line could be completed, almost due east against long lines of infantry and ordered by the low flanks at which they now saw for the first time about 1,000 yards in front of them.

This distance was covered at the fullest speed of the horses, and reaching the infantry they swept over them "like hounds over a fence"—in the words of an eyewitness. So sudden had been their onset that very few were hit until the infantry had been passed; then the latter, recovering from the shock, turned and fired into the cavalry from behind, whilst a whole fresh division of French horsemen charged them in flank. After a desperate mêlée of some minutes, the rally was sounded, and the survivors of the charge, breaking their way a second time through the French infantry, eventually reached the shelter of their own lines, having lost rather more than half their numbers, but having saved the situation momentarily for their own army. Again there was a lull in the operations.

Meanwhile, unknown to Alvensleben, a fresh storm was brewing on his left rear.

Ladmirault, commanding the French 41st Corps had seen, during the afternoon of the 15th, the terrible crowd and confusion prevailing in the defiles leading to Gravelotte, and resolved to disobey his orders and to move from his bivouac by the road from Woippy to St Privat, disregarding altogether the alleged danger from the Prussians supposed to be advancing from Thionville. Thus, about noon on the 16th he reached the high ground between St Privat and Amanvillers, and still without instructions he determined to direct his corps on Bruvill and Doncourt, whence he could judge from the drift of the smoke-clouds whether he could fall on the Prussian left.

Much time was lost owing to the heat of the day and the fatigue of the troops, but shortly after 3 p.m. he reached a position north of the Thronville copses whence his guns could fire into the left rear of the rear of the 2nd Division (von Donzel) of the 2nd Corps (20th division and corps artillery) on the heights above Vionville and Flavigny. Their fire threw the latter into serious confusion and he had already decided to attack with his nearest division (de Cisy) in the direction of the steeple of Vionville, when his attention was caught by the outbreak of heavy firing in the copse below him, and the entry of fresh Prussian guns into action.

This diversion was brought about by the arrival of the corps artillery of the X. Corps and of the 40th brigade, which latter had been at one end of the Tronville copse in order to check portions of Tixier's division of the French 3rd Corps, which under cover of these copses had gradually worked round the Prussian flank. Seeing then that the troops before him could hold their own, Ladmirault continued his preparations for his counter-stroke, and Cisy's division had begun to move into its prescribed alignment, facing towards Vionville, when the sudden appearance of a closed mass of Prussian troops detaching itself from the low dust-cloud of a slow-moving infantry column, and forming to the south of Mars-la-Tour, again arrested his attention. Unanimously he and his staff agreed that this fresh enemy column could only be the advanced guard of a large Prussian corps, possibly, it was suggested, of the crown prince's army, from Alsace and Nancy, and a fresh delay arose while the situation was investigated. Actually this body consisted only of the 38th brigade (von Wiedell), forming part of the X. Corps. It had no knowledge of the state of affairs on the battlefield, or in the direction of Bruvill, though Prussian cavalry had been observing the approach of Ladmirault's corps for some hours. It was now ordered to deploy and to co-operate with the 40th brigade in an attack on the Tronville copses. This meanwhile had been delivered, and had more or less failed.

The deployment completed, about 4 p.m. the 38th brigade began its advance on the north-west corner of the Tronville copses, this direction taking them diagonally across the front
of Cissey's division, still out of their sight but moving due south. Hardly had they stepped off when Cissey's first line, catching sight of them, opened a devastating fire upon their left flank, and to meet this fresh danger the Prussians endeavored to change front half-left whilst still on the move. Without pausing to fire, the men raced onward, but the French striking their outer wing rolled up the whole line in succession, the actual collision occurring in and near the Bruvillie ravine, a deep-cut natural trench which, starting from the Tronville copse, here intersects the plateau from west to east. Against the weight of French numbers, nearly three to one, the Prussians were unable to stand, and presently they broke and drifted backwards, completely routed. Then the 1st Guard Dragoons (since known as Queen Victoria's regiment), after a brilliant manœuvre under heavy fire, to get into the best position for delivering a charge, rode down the whole French line of pursuers from left to right, and by their heroic self-sacrifice relieved the remnants of the infantry from further pursuit.

This was the scene which for the moment held the attention of Prince Frederick Charles when at length he reached the battlefield from Pont-à-Mousson. All along the rest of the line the Prussians were still holding their own, and on the extreme right fresh troops from the IX. Corps were streamlining through the woods against the French left wing. But on the left there was a dense cloud of smoke and dust, and to arrest this only the cavalry were at hand. Sending, therefore, hasty orders to the 5th and 6th cavalry divisions to concentrate to the west of Mars-la-Tour, the prince ordered them from there to sweep round on the right rear of the French army. The same idea had, however, occurred to Ladmirault, and he had called on the two nearest French cavalry divisions to put it into execution, and as the Prussians began to reach the plateau west of Mars-la-Tour and the Yron brook from the south, the French were deploying across it some two thousand yards to the north.

Thus 24th August—the one of the great cavalry duel of the war—between upwards of two thousand horsemen a side. But it was delivered by both sides in a series of regimental charges, and in result was singularly indecisive. For about half an hour great crowds of riders, hidden by dense clouds of dust, drifted aimlessly about the plain, till at length the charge of a single squadron of the Oldenburg Dragoons (who had joined in on their own initiative) delivered on the outer French flank, brought the whole mass into motion north-eastward, and, while both sides sounding the rally, the engagement gradually ceased.

It was now about 7 p.m. and night was coming on. Seeing the tide of battle rolling away northward, and noting the lethargy which seemed to have settled over the whole French line, Prince Frederick Charles decided to assert his own independent will to conquer by a final assault along his whole front. Guns, cavalry, infantry, everything that could still stand were to take part in it. Weary as they all were, his indomitable will put fresh life into the whole army. With drums beating and colours flying, every unit within call went forward for the final effort. It was almost dark when the Prussians approached the French position between Rezonville and the woods to the northward, and the troops soon lost direction in the smoke and became involved in the densest confusion; the firing again blazed out for a few moments, only to die away as utter exhaustion at length put an end to the Prussian advance. Then the wearied troops, for the most part, lay down and slept in the positions they had reached.

Thus closed the hardest fought battle of the Franco-German War. From 9 a.m. to 3 p.m. only 23,700 rifles, 8,000 sabres and 126 guns had been brought into action by the Germans against 59,100 rifles, 6700 sabres, and 300 guns on the French side, and even at the close of the day the former had only deployed 47,100 rifles, 8300 sabres and 222 guns against 83,000 rifles, 8000 sabres and 432 guns including 54 mitrailleuses. The chief characteristic of the day's fighting was the terrible effectiveness of the Prussian artillery, which was handled in masses and not, as on the French side, by batteries. The manouevring power of the latter attracted the admiration of the Germans, but arriving singly on the field they were generally reduced to silence in a few minutes. Deprived of their support, not all the gallantry of the French infantry could avail anything. Again and again, particularly on their left wing, they chased the German infantry before them, but the moment the retreat of the latter downhill in the pursuing French to the Prussian guns, a tornado of shells shattered the ranks and compelled them to retreat. Though the cavalry were freely engaged, the training of both was so far beneath the standard of the present day that the most that can be credited to them in respect of results is that they from time to time averted imminent disaster, but failed altogether to achieve such a decision as was well within their potential capacities.

3. Grandville—St Privat (August 18).—The position on which the French army fell back from the field of Vionville is formed by a ridge some six miles long running from Roziereuilles almost due north to Roncourt, a little village overhanging the steep and wooded banks of the Orne, and connected with the general plateau between the Meuse and Moselle by a gentle saddle running from about Amunvillers nearly due west through the Bois de la Cusse towards Doncourt. North of this saddle the slopes show a slight concavity, but are passable by troops of all arms in close order. To the south the rivulet of the Mance soon forms a formidable obstacle as its bed cuts its way through the sandstone. Scrub and woods with dense undergrowth line both the central ridge, and, except by the great chaussee from Metz to Verdun, access to the French side becomes impossible to troops in ordered bodies.

It does not appear that the position had been systematically examined, or apportioned to the several corps in accordance with any predetermined plan. The army merely swung backwards, pivoting on its left wing, the corps preserving their relative order as it had been on the 16th, with the exception that the Imperial Guard was withdrawn to the spur on which Fort Plappeville stands, and the 6th Corps (Marshal Cambert) took the line of march of the 5th and 4th Corps in order to gain St Privat la Montagne. The line of march in general was divided into three parts, one each to the several units, consequently the confusion became so great that though the distance to be traversed in no case exceeded six miles, only the right wing and centre reached their destinations as night was falling. Many of them had so little idea of the general situation that they actually placed outposts to the north and east, whilst the whole of the enemy's army lay to the south and west. No attempt was made to entrench the position systematically, but on the left the 2nd and 3rd Corps made some disconnected shelter trenches and gun-pits, while the 4th Corps in the centre began to improve available cover about an hour before the battle began, and the 6th corps on the right, not yet having received any entrenching tools, could do no more than improvise a few loopholes in the walls of the villages of St Privat and Roncourt with such tools as the sappers could obtain from the inhabitants.

Fortunately for the French the Germans were too exhausted by the battle of the 16th to attempt to interfere with these movements. At daybreak on the morning of the 18th the royal headquarters (which now for the first time arrived at the front) still had no certain knowledge as to whether the French main army was in retreat—covered by the force which they could see on the high ground north of the Metz road—or whether they had taken up a position in order to fight.

Hence the orders issued overnight on the presumption that the main force of the French was retreating to the north and west were allowed to stand, and the whole II. Army (Prince Frederick Charles) moved off in echelon from left to right, the I. army under Steinmetz, consisting for the day of the I., II. and VII. Corps, being left in observation of the troops visible on their front and of the garrison of Metz itself. The I. Corps was kept back beyond the Moselle on the east side of Metz, the II. was not due to arrive at Rezonville before 4 p.m., hence the VII. only was immediately available if the enemy counter-attacked. But Steinmetz had not ordered, nor had von Zastrow, the corps commander, undertaken, any preparations to meet an emergency. About 10 a.m. the corps had reached the following positions:
VIII. Corps, Rezonville; XL near St Marcel; Guard approaching Doncourt; XII. towards Jarny; the III. and X., which had been so heavily engaged on the 16th, still in their bivouacs preparing to move. The cavalry of the Saxons had established the fact that the French had not retreated northward, but though scouts from the Guard had already seen the enemy on the heights of St Privat, this information had not yet reached headquarters, nor had it been transmitted to the IX. Corps, which it most closely concerned.

Shortly after 10 a.m. Moltke, still under the impression that the French right extended no farther than La Folie (2 m. north of the Metz road), determined to attack with the IX. and VIII. Corps whilst the Guard executed a turning movement via Habonville against the French right. The IX. Corps was to engage, but not to push its attack home until the Guard could co-operate. The XII. Corps was left to its own devices, but fortunately the crown prince of Saxony, who commanded it, had ridden forward and, seeing the French in force towards Roncourt, had issued orders which in the event proved decisive.

In pursuance of his instructions von Manstein, commanding the IX. Corps, set his two divisions in motion towards La Folie and the Bois de la Coupe, and advanced to reconnoitre the French position. From the eastern edge of the above-named copses he suddenly descried the camp of a whole French Corps (the 4th), evidently ignorant of their danger, on the slopes trending westward from Amanvillers. Unmindful of the experience of the 16th, he decided to execute an artillery surprise on a grand scale, and send orders to his corps artillery to come into action on the long spur overlooking the French camps from the westward. At noon, just as the French infantry were falling in for midday roll-call, sufficient guns were in position, and suddenly opened fire. But the effect was disappointing. The French infantry ran to their arms, piled along the front of their positions, and moved forward to attack, covering their advance by a hail of bullets. Simultaneously the French artillery also took up the challenge, and from the heights near St Privat the 6th Corps, whose presence had been unsuspected by the Prussians, joined in the fight.

In a few minutes the batteries on the extreme Prussian left were completely overwhelmed, and suddenly dense lines of French skirmishers emerged from a fold in the ground upon their flank and front, and the gunners were compelled to resort to case-shot, so imminent was their danger. But at this critical moment the leading companies of the Hessian infantry arrived, re-established the equilibrium (though not before four Prussian battalions had been temporarily overrun by the enemy), and a most obstinate fight ensued.

Prince Frederick Charles now rode forward to a point north-east of Vernéville, whence the southern boundary of St Privat could be seen. But the northern side of the village and the country towards Roncourt was hidden from his view by the high poplars bordering the Metz-Briey road. Seeing the Hessians hard pressed, he now brought forward the 2nd division of the Guard to their assistance, sending in the 3rd brigade immediately, and holding the 4th brigade in reserve. The 1st division, warned by their own scouts that French troops were in St Marie, deployed to attack this village, and were assisted in this undertaking by a brigade of Saxons detached by the crown prince of Saxony, who from his position could see behind the poplar screen that limited the view of the commander-in-chief. Hence he was already aware that the French position extended to Roncourt at least, and had despatched a whole division down the valley of the Orne to outflank them. No news of this movement, however, appears to have reached Prince Frederick Charles.

In St Marie were only an outpost of the 6th corps, and seeing themselves outnumbered, they withdrew about 2.30, the Prussians rushing the village immediately afterwards. Considerable confusion arose from the convergence of these three brigades upon one village, and more than an hour passed before the troops could be disentangled and massed for further operations. The leaders of the two Guard brigades, still ignorant of the extent of the French position, rallied their men on the main bodies of their commands (which had not been engaged) and then lay down facing exactly as they had done when brought forward to the attack. Thus the 1st brigade lay, facing about east-south-east, south of the chaussee and some five hundred yards west of the village. The 2nd brigade lay south-west of the village about three hundred yards away from it facing north-east.

The Saxons were on the left rear of the 1st brigade, but took longer to recover themselves than the Guards. With the Hessians and the IX. Corps the action still dragged; the 3rd brigade of the Guards had become involved in the fight, and notwithstanding the arrival of the corps artillery of the III. Corps in the centre the situation was still critical. From the south also came the thunder of guns and no encouraging news from that quarter had as yet reached the prince's headquarters.

About 4.30 p.m. the prince therefore had to consider how long it would take to obtain a decision. To postpone it till the morrow seemed undesirable: to achieve it before nightfall was only possible at the cost of immediate effort.

He therefore decided to assault St Privat, with all the Guards available, and called up the III., X. and Saxons to assist them.

The 4th division of the Guards now received their orders to attack Jérusalem (a hamlet a little south of St Privat), and the 1st division was ordered to assault St Privat itself.

Von Pape, commanding the latter division, pointed out that no artillery force adequate to prepare the way for him had yet been brought to the front and that the 4th division should make its way forward to the rear. But his orders were imperative, and the 4th brigade was already moving off and had to be supported at any cost. Actually all available batteries had already been sent for and were trotting forward from every quarter towards the objective. He accordingly transmitted his orders, and the 2nd brigade was the first to attempt their execution.

It had to wheed half-right in mass to bring it in the required direction, and then to advance till its rear was clear of the obstruction formed by the gardens of St Marie. By the time (4.36) it had sufficiently cleared this village it became apparent that the 4th brigade in its extension for attack would overlap the front assigned to the 2nd, hence a further (half-left) wheel, still in mass, had to be undertaken before room for deployment could be obtained. Almost as the commands were given, the French suddenly opened an overwhelming long-range fire and their bullets swept like hail through the crowded mass of the German troops. Nevertheless the wheel was effected, the fresh direction taken, the troops extended for attack, and then the whole brigade dashed towards the houses assigned as its objective. Meanwhile the 1st brigade had moved round the north of the village and, having reached the road without serious hindrance, but emerging from the hollow running north from St Marie, they came under a heavy fire not only from St Privat but also from Roncourt, which latter village they now saw for the first time. Instinctively a portion of their line worked to the left to face this new menace, and the front thus became dangerously extended. They were, however, now abreast of the 2nd brigade, and the whole line raced forward to reach the effective range of their very light weapons, which were about equal at 500 yds. to the French rifle at 500 yds. The 2nd brigade, particularly in officers, had been too heavy and the rush died out whilst 500 yds. from the two villages.

It was now about 6 p.m. and a long pause ensued, while the 220 guns, which by 'degrees had unlimbered behind them, brought St Privat and Roncourt under fire. About 7 p.m. the Saxon turning-movement took effect; their infantry from the Orne valley attacked Roncourt from the north, and about 7.15 the village was carried.

Neither Prince Frederick Charles nor the troops in the fighting line could see what had taken place; but the former seeing other Saxons moving towards Montois and the masses of the III. and X. Corps approaching, whilst the rain of shells into St Privat exceeded anything hitherto seen on any battlefield, decided to call on the whole of his force to attack. He was in
the act of issuing his orders when a psychological wave swept through the fighting-line, and the men rose and rushed the village at the point of the bayonet. It was now about eight o'clock, and the light was rapidly failing.

The French artillery had already evaded the coming blow, and when the order was “right back,” to cover the flank of the rest of the army, and the Prussian and Saxon artillery trotting forward conformed to this new front, their shells sweeping the ground for 2000 yds. to the south of Amanvillers. The confusion in and around St Privat, where troops from four several corps were all intermingled, became so extreme that no further infantry-advance could be attempted; so under cover of the fierce artillery duel the remnants of the unfortunate 6th corps drifted away towards Metz down the many ravines leading into the river valley. The “annihilation of the Guard at St Privat has become historic. Yet, heavy as were the losses of the 1st Guard division they were not excessive compared to those previously endured. In round numbers one-third of their effectives had fallen—most of them in the first great rush forward at 5.30 p.m.; but actually they had been more or less under fire since about 2 p.m., and many were hit by French shells plunging into the turmoil about St Privat from 8 to 10 p.m. But the legend cannot be justified when the facts are compared with the slaughter of the Seven Years' War, of Napoleon's battles, the Crimea, and the American Civil War, and with the horrors of the massed punishment of von Wedell's brigade (38th) only two days before.

It is now time to return to the southern theatre of the battlefield, where an entire independent engagement had been raging all the afternoon. Von Goeben with the VIII. Corps was standing massed about Rezonville when von Manstein's guns opposite Amanvillers suddenly made themselves heard. Wheeling his corps to face the French to the eastward he immediately sent forward his artillery and prepared to support his comrades. Von Zastrow with the VII. Corps followed his example. Both commanders at the same time pressed their pieces down upon the heights of the Hubert and Point du Jour, standing just above the defile made by the Verdun-Metz road where it climbs out of the Mance ravine towards the French position. About 3.30 p.m. St Hubert was carried by a confused mass of some 40 companies, and von Steinmetz, believing the main French position to have been pierced, ordered the 4th cavalry division to cross the ravine by the chausée and pursue. Simultaneously von Zastrow, under the same impression, had ordered his corps artillery to advance by the same road, and von Goeben, thinking his troops in front required support, had sent forward an infantry brigade, consisting of the 1st infantry division and the 1st cavalry division, and set about the reorganization of his troops in the most leisurely manner. The Metz forts, though neither sufficiently armed nor even completely finished in some cases, were nevertheless, with their deep ditches and self-protecting bastion trace, far too formidable for any field army to attempt without the aid of a siege train of some 200 guns, which for the moment were not available. Of this fact the Germans were well aware, and hence they decided from the first to reduce the place by hunger, calculating that with the extra 150,000 men thrown back upon the fortress, its food supply could not last long. On the morning of the 19th the German artillery was far too exhausted for further efforts. Except the I. Corps, which had been summoned overnight from its position about Courcelles towards the battlefield of Gravelotte and had almost reached the Moselle before this move could be counterordered, the remainder kept their places of the previous night, only following the French retreat with a screen of outposts. They were sufficiently occupied in collecting the wounded and clearing up the confusion resulting from an accumulation of trains and transport in the defiles of Gorze and about Novéau. No extended movement could have taken place that day. In the course of the afternoon of the 19th the royal headquarters, creating a new army under the crown prince of Saxonv (Guard, IV. and XII. (Saxons) Corps) for field operations towards the Meuse, assigned the remainder of the I. Army, and the whole
of the I, to Prince Frederick Charles as commander-in-chief of the army of investment. This brought the strength of his command up to eight corps, numbering some 250,000 men; an enormous mass to be shifted in the next two weeks. Besides, in the north-west of France were at hand 60,000 Germans with 452 guns, and had been beaten off with a loss of 3,500 men. The Germans had lost about 3,000.

The investment now resumed its regular course. The Germans, secure in the strength of their position on the left bank of the Moselle, drew more troops over to the right, and added to their defences and communications. The idea was even mooted of damming up the river near Hauconcourt, and thus flooding the whole of the civil population of Metz; but this was not carried out. Civil engineers, who were sent from Germany, reported against the proposal.

As time wore on the conditions in Metz and the surrounding camps became deplorable. The hospitals and private houses had been crowded with wounded from the first, and now, owing to the persistent wet weather, smallpox and dysentery became epidemic. Towards the close of September rations had to be reduced, and the troops began slaughtering the cavalry horses for food. Probably to cheer the men by a semblance of activity, attempt was made on the 1st of October in the direction of Ladorcamps, and fighting continued into the 2nd, but without prospect of success, and the profound depression following on defeat sent up the sick list rapidly. One other sortie towards Neisseville followed on the 7th, the alleged reason for which was the hope of obtaining provisions in the neighbouring villages. But it was beaten off with the utmost ease by the investing troops, who were well fed and cared for; and as by this time even the gun-teams had followed the cavalry horses to the slaughter-house, the French army as an army—i.e. a combination of the three arms—had ceased to exist. On the recognition of this fact negotiators for the capitulation of Metz were begun on the 13th of October, and on the 14th the Army of the Rhine surrendered. Had it held out even forty-eight hours longer events before Paris and Orleans might have taken a different turn.

The investment of Metz had lasted 54 days, and the death-roll of the civil population had risen to 38,877 against 1,200 in the corresponding period of a normal year. The army itself had only lost from sickness 2,600 men, or barely 2% of its full effective strength.

MEULEN—MEULEN

1663—1690

Flemish painter, born in Brussels, was called to Paris about 1666 by Colbert, at the instance of Le Brun, to fill the post of battle painter to Louis XIV. His paintings during the campaigns of Flanders (1667) so delighted Louis that from that date Van der Meulen was ordered to accompany him in all his expeditions. In 1673 he was received into the French Academy, attained the grade of councillor in 1681, and died full of honours in Paris in 1690. He is best represented by the series of twenty-three paintings, mostly executed for Louis XIV, now in the Louvre. The show that he always retained his Flemish predilections in point of colour, although his style was modified by that of the French school.
MEUNIER—MEUSE

MEUNIER, CONSTANTIN (1831-1905), Belgian painter and sculptor, was born at Etterbeek, Brussels. His first exhibit was a plaster sketch, "The Garland," at the Brussels Salon in 1851. Soon afterwards, on the advice of the painter Charles de Groux, he abandoned the chisel for the brush. His first important painting was "The Sale St. Remy" (1853), followed by a series of paintings including "A Trappist Funeral" (1856), "Trappists Floughing" (1863), in collaboration with Alfred Vervée, "Divine Service at the Monastery of La Trappe" (1871) and episodes of the Peasants' War (1878). About 1880 he was commissioned to illustrate those parts of Camille Lemonnier's description of Belgium in Le Tour du monde which referred to miners and factory-workers, and produced "The Factory," "Smithy at Cockerill's," "Melting Steel at the Factory at Seraing" (1882), "Returning from the Pit," and "The Broken Crucible" (1884). In 1882 he was employed by the government to copy Pedro Campana's "Descent from the Cross" at Seville, and in Spain he painted such characteristic pictures as "The Café Concert," "Procession on Good Friday," and "The Tobacco Factory at Seville" (Brussels Gallery). On his return to Belgium he was appointed professor at the Louvain Academy of Fine Arts. In 1885 he returned to stationary and produced "The Puddler," "The Hammerer" (1886), "Firedamp" (1889, Brussels Gallery), "Ecce Homo" (1891), "The Old Mine-Horse" (1891), "The Mower" (1892), "The Gele" (1893), the monument to Father Damien at Louvain (1893), "Puddler at the Furnace" (1893), the scheme of decoration for the Botanic Garden at Brussels in collaboration with the sculptor Charles van der Steappen (1893), "The Horse at the Pond," in the square in the north-east quarter of Brussels, and two unfinished works, the "Monument to Labour" and the Zola monument, in collaboration with the French sculptor Charpentier. The "Monument to Labour," which was acquired by the State for the Brussels Gallery, comprises four stone bas-reliefs, "Industry," "The Mine," "Harvest," and the "Harbour"; four bronze statues, "The Sower," "The Smith," "The Miner," and "The Puddler." At Ronchamp and Gare d'Orléans he founded Maternity, Meunier died at Brussels on the 4th of April 1905.

MEURICE, FRANÇOIS PAUL (1818-1905), French dramatist, was born in Paris on the 7th of February 1818. In 1848 he became the editor of the Événement, founded by Victor Hugo, and in 1868 he was one of the promoters of the Rappel, a journal on similar lines. He was the literary executor of Victor Hugo, and edited his works (1880-1885). In collaboration with Auguste Vacquerie and Théophile Gautier, he produced Paidoff (1842), a play in imitation of Shakespeare, and in 1843 an imitation of the Antigone; and with Alexandre Dumais a Hamlet (1843). "Puddler at the Furnace" (1883), the scheme of decoration for the Botanical Garden at Brussels in collaboration with the sculptor Charles van der Steappen (1893), "The Horse at the Pond," in the square in the north-east quarter of Brussels, and two unfinished works, the "Monument to Labour" and the Zola monument, in collaboration with the French sculptor Charpentier. The "Monument to Labour," which was acquired by the State for the Brussels Gallery, comprises four stone bas-reliefs, "Industry," "The Mine," "Harvest," and the "Harbour"; four bronze statues, "The Sower," "The Smith," "The Miner," and "The Puddler." At Ronchamp and Gare d'Orléans he founded Maternity, Meunier died at Brussels on the 4th of April 1905.

MEURS, JOHANNES VAN MEURS (1579-1639), Dutch classical scholar and antiquary, was born at Loosduinen, near the Hague. He was extremely precocious, and at the age of sixteen produced a commentary on the Cassandra of Lyco- phon. In 1610 he was appointed professor of Greek and history at Leiden, and in the following year historiographer to the states-general. He composed a disturbed state of his country he welcomed the offer (1625) of Christian IV. of Denmark to become professor of history and politics at Sorø, in Zealand, combined with the office of historiographer royal. He died at Sorø on the 20th of September 1639. Meursius was the author of classical editions and treatises, many of which are printed in J. F. Gronovius's Thesaurus antiquitatum graecarum. Their lack of arrangement detracts from their value, but they are a storehouse of information, and Meursius does not deserve the epithets of "pedant" and "ignoramus" which Scaliger applied to him. Meursius also wrote on the troubles in the Netherlands and the history of Denmark.

MEURTHE-ET-MOSELLE, a department of north-eastern France, formed in 1871 out of some parts of the old departments of Meurthe and Moselle which continued French. Before 1790 it belonged to Lorraine, or to one or other of the bishoprics of Toul, Metz and Verdun. Pop. (1906), 577,508. Area 2038 sq. m. It is bounded E. by Lorraine, N. by Belgium and the department of Luxembourg, W. by the department of Meuse, and S. by that of Vosges. Meurthe-et-Moselle is of a hilly character, the highest elevation, the Grand Rougimont (2041 ft.), being in the Vosges. The valley of the Moselle runs through it from south to north. Extensive forests, the chief of which is the Forest of Haye, are found in the south-western region. Only a small part of the drainage of Meurthe-et-Moselle flows into the Meuse, by far the greater part reaching the Rhine by way of the Moselle. The principal affluents of the Moselle are the Madon and the Orne on the left, and on the right, besides the Meurthe, the Seille, which in one part of its course forms the boundary of Alsat-Lorraine. The principal tributary of the Meuse within the department is the Chiers. Climatologically Meurthe-et-Moselle belongs to the Vogian region, and has hot summers and severe winters. Its mean annual temperature is between 48° and 49° F., being 2° lower than that of Paris (which has the same latitude). The annual rainfall averages between 28 and 32 in. The department possesses much fertile land, the chief crops being cereals and potatoes, together with clover, mangel-wurzels, tobacco, hops and beetroot. The vine is also cultivated, its best products being those of the Toul district. The most common fruits are the apple, the walnut, the cherry and the plum. Of forest trees the oak and the yew-elm are most frequent in the west of the department, the beech and the fir in the Vosges. The French school of forestry has its seat at Nancy. The saltworkings (the chief of which lie between Nancy and St. Nicolas) and the iron-mines (round Nancy and Longwy) of Meurthe-et-Moselle are the most productive in France. Other important industries are the manufacture of boots and shoes, straw and felt hats, pottery, and tanning and brewing (at Tavantville). Cotton and wool spinning, and the manufacture of cotton goods, hosiery, embroidery, chemicals (at Dombasle, close to Nancy), soap, tobacco, matches, crystal (at Baccarat, which has a population of 3617), mirrors (Cirey), glass, army clothing and paper may also be mentioned. The department is served by the Eastern railway, the chief line being that from Paris to Strassburg through Nancy. The main waterway is formed by the canal between the Marne and the Rhine. This canal communicates with the Moselle, which is navigable from Frouard downwards, and with the Eastern canal, which unites the Meuse and the Moselle with the Saône and the Rhone. The department constitutes the diocese of Nancy, has its court of appeal at Nancy, and forms a part of the district of the VI. army corps (Châlons-sur-Marne), and of the académie (educational division) of Nancy. There are 4 arrondissements (Nancy, Briey, Lunévile and Toul), 29 cantons and 598 communes. The principal towns of the department are Nancy, the capital, Lunévile, Toul, Longwy, Pont-a-Mousson and St. Nicolas. Other places of interest are Prény, with ruins of an important stronghold (12th and 13th centuries) of the dukes of Lorraine; and Vaudémont, seat of a Benedictine Abbey, with ruins of a stronghold of the 12th and 14th centuries.

MEUSE (Flem. Moes, Du. Maas), a river rising at Pouilly, in the department of Haute-Marne, France. After passing through a great part of Belgium and Holland it flows into the Waal channel of the Rhine at Fort Loevenstein. A few miles below Gorinchem the Meuse, or Waal as it is then called, divides into two branches. The northern flows almost due west, and joins the Lek (Rhine) above Rotterdam, and enters the North Sea at the Hook of Holland. Ocean-going steamers for Rotterdam use, however, the New Waterway (Nieuwe Waterweg), a little north of the Meuse. The southern branch turns south, crosses the marsh of Biesbosch by the canalized channel of New Merwede, enters the Hollandisch Diep, and reaches the sea by the arms called Harlingen and Krammen.
The length of the Meuse is nearly 560 m., of which 360 are navigable, and probably its traffic is only exceeded by that of the Rhine. Near Bazelles it disappears under ground for a distance of over 3 m. The Chiers, the Semois, the Lesse, the Sambre, the Ourthe and the Roer are its most important tributaries. In Belgium it is canalized between Liége and Vic, and the Dutch are engaged on the same operation below Maestricht. The principal towns on the Meuse are: in France, Verdun, Sédan, Mézières and Givet; in Belgium, Dinant, Namur, Huy, Liége and Maaseyck; in Holland, Maestricht, Roemond, Venlo, Dordrecht and Rotterdam.

MEUSE, a department of north-eastern France, formed out of a part of Lorraine (portions of the Three Bishoprics, and the Barrois and Clermontais) and Champagne. Pop. (1906), 280,220. Area, 2,409 sq. m. It is bounded by Belgium and the department of Ardennes, E. by that of Meurthe-et-Moselle, S. by those of Voges and Haute-Marne, and W. by those of Marne and Ardennes. About one-half belongs to the basin of the river Meuse, which is enclosed on the west by the wooded region of Argonne, on the east by the hills known as the Côtes de Meuse. On the north-east it is watered by the Orne, a tributary of the Moselle, and the Chiers, which runs by Montmédy to join the Meuse. The other half sends its waters to the Seine by the Aire, a tributary of the Aisne, both of which take their rise here, and by the Oinnan, an affluent of the Saulx, the two last being tributary to the Marne. The highest elevation (1388 ft.) occurs to the south-west, on the line of the ridge which separates the basin of the Meuse from that of the Seine. The heights gradually sink from south to north, but seldom fall below 1000 ft. The hills of the Argonne similarly sink rapidly down to the valley of the Saulx, where the lowest level of the department (377 ft.) is reached. Its winters are less severe than those of the Voges, but it is not so temperate as the Seine region. The average annual rainfall is about 30 in. The chief crops of the department are wheat, oats, rye, barley, clover, potatoes and mangel-wurzels. The vine is cultivated to some extent, the best growths being those of Bar. The forests, occupying more than a quarter of the area, are principally of oak, and are rich in game, as are the rivers in fish. Basket-making is prosecuted in the Argonne. The mineral wealth of the department includes good freestone (Euville, Lérouville). It has iron and steel works, wire-works, and manufactories of files, hardware and edge tools. Ligny-en-Barrois (pop. 4879) manufactures scientific instruments. There are cotton-spinning, wool-weaving, and hemp, flax and jute factories, saw-mills, carriage works, leather manufactures, glassworks, paper-mills, distilleries and flour-mills. The department is served by the Eastern railway, the principal lines being that from Paris to Strasbourg through Bar-le-Duc and Commercy, that from Paris to Metz through Verdun, and the branch line of the Meuse valley. The chief waterways are the canal connecting the Marne with the Rhine and the Eastern canal along the Meuse valley; the two together have a length of 145 miles. Ecclesiastically the department forms the diocese of Verdun; it has its court of appeal at Nancy, and constitutes part of the district of the army corps of Châlons-sur-Marne, and of the educational division of Nancy. There are 4 arrondissements—Bar-le-Duc, Commercy, Montmédy and Verdun—38 cantons and 486 communes. The principal places in the department are Bar-le-Duc, the capital, Commercy, Verdun and St. Mhiel, which receive separate treatment. Other places of interest are Avioth, which has a church of the 14th and 15th centuries with a beautiful chapel of the 15th century adjoining it, and Remercourt-aux-Pots with a fine church of the 15th century.

MEUSE-LEINE, the chain of French forts closing the passages of the Meuse between Verdun and Toul. The total length of the line is 31 m., and the forts d'arrêt are disposed along the railroad between Verdun and St. Mihiel, Génicourt and Troyon; near St. Mihiel, Les Paroishes (left bank) and Camp des Romains; near Commercy—Les Paroises, St. Aignant, Gironville and Jouy-sous-les-Côtes. Above the circle of the Toul defences there are barrier forts on the Upper Meuse at Pagny (la-Blanche-Côte) and near Neufchâteau; but these last are practically in second line, and between Toul and Épinal the frontier districts are designedly left open. At Épinal the "Moselle-Line" begins. These lines form part of the defensive scheme adopted by France in 1873-1875. Their general design is that of the French fort illustrated in Fortification and Siegecraft, fig. 45, though they are varied in accordance with the site. MEVANIA, (mod. Beerga), an ancient town of Umbria, on the river Clitunnum and on the Via Flaminia, 8 m. W.S.W. of Forum Flaminii, and 5 m. W. of Fulginiun (Foligno), 738 ft. above sea-level. There are remains of a temple near the north gate, and of an amphitheatre built into the modern houses. The walls, which have disappeared, were, according to Pliny (Hist. Nat. xxxv. 173), built of unbaked bricks. In 510 B.C. the consul Fabius broke the Umbrian forces here; but otherwise it is not mentioned until the 1st century A.D. In 69 the army of Vitellius awaited here the advance of Vespasian. Its position near the river and its white walls are mentioned by Propertius, whose family belonged to Assium (mod. Assissi) and after him by Silius Italicus, Lucan and Statius. The town was a municipium. The churches of S. Michele Arcangelo and S. Nicolo are Romanesque buildings of the 12th century.

MEW. (i) An imitative word, also spelled miasou, representing the cry of a cat or of sea-birds. The name mew, usually sea-mew, as applied to the Larus canus, or common sea-gull, is, according to Skeat, also imitative. As the name of the sea-bird it appears in Du. mues, Ger. Mue, and other languages. (ii) An old form of the name of a town near York, which has been accepted as a term originally applied in French to the mounting of a hawk or falcon, and then to the caging of the bird during that period; thus "to mew up" has come to mean to confine. The English word chiefly survives in the plural form mews, applied to a stable-yard, coach-houses, stalls for horses, and living accommodation, found in narrow streets in large towns. This use was due to the Royal Mews at Charing Cross, where the royal hawks were kept from 1577 to 1537, when the building became the royal stables.

MEWS, PETER (1610-1706), English royalist and divine, was born at Caundle Purse in Dorset on the 25th of March 1610, and was educated at the Merchant Taylors' school, and at St John's College, Oxford, of which he was scholar and fellow. When the Civil War broke out in 1642 he joined the Royalist army, and, having been made a captain, was taken prisoner at Naseby; but he was soon released and in 1648 sought refuge in Holland. He became friendly with Charles I's secretary, Sir Edward Nicholas, and being skilful at disguising himself was very useful to the Royalists during the rule of Oliver Cromwell, undertaking two journeys to Scotland in 1653. Before this Mews had been interested in writing, and regaining his fellowship at Oxford after the Restoration, he became archdeacon of Huntingdon, vicar of St Mary's, Reading, and chaplain to the king; then, having obtained other livings, he was made canon of Windsor, canon of St David's, and archdeacon of Berkshire. In 1667, when at Breda arranging peace between England and Holland, he was chosen president of St John's College, Oxford, in succession to his father-in-law, Dr Richard Baylie, afterwards becoming vice-chancellor of the university and dean of Rochester. Appointed bishop of Derry and Wells in 1672, Mews resigned his presidency in 1673, and in 1684 he was elected bishop of Winchester, a position which this "old, honest cavalier," as Thomas Hearne calls him, filled until his death on the 9th of November 1706. The bishop is buried in Winchester cathedral. Mews lent his carriage horses to pull the cannon at a critical moment during the battle of Sedgemoor, where he was wounded whilst accompanying the royal army. He was, however, in sympathy with the seven bishops, and was only prevented by illness from attending their meeting; and as visitor of Magdalen College, Oxford, he supported the fellows in their resistance to James II, admitted their nominee, John Hough, to the presedency, and restored the ejected fellows in October 1688.
He took the oaths to William and Mary in 1689. In the absence of Compton, bishop of London, Mews took the chief part at the consecration of Tillotson as archbishop of Canterbury in 1694.

MEXBOROUGH

The town takes its name from "the West Riding of Yorkshire, England, on the Don, 11 m. N.E. of Sheffield on the Great Central and Midland railways. Pop. (1891), 7734; (1901), 10,430. The Don affords water communication with the sea. The church of St John the Baptist has Early English portions. The large industrial population is mainly employed in glass, pottery and iron works, and in the neighbouring stone-quarries. The Castle Hill is crowned with some fine earthworks of uncertain date.

MEXICO

(Span. Méjico, or Mexico), officially styled Estados Unidos Mexicanos and Repúblicas Mexicanas, a federal republic of North America extending from the United States of America, southward to Guatemala and British Honduras, and lying between the Pacific Ocean on the west and the Gulf of Mexico and Caribbean Sea on the east. Its northern boundary line was fixed by the Guadalup-Hidalgo treaty of 1848 and the Gadsden treaty of 1853; it follows the Rio Grande del Norte from its mouth north-westward to lat. 31° 47' N., thence on that parallel W. 100 m., thence S. to lat. 31° 20' N., thence due W. to the 111th meridian, thence in a straight line (nearly W.N.W.) to a point on the Colorado river 20 m. beyond the mouth of the Gila river, thence northward to the mouth of the Gila, and thence, nearly due W., along the old line between Upper and Lower California to a point on the Pacific coast one marine league S. of the southernmost point of San Diego Bay; this line has a total length of 1,810 m., of which the Rio Grande comprises 1136 and the land route 674 m. The boundary line with Guatemala, for a long time in dispute, was fixed by the treaties of 1882 and 1895. It is an arbitrary line and follows only two natural lines of demarcation—the Suchiate river from the Pacific coast to its source, and the Chixoy and Usumacinta rivers from near the 16th parallel N.W. to a point on the latter 135 km. S. of Tenosique (Tabasco). Between these rivers the boundary line is determined by the peaks of Tacaná, Buenavista and Ixibal, and from the Usumacinta eastward it follows two parallels of latitude, one on the point of departure from that river, and the other, the longer, on that of 17° 40' to the British Honduras frontier. The boundary with British Honduras was determined by a treaty of 1893 and is fixed in part by the Hondo river down to the head of Chetumal Bay, and thence through that bay to the Boca Bacalar Chico; the channel separating Yucatán from Ambergris Cay. Geographically, Mexico extends from 4° 36' 45" N. latitude to the 10° 32' 42" N. lat., and from 86° 46' 08" to 117° 07' 31" W. long. Approximately its greatest length from N.W. to S.E. is 1900 m., its greatest width 750 m., and its least width a little short of 140 m. In outline it is sometimes compared to a huge cornucopia with its small end curving S.E. and N. The interior curve formed by the Gulf of Mexico is comparatively regular and has a coast-line of about 1400 m. The Caribbean coast-line is about 327 m. long, exclusive of indentations. The outer curve facing the Pacific is less regular, is deeply broken by the Gulf of California, and has a coast-line of 4754 m., including that of the Gulf. The peninsula of Lower California (q.v.) lies parallel with the mainland coast and extends southward to about 22° 55' N. lat., a distance of nearly 750 m. The area of Mexico is commonly given by English authorities as 767,005 sq. m., by German statisticians as 1,987,201 sq. kilometers (767,290 sq. m.), and by H. H. Bancroft, who quotes official figures, as 1,962,899 sq. kilometers (757,907 sq. m.).

Physiography.—The surface features consist of an immense elevated plateau with a chain of mountains on its eastern and western margins, which extends from the United States frontier southward to the last ranges of the Transverse chains (tierras calientes) between the plateau and coast on either side; a detached, roughly mountainous section in the south-east, which belongs to the Central American Plateau, and a low sandy plain covering the greater part of the Isthmus of Yucatán. The peninsula of Lower California is traversed from north to south by a chain of immense mountains crowned by the volcanoes of the same name. The slopes are precipitous on the east coast, but on the west they break down in hills and terraces to the Pacific. This range may be considered a southward continuation of the Californian Sierra Nevada. The great Mexican plateau is in fact of Hercynian origin. Its superstructure consists of igneous rocks of all descriptions with which the original valleys between its marginal ranges have been filled by volcanic matter. The central part, the Valley of Mexico and Bósón de Mapimi, once contained large bodies of water, of which only small lakes and marshy lagoons now remain. The high point of the great plateau is to be found in the states of Mexico and Puebla, which is about 8000 ft. Southward the slope is broken into small basins and terraces by transverse ranges, and is comparatively abrupt. Northward the slope is gentle, and is broken by several transverse ranges. At Ciudad Juarez (adjoining El Paso, Texas), on the northern frontier, the elevation is 3600 ft., which shows a slope of only 200 ft. per mile. It is definitely known of the elevated regions of Chiapas, on the border of Guatemala, which are separated from the great Mexican Plateau by the low Isthmus of Tehuantepec (718 ft. at the highest point of the transisthmian railway), but their elevations are unknown, and they are broken by wooded sierras and eroded by water-courses.

The mountain ranges which form part of the great Mexican Plateau consist of two marginal chains known as the Sierra Madre Oriental and the Sierra Madre Occidental, with numerous transverse chains and ridges between the 18th and 20th parallels as the Cordillera de Anáhuac. All these are separated and divided by under water courses. The Sierra Madre Occidental consists of several mountain ranges lying in the north, where a broad belt of country is covered with a labyrinth of ridges and valleys. The most eastern of these are known as the Sierra Madre del Sur and the Sierra Madre del Norte, with the Sierra de la Nazarena, Sierra Yaqui and Sierra Fuerte. These converge in southern Sinaloa and Durango to form the Sierra de Nayarit. Near the 20th parallel the great chain again divides, the eastern part crossing the northern extremities of the western, or Sierra Madre del Sur, following the shore line closely to Tehuantepec. The Sierra Madre Occidental has few noteworthy elevations, its culminating points being the Nevado de Colima (14,365 ft.) and Volcán de Colima (12,750 ft.) in the state of Jalisco. In the Sierra de Nayarit the Cerro Pinal rises to an elevation of 11,319 ft., and in the extreme south the Cerro del Leon arrives at 10,902 ft. These sierras lying near the coast have an imposing appearance from the lowlands, but when seen from the plateau their general elevation is so dwarfed as to render them comparatively insignificant. The Sierra Madre Oriental consists of a profusion of ranges and ridges, from the Sierra de Baja California, from the great bend in the Rio Grande south-eastward to about the 10th parallel. In the north these ranges are low and suffer few impediments from the drainage and building up; however, they are concentrated in a single lofty range. This range extends south-eastward along the western frontier of Vera Cruz (state) and includes the snow-capped cone of Orizaba or Citaltepétl (18,625 ft.) and the Cerro de la izuiga del Norte, or Iztaccíhuatl (18,552 ft.). The eastern slopes are abrupt and difficult, and are a serious impediment to communication with the coast. Rising from the open plateau half way between this range and the city of Mexico is the isolated cone of Malinche, or Malintzin (14,636 ft.). Crossing the highest part of the Mexican Plateau is a broken series of ranges, which form the water-parting between its northern and southern slopes. To a part of these ranges has been given the common name of Cordillera de Andahuac, but there is no true cordillera across this part of Mexico. In a general sense these ranges may be considered part of the eastern branch of the Sierra Madre Occidental, which turns southward on the line of the coast and which extends south by east direction. Southward the plateau is traversed by many low ranges and breaks down in terraces, forming one of the most fertile and attractive parts of the republic. Close to the capital of the Sierra and State of Durango, and at the foot of the highest point is 13,078 ft. above sea-level, the Nevado de Toluca (15,168 ft.), in a range which separates the valleys of Mexico and Toluca, the Montes de las Cuyas, as that volcano, which offers a magnificent view of the right angles to the axis of other ranges, whose culminating points, some 20 m. south-east of the city, are the gigantic, snow-clad volcanoes of Popocatepetl (Smoking Mountain) and Ixtacuichuatl, which in the popular imagination there are no longer smokers. Their elevations, according to the Comisión Geográfica Exploradora, are 17,888 and 17,543 ft. respectively, that of Ixtaccihuatl being the higher. A remarkable fact in this character, the transverse ridge just described having a large number of extinct volcanoes and at least three (Colima, Jorullo and Cebreros) that are either active or semi-active. Colima was in a state of eruption as late as 1909,
Jorullo (4263 ft.) is said to date from 1759, when its cone was formed, and Celororo (7100 ft.) in the territory of Tepic, shows occasional signs of activity. Near the coast in the state of Vera Cruz is San Martín, or Tuxta (7078 ft.), which has been quiescent since its violent eruption on the 2nd of March 1793. Orizaba is sometimes included among the semi-active volcanoes, but this is a mistake. It has been quiescent since 1566, and is now completely extinct. Earthquakes are common throughout the greater part of the republic, especially in the western coast. They are most violent from San Blas southward to the Guatemala frontier, and some of the Spanish towns on or near this coast have suffered severely. Chilpancingo, in Guerrero, was badly shattered in 1902, and in 1907, and in 1909 was reduced to a mass of ruins. The earthquake shocks of the 30th and 31st of July 1909 were unusually severe throughout southern Mexico, reducing Acapulco and Chilpancingo to ruins and shaking the city of Mexico severely. In Acapulco a tidal wave followed the shock. Slight shocks, or temblorcs, are of almost daily occurrence. According to Humboldt's theory there is a deep rent in the crust of the globe along the 10th parallel through which at different periods the underground fires have broken at various points between the Gulf of Mexico and the Revillagigedo Islands. "Only on the supposition that these volcanoes, which are on the surface connected by a skeleton of volcanic rocks, are also united under the surface by a chain of volcanic elements in continual activity, may we account for the earthquakes which in the direction mentioned cause the American continent, from the Gulf of Mexico to the Pacific Ocean, to oscillate at the same time." (Egloffstein, p. 57.)

The lowland or tierra caliente region, which lies between the sierras and coast on both sides of Mexico, consists of a sandy zone of varying width along the shore-line, which is practically a tide-water plain broken by inland channels and lagoons, and a higher belt of land rising to an elevation of about 3000 ft. and formed in great part by the debris of the neighbouring mountain slopes. On the Pacific side there are places where the mountain spurs extend down to the coast, but in general this lowland region ranges from 30 to 40 m. in width, except in southern Vera Cruz, Tabasco, Campeche, and Yucatan, where it extends farther into the interior. The talus zone of this region, especially at elevations of 1000 to 3000 ft., is noted for its great fertility and the luxuriance of its vegetation.

There are no large islands on the coast of Mexico, and most of the smaller ones are unimportant. Many of those that fringe the Gulf coast are sand-keys, or parts of a new coast formation. They are commonly barren and uninhabitable. The Isla del Carmen, which partly shuts in the Laguna de Términos (Campeche), is one of the largest of this class, and has the town and port of Carmen at its western extremity. On the northern coast of Yucatan there are the small, inhabited island of Holbox or Holbox, and on the eastern coast the islands of Mujeres, Cancun and Cozumel, of which the first and last have a considerable population and good ports. On the Pacific coast there are a number of islands off the rocky shores of Lower California and in the Gulf of California—most of them barren and uninhabitable like the adjacent coast. The largest of these, some of them inhabited, are: Guadalupe—about 75 m. west of the coast on the 45th parallel, which is fertile and stocked with cattle; Cerros, off Visacino Bay, and Santa Margarita, which partly shelters Magdalena Bay, on the Pacific side; and Angel de la Guarda, Santa Cruz, San Marcos, Carmen, Monserrat, Santa Catalina, Santa Maria, San Jose, Espiritu Santo and Cerralvo in the Gulf. Lying off San Blas in the broad entrance to the Gulf are the Tres Marias, and directly west of Colima, to which it belongs, is the scattered volcanic group of Guajalotes.

The peculiar surface formation of Mexico—a high plateau shut in by mountain barriers, and a narrow lowland region between it and the coast—does not permit the development of large river basins. Add to this the light rainfall on the plateau and a lack of forests, and we have conditions which make large rivers impossible. The hydrography of Mexico, therefore, is of the simplest description—a number of small streams flowing from the plateau or mountain slopes eastward to the Gulf of Mexico and westward to the Pacific. Most of these are little more than mountain torrents flowing into the Pacific, and the chief of these is the Magdalena, which in north-eastern Guatemala and flowing north-east through a heavily forested region to Chetumal Bay. The peninsula of Yucatan has no rivers, and that of Lower California only a few insignificant streams in the north. This is due to the porosity of the soil in the former, and the very limited rainfall in the latter. The largest rivers of Mexico are: the Rio Grande de Santiago, called the Lerma above Lake Chapala, rising in the state of Mexico and flowing westward across Guanajuato, Jalisco and
Tepic to the Pacific coast, with a total length of 540 m., celebrated for its deep canyons and waterfalls; the Rio de las Balsas, or Mescala, which flows north-west to the south, with a course of 426 m.; the Yaqui, which rises in western Chihuahua and, after breaking through the northern ranges of the Sierra Madre Occidental, flows south-westerly across Sonora to the Gulf of California (cf. vol. 2, p. 127). There are no protected harbours, except for small natural jetties, but there are two small ports: a small wharf on the north-west coast of Tlaxcala, on its upper course, which has its source in the state of Chiapas and flows north-west and north across Tabasco to the Gulf of Mexico, with a total length of 390 m.; the Fuerte, which rises on the eastern border of Chiapas and flows south-west across Sinaloa to the Gulf of California, with a course of 340 m.; the Usumacinta, which is formed by the confluence of the San Juan and Rio Grande, two small streams that flow north-west across Tabasco to the Grijalva, with a course of 330 m.; and the Panuco, which has its source in the north-west of the state of Mexico and flows north-eastward to the Gulf of Mexico. The river districts of the Panuco and Grijalva, having a great deal of territory between them, but many on the Gulf coast are navigable for considerable distances. The more important of them are in Tabasco—the Grijalva, navigable for about 93 m., and the Usumacinta, for about 270 m. The country about the Laguna de Términos is low and flat, and is traversed in all directions by deep, sluggish streams. Many of the rivers crossing the lowlands bordering the Gulf have short navigable channels, the most important of which is the Panuco and its tributaries. The Rio Grande is navigable for small vessels up to Matamoros (31 m.), and for smaller craft 65 m. farther. Nearly all the Gulf coast rivers, however, are obstructed by bars over which the water breaks from the sierras and the prevailing winds and currents on the coast.

The lakes of Mexico are small and few in number. They may be divided into two principal groups: the lakes of La Paz, in the region of Michoacán, and the lacustrine depressions and receive the drainage of the surrounding country; and the tide-water lakes of the coast formed by the building up of new sand beaches across the indentations in the shore line of the interior, the latter being the lakes of the Valley of Mexico—Tezoco, Chalco, Xochimilco, Zumpango, Xaltocán and San Cristóbal—which are probably the remains of a lake once occupying the whole Valle de México. By far the greatest of the lakes of the interior, however, is the laguna de Términos, on the coast of Tabasco, having a length of about 370 m. Its aerial photographs shows that the lake is situated in the middle of the Gulf of Mexico and that the lake is connected with the sea by a narrow channel. The lake is navigable for small vessels, but the entrance is so narrow that only small boats can pass through it without difficulty. The lake is about 15 km. in length and 8 km. in breadth, with an average depth of about 2 m. The lake is separated from the sea by a narrow channel, about 3 km. wide, which is navigable for small vessels. The lake is connected with the sea by a narrow channel, about 3 km. wide, which is navigable for small vessels. The lake is separated from the sea by a narrow channel, about 3 km. wide, which is navigable for small vessels. The lake is connected with the sea by a narrow channel, about 3 km. wide, which is navigable for small vessels. The lake is separated from the sea by a narrow channel, about 3 km. wide, which is navigable for small vessels. The lake is connected with the sea by a narrow channel, about 3 km. wide, which is navigable for small vessels. The lake is separated from the sea by a narrow channel, about 3 km. wide, which is navigable for small vessels.
deeply into the tropical heart of the country, carry with them temper-ate and arid conditions over much the greater part of the region. Above the plateau rise the marginal sierras, while a few isolated peaks in the region of perpetual snow give to Mexico a considerable area of cold temperature. Some of the principal altitudes of architecture, either side of the plateau, the tempera-ture rises steadily until the upper limit of the tropical region, called *tierras calientes*, is reached, where the climate is the hottest, least unhealthy, as elsewhere in the forested coastal plains of tropical America.

The *tierras calientes* (hot lands) of Mexico include the two coastal zones, the Isthmus of Tehuantepec, the states of Tabasco, Campeche, and the peninsulas of Yucatan and a part of eastern and southern Oaxaca. The mean temperature ranges from 77° to 82° F., seldom falling below 66°, but often rising to 105°, and the humidity is high, but not distictive. The coastal plains of Oaxaca rise to over 1000 feet. The rainfall is heavy in the south, except Yucatan, but diminishes gradually toward the north, until on the Pacific and Gulf of California coasts it also falls to very low amounts. The great fertility of these regions and the marvellous wealth of their forests are irresistible attractions to industrial and commercial enterprise, but their unhealthy climate restricts the number and character of the population. The heavy rainfall on the Gulf coast, however, which reaches a maximum of 90 to 100 in. in the Huatulco district of Vera Cruz, causes the flooding of large rivers in the provinces near the coast, and makes for very rich soil; consequently there are no rivers and no lakes except near the forested region of the south-east. These exceptional conditions give to Yucatan a moderately hot, dry, and comparatively healthful climate. Another hot, dry climate is that of the *tierras altas* of Sonora. The coast is low and extremely arid, and would be uninhabitable were it not for the proximity of the Sierra Madre, where a light rainfall is experienced, and in which the arid belt between the mountains and the sea is narrow. The maximum temperatures in this region are 98° at Hermosillo and 110° at Guaymas.

To a large extent the climate of Mexico is determined by vertical zones. According to H. H. Bancroft (*Resources of Mexico*, pp. 3-4), the *tierras calientes*, which include a coastal zone 30 to 40 m. wide, and the low-laying states already mentioned, rise from sea-level to an elevation of 1500 feet, or higher in some regions, and from a sea-level rise to an elevation of 5577 feet, and comprises "the greater portions of Coahuila, Nuevo Leon, "San Luis Potosi, nearly half of Tamaulipas, a small part of Tixtla, northern part of Chihuahua, the northern part of Oaxaca, a large portion of Guerrero, Jalisco, Sinaloa and Sonora," together with small parts of the inland states of Puebla, Mexico, Morelos and Michoacan. The mean annual temperature is about 75° F., but the temperature on the fringes of the desert area, and includes all the higher portions of the Mexican plateau, and which corresponds to the temperate regions of Central United States where frosts are very rare experienced. Even here the high land temperatures give a start to the sub-tropical character to the country. In the sierras, above the *tierras frias*, which are not "cold lands" at all, are the colder climates of the temperate zone, suitable for cereals, grazing and forest industries, and farther up, the isolated peaks which rise into the regions of snow and ice.

Speaking generally, the four seasons are clearly marked north of lat. 25° N. south. Of that parallel they merge in the *estacion de las lluvias*, or rainy season, from mid-June to mid-September, *estacion seca*, or dry season, which prevails for the rest of the year. The rains generally begin on the east coast and gradually move northward and upward along the coast until they reach the slope of the plateau. They receive the greater part of the rainfall, and the winds, deprived of their moisture, pass over the northern plateau without further precipitation. On the Pacific coast the belt of calms, known as the "norte" is broken, and the northern riposo, "norte," receive an abundant rainfall in the wet season, especially during the prevalence of heavy "nortes" on the Gulf coast. The precipitation varies widely, that of the western side of the northern plateau (Cortezco) being 8 to 15 inches, the eastern side, on the Gulf of California, Mexico about 25 in., and that of the whole republic 59 in. Long droughts are common in many parts of the country, and on the highest plateaus of the plateau the rains drain away rapidly, leaving but slight beneficial results.

*Flora and Fauna.*—The types of animal and vegetable life found in Mexico belong, in general sense, to those of the northern temper-ate region, and those of the tropical regions of Central and South America. The great central plateau and its bordering lowlands form an intermediate territory, in which many tropical species extending northward along the coast to the United States, while the northern species have found their way to the southern limits of the plateau. The jaguar and puma have found the plains, which the bear and beaver have gone far southward on the plateau, and the buffalo was once found in large numbers on its more favoured northern plains. This intertwining of types does not apply to south-eastern Mexico, where the great majority of the genera and species found in the forested lowlands of the great Amazon basin.

Aside from its origin, the fauna of Mexico includes at least five species of monkeys, the squirrel, jaguar, puma, ocelot (*Felis pardalis*), wolf, coyote, lynx, badger, otter (*Lutra lutina*), beaver, muskrat, bear, racoon (*Procyon*), tapir (*Nasua*), tapir, two species of peccary (*Dicotyles ruber* and *D. nitidus*), the sponge-nosed boar (*Sus scrofa*), martens, several species of opossum (including a pinyg species of the Tres Marias islands), sloth, three species of ant-bear (*Myrmecophaga tridactyla* and *Cycolobus didactylus*), armadillo (*Dipus mexicanus*), the kinkajou (*Cercoceps caudovatus*), three species of deer—the white-tailed *Catilurus leucurus*, the little black-faced *Ibexus* (*I. olivaceus*), which is also found in Brazil, and the large green and tortoise-shell species. In some places the capture of the latter is the source of a considerable export trade in tortoise-shell.

The coast of Lower California is a popular resort for the sea-birds and marine mammals. The following is a list of representative species: bats, numerous, ranging from the comparatively harmless *hoa-constructor to the deadly *palanca*, or "fer de lance* (*Lachesis loricata*); lizards and rattlesnakes (*Crotalus*), of which there are several species. In general, the coastal regions are rich in cuttlefish, octopuses, chupas, mussels, and clams. There are many different species of fish, especially the "toro" or "bacalar" and "gutierrez", which are good to eat, and "tarra" or "grandes*" which are less good, and the "escamoles*" or "escamoles" which are very good. The fish are abundant in the Gulf. There are some good fishing-gounds on the coasts, but fishing as an organized industry does not exist. The inland waters, with the exception of Lake Chapala, have considerable numbers of fish, but the Mexican government has introduced carp, brook-trout and salmon-trout.

The avifauna of Mexico includes most of the species of the tropical and subtropical plains and forests. Here bird life is found in the yellow-headed *Chrysophus*, parakeets (*Conurus caninus*), macaws (*Arara macro* and *A. militaris*), toucans, trogons, herons, egrets, ibis, spoonbills, boat-bills (*Ciconia*), ducks, pelicans, cormorants, herons, stilts, sandpipers, curlews, gulls, kingfishers, motmots, "Chacalacas" (*Oriolus poliocephala*), woodpeckers, jays, cuckoos, "garrapaters" (*Crotaphaga sulphostrida*), the ingenious weaver-bird (*Cerules*), and another species (*Cassius*), whose curiously woven nests have been described as "the most extraordinary in the world," and sometimes even from telegraph-wires, scarlet-crested fly-catchers (*Musciora mexicana*), manakins, mocking-birds (called "zenontzi"). The black "chachalaca" (*Chnenetes clypeatus*), doves, pigeons, eagles, caracara hawks (*Polyborus*), fish-hawks, falcons, crows, and turkey-buzzards (both the red-faced "aura" of North America and the black-faced "zapilote" of the south-western United States) are also found in the valleys, together with the beautiful "huizilin" (*Spizella*) by the Artzacs, and "collirf", "chuanh-ter", and "huicac=

*mosca* (fly-bird) by the Spanish-speaking Mexicans. These descriptive names are highly poetic, as also that of the Portuguese, "arrozal", which is the name of the largest and most beautiful of the brown jays, and thrugs its long bill into flowers in search of insects instead of honey. Mexico is credited with a great variety of song-birds, but these are to be found chiefly in the partly forested country of the Sierra Madre. In the south-western United States, however, is in birds of varied and gorgeous feathering. The wonderful plumage of the "guetal* (*Trogon resplendens*) was, it is said, reserved
by the Aztec rulers for their own exclusive use. Of the indigenous birds, the turkey has been fully domesticated, and the musk-duck and the pelican have been taught to fish. Others, which are found on the coasts of Lower California, where certain islands in the ariel belt are frequented at night by countless numbers of them. It should be added that many of the migrating birds of North America pass through the Gulf of California.

The insect fauna of Mexico covers a very wide range of genera and species which, like the other forms of animal life, is largely made up of those of the Neotropical region. Though some forms are made of this fauna, but much has been, and is being done by the U.S. Biological Survey and Plant Industry Bureau. To the traveller the most conspicuous among the Mexican insects, perhaps, are the butterflies which are found on every hand. There are few species of butterflies which are not represented in Mexico, and of some species there are numerous subspecies. Among the mosquitoes, which are extra-ordinarily numerous in some of the hot lowland districts, are the species credited to the ground yelloe and black. In Mexico there are even more numerous than the mosquitoes. In pleasing contrast to such pests are the butterflies of all sizes and colours, beetles of an inconceivable variety of size, shape and colouration, and ants of widely dissimilar appearance and habits.

An interesting species of the last is the leaf-cutting ant (Eciton), which lives in large underground colonies and feeds upon a fungus produced by leaf-cuttings stored in subterranean passages to promote fermentation. These ants will strip a tree in a few hours and are very destructive to fruit plantations. Some of the native trees have developed ingenious methods of defence, one of which is that of the pine of the Baja California peninsula, more commonly called chaparral. This tree has a thick trunk and a crown of needle-like leaves, a characteristic which is shared by the species sometimes termed "oote" and "chacchula." The trunk is thick and solid, and the branches, which are supported on the larger branches, and connected with the ground by covered passages on the outside of the tree. These insects are blind and avoid the light. Beez find a highly congenial habitat in Mexico and are very destructive to fruit plantations. Other trees, represented by a large number of genera and species, the most dreaded being the venomous "tarantula," and the savage "mygale." There is a great diversity of insects and animals in the life as Mexico. It is due not only to its geographical position and its vertical climatic zones, which give it a range from tropical to arctic types, but also to its peculiar combination of humid and arid climates, where trees have been grown together, which are interposed between two tropical forested coastal zones. These widely divergent conditions give to Mexico a flora that includes the genera and species characteristic of nearly all the zones of plant life in the western continents—the tropical jungle of the humid coastal plains with its rare cabinet-woods, dye-woods, lianas and palms; the semi-tropical and temperate mountain slopes where oak forests are to be found and wheat supplants cotton and sugar-cane; and above these the region of pine forests and pasture lands. Then, there are the mangrove-fringed coasts and the drippling wooded slopes where rara orchids thrive, and above these, on the inland side, the lower and higher monte, where the trees give way to the cacti, yucca, and other coarse vegetation of the desert can thrive without irrigation.

As regards the description, the flora of Mexico may be divided into four great divisions: that of the comparatively barren plateau and the arid coast regions, the humid tierras calientes, the intermediate tierras templadas and tierras frias, and the higher regions. The plateau and the coast region are sharply drawn, as the zones everywhere overlap each other and local climatic conditions greatly modify plant types. In general, the aspect of the great central plateau north of the Anahuac sierras is that of a dusty, treeless plain. There is but little natural vegetation to be seen—ragged yucca trees, many species of agave and cactus, scrubby mesquite bushes, sage bushes and occasional clumps of coarse grasses. The rainy season completely changes the appearance of these plains, new grass appears, and wheat and Indian corn are cultivated. The rains do not last long, however, and sometimes fail altogether. The most common plants of the Mexican plains are mesquite (Prosopis velutina), ocotillo (Fouquieria splendens), and mesquite. The acacia is usually described as the Agave americana, though A. aculeata and several others are credited with the product. The mesquite plant is valuable, and is credited with the exception of the species producing the "tequila" mescal. The chief value of the agaves, however, is in their fibres, of which a great variety is produced. The principal plateau agaves producing fibres are the "jaguar" and the "palo blanco." The former is found in the Jauhavie Valley, Tamaulipas, which furnish what may be termed the genuine jute fibre. The "tapertex" fibre of western Mexico is credited by Mr. E. W. Nelson to the A. viscosa, which is found on open plains. Other fibres of some value are: the "tama," the "tejera," and the "monte." There are many other fibre-producing agaves, including some of which from which pulp is made. The cactus is unquestionably the characteristic plant of Mexico. About one thousand species have been described, a very large percentage of which are to be found on the Mexican plateau. The United States Department of Agriculture have been made in many localities, in Jalisco, Zacatecas, Michoacan and Tamaulipas, but many years must elapse before the whole ground can be covered. In central and southern Mexico the pines to the slopes are found of 12,000 feet above sea level, and the bushes continuing up to 14,000 feet. The forests consist of several species of evergreen and deciduous, including the long-leaved Pinus hophysta and the short-leaved "oote" or Pinus monesiensis, both with an undergrowth of elder (Sambucus mexicana), broom and shrub-leaf. In the Southern Sierra Madre, the "oote" and "oote" pine produce a number of species, and are called "roble" and "encahueta" by the natives.

In the intermediate zones between the higher sierras and the tierras calientes the flora is very largely composed of species characteristic of the bordering hot and cold regions. Oaks are everywhere common and the "oote" pine on the Gulf coast is found as far down as 6300 ft. In southern Mexico the pine is found at even lower elevations where the tropical growth has been destroyed by cultivation and fire. The lower slopes of the sierras, especially those of southern Mexico, are well forested and include an immense number of species. The most common families in the eastern sierras, where it is humid and rainy, are the magnolias, crotonas, mimosas, acacias, myrtles, oaks, palms and cacti and agaves. Palms are common, the chestnut abound in many places, the cacti are almost as numerous as on the open plateau. On the southern slopes of the Vicus communitis are found the "ahuehuete" or cypress (Taxodium distichum) are to be found. The "higuera" or castor-oil plant (Ricinus communis) is widely distributed throughout the plateau and the open plains of the lower zones. In some localities it is the chief oil producing tree of the western hemisphere. It is the most important of all tropical trees, but the most important of the two climatic extremes, the palm and the pine, are to be found growing side by side.

No brief description can adequately portray the marvellous variety and magnificence of the flora of the tierras calientes. Its forests are not composed of one or a few dominating species, as in the cold temperate zone, but of countless genera and species which, though they are mingled together and interweave with each other, are separable by the eye and epiphytes struggling to reach the sunlight. This struggle for existence has completely changed the habits of some plants, turning the palm and the cactus into climbers, and even some of the annual species into epiphytes. Among the more important and conspicuous trees of these tropical forests are mahogany, rosewood, Spanish cedar ( Cedrela), cassas, ceiba, (Bombax), rubber (Castillia), palms of many species including the oil-producing Atlases of Manzanillo and Acrocomia of Acapulco, guayacan (Guaiacum), logwood (Haematoxylin campechianum), braziliwood (Bo boreale), which should not be confounded with the Brazilian Caesalpinia, palo blanco (Lysotoma), and cascarilla (Ceratonia). The most important fruit and nut trees are the "zapote" or zapote (Diospyros ebulus), wild fig, and "ahuehuete" (Lobat inus) and "mameyes" (Bignonias). The type of the tropical tree is that of the tree of the sub-tropical zone. Of the 114 species of trees and cabinet-woods, 17 of oil-bearing plants, and over 60 of medicinal plants and dyewoods indigenous to Mexico, by far the larger part are of the "zapote" or "mameyes" type. The trees of the two forest products of this zone are arnatto, jalap, ispecacuana, sarcasparilla, rubber, orchids and a great variety of gams. Economic plants and products of Mexico, the list is surprisingly long and interesting. The cereals, fruits and vegetables of Europe have been introduced and some of them have done well. Wheat is widely cultivated and a considerable part of the population depend upon it for their bread. Indian corn, which is believed to have had its origin in Mexico, also provides food for a large part of the population. "Tunas" or cactus fruit, red peppers, "zapotes" (the fruit of various trees), "arrayán" (Myrtus oivais), "chichipas" (Ficus sp.) are also used as food. The commercially important "pimiento" (Capsicum), "queso" (Citrus dulce), tamariquas, aguardientes, "cerasalina" (Fors a glatisima), bananas, plantains, pineapples, grapes, oranges, lemons, limes, granadillas, chirimoyas, mameyes (Mammea americana), coco-nut, cacao, manioes, olives, gourds and melons, are among the fruits of the subtropical zone. Rice, wheat, Indian corn, beans, yams, sweet potatoes, onions and tomatoes (Physalis) are among its better-known food products. The "tomatillo" or "tomatillo" mentioned, is the fruit of the Physalis ixocarpa, sometimes called the "strawberry tomato" or the "Mexican tomato" which is used in the making of Mexican sauces. The common potato (Solanum tato) of which wild varieties are found, is not commonly used as a vegetable, but as a flavouring for soups and other dishes. Among other economic plants are the fibre-producing agaves, the best known of which is the A. rigida. FLORA AND FAUNA

MEXICO
var. elongata which produces the "henequen" fibre, or sisal hemp, of Yura, the palm, silk or reed-cotton (Ceiba casearia), sugar-cane, cotton (Gossypium), indigo and "canagro" (Rumex hymenosepalus) whose root contains a large percentage of tannin.

Mexico has suffered from the careless destruction of her forests, not only for industrial purposes but through the careless burning of grassy areas. The denuded mountain slopes and plateaus of southern Mexico are due to the total destruction of their Indian corn fields, and then left them to the erosive action of the tropical rains and subsequent occupation by coarse grasses. Fire was generally used in clearing fields, and the result that their arboreal vegetation was ultimately killed and their fertility destroyed. In the valleys of some of these denuded slopes oak and pine are succeeding the tropical species where fires have given them a chance to get a foothold.

Population.—According to the census of 1900 the population of Mexico numbered 13,607,259, of which less than one-fifth (15%) were classed as whites, 35% as Indians, and 45% as mixed bloods. There were 57,507 foreign residents, including a few Chinese and Filipinos. Since then the Japanese have acquired an industrial footing in Mexico. Under the constitution of 1824 all race distinctions are abolished, and these divergent ethnic elements are nominally free and equal. For many years, however, the Indians remained in the subject condition and no laws were made for the protection of their native country. Since about 1866, spurred on by the consciousness that one of their own race, Benito Juárez, had risen to the highest positions in the gift of the country, they have taken greater interest in public affairs and are already making their influence felt. In southern Mexico the Zapotecas furnish schoolmasters for the village schools. Peonage, however, is still prevalent on many of the larger estates, and serious cruelties are sometimes reported. The government itself must be held partly responsible, as for the transportation of the mountain-bred Yaquis to the low tropical plains of Yucatán (see Herman Whitaker's _The Planter_, 1909), but the influence of three and a half centuries of slavery and peonage cannot be shaken off in a generation.

According to Humboldt, the census of 1810 gave a total population of 6,122,354, of which the whites had 16%, the mestizos 22% and the Indians 60%. The census of 1855 increased the whites to 22%, which was apparently an error, the mixed bloods to 47%, and reduced the Indians to 31%. It is probable that the returns have never been accurate in regard to the mixed bloods and Indians, but it is the general conclusion that the Indians have been decreasing in number, while the mixed bloods have been increasing. Neglect of their children, unsanitary habits and surroundings, tribal intermarriage and peonage are the principal causes of the decreasing Indian population. Recent observers, however, deny the assertion that the Indians are now decreasing in number except where local conditions are exceptionally unfavourable. The death rate among their children is estimated at an average of not less than 50%, which in families of five and six children, on an average, permits only a very small natural increase. The larger part of the population is to be found in the southern half of the republic, owing to the arid conditions prevailing in the north. The unhealthfulness of the coastal plains prevents their being thickly populated, although Vera Cruz and some other states return a large population. The most favourable regions are those of the tierras templadas, especially on the southern slopes of the great central plateau which were thickly populated in prehistoric times.

The dissimilar races that compose the population of Mexico have not been sufficiently fused to give a representative type, which, it may be assumed, will ultimately be that of the mestizos. Mexico was conquered by a small body of Spanish adventurers, whose success in despoothing the natives attracted thither a large number of their own people. The discovery of rich deposits of gold and silver, together with the coveted commercial products of the country, created an urgent demand for labourers and led to the enslavement of the natives. To protect these adventurers it was for itself the largest possible share in these new sources of wealth, the Spanish crown forbade the admission of foreigners into these colonies, and then harassed them with commercial and industrial restrictions, burdened them with taxes, strangled them with monopolies and even refused to permit the free emigration thither of Spaniards. Out of such adverse conditions has developed the present population of Mexico. It was not till after the middle of the 19th century that a long and desperate resistance to foreign intervention under the leadership of Benito Juárez infused new life into the masses and initiated the creation of a new nationality. Then came the long, firm rule of Porfirio Díaz, who first broke up the Mexican war of 1896 that infected the republic, and then sought to raise Mexico from the state of discred and disorganization into which it had fallen. Suspicion and jealousy of the foreigner is disappearing, and habits of industry are displacing the indolence and lawlessness that were once universally prevalent.

The white race is of Spanish descent and has the characteristics common to other Spanish-American creoles. Their political record previous to the presidency of Porfirio Díaz was one of incessant revolutionary strife, in which the idle, unsettled half-breeds took no unwilling part. The Indian element in the population was made up of several distinct races—those of the Aztec or Mexican, Mixtec-Zapotec, Maya or Yucatec, Otomi or Othomi, and in smaller number the Totonac, Tarasco, Apache, Matlanzino, Chontal, Mixe, Zoque, Guaicuro, Opata-Pima, Tapiculapa, Seri and Huavi. As the tendency among separated tribes of the same race is to develop dialects and as that is the case among the mestizos. Hence, it may be that some of these smaller families are branches of the others. In 1864 Don Manuel Orozco y Berra found no fewer than 51 distinct languages and 69 dialects among the Indian inhabitants of Mexico, to which he added 62 more in the districts outside Mexico. These fifty of these languages, with 69 dialects, he succeeded in classifying under 11 linguistic families. A later investigator, Don Francisco Belmar (Lenguas indígenas de Mexico, Mexico, 1903), has been able to reduce these numerous idioms to a very few groups. None of them were written except through the use of ideographs, in the making of which the Aztecs used colours with much skill, while the Maya used an abbreviated form, or symbols.

The Aztecs, who called themselves Mejica or Mexicans after they had established their new empire, were a tall, slender people, with large bodies and small heads. They were dark-complexioned and thick-haired. Their language was divided into a great number of distinct groups that, though they were not mutually intelligible, were somewhat related. Their empire was large and powerful, but it was destroyed by the Spanish, who conquered it in the 16th century. Afterward, the Spanish built new towns and cities, and the population increased greatly. Today, Mexico is a very wealthy country, with many large cities and a thriving economy. It has a population of over 120 million people, and is one of the most important countries in Latin America. The capital city is Mexico City, which is located in the central part of the country.
evidence of this is to be found, not only in the character of their constructions, but in the circumstance that a tribe closely akin to the Mayas (the Hunutecos) still occupies a retired mountain valley of Vera Cruz, entirely separated from their kinsmen of the south, and that a dialect of the Maya language is still spoken in northern Vera Cruz. There is evidence to show that the Aztecs adopted the civilization of the Toltecs, including their religion (Quetzalcoatl being the god of the Toltecs and the Mayas), calendar and architecture. Perhaps the most remarkable of the Mexican races are the Mayas, or Maya-Quiché group, which inhabit the Yucatán peninsula, Campheche and parts of Tabasco, Chiapas, and the neighboring states of Central America (q.v.). The remarkable ruins of Palenque, Uxmal, Chichenitza, Lorrillat, Ixinché, Tikal, Copan and Quirigüa, with their carved stonework and astonishing architectural conceptions, show that they had attained a high degree of civilization. They were agriculturists, lived in large, walled towns, cultivated the mountain sides by means of terraces, and had developed what must have been an efficient form of government.

The Mistecas, or Mictzecas, and Zapotecas, who occupy the southern slopes of the central plateau, especially Puebla, Morelos, Oaxaca and Guerrero, form another distinct race, whose traditional history goes back to the period when the structures now known as Mitla, Monte Alban, Xochicalco and Zaachila were built. Their prehistoric civilization appears to have been not inferior to that of the Mayas. They were an energetic people, not so warlike as the Aztecs, and are now recovering from their long subjection to Spanish enslavement more rapidly than any other indigenous race. The Otomis comprise a large number of tribes occupying the plateau north of the Anáhuac sierras. They are a hardy people, and are the least civilized of the four principal native races.

The Totonacs inhabit northern Vera Cruz and speak a language related to that of the Mayas; the Tarascos form a small group living in Michoacán; the Matlatzincas, or Matlatzcanas, live near the Tarascos, the savage Apache, a nomadic people, and tribes ranging from Durango northward into the United States, the Opata-Pima group, inhabiting the western plateau region from Sonora and Chihuahua south to Guadalupe, is sometimes classed as a branch of the Nahuan culture; the Seris, a very small family of savages, occupy Tiburon Island and the adjacent mainland of Sonora; and the Guáicuros, or Yumas, are to be found in the northern part of the peninsula of Lower California. In southern Mexico, the Chontales, Tapijulapas, Mixes and Zoques inhabit small districts among and near the Zapotecas, the first being considered by Belmar a branch of that family. The Huave inhabit the smaller islands of the Pacific, and the southern shore of Tehuantepec and have been classed by Belmar as belonging to the Maya stock. The census of 1895 gave these Indian races an aggregate population of nearly 4,000,000, of which nearly 3,450,000 belonged to the first four groups. Three of these four had made important progress toward civilization. Some of the others had likewise made notable progress, among which were the Tarascos, Totonacas and Zoques.

The builders of Casas Grandes (q.v.), in Chihuahua, evidently belonged to the Pueblo tribes of Arizona and New Mexico. As for the builders of Quemada, in Zacatecas, nothing positive is known. The ruins apparently are of an earlier period than those of Mitla and Xochicalco, and have no inscriptions and architectural decorations, but the use of dressed stone in the walls, rather than adobe, warrants the conclusion that they belonged to the civilization of southern Mexico.

From the records made at the time of the Spanish conquest, and from the comparative investigations of the various cities of Lower Mexico, it is certain that the Indians lived in substantial houses sometimes using dressed stone, inscriptions and ornamental carvings on the more pretentious edifices; they cultivated the soil, rudely perhaps, and produced enough to make it possible to live in large towns, they made woven fabrics for dress and hangings, using colours in their manufacture; they were skilful in making and ornamenting pottery, in making gold and silver ornaments, and in featherwork; they used the fibres that Nature lavishly provided in weaving baskets, hangings, mats, screens and various household utensils. Copper was known to them, and it is possible that they knew how to make cutting instruments from it, but they generally used stone axes, hammers and picks, and their most dangerous weapon was a war-club into which chips of volcanic glass were set. Many of these primitive arts are still to be found in the more secluded districts, and perhaps the best work in pottery moulding in Mexico to-day is that of uneducated Indian artists.

Of the half-breed element which has become so important a part of the Mexican population, no safe estimate can be made. Education, industrial occupation, commercial training and political responsibility are apparently working a transformation of this class that was once known chiefly for its mendacity and criminal instincts, and many of the leaders of modern Mexico have sprung from this race. Settled government, settled habits, remunerative employment and opportunities for the improvement of their condition are developing in them the virtues of the two parent races. Brigandage was formerly so common that travel without an armed escort was extremely dangerous; under President Díaz, however, not only has such lawlessness been repressed but the brigands themselves have been given regular employment as rural guards under the government. This class is also furnishing the small traders of the towns, overseers on the plantations and public works, petty officials, and to some extent the teachers and professional men of the provincial towns.

Political Divisions.—The Mexican Republic is politically divided into 27 states, one federal district, and three territories. The states are generally subdivided into distritos (districts) or partidos, and these into municipios (municipalities) which correspond to the townships of the American system. The state of Nuevo León, however, is divided into municipios only, while some other states use entirely different titles for the divisions, the larger being described as departamentos, cantons and municipios, and the smaller as partidos, directorías and vecindarios rurales. The Federal District consists of thirteen municipalities. The territory of Lower California is divided into two large districts, northern and southern, and the latter into partidos and municipios—the larger divisions practically forming two distinct territories.

The states and territories, with their areas, capitals and populations, are as follows:

</table>
The area and population of Yucatán include those of the territory of Quintana Roo, which formed part of that state at the time of the census. Baja, or Lower California, is divided into two districts for administrative convenience. The Distrito del Norte is credited with a population of 7583 and has its capital at Ensenada (pop. 1026); the Distrito del Sur has a population of 49,041 and has its capital at La Paz. This region was detached from the north-west part of Jalisco and organized as a territory in 1839. Quintana Roo was detached from the state of Yucatán in 1902 and made a federal territorial government.

The principal cities of Mexico, other than the capitals above mentioned, are as follows, the populations being those of 1900 except when otherwise stated:

Mexico City, the seat of government, and the capital of the nation, is situated on the Gulf of California. It is the largest city in the Americas, with a population of 13,199,916. It is divided into 16 sections, each with its own mayor, and is governed by a mayor-president. The city is a major cultural, economic, and political center, with a rich history dating back to the Aztec Empire.

Indirectly the capital has a Pacific coast connexion by way of Cor- doba and the F.C. Vera Cruz Al Pacifico to a junction with the Tehuantepec line of the N. I. C. Nacional Interoceánico de Tehuantepec, also called the Tehuantepec National, and the Mexican Isthmus railway, which is 192 m. long and was formally opened in 1907. This line crosses the interior of Tehuantepec by Coatzacoalcos (officially Puerto Mexico) on the Gulf coast to Salina Cruz on the Pacific coast, and has been under construction many years. The railway was first completed in 1894, but light and defective construction, together with lack of disciplined personnel, rendered the line inefficient and expensive to operate. To correct these defects the line was completely rebuilt and terminal ports constructed. In 1909 the ports were ready to receive large ocean steamships, and the railways were ready to carry sugar for New York. The highest point on the line (Chivela Pass) is 735 ft. above sea-level. The railway has been built by the Mexican government as a transcontinental route for inter- national commerce. Its final construction together with that of its two ports was executed by S. Pearson & Sons, Ltd., of London, who also undertook the working of the line when open. It was estimated in 1907 that the total cost of the railway and ports when completed would be $10,000,000. The total cost was about $15,000,000.
The natural and forest products of Mexico include the agave and yucca (ixtle) fibres already mentioned; the "ceibo" fibre derived from the silk-cotton tree (Bombax pennandia); rubber and vanilla in the world, and the cultivated products; palm oil; castor beans; ginger; chicle, the gum from the large white sapodilla tree (Achras sapota); logwood and other dye-woods; mahogany, rosewood, ebony, cedar and other valuable woods; "cascabel" or "blowfish"; jalap root (Pennaea); sarsaparilla (Smilax); nuts and fruits.

Stock-raising dates from the earliest Spanish settlements in Mexico and received no slight encouragement from the mother country. For a time there was much increase in the cattle, sheep, and wool industry, and stock-raising of some sort is to be found in every state of the republic, though not always to a great extent. The Spanish sheep were found no unsuitable for domestic agriculture, and introduced their own horses, cattle, sheep and swine. From these are descended the herds and flocks of to-day, with no admixture of new blood until toward the end of the 19th century. The open grazing land in the extreme west of the country are of great extent and are utilized by herdsmen who are not insured to neglect and hard Usage.

Traditional text continues with details about the agriculture and industries of Mexico, including the cultivation of cotton, tobacco, sugar, and various crops, as well as the raising of livestock. It highlights the importance of native plants and their uses, such as the cultivation of the agave for its fibers and cape gooseberry for its seeds. The text also mentions the use of chicle for rubber production, yucca for making fibers, and various other agricultural products. It discusses the history of stock-raising and the diversification of crops to meet the needs of the growing population and the economy. The natural and forest products of Mexico are described, including the agave and yucca fibres, rubber, vanilla, and a variety of timber and fiber materials. The text concludes with a discussion of the historical and modern industries, particularly in the context of the Spanish settlement and the subsequent development of Mexico's agriculture and livestock sectors.
to a large number of natives in the season, and considerable quantities of the shell are exported. Other industries of a desultory character include the collection of asphalt, or Spanish moss, on the western side of the Californian peninsula, hunting herons for their plumes, the raising of black oak for turned ware (the wood is much used for making baskets and sweetbriers, or wild honey), and the gathering of cochinilla and ni-in insects. The cochinilla insect was once an important commercial product, but the industry has fallen into decay. Many other insects are also known as sources of dye for carpeting, underwear and hosiery manufactured. An important branch of this industry is the manufacture of "zarapes" (called "ponchos" in other parts of Mexico), a blanket slung in the Mexican fashion to pass through, and worn in place of the coat by men of the lower classes. The most important textile industry is cotton manufacture, which has become a highly successful feature of the industrial life of the republic. There were 146 factories in 1905, of which 19 were idle, and these were distributed over a very large part of the country. About one-half the raw cotton consumed was produced in Mexico, and the balance imported in fibre or yarn. The industry is protected by a high tariff, and raw cotton and further encouragement is offered through a remission of internal revenue taxes where Mexican fabrics are exported for foreign consumption. The cotton factories of 1896 were equipped with 22,021 looms having 678,058 spindles, and with 38 stamping machines, employed 30,162 operatives, and turned out 13,731,638 pieces of cloth. Statistical returns, however, are somewhat incomplete.

Mining.—The best-known and most productive of the industries of Mexico is that of mining. It was the chief object of Spanish policy, and the source of the great wealth of the Empire and the capital during the Spanish rule of the country. British investors have found in this country (called "terri-"

fiber)," and other raw products, a market for their goods. The arrival of the railroad has made the exportation of all kinds of raw materials, and especially of coal, much easier. The coalfields of the country are extensive, and the output is considerable. The mining industry is also very important, and the country is well provided with coalfields and other mineral resources.

The coalfields of Mexico are extensive and productive. The coal is chiefly used for domestic purposes, and very little is exported. The coalfields are located near the coast, and the coal is sent to the markets by rail. The coal is of good quality, and is used for the manufacture of coke, and for the generation of electricity. The coal is also used for the manufacture of fertilizers, and for the production of coke and charcoal. The coalfields are extensive, and the output is considerable. The mining industry is also very important, and the country is well provided with coalfields and other mineral resources.
citizen in the full exercise of his political rights, 35 years of age, not an ecclesiastic, and a resident of the republic at the time of the election. Although the authority of the president is carefully defined and limited by the Constitution, the exercise of dictatorial powers has been so common that the executive may be considered practically supreme and irresponsible. Previous to the presidency of General Porfirio Díaz in 1877 political disorders and changes in government were frequent.

The legislative branch of government consists of a Congress of two chambers—a senate and a chamber of deputies. Two ordinary constitutional sessions are held each year, from September 16 to December 15 and a permanent committee of 29 members (14 senators and 15 deputies) sits during recess, with the power to confirm executive appointments, to give assent to a mobilization of the national guard, to convene extra legislative sessions, to administer oaths, and to report at the next session on matters requiring congressional action. The senate is composed of 56 members—or two from each state and from the federal district—who are elected by popular vote for a term of four years, one-half the number retiring every two years. A senator must be not under 35 years of age, a naturalized citizen, and he holds the Senate rights, a national of the state he represents, and not an ecclesiastic. The chamber of deputies is composed of popular representatives, in the proportion of one deputy for each 40,000 inhabitants or fraction over 20,000, who are elected for a term of two years. A deputy must be not less than 25 years of age, other qualifications being the same as those for a senator. The salary for either senator or deputy is $3,000 and that of the president $50,000. Federal officials and ecclesiastics are ineligible for election to either chamber.

Mexican Citizenship includes all persons born of Mexican parents, all naturalized aliens, and all foreigners owning real estate in the republic or having children by Mexican mothers unless formal declaration is made of an intention to retain the citizenship of another country. In some cases exemptions are granted from specified taxes and military duties, otherwise naturalized citizens are treated the same as native-born. Aliens are granted the civil rights enjoyed by Mexicans, but the government reserves the right to expel those guilty of pernicious conduct. Suffrage is extended to all Mexican citizens who possess honest means of livelihood, the age limit being 18 for the majority and 21 for the unmarried. The judicial branch of the government consists of a supreme court of justice, three circuit courts, and 32 district courts. The supreme court is composed of 11 “ministros” or justices, four alternates, a “fiscal” or public prosecutor and the attorney-general—all elected by popular vote for a term of six years. It has jurisdiction in cases arising from the enforcement of the federal laws, except cases involving private interests, in admiralty cases, in cases where the republic is a party, in those between two or more states, or between a state and the citizens of another state, in those originating in treaties with foreign states, and in those affecting diplomatic and consular officials. There are likewise supreme and inferior courts in most of the states, governed by the civil and criminal codes in force in the federal district. The territories are governed by federal laws. The department of justice has oversight in matters relating to the enforcement of the federal laws and the administration of justice through minor courts. The police service is both municipal and federal in character. In some states a local police service is maintained, but in most states the federal government maintains a very efficient force of mounted “rurales.”

The states are organized very much like the federal government, each with its own governor, legislature, laws and judiciary. Elections are generally indirect, like those for the national executive, and official terms correspond closely to those of similar offices in the national organization. The state is nominally sovereign within its own boundaries, and the authority of its officers and courts in local questions is supreme except in cases where federal intervention or supervision is provided for by the federal constitution. The larger political divisions of the state (parides, distritos, &c.) are governed by a jefe politico, or prefect, and the smaller by a municipal council called an ayuntamiento. Defense—The Mexican army consisted in 1908 of 2,474 officers and 24,132 men, organized on modern lines, and commanded by a general staff at the capital. There were 30 battalions of infantry divided into five divisions, comprising 775 officers and 14,898 men; 14 regiments of cavalry and 4 regimental ca

states have control of the schools within their own boundaries through lack of uniformity, but the national system is being generally adopted. In the official report for 1904 the number of public schools, exclusive of infant schools, was returned at 9,394 (against 5,543 in 1894), of which the 3,934 were supported by the national and state governments and 276 by the municipalities. The private, religious, and association schools numbered 2,281, with 1,55,818 pupils. For secondary investigations national and state governments numbered 796, pupils, and for professional instruction 65 with 9,018 students, of whom 3,790 were women. Normal schools for the training of teachers are also maintained at public expense and are giving good results. Besides those already discussed, the government maintains the law, medical, and agricultural schools of agriculture and veterinary practice, engineering, mining, commerce and administration, music and fine arts. There is also a mechanics' training school (arte y oficio) for mechanics and a single school for women, schools for the blind and for deaf-mutes, reform schools, and garrison schools for soldiers. Early estimates were that 90% of the population were illiterate. In 1895 this percentage was reduced to about 84% and the world of schools is daily cutting it down. Mention must be made of the National Library in Mexico City with about 225,000 volumes, and 138 public libraries in (1904) in parts of the republic, 34 museums for scientific, educational, and art purposes, and 11 meteorological observatories. Newspapers and periodicals, whose educational value varies widely, numbered 459 in 1904, of which 439 were in Spanish and 12 in English.

The people of Mexico are almost all of the Catholic faith, the census of 1900 returning 13,333,013 communicants of that church, 5,795 Protestants (in great part foreigners), 3,811 of other religious beliefs, and 26,085 of no faith. The toleration to all religions, and since 1868 several Protestant denominations have established missions in the towns, but their numbers are still comparatively small. The Roman Catholic religion was entered upon the conversion of the conquerors by the conversion of the natives may still be considered semi-pagan, the gods of their ancestors being worshipped in secret, and the tenets of the doctrine of the priests they but thinly comprehend, being largely adulterated with superstitions and practices of pagan origin. The church hierarchy consists of 3 archbishops and 23 suffragan bishops. It dates from the creation of the bishopric of Mexico in 1530, with Francisco de Zumarraga as bishop, although two previous bishops had been proclaimed at Rome, that of Yucatan in 1518 and Puebla in 1525. In 1545 the bishopric of Mexico was elevated to an archbishopric, with Mexico as its see: three archbishops were successively of Mexico, Michoacan, and Guadalajara. An Inquisition tribunal was established in the capital in 1571, and in 1574 its first auto-da-fé was celebrated with the burning of twenty-one pestilent Lutharians. The Inquisition was active in Mexico during two and a half centuries and was finally suppressed on the 31st of May 1820. The great power exercised by the Roman Catholic church during the colonial period enabled it not only to mould the spiritual life of the whole people, but to control their education, tax their industries in the shape of the political policies governing their daily life. In this way it acquired great wealth, becoming the owner of extensive estates in every part of the country and of huge productive properties in the towns. It was said in 1895 that the church owned one-third of the real and personal property of the republic. The reform laws of that year nationalized its property, abolished its numerous orders and foundations and deprived it of state support and of all participation in political affairs. Subsequent legislation removed clerical influence from public instruction, made marriage a civil ceremony and closed all conventual establishments. The church still exercises a boundless influence over the Mexican lower classes, and is still the most influential organization in the republic.

Finance.—The national revenues are derived from import and export duties, port dues and other taxes levied on internal business transactions; from direct taxes levied in the federal district and national territories, covering a large tax in rural districts, a house tax in the city, commercial and professional licences, wages and salaries, and sundry taxes on bread, pulses, vehicles, saloons, theatres, &c.; from probate duties and registry fees; from a surcharge on all taxes levied on the railways, called the "transporte"; from customs duties paid in federal revenue stamps; from post and telegraph receipts; and from some minor sources of income. The most fruitful revenue is the tax on export, which is now about 2% of the total receipts. The excise duties are levied on tobacco, alcohol and alcoholic beverages, and on cotton goods. Mining taxes, which are very considerable, are levied on the basis of an initial tax on the claim (pertencencia), an annual or rental tax on each claim, and a tax of 3% (1905) on the export of unrefined gold and silver. Bonds are sold in denominations of 50 pesos, and at a rate above 3% on pure silver. The expenses, public works and internal affairs (Department of the Interior). The public debt service alone required $26,201,873 (2,562,187) in 1905.

For the fiscal year 1906-1907 the revenue produced a total of 114,286,122 pesos (dollars), of which, approximately $14,128,612, and the expenditure was $8,076,641 pesos, or $1,867,664. The estimates for 1908-1909 show a marked decline owing to the commercial depression, the revenue being computed at 103,385,800 pesos, and the expenditure at 103,203,830 pesos. Of the former 45,900,000 pesos are credited to import duties, 31,900,000 pesos to stamps, excise duties, and import duties, 23,900,000 pesos to interest, and 1,400,000 pesos to interest on loans from various sources. Owing to the circumstance that the greatest part of the Mexican people own no property, carry on no industry, and are not even to be considered regular productive laborers, their taxes are small in relation to the population and are comparatively inelastic.

The revenues and expenditures of the states and municipalities in 1904, the latest date available, aggregated as follows:

The taxes cover a great variety of occupations and property, often to a minute and insignificant degree, and the expenses of local administration, schools, police, streets and other objects of purely local interest.

The public indebtedness of Mexico includes a foreign debt payable in gold, an internal debt payable in silver, and a floating debt covering unpaid balances on appropriations, unpaid interest, and other credits and obligations. The paper money issues are by banks and not by the government, and there is no cash in its vaults and has no sinking funds to offset this indebtedness. The foreign debt dates from 1825, when $10,000,000 were borrowed in London through two loans. Interest defaults led to a conversion of the public debt by foreign bonds, at a time when the process of nationalization had been adopted. Further defaults followed and in 1888 another adjustment was made by the issue of 6% gold-bearing bonds. From this time the Mexican government has met its obligations promptly, in consequence of which its credit is rated high and its bonds have been quoted at a premium. In 1890 the government placed a loan of $22,700,000 in Europe at 5% for the conversion of its 6% bonds. To meet the debt, the revenues of the country being insufficient to meet the subsidey obligations, but as the railways are built for the development of valuable resources and the opening of needed trade communications, the increase has occurred without loss of credit. At the end of 1907 the public debt stood at $258,976,668.

Previous to 1905 all monetary transactions in Mexico were based in 1905 in the barter of circulating silver standard and free coinage. By a law of the 9th of December, 1894, a decree of the 25th of March 1905, the gold standard was adopted, and the silver pesos, 900 fine and containing 24.343 grammes of pure silver, was made the monetary unit with a valuation of 75 grammes of gold. At the same time the free coinage of silver was suspended, the government reserving to itself the sole privilege of minting money. The coinage of Mexico, now concentrated at the mint in the capital, represents having 3% of its base gold (since November 28, 1867) on the decimal system—the peso being divided into 100 centavos—and consists of gold, silver, nickel and bronze coins, whose weight and fineness are determined by the monetary law of 1904. The coins minted under this law are:

History

I.—Ancient Mexico.

The name Mexico is connected with the name of the group of American tribes calling themselves Mexico (sing. Mexicoll or Azteca). The word is related to or derived from the name of the Mexican national war-god, Mexitl, better known as Huiztilo- pochitl. The Aztecs from the 12th century appear to have migrated from place to place over the mountain-walled plateau of Anahuac, the country "by the water," so called from its salt lagoons, which is now known as the Valley of Mexico. About 1355 they founded on the lake of Texcoco the permanent settlement of Mexico Tenochtitlan, which is still represented by the capital city, Mexico. The name Mexico¹ was given by the Spanish conquerors to the group of countries over which the Aztec power more or less prevailed at the time of the European invasion. Clavigero (Storia antica del Messico, vol. i.) gives a map of the so-called "Mexican empire," which may be roughly described as reaching from the present Zacatecas to beyond Guatemala; it is noticeable that both these names are of Mexican origin, derived respectively from words for "straw" and "water." Eventually Mexico and New Mexico came to designate the still vaster region of Spanish North America, which (till cut down by changes which have limited the modern republic of Mexico) reached as far as the Isthmus of Panama on the south and took in California and Texas on the north. Mexico in this wide sense is of high interest to the anthropologist from the several native American civilizations which appear within its limits, and which conveniently if loosely group themselves round two centres, the Mexican proper and the Central American.

When early in the 16th century the Spaniards found their way from the West India Islands to this part of the mainland of America, they discovered not rude and simple tribes like the islanders of the Antilles, but nations with armies, official administrators, courts of justice, high agriculture and mechanical arts, and what struck the white men especially, stone buildings whose architecture and sculpture were often of dimensions and elaborateness to astonish the builders and sculptors of Europe. Here was a problem which excited the liveliest curiosity and gave rise to a whole literature. Hernandez and Acosta shared the opinion of their time that the great fossil bones found in Mexico were remains of giants, and that, as before the deluge these giants on the earth, therefore Mexico was peopled from the Old World in antediluvian times. On the other hand the multitude of native American languages suggested that the migration to America took place after the building of the tower of Babel, and Siguenza arrived at the curious and definitely curious that the Mexicans were descended from Naphuthim, son of Mizarim and grandson of Noah, who left Egypt for Mexico shortly after the confusion of tongues. Although such speculations have fallen out of date, they induced the collection of native traditions and invaluable records of races, languages and customs which otherwise might have been lost. In the 19th century Lord Kingsborough spent a fortune in printing a magnificent compilation of Mexican picture-writings and documents in his Antiquities of Mexico to prove the theory advocated by Garcia a century earlier, that the Mexicans were the lost tribes of Israel. Modern archaeologists approach the question from a different standpoint, but the origin of the American aborigines and of Mexican civilization remains extremely obscure (see AMERICA, where the primitive Mexican cultures are fully illustrated, and CENTRAL AMERICA).

Real information as to the nations of Mexico before Spanish

1 In this, as in all other Aztec names, the x (or J) represents the English sound ch; hence Mexitl and Mexico should be properly pronounced Mes quitl, Mes quitl. But they do not appear to have ever been so pronounced by the Spaniards, who naturally gave to the x its ordinary Spanish sound of the German ch.
times is very imperfect, but not altogether wanting. The accurate and experienced Alexander von Humboldt considered the
native Americans of both continents to be substantially
similar in race-character. Such a generalization will become
sounder, if, as is now generally done by anthropologists, the
Eskimo with their pyramidal skulls, dull complexion and flat
noses are removed into a division by themselves. Apart from
these polar nomads, the American indigene group roughly
to a single division of mankind, of course with local variations.
If our attention is turned to the natives of Mexico especially,
the unity of type will be found particularly close. The native
population of the plateau of Mexico, mainly Aztecs, may still
be seen by thousands without any trace of mixture of European
blood. Their stature is estimated to be about 5 ft. 3 in., but
they are of muscular and sturdy build. Measurements of their
skulls show them mesocephalic (index about 78), or intermediate
between the dolichocephalic and brachycephalic types of men.
The face is oval, with low forehead, high cheek-bones, long
eyes sloping outward towards the temples, fleshy lips, nose
and in some cases flat-topped but in others aquiline, coarsely
moulded features, with a stolid and gloomy expression. Thick-
ness of skin, masking the muscles, has been thought the cause
of a peculiar heaviness in the outlines of body and face; the com-
plexion varies from yellow-brown to chocolate (about 40 to 43
in the anthropological scale); eyes black; straight coarse glossy
black hair; beard and moustache scanty. Among variations from
this type may be mentioned higher stature in some districts,
and lighter complexion in Tehuantepec and elsewhere. If now
the native Americans be compared with the races of the region
across the oceans to their east and west, it will be seen that their
unlikeness is extreme to the races eastward of them, whether
white Europeans or black Africans. On the other hand they
are considerably like the Mongold peoples of north and east
Asia (less so to the Polynesians); so that the general tendency
among anthropologists has been to admit a common origin,
however remote, between the tribes of Tartary and of America.
This original connexion, if it may be accepted, would seem to
belong to a long-past period, to judge from the failure of all
attempts to discover an affinity between the languages of
America and Asia. At whatever date the Americans began to people
America, they must have had time to import or develop
the numerous families of languages actually found there, in none
of which has community of origin been satisfactorily proved with
any other language-group at home or abroad. In Mexico itself
the languages of the Nahua nations, of which the Aztec
is the best-known dialect, show no connexion of origin with
the language of the Otomi tribes, nor either of these with the
languages of the regions of the ruined cities of Central America,
the Quiché of Guatemala and the Maya of Yucatan. The
remarkable phenomenon of nations so similar in bodily make
but so distinct in language can hardly be met except by supposing
a long period to have elapsed since the country was first inhabited
by the ancestors of peoples whose language has since passed into
so different forms. The original peopling of America might then
well date from the time when there was continuous land between
it and Asia.

It would not follow, however, that between these remote ages
and the time of Columbus no fresh immigrants can have reached
America. We may put out of the question the Scandinavian
sea-rovers who sailed to Greenland about the 10th century. But
at all times communication has been open from east Asia, and
even the South Sea Islands, to the west coast of America. The
importance of this is evident when we consider that late in the
10th century Japanese junks still drifted over by the ocean
current to California at the rate of about one year, often with
some of the crew still alive. Further north, the Aleutian islands
offer a line of easy sea passage, while in north-east Asia, near
Bering's Strait, live Chukchi tribes who carry on intercourse with
the American side. Moreover, Mexico are described as having
Mexican civilization which are most easily accounted for on the
assumption that they were borrowed from Asia. They do not seem
ancient enough to have to do with a remote Asiatic origin of the
nations of America, but rather to be results of comparatively
modern intercourse between Asia and America. Humboldt
(Vues des Cordillères, Pl. xxii.) compared the Mexican calendar
with that in use in eastern Asia. The Mongols, Tibetans,
Chinese and other neighbouring nations have a cycle or series
of twelve animals, viz. rat, bull, tiger, hare, dragon, serpent,
horse, goat, ape, cock, dog, pig, which may possibly be an imita-
tion of the ordinary Babylonian-Greek zodiac familiar to our
spectators. The Mongolian peoples not only count their lunar
months by these signs, but they reckon the successive days by
them, rat-day, bull-day, tiger-day, &c., and also, by combining
the twelve signs in rotation with the elements, they obtain a
means of marking each year in the sixty-year cycle, as the wood-
rat year, the fire-tiger year, &c. This method is highly artificial,
and the reappearance of its principle in the Mexican and Central
American calendar is suggestive of importation from Asia.
Humboldt also discussed the Mexican doctrine of four ages of
the world belonging to water, earth, air and fire, and ending
respectively by earthquake, tempest, and meteors. The
resemblance of this to some versions of the Hindu doctrine of
the four ages or yuga is hardly to be accounted for except
on the hypothesis that the Mexican theology contains ideas learnt
from Asiatics. Among Asiatic points of resemblance to which
attention has since been called is the Mexican belief in the nine
stages of heaven and hell, an idea which nothing in nature
would suggest directly to a barbaric people, but which correponds
to the idea of successive heavens and hells among Brahmans
and Buddhists, who apparently learnt it (in common with
many other notions) from the astronomers of ancient
Asia. Apart from their work in astronomy, the history of
successive stages or concentric planetary spheres belonging to
the planets, &c. The Spanish chronicles also give accounts of
a Mexican game called patolli, played at the time of the conquest
with coloured stones moved on the squares of a cross-shaped
figure, according to the throws of beans marked on one side; the
descriptions of this rather complicated game correspond closely
with the Hindu backgammon called pachisi (see Tylor in Jour.
Antrop. Inst., viii. 110).

The native history of Mexico and Central America is entitled
more respect than the mere recounts of savage tribes. The
Mexican pictures so far approached writing proper as to set
down legibly the names of persons and places and the dates of
events, and at least helped the professional historians to remem-
ber the traditions repeatedly orally from generation to generation.
Thus actual documents of native Aztec history, or copies of
them, are still open to the study of scholars, while after the
conquest interpretations of these were drawn up in writing by
Spanish-educated Mexicans, and histories founded on them
with the aid of traditional memory were written by Itxilxochitl
and Tezozomoc. In Central America the rows of complex
hieroglyphs for the creation, painted on the ruins temples purely
served a similar purpose. The documents written by natives
in later times thus more or less represent real records of the past,
but the task of separating myth from history is of the utmost
difficulty. Among the most curious documents of early America
is the Popol-Vuh or national book of the Quiché kingdom
of Guatemala, a compilation of traditions written down by native
scribes, found and translated by Father Ximenes about 1700,
and published by Scherzer (Vienna, 1857) and Brasseur de Bour-
bourg (Paris, 1861). This book begins with the time when there
were no men, but after the heavens with its boundaries towards the
four winds, but as yet there was no body, nothing that clung to any-
thing else, nothing that balanced itself or rubbed together or
made a sound; there was nothing below but the calm sea alone
in the silent darkness. Alone were the Creator, the Former,
the Ruler, the Feathered Serpent, who give being and whose
name is Gucumatz. Then follows the creation, when the crea-
tors said "Earth," and the earth was formed like a cloud or a
frog, and the mountains appeared like lobsters from the water,
cypress and pine covered the hills and valleys, and their forests
were peopled with beasts and birds, but the Indians would ask
the name of their creators, but could only chatter and croak. So
man was made first of clay, but he was without strength and senseless
and melted in the water; then they made a race of wooden mannikins, but these were useless creatures without heart or mind, and they were destroyed by a great flood and pitch poured down on them from heaven, those who were left of them being turned into the apes still to be seen in the woods. After this comes the creation of four men and their wives, they being ancestors of the Quichés, and the tradition records the migrations of the nation to Tulan, otherwise called the Seven Caves, and thence across the sea, whose waters were divided for their passage. It is worth while to mention these few early incidents of the national legend of Guatemala, because their Biblical incidents show how native tradition incorporated matter learnt from the white men. Moreover, this Central American document, mythical as it is, has an historical importance from its bringing in names belonging also to the traditions of Mexico proper. Thus Guacamatz, "Feathered Serpent," corresponds in name to the Mexican deity Quetzalcoatl; Tulan and the Seven Caves are familiar words in the Aztec migration traditions, and there is even mention of a chief of Toltec, a name plainly referring to the famed Toltecs. Thus the legends of the *Popol-Vuh* confirm what is learnt from comparing the culture of Central America and Mexico proper, that, though these districts were not connected by language, the intercourse between them had been sufficient to justify the anthropologist in including both districts in one region. Historical value of the ordinary kind may be found in the latter part of the *Popol-Vuh*, which gives names of the creation of these tribes; when they began to bear Spanish names and the great city of Quiché became the deserted ruin of Santa Cruz. The Maya district of Yucatan has also some vestiges of native traditions in the manuscript translated by D. Pio Perez, (in Stephens, *Incidents of Travel in Yucatan*) and in the remarkable 16th century *Relacion de las cosas de Yucatan* by Diego de Landa, published by Brasseur de Bourbourg (Paris, 1864). As in the Guatemala traditions, we hear of ancient migration from the Mexican legendary region of Tula; and here the leaders are four famous chiefs or ancestors who bear the Aztec name of the Tutul-Xiu, which means "Bird-Tree." Unfortunately for the historical standing of these four ancestors, there are in the Aztec picture-writing representations of four trees, each with a bird perched on it, and placed facing the four quarters, which make it probable that the four Tutul-Xiu of tradition may be only mythic personifications of the four cardinal points (see Schultze-Sellack in *Zeitschr. f. Ethn.*, 1879, p. 209). Nevertheless, part of the later Maya records may be genuine—for instance, when they relate the war about three centuries before the Spanish conquest, when the king of Chichen-Itza destroyed the great city of Maya-pan. Though the Central American native kings have too little interest for them of the Toltecs and Aztecs to dwell on, the few survive, the more important point historical by this the names of those native settlements and tribes, the few survivals, which are given in the curious migration map, published by Gemelli Careri (*Giro del mondo*, Venice, 1728) and commented on by Humboldt; among these local names are Tzompango, "place of skulls," now Zumpango in the north of the Mexican valley, and Chapultepec, "grasshopper hill," now a suburb of the city of Mexico itself, where the Aztecs are recorded to have celebrated in 1195 the festival of tying up the "bundle of years" and beginning a new cycle.

The Aztecs moving from place to place in Anahuac found little warfare from the Nahua peoples already settled there. One of the first clear events of the Aztec arrival is their being made tributary by the Tepanecs, in whose service they showed their warlike prowess in the fight near Tepeyacac, where now stands the famous shrine of Our Lady of Guadalupe. Thus they overcame the Acolhuas, who had made Tezcuco a centre of prosperity. By the 13th century the Aztecs by their ferocity had banded their neighbours together against them; some were driven to take refuge on the reedy lake shore at Acoculco, while others were taken as captives into Culhuaucan. The king of this district was Coxcoxtli, whose name has gained an undeserved reputation even in Europe as "Cozcoz, the Mexican Noah," from a scene in the native picture-writing where his name appears together with the figure of a man floating in a dug-out tree, which has been mistaken even by Humboldt for a representation of the

MEXICO
Mexican deluge-myth. Cocoyxtli used the help of the Aztecs against the Xochimilco people; but his own nation, horrified at their bloodthirsty sacrifice of prisoners, drove them out to the islands and swamps of the great salt lagoon, where they are said to have taken to making their chinnampas or floating gardens of mud heaped on rafts of reeds and brush, which in later times were so remarkable a feature of Mexican garden art. One of the chief battlefields at the time of the founding of their city was called Tenochtitlan, it is likely that from him was derived the name Tenochtitlan or Stone-crest place.” Written as this name is in pictures or rebus, it probably suggested the invention of the well-known legend of a prophecy that the war-god’s temple should be built where a prickly pear was found growing on a rock, and perched on it an eagle holding a serpent; this legend is still commemorated on the coins of Mexico. Mexico-Tenochtitlan, founded about 1325, for many years afterwards probably remained a cluster of huts, and the higher civilization of the country was still to be found, especially among the Acolhuas in Tezcoco. The war of this nation with the Tepanecs, which went on into the 15th century, were merely destructive, but larger effects arose from the expeditions under the Cihuate king Acamapichtli, where the Aztec warriors were prominent, and which extended far outside the valley of Anahuac. Especially a foray southward to Quauh nahuac, now Cuernavaca, on the watershed between the Atlantic and Pacific, brought goldsmiths and other craftsmen to Tenochtitlan, which now began to rise in arts, the Aztecs having discarded their rude garments of ollin-ibre and costly clothing, and going into business as traders for foreign merchandise. In the 14th cen tury the last great national struggle took place. The Acolhuas had at first the advantage, but Itxlxochilt did not follow up the beaten Aztecs but allowed them to make peace, whereupon, under professions of submission, they fell upon and sacked the city of Tezcoco. The next king of Tezcoco, Nezahualcoyotl, turned the course of war, when Aczcapulco, the Tepanec stronghold, was taken, and the inhabitants sold as slaves by the conquering Acoulhuas and Aztecs; but this place then disappeared; it became afterwards the site of the present annual market of of Mexico. In this war we first meet with the Aztec name Motecuzoma, afterwards so famous in its Spanish form Montezuma. About 1430 took place the triple alliance of the Acolhuas, Aztec and Tepanec kings, whose capitals were Tezcuco, Mexico and Tlacopan, the latter standing much below the two other. In fact the rest of native history may be fairly called the Aztec period, not withstanding the grand magnificence and culture which made Tezcuco celebrated under Nezahualcoyotl and his son Nezahualpilli. When the Aztecs took Tenochtitlan, the former capital of the Mictztec country was extended far beyond the valley plateau of its origin, and the gods of conquered nations around had their shrines set up in Tenochtitlan in manifest inferiority to the temple of Huitzilopochtli, the war-god of the Aztec conquerors. The rich region of Quauhnahuac became tributary; the Mictztec country was invaded southward to the Pacific, and the Xicalanca region to what is now Vera Cruz. It was not merely for conquest and tribute that the fierce Mexicans ravaged the neighborhood, but they had a stronger motive than either in the desire to obtain multitudes of prisoners whose hearts were to be torn out by the sacrificing priests to propitiate a pantheon of gods who well personified their bloodthirsty worshippers. (E. B. T.)

Ancient Civilization.

While the prairie tribes of America lived under the loose sway of chiefs and councils of old men, the settled nations of Mexico had attained to a highly organized government. This may go to explain why the elaborate balance of power maintained in the federation of Motecuzoma and Tlacopan, where each king was absolute in his own country, but in war or other public interests they acted jointly, with powers in something like the property of marriage which they had in the case of the two kings which was a twofold things to each and was an elaborately elaborated device for securing practical advantages, seems rather to have arisen out of the law of choice among the descendants of the female line, found in American tribes of much lower culture. Something like this appears in the succession of kings of Tezcuco and Tlacopan, which went to sons by the principal wife whom was usually the Aztec royal family. The Mexican chronicles, however, show instances of the king’s son succeeding or of powerful leaders being elected to the kingship. The term republic is sometimes used to denote the little city-state which this was, the federation of four chiefs, with an assembly of nobles. In the Zapotec district the Wyiiyato or high-priest of Zapoa was a divine ruler before whom all prostrated themselves with faces to the ground; he was allowed to draw his foot to touch the earth, as was only seen carried in a litter.

The accounts of the palaces of the native kings must be taken with some reserve, from the tendency to use descriptive terms not accurately corresponding to our meanings, but rather to suggest the environment of the ancient Aztec city. It is supposed that Tezcuco now has its stone steps and terraces; and the immense embankment carried out by the Aztecs from Montezuma is supposed by some to be the site of the pyramid of Chapultepec, but these as well as the hanging gardens have been destroyed, and only the groves of ahuehuete (cypress) remain of the ancient beauties of the place. That in the palace gardens flowers and fruit trees must have been grown, and that they raised near fresh and salt pools fit for each kind, that all kinds of birds and beasts were kept in well-appointed zoological gardens, where there was a special household even for horses and wood-lice; the cultivation of natural history which was really beyond the European level of the time. From the palaces and retinues of thousands of servants attached to the royal service may be inferred at once the fact of the wealth of the native rulers of the great cities, and the numbers of the people; in fact some of the most remarkable of the picture-writings are tribute-rolls enumerating by hundreds and thousands the mantles, ocelot-skins, bags of gold-dust, bronze hatchets, loads of chocolate and gupips, full of their gold and jewels. In Tezcuco was a numerous and powerful class of nobles, the highest of whom (tlatoani) were great vassals owing little more than homage and tribute to their feudal lord, while the natural result of the unwrinkled of the noble class was that the king to keep them in check increased their numbers, brought them to the capital as councillors, and balanced their influence by military and household officers, and by division of the greater power among them or their noble sons. These united privileges and rank, and dignity, but substantial power over the plebeian or peasant class (macehualtin). The great estates belonged to the king, or had been granted to military chiefs whose sons were expected to serve him. The relations of this system of landholding or village community still survived, and each freeman of the tribe held and tilled his portion of the common lands. Below the freemen were the slaves, whom they were not allowed to sell or to perform any service for another or children sold by their parents. Prisoners of war were mostly doomed to sacrifice, but other classes of slaves were mildly treated, retaining civil rights, and their children were born free. The superior courts of law formed part of the palace, and there were tribunals in the principal cities, over each of which presided a supreme judge or cihuatocatl, who was irremovable, and whose criminal decisions not even the king might reverse; he appointed the lower judges and heard appeals from them; it is doubtful whether he judged in civil cases, but both kinds of suits were heard in the court below, by the tlacateceltli and his two associations. The titles of whom were changed into titles of support for the maintenance of the judges, and indeed nothing gives a higher idea of the elaborate civilization of Mexico than this judicial system, which culminated in a general court and council of state presided over by the king. The Courts of the Twelve Tribes had a picture-writings, of which some are still to be seen; sentence of death was recorded by drawing a line with an arrow across the portrait of the condemned, and the chronicles describe the barbaric solemnity which marked the ceremonies. The king seated on a dais clothed throne in the divine tribunal, with one hand on an ornamented skull and the golden arrow in the other. Among the resemblances to the Asiatic court is the making of the condemned die under a tree, in the ground with his finger and putting it to his lips, thus swearing by Mother Earth. The criminal laws were of extreme severity, even petty theft being punished by the thief being enslaved to the person who had the wrong done him, or worse, when the crime was of such a nature that he would die; he who pilfered in the market was then and there beaten to death, and he who insulted Xipe, the god of the gold- and silversmiths, by stealing his precious metal, was skinned alive and sacrificed to the offended deity. Though alox-beer or “pulque” was allowed
for feasts and to indulge in moderation, and old people over seventy seem to be represented in one of the picture-writings as having liberty of consuming pulque and adobo pibil, a starchy drink and young women stoned. For such offenses as witchcraft, fraud, removing landmarks, and adultery the criminal had his heart cut out and his body burned at the stake, and his body and bones were scattered to the four quarters, an evidence of the importance of their worship. The war-god Huiztilpopochtli was the real head of the Aztec pantheon; his name occurs in Mexico, a huge block of basalt on which is sculptured on the one side a group of the most hideous-looking humming-bird feathers on the left hand which signify his name, while the not less frightful war-goddess Toyoayomi, or "divine war-dress," employs the same type as a characteristic weapon.

War.

To a fighting community. To be a tried soldier was the road to honour and office, and the king could not be enthroned till he had won by his own hand taken captives to be butchered on the war-god's altar. The conqueror's spoils were distributed even, and the lesser punishments were harsh, such as that of slanderers, whose hair was singed with a pine-torch to the scalp.

Based on conquest as the Aztec kingdom was, and with the most bloodthirsty and unscrupulous methods employed, it is no wonder the Aztecs numbered people as a warlike nation. The Mexican art pictures are to be seen in the picture-writings, where the military orders of princes, eagles and tigers are known by their braided hair, eagles' beak, and feathers, the most brilliant in savage war-paint, but those of higher rank had helmets like birds and beasts of prey, armour of gold and silver, wooden greaves, and especially the tezcapilli, the quilted cotton tunic two inches thick, which was as good as a coat of mail. The Spanish invaders were glad to adopt it. The archers shot well and with strong bows, though their arrows were generally tipped only with stone or bone; their shields or targets, mostly round, were of ordnance; and their javelins and lances, divided in length, were tipped with bronze or antaui, of which pictures and specimens still exist, showing it to be similar in point of weight and size to the American tomahawk. The characteristic weapon of the Mexicans was the aztecahuilli or "hand-wood," a club set with two rows of large sharp obsidian flakes, a well-directed blow with which would cut down man or horse. These were worn by the nobles and the common people in savage forms, while on the other hand the military organization was in some respects equal to that of an Asiatic nation, with its regular companies and captains which commanded each his company and provided for its subsistence. The military strength of the Aztecs was divided into eight divisions, each numbering eight thousand men; but the tactics of the commanders were quite rudimentary, consisting more of ambush and quick by arrows and javelins at a distance, gradually closing into a hand-to-hand fight with clubs and spears, with an occasional feigned retreat to draw the enemy into an ambush. Fortification was well understood, as may still be seen in the remains of walls and castles and covered roads in hills and on steep ravines, while city-cities like Mexico had the water approaches defended by fleets of boats and the causeways protected by towers and ditches; even after the town was entered, the pyramid-temples with their surrounding buildings and courts and enclosure served as a stockade. The whole nation, whose members were expected to hold unrighteous to invade another nation without a solemn embassy, to warn their chiefs of the miseries to which they exposed themselves by it, and whom the Aztec king again warred by a declaration of war, but in Mexico this degenerated into a ceremonial farce, where tribute was claimed or an Aztec god was offered to be worshipped in order to pick a quarrel as a pretext for an invasion which was merely for the enclosures of pueblos and protection to meet the priests' incessant demands for more human sacrifices.

Religion.

Among the accounts of the Mexican religion are some passages referring to the belief in a supreme deity. The word teoci, god, has been thought in some cases to bear this significance, but its meaning is that of deity in general, and it is applied not only to the sun-god but to very interior gods. It is related that Nezahualcoyotl, the poet-king of Tecomaco, built a nine-storied temple with a starry roof above, in honour of the invisible deity called Tloquehuanahua, "he who is all in himself," or Ipalennau, he by whom we live," who had no image, and was prostrated not by the gods and human divinities, however, seem to have had little or no place in the popular faith, which was occupied by polytheistic gods of the ordinary barbaric type. Texcatlipoca was held to be the highest of these, and attributes, the same as those of Tezcatlipoca, who was a god of the sun and war, and Queztalcoatl, ancient deity of Cholula, had been old rivalry. As is related in the legends, Quetzalcoatl came into the land to teach men to till the soil, to work metals and to rule a well-ordered state; the two gods played the chief part in the history of the Aztecs, and Tezcatlipoca haunted the weary Quetzalcoatl to drink the magic pulque that sent him roaring to the distant ocean, where he embarked in his boat and disappeared from among men. These deities are not easily

1 One of the most important sources for the ancient Mexican traditions and myths is the so-called Codex Chimalpaho, a manuscript of the Mexican language discovered by Fr. Abídi. It has been extensively studied and translated, providing valuable insights into the Mexican culture and religious beliefs.

Brasseur de Bourbourg. It is the interpretation of different mythological and historical Mexican picture-writings, composed by several authors some time after the conquest and copied by Fernan de Alva (Itxilxochitl, 1568-1648). It belonged to the private collection of the same Brasseur de Bourbourg. It was published in the 17th century by Lorenzo Boturini (see his "Catlogo del Museo historico indiano," appendix of his Idea de una nueva historia general de la America septentrional, Madrid, 1746, § viii., No. 13). It is named there Historia de los reyes de Colhuacan y de Mexico. The original copies of the same manuscript, made by Leon y Gama, Jose Pichardo, Aubin and Brasseur, exist in the Paris National Library in the Aubin-Goethals collection. Brasseur died before he could realize his plan to publish the whole MS, in Nahua with a translation. Some extracts are to be found in his Historie des nations civilisdes du Mexique, and in Leon y Gama, Dos Piedras, ed. Bustamente (Mexico, 1923), Lapidaria de los Mayas, and in "The Endime," first published in the Anales del Museo nacional de Mexico, tom. iii., app. pp. 77-79; but in this edition the Mexican text is very corrup, and the two Spanish translations are by no means exact. The MSS. and the Itxilxochitl copy were carefully collated by Dr Walter Lehmann (see Zeitschrift für Ethnologie, 1906, pp. 755-756; Journal de la Société des Américanistes de Paris, nov. ser. vol. iii., 1909, no. 2; Dr E. Seler, Die mexikanischen Amerikanisten-Kongresse, Vienna, 1909, II., pp. 129-150). The precious Itxilxochitl copy was found by Lehmann in the library of the National Museum of Mexico, and was made at the direction of the RS. by Dr W. Lehmann, and Professor E. Seler. Another very important MS was discovered by Dr Lehmann, in Guatemala. It is the MS. of Father Francisco Ramirez, Historia de la Provincia de San Vicente de Chiafa y de Quiché, in three books, and, in 1722, it was printed in the Spanish translation of the Quiché myths or the "Popol-Vuh." The MS. was bought at the expense of the duke of Loubat, who decided to present it, after the death of Dr Lehmann, to the Royal Library of Berlin.
MEXICO

ANCIENT CIVILIZATION

Chants, fasting and other austerities, but there are some peculiarities of detail. Prayers and other formulas have been copied down by Sahagun and other chroniclers, of endless prolixity, but without occasional touches of pathos. During the attack on the Toltec capital, Cacaxochitlan, there was not even a native Indian model from which they could have been imitated; but at the same time it must be remembered that they come down in Spanish writing, and not untouched by translation. It is interesting to note that the capo of a sheep, an animal unknown to the Mexicans. As to sacrifice, maize and other vegetables were offered, and occasionally rabbits, quails, &c., but, in the absence of cattle, the Mexican sacrifice consisted chiefly of human victims presented at the feasts. Incense was constantly used, especially the copalli (copal) well known to us for varnish; little terra-cotta statuettes are among the commonest of Mexican offerings, and these was offered in large numbers. The fires were lighted at special seasons, and drawing blood from the arms, legs and body, by thrusting in aloco-thorns, and passing sharp sticks through the tongue, was an habitual act of devotion recalling Asia. The skullcap wore the Indians in the time of the Spanish conquest, and the Mexican festival of the great hero and last of the Aztecs, mo-quauhtin, was celebrated with all the solemnity of the life of its namesake. The calendar of prominent festivals for the Mexican year has been preserved. Each 20-day period had one or more such celebrations. In the month of the "drowning of waters" the rain gods or Tlaloc were propitiated by a procession of priests with music of flutes and trumpets carrying on plumed litters infants with painted faces, in gay clothing with coloured paper wings, to be sacrificed on the mountains or in a whirlpool in the sea. They do not respect the Mexicans. If so, this may have been a customary formality, for the religion of these nations must have quenched all human sympathy. In the next month, the captives of the previous year were sacrificed, halting the "slaying" of men from the human victims being slain, after their hearts were torn out, for young men to dress in their skins and perform dances and sham fights. The succeeding festival of Quauhtinam, the fourteenth moon, when the priests were buried in cemeteries, the stone knives were prepared with which a hole was cut through the tongue of each, and numbers of sticks passed through. For the great festival of Tlacopan, the capital, if most celebrated and noblest of the captives of the year had been chosen as the incarnate representative of the god, and paraded the streets for public adoration dressed in an embroidered mantle with feathers and garnished on his head a retinue like a king; for the last month they married it to a sea-grass, and girls representing four goddesses; on the last day wives and pages escorted him to the little temple of Tlacochcalco, where he mounted the throne of a war-god. On the following day he laid a symbolic farewell to the joys of the world, for as he reached the top he was seized by the priests, his heart torn out and held up to the sun, his head split on the tzompantli, and his body eaten as sacred food, the people drawing from his fate the moral lesson that the riches and pleasure may turn into poverty and sorrow. The manner of the victim's death in these festivals afforded scope for variety; they dressed them and made them dance in character, throw them into the fire for the fire-god, or crushed them between two balanced stones at the harvest-festival. The ordinary pleasures of festivals were mingled with all this, such as dances in beast-masks, sham fights, parades, processions, and the like. The "spelling" of the king's picture-writing, his picture-writing, was of the utmost importance in the life of the Aztec. The gods are represented with their appropriate attributes—the fire-god hurling his spear, the moon-goddess with a shell, &c.; the scenes of human life are pictured of warriors fighting with weapons and spear, men paddling in canoes, women spinning and weaving, &c. An important step towards phonetic writing appears in the picture-names of places and persons. The simplest forms of these objects are signed by the name, as where Chapultepec or "grasshopper-hill," &c., or "mountain of the grasshopper-hill," or a stone with a cactus on it stands for Tenoch or "stone-cactus," the founder of Tenochtitlan. The system had, however, risen above this stage, and it was possible to draw a man to be himself, not themselves, but the syllables forming their names, as where a turkey, eagle, a pricker, and a hand are put together not to represent these objects, but in order that the syllables of their names ma-guausk-zo-na should spell the word in question, as in Atzcasunto to Brasseur, Hist. du Mexique, i. 68. The analogy of this manner in which the Egyptian hieroglyphs passed into phonetic writing, and which must by the time of the Spanish contact have been a master. The Mixteco-Zapotecan codices have also been published at the expense of the Duke of Loubat and by the Junta Colombina (Mexico, 1892). Gods are represented with their appropriate attributes—picture-sings, of which the four principal were the rabbit, reed, flint, house—tocalli, acatl, tecpatl, calli. The cycle of 52 years was reckoned by combining these signs in rotation with numbers up to 13, thus: 52 moons are said to have been passed since the last "end" of the world. It is probable that this may be exactly illustrated with a modern pack of cards laid out in rotation of the four suits, as, ace of hearts, 2 of spades, 3 of diamonds, 4 of clubs. The figure 13 is the Aztec symbol of the 365-day year. It is plain that this rotation of signs served no useful purpose whatever, being less convenient than ordinary counting with the figures. The "kings of rolls," or "years" which Hildebrand numbers, 1072, at the beginning of the Maya era, are the 20-day periods each had a name like our months, and the years had signs in regular order. Its historical interest depends on its resemblance to the calendar-system of central and eastern Europe, where the 20-day periods are combined in rotation with numbers up to 13; as this cycle of days only reaches the end of the year after 52 years, so is the prolixity of to the 365-year day. Mexico civilization being borrowed from Asia. Suddenly the Mexican calendar-system lent itself to magic in the same way as the similar zodiac-signs of the Old World, each person's fate being affected by the qualities of the signs he was born under, and the astrologer-"mystic" Chichimeca-Warera. There is a great number of the Mexican festivals the most solemn was that of the ixtihuipolli, or "year-binding," when the 52-year cycle or bundle of years came to an end. The people were dressed in the Hindustani manner, the Aztecs dressed in the garb of gods, set out in procession for the hill of Huizachaltla, there to watch for the approach of the Pleiades to the zenith, which gave the auspicious signal for the lighting of the new year. The finest of the captives was sacrificed to the god of the sun on his breast with the wooden drill of the priest; then the victim's was torn out, and his body flung on the pile kindled with the wood. The blood was collected in baskets, and passed in each over a girt round saw with joy the flame on the sacred hill, and hailed it with a thank-offering of drops of blood drawn from their ears with sharp stone-blades. Swift runners carried burning brands to re-kindle the fires of the land, the sacred fire on the teocalli of the war-god blazed up again, and the people began with feasting and rejoicing the new cycle.

Mexican education, in any rate that of the upper class, was a systematic discipline much under the control of religion, which here presents itself under a more favourable light. After Education. the birth of a child, the tonalpohualli or "sun-calculator" was called, &c., to decide the life of the child, and fixed the time for its solemn lustration or baptism, performed by the nurse with appropriate prayers to the gods, when a toy shield and bow were provided if it was a boy, or a toy spindle and distaff if it was a girl. As soon as the child was born it was washed with the smoke from the sacred fire which had been kept from the fire of the nuptial feast, the fire of the dead, and had been set up in the middle of the courtyard. The children were taught in the streets, to recite in picture-writing, to be seen in Kingborough, shows the details of the boy's and girl's education, from the early time when three small cards were put into their mouth, may consist of half a tortilla or corn-cake shows its allowance for each meal; as they grow older the lads are seen beginning to carry burdens, paddle the canoe and fish, while the girls learn to spin and weave, grind maize and cook—good conduct being enforced by punishment of increasing severity, up to pricking their bodies with alocthorns and holding their faces over burning chilies. The schools were extensive buildings attached to the temples, where from early age boys and girls were taught by the priests to Mexican sanctuaries and keep up the sacred fires, to fast at proper seasons and draw blood for penance, and where they received moral teaching from the priest and the elder boys and girls were trained to the use of weapons and sent early to learn the hardships of war; children of craftsmen were usually taught by their fathers to follow their trade; and for the children of nobles there was elaborate instruction in history, picture-writing, astrology and religious doctrines and laws. Marriages depended much, as they do still in the East, on comparison of the horoscopes of the pair, but if their birth-signs were compatible. Old women were employed as go-betweens and conducted by a priest who after moral exhortations united the young couple by tying their garments together in a knot, after which they were together to see their parents and by the other of the performance of the marriage ceremony, the pair entered together on a four days' fast and penance before the marriage was completed. The funeral rites of the Mexicans are best in the Teocalli of Tlahquitzin, at the center of the sacrificial road, where the sacrifices in state was provided by the priest with a jug of water for his journey, and with bunches of cut papers to pass him safely through each danger of the road—the place where the two mountains strike
together, the road guarded by the great snake and the great alligator, the eight deserts of the eight winds. In this way the rain god, protect him from the cutting wind, and buried a little dog by his side to carry him across the nine waters. Then the royal body was invested in golden armor and buried, when some Aztec birds, war-god, for Mexican kings were warriors; on his face was placed a mask of turquoise mosaic, and a green chalchihuité stone as a heart between his lips. In older times the dead king was buried on a high platform, and the temple and tower over which was sacrificed and his bodies burnt. Common people would not thus be provided with a ghostly retinue, but their simpler funeral ceremonies included the burning of their own bodies and the burning of the wood on which they died.

The staple food of the Mexicans before the conquest has continued with comparatively little change among the native race, and has even been adopted by those of European blood. Maize or Indian corn was cultivated on patches of ground where, as in the Hindu jfam, the trees and bushes were burnt and the seed planted in the soil manured by the ashes. A sharp-pointed planting stick, a woven shovel, and a bronze-blade hoe called a coatl were the simple implements. The Mexicans understood digging channels for irrigation, especially for the cultivation of the cacahuatl, from which they taught the Europeans to provide their crops by means of irrigation. The plant was known in America as the metate, and the meal baked into thin oval cakes called by Aztecs tlaclalli, and by Spaniards tartilla, which resemble the doughnut. The cakes were made with the addition of corn meal, as also skillful makers of earthen pots, in which were cooked the native beans called by the Spanish frijoles, and the various savoury stews still in vogue. The juice extracted by tapping the great abuse before the trees was used as a solvent for gold and silver, and was also used in hammering work and chasing. The skins of the domestic animals modelled with gold and silver, fur, feathers and scales have disappeared. Iron was not known, but copper and tin ores were smelted and worked, a bronze alloy as in the Old World, of which hatchet blades and other instruments were made, though their use had not superseded that of obsidian and other sharp stone flakes for cutting, shaving, &c. Mexico was rich in the mineral wealth of the earth, in gorgeous quills of gold-dust and T-shaped pieces of copper, while cacao-beans furnished small change. The vast size of the market-squares with their surrounding porches, and the importance of the caravans of merchants who traded with other nations, show that mercantile had risen into some proportion to military interests. Nor was the wealth and luxury of Mexico and surrounding regions without a corre- sponding development of art. The stone sculptures, such as that remaining of Xochicalco, which is figured by Humboldt, as well as the ornamented woodwork, feather-mats, and vases, are not without artistic merit. The often-cited bird-dance is a relic, and perhaps the rite which Huspedal ascribed to the gods of Chalchihuitzinco, an ancient city, but at any rate poetry had risen above the barbaric level, while the mention of ballads among the people, court odes, and the chants of temple choirs would indicate a vocal cultivation above the average of the indigenous race. There were also characteristic and whistled, the latter often of pottery. Sollem and gay dances were frequent, and a sport called the bird-dance excited the admiration of foreigners for the skill and dexterity with which groups of performers dressed as birds let themselves down by ropes wound round the top of a high mast, so as to fly whirled in circles far above the ground. The ball-game of the Mexicans, called tlachtli, was, like tennis, the pastime of the princes and their nobles only. But the use of a rubber ball, perhaps as the first in which Europeans became acquainted with this valuable material might not be touched by the hands, but was driven against the walls by blows of the knee or elbow. The Aztecs had this rubber ball, so well known in modern Mexico, already mentioned for its similarity to the pachis of modern India.

The accounts given by Spanish writers of the Central Americans in their state after the Spanish conquest are very scanty in compari- son with the voluminous descriptions of Aztec life. They were particularly ignorant of the history of the two civilizations. Some Central-American peoples were actually Mexican in their language and culture, notably the Pipils and a large part of the population of Nicaragua. The evidence of Dr. Lehmann in Central America (1907-1909), prove that these Mexican elements were extended through Guatemala, Salvador, a small part of Honduras, and considerable areas of the territory of the Pipils and the Cacaopera (Pacific Coast) amongst the autochthonous Choro- tega or Mangue. It is an error of the Spanish authorities to pretend that the Pipil civilization in Guatemala and Salvador is not older than the Spanish conquest. The language spoken by the Pipils of Salvador (Balsam Coast) is a very old dialect of the Mexican language of the highland of Mexico. It has preserved elements which are older than the classical Nahualt itself. The architectural remains of the Pipils from the chief tribes of the Nahualti branch happened centuries before the conquest, and they developed a singular and characteristic civilization, which can be seen in the immediate neighbourhoods of the large sculptured barrows near St Lucia de Cozumalhuapa on the Pacific coast of Guatemala.

Dr Lehmann's archaeological and linguistic researches, especially in Salvador and Nicaragua, also enabled him to prove another very important fact, viz., that these Pipils, who may be descendants from the peoples of the Mexican Plateau, migrated into territories pres- enly occupied by another race of Mayan origin. The archaeological and linguistic evidence proves also that a great part of Salvador and Honduras was once occupied by peoples of the Maya race—Pokomam, Chorti and perhaps other unknown tribes. They left no evidence of their presence in the form of prehistoric Maya buildings or even archaeological remains more than the classical Nahualt itself. The architectural remains of the Pipils from the chief tribes of the Nahualti branch happened centuries before the conquest, and they developed a singular and characteristic civilization, which can be seen in the immediate neighbourhoods of the large sculptured barrows near St Lucia de Cozumalhuapa on the Pacific coast of Guatemala.

It is noteworthy that architectural objects of the type characteris- tic of northern Central American (Ulua Valley) have been found on the Pacific coast of Salvador. A strange stone sculpture of the so-called Chac-Mol type, known before only from the country of the Tarases, from Tlacaxla and Chichen Itza, was discovered in Salvador (Valle-achapam).

In the nearly unexplored central part of Nicaragua Dr Lehmann found fragments of painted polychrome clay pottery similar to objects known from the Cacaopera Valley (Pacific Coast). Some white ceramic pieces which seem to have been left by the ancestors of the Sumo Indians, now extinct in that territory. It is possible that these remains of Mayan pottery came into central Nicaragua as articles of commerce.

It is significant that Mayan civilization cannot be traced in any other part of Nicaragua or Costa Rica.

The above-mentioned prehistoric Mayan peoples lived in contact with an another little-known civilized race. The barbarians belonged to the great family of the Sumo-Misquito Indians, the civilized race was that of the Chorotega or Mayians of Misquito Land (or Misquita Motagua). These people occupied the Atlantic coast and the interior of Nicaragua and Honduras, where they still live in small tribes; a dialect of the hitherto unknown Sumo languages is the Matagalpa, now extinct in Nicar- agra, and nearly identical in vocabulary with the language spoken by the Indians of Cacapoeira in Salvador (Ultra-Lempa territory).

There is no doubt that, at the time of the Pipil invasion, tribes of the Sumo-Misquito family were seen in the immediate neighbourhoods of the Pipils towards the east and north. This fact is proved by the names of some places in Salvador, e.g. Santiago Nonohualco, San Juan Nonohualco and San Pedro Nonohualco. The word Nonohualco signifies in the Mexican language a place where a language changes, where another idiom begins. To the east of the three places whose names are compounded with "Nonohualco," must have dwelt, in the time of the Pipils, the Nonohualcos, called also by Mexican tribes by the name of T-session and by the non-Mayan peoples of the interior of Nicaragua and Honduras were and are (though few still survive) the Lenca Indians, who formerly occupied large parts of Honduras. A linguistic relation- ship can be established between all the Indian languages spoken in the Pacific coast and in the interior of Nicaragua and Honduras.

Several tribes, such as the Paja (or Poya) and the Jicaques, form together with the Lenca, Sumo (Matagalpa, Taunkha and Ulua) and Misquito one great family race of Mayan origin.

The position of the isolated Xinca (or Sinca) Indians, regarded from this point of view, becomes very interesting. There are scientific reasons to believe that the Xinca also belong to the same family. It may be possible that these tribes are the autochthonous inhab- itants who dwelt in Guatemala, Salvador, Honduras and Nicaragua before the immigration of the historic Maya. We are certain that the separation of the languages spoken by them after it had been deserted by a prehistoric branch of the Maya family.

The Chorotega race had its centre in Nicaragua (Pacific coast) and at one time extended thence as far as Guanacaste (Costa Rica) at
another time it extended as far as Honduras (actual department of Choluteca) and into eastern Salvador as far as the site of Chiapa in Mexico, where the Chortegues people had occupied a small territory. The Chortegues language is now extinct, but its former extension is to be recognized by many Indian local names. It seems that there was formerly a Chortega tribe that bordered the Sumo and Uala tribes.

The territories of all these tribes can be more or less exactly calculated by the existence of Indian local names. The Missipiqui country is characterized by names derived from the names in laya, laya, itzet, and Uala country by names in sav, water, and water streams. The Chortegues language also has a strange that there is not a single place-name in Salvador either of Mayan origin, or, as it seems, of Chortegues origin. Probably the Mexican elements superseded the Maya so completely that these two races and the Chortegues vanished; it is to be supposed that the Lenca and Sumo tribes superseded the Chortegues in Salvador. If we can be sure—and the linguistic evidence admits of no doubt—that the Chortegues had their centers in Nicaragua and thence extended north-westwards, it may be hoped that Chortegues remains will be found in the vast territory occupied for many centuries by the Maya peoples in the Pacific part of Guatemala. These remains would, of course, be archaeological or place-names.

How closely related some of the Central-American nations were in institutions is shown by their habit of being named in the same way, as in the names of the Aztec empire, under which the various states entered, but in the similarity of their religious rites; the connexion is evident in such points as the ceremony of marriage by tying together the garments of the couple, or in holding a feast of libations. In these customs the Teotihuacán legends of Central America make mention of the royal ball-play, which was the same as the Mexican game of tlachihl already mentioned. At the same time mention is made of the Central-American nations divided into the waters. Thus we find the custom of the youths sleeping in a great bachelor's house, an arrangement common in various parts of the world, but not in Mexico; the same remark applies to the Maya exorcism of a man not taking a wife of his own family name (see Diego de Landa, Relacion de Yucatan, ed. Brasseur de Bourbourg, p. 140), which does not correspond with Mexican custom. We have the means of comparing the official language of the Mexican and Central-American nations with their portraits on early sculptures, vases, &c.; and, though there does not appear any clear distinction of race-type, the extraordinary back-sloping forehead and the general aspect of the people show that there is the same custom of flattening the skull in infancy prevalent in Central America to an extent quite beyond any such habit in Mexico.

The notion that the ruined cities now buried in the Central-American forests were of great antiquity and the work of extinct nations has no solid evidence; some of them may have been already abandoned before the conquest, but others were inhabited by the ancestors of the modern Mexicans. Though they did their works of art in the same manner as the Maya, it is evident that the ruined cities were relatively of the same age on the Pacific coast of Central America as those of Maya in the Valley of Mexico and the Yucatan peninsula. The summit of the Teotihuacán ruins was made of adobe bricks (reproduced by A. F. Bandelier, Report on an Archaeological Tour in Mexico, 1881 (Archaeol. Inst. of America, paper, Am. Ser. II.)); Leopoldo Batres, Cuadro arqueologico y etnografico de la Republica Mexicana (Mexico, n.d.); W. W. Bishop, "Lugares de la Conquista," and Charles H. Washburn, "The National Museum of Mexico (Mexico, 1884); E. Boban, Cuadro arqueologico y etnografico de la Republica Mexicana (Paris, 1885); and A. F. Bandelier, "The Maya Type and the Early Mexicans" (in the American Antiquities, 1886-1887; "The Ancient Cities of the New World" (Transl. New York, 1887); and Viollet-le-Duc, Cite et ruines americaines (Paris, 1863); Alfredo Batres, "Antiguos y modernos monumentos de las rutas de los Mayas" (in the American Antiquities, 1884-1886); E. Forstmann (Numerous articles in Globus and other German publications, 1863-1897, on Maya inscriptions); E. T. Hamy, Decades americaines (Paris, 1888, 1890); Wm. H. Holmes, Archaeological Studies among the

The explorations made by Dr Lehmann in 1909 in the famous ruins of Teotihuacan, near Mexico city throw new light upon certain of these and other problems. In the early part of the 9th century the Mayas abandoned the Classic period. In the north west Uale in Peru, they tend to determine the relative antiquity of the different periods of the ancient civilization. They also show that these various culture-periods followed one another almost in the same sequence as among the Peruvians.

At a considerable depth below the foundations of a temple-palace at Teotihuacan, Dr Lehmann discovered certain ceramic fragments of a Maya character different from any hitherto known. The pottery is painted on a fine stucco in beautiful colours (notably a kind of turquoise-green) and represent archaic forms of flowers and butterflies. The relation between the wall-paintings of Teotihuacan and those of Yucatan has thus been proved. These interesting works of art also throw some light on the relations of the Maya peoples of the Atlantic coast of the Mexican Gulf from Campeche as far as Tabasco and Vera Cruz.

Attempts to trace the architecture of Central America directly from the sites now buried by the forest have proved difficult, but the hand its decoration shows proof of original invention, especially in the imitations of woodwork which passed into sculptural ornament when the material became stone instead of wood. Thus the architectural remains, though they fail to solve the problem of the culture of the nations round the Gulf of Mexico, throw much light on it when their evidence is added to that of religion and customs. The Teotihuacan civilization was also the chief source of Many Mexico and Central America were pervaded by a common influence in religion, art, and custom; second, that this common element shows traces of the importation of Asiatic ideas into America.

In the early years of this century, the work on Mexican archaeology is the Gesammtliche Abhandlungen, of Eduard Seler (vol. i. Berlin, 1902; vol. ii., 1904). For the earliest descriptions of the ancient cities of Mexico the writings of Colognolo, Land, Antonio del Rio, Sahagan, Torquemada and others are of the greatest value. The account by Antonio de Leon y Gama, Descripcion historica y cronológica de las dos piezas que, de hallaron en el norte de Mexico la ciudad de la, published by M. A. de Salas, (ed. by C. M. de Mustamento), may be specially mentioned. Much of this material may be found in Lord Kingsborough's monumental work in 9 vols., seq., on the Antiquities of Mexico (London, 1831-1836), and the illustrations of the same. Two other things which最有 of Mexico and Central America were pervaded by a common influence in religion, art, and custom; second, that this common element shows traces of the importation of Asiatic ideas into America. The first and more comprehensive work on the subject is the work on Mexican archaeology is the Gesamtliche Abhandlungen, of Eduard Seler (vol. i. Berlin, 1902; vol. ii., 1904). For the earliest descriptions of the ancient cities of Mexico the writings of Colognolo, Land, Antonio del Rio, Sahagan, Torquemada and others are of the greatest value. The account by Antonio de Leon y Gama, Descripcion historica y cronológica de las dos piezas que, de hallaron en el norte de Mexico la ciudad de la, published by M. A. de Salas, (ed. by C. Much of this material may be found in Lord Kingsborough's monumental work in 9 vols., seq., on the Antiquities of Mexico (London, 1831-1836), and the illustrations of the same. Two other things which
The church rapidly supplemented the work of the conquerors. The first Franciscan mission arrived in 1524; other orders followed. The announcement of the apparition of the Virgin to an Indian near Mexico City provided a place of pilgrimage and a petroness in Our Lady of Guadalupe, and the friars ingeniously used the hieroglyphic writing for instructing the Indian converts in the natives' trades, for which they showed much aptitude. The university of Mexico was founded in 1553. The Jesuits established themselves in 1572, devoting themselves actively to the education both of whites and of natives, and were a powerful factor in the exploring and civilizing of the northern districts. The Inquisition was introduced in 1571. With the natives south of the latitude of Tampico there was little trouble after the Mixtón War (in Guadalajara) in 1540-1562, save for occasional risings in Yucatán, Tehuantepec, and in 1717 in the Nayarit mountain region west of Zacatecas, and Tamaulipas was conquered in 1748; but the wild Indians of Sonora and New Mexico gave constant trouble to the missions and outlying settlers. There were occasionally riots due to scarcity of corn (notably in Mexico itself in 1692). As in other Spanish possessions, Indian labour was replaced or supplemented by that of negro slaves, but these were almost wholly confined to the coast regions of Vera Cruz and Acapulco, and early in the 19th century there were only some 10,000 in all.

The Indians brought few women, there was much mixture of races. Among the pure whites—who were practically all of Spanish extraction—there were two well-defined classes, the Gachupines or chapatones, Spaniards born in Europe, said to be so named in allusion to their spurs, from Aztec words meaning "prickers with the foot," and the native-born or creoles: the former, though a small minority, had almost all the higher positions both in the public services and in commerce. Besides these there were five well-defined castes: mestizos (Indian and white); mulattoes, children of Indian and white parents, and Zambos (negro and Indian), who were regarded as specially vicious and dangerous; native Indians and negroes. But there were about a dozen intermediate "named varieties," of which the salto-atares (tending away from white) and tiente en laire (tending towards white) may be mentioned; and many of the last named eventually passed into the Creole class, sometimes by the decree of a court. The fact that the trade route to Manila passed through Vera Cruz, Mexico City and Acapulco entailed the settlement also of a few Chinese and Malays, chiefly on the Pacific coast.

The natives were subject to tribute and kept in perpetual tutelage: divided at the conquest, with the land, asserfs of the conquerors, in repartimientos or encomiendas, they were gradually freed at an early date from their servage, and allowed to sell their labour as they pleased; they were, however, to a great extent kept in villages or settlements, compelled to cultivate land which they held for their life only, and strictly controlled by the friars or the priests. Their numbers were several times seriously reduced by the malachual, apparently analogous to yellow fever, but not attacking the whites, and unknown before the conquest. The whites were allowed to buy their freedom gradually at rates fixed by the judicial authorities, and slavery seems never to have taken much hold except in the coast region.

Of the events of this period only a bare outline can here be given. The term of office of the first viceroy, Antonio de Mendoza, was marked by the Mixtón War, by an attempt to suppress the encomienda system, and by a violent epidemic among the natives. Under his successor, Velasco, the measures taken for the relief of the natives provoked the landowners to a突破pressured (with great severity) to set up Cortés' son as king of New Spain. In 1568 the island of Sacrificios, near Vera Cruz, was seized by John Hawkins (q.v.), who was surprised by the Spanish fleet accompanying the new viceroy, de Almansa, and escaped with Sir Francis Drake (q.v.), but without the remaining ships of his squadron. In 1572 and 1578, however, Drake took abundant

\[\text{Colonial Period 1520-1821} \]

The conquest of Mexico by the Spanish forces under Hernando Cortes (q.v.) in 1520, and the death of the last Aztec emperor, Motecuhzoma, Guatemoxtin, introduced what is known as the colonial period of Mexican history, which lasted down to the enforced resigna- tion of the last viceroy, O'Donojo, in 1821. During these three centuries, after a brief but most unsatisfactory experience of government by the viceroy, both the Spanish colonial government and the audiencias or judicial districts of Mexico, San Domingo and Guatemala, and the viceroy had some sort of authority over them; but in its narrower meaning it comprised the audiencia district of Mexico and the subordinate audiencia district of Guadalajara, which together extended from Chiapas and Guate- mala to the eastern boundary of the modern state of Texas and northwards, eventually, to Vancouver's Island. In the course of the 18th century this came to consist of the following divisions: (1) the kingdom of Mexico, which included the peninsula and the province of New Spain; (2) the states of Chihuahua and Durango; (3) the province of Sonora and Sinaloa, Coahuila, Texas (from Corpus Christi Bay to the mouth of the Mermenton in the present state of Louisiana), and the two Californias.

The audiencia councils also advised the viceroy in matters of administration; and, as with other officials, his career was subject at its close to a formal examination by a government and organization commission—a process known as "taking his The church rapidly supplemented the work of the conquerors. The first Franciscan mission arrived in 1524; other orders followed. The announcement of the apparition of the Virgin to an Indian near Mexico City provided a place of pilgrimage and a petroness in Our Lady of Guadalupe, and the friars ingeniously used the hieroglyphic writing for instructing the Indian converts in the natives' trades, for which they showed much aptitude. The university of Mexico was founded in 1553. The natives very subject to tribute and kept in perpetual tutelage: divided at the conquest, with the land, as serfs of the conquerors, in repartimientos or encomiendas, they were gradually freed at an early date from their servage, and allowed to sell their labour as they pleased; they were, however, to a great extent kept in villages or settlements, compelled to cultivate land which they held for their life only, and strictly controlled by the friars or the priests. Their numbers were several times seriously reduced by the malachual, apparently analogous to yellow fever, but not attacking the whites, and unknown before the conquest. The whites were allowed to buy their freedom gradually at rates fixed by the judicial authorities, and slavery seems never to have taken much hold except in the coast region.

Of the events of this period only a bare outline can here be given. The term of office of the first viceroy, Antonio de Mendoza, was marked by the Mixtón War, by an attempt to suppress the encomienda system, and by a violent epidemic among the natives. Under his successor, Velasco, the measures taken for the relief of the natives provoked the landowners to a breakthrough (with great severity) to set up Cortés' son as king of New Spain. In 1568 the island of Sacrificios, near Vera Cruz, was seized by John Hawkins (q.v.), who was surprised by the Spanish fleet accompanying the new viceroy, de Almansa, and escaped with Sir Francis Drake (q.v.), but without the remaining ships of his squadron. In 1572 and 1578, however, Drake took abundant
vengance, and in 1587 Cavendish captured the Manila galleon—a success repeated in the next century.

For the next sixty years an urgent question was the prevention of floods in the capital. Situated on the lowest of four lakes, the city was flooded on an average once every twenty-five years. It had been protected under the native kings by a system of dikes, which were added to under the earlier viceroys, but serious inundations in 1553 and 1580 flooded the city, and the latter suggested the relief of the highest lake, that of Zumpango, by a tunnel carrying its chief affluent into a tributary of the Panuco, and so to the Atlantic. This, however, was not then undertaken, and when mooted again in 1603 was opposed as certain to involve a heavy sacrifice of Indian life. Another inundation, in 1604, suggested the transfer of the city to Tacubaya, but the landowners opposing and the city being again inundated in 1607, the Nohchistongo tunnel was begun under the auspices of a Jesuit, Enrique Martinez, and roughly completed in eleven months. It passed under a depression in the mountains of the extreme north of the valley. Humboldt states that it was 6600 metres long, 32 wide and 4 high. But it did nothing for the southern lakes, so that a further system of dikes was recommended in preference, in 1614, by the Dutch engineer Adrian Boot; it was inadequate for its work and, not being lined with masonry, it was liable to be choked by falls. Repairs were suspended in 1623, and a further inundation, with great losses of life, occurred from 1629 to 1634. The removal of the city was again mooted and, though sanctioned by the king of Spain, successfully opposed by the landowners. Another flood occurred in 1645. After a disastrous attempt to enlarge the tunnel in 1675, it was eventually converted into an open cut, but the work was not finished till 1789, and the bottom was then 29 ft. 6 in. above the level of the lowest lake. The drainage was only satisfactorily accomplished at the end of the 19th century (see below).

A negro revolt in the Vera Cruz region (1609) and an Indian rebellion in Sinaloa and Durango may be mentioned among the events of the earlier part of the 17th century. The regular and secular clergy had early come into conflict, particularly over the tithes and the control of the Indians; and in 1621, the marquis de Gelves, an energetic reformer, who as viceroy favoured the appointment of the regulars to deal with the natives, came into conflict with Archbishop Serna of Mexico, who placed the city under interdict, excommunicated the viceroy and constrained him to hide from the mob. Some years later the bishop of Puebla, Juan de Palencia de Vependua, transferred many native congregations, from the friars to secular priests, and subsequently, in 1647, came into conflict with the Jesuits, whom he excommunicated, but who eventually triumphed with the aid of the Dominicans and the archbishop. The power of the church may be judged from the petition of the Ayuntamiento of Mexico to Philip IV. (1644) to stop the foundation of religious houses, which held half the property in the country, to suspend ordinances because there were 6000 unemployed priests, and to suppress fast days because there were at least two per week.

To check the Dutch and British corsairs the Barlovento ("windward") squadron had been set up in 1635; but the British capture of Jamaica (1655) aggravated the danger to the Spanish convoys. During the rest of the century the ports of Yucatan and Central America were frequently raided, and in 1682 Tampico suffered a like disaster; in May 1683 Vera Cruz itself was captured through stratagem by two buccaneers, Van Horn and Laurent, who plundered the town for ten days, committed shocking outrage, and escaped as the Spanish fleet arrived. In 1685-86 the Pacific coast was ravaged by Dampier and Swan, and in 1700 Woodes Rogers, with Dampier as pilot, captured the Manila treasure galleon, a feat repeated by Anson in 1743.

But the European wars of the 18th century had little effect on Mexico, save that the privileges of trade given to Great Britain by the treaty of Utrecht facilitated smuggling. In the first half of the 18th century we may note the appearance, intermittently at first, of the first Mexican periodical—the Gaceta de Mexico—in 1722, a severe epidemic of yellow fever in 1756, and the establishment about 1750 of a standing army with a nucleus of Walloons and Swiss, negroes and Indians being excluded and the half-breeds admitted under restrictions. But the great event of the 18th century was the expansion of the Spanish dominions in Mexico, as from the other Spanish dominions, in 1767, under orders from Charles III. They were arrested en masse on the night of the 26th of June; their goods were sequestered, and they themselves deported to Havana, then to Cadiz, Genoa, and eventually Corsica. They had done much to civilize the natives and to educate the whites, and their expulsion, which was greatly resented by the Creoles, probably tended to increase the popular discontent and prepare for the overthrow of Spanish rule.

In 1769 Don Jose de Galvez was sent out as special commissioner to devise reforms, with powers independent of the then viceroy, but without much immediate result. It was, however, a consequence of his work that in 1786 the provinces and kingdoms were replaced by twelve intendencias (Guadalajara, Zacatecas, Durango, Sonora, Puebla, Vera Cruz, Merida, Oaxaca, Valladolid, Guanajuato, San Luis Potosi, Mexico), whose governors and minor officials were directly dependent on the viceroy, the former alcalde, mayors and corregidores, who were very corrupt, being abolished. Possibly it is from this reform that we may date the antithesis of the word intendencia?

The European wars of the French revolutionary period interfered with the traffic with Spain, and so relieved the bonds of a commercial system which hampered the manufactures of Mexico and drained away its wealth. Already in 1783 the Conde de Revillagigedo (1789-1794) abrogated the treaty of 1810 which guaranteed to the Spanish king the scheme of setting up three Spanish-American kingdoms bound to Spain by perpetual treaties of alliance and reciprocity and by frequent royal intermarriages, and with the king of Spain as overlord. The plan was devised as a means of ridding Anglo-Saxon supremacy, but was rejected through fear of the mixed races predominating over the whites. A similar fear helped to keep down the tendencies inspired by French revolutionary literature, though plots occurred against the viceroy, Don Francisco de Borja, in 1798 and 1799. But the real causes of the revolution were local. The chief was the Creole jealousy of the Spanish Imperial monopoly, with all its attendant restrictions on commerce and manufacture, in the interest of Spain, even vineyards having been prohibited; and the courts were very corrupt. But to these grievances was added in 1804 the sequestration, to provide for Spain's needs, of the benevolent funds (obras pias) in Mexico, amounting to about $45,000,000, and nearly all invested on mortgage. The mortgages were called in: forced sales were necessary, the mortgagees were frequently ruined, and less than a fourth of the total was realized. Other confiscations and exactions followed; and when the rule of the French in 1808 was ended, the 11th of May, 1811, was proclaimed the anniversary of the French armies. The municipality of Mexico invited Iturriagary, the viceroy, to declare the country independent. He proposed the convocation of a national congress, but was overthrown by a conspiracy of Spaniards under one Yermo, who feared that they would lose their privileged position through servitude from Spain. The two next viceroys were incompetent; further demands from the Spanish authorities in revolt against Joseph Bonaparte increased the dissatisfaction, which was not allayed by the grant of representation in the Spanish Cortes to the colonies; and, on the demands being repeated by a third, which was to consist of Portuguese and English, the authorities arose in Querétaro and Guanajuato. Their discovery in 1810 was followed by the outbreak of the revolution. Hidalgo, a parish priest, and Allende, a captain of cavalry, with forces
consisting largely of Indians, captured a stronghold at Guanajato and even threatened the capital; but the revolutionists were defeated in 1811 at Calderon, and the leaders executed. Another priest, however, named Morales, continued the movement, and, despite defeat in the terrible siege of Cuautla (now Morelos) on the 2nd of May 1812, raised the south, so that in the next year his forces overran most of the kingdom of Mexico and held its southern parts, and he was able to convok a congress and issue a constitution. But he also was captured, and executed at Mexico City in 1814. Though revolutionary movements still continued, by 1817 only one leader, Vincente Guerrero, was left in the field. But in March 1820 the Spanish constitution, repudiated by King Fernando VII. soon after his restoration, was restored after a military rising in Spain. It was promulgated in Mexico, and the ecclesiastics and Spaniards, fearing that a Liberal Spanish government would force on them demoralization, toleration and other changes, induced Augustin de Iturbide, who had already been conspicuous in suppressing the risings, to take the field in order to effect what may be called a reactionary revolution.

### III. — Independent Mexico.

Thenceforward, till the second election of Porfirio Diaz to the presidency in 1884, the history of Mexico is one of almost continuous warfare, in which Maximilian’s empire is a mere episode. The conflicts, which may at first sight seem to be merely between rival generals, are seen upon closer examination to be mainly (1) between the privileged classes, i.e. the church and army, and the new middle class, and (2) between Centralists and Federalists, the former being identical with the army, the church and the supporters of despotism, while the latter represent the desire for republicanism and local self-government. Similar conflicts are exhibited, though less continuously, by most of the other Spanish-American states. On both sides in Mexico there was an element consisting of honest doctrines; but rival military leaders exploited the struggles in their own interest, sometimes taking each side successively, and the instability was intensified by the extreme poverty of the peasantry, which made the soldiery reluctant to return to civil life, by the absence of a regular middle class, and by the concentration of wealth in a few hands, so that a revolutionary chief was generally sure both of money and of men. But after 1884 under the rule of Diaz, the Federal system continued in name, but it concealed in fact, with great benefit to the nation, a highly centralized administration, very intelligent, and on the whole both popular and successful—a modern form of rational despotism.

Iturbide eventually combined with Guerrero, and proclaimed the "Plan of Iguala," which laid down, as the bases of the new state, the maintenance of the Roman Catholic religion and the privileges of the clergy, the establishment of a limited monarchy, and equality of rights for Spaniards and native-born Mexicans. Iturbide sought the co-operation of the viceroy Apodaca, who, however, refused; but he was presently superseded by General O’Donojö, who, being unable to get beyond Vera Cruz, recognized the independence of Mexico. O’Donojö shortly afterwards died; the Spanish government repudiated his act; and Spanish troops held the fortress of San Juan de Ulúa, off Vera Cruz, till 1827. A provisional Junta, nominated by Iturbide, issued a declaration of independence (Oct. 1821), and nominated a regency of five, with Iturbide as its president. The first Mexican Congress met on the 24th of February 1822. A section of it favoured a republic; another, monarchy under Iturbide; another, which was broken up by the refusal of Spain (continued until 1836) to recognize Mexican independence, monarchy under a Bourbon prince. A conflict now arose between the republican majority and Iturbide, which was settled by a military pronouncement in his favour, and the Congress elected him emperor. He was crowned on the 29th of July 1822. Fresh conflicts broke out between him and the Congress, and Antonio Lopez de Santa Anna, captain-general of Vera Cruz, proclaimed a republic, promising to support the Plan of Iguala. He was defeated at Jalapa and driven to Vera Cruz; but the army deserted Iturbide, who was compelled to abdicate (April 19, 1823). The Congress deported him to Italy, and granted him a pension. He returned almost immediately, on the pretense that Spain was intriguing against Mexican independence, and on landing (having been previously outlawed) was arrested and executed (July 1, 1824).

The Congress had meanwhile undone much of his work, and had divided into Federalists and Centralists, the latter largely Monarchists and Freemasons. The Federalists were strong enough to secure the adoption of a constitution (Oct. 4, 1824) modeled on that of the United States, with additional clauses, notably one declaring the Roman Catholic religion to be alone recognized. A source of abundant discord was opened by the provision that each state should contribute its quota to the Federal revenues. No proper statistical basis for estimating the quotas existed, and the device gave each state a plausible reason for attempting secession on occasion. Moreover, the capital and some territory round it was made into a "Federal district"—another grievance intensifying the antagonism of the state to the central power. The Freemasons had been largely instrumental in overthrowing Iturbide; they now divided into the Escoceses (lodges of the Scottish ritual), who were Monarchist and Centralist, and the Yorkinos, who took their ritual from New York, and their cue, it was alleged, from the American minister, Joel Poinsett. An attempt at revolt, headed by Nicolas Bravo, vice-president, the Grand Master of the Escoceses, was suppressed, but dissensions ensued in the Yorkino party between the followers of President Guerrero (a man largely of native blood, and the last of the revolutionary leaders) and of Gomez Pedraza, the war minister. A conflict broke out, the guerrilleros were victorious, and the pillage of foreign shops in Mexico City (1828), among them that of a French baker, gave a basis for the foreign claims which, ten years later, caused the "Pastry War" with France. Meanwhile, attacks on Spanish ships off Cuba by a Mexican squadron, commanded by an American, David Porter, had induced Spain to send an expedition to reconquer Mexico (1829) which was checked at Tampico by Santa Anna. During the invasion Vice-President Antonio Bustamante declared against President Guerrero; the bulk of the army supported him. Guerrero was deposed, and his partisans in the south were defeated at Chilpancingo (Jan. 2, 1831); and Guerrero, retreating to Acapulco, was enticed on board an Italian merchant-ship, and treacherously seized, tried and executed (Jan.–Feb. 1831). Next year, however, a revolt broke out against Bustamante, which was joined by Santa Anna, who was proclaimed president. A new constitution was enacted, but dissensions in favour of Gomez Pedraza. He, and his successor, Vice-President Gomez Farias (1833), assailed the exemption of the clergy and of military officers from the jurisdiction of the civil courts, and the latter attempted to laicize higher education and to relax monastic bonds. Santa Anna took advantage of the situation to assume the presidency. He eventually became dictator, dissolved Congress (May 31, 1834) and the Díctator, 1832–1835, 1846–1847, 1855–1857, and substituted creatures of his own for the governors of the states and mayors of towns, then retiring into private life. A new Congress, having resolved to set up a new constitution, assembled, followed up this Centralist policy (Dec. 30, 1836) by framing a new constitution, the Siete Leyes or Seven Laws, which converted the states into departments, ruled by governors appointed by the central authority, and considerably reduced popular representation. Antonio Bustamante became the first president under it. The French claims set up by the pillage of foreign shops in Mexico had, however, remained unsatisfied, and in 1838 a French fleet blockaded the coast, bombarded the fortress of San Juan de Ulúa, off Vera Cruz, and occupied the town. The Mexican government gave way, threatened by Federalist risings and secessions of states, which culminated in 1841. Santa Anna appeared, nominally as a
mediator, and put forward the bases of Tacubaya (Sept. 25, 1841), abolishing all the Six Laws except the part relating to the judicial system, arranging for a constituent assembly, and observing for the president the power of re-organizing the administration. The Centralist government, after a vain attempt to defeat him by professing a more thorough Federalism, gave way to force, and Bustamante was allowed to leave the country. But the new Congress was too Federalist for Santa Anna, and he retired, leaving the reins to Nicolas Bravo, under whom a new Centralist constitution was established (1843). This expressly retained the privileges of the clergy and army, and was in some respects more anti-Liberal than that of 1836. But new complications were now introduced by the question of Texas. Though a state of the Mexican Union, it had been settled from the United States in consequence of a land grant given by the Spanish viceroys to Stephen Austin in 1820, and had been estranged from Mexico partly by the abolition of slavery under a decree of President Guerrero, and partly by the prospect of the Centralist constitution of 1836. It then seceded. Santa Anna attempted to reduce it, showing great severity, but was eventually defeated and captured by Houston at the battle of San Jacinto, and consented to sign a treaty recognizing Texas independence, which was disavowed on his return to Mexico. A state of war thus continued nominally between Mexico and its seceded member, whose independence was recognized by England, France and the United States. The slaveholders in the United States favoured annexation of Texas, and pressed the claims due from Mexico to American citizens, partly perhaps with the aim of forcing war. Most of these claims were settled by a mixed commission, with the king of Prussia as umpire, in 1840–41, and a forced loan was raised to pay them in 1843, which stimulated the revolt of Paredes against Santa Anna, who had returned to power in 1834. It resulted in Santa Anna's downfall, imprisonment at Perote and eventual exile (Dec. 1844 to Jan. 1845), and the election of General José Joaquín Herrera as president. But Herrera was displaced in the last days of 1845 by a pronunciamento in favour of Paredes, who undertook to uphold the national rights against the United States, and who was elected president on the 3rd of January 1846. Texas had meanwhile applied for admission into the American Union. The annexation, rejected in 1843, by the United States Senate, was sanctioned on the 1st of March 1845, and carried out on the 22nd of December 1845. The Mexican minister withdrew from Washington, and both sides made active preparations for war.

The United States forces were ordered by President Polk to advance to the Rio Grande in January 1846. They established a depot at Point Ysabel (behind the opening of Brazos Santiago), and erected a fort in Texas territory, commanding Matamoros, on the Mexican side of the Rio Grande. This provoked the Mexican forces into a defensive invasion of Texas, to cut the American communications with Point Ysabel. They were, however, defeated at Palo Alto (May 8) and Resaca de la Palma (May 9). There was an outburst of warlike feeling in the United States (with a counter-movement in the North), and an invasion of Mexico was planned by three routes—from Matamoros towards Monterey in New Leon, from San Antonio de Bexar to Chihuahua, and from Fort Leavenworth to New Mexico. Importance attaches chiefly to the movements of the first force under General Zachary Taylor. During the war preparations President Paredes, suspected of intriguing to overthrow the Republic and set up a Spanish prince, had to give place to his vice-president Bravo. But his turn gave way before Santa Anna, who was hastily recalled from his exile at Havana to assume the presidency and the conduct of the war (Aug. 1846). He was allowed by the American squadron blockading Vera Cruz to pass in without hindrance. Probably it was thought his presence would divide the Mexicans.

The preparations of the United States took some months. It was not till the 5th of September 1846 that General Zachary Taylor could leave his depot at Camargo on the Rio Grande, and march on Monterey. It was taken by assault on the 23rd of September; Santa Anna was defeated at Buena Vista (near Saltillo) on the 23rd of February 1847, and forced back on San Luis Potosi. New Mexico was occupied without opposition; Chihuahua was occupied, but not held, owing to the difficulties in maintaining communications; and Upper California was seized in the autumn of 1846 by John C. Fremont, who had been exploring a route across the continent, and by the United States Pacific squadron, and made secure by the aid of the New Mexico expedition. But as Mexico still continued to fight, it was determined to reach the capital via Vera Cruz. The city was invested by land (March 7 to 29, 1847), and after winning the battle of Cerro Gordo (April 18), and a long delay at Puebla, Scott marched on Mexico City, stormed its defences against greatly superior forces, and effected an entrance after severe fighting on the 13th of September 1847. This virtually ended the war; Santa Anna was deprived of his command, and the treaty of Guadalupe Hidalgo, concluded on the 2nd of February 1848, ceded to the United States Texas, New Mexico and Upper California, in return for a payment of $15,000,000 by the United States to Mexico, and a substitution of liability by it for the claims of its subjects which it had hitherto been pressing against Mexico. This payment was doubtless intended to strengthen the United States title to the conquered territory. It is generally admitted that Mexico was provoked into aggression in order that additional territory might be available for the extension of slavery.

The American forces were withdrawn in May and June 1848 after the ratification of the treaty by Mexico. Under the presidency of Herrera (1848–1851) attempts were made to restore order and the public credit. An arrangement was effected with England, but with Mexican stock; a treaty was signed for the abandonment of all claims. But the financial situation was desperate; the federal revenue, mostly from customs—which were evaded by extensive smuggling—was not half the expenditure; and Indian revolts in Yucatan (1847–1850) and in the Sierra Gorda had added to the strain. Arista succeeded Herrera as president (Jan. 1851), but resigned in July 1852.

After a short interregnum (Jan.–March 1852) Santa Anna was recalled (by a vote of the majority of the states under the Plan of Arroyojarco, on the 4th of February 1853, the result of a pronunciamento), and made dictator in the interests of federation. His measures, partly inspired by an able Conservative leader, Lucas Alaman, proved strongly Centralist: one is especially noteworthy, the establishment of the ministry of "fomento," or encouragement to public works, education, and intellectual and economic development, which is a conspicuous aid to Mexican welfare to-day. He also negotiated (at the end of 1853) the sale of the Mesilla valley (now Arizona) to the United States, but the purchase money was soon dissipated. On the 16th of December 1853 Santa Anna issued a decree making himself dictator, with the title of supreme highness. On the 1st of March 1854, at Ayutla in Guerrero, a section of the army under Colonel Villarreal proclaimed the Plan of Ayutla, demanding Santa Anna's deposition and the establishment of a provisional government to secure a new constitution. Among the leaders in the movement were Generals Alvarez and Comonfort, and it is said that Porfirio Diaz, subsequently president, then a young soldier, made his way to Benito Juarez, then in prison, and arranged with him the preliminaries of the revolt. It spread, and Santa Anna left the country (Aug. 1854).

Two filibustering expeditions at this time—one by William Walker, afterwards notorious in Nicaragua, in Lower California

1 Santa Anna tried to get back to politics in Mexico after Maximilian's fall, without success. He was assassinated with other exiles in 1874, and died in obscurity in 1876.
**MEXICO**

(Dec. 1853), the other by Count Rauusset de Boulbon in Sonora (July 1854)—added to the general disorder.

The provisional president, General Carrera, proving too Centralist, was replaced by Alvarez (Sept. 24, 1855), two of whose ministers are conspicuous in later history—Ignacio Comonfort, minister of war, and Benito Juarez, minister of finance. Juarez and his friends were shot, with Valentins blood.

Benito Juarez.

The son of a Zapotec peasant in a mountain village of Oaxaca, he was employed as a lad by a bookbinder in Oaxaca city, and aided by him to study for the priesthood. He soon turned to the law, though for a time he was teacher of physics in a small local college; eventually went into politics, and did excellent work in 1847 as governor of his native state. Juarez almost immediately secured the enactment of a law (Ley Juarez, Nov. 23, 1855) subjecting the clergy and the army to the jurisdiction of the ordinary courts. Benefit of clergy was the curse of Mexico. Officers and soldiers could be tried only by courts-martial, the clergy (including numbers of persons in minor orders, who were practically laymen) only by ecclesiastical courts. The proposed reform roused the Clericals to resistance. Alvarez gave place (Dec. 8, 1855) to his war minister Comonfort, who represented the less anti-Clerical Liberals. He appointed a commission to consider the question of draining the valley of Mexico, which adopted the plan ultimately carried out in 1890-1900; suppressed a Clerical rising in Puebla (March 1856), which was punished by a considerable confiscation of church property; sanctioned a law releasing church land from mortmain, by providing for its sale, for the benefit, however, of the ecclesiastical owners (called after his author Miguel Lerdo de Tejada, brother of the subsequent president), and a new draft constitution, largely modelled on that of the United States (Feb. 5, 1857). The clergy protested violently, and the Plan of Tacubaya (Dec. 17, 1857), which made Comonfort dictator, provided for the construction of a new constitution under his auspices. He was presently displaced by a thorough reactionary, General Zuloaga, and expelled from Mexico early in 1858; and for three years Mexico was a prey to civil war between two rival governments—the Republicans at Vera Cruz under Juarez, who, as Chief Justice of the Supreme Court, succeeded Comonfort; and the reactionaries at the capital. The latter were at first presided over by Zuloaga, who, proving incompetent, was replaced at the end of 1858 by Puezuela, who early in 1859 gave place to Miguel Miramón, a young, able and unscrupulous soldier who was shortly afterwards accepted as “constitutional” president by his party. The Juarists were defeated outside the city of Mexico twice, in October 1858 and on the 11th of April 1859.

Miramón.

On the second occasion the whole body of officers, who, according to the authorities of the United States, had authority, if not by his express orders, together with several surgeons (including one Englishman, Dr Duval) (the fifty-three “martyrs of Tacabuya”). This atrocity caused great indignation in Mexico and abroad: the reactionists were divided; their financial straits were extreme, as the Juarists held all the chief ports. Juarez was recognized by the United States, and allowed to draw supplies of arms and volunteers thence; and in July 1859 he published laws suppressing the religious religions, nationalizing ecclesiastical property (of the estimated value of $45,000,000), establishing civil marriage, etc.; registration, transferring the cemeteries to civil control, and, in short, disestablishing the church. But the apparent hopelessness of any ending to the conflict, together with the frequent outrages of both parties on foreigners, afforded strong reasons for foreign intervention. Early in 1859 President Buchanan had recommended the step to Congress, which did not respond. On the 11th of December 1859 the McLean-Juarez treaty was concluded, which gave the United States a sort of disguised protectorate over Mexico, with certain rights of way for railroads over the Isthmus of Tehuantepec and between the Rio Grande and Pacific. The American Senate, however, refused to ratify the treaty, and a motion for its reconsideration late in 1860 came to nothing, owing to the approach of the War of Secession.

When Napoleon III. was in captivity at Ham he dreamed of a Central America civilized and opened up to modern enterprise by a transoceanic canal; and the clerical refugees in Paris, among them Labastida, archbishop of Mexico, easily influenced the Empress Eugénie, herself a Spaniard, to interest her husband in the cause of centralized monarchy and the church: it is said that even in 1859 they had thoughts of setting up the Archduke Maximilian as ruler of Mexico.

The question of a joint intervention of Great Britain, France, Spain and Prussia was mooted between those powers in 1860. Early in 1859 the outrages on British subjects had caused the British minister to break off diplomatic relations. Forced contributions had been levied by 1860. Both sides on goods or bullion, being European property, the reactionaries being the worst offenders; and there were numerous cases of murder and robbery of Europeans. At last, on the 17th of November 1860, Miramón, under the plea of necessity, seized $630,000 in specie which had been left under seal at the British Legation and was intended for the bondholders. On the 22nd of December 1860 his forces were routed by the Juarist general Ortega at Arroyoazarco, and his government was overthrown.

Juarez entered Mexico City on the 11th of January 1861. He soon found that his government was held responsible to Europe for the excesses of its rival as well as its own. Miramón’s government had violated the British Legation; the Spanish minister, the papal nuncio and the representatives of Guatemala and Columbia were expelled from the country for undue interference on behalf of the reactionaries. The British loan were suspended by Juarez’s Congress in July 1861; and various outrages had been committed on the persons and property of Europeans for which no redress could be obtained. The French chargé d’affaires, Dubois de Saligny, who had been sent out in November 1860, urged French intervention, and took up the Jecker claims. Jecker, a Swiss banker settled in Mexico, had lent Miramón’s government in 1859 $750,000 (subject, however, to various deductions); in return, Miramón gave him 6% bonds of the nominal value of $15,000,000 which were ingeniously disguised as a conversion scheme. Jecker had failed early in 1860, Miramón was overthrown a few months later. Jecker’s creditors were mostly French, but he still held most of the bonds, and there is reason to believe that he won over Dubois de Saligny by corrupt means to support his claims. Intercepted correspondence (since confirmed from the archives of the Tuileries) showed that the Duc de Morny promised Jecker his patronage in return for 30% of the profits (De la Gorce, Histoire du Second Empire, IV. c. 1). An imperial decree naturalized Jecker in France, and Napoleon III. took up his claim. A convention between Great Britain, France and Spain for joint interference in Mexico was signed in London on the 31st of October 1861. A separate arrangement of the British claims was negotiated by Juarez, but rejected by the Mexican Congress, November 1861; and the assistance of the United States with a small loan was declined, Mexican territory being demanded as security. On the 14th of December Vera Cruz was occupied by Spanish troops under General Prim; the French fleet and troops arrived soon after, with instructions to seize and hold the Gulf ports and collect the customs for the three Powers till the money due from Spain for the French intervention in Mexico was paid. The convention of Soledad was concluded with the Mexican government, permitting the foreign troops to advance to Oaxaca and incidentally recognizing Mexican independence. But as the French harboured leaders of the Mexican reactionaries, pressed the Jecker claims and showed a disposition to interfere in Mexican domestic politics, which lay beyond the terms of the joint convention, Great Britain and Spain withdrew their forces in March 1862. More troops were sent from France. Their advance was checked by Zaragoza and Porfirio Díaz in the battle of Cinco de Mayo, on the 5th of May 1862; and in September of that year 30,000 more French troops arrived under General Forey. Wintering at Oaxaca, they recommended their advance
MEXICO

(Feb. 17, 1863), besieged and reduced Puebla, and entered Mexico City on the 7th of June. A provisional government of Mexicans, French-supported and assumed indirectly by Dubois de Estévez, Saligray, adopted monarchy, offered the crown to Maximilian of Austria, brother of the Emperor Francis Joseph, and he refused, left its disposal to Napoleon III. Maximilian, after some difficulty as to renouncing his right of succession to the throne of Austria, accepted the crown which subject to the approval of the Mexican people, the Emperor, with the proviso that he should return to Rome, reached Mexico City on the 12th of June 1864. Juarez, however, had meanwhile had set up his capital, first in Saltillo, then in Chihuahua. The new empire was unstable from the first. Before Maximilian arrived the provisional government had refused to cancel the sales of confiscated Church lands, which the clericals demanded. When he came, a host of new difficulties arose. A new loan, nominally of about eight millions sterling, but yielding little more than four, owing to discount and commission, was raised in Europe, but no funds were really available for its service. Maximilian carried the elaborate etiquette of the court of Vienna to Mexico, but favouring toleration of Protestantism, and the suppression of the Church, he was too liberal for the clericals who had set him up. As a foreigner he was unpopular, and the regiments of Austrians and Belgians which were to serve as the nucleus of his own army were more so. His reforms, excellent on paper, could not be carried out, for the trained bureaucracy necessary did not exist. For a time he nominally held sway over about two-thirds of the country—roughly, from lat. 18° to 23°, thus excluding the extreme north and south. Oaxaca city, under Porfirio Diaz, capitulated to Bazaine—who had superseded the pro-clerical Forey in October 1864—in February 1865, and by the autumn of that year the condition of the Juarists in the north seemed desperate. But the towns asked for permanent French garrisons, which were refused, as weakening their own power of self-defense. Instead, the country was traversed by flying columns, and the guerillas dealt with by a French service of "contre-guerilla," who fought with much the same savagery as their foes. Directly the French troops had passed, Republican bands sprang up, and the non-combatant Mexicans, to save themselves, could only profess neutrality. Yet on the 3rd of October 1865, Maximilian, misled by a false report that Juarez had left the country, issued a decree declaring the Juarists guerillas, who, whenever captured, were to be tried by court-martial and shot. Mexican generals on both sides had done as much. But Maximilian's decree prepared his own fate.

The American Civil War ended in the spring of 1865, and a strong popular feeling was at once manifested in favour of asserting the Monroe doctrine against Maximilian's government. In the summer there were threatening movements of United States troops towards the Rio Grande; early in 1866, Maximilian, deserted by Napoleon III, announced his intention of withdrawing France's forces; in response to a note of Seward, the United States secretary of state, of the 13th of February 1866, he was induced to promise their return by three instalments—in November 1866, March and November 1867. Maximilian now turned for support to the Mexican clericals; mediated abdication, but was dissuaded by his wife Charlotte, the daughter of Leopold I. of Belgium (and "the better man of the two," as he had once jestingly said), who went to intercede for him with the emperor of the French. Finding him obdurate, she went on to appeal to the pope; while at Rome she went mad (end of September 1866).

Maximilian had meanwhile drawn nearer to the clericals and farther from the French, and, to protect French interests, Napoleon III. had decided to send out General Castelnau to supersede Bazaine, arrange for the withdrawal of the French forces in one body, and restore the Republic under Ortega, who had quarrelled with Juarez, and was therefore, of all republicans, least popular with the clericals. But fearing the prospect, they induced Maximilian, who had retired to Orizaba for his health, to remain. He yielded on condition that a congress of all parties should be summoned to decide the fate of the empire. Hereupon he returned to the capital; the Juarist dominion extended rapidly; the French troops left (in one body) on the 5th of February 1867, and shortly after Maximilian took command of the army at Querétaro. Here, with Miramon, he was besieged by the Juarists under Escobedo, and the garrison, when about to make a last attempt to break out, was betrayed 1 by Colonel Lopez to the besiegers (May 15, 1867). Execution of Maximilian, with the Mexican generals Melo and Mejia, was tried by court-martial, and, refusing (or neglecting) to avail himself of various opportunities of escape, was convicted on charges which may be summarized as rebellion, murder and brigandage, on the 14th of June, and shot, with Miramon and Mejia, on the 19th of June 1867, despite many protests from European governments and prominent individuals, including Garibaldi and Victor Hugo. (An effort to save him made by the U.S. Government was frustrated by the dilatoriness of the U.S. Minister accredited to Juarez's Government.) After considerable discussion, the Republican Government, his bones brought to Europe.

Meanwhile Porfirio Diaz had captured Puebla (April 2) and besieged Mexico City, which fell on the 21st of June. The last Anti-Juareist stronghold (Inayarat) submitted on the 20th of July 1867. A good deal of discontent existed among the republican rank and file, and Juarez's election in October to the presidency was opposed by Diaz's friends, but without success. But so soon as Juarez was elected, insurrections broke out, and brigandage prevailed throughout the following years. There were two unsuccessful insurrections also in 1869 (clerical) and 1870 (republican), but an amnesty, passed on the 13th of October 1870, helped to restore peace; trouble again arose, however, at the 1871 election, at which the candidates were Juarez, Sebastian Lerdo de Tejada and Diaz. Juarez's continued re-election was regarded as unconstitutional, and no party obtaining a clear majority, the matter was thrown into Congress, which elected him. Diaz's supporters refused to recognize him, and a revolution broke out, which went on sporadically till Juarez's death on the 18th of July 1872, Sebastian Lerdo de Tejada, as president of the Supreme Court, succeeded him, and annulled the rebels, but made no further concessions. In the next year, however, laws were passed repeating in a stronger form the attacks of 1857 on the supremacy of the Church, and prohibiting monastic life. The first day of 1873 was marked by the opening of the Vera Cruz & Mexico railway. Protestant missions established themselves (with some opposition) in the country, and diplomatic relations were renewed with France and Spain (1874). But towards the close of Lerdo de Tejada's term he was suspected of aiming at a dictatorship, and Diaz, whom he had proscribed, made preparations for a rising, then retiring to Texas. At the beginning of 1876 the revolution broke out in Oaxaca with the plan of Tuxtepec, which was adopted by Diaz, and proclaimed as the plan of Palo Blanco (March 21). Diaz's attempt to raise the north, however, failed, and, trying to reach Vera Cruz by sea, he was recognized on the steamer, and recaptured while attempting a four-mile swim ashore. The purser, however, made it appear that he had again jumped overboard, concealed him for some days—generally inside one of the saloon sofas—and helped him to get ashore in disguise at Vera Cruz. He then escaped to Oaxaca and raised a force. Lerdo was declared re-elected, but was overthrown by Diaz after the battle of Tecoac (Nov. 16, 1876) and forced into exile (Jan. 1877), and Diaz was declared president on the 2nd of May 1877. A law forbidding the re-election of a president till three years had elapsed from his retirement from office was passed in the autumn of that year.

1 Lopez said he acted as Maximilian's agent, but his story rested on an alleged letter from Maximilian which was discredited as a forgery. The evidence of his treason was published in El Nacional of Mexico, Sept. 11, 1887.
Diaz's first presidency (1876–1880) was marked by some unsuccessful attempts at revolution notably by Escobedo from Texas in 1878, and by a more serious conspiracy in 1879. Diplomatic relations were resumed with Spain, Germany, Italy and some South American states (1879), and France (1880). The treaty of 1880 formally recognized the United States and with Guatemala, which revived a claim dropped since 1858 to a portion of the state of Chiapas; and there was considerable internal unrest, aided by a too liberal policy of subsidies to railways and even to lines of steamships. The boundary questions were settled under President Gonzalez (1880–1884); relations with Great Britain were renewed in 1884. The claims of the railways, however, necessitated reenforcement on official salaries, and the president's plan for, conversion of the debt roused unexpected and successful opposition in an ordinarily subservient Congress. At the end of 1884 Porfirio Diaz was again elected president, and was continually re-elected, the constitution being modified expressly to allow him to continue in office.

The history of Mexico from 1884 to 1910 was almost void of political strife. President Diaz's policy was to keep down disorder with a strong hand; to enforce the law; to foster railway development and economic progress; to develop native manufactures by protective tariffs; to introduce new industries, e.g. the production of silk and wine, of coca and quinine; to promote forestry; to improve elementary and higher education—for all which purposes the Ministerio del Fomento is a potent engine; to encourage colonization; and, above all, to place the national credit on a sound basis. The first step in this process was a settlement of the British debt by direct arrangement with the bondholders. In 1890 the Spanish bondholders' claims were satisfactorily arranged also. In 1891 the tariff was made more protectionist. In 1893 the deprecation of silver necessitated stringent reenforcement; but the budget balanced for the first time during many years, the floating debt was converted, and a loan raised for the completion of the Tehuantepec Railway. After 1896 substantial annual surpluses were spent in reducing taxation and in the extinction of debt. In 1895 the 6% external debt was converted into a 5% debt, the bonds of which remained at a premium for 1922; in 1896 the alcalabas or interstate customs and municipal alcobas were abolished, and replaced in part by direct taxation and increased stamp duties.

The institution by Diaz of the guardias rurales, a mounted gendarmerie composed of the class who in former days drifted into brigandage, pacified to a great extent the interior of the country, and telegraphs enabled the government to cope at once with any disturbance. The old local revolutions practically disappeared. In 1886–1887 there were some disturbances in Coahuila, New Leon, Sinaloa and Tamaulipas; subsequently hardly anything was heard of such disorders except on the Texan frontier, where in 1890 Francisco Ruiz Sandoval and in 1891 Catarrino Garza made incursions into Mexico. Occasionally the Church gave trouble—the presence of foreign priests was complained of; attempts to evade the law prohibiting conventual life were detected and foiled (1891, 1892); and in 1893 a number of rising, especially in the Mayas of Ucayactan, whose last stronghold was taken in 1891, and the Yaque of Sonora (1890–1900). Under federal and democratic forms, Diaz exercised a strictly centralized and personal rule. He was invited to approve the candidates proposed for state governorships; in all law cases affecting the Government or political matters the judges asked his opinion; he drafted bills, and discussed their text with individual members and committees of congress. Similarly, the state legislatures, as well as the judges and municipal officers, were actually or virtually selected by the state governors, who were practically agents of the president. Now and then the old passions broke out: in September 1898 an absurd attempt to assassinate President Diaz was made by a countryman named Arroyo, but discontent with Diaz's rule was apparently confined to a small minority. In 1900 there were some disquieting symptoms. Owing to Diaz's age the vice-presidency had been revived in 1904, and Don Ramon Corral elected to it; but at the elections of 1909 a movement arose in favour of replacing him by General Bernardo Reyes, Governor of Nuevo Leon, but he was defeated in his opposition from the surplus wealth of the military systems of Europe. It was, therefore, regarded as certain that, should President Diaz die in office, Señor Corral would succeed him without serious difficulty.

In foreign affairs the rule of Diaz was uneventful. There were transient disputes with the United States (1886, 1888). In 1888–1890 and 1894–1895 a boundary dispute with Guatemala became serious. But Guatemala gave way at the threat of war (Jan. 1895) and a new treaty was made (April 1, 1895). Again in 1907 there was some friction owing to the murder of a Guatemalan ex-president by a compatriot in Mexico: later in the year, however, the Mexican government was active in stopping a war between its Central American neighbours. In the difficulty between England and the United States over the Venezuelan boundary (Dec. 1895) Mexico expressed strong adherence to the Monroe doctrine in the abstract, and suggested that its maintenance should not be left wholly to the United States, but should be undertaken by all American Powers. The first Pan-American congress met in Mexico City in 1901, and the country was represented at the second, held in Rio Janeiro in 1906. Mexico also took part in establishing the permanent Central American Court of Arbitration, inaugurated on the 25th of May 1908 at Cartago, Costa Rica, under the Washington treaties of December 1907, and showed readiness to associate herself with the Government of her great northern neighbour in preserving peace among the Central American States. On the 17th of October 1909 President Talt and President Diaz exchanged visits at the frontier at El Paso, Texas.

In brief, under President Diaz's rule the history of Mexico is marked by the development of the six financial years 1893–1894 to 1899–1900 inclusive the yield of the import duties increased by upwards of 86%; the revenue from stamps over 60%, though the duties were reduced; the postal revenue from 1895–1896 to 1899–1900 rose 60%; the telegraph revenue over 75%. Again, in 1898–1899 the total ordinary revenue of the state was $6,013,921; in 1905–1906 it had increased to $11,428,612, or by more than 90%, and though 1907–1908 was a year of depression its total revenue ($17,177,180) exceeded that of any year save its immediate predecessor. The great drainage scheme which completed the second, or the 17th of Diaz's administration, the conversion of the southern lakes of the valley of Mexico was devised in 1856, begun under Maximilian, proceeded with intermittently till 1885, then taken up with improved plans, practically completed by 1896, and inaugurated in 1900; the harbour of Vera Cruz was finished in 1902; the Tehuantepec railway, likely to prove a formidable rival to any interoceanic canal, was opened on the 24th of January 1906. All three were the work of an English firm of contractors, the head of which was Sir William Pearson. American, and later Canadian, capital and enterprise have also been very largely concerned in the development of the country; economic progress was not permanently interfered with by the great earthquakes of April 1907 and July 1909 at Acapulco, and the floods in August 1910 at Monterey. In 1891 elementary education was reorganized, and made compulsory, secular and gratuitous. Great attention has been paid to higher education, and—in at least in the hospitals—to modern sanitation and hygiene.

Authorities.—For English readers the standard work is H. H. Bancroft, Collected Works (Histories of the Pacific States, Central America, &c., vols. x.–xiv. (Mexico, 1852–1887) with vols. xv., xvi. of the American Historical Association, the Collected works of the works see J. B. Bodley in Proceedings of the Institution of Civil Engineers, cxxiii. 286, sqq.

1 Don Augustin Icurbide, grandson of the emperor, godson and (perhaps) at one time the destined heir of Maximilian, was turned out of the army and imprisoned in 1880 for abusing President Diaz.

2 A full account of the works see J. B. Bodley in Proceedings of the Institution of Civil Engineers, cxxiii. 286, sqq.
MEXICO—MEXICO CITY

Lake Xochimilco is celebrated for its "floating gardens" or chinampas (see MEXICO, FEDERAL DISTRICT OF). The principal industries of the state are agricultural, and the principal products are cereals, sugar, maizy (from which pulque is made), coffee, and fruit. Stock-raising also has been profitable in the development, owing to the smallness of the national capital. The manufacturing industries are important; among the manufactures of cotton and woollen fabrics, flour, dairy products, glassware, pottery, bricks, wines and spirits. The making of "pulque" from the sap of the maquey plant (Agave americana) is the chief industry of the state, and the product is exported in large quantities to the national capital. The state is traversed by the Central, National, Mexican International and Interocceanic railways, and by short lines from the national capital to neighbouring towns. The capital is Toluca, and other important towns are Zumpango (pop. 9424 in 1900), 36 m. of the national capital, Tenango del Valle (681 in 1900), 15 m. S.E. of Toluca, and Lerma (estimated, 7200), near the western frontier of the state.

MEXICO, a city and the county-seat of Audrain county, Missouri, U.S.A., N.E. of the centre of the state, and about 110 m. N.W. of St Louis. Pop. (1890), 4789; (1900), 5099, including 948 negroes and 111 foreign-born; (1910), 5939. It is served by the Chicago & Alton, the Chicago, Burlington & Quincy, and the Wabash railway systems. Mexico is the seat of Hardin College and Conservatory of Music, an institution founded and endowed by Charles H. Hardin (1820–1892), governor of the state in 1872–1874, and of the Missouri Military Academy (1889). The city is situated in the blue grass region of Missouri, and is a shipping-point for horses and mules. Among the manufactures are flour, shoes and fire-clay products. Mexico was laid out as "New Mexico" in 1836, and became the county-seat under its present name in 1857. It was incorporated as a town in 1853, was entered by the Wabash road in 1858 and by the Alton in 1874, and was first chartered as a city in 1874. MEXICO CITY, capital of the Republic of Mexico and chief town of the Federal District, near the southern margin of the great central plateau of Mexico, in lat. 20° 25' 45" N., long. 96° 7' W. It is about 200 m. in a direct line W. by N. of Vera Cruz, its nearest port on the Gulf of Mexico, with which it is connected by two railway lines, one of which is 364 m. long; and about 181 m. in a direct line N.N.E. of Acapulco, its nearest port on the Pacific, with which it is connected partly by rail and partly by a rough mountain trail (the camino real) to the coast. Pop. (1900), 344,721.

MEXICO, a state of the republic of Mexico, bounded N. by Hidalgo, E. by Tlaxcala and Puebla, S. by Morelos and Guerrero, and W. by Michoacán. Pop. (1900), 934,438, large majority of which stands on the state. Area 9247 sq. m., of which 463 sq. m. are devoted to native forest. The most important products are hides which give that great depression of the Mexican plateau known as the Valley of Mexico. Enclosed within its boundaries, except on the south, is the Federal District and capital city of Mexico with an area of 463 sq. m., which is not included in that of the state. The state is divided into two unequal parts by the Sierra de Aguac and Monte de las Cruces, which form a wooded ridge across it from east to west, with a general elevation of about 10,000 ft. above sea-level, or about 2500 above the plateau level. These ranges extend from the central part of the state southwards and are bordered on the west by the mountain range known by the name of Anahuc. A considerable part of this western plateau consists of a broad plain, once the bed of a great lake but now covered with swamps, sodden meadows and lakes. The surrounding country drains into this depression, but an artificial outlet has been created by the opening of the Tequixquiac tunnel. Beyond its margin the plateau drains westward to the Pacific through the Lerma, and north-east to the Gulf through the San Juan and Fánico. South of the Sierra de Aguac the country is the fertile, mountainous and drains to the Pacific through the Leon Valley. The large part of the great depression of the north are the lakes of Zumpango, San Cristóbal, Taltocan, Chalco, Xochimilco, and Texcoco, the latter three lying partly or wholly in the Federal District. Texcoco has the lowest level and its water is brackish and undrinkable, though that of the streams flowing into it and of the other lakes is sweet.
defend its approaches against a greatly superior force. The Chalco and Xochimilco lakes, 8 or 9 m. to the southward, which are separated by a narrow ridge of land, are connected with the lower part of the city by an artificial canal, called “La Viga,” 16 m. wide and 9 ft. deep, which runs along the edge of a relatively low, swampy region through which has been cut an outlet for the water, and in this way the lakes are made to flow into the main valley of the city. Thus, the whole mass of water that collects in the large body of lakes, and is brought to the city in this way, serves as a waterway for the natives who bring in flowers and vegetables for sale. Lake Xochimilco, celebrated for its chinampas, or “floating gardens” (see MEXICO, FEDERAL DISTRICT or), is supplied very largely by fresh-water springs opening within the lake itself, which the city has partially diverted for its own water supply. Lake Chalco is also greatly reduced in size by railway fillings and irrigation works, to the great distress of the natives who have gained their living by fishing in its waters since long before the Spanish conquest.

The climate of the city is temperate, dry, and healthful. The temperature ranges from a minimum of 35° F. in winter to a maximum of 70° in summer. The winter range is 35° to 68°, and the summer 50° to 70°. The nights are always cool. The year is divided into a wet and dry season, the former from April to September, the latter from October to March. The rainfall, however, is light, about 20 to 25 in., but, with the assistance of irrigation, it serves to sustain a considerable degree of cultivation in the neighbourhood of the city. The health of the city, unfortunately, does not correspond with its favourable climatic conditions. With a wet, undrained subsoil and a large population of Indians and half-breeds living in crowsowed fields, the death rate has been notoriously high, though the completion of the Valley drainage works in 1900, supplemented by underground sewers in the better parts of the city, and by better sanitation, have recently improved matters. The annual death-rate per 1000 was 54 per 1000 for the Federal District in 1901, 30 in 1902, 43 in 1903, 46 in 1904, and 36 in 1905; the increase for the last-mentioned year being due to an epidemic of typhus fever.

The city is laid out with almost unbroken regularity and is compactly built—the streets running nearly with the cardinal points of the compass. The new and better residence sections are on the western side; the poorer districts are on the eastern side nearer the swampy shores of Lake Texcoco. As the name of a street changes with almost every block, according to the old Spanish custom, a list of street names is sometimes mistakenly accepted as the number of continuous thoroughfares in the city, so that it has been said that Mexico has 600 to 900 streets and alleys. An attempt was made in 1839 to rename the streets—all running east and west to be calledavenidas, all running north and south to be called calles; later a compromise was made in which each had one name—but the people clung tenaciously to the old names that the government was compelled to restore them in 1907. Outside the Indian districts of the eastern and southern outskirts, the streets are paved with asphalt and stone, lighted with electricity and gas, and served with an efficient street railway service. The commercial and political centre of the city is the Plaza Mayor, or Plaza de la Constitucion, on which face the cathedral, national palace, and municipal palace. Grouped about the Plaza de Santo Domingo are the old convent and church of Santo Domingo, the court of the Inquisition now occupied by the School of Medicine, the offices of the Department of Comunicaciones, and the old custom-house (aduana). Close by are the old church of the Jesuits and the mechanics’ school (aristas y oficios) with its large and well-equipped shops. Among other well-known plazas are: Loreto, on which faces the great enclosed market of the city; Guardiola, in the midst of hand- some private residences; San Fernando, with its statue of Vicente Guerrero; and Morelos, with its marble statue of the national hero of that name. The Paseo de la Reforma, the finest avenue of the city, is a broad boulevard extending from the Avenida Juárez south-west to Chapultepec, a distance of nearly three miles. At intervals are circular spaces, called “glorietas” with statues (the famous bronze equestrian statue of Charles IV., and monuments to Columbus, Cuauhtemoc the last of the Aztec emperors, and Juárez). Other notable avenues are: Bucareli and Juárez, and the Avenida de la Viga, which skirts the canal of that name. The principal business streets runs westward from the Plaza Mayor toward the Alameda, and is known as the Calle de los Plateros (Silversmiths’ Street) for two squares, Calle de San Francisco for three squares, and Avenida Juárez along the south side of the Alameda to its junction with the Paseo. The Alameda, or public garden, ½ m. west of the Plaza Mayor, covers an area of 40 acres, and occupies the site of the old Indian market and place of execution, where occurred the first auto-da-fé in Mexico in 1574.

The great cathedral stands on or near the site of the Aztec temple (teocalli) destroyed by Cortés in 1521. The foundations were laid in 1573, the church was finished in 1615, the roof was finished in 1625, its consecration took place in 1655 and dedication in 1667, the towers were completed in 1791, and the great church was finished about 1811. It is 426 ft. in length by 197 ft. in width, and its towers rise to a height of 204 ft. Its general plan is that of a Greek cross, with two great naves and three aisles, twenty side-chapels and a magnificent high altar supported by columns and surmounted by a tambóculo balustrade with sixty-two tambóculo statues carrying elaborately carved candelabres made from a rich alloy of gold, silver and copper. The elaborately carved choir is also enclosed by tambóculo railings made in Macao, weighing 26 tons. The vaulted roof is supported by twenty Doric columns, 180 ft. in height, and the whole interior is richly carved and gilded. The walls are covered with rare paintings. Standing close beside the church is the highly ornamented façade of a smaller church called El Sagrado Mayor, which contains several of the finest edifices, including La Profesa, Loreto, Santa Teresa, Santo Domingo and San Hipólito. At the time of the secularization of Church property, these were among the largest religious foundations in the city, churches, convents, monasteries, &c.,—many of which were turned over to secular uses.

The national palace, also on the Plaza Mayor, has a frontage of 600 ft. on the east, and cover nearly 7 acres, or nearly 40,000 yds., or nearly 10 acres. It contains the executive offices of the government and those of five cabinet ministers (interior, foreign affairs, navy, war, and justice; the senate chamber, the general archives, national museum, observatory and meteorological bureau. The palace occupies the site of the residence of Moctezuma, which was destroyed by the Spaniards, and that of Hernando Cortés, which was also destroyed. The city, carrying on the “liberty bell” of Mexico, first rung by the humble parish priest Hidalgo, on the night of the 16th of September 1810, to call the people of Dolores to arms, and now rung at midnight on each recurring anniversary by the president himself. The national museum, which occupies the east side of the national palace, is rich in Mexican antiquities, among which are the famous “calendar stone,” supposed to be of Toltec origin, and the “sacrificial stone” found in the ruins of the great teocalli destroyed by Cortés. Near the cathedral is the monte de piedad, or government pawnshop, endowed in 1775 by Pedro Daza y Bertreras (known as Daza y otros), with the avails of a government loan, and now continuing to carry on a regular banking business including the issue of banknotes. Its business is now limited to the issue of small loans on personal property, and the aggregate sometimes reaching nearly $2,000,000 a month. The jail and chapel in which the Emperor Maximilian, in 1840, after 255,000 volumes, occupies the old St Augustine Church, dedicated in 1692 and devoted to its present use by Juárez in 1867. It also houses the interesting collection of the works of the best Mexican artists. The academy of San Carlos and school of fine arts (founded in 1778) likewise contains good collections of paintings and statuary.

Among other institutions are the new post office, begun in 1902 and finished in 1907; the Minerva, occupied by the schools of mining and engineering; the military school, occupying a part of the castle of Chapultepec; the Iturbide palace, now occupied as a hotel; the Iturbide theatre, occupied by the chamber of deputies, from a new legislative palace to cost 2,500,000 pesos was under construction in 1909; the new palace of justice; the old mint, dating from 1537; the new penitentiary, completed in 1900; the Pantheon, containing the tombs of famous persons; the national observatory; the national hospital; the jockey club on Plaza Guardiola, a new university (1910) and new school edifices of modern design. The city is likewise generously provided with hospitals and asylums. The Spanish edifices, mainly constructed of stone, and private residences were provided with iron gates and window guards strong enough to withstand an ordinary assault. Private houses were also provided with roofs and chimneys, and in the midst of the old style were commonly of two stories—the ground-floor being occupied by shops, offices, stables and servants’ quarters. The more modern constructions of the Colonia Juárez and other districts are attributed to the influence of Germanic appearance, but are last solidly built.

1 Baedelarer thinks it should be called the “Stone of the Sun.”
MEXICO CITY

Mexico was formerly one of the worst drained large cities of the New World, its subsoil being permanently saturated and its artificial drainage being through open ditches in the San Lazaro Canal which was dug, and for which a grade of 8 ft. per mile was planned. This level between the city and the lake being less than six feet and the lake having no natural outlet, typhus fever became a common epidemic in its lower and poorly scented section. One of the most surprising facts of the history of Mexico is the birth of the Mexican engineer Maertens (Span. Martinez), who planned a deep cutting through the Nanchistongo Hill, north of the city, to carry away the overflow of Lake Zumpango (7493 ft. elevation), in 1833, a tributary of the Tlaxcala River. The cutting was 13 m. long and is known as the Tajo de Nochistongo. It was begun in 1857—a year when the city was completely flooded—but was not completed until 1879, and then it was found that the city was not drained, for the plain to the north was lower than the upticks of money and 70,000 lives of Indian labourers had been expended upon it. The worst inundation in the history of the city occurred in 1926 when the port and 1375 private armmen were lost in the city. All heights remain flooded until 1934. In 1866 President Ignacio Comonfort invited tenders for drainage works conditional on the use of waste waters for irrigation purposes, and the plan executed consists of a canal and tunnel 43 m. long, starting from the eastern hill and 43 ft. below the mean level of the city and running north to Zumpango and thence eastward into a tunnel over 6 m. long, which discharges into a small tributary of the Panuco River near the suburbs of Texcoco. The greatest depth of the tunnel is 308 ft. below the surface.

Considerable attention has always been given to education in Mexico, but in colonial times it was limited in scope, and to the dominant classes. The old university of Mexico, with its schools of theology, law and medicine (founded 1551 and inaugurated 1553), ceased to exist in 1866 and was succeeded by schools of engineering, law, and medicine which have been curiously saved, and the government also maintains schools of agriculture, commerce, fine arts, music, pharmacy, technology, and an admirable preparatory or high school, besides a large number of primary and secondary schools for which modern school buildings have been erected. Normal and industrial schools for both sexes are maintained, the latter (aerias y oficios) performing a very important service for the inferior classes. In 1908 there were 353 government schools in the city, including 13 professional and technical schools, and nearly 200 private schools. There are also several scientific organizations and societies. The Mexican Geographical Society (Sociedad mexicana de Geografia) was founded in 1832, and the Mexican Academy of History (Academia de Historia) in 1853.

The water supply of the city is not wholly adequate. It is partly derived from the Panuco, which passes through the city, and partly from the Tlaxcalan, which is taken through the city at Texcoco and drained into the Panuco to the south. This was needed to provide the Mexican national capital direct communication with the large cities of the country, and the Mexican Southern runs southward, via Puebla, to the city of Oaxaca. These railways, with the shorter lines radiating from the city, connect it with nearly all the state capitals and principal ports.

The population by the census of 1900 was 344,721—an increase of 14,947 over the returns of 1895. The great majority of the inhabitants are of half-breeds, from whom come the factory workers, labourers, servants, porters, and other menial wage-earners. In former times Mexico was overrun with mendicants (pordioseros), vagrants and criminals (rateros), and the name San Luis Potosí or Even to-day is often used as the favourite "hunting-ground" for them because of its proximity to the cathedral; but modern conditions have largely reduced this evil. The foreign population includes many capitalists and industrialists, but is otherwise small. Between the old town and the new, the American colony being concentrated in a fine modern residential district on the south-western side of the city.

History.—The city of Mexico dates, traditionally, from the year 1325 or 1327, when the Aztecs settled on an island in Lake Texcoco. The Aztec name of the city was Tenochtitlán, derived either from Tenoch, one of their priests and leaders, or from TenUCH, the Indian name for the "nopal," which is associated with its foundation. The modern name is derived from Mexicî, one of the names of the god of war Huiztilopochtli, which name was later on applied also to the Aztecs themselves. The island settlement, which was practically a lake-village built on islets—some of them undoubtedly artificial, and perched on stakes—grew rapidly with the increasing power and civilization of its inhabitants, who, besides planting corn, cotton, and other crops, and with the help of an earlier civilization (Toltec), developed a large agricultural, commercial, and manufacturing commerce.

The history of the city is marked by a series of events of great importance. In the 16th century its situation as a hunting-ground for the Aztecs and its general importance made it a centre of Indian population and a starting place for expeditions into the interior. The city was captured by Cortés and other Spanish adventurers in 1519, and the city was founded in 1521. Cortés employed some 400,000 natives in rebuilding the city on its former site. Since then the lake has decreased greatly in extent, its area being reduced to 11 sq. m. and its shore-line being more than 3 m. distant from the city it once surrounded. During Spanish rule the only break in the course of events was the revolt of 1862, which resulted in the destruction of the municipal buildings. The city was not much disturbed by the struggle for independence, although it was largely destroyed in 1521 and 1812.
MEXICO, FEDERAL DISTRICT OF

but it was afterwards the scene of many a revolution until the dictatorial authority of Porfirio Diaz put an end to petty pronunciamentos and partisan intrigues.

Then the war between Mexico and the United States the most decisive campaign was that of General Winfield Scott directed against the Mexican capital. With the advanced guard of an army of about 10,000 men he arrived on the 20th of August 1847 at Aoytle, on the national road 16 m. south-east of the city; but as the approaches from this direction were very strongly fortified he cut a new road southward along the eastern shore of Lake Chalco and westward along the southern shore of lakes Chalco and Xochimilco to San Augustine, where his army arrived on the 17th and 18th of August. The city was now 10 m. distant, and the main Mexican army was driven from the stone church and intrenchments at Churubusco. Three days later General Scott agreed to an armistice, but Mexico rejected the terms of peace, and hostilities were resumed on the 7th of September. During the armistice the American troops were quartered in and about the village of Tacubaya, about 2 3/4 m. west by south of the city. Near Tacubaya, on the north by west, were some massive stone buildings known as El Molino del Rey, or the King's Mill. When attacked by the Americans under the immediate command of General W. J. Worth in the early morning of the 8th of September, they were not attacked by the adjutant Mexican army; they resisted after a desperate fight, which cost the Americans 787 killed and wounded and the Mexicans at least 2000 killed, wounded, and prisoners. To enter the city by way of the Tacubaya causeway it was still necessary for the Americans to capture Chapultepec. This hill, defended by about 4000 Mexicans under General Nicolas Bravo, was bombarded on the 12th of September, and was carried by assault on the 13th. On the following day the City of Mexico surrendered. It was then that the Mexican army under General Winfield Scott, and held by them until the signing of the treaty of Guadalupe-Hidalgo (May 1848).

The French intervention of 1861 led to a second occupation by a foreign power—a French military force under General Forey taking possession in June 1863. Maximilian, archduke of Austria, was crowned emperor of Mexico in the cathedral in June 1864, and held possession of the capital until the 21st of June 1867, when it was captured by General Porfirio Diaz. Earthquake shocks are of frequent occurrence, but the city rarely suffers any material damage. The great earthquake shocks of the 30th and 31st of July 1900, however, caused considerable damage in the city, and a few lives were lost.

For further description see H. H. Bancroft, History of Mexico (6 vols., San Francisco, 1893); Robert S. Barrett, Standard Guide to the City of Mexico and Vicinity (Mexico, 1904); Thomas A. Janvier, The Mexican Guide (3rd ed., New York, 1890); D. Charrán, Ancien Cities of the New World (Eng. ver., New York, 1887); and the Plano de la ciudad de Mexico, in the Diccionario enciclopédico hispano-americano (Barcelona, 1893), xii. 740.

MEXICO, FEDERAL DISTRICT OF

is a territory set apart for the independent and exclusive use of the Mexican Federal Government, occupying the south-eastern part of the Valley of Mexico, and taken from and lying within the State of Mexico, which forms its boundaries on all sides except the south where it touches the state of Morelos. Pop. (1900), 540,478, largely Indian and half-breeds; area, 463 sq. m., or according to later computation 1493 8/10 sq. kilom. (578 3/10 sq. m.). The district is very irregular in outline, its greatest length (N.W. to S.E.) being 30 m., and its greatest breadth 25 m. It was formerly divided into one urban municipality and four rural prefectures, but under the law of the 26th of March 1903 it is divided into 13 municipalities, Mexico, Guadalupe-Hidalgo, Atzcapotzalco, Tacuba, Tacubaya, Mixcoac, Cuajimalpa, San Angel, Coyocacan, Tlalpan, Xochimilco, Milpa Alta and Ixtapalapa; the first of these comprises the national capital and its immediate suburbs, and the other 12 the unequal divisions of the district with a considerable number of towns and villages. Indians and half-breeds form more than one-half of the rural population engaged in agriculture and gardening, beside which there is a large percentage employed in manufacturing industries. The government of the district is exercised by the national executive in accordance with the organic law of 1903, under the presidency of the popular government is vested in municipal councils (ayuntamientos) elected for terms of four years. These councils have lost much of their original legislative character, but they must be consulted in matters of local importance, such as water supply, sanitary works, and the exploitation or sale of municipal property, and in regard to all contracts affecting the municipality. They can veto by a two-thirds vote the execution of any contract or administrative project, which then, at the end of four months, if again vetoed must be taken before the President of the Republic. The director-general of the federal district, the director-general of public works, and the president of the superior board of health. The three form a superior council of district government which exercises a supervisory and advisory power, "reviving, confirming, reforming or revoking the acts of each one of the members of the council, whenever these acts are called in question." The council also exercises a general supervision of the making of contracts. The governor represents the national government, issues ordinances, appoints and dismisses officers, and the executive, who are appointed by the national executive, is charged with the direction of the government, the sanitary administration of markets, slaughter-houses and cemeteries, and the introduction of meats from other localities. The government of the district is copied, in part, from that of the District of Columbia in the United States, but its citizens are not disfranchised. They elect the ayuntamientos, which exercise no slight influence in local affairs, and, like any state, elect senators and deputies to the National Congress.

The principal towns of the district, some of which are merely suburbs of the capital, are Guadalupe, Tacubaya, Tlalpan and Xochimilco. Within the municipal limits of Mexico City are Chapultepec, Santa Ana and the hot springs of El Peñón, which are popular suburban resorts easily reached by the ordinary urban tramway service. Chapultepec (Grasshopper Hill) is an isolated rock nearly 200 ft. high surrounded by a beautiful park and surrounded by a fortified structure called the "Castle," containing the summer residence of the president and the national military school. A finely graded road leads to the summit. The park contains a grove of old cypress trees (Taxodium distichum, called "ahuehuetes" by the natives), one of which is 45 ft. in circumference and nearly 200 ft. high. The hill is nearly 3 m. south-west of the city and once commanded one of its principal causeways. The park is open to the forces under General Winfield Scott on the 13th of September 1847, after a stubborn resistance. A monument to the cadets of the military school who died in this battle stands in the park. The castle, which was built by the viceroys, was twice occupied by the emperor Maximilian, who planned for it the drive known as the Paseo de la Reforma. Of the neighbouring towns Guadalupe or Guadalupe-Hidalgo (pop. 5834 in 1900), 23 m. north by east of Mexico City, near the shore of Lake Texcoco, is famous for its shrine to Our Lady of Guadalupe, who is said to have appeared there to the Indian Juan Diego in 1531. The shrine stands on the
MEXICO, GULF OF—MEYER, J. L.

 Principal plaza and is visited by many thousands of pilgrims during the year, whose pious contributions have so enriched the church that its sacred vessels, altar-vessels, candelabra and other ornaments are as costly as those in any similar establishment in the world. The treaty of peace between Mexico and the United States was signed here on the 2nd of February 1848. Tacubaya (pop. 18,342 in 1900), on the lower slopes of the Molino, is 5 miles south and standing partly on a plain below by the west of the capital. In both much attention is given to floriculture, and both are favourite country residences of the richer citizens. Xochimilco (field of flowers), (pop. 10,712 in 1890) on the west shore of the lake (45 miles north and 10 miles south of the city), is an Indian town dating long before the discovery of America. It lies in the midst of a fertile plain devoted to the production of fruit, vegetables and flowers for the city markets. Its gardens are carried out on the shallow lake by floating masses of water-plants covered with soil and secured by poplar stakes, which, taking root, soon surround them with living boundaries. These remarkable and productive gardens, called chinampas, have so increased in number and extent that the lake is practically covered by them, with the exception of the waterways, which are kept open by scooping up mud from the bottom. From the lake runs northward and the eastern boundary of the city. It is known as the Viga, and is believed to have been opened by the Aztecs for the transportation of garden produce to their island capital.

MEXICO, GULF OF, a Mediterranean gulf almost surrounded by the coasts of the United States and Mexico, and forming the northern division of the extension westward of the west Atlantic trench (see Atlantic Ocean). Its southern boundary is defined by the partly submerged ridge which extends eastwards from the peninsula of Yucatán, and on which the island of Cuba is situated: to the east it communicates directly with the Atlantic by the Strait of Florida. On the western side of Yucatán a southerly embayment is formed by the Gulf of Campeche. The United States coast closely follows the parallel of 30° N., while the parallel of 29° N., cuts across the Gulf of Campeche, by its greatest length—Vera Cruz to Florida—is 1120 m., and greatest width—Galveston to Campeche—680 m. The total area is approximately 710,000 sq. m.

The deepest part of the Gulf of Mexico, the so-called "Sigsbee" deep, lies below the line of 2000 fathoms, between 23° and 25° N., and 84° to 95° W. It is widest in the west, where the breadth is about 120 m., and narrows to 25 m. at its greatest depth (2119 fathoms) between 25° and 28° W., widening again to some 80 m. farther eastward. The continental shelf is for the most part narrow; the breadth is about 5 m. west-south-west of Florida, 25 m. along the west coast of Florida, 10 m. at the south and 10 m. to the Mississippi, 130 m. near the boundary of Texas and Louisiana, and 15 m. off Vera Cruz. The shores are low, sandy and marshy, the coast-line being frequently doubled by lagoons. There are no islands except the "Keys" of Florida and Yucatán, and Cuba. The tides in the Gulf of Mexico are of comparatively small range (springs rarely exceed 4 ft. and neaps 2 ft.), but a remarkable feature is the exaggeration of the diurnal inequality to an extent as almost to extinguish the semi-diurnal tide in the Indian gulf, giving rise to tides of water only once daily. The mean level of the water in the Gulf of Mexico is now, as formerly given as about 40 in. above that of mean sea-level at New York, but later reports on precise levellings from New York to Biloxi through St Louis describe it vaguely as "some what higher." The current movement in the Gulf of Mexico consists of a rotational movement in the direction of the hands of a watch, the branch of the equatorial current which enters the Caribbean Sea passing into the Gulf by the Strait of Yucatán and flowing from the Straits of Florida as the Gulf Stream, which unites with the remaining part of the northward moving water, forming the Antilles current. From March to September the prevailing winds are the north-east trades; these undergo considerable modification on account of the configuration of the surrounding land, and the rains which accompany them are interrupted by spells of calm thick weather, and rarely by northerly winds known as Norte del hueso colorado and Chocolateros. In the colder dry season, from October to April, the climatic situation is dominated by the relatively high temperature of the surface of the gulf, causing a cyclonic inflow of air which is associated with the strong northerly winds "norther" prevailing on the western side, more particularly along the Mexican coast. The norther sometimes blow with terrific force and are at times accompanied by rain. The form and position of the Gulf of Mexico exercise a profound influence on the climate of the whole of the southern and south-eastern states of the Union, and indeed of the greater part of North America.

MAYER, CHRISTIAN ERICH HERMANN VON (1801-1869), German palaeontologist, was born at Frankfort-on-the-Main, on the 3rd of September 1801. In 1832 he issued a work entitled Palaeologica, and in course of time he published a series of memoirs on various fossil organic remains: molluscs, crustaceas, fishes and higher vertebrata. His more elaborate researches were those on the Carboniferous amphibians, the Permian reptiles, the Triassic amphibians and reptiles, and the reptiles of the Lithographic slates; and the results were embodied in his great work Zur Fauna der Vorwelt (1845-1860), profusely illustrated with plates drawn on stone by the author. He was associated with W. Dunker and K. A. Zittel in the publication of the Palaeontographica, which began in 1851. He was awarded the Wollston medal by the Geological Society of London in 1858. He died on the 2nd of April 1869.

MEYER, HEINRICH AUGUST WILHELM (1800-1873), German Protestant divine, was born at Gotha on the 10th of January 1800. He studied theology at Jena, and eventually became (1841) pastor, member of the consistory, and superintendent at Hanover. He died on the 21st of June 1873. He is chiefly noted for his valuable Kritische exegetischer Kommentar zum Neuen Testament (16 vols.), which began to appear in 1832, was completed in 1859 with the assistance of J. E. Huther, Friedrich Dürsterleid and G. K. Lüdemann, and has been translated into English. New editions have been undertaken by such scholars as A. B. Ritschl, B. Weiss, H. Wenzel, K. F. G. Heinrici, W. Beyerlag and F. A. E. Sieffert. Mayer also published an edition of the New Testament, with a translation (1829) and a Latin version of the symbolical books of the Lutheran Church (1830).

He is not to be confounded with JOHANN FRIEDRICH VON MEYER (1772-1849), the senator of Frankfort, who published a translation of the Bible in 1816 (Die heilige Schrif in berichtiger Übersetzung mit kurzen Anmerkungen; 2nd ed., 1843; 3rd ed., 1885). MEYER, JULIUS LOTHAR (1830-1895), German chemist, was born on the 19th of August 1830, at Varel in Oldenburg. He was the son of a physician, and went to study medicine first at Zurich University in 1851, and then, two years later, at Würzburg, where he had R. Virchow as his teacher in pathology. The influence of C. F. W. Ludwig, under whom he studied at Zürich, decided him to devote his attention to physiological chemistry, and therefore he went, after his graduation (1854), to Heidelberg, where R. Bunsen held the chair of chemistry. There he was so influenced by G. R. Kirchhoff's mathematical teaching that he took up the study of mathematical physics at Königsberg under F. Neumann, and then of electrical and optical physics of mechanics, and worked in the year 1854 at the University of Berlin, where he graduated as Ph. D. with a thesis on the action of carbon monoxide on the blood. In 1866 he accepted a post in the School of Forestry at Neustadt-Eberswalde, but soon moved to Carlsruhe Polytechnic. During the Franco-German campaign the Polytechnic was used as a hospital, and he took an active part in the care of the wounded. Finally, in 1876, he became professor of chemistry at Tübingen, where he died on the 11th of April 1895. His name is best known for the share he had in the periodic classification of the elements. He noted, as did J. J. R. Newland, in England, that if they are arranged in the order of their atomic weights they fall into groups in which similar chemical and physical properties are repeated at periodic intervals; and in particular he showed that if the atomic weights are plotted
as ordinates and the atomic volumes as abscissae, the curve obtained presents a series of maxima and minima, the most electro-positive elements appearing at the peaks of the curve in the order of their atomic weights. His book on *Die modernen Theorien der Chemie*, which was first published in Breslau in 1864, contains a discussion of relations between the atomic weights and the properties of the elements. In 1882 he received from the Royal Society, at the same time as D. J. Mendeleeff, the Davy medal in recognition of his work on the Periodic Law. A younger brother, O. E. Meyer, became professor of physics at Breslau in 1864.

MEYER, KONRAD FERDINAND (1852-1989), Swiss poet and novelist, was born at Zürich on the 11th of October 1825. After studying law at the university, he went for considerable periods to Lausanne, Geneva and Paris, and in Italy interested himself in historical research. In 1875 he settled at Kilschberg near Zürich, was created in 1880 a doctor philosophiae honoris causa by that university, and died at Kilschberg on the 28th of November 1898. After Gottfried Keller, Konrad Meyer is the most important Swiss poet of modern times, though as a novelist he was perhaps more successful. His poetical works include *Balladen* (1857); *Romantisch und Bildern* (1870); the epic poem, *Haitiens letzte Toge* (1871); and *Gedichte* (1882; 2nd ed., 1901). Among his novels must be specially mentioned *Johanna (1881)*; *Der Schatz* (1882); *Der Heilige* (1889; 12th ed., 1894); English by M. von Wendheim, *Thomas à Becket, der Saint*, (1885); *Die Richterin* (1885); *Die Versuchung des Pescara* (1887); *Angela Borges* (1891). His shorter stories were collected in two volumes in 1885 (1st ed., 1892).

See A. Reitler, Konrad Ferdinand Meyer (1858); Lim Frey, K. F. Meyer's Gedichte und Novellen (1892); K. E. Franzos, K. F. Meyer (1899); A. Frey, K. F. Meyer (1899); H. Kraeger, K. F. Meyer: Quellen und Wandlungen seiner Gedichte (1901); B. Meyer, K. F. Meyer in der Erinnerung seiner Schwester (1904); Briefwechsel zwischen Louis von François et K. F. Meyer, herausg. von A. Bettelheim (1908); A. Langmesser, K. F. Meyer (1906).

MEYER, [MARIE] PAUL HYACINTHE (1840- ), French philologist, was born in Paris on the 17th of January 1840. He was educated at the Ecole des Chartes, and in 1868 was attached to the manuscript department of the Bibliothèque Nationale. In 1876 he became professor of the languages and literatures of southern Europe at the Collège de France. In 1882 he was made director of the Ecole des Chartes, and a year later was nominated a member of the Academy of Inscriptions. He was one of the founders of the Revue critique, and a founder and the chief contributor to *Romantic* (1872). Paul Meyer began with the study of old Provençal literature, but subsequently did valuable work in many different departments of romance literature, and ranks as the chief modern authority on the French language. He is the author of *Recherches sur les documents manuscrits de l'ancienne littérature de la France conservés dans les bibliothèques de la Grande Bretagne* (1871); *Recueil d'anciens textes bas-latins, provençaux et français* (2 pars., 1874-1876); *Alexandre le Grand dans la littérature française du moyen âge* (2 vols., 1886). He edited a great number of old French texts for the Société des anciens textes français, the Société de l'Histoire de France and independently. Among these may be mentioned *Aye d'Avignon* (1861), with Guissard; *Flamenco* (1865); the *Histoire de Guillaume le Maréchal* (3 vols., 1892-1903); *Rouault de Cambrai* (1892), with A. Longion; *Fragment d'une vie du Saint Thomas de Cantorbery* (1885); *Guillaume de la Barre* (1894).

MEYER, VICTOR (1848-1897), German chemist, was born at Berlin on the 8th of September 1848, and studied at Heidelberg University under R. W. Bunsen, H. F. M. Kopp, G. R. Kirchhoff and E. E. von Holmoltz. At the age of twenty he entered J. F. W. A. Baeyer's laboratory at Berlin, attacking among other problems that of the composition of camphor. In 1871, on Baeyer's recommendation, he was engaged by H. von Fehling as his assistant at Stuttgart Polytechnic, but within a year he left to succeed J. Wielisius at Breslau. There he remained for thirteen years, and it was during this period that he devised his well-known method for determining vapour densities, and carried out his experiments on the dissociation of the halogenes. In 1882, on the death of W. Weith (1844-1881), professor of chemistry at Zürich University, he undertook to continue the lectures on benzenoid derivatives, and this led him to the discovery of thiophene. In 1885 he was chosen to succeed Hans Hübner (1837-1884) in the professorship of chemistry at Göttingen, where stereo-chemical questions especially engaged his attention; and in 1886, on the resignation of his old master, Bunsen, he was appointed to the chair of chemistry in Heidelberg. He died on the 8th of August 1897. In recognition of his brilliant experimental powers, and his numerous contributions to chemical science, he was awarded the Davy medal by the Royal Society in 1891.

MEYERBEER, GIACOMO (1791-1865), German composer, first known as Jakob Meyer Beer, was born at Berlin on the 5th of September 1791,1 of a wealthy and talented Jewish family. His father, Herz Beer, was a banker; his mother, Amalie (née Wulf), was a woman of high intellectual culture; and two of his brothers distinguished themselves in astronomy and literature. He studied the pianoforte, first under Lauska, and afterwards under Lauska's master, Clementi. When seven years old he played Mozart's Concerto in D Minor in public, and at nine he was pronounced by the best pianist in Berlin. For composition he was placed under Zelter, and for conducting at the age of twenty under the director of the Berlin opera, by whom he was introduced to Abbé Vogler. Vogler invited him to Darmstadt, and in 1810 received him into his house, where he formed an intimate friendship with Karl Maria von Weber, who also took daily lessons in counterpoint, fugue and extempore organ-playing. At the end of two years the grand duke appointed Meyerbeer composer to the court. His first opera, *Jephtha's Gölubäde*, failed lamentably at Darmstadt in 1811, and his second, *Wirth und Gast* (Alindeke), at Vienna in 1814. These checks discouraged him so cruelly that he hid his sensitive organs. It was not until after the publication of his master, Weber, he determined to study vocalization in Italy, and then to form a new style. But at Venice he was so captivated by Rossini that, renouncing all thought of originality, he produced a succession of seven Italian operas—*Romilda a Costanza*, *Semiramide riconosciuta*, *Edouard et Cristina*, *Emma di Resburgo*, *Margherita d'Anjou*, *L'Esule di Granata* and *Il Crociato in Egitto*—which all achieved a success as brilliant as it was unexpected. Against this act of treason to German art Weber protested most earnestly; and before long Meyerbeer himself grew tired of his debility. An invitation to Paris in 1826 led him to review his position dispassionately, and he came to the conclusion that he was wasting his powers. For several years he produced nothing in public; but, in concert with Scribe, he planned his first French opera, *Robert le Diable*. This gorgeous spectacle was produced at the Grand Opéra in 1831. It was the first of its race, a grand romantic opera, with situations more theatrically effective than any that had been attempted either by Cherubini or Rossini,1 and with ballet-music such as had never yet been heard, even in Paris. Its popularity exceeded all expectations; yet for five years Meyerbeer appeared before the public no more. His next opera, *Les Huguenots*, Meyerbeer was first performed in 1836. In gorgeous colouring, rhetorical force, consistency of dramatic treatment, and careful accentuation of individual types, it is at least the equal of *Robert le Diable*. In two points only did its interest fall short of that inspired by the earlier work. Meyerbeer had shown himself so eminently successful in his treatment of the supernatural that one regretted the omission of that element; and, more important still, the fifth act proved to be an anti-climax. The true interest of the drama culminates at the close of the fourth act, when Raoul, leaping from the window to his death, leaves Valentine fainting upon the ground. The opera now usually ends at the fourth act.

After the production of *Les Huguenots* Meyerbeer spent many years in the preparation of his next greatest works—*L'Africaine* and *Le Prophète*. The librettist of both these operas were furnished

---

1 Or, according to some accounts, 1794.
by Scribel; and both were subjected to countless censures; in fact, the story of L'Africaine was more than once entirely rewritten.

Meanwhile Meyerbeer accepted the appointment of kapellmeister to the king of Prussia, and spent some years at Berlin, where he produced Ein Feldzuge in Schlesien, a German opera, in which Jenny Lind made her first appearance in Prussia. Here also he composed, in 1846, the overture to his brother Michael's drama, Sturneise. But his chief care at this period was bestowed upon the worthy presentation of the works of others. He began by producing his dead friend Weber's Euryanthe, with scrupulous attention to the composer's original idea. With equal unselfishness he procured the acceptance of Rienzi and Der fliegende Holländer, the first two operas of Richard Wagner, who, then languishing in poverty and exile, would, but for him, have found it impossible to obtain a hearing in Berlin. With Jenny Lind as prima donna and Meyerbeer as conductor, the opera flourished brilliantly in the Prussian capital; but the anxieties materially shortened the composer's life.

Meyerbeer produced Le Prophète at Paris in 1849. In 1854 he brought out L'Étoile du nord at the Opéra Comique, and in 1859 Le Pardon de Ploermel (Dinorah). His last great work, L'Africaine, was in active preparation at the Académie when, on the 23rd of April 1863, he was seized with a sudden illness, and died on the 2nd of May. L'Africaine was produced with pious and attention to the composer's minutest wishes, on the 28th of April 1865.

Meyerbeer's genius was criticized by contemporaries with widely different results. Mendelssohn thought his style exaggerated; Féti thought him one of the most original geniuses of the age; Wagner ungratefully calls him "a miserable music-maker," and "a Jewish banker to whom it occurred to compose operas." The reality of his talent has been recognized throughout all Europe; and his name will live so long as intensity of passion and power of dramatic treatment are regarded as indispensable characteristics of dramatic music. The work shows that these qualities, with the aid of an experienced stage-manager, may be entirely independent of genuine musical insight.

Meynell, Alice Christiana (1830— ), English poet and essayist, was the daughter of T. J. Thompson. Her early life was spent chiefly in Italy, and she was educated by her father. Her first volume of verse, Preludes (1875), illustrated by her sister Elizabeth, afterwards Lady Butler, attracted little public notice, but the delicacy and beauty of the poems and especially of the sonnet "Renunciation," were warmly praised by Ruskin. She married in 1877 the well-known Roman Catholic journalist and author Wilfrid Meynell, who became proprietor and editor of the Weekly Register. Under W. E. Henley's editorship she wrote regularly in prose for the National Observer, and also later for the Pall Mall Gazette, the Saturday Review, &c. Her Poems (1893), including much of the earlier volume of Preludes, brought her at last more definitely before the public; and this was followed in 1901 by another slender book of delicate verse, Later Poems. Mrs Meynell also showed herself a fine critic of poetry by her admirable selection, The Flower of the Mind (1897), an anthology of English verse. She edited the Selected Poems (1894) of T. G. Hake, the Poetry of Papworth and Night (1896) of her intimate friend Coventry Patmore, and the selections from Patmore in the "Muses' Library." Her prose essays, remarkable for freshness of culture and peculiar restraint of style, appeared in successive volumes as The Rhythm of Life (1893), The Colour of Life and other Essays (1896), The Children (1897), and The Spirit of Place (1898). Later books are London Impressions (1898) and The Work of John S. Sargent (1903).

See W. Archer, Poets of the Younger Generation (1902).

Meyr, Melchior (1810-1871), German poet, novelist and philosopher, was born at Ehringen on the 28th of June 1810, and died at Munich on the 22nd of April 1871. He read law and philosophy at Heidelberg and Munich. His greatest success was the Entdeckungen aus dem Ritz (4th ed. Leipzig, 1892), remarkable as an accurate and sympathetic picture of rural life and character. He wrote also tragedies (Hertog Albrecht, 1851; Karl der Kühne, 1852), novels (Vier Deutsche, 1861; Ewige Liebe, 1864), and, in later life, philosophical works with a strong religious tendency. Among these were Émilie (philosophical dialogues, 1863), Die Religion des Geistes (1871), Die Fortdauer nach dem Tode (1860), Die Religion und ihre zehn gebotene Fortbildung (1871), and Gedanken über Kunst, Religion und Philosophie (1874). In these works he, attempted to develop a Deistic system of philosophy. He was the author of an anonymous work entitled Gespräche mit einem Grobian (1860).

Meyerab, a small semi-nomad tribe of Africans of Semitic stock, settled on the east bank of the Nile near Berber. Contrary to Arab custom, it is said they never marry slaves.

Mézeray, François Eudes de (1610-1653), French historian, was born at Rye near Argentan, where his father was a surgeon. He had two brothers, one of whom, Jean Eudes, was the founder of the order of the Eudists. François studied at the university of Caen, and completed his education at the college of Ste Barbe at Paris. His Histoire de France depuis Paramond jusqu'à Louis le Juste (3 vols. 1643-1651), is a fairly accurate summary of French and Latin chronicles. Mézeray was appointed historiographer of France, and in 1649, on the death of Vincent Voiture, was admitted to the Académie Française. His Abrégé chronologique (3 vols., 1667-1668) went through fifteen editions between 1671 and 1766. He was not hostile to religion in this work to attack the financiers, with the result that his position as historiographer was diminished by Colbert. Mézeray succeeded Conrart as permanent secretary to the Académie Française (1675), and died at Paris on the 10th of July 1683. He translated Grotius's Traité de la religion chrétienne (1640), and a Histoire des Turcs depuis 1012 jusqu'en 1649 (1659), which is an addition to a continuation of Chalcondyles.

See Daniel de Larroque, Vie de François Eudes de Mézeray (1720); vol. 1; and Poésies de Jehan Buée, and Levasseur's Notice sur les trois frères: Jean Eudes, François Eudes, et Charles Eudes (1855).

Mézières, Philippe de (c. 1327-1409), French soldier and author, was born at the château of Mézières in Picardy. He belonged to the poorer nobility, and first served under Lucchino Visconti in Lombardy, but within a year he entered the service of Andrew, king of Naples, who was assassinated in September 1344 and the autocrat of the Lusignan line set out for the East in the French army. After the battle of Smyrna he was made a knight, and when the French army was disbanded he made his way to Jerusalem. He realized the advantage which the discipline of the Saracens gave them over the disorderly armies of the West, and conceived the idea of a new order of knighthood, but his efforts proved fruitless. The first sketch of the order was drawn up by him in his Novo religio passionis (1367-1368; revised and enlarged in 1368 and 1396). From Jerusalem he found his way in 1347 to Cyprus to the court of Hugo IV., where he found a kindred enthusiast in the king's son, Peter of Lusignan, then count of Tripoli; but he soon left Cyprus, and had resumed his career as a soldier of fortune when the accession of Peter to the throne of Cyprus (Nov. 1358) and his recognition as king of Jerusalem induced Mézières to return to the island, probably in 1360, when he became chancellor. He came under the influence of the pious legate Peter Thomas (d. 1366), whose friend and biographer he was to be, and Thomas, who became patriarch of Constantinople in 1364, was one of the chief promoters of the crusade of 1365. In 1362 Peter of Cyprus, with the legate and Mézières, visited the princes of western Europe in quest of support for a new crusade, and when the king returned to the east he left Mézières and Thomas to represent his case at Avignon and in the cities of northern Italy. They preached the crusade throughout Germany, and later Mézières accompanied Peter to Alexandria. After the capture of this city he received the government of a third part of it and a promise for the creation of his order, but the Crusaders, satisfied by the immense hooty, refused to continue the campaign. In June 1366 Mézières was
sent to Venice, to Avignon and to the princes of western Europe, to obtain help against the Saracens, who now threatened the kingdom of Cyprus. His efforts were in vain; even Pope Urban V. advised peace with the sultan. Mézières remained for some time at Avignon, seeking recruits for his order, and writing his Vie de St. Thibaut (1599). This, which is invaluable for the history of the Alexandrian expedition, is entitled Le Prieur de la rue de la Tour on the Place. Its chief interest lies in the fact that it was written at the dictation of Charles V., although this king had refused to be dragged into a crusade. He was tutor to his son, the future Charles VI., but after the death of Charles V. he was compelled, with the other counsellors of the late king, to go into retirement. He lived thenceforward in the convent of the Celestines in Paris, but nevertheless continued to exert an influence on public affairs, and to his close alliance with Louis of Orleans may be put down the calamities with which the Burgundian historians covered his name. When Charles VI. freed himself from the domination of his uncle, the power of Mézières increased. To this period of his life belong most of his writings. Two devotional treatises, the Contemplatio horae moris et the Soliloquia peccatoris, belong to 1386-1387. In 1389 he wrote his Songs du vieil pêlerin, an elaborate autobiographical work in which he described the customs of Europe and the near East, and advocated peace with England and the pursuit of the Crusade. His Oratio tragica, largely autobiographical, was written with similar aims. In 1395 he addressed to Richard II. of England an Épitre pressing his marriage with Isabella of France. The Cardinal smiled. "On ce mot de Mézières le diable s'arrête," says the chronicler of Nicolas on the 28th of September 1396 justified his fears and was the occasion of his last work, the Épitre lamentable et consolatoire, in which he put forward once more the principles of his order as a remedy against future disasters. Mézières died in Paris on the 29th of May 1405.

Some of his letters were printed in the Revue historique (vol. xiii.), and the two Épitres just mentioned in Kervyn de Lettenhove's edition of Froissart's Chroniques (vols. xvi. and xvi.). The Songs du vergier or Song of the Apple-trees, written about 1376, is sometimes attributed to him, but without definite proof.

See Antoine Becquet, Gallica coelestinarum congregationis monasteria, foundationes ... (1716); the Abbé Jean Lebeuf's Mémoires de l'Académie des Inscriptions, vol. xvi. and xvii. (1752 and 1753); J. Delaville le Roulx, La France en Orient au xiv. siècle (1886-1890); A. Molinier, Manuel de bibliographie historique vol. iv. (1904); and especially the researches of N. Jorga, published in the Bibliothèque de l'École des hautes études vol. 110 (Paris 1896); and the same writer's Philippe de Mézières, et la croisade au xiv. siècle (1896). Jorga gives a list of his works and of the MSS. In which they are preserved, and analyses many of them. One Song du vergier, see P. Paris, in Mémoires vol. xv. (1843) of the Academy of Inscriptions.

MÉZIÈRES, a town of northern France, capital of the department of Ardennes, 55 m. N.E. of Reims by the Eastern railway. Pop. (1900), town, 7007; commune, 9393. The town itself, the streets of which are narrow and irregular, is situated on the neck of a peninsula formed by a loop of the Meuse. The river separates it from its suburb of Arches and the town of Charleville on the north and from the suburb of Pierre on the south. Adjoining Pierre is Mohon (pop. 5747), with metallurgical works. The fortifications of Mézières, as well as the citadel still dominating the town on the east, were built under Vauban's direction, but largely re-erected in 1839 and 1880. Immediately to the east of the citadel runs a canal, which provides river-traffic with a short cut across the isthmus. The parish church (16th cent.) contains inscriptions commemorating the raising of the siege of Mézières in 1521 and the marriage of Charles IX. with the daughter of the emperor Maximilian II. (1570). The north and south portals, the Renaissance tower at the west end, and the lofty vaultings, are worthy of remark. The church, which suffered severely in 1870-71, has since been restored. The prefecture and the hôtel de ville, which contains several interesting pictures relating to the history of the town, belong to the 18th century. Mézières is the site of a prefect and of a court of assizes, and there are manufactures of bicycles, and iron and steel castings for motors, railway-carriages, &c.

Founded in the 9th century, Mézières was at first only a stronghold belonging to the bishops of Reims, which afterwards became the property of the counts of Rethel. The town was increased by successive immigrations of the people of Liége, flying first from the emperor Otto, and afterwards from Charles the Bold; and also by concessions from the counts of Rethel. Walls were built in the 13th century, and in 1521 it was defended against the Imperialists by the Chevalier Bayard, to whom a statue was erected in 1803. The anniversary of the deliverance is still observed yearly on the 27th of September. In 1815 the Germans were kept at bay for six weeks, and in 1871 the town only capitulated after a bombardment during which the greater part of it was destroyed.

MEZÔTÛR, a town of Hungary, in the county of Jász-Nagykun-Szolnok, 88 m. S.E. of Budapest by rail. Pop. (1900), 25,367. It possesses important potteries. Large herds of cattle are reared on the communal lands, which are productive also of wheat, rapeseed and maize. Several well-attended fairs are held here annually.

MEZZANINE (It. mezzano; Fr. entresol; Ger. Zwischengeschoss), in architecture, a storey of small height introduced between two lofty storeys, or sometimes employed to allow of the introduction of two storeys equal together in height to lofty rooms on the same floor.

MEZZOFANTI, GIUSEPPE CASPAR (1774-1849), Italian cardinal and linguist, was born on the 17th of September 1774, in the town of Bassano. He was ordained priest in 1797, and in the same year became professor of Arabic in the university of Padua, but shortly afterwards was deprived for refusing to take the oath of allegiance to the Cisalpine Republic. In 1803 he was appointed assistant librarian of the institute of Bologna, and soon afterwards was reinstated as professor of oriental languages and of Greek. The chair was suppressed by the viceroy in 1808, but again rehabilitated on the restoration of Pius VII. in 1814, and continued to be held by Mezzofanti until his removal from Bologna to Rome in 1831, as a member of the congregation of propaganda fidei. In 1833 he succeeded Angelo Mai as chief keeper of the national library, and in 1838 was made cardinal and director of studies in the Congregation. He died at Rome on the 15th of March 1849. His peculiar talent, compatible in many respects to that of the so-called "calculating boys," was not combined with any exceptional measure of intellectual power, and produced nothing of permanent value. It seems certain, however, that he spoke with considerable fluency, and in some cases even with attention to dialectical peculiarities, some fifty or sixty languages of the most widely separated families, besides having a less perfect acquaintance with many others.

MEZZOTINT. During the 17th century two revolutions occurred in the British art of mezzotinto engraving—"la manière anglaise." The original defect of the method was the incapacity of the mezzotint "hurt" on copper to yield as many fine impressions as other forms of engraving. To this defect was attributable the introduction, in 1823, of steel instead of the soft copper previously used—a change which, with the endeavour to avoid technical difficulties, led to the "mixed style," or combination of mezzotint with etching, and a general departure from the traditional form of the art, "pure mezzotint," on copper. The affinity of the method to painting in black and white which differentiates it from other kinds of engraving, and was the distinguishing charm of the mezzotints of the 17th and 18th centuries, was for a time lost, but a revival of pure mezzotint on
MEZZOTINT

copper, beginning in 1880—a return, in fact, to the mode in which the classics of the art were engraved in the time of Sir Joshua Reynolds—was made possible by the invention of steel-facing. By this process engraved copper plates are electroplated with a film of steel, renewable when worn in course of printing; and a mezzotint on copper, so protected, yields more fine impressions than if it had been engraved on steel, whilst the painter-like quality remains unimpaired.

In "pure mezzotint" the design is evolved from dark to light entirely by scraping away more or less of the previously "ground" burr. The "ground" is left untouched in the extreme darks, and no acid, etching or line-work is used in it at all. The usual short descriptions of the method are misleading, because they fail to convey the fact that the "ground" is not the surface of the plate, which is scraped away in greater or smaller degree to produce the varying tones of the design. The necessity of realizing that there are two constituents of the "ground," the "burr" and the indentations out of which the "burr" is raised, will be appreciated later. The "rocking-tool," with which the "ground" is laid, somewhat resembles a carpenter's chisel, but the blade is 3 in. wide and only about 2 in. long, whilst the cutting edge, instead of being straight, is curvilinear in the segment of a circle. One side of the blade is deeply engraved with lines from edge to handle, and the ridges which remain between these lines form teeth at the cutting edge which, when the side of the tool is bevelled as an ordinary chisel is sharpened.

The tools contain from 35 to 120 teeth to each inch of their width, those with the most teeth producing grounds of fine lines of dots. The ridge is the slope of the tool from side to side on the bare copper plate, causing the tool to travel toward, whilst each tooth makes an indentation in the copper and throws up an article of matter called a "burr." When the whole plate has been so rocked across in 45 to 60 different directions, so that no visible speck of the original bright copper surface remains unseared by the teeth of the "rocking-tool," the "ground" is termed "full" and is ready for scraping the design. The innumerable particles of copper forming the raised "burr" give to a "full ground" much the appearance of copper-coloured paper. A print from it, taken before any scraping has been done on it, looks not unlike a piece of black velvet. The lights and semi-tones of the design are produced by subsequent scraping and burnishing.

Assuming that a mezzotint is to be scraped from a lady's portrait by Sir Joshua Reynolds in which a piece of black drapery crosses a white dress—the engraver begins to work on a previously laid "ground" which would print uniformly black before scraping commences. In the extreme darks of the black drapery the raised "burr" is left untouched by the "scraper,"—a two-edged steel instrument resembling an ancient Roman sword-blade in miniature, but with the "scraper" edge of the blade so sharpened that the engraver produces the varying tones of the folds of the black drapery by scraping the raised "burr" down more or less, lowering in fact so that it will not hold so much ink as where it is left untouched. In the extreme darks, then, the piece of black drapery all the raised "burr" will have been removed and the original surface of the plate reached, but as yet the engraver has not even begun to tone his lighter form. But he has made absolutely a full black drapery, because the indentations out of which the "burr" was raised still remain in the plate and hold in printing. In order to produce the infinite gradation of delicate tones in the white dress, or in a sky, the scraping is continued, the indentations being thus made shallower in the passages scraped, and therefore less capable of holding ink, which they are obliterated almost entirely in the higher lights. When the mezzotint is finished the black drapery will stand higher than the surface of the plate modelled in a relief composed of the raised "burr," whilst all the tones of the white dress, from middle tints to lights, will be so many degrees above the highest lights being the deepest. The speck of light in the eye, for instance, is a pit in the plate, surrounded by a tract of more or less black which provides the necessary blackwards and the half-tints of the iris. The difference of surface levels is very appreciable where high-lights impinge on strong darks, but it exists in varying degree all over the plate, and the greatest technical difficulty of the whole operation is to obtain adequate edge and definition, because the tendency is to remove too much "ground" from the edges of adjacent darks in the course of the constant scraping of the adjacent lighter and lighter lights.

In printing a mezzotint a non-fluid ink is thoroughly worked into every part of the plate, and the superfluities wiped off again, leaving as much ink as possible in the darks, the raised "burr." If any ink is under the small lights it will be taken away in the roughness and they print dark instead of light, or the printer has to wipe so hard to get the ink out of the depressed lights that he will plague the blacks. In either case lack of definition and contrast of effect results. This inherent difficulty of scraping to a sharp edge caused the use of the "mixed" methods, in which the details were sharpened by outlining them with stipple or line etching.

Mezzotint is the best form of engraving for completeness of representation, but etching is better adapted for sketching from nature or for the expression of any fleeting idea. The two arts have, however, been made as close and limited in their applications as practised by Rembrandt lies in economy of expressive line to suggest the artist's meaning, and that of mezzotint in completion of tonality to explain it. Artistic suggestion, which is not inherent in the process, is due to the spontaneous working entirely by the free play of the "scraper" on the "ground," much as the painter attains it on canvas with the brush.

A process called electro-plating mezzotint was invented in Amsterdam in 1643 by Ludwig von Siegen, an officer in the service of the Landgrave of Hesse, and an amateur artist; but the work was a direct drawing on copper with an instrument of some kind of "scraper," the "ground" being the surface of a mezzotint, ground laid with the rocking-tool and scraped from dark to light in the present manner of the art. Siegen's innovation was led up to by the contact prints, or "proofs," by D. van Campagno and Janus Lutma; the roulette appears to have been in use long before this time; and though he shared in the evolution of the rocking-tool, he was not the sole inventor of it. The earliest works referable to the method at the print room of the British Museum afford evidence, though inconclusive, that Prince Rupert, to whom Siegen showed his mode of work in 1654, and possibly also their common friend, Th. Caspar von Fürstenberger, and Rupert's assistant, Vandyck and Rubens, may in a year or two have adopted this method in the development of mezzotint engraving. The rocking-tool was apparently improved by Abraham Blooteling, a Dutch painter and portrait engraver, very early in the 17th century. The "mixed" methods of mezzotint, to have been invented to the workmen to the advantage of the plate. Until the middle of the 18th century the tools continued somewhat archaic, causing in the prints an appearance of solid wood, like copper, and the charm of the relief engraving is lost.

The mezzotint was certainly made in the prints of F. Place and Luttrell, Beckett and Williams, and later those of John Simon, John Smith and John Faber, jun., who were the principal exponents of mezzotint in the first years of the seven- teenth century. The highest standard of mezzotint was then in Black Country engraving, and a series of portraits after Vandyck, Lely, Kneller and the Dutch painters then practising in England, representing such interesting group as Van Dyck, Poussin, Velasquez, Repton, Gainsborough and Reynolds. This was the period of its great celebrity in the hand of Congreve and Wycherley, Locke and the great duke of Marlborough.

The classics of mezzotint engraving are to be found amongst the best plates after Sir Joshua Reynolds by James M'Ardeil, J. R. Smith and Valentine Green, the Watsons, Dickinson, Fisher, Dixon and some others, who worked during the last half of the 18th century. The brushwork of Reynolds was more in harmony with the mezzotint method than the slighter painting technique of Gainsborough and Romney, who were much less frequently engraved, perhaps because it is the highest technical difficulty in mezzotint to render the sharp edges of a sketch. For this reason many of the etchings of Reynolds are inferior to the engravings of the mezzotint. This is mostly the result of the method. Though professional publishers and print makers existed at this time and earlier, the word "execut" or on an old print, implying "published," not "engraved," the authors of the "Sir Joshua Reynolds in most cases use the word engraving, their own works, and pure mezzotint, unmixed with etching, was exclusively the method they employed. Mezzotints were occasionally printed in colour, notably those engraved later by George Morland, the principal object being to colour the important sections of the plates.

The departure from pure mezzotint and temporary decay of the art in the 19th century, however, seems to have been reversed in the time of the Duchy of Marlborough, when Richard Earlom, otherwise a fine artist in the traditional method, notably in translations of Vandyck and Wright of Derby, began to outline the delicacy of his plates with stipple etching in order to avoid the labour and difficulty of the "rocking-tool," while the "ground" alone. Earlom, however, did not destroy the mystery of the rich velvety darks by etching into them. A demand then arose for larger editions than the work copper plates would yield, and the engravers attempted to meet it by combining mezzotint with
positive line-cutting throughout the work, thus shortening the labour of scraping the details, and fortifying the darks with lines sunk deeply. For this purpose the plate was kept clean, and the engraver's attention was directed more to the lines than to the blacks. There was, however, a certain artistic significance in the etched line itself apart from the mezzotint tone, but every touch of line in a mezzotint does something to destroy the painter-like quality, and a deep wash was in order. The same mixed method on copper was used by J. W. M. Turner in his Liber Studiorum series of landscape plates, his object being to rival the pen-and-wash drawings of Claude's Liber Veritatis. Turner's illustrations were perhaps more exacting or meticulous, and the engravers before mentioned, and the etched foundation of the Liber Studiorum was too strong for the mezzotint tone, destroying the breadth of a painting, and leaving the mezzotint quality, as the "keen" or light part, of the whole effect. It is the grand design of Turner reflected in the plates, rather than any quality of mezzotint or etching in them, which appeals to the artist and the connoisseur. Perhaps the greatest success in harmonizing line and tone in one plate was achieved by David Lucas in his "English Landscape" series of mezzotints after John Constable, in which he sharpened his details with the roulette, or with a slight line put in with the point of the scraper as scraping ceased, retaining the pure black, or copper, the rocking-tool penetrated less deeply, raising less "burr," and the consequent loss of force in the darks necessitated the scraping up of the lights to a higher key to force contrast of effect, which was accomplished by the use of various white papers and a coarse black ink. It was soon found that the unfortified "burr," even on steel, would not yield the constantly increasing numbers of impressions demanded. The labour of scraping sharp lights was greatly enhanced, and though some pure mezzotints were made on steel, painter-like touch was practically unattainable on it, and the general effect was cold and uninteresting. See Samuel Cousins and Samuel Cousin, or Lawrence in the comparatively pure method, and the final development of the "mixed style" on steel in his later plates after Reynolds, Millais and Landseer, are referred to in the article on Samuel Cousins. For nearly forty years pure mezzotints ceased to be practised altogether, and the revival of it, which began in 1880, was led up to by the invention of steel-facing. The competition of photogravure, which steel-facing made a commercial possibility, for a time checked the renewal movement, but a tone-engraving, despite a main surface resemblance to a mezzotint, is a photographic manipulated to imitate an engraving, entirely devoid of artistic individuality. In 1897, for the first time a Society of Mezzotint Engravers was formed to foster the art. AUTHORITIES.—British Mezzotinto Portraits, by John Chaloner Smith (London, 1878), a standard book of reference, contains a long list of portraits. The practice of copper engraving, or Mezzotint, by Hubert von Herkomer, R.A. (London, 1890), the most useful work on the technique. Etching, Engraving and other Methods of Printing Pictures, by H. W. Singer and William Strang (London, 1877); On the Making of Etchings, by Frank Short (London, 1898), containing a slight reference to mezzotint technique; Art of Engraving, by T. H. Fielding (London, 1854); Alfred Whitman, Masters of Mezzotint (London, 1898); Valentine Green (1902). Samuel William Reynolds (1903), Samuel Cousins (1904). Charles Turner (1907); Gordon Gordain, James McArdell (1903), Thomas Watson, James Watson, Elizabeth Judkins (1904); W. G. Rawlinson, Drawings in the Artisian Calotypic and Photographic (London, 1906); F. Wedmore's catalogue of the David Lucas mezzotints. A little anonymous book, A History of the Art of Engraving in Mezzotinto, from Its Origin to the Present Times (by Dr James Chalmers, London, 1837), is of considerable interest, as it describes the technique as somewhat elementary, and no complete history of the art exists.

MFUMBIO, or Kirunga, general names for a chain of volcanic mountains extending across the Central African, or Albertine, rift-valley immediately north of Lake Kyu. The range, the result probably of recent geological changes, comprises four peaks, the southernmost being the loftiest. The rivers flowing north to the Nile and the waters of Lake Kyu, connected through Tanganyika with the Congo system. The chain consists of two groups of mountains, surrounded by a vast lava field. The western group lies directly north of Lake Kyu, and contains two active volcanoes, Kirunga-ch'ango, the nearest to the lake (11,704 ft. high), and Kirunga-namlagira (1071 ft.), some 10 mi. further north. The eastern group contains several higher peaks—some rising to needle-like points, others being truncated cones. The most lofty, Kirissimbi (14,683 ft.), lies in 29° 27' 20" E., 1° 30' 20" S. Mikeno, a few miles north of the rest of Kirissimbi, is 14,385 ft. high. The most southerly of the group, Muhavura (iv), in 29° 40' 30" E., 2° 25' S., is an isolated sugarloaf-shaped mass with a crater filled with water on its summit. This is the mountain to which the names Mfumbio and Kirunga were originally applied. Some 6 m. west and a little north of Muhavura is Sabiyia (Sabingo), 11,881 ft. high. The eastern peaks are snow clad for a part of the year. North of these high mountains is a district, extending towards Albert Edward Nyanza, containing hundreds of low peaks and extinct volcanoes. It is to this region that the name Umfumbio or Kirunga is said property to belong.

MFumbio, i.e. Muhavura, was first seen by a white man in 1861, J. H. Speke, in his journey to discover the source of the Nile, obtaining a distant view of the cone, which was also seen by H. M. Stanley in 1876. By its Baganda name of Mfumbio (cook-house mountains) it figured on the maps somewhat east of its true position, first ascertained by Franz Stuhlmann in 1801. In 1894 Count von Götzen travelled through the volcanic region, and the range was subsequently explored by E. S. Grogan, Major St. Hill Gibbons, Captain Herrmann, Dr R. Kandt and Captain von Muhlfeldt, the principal party which visited the ground. In 1907-1908 the range was geologically and topographically examined by the duke of Mecklenberg's expedition. By the Anglo-German agreement of the 1st of July 1890 "Mount Mfumbio" was included in the British sphere in East Africa.

MIHOW, a town of Central India, with British military cantonment, within the native state of Indore, on the Malwa branch of the Rajputana railway, 13 m. S. of Indore. Pop. (1901), 36,039. It is the headquarters of the 5th division of the southern army, and one of the chief military stations of India. There are two high schools, a Zoroastrian and a Canadian mission, the Dorabji Pestonji dispensary, and a gaol.

MIAGAO, a town on the southern coast of the province of Iloilo, island of Panay, Philippine Islands, about 25 m. W.S.W. of the town of Iloilo, the capital. Pop. (1903), 20,656; in the same year the neighbouring town of San Joaquin (pop. 1903, 14,333) was incorporated with Miagao. It has a cool and healthful climate, with an average temperature of 78°, producing sibouco in considerable quantities. The weaving of fabrics of abacá (Musa textilis), or Manila hemp, and pineapple fibre is the most important local industry. The language is Panay-Visayan.

MIALL, Edward (1800-1881), English Nonconformist divine and journalist, was born at Portsmouth on the 8th of May 1800. He was Congregational minister at Ware (1831) and Leicester (1834), and in 1841 founded the Nonconformist, a weekly newspaper in which he advocated the cause of disestablishment of the Church of England. In 1854 he retired from public life, and received from his admirers a present of ten thousand guineas. He died at Sevenoaks on the 29th of April 1881.

See the Life, by A. Miall (1884).
MIAMI, a city and the county-seat of Dade county, Florida, U.S.A., in the S.E. part of the state, on the N. bank of the Miami river and on Biscayne Bay. Pop. (1900), 1681; (1905), 4733; (1910), 5471. It is served by the Florida East Coast railway and by lines of coastwise steamships, and is the point of departure of the P. & O. steamships for Nassau and Havana. Miami is the centre of a farming country in which citrus fruits, especially grape-fruit, pineapples and winter vegetables are raised for northern markets. There is excellent red-fishing; Spanish and king mackerel and blue-fish are shipped from Miami in large quantities; and in Biscayne Bay there are important sponge fisheries. An alligator "farm" and the Subtropical Laboratory of the U.S. government are points of interest. In the city is Fort Dallas (now abandoned), where American troops were quartered during the Seminole War; and Miami is still the trading point of the Seminole Indians, being immediately south of the Everglades, their home. In 1909 a project was on foot to cut a channel from Miami to Lake Okeechobee and from the other side of that lake west to the Gulf at Fort Myers, thus providing an inland waterway and draining much swampy but fertile land. In 1866 there were only two dwellings and one storehouse within the present corporate limits, but in that year the place was chosen as the southern terminal of the Florida East Coast railway, which was afterwards extended towards Key West. Soon afterwards Henry M. Flagler (b. 1830), the owner of the railway, began the construction of the magnificent Royal Palm hotel, and Miami became a popular winter resort. Then came the development of commerce by the improvement of the harbour, by donations from Mr Flagler and grants by the United States government.

MIAMI, a tribe of North American Indians of Algonquian stock. The English called them Twighness, a corruption of the native name, which meant the cry of the crane. They were first found in south-eastern Wisconsin, and in 1764 numbered about 1750. Their civilization was advanced and they lived in stockaded towns. They took part in Pontiac's conspiracy in 1764 and in the American War of Independence and American War of 1812 they fought on the English side. At the close of this war they were greatly reduced in numbers. A few Miami still live on a reservation in Oklahoma and in Wabash county, Indiana.

MIANTONOMO (?-1643), chief of the Narraganset tribe of North American Indians, nephew of their grand sachem, Canonicus (d. 1647). He seems to have been friendly to the English colonists of Massachusetts and Connecticut, though he was accused of being treacherous. In 1636, when under suspicion, he went to Boston to prove his loyalty to the colonists. In the following year he permitted John Mason to lead his Connecticut expedition against the Pequot Indians through the Narraganset country, and in 1638 he signed for the Narraganset the tripartite treaty between that tribe, the Connecticut colonists and the Mohegan Indians, which provided for a perpetual peace between the parties, and he agreed to take under his jurisdiction eighty of the two hundred troublesome Pequot. In 1643 a quarrel broke out between the Mohegan and the Narraganset, and Miantonomo led his warriors against those of Uncas, the Mohegan sachem. He was defeated and captured at what is now Norwich, Conn., was turned over to the Connecticut authorities, and was later tried at Boston by the commissioners of the United Colonies of New England. A committee of five clergyman, to whom his case was referred, recommended that he be executed, and the commissioners accordingly sentenced him to death and chose Uncas as his executioner. Miantonomo, who was kept in ignorance of this sentence, was taken to the scene of his defeat and was there tomahawked in cold blood by Wawequa, the brother of Uncas. There is a monument to Miantonomo in South's Park, Norwich, Conn.

MIANWALI, a town and district of India in the Multan division of the Punjab. The town is situated on the left bank of the Indus, 653 ft. above sea-level. Pop. (1901), 3591. The district was formed in 1901, after the creation of the North-West Frontier Province, out of the Cis-Indus portions of Bannu and Dera Ismail Khan districts. Area 7816 sq. m. Pop. (1901), 424,588, showing an increase of 6·1% in the decade. About three-quarters of the district lies to the east of the Indus. Along the river is a low fertile tract, liable to floods. The remaining upland, known as the Thal, is barren and sandy, cultivable only where irrigation is possible. In the north-east the district includes the western flank of the Salt Range. The part of the district west of the Indus is a level and fairly fertile plain, enclosed by the Chichali and Maidani hills. The chief agricultural products are wheat and other grains and oil-seeds. Hides and wool are also exported, together with small quantities of alum (abundant in the Salt Range), salt (from the Salt and Maidani ranges), and coal of poor quality, which is found at several points. Petroleum has been discovered. The district is served by the Multan-Rawalpindi line of the North-Western Railway.

MIAOTSZE, or MIAOTSE, one of the aboriginal tribes of southern China. At one time they occupied a considerable portion of the fertile soil which now forms the central province of the empire, but as the Chinese advanced southwards they were driven into the mountain districts of the provinces of Yunnan, Kwei-chow, Kwang-si and Kwang-tung, where they are found at the present day. As early as the reign of King Suan (about 800 B.C.) we read of an expedition having been sent to drive them out of Hu-nan. The last important campaign against them was undertaken by the emperor K'i-en-lung, who, having completely subjugated the Eleuths, attacked the Miaotse, who suffered a crushing defeat, and were compelled to purchase peace by swearing allegiance to their conquerors. They were then permitted to remain in their mountain-homes, but are a decaying race, gradually giving way before the Chinese. They are allowed to govern themselves on their own patriarchal system. The Miaotse of both sexes are shorter and darker-complexioned than the Chinese, their faces are rounder and their features sharper.

MIAOULIS, ANDREAS VOKOS or BOKOS (1768-1835), Greek admiral and politician, was born in Negropont. The surname Miaoulis, which was added to his family name of Vokos, or Bokos, is said to be derived from the Turkish word miaoul, a felucca. He settled in the island of Hydra on the east of the Morea, and when the Greek War of Independence began was known among his fellow townsmen as a trader in corn who had gained wealth, and who made a popular use of his money. He had been a merchant captain, and was chosen to lead the naval forces of the islands when they rose against the government of the Sultan. The islanders had enjoyed some measure of exemption from the conscription of the Turks, and in the same year that the conscription raised to man the Turkish ships; and though they seemed to be peculiarly open to attack by the Sultan's forces from the sea, they took an early and active part in the rising. As early as 1822 Miaoulis was appointed navarch, or admiral, of the swarm of small vessels which formed the insurgent fleet. He commanded the expedition sent to take revenge for the massacre of Chios (see KANARIS) in the same year. He continued to be the naval chief of the Greeks till Lord Donoughmill entered their service in 1827, when he retired in order to leave the English officer free to act as commander. In the interval he had been the general direction of the naval side of the Greek struggle for freedom. He had a share in the successful relief of the first siege of Missolonghi in December 1822 and January 1823. In 1824, after the conquest of Psara by the Turks, he commanded the Greek forces which prevented the further progress of the Sultan's fleet, though at the cost of the loss of many fire ships and men to themselves. But in the same year he was unable to prevent the Egyptian forces from occupying Navarino, though he harassed them with some success. During 1825 he succeeded in carrying stores and reinforcements into Missolonghi, when it was reduced for the second time by the same forces as before. His efforts to interrupt the sea communications of the Egyptian forces failed, owing to the enormous disproportion of
the two squadrons in the siege and strength of the ships. As the war went on the naval power of the Greeks diminished, partly owing to the penury of their treasury, and partly to the growth of piracy in the same manner as the Venetians. When Minoaus retired to make room for Dandonaull the conduct of the struggle had really passed into the hands of the powers. When independence had been obtained, Minoaus in his old age was entangled in the civil conflicts of his country, as an opponent of Capodistrias and the Russian party. He had to employ his skill in the employment of fireships against them at Poros in 1831. He was one of the deputation sent to invite King Otho to accept the crown of Greece, and was made rear-admiral and then vice-admiral by him. He died on the 24th of June 1853 at Athens.

**MICA**, a group of widely distributed rock-forming minerals, some of which have important commercial applications. The principal members of the group are muscovite, biotite, phlogopite, and lepidolite (q.v.). The name mica is probably derived from the Latin *micara*, to shine, to glitter; the German word *glimmer* has the same meaning. The mineral was probably included with scleinite under Pliny's term *lapis specialis*.

**Mineralogical Characters.**—The micas are characterized by a very easy cleavage in a single direction and by the high degree of flexibility, elasticity and toughness of the extremely thin cleavage flakes. They all crystallize in the monoclinic system, but, however, in forms closely resembling those of the rhombohedral or orthorhombic systems. Crystals usually have the form of hexagonal or rhomb-shaped scales, plates or prisms, with plane angles of 60° and 120°, and, with the exception of the basal planes, are only rarely bounded by smooth and well-defined faces. The crystal represented in fig. 1 is bounded by the basal pinacoid *c* (001) parallel to which is the perfect cleavage, the clinopinacoid *b* (010) parallel to the plane of symmetry, and the pyramids *m* (221) and *o* (112). The angles between these pyramids and the basal plane are 85°3 and 75° respectively. The prism (110) at 90° from the basal plane is not developed as a crystal face, but is a plane of twinning, the two individuals of the twin being united parallel to the basal plane (fig. 2). The different species of mica have nearly the same forms and interfacial angles, and they not infrequently occur intergrown together in parallel position. The best developed crystals are those of Vesuvian biotite.

When a cleavage flake of mica is struck a sharp blow with a blunt needle-like an exfoliated star of cracks or "percussion figure" is developed; the rays intersect at angles of approximately 60°, and the pair most prominently developed are parallel to the plane of symmetry of the crystal. A similar six-rayed system of cracks, bisecting the angles between the rays of the previous set, is produced when a blunt punch is gradually pressed against a sheet of mica; this is known as the "pressure figure." These cracks coincide with planes of easy separation or of gliding in the crystal; they are especially useful in helping to determine the crystallographic orientation of a cleavage flake of mica when crystal faces are absent. Sheets of mica which have been subjected to earth-movements are frequently cracked and ridged parallel to these directions, and are thus valueless for economic purposes.

In their optical characters the micas exhibit considerable variations. The indices of refraction are not high, the mean index being about 1.58-1.60, but the double refraction is very strong (0-04-0.05) and is negative in sign. The angle between the optic axes varies from 70°-50° in muscovite and lepidolite to 10°-9 in biotite and phlogopite; they are therefore and thus frequently optically uniaxial. The acute bisectrix of the optic axes never deviates from the normal to the basal plane by more than a degree or two, hence a cleavage flake of mica will always show an optic figure in convergent light when placed on the stage of a polarizing microscope. The plane of the optic axes may be either perpendicular or parallel to the plane of symmetry of the crystal, and according to its position two classes of mica are distinguished. To the first class belong muscovite, lepidolite, paragonite, and a rare variety of biotite called aasinite; the second class includes zinnwaldite, phlogopite, lepidolite and most biotites. Dark coloured micas are strongly pleochroic. Accurate determinations of the optical orientation, as well as the symmetry of the etching figures on the cleavage planes, seem to suggest that the micas, except muscovite, may be anorthic rather than monoclinic in crystallization.

The different kinds of mica vary from perfectly colourless and transparent—as in muscovite—through shades of yellow-green, red and brown to black and opaque—especially in lepidolite; the former have a pearly lustre and the latter a submetallic lustre on the cleavage surfaces. Sheets of mica very often show coloured rings and bands (Newton's rings), due to the interference of light at the surfaces of internal cleavage cracks. The spec. grav. varies between 2.7 and 3.1 in the different species. The hardness is 2-3; smooth cleavage surfaces can be just scratched with the finger-nail. The micas are bad conductors of heat and electricity, and it is on these properties that many of their technical applications depend.

Inclusions of other minerals are frequently to be observed in mica. Flattened crystals of garnet, films of quartz, and needles of tourmaline are not uncommon. Cleavage sheets are frequently disfigured and rendered of little value by brown, red or black spots and stains, often with a dendritic arrangement of iron oxides. Minute acicular inclusions, probably of rutile, arranged parallel to the rays of the percussion figure, give rise to the phenomenon of asterism. In some cases, particularly phlogopite, a candle-flame or spot of light viewed through a cleavage sheet of such mica appears as a six-rayed star.

**Chemical Composition.**—The micas are extremely complex and variable in composition. They are silicates, usually orthosilicates, of aluminium together with alkalis (potassium, sodium, lithium, rarely rubidium and caesium), basic hydrogen, and, in some species magnesium, ferrous and ferric iron, rarely chromium, manganese and barium. Fluorine is also often an essential constituent, and titanium is sometimes present.

The composition of the several species of mica is given by the following formulae, some of which are only approximate. It will be seen that they may be divided into two groups—alkali-micas (Li, Na, K, and Ca, &c.) and ferro-magnesian micas (Fe, Mg) which correspond roughly with the division into light and dark micas.

The water which is present in muscovite to the extent of 4 to 6%, and rather less in the other species, is expelled only at a high temperature, and therefore water of constitution, existing as basic hydrogen or as hydroxyl replacing fluorine.

Roscoelite is a mica in which the aluminium is largely replaced by vanadium (V₂O₅, 50%); it occurs as brown-green scaly aggregates intimately associated with gold in California, Colorado and Western Australia.

Various attempts have been made to explain the variations in composition of the various micas from the standpoint of the common commercial varieties. In 1878, regarded by some workers as anomalous, is often considered as the isomorphous mixture of the following fundamental molecules: H₂K₂Al₂(SiO₄)₃, corresponding to muscovite; Mg₃Si₂O₆, a hypothetical polymer of olivine; and H₂Si₄O₁₀, a hypothetical aluclidean acid. F. W. Clarke (1889-1893) supposes them to be substitution derivatives of normal aluminium orthosilicate Al₂(SiO₄)₃, in which part of the aluminium is replaced by alkalis, magnesium, iron and the univalent groups (MgF₂, Al₂O₃, MgOH) and an excess of silicic acid formed by the isomorphous replacement of H₂SiO₄ by the acid H₂SiO₄.

Artificially formed crystals of the various species of mica have been observed in furnace-slags and in situagations.

**Occurrence.**—Mica occurs in primary and essential constituent of many rocks of almost all kinds; it is also a common product of alteration of many mineral silicates, both by weathering and by contact- and dynamo-metamorphic processes in sedimentary rocks it occurs as detrital material.

Muscovite and biotite are commonly found in silicious rocks, whilst phlogopite is characteristic of calcareous rocks. The best crystallized specimens of any mica are found in small brilliant crystals of biotite, which fill cavities in the limestone blocks ejected from Monte Somma, Vesuvius. Large sheets of muscovite, such as are of commercial value, are found only in the very coarsely crystalline pegmatites, or after metamorphism, goethite or muscovite schist. These veins consist of felspar, quartz and mica, often with smaller amounts of other crystallized minerals, such as tourmaline, beryl and garnet; they are worked for mica in India, the United
States (South Dakota, Colorado and Alabama), and Brazil (Goyaz, Bahia and Minas Gerais). The commercially valuable micas of Canada and Ceylon are mainly phlogopite (q.v.). The price of mica varies very considerably according to the size, transparency and quality of the sheets. An average price for cut sheets of all sizes is about 4s. per lb, but for large sheets it may be as high as 54s. per lb.

MICAH (mî-kâ), in the Bible, the name prefixed to the sixth book of the books of the minor prophets. He was a contemporary and fellow-worker of Isaiah. The name in various modifications—Mîkâh, Mîkâth, Mîkâhâ—occurs in the Old Testament, expressing as it does a fundamental point of Hebrew faith: Who is like Yahweh? It was also borne among others by the Danite whose history is given in Judges xvii. seq. (see separate article), by the prophet who opposed Ahab's expedition to Ramoth-Gilead (1 Kings xxii.), and by the son of Jonathan (see Saul).

The editorial title of the book of Micah declares that Micah prophesied in the days of Jotham (739-734), Ahaz (733-721) and Hezekiah (722-693), kings of Judah. Nothing in the book itself can claim to belong to the reign of Jotham, but the prophecy against Samaria (i. 5-8) may have been uttered originally before the fall of Samaria in 722, i.e. in the reign of Ahaz. In its present form, however, it has been incorporated in a prophecy against Judah, belonging, most probably, to the years 705-701, when a new Palestinian rising provoked Sennacherib's campaign of 701 (Nowack; cf. Marti). This prophetic activity of Micah under Hezekiah is confirmed by the tradition (cf. ii. 3) that he was present at the Babylonian capture of Jerusalem (605 B.C.), and by ii. 12 ("Zion shall be plowed as a field") and other passages. The verses quoted form the climax of Mic. i.-iii., from which chapters only any certain conclusions as to the prophetic message of the historic Micah can be drawn; the remaining sections of the present book (iv.-v., vi.-vii.) consist, in whole or in greater part, of writings belonging to a later period.

Chs. i.-iii. (with the exception of two verses, ii. 12, 13) are a prediction of judgment on the sins of Judah and Ephraim. In a majestic exordium Yahweh Himself is represented as coming forth in the thunderstorm (cf. Amos i. 2) from His heavenly palace, and descending on the mountains of Palestine, at once as witness against His people, and as judge of their sins. The first verses of each chapter have been rendered as notices of the visits of Jehovah to the Jerusalem temple (Ezra, iv. 4-10; Neh. vii. 5-10; viii. 5-9), and as indicating a revival of worship and a return to the old covenant and its laws. This interpretation is of course very plausible; but it is not in all respects satisfactory. The prophet clearly foresees that the people of his own day would be more interested in the safety of the temple than in the purity of its worship. The original exordium was probably intended to indicate the purposes of the prophecy as a whole; it is followed by a series of very pathetic and very weighty warnings and exhortations, delimiting in which cases the restoration will be possible. And the last prediction is of a nature to be applicable at any time, and to teach the people to expect the coming of the Lord in the way of judgment and mercy.

1 A confusion between the two prophets of the name has led to the insertion in the Massoretic text of 1 Kings xxi. 28 of a citation from the prophecy of Micah.

2 See, however, Gray, Hebrew Proper Names, p. 157: "In later times they were perhaps virtually synonymous; but this is not to be assumed for early times. The shorter forms may well have had a purely secular reference, signifying 'who is like this child?'"

3 He is called "the Morashite" (Mic. ii. 1; Jer. xxvi. 18) from his birthplace, Moresheth-Gath. That Micah lived in the Shephelah or Judanean lowland near the Philistine country is clear from the local colouring of i. 10 seq., where a number of places in this quarter are mentioned together (in connexion with the war in Philistia), and their names played upon in a way that could hardly have suggested itself but to a man of the district. The paronomasia makes the verses difficult, and in i. 14 none of the ancient versions recognizes Moresheth-Gath as a proper name. The word Morashite (Môrašîth) was therefore obscure to them; but this only gives greater weight to the traditional pronunciation with Ê, the first syllable, which is as old as the LXX., and goes against the view, taken by the Targum both on Micah and on Jeremiah, and followed by some moderns (including Cheyne, E. L., 1898), that Micah is Babylonian. When Ezechiel placed Moresheth near Eleutheropolis it is not likely that he is thinking of Moresheth (Maraesh), for he speaks of the former as a village and of the latter as a ruin (Ezek. xxv. 12). Eleutheropolis is a town near Nablus (W. 189), speaking as an eye-witness, distinguishes Morashith, with the church of Micah's sepulchre, from Maraesh. This indeed was after the pretended miraculous discovery of the relics of Micah in that town. The name Micah (mî-kâ) in existence (Præf. in Mâch.) can hardly have been part of a pious fraud.

4 These two verses are a prophecy of restoration; they are admitted an interruption in their present context (so, e.g., Driver, 'Jeb.', 1891); they belong in substance to the second section of the book (iv. v.).
judgment to be also a prophet of comfort; but the internal evidence of composite and (in whole or part) later authorship must outweigh the traditional attachment of these passages to a MS. containing the work of Micah.

The sequence of thought in chs. iv. v. is really difficult, and has hitherto raised to masterly confusion. Thus iv. 11-13 stands in direct contradiction to iv. 9, 10, and indeed iv. 12. The last two passages agree in speaking of the capture of Jerusalem, the first declares Zion inviolable, and its capture an impossible proposition. Such a contradiction is hardly to be reconciled; but we resort to the violent harmonic process of imagining that two quite distinct sieges, separated by a renewal of the theocracy, are suggested. In consequence, however, another difficulty lies in the words "and thou shalt come even from the land of Micah unquestionably looked for the destruction of Jerusalem as well as of Samaria in the near future and by the Assyrians (i. 9), and this wish is natural to Micah with his local interests. Another difficulty here lies in the prophecies, which, therefore, belong to the original context, they mark it as not from Micah's hand; though they might be a later gloss.

The poetic thought is that the daughter (population) of Zion shall not be saved by her present rulers or defensive strength; she must come down from her bulwarks and dwell in the open field; there, and not within her proud ramparts, Yahweh will grant deliverance from her enemies. To present tyranny expresses itself in recurrence to the old popular ideal of a people under a Godly kingdom (iv. 8). These old days shall return once more. A new Davi, like him whose exploits in the district of Micah's home were suggested by the Mount Zion passage, may arise, which would take from the throne the sacerdotial and theocratic power, and restore to the people their ancient inheritance. Yahweh, the king on Mount Zion, and no inventions of man come between Him and His people.

The last chapter of Micah presents a very different situation from that of chs. i.-iii. or iv., v., v. v. v. y. and Micah appears to plead with His people for their sins, but the sinners are no longer a careless and oppressive aristocracy buoyed up by deceptive assurances of Yahweh's help, by prophecies of wine and strong drink; they are bowed down by a religion of terror, wearied with attempts to propitiate an angry God by countless offerings, and even by the sacrifice of the first-born. Meantime the substance of true religion—justice, charity and a humble walk with God—is forgotten, and defeat and ruin in all classes, the works of the house of Ahab are observed (worship of foreign gods). Yahweh's judgments are not only against the kingdom, but against the whole nation, which can be nothing else than its total desolation. All these marks may be held to denote not only the evil times of Manasseh as described in 2 Kings xvi. but also to express the progressive development of the nation of Israel and Judah to its final ruin.

Micah may very well have lived into Manasseh's reign, but the title in 1 does not cover a prophecy which certainly falls after Hezekiah's death, and the style has nothing in common with the earlier part of the book. It is therefore prudent to regard the prophecy, with Ewald, as anonymous. Ewald ascribed the whole of chs. vi. vii. viii. to one author. Wellhausen, however, remarks with justice that the thread is abruptly broken at vii. 6, and that verses 7-20 represent Zion as already fallen before the heathen and her inhabitants as pining in the darkness of captivity. The hope of Zion is in future restoration after she has patiently borne the chastisement of her sins. Then Yahweh shall arise manifestly to save her, and "the nations shall be gathered to her, and the heathen humbled. The faith and hope which breathe in this passage have the closest affinities with the book of Lamentations and Isa. xl-xlvi. Indeed, as Marti points out (p. 259) the triple division of the book of Micah (i.-iii.; iv. v. vi. vii.) corresponds with that of the book of Isaiah (i.-xxix.; xl.-xxi.); the character of the three divisions (judgment; coming restoration; prayer for help in adversity) respectively, and in the fact that the first alone gives us pre-exilic writing in the actual words of the prophet to whom the whole book is ascribed. In both cases, it need hardly be said, the deeper spiritual value of the latter passages ought in no way 1 Regarded by Stade (Z. A. T. W., 1903, p. 164 seq.) as an independent psalm.
to suffer prejudice from critical conditions as to their date and authorship.

**Literature.**—The chief modern commentaries are those of Noyes (Die Kleinen Propheten, 1897; 2nd ed., 1904) and Marti (Diedagaprophoton, 1904), where detailed references to the older literature may be found; cf. Wellhausen, Die Kleinen Propheten (3rd ed., 1892). A recent reference may also be made to Cheyne and the Bible in the Cambridge Bible, 1882; 2nd ed., 1895), and to G. A. Smith ("The Book of the Twelve," vol. I., in, *The Expositor's Bible*, 1896; also to the articles on "Micah" by Noyes in Hastings, in Harper's Ency. of the Bible (1900), iii. 359, 360, and by Cheyne in the Ency. Bibl. (1902), iii. c. 3068-3074, the latter incorporating most of the original article (Ency. Brit. 9th ed.) by W. Robertson Smith, which has been revised above in. For a review to recent criticism see Cheyne, introduction to W. R. Smith's *The Prophets of Israel*, 2nd ed., pp. xxviii.-xxvii.; also Ency. Bibl. loc. cit. J. M. P. Smith discusses The Strophic Structure of the Book of Micah, valuable (Oxford) and Semitic Studies: a bibliography of W. R. Harper (Chicago, 1908).

**MICAH,** a man of the hill-country of Ephraim whose history enters into that of the foundation of the Israelite sanctuary at Dan (Judges xvii. seq.). He had stolen from his mother eleven hundred pieces of silver (for the number cf. Judges xvii. 5), and when she uttered a curse upon the unknown thief he restored the money and she consecrated it to Yahweh. A carved image was also set up in the temple to his honour with an ephod-idol and teraphim (objects used in divination, cf. Gen. xxxi. 19, 30; Hos. iii. 4). He employed one of his sons to serve as priest, but when a Levite from Bethléem in Judah came also he gladly installed him as "father and priest." When the tribe of Dan subsequently sought new territory and sent men to search for a suitable district they passed by Micah's house, recognized the Levite and requested an oracle from him. When, later, they migrated, they despoiled the sacred place and carried off the gods and priest to their new home.

**MICA-SCHIST,** in petrology, a rock composed essentially of mica and quartz, and having a thin parallel-banded or foliated structure, with lamellae rich in mica alternating with others which are principally quartz. They split readily along the micaceous films, and have smooth or slightly uneven surfaces covered with lustrous plates of muscovite or biotite; the quartzose lamellae are often visible only when the specimens are looked at edgewise. Mica-schists are very common in regions of Archean rocks, accompanying gneisses, crystalline limestones and other schists. Some flat bands of muscovite or biotite are crumpled or contorted with undulating foliation. Occasionally the quartz forms elliptical lenticles or "eyes." In some cases mica composes nearly the whole of the rock, in others quartz preponderates so that they approach quartz-schists and quartzites.

The mica may be muscovite or biotite; both are often present, while paragonite, vermiculite, or chrome-mica are not so common. In addition to quartz there may be a small amount of feldspar, usually albite. A great number of accessory minerals are known in mica-schists, and when these are conspicuous or important they may be regarded as constituting special varieties receiving distinctive names. Garnet, in rounded red crystals, not uncommonly idiomorphic, is the most frequent. Brown staurolite, pinkish andalusite, and grey or blue kyanite occur in some kinds of mica-sheets separately or together. The white mica-schists of the St. Gothard contains kyanite and staurolite. Graphite (or graphiodot) is also a very frequent ingredient of these rocks, giving them a leaden grey colour and causing them to soil the fingers when handled. In some mica-schists there is much calcite (calcite-mica-sheets) and hornblende, scapolite and augite are often seen in rocks of this sort. Tourmaline occurs, sometimes in large black prisms but more commonly in minute crystals visible only in microscopic sections. Rutile in tiny prisms, ilmenite and hematite in black or brown scales, zircon, apatite, granules of epidote or zoisite chlorite, chloritoid and pyroxene are also occasionally seen in the rocks of this group.

Mica-schists are in nearly all cases the products of igneous rocks which have been recrystallized and have obtained a schistose structure during the process. This can be proved by their chemical composition, which is quite the same as that of basalt, but which, in some districts it is possible to trace every gradation from a slate (q.v.) to a mica-schist, the intermediate stages being represented by "glaucophane schists," which consist of quartz, muscovite and chlorite, and are neither so crystalline nor so well foliated as the schists. In a few places, e.g., Bergen in Norway, fossils have been found in mica-schists. The association of quartzites and quartz-schists, graphite-schists and crystalline limestones with mica-schists in the field is explained by the fact that all these rocks are altered sediments, recent sandstones, carbonates, etc.

Under the microscope the appearance presented by mica-schists differs according to whether the rock is cut parallel to or across the planes of foliation. In the latter case thin alternating bands composed of mica and quartz alternate. At the edges of the foliation the mica-sheets may be thick and the quartz flat (see Petrology, Plate 4, fig. 8). The mica scales have their cleavages and their flat sides parallel; the quartz occurs in rounded, elliptical or irregular grains, with usually a small admixture of feldspar (albite). apatite and iron oxides are rarely absent from these rocks. If garnet is present it may form large well-shaped crystals containing innumerable enclosures of quartz, biotite and muscovite, and in some cases the garnets are cracked as if they had been broken by the pressures to which the rock had been subjected. Often the garnets are surrounded by small "eyes" of quartz, and they may be embedded in green chlorite, which is probably a secondand of igneous origin. The green garnets and the quartz are not often found to have a magma relationship.

Like all metamorphic rocks, mica-schists are principally found in Archean areas; the great majority of them are of pre-Cambrian age. There are, however, in the Alps, Himalayas, &c., many rocks of which are believed to be secondary or even tertiary; the evidence for this is not in all cases satisfactory, as of course the fossils, which if preserved would be sufficient to prove it, are nearly always destroyed by the metamorphism. Mica-schists are rarely original rock fragments, but have been only as fragments in the manner in which they are found in rocks of the later stages of gneissic movements.

MICCA, PIETRO, Piedmontese soldier (d. 1706), was born at Andorno, and achieved fame by his death in the defence of Turin. During the siege of that city by the French in 1706 a party of the besiegers had succeeded in penetrating by surprise into the most of the fortress on the night of August 29-30, and would probably have captured it had not Micca, a soldier in the engineers, fired a mine, with the result that they were blown into the air and the rest of the force driven back with heavy losses. Micca's heroism has been the subject of poems, plays and romances. But, according to Count Giuseppe Solaro della Margherita, the commander of the Turin garrison at the time, it was through a miscalculation of the pace of the fuse, and not by deliberate intent, that he sacrificed his life.

See A. Manno Pietro Micca ed il generale conte Solaro della Margherita (Turin, 1883).

**MICHEL.** (Hebrew מיהל, "Who is like God?")}, an Old Testament name, synonymous with Micaiah or Micah (Num. xiii. 13; 1 Chron. v. 13 et passim). In the book of Daniel the name is given to one of the chief "princes" of the heavenly host, the guardian angel or "prince" of Israel (Dan. x. 13, 22; xii. 1; cf. Enoc xx. 5 and possibly Mal. iii. 1), and as such he naturally appears in Jewish theosophy as the greatest of all angels, the first of the four (or seven) who surround the throne of God, and the antagonist of Sammael, the enemy of God. He holds the secret of the mighty "word" by which God created heaven and earth (Enoch lix. 14), and was "the angel who spoke to Moses in the Mount" (Acts viii. 38). It was through Babylonian and Persian influence that names were given to the angels, and according to Kohut (Jud. Angel. p. 24) Michael is parallel to Vohumano, "Ahura's first masterpiece," one of the Zoroastrian Ameana-sspents or archangels. It is as guardian angel of Israel, or of the Church, that Michael appears in Jude 1 and Rev. xii. 7. This latter passage is of distinctly pre-Christian origin; it is not the Child that overthrows Satan, the figure of the Messiah is ousted by that of Michael. There is also here a relic of the primordial Babylonian myth of the struggle between the light god Marduk and the forces of chaotic darkness. In the Western Church the festival of St Michael and All Angels (Michaelmas) is celebrated on the 29th of September; it appears to have grown out of a local celebration of the dedication of a church of St Michael either at Mount Garganus in Apulia or at Assisi, both of which was a garnet. It was celebrated by the beginning of the 9th century. The Greek Church dedicates the 5th of November to St Michael, St Gabriel and All Angels.
MICHAEL (1596-1643), tsar of Russia, was the first tsar of the house of Romanov, being the son of Theodore Nektitch Romanov, afterwards the Patriarch Philaret (p.v.), and Xenia Chestovaya, afterwards the nun Martha. He was elected unanimously tsar of Russia by a national assembly on the 21st of February 1613, but not till the 24th of March did the delegates of the council discover the young tsar and his mother at the Ipatievsky monastery near Kostroma. At first Martha protested that her son was too young and tender for so difficult an office in such troublesome times. At the last moment, however, Michael consented to accept the throne, but not till the weeping boyars had solemnly declared that if he persisted in his refusal they would hold him responsible to God for the utter destruction of Muscovy. In so dilapidated a condition was the capital at this time that Michael had to wait for several weeks at the Troitsa monastery, 75 m. off, before decent accommodation could be provided for him at Moscow. He was crowned on the 22nd of July. The first care of the new tsar was to clear the land of the robbers that infested it. Sweden and Poland were then got rid of respectively by the peace of Stolbova (March 20, 1617) and the truce of Deulina (Feb. 13, 1619). The most important result of the truce of Deulina was the return from exile of the tsar's father, who henceforth took over the government till his death in October 1633, Michael occupying quite a subordinate position. He was a gentle and pious prince who gave little trouble to any one and efficacy himself behind his counsellors. Fortunately for him they were relatively honest and capable men. Michael's failure to wed his daughter Euphrosyne, with Waldemar of Denmark on account of the refusal of the latter to accept orthodoxy, so deeply afflicted him as to contribute to bring about his death on the 12th of July 1645.

MICHAEL, the name of nine East-Roman emperors.

Michael I, Phragabees (d. 845), an obscure nobleman who had married Procopia, the daughter of Nicephorus I, and been made master of the palace. He was made emperor in a revolution against his brother-in-law, Stauricius (811).

Michael II, called Psellus, "the stammerer," emperor 820-829, was native of Anoomus in Phocis, to which province he returned after a nobleman sold by his talents to the rank of general. He had favoured the enthronement of his old companion in arms Leo the Armenian (824), but, detected in a conspiracy against that emperor, had been sentenced to death in December 820; his partisans, however, succeeded in assassinating Leo and called Michael from the prison to the throne. The principal features of his reign were a struggle against his brother general, Thomas, who aimed at the throne (822-824); the conquest of Crete by the Saracens in 823; and the beginning of their attacks upon Sicily (827). In spite of his Iconoclastic sympathies, he endeavoured to conciliate the image-worshippers, but incurred the wrath of the monks by entering into a second marriage with Euphrosyne, daughter of Constantine VI, who had previously taken the veil.

Michael III. (839-867), "the drunkard," was grandson of Michael II, and succeeded his father Theophillus when three years old (842). During his minority the empire was governed by his mother Theodora, who in spite of several defeats inflicted upon her generals maintained the frontiers against the Saracens of Bagdad and Crete. The regent displayed her religious zeal by restoring image-worship (842) and persecuting the Paulician heretics, but she entirely neglected the education of her son. As a result Michael grew up a debauche, and fell under the sway of his uncle Bardas, who induced him to banish Theodora to a convent and practically assumed the chief control (857). Bardas justified this usurpation by introducing various internal reforms; in the wars of the period Michael himself took a more active part. During a conflict with the Saracens of the Euphrates (856-63), the emperor sustained a personal defeat (860), which was retrieved by a great victory on the part of his uncle Petronas (863). In 867 Michael and Bardas invaded Bulgaria and secured the conversion of the king to Christianity. On sea the empire suffered under the ravages of the Cretan corsairs; and in 865 the first pillaging expedition of the Russians endangered the Bosphorus. In 867 Michael was assassinated by Basil the Macedonian, a former groom, who had overthrown the influence of Bardas and in 866 been associated in the Empire.

Michael IV. (d. 1041), "the Paphlagonian," owed his elevation to Zoe, daughter of Constantine VIII., who was the wife of Romanus III., but becoming enamoured of Michael, her chamberlain, poisoned her husband and married her attendant (1034). Michael, however, being of a weak character and subject to epileptic fits, left the government in the hands of his brother, John the Eunuch, who had been first minister of Constantine and Romanus. John's reforms of the army and financial system revived for a while the strength of the Empire, which held its own successfully against its foreign enemies. On the eastern frontier the important post of Edessa was relieved after a prolonged siege. The western Saracens were almost driven out of Sicily by George Manikakes (1038-40) but an expedition against the Italian Normans suffered several defeats, and after the recall of Manikakes most of the Sicilian conquests were lost (1041). In the north the Serbs achieved a successful revolt (1040), but a dangerous rising which the Bulgarians and Slavs which threatened the cities of Thrace and Macedonia was repressed by a triumphant campaign which the decrepit emperor undertook in person shortly before his death (1041).

Michael V. Calaphates, or "the caulker," nephew and successor of the preceding, surnamed after the early occupation of his father. He owed his elevation (Dec. 1041) to his uncle John, whom, along with Zoe he almost immediately banished; this led to a popular tumult in consequence of which he was dethroned after a brief reign of four months, and relegated to a monastery. His unpopularity seems largely due to his attempts at administrative reform, which were strongly resented by the dominant classes.

Michael VI., "the warlike," was already an old man when chosen by the empress Theodora as her successor shortly before her death in 1056. He was unable to check the disaffection of the feudal aristocracy, who combined with an officer named Jonas to depose him. After a successful battle in Phrygia, the rebels had no difficulty in dethroning Michael (1057), who spent the rest of his life in a monastery.

Michael VII. Ducas, or Parpinaces, was the eldest son of Constantine X. Ducas. After a joint reign with his brothers, Andronicus I. and Constantine XI. (1067-1071), he was made sole emperor through his uncle John Ducas. The feebleness of Michael, whose chief interest lay in trifling academic pursuits, and the avarice of his ministers, was disastrous to the empire. As the result of anarchy in the army, the Byzantines lost their last possessions in Italy (1071), and were forced to cede a large strip of Asia Minor which they had held for centuries to the Seljuk Turks (1074). These misfortunes, which were but partially retrieved by the suppression of a Bulgarian revolt (1073), caused widespread dissatisfaction. In 1078 two generals, Nicephorus Bryennius and Nicephorus Botaniates, simultaneously revolted. Michael resigned the throne with hardly a struggle and retired into a monastery. His nickname Parapinaces ("stavar") was due to his causing the price of wheat to rise.

Michael VIII. Paleologus (1254-1282) was the son of Andronicus Palaeologus Comnenus and Irene Angelina, the granddaugther of Alexius Angelus, emperor of Constantinople. At an early age he rose to distinction, and ultimately became
commander of the French mercenaries in the employment of the emperors of Nicaea. A few days after the death of Theodore Lascaris II. in 1259, Michael, by the assassination of Muzale (which he is believed but not proved to have encouraged) became joint guardian with the patriarch Arsenius of the young emperor, John Lascaris, then a lad of eight years. Afterwards invested with the title of "despot," he was finally proclaimed joint-emperor and crowned alone at Nicaea on the 1st of January 1260. In July 1261 Michael, who had attacked Constantinople with the help of the Genoese, conquered the town through his general Strategopoulos. He thereupon had John Lascaris blinded and banished. For this last act he was excommunicated by Arsenius, and the ban was not removed until six years after (1267) on the accession of a new patriarch. In 1263 and 1264 respectively, Michael, with the help of Urban IV., concluded peace with Villehardouin, prince of Achais, and Michael, despot of Epirus, who had previously been incited by the pope to attack him, but had been decisively beaten at Pelagonia in Thessaly (1259); Villehardouin was obliged to cede Mistra, Monemvasia and Maina in the Morea. Subsequently Michael was involved in wars with the Genoese and Venetians, whose influence in Constantinople he sought to diminish by maintaining the balance of strength between them. In July 1267 Charles of Anjou, who was represented by John Meliarakes, made war with the alleged purpose of restoring Baldwin to the throne of Constantinople, and pressed Michael so hard that he consented to send deputies to the council of Lyons (1274) and there accept the papal supremacy. The union thus brought about between the two Churches was, however, extremely distasteful to the Greeks, and the prosecution of his "schismatic" subjects to which the emperor was compelled to resort weakened his power so much that Martin IV. was tempted to enter into alliance with Charles of Anjou and the Venetians for the purpose of reconquering Constantinople. The invasion, however, failed, and Michael so far had his revenge in the "Sicilian Vespers," which he helped to bring about. He died in Thrace in December 1282. In reconstituting the Byzantine Empire Michael restored the old administration without endeavouring to correct its abuses. By debasing the coinage he hastened the decay of Byzantine commerce.

MICHAEL IX. PALAEOLOGUS, was the son of Andronicus II., and was associated with him on the throne from 1259, but probably January 1261 (1300). He took the field against the Turks (1301, 1310) and against the Grand Catalan Company (1305), but was repeated defeated.

See Gibbon's Decline and Fall (ed. Bury, 1896); G. Finlay, Hist. of Greece (ed. 1877); G. Schliumberger, L'Empere byzantin (1896); J. Bury, in Eng. Hist. Rev. (1886); Mährisches, 'Istoria του βασιλείου της Νικαιας και των συνταγμάτων της Πελοποννήσου', pp. 539-627 (Athens, 1899).

MICHAEL OBRENOVICH III. (1823-1868), Prince of Servia, was the youngest son of Prince Milosh, the founder of the Obrenovich dynasty. After the abdication of his father (1850) and the death of his elder brother Milan Obrenovich II. (1849) he ascended the throne of Servia. He wished to continue the work of his father, in liberating all the Servian people, and if possible all other Balkan Christians, from direct Turkish rule. But while this programme made the Sultan hostile, it also failed to win the support of Austria, which did not wish the Eastern Question to be opened by the ambitious Servian. The support which his aspirations found in Russia increased Turkey's and Austria's suspicions of the prince's activity. At the same time the political situation at home was not favourable to his anti-Turkish policy. The power was in the hands of men who actively forced Obrenovich I. to abdicate, and feared that Obrenovich III. might avenge his father. They thought it safer for them to replace him on the throne by a man who was not an Obrenovich, and who would be personally obliged to them for his elevation. These motives were at the bottom of the revolt, started and led by Vuchich in August 1847, the outcome of which was that Prince Michael left the country and that his equrry, Alexander Karageorgevich, was elected Prince of Servia. As an exile Prince Michael lived principally in Vienna, improving his educa-

tion by studies and travels, and frequently visiting England. He constantly refused to agree to suggestions for his restoration by forcible means. His device was Tempus et num quae, "Time and my right." He supported Servian authors and artists, and wrote himself a book in defence of his father Milosh against the attacks of Cyprian Robert. He wrote poetry too, and some of his songs, set to beautiful music, were very popular amongst the Servians. He married in 1856 the beautiful Julia, Countess Huyndi.

In 1858 the Servians, having dethroned Prince Karageorgevich, recalled Michael's father Milosh Obrenovich I. Michael returned to Servia on the morrow of his father's death (1860) ascending the throne for the second time. His proclamation "that henceforth the law is the highest will in Servia," opened a new era of strict legality and at the same time of entire emancipation from foreign influences, and more especially from Turkey's interference with the internal affairs of Servia. The old constitution, granted to Servia by the sultan as the suzerain and the tsar as the protector of Servia as far back as 1839, was discarded and replaced by one which limited the power of the oligarchic senate and gave a certain share in legislation to the "Narodna Skupshta" (Assembly), as well as to the Senate. The collective responsibility of the national army and increased the regular army. Referenda in all branches of public administration were introduced, and Servia, unthen until a half-oriental and half-patriarchal state, was resolutely led to become a civilized country in a European sense. When in 1862 the Turkish garrison bombarded the town of Belgrade from its citadel, Prince Michael, supported by the European diplomacy, succeeded in obtaining evacuation of some of the smaller forts in Servia, but the strong fortress of Belgrade still remained garrisoned by the Turkish troops. Prince Michael now made vigorous political and military preparations for war against Turkey. He made secret arrangements with the Bulgarian, Bosnian and Albanian leaders, an alliance with Montenegro and an understanding with Greece, with the object that they all should rise if Servia declared war on Turkey. He even succeeded in obtaining Austria's promise, that it would observe an attitude of friendly neutrality and would have nothing against an eventual annexation of the largest part of Bosnia to Servia, and he secured to himself the sympathy of Napoleon III. and his government. In the beginning of 1867 he formally asked the Porte to withdraw the Turkish garrisons from the fortresses of Belgrade, as well as from other two fortresses of minor importance (Shabots and Smederevo (Serbia)). For some time the chances were that a war would take place that spring (1867) between Servia and Turkey, but peace was kept by the action of Great Britain, who advised the sultan to withdraw the Turkish garrisons from the Servian fortresses; and this advice, backed by Russia, France and Austria, prevailed at last with the sultan. On the 26th of April 1867 the fortresses were delivered over to Prince Michael, who shortly afterwards went to Constantinople to thank the sultan personally.

Prince Michael's policy had triumphed. But his success was short-lived. A group of young men, mostly educated in France and Germany, now started a liberal movement under the leadership of Yovan Ristic or Kistitch. They wanted a more liberal constitution than that which Prince Michael had given; and this movement tended to qualify his popularity. Meanwhile the prince contemplated divorce from his wife Princess Julia, by whom he had no children, and marriage with the daughter of his cousin Madame Anka Constantinovich; and the adherents of the exiled Karageorgevich dynasty were alarmed at the prospect of his eventually having legal heirs to the throne. A former private secretary to Prince Alexander Karageorgevich, and two of the same prince's brothers-in-law, formed a conspiracy, which resulted in the brutal assassination of Prince Michael on the 20th of May (June 10 (O.S.), 1868), whilst he was walking in the park of Koshtunyak, a few miles distant from Belgrade.

MICHAELIS, JOHANN DAVID (1717-1791), German biblical scholar and teacher, a member of a family which had the chief part in maintaining that solid discipline in Hebrew and the
of his autobiography with the aid of the other materials collected by J. M. Hassencamp (1743-1797) the editor (J. D. Michaud
Lebensbeschreibung, 2., 1793). The same volume contains a full
list of his works. Besides those already mentioned it is sufficient to
refer to his New Testament Introduction (the first edition, 1750,
preceded the full development of his powers, and is a very different
work from the later editions), his reprint of Robert Lowth's Prœduc
tiones with important additions (1758-1762), his German translation
of the Bible with notes (1773-1792), his Orientalische und exegetische
Bibliothek (1775-1785) and Neue O. and E. Bib. (1780-1791), his
Hesychisches Recht (1770-1792) and his edition of E. Castel's Lexicon
syriacum (1778-1788). His Literarischer Briefwechsel (1794-1796)
contains much that is interesting for the history of learning in his
time.

MICHAUD, JOSEPH FRANÇOIS (1767-1830), French his
torian and publicist, was born of an old family on the 10th
of June 1767, at Albens, Savoy, was educated at Bourg-Bres,
and afterwards engaged in literary work at Lyons, where
the events of 1789 first called out the strong dislike to
revolutionary principles which manifested itself throughout
the rest of his life. In 1791 he went to Paris, where, not without
danger, he took part in editing several royalist journals.
In 1796 he became editor of La Quotidienne, for his
connexion with which he was arrested after the 10th of Vendémiaire;
he succeeded in escaping his captors, but was sentenced to death
par contumace by the military council. Having resumed
the editorship of his newspaper on the establishment of the Directory,
he was again proscribed on 1st of March, 1797, at Fontaine,
but at the close of two years returned to Paris, his sister
superseded the Directory. His Bourbon sympathies led to a
brief imprisonment in 1800, and on his release he for the time
abandoned journalism, and began to write or edit books.
Along with his brother and two colleagues he published in 1806 a
Biographie moderne, ou dictionnaire des hommes qui se sont fait
un nom en Europe depuis 1789, the earliest work of its kind;
and in 1811 appeared the first volume of his Histoire des croisades
and also the first volume of his Biographie universelle. In
1814 he named the editor of the Histoire des croisades, and in the
same year was elected Academician. In 1815 his brochure
entitled Histoire des guerres seculaires ou le dernier règne de Bonaparte
met with extraordinary success, passing through twenty
seven editions within a very short time. His political services
were now rewarded with the cross of an officer in the Legion
of Honour and the modest post of king's reader, of which last
he was deprived in 1827 for having opposed Peyronnet's "Loi
d'Amour" against the freedom of the Press. In 1830-1831 he
travelled in Syria and Egypt for the purpose of collecting addi
tional materials for the Histoire des croisades; his correspondence
with a fellow explorer, J. F. Pouchoulin, consisting practically
of discussions and elucidations of various points in that work,
was afterwards published (Correspondance d'orient, 7 vols.,
1833-1835). Like the Histoire, it is more interesting than exact.
The Bibliothèque des croisades, in four volumes more, contained
the "Pièces justificatives" of the Histoire. Michaud died on the
30th of September 1830, at Passy, where his home had been
since 1823.

His Histoire des croisades was published in its final form in six
volumes in 1840 under the editorship of his friend Pouchoulin (6th ed.,
with appendices, by Hulsen-Brochard, H. G. D. de Tilly and
Pouchoulin, also edited Nouvelle collection des mémoires pour servir
t'à l'histoire de France (32 vols., 1836-1844). See Sainte-Beuve,

MICHAX, ANDRÉ (1746-1802), French botanist and
traveller, was born at Versailles on the 7th of March 1746.
In 1770 he spent some time botanizing in England, and in 1778
he explored Auvergne, the Pyrénées and the Alps; and in
1782 he was sent by the French government on a botanical
mission to Persia. His journey began unfavourably, as he was
robbed by Arabs of all his equipment except his books; but he
gained influential support in Persia, having cured the shah
of a dangerous illness. After two years he returned to France
with a fine herbarium, and also introduced numerous Eastern
plants into the botanic gardens of France. In 1785 he was
sent by the French government to North America, and travelled
with his son François André (1770-1852) through Canada,
Nova Scotia and the United States. On his return to France in 1792 he was shipwrecked and lost most of his collections. In 1800 he went to Madagascar to investigate the flora of that island, and died there on the 16th of November 1815. His work as a botanist was chiefly done in the field, and he added largely to what was previously known of the botany of the East and of America.

MICHEL, CLAUDE, known as CLODION (1738–1814), French sculptor, was born on the 20th of December 1738 in Nancy. Here and probably in Lille he spent the earlier years of his life. In 1755 he came to Paris and entered the workshop of Lambert Sigisbert Adam, his maternal uncle, a clever sculptor. He remained four years in this workshop, and on the death of his uncle became a pupil of J. B. Pigalle. In 1759 he obtained the grand prize for sculpture at the Académie Royale; in 1761 he obtained the first silver medal for studies from models; and in 1762 he went to Rome. Here his activity was considerable between 1767 and 1771. Catherine II. was eager to secure his presence in St Petersburg, but he returned to Paris. Among his patrons, which were very numerous, were the emperors of Russia and Languedoc, and the Direction générale. His works were frequently exhibited at the Salon. In 1782 he married Catherine Flore, a daughter of the sculptor Augustin Pajon, who subsequently obtained a divorce from him. The agitation caused by the Revolution drove Clodion in 1792 to Nancy, where he remained until 1798, his energies being spent in the decoration of houses. Among Clodion's works are a statue of Montesquieu, a "Dying Cleopatra," and a chimneypiece at present in the South Kensington Museum.

One of his last groups represented Homer as a beggar being driven away by fishermen (1810). On the 29th of March 1814 Clodion died in Paris, on the eve of the invasion of Paris by the allies.

Thirion's Les Adam et Clodion (Paris, 1883) contains a list of the sculptor's works sold between 1767 and 1884. See also A. Jacquot, Les Adam et les Mich ć et Clodion (Paris, 1898).

MICHEL, CLÉMENCE LOUISE (1830–1903), French anarcho-communist, called la Vierge rouge de Montmartre, was born at the château of Vioncourt (Haute-Marne) in 1830, the daughter of a serving-maid, Marianne Michel, and the son of the house, Étienne Charles Demahis. She was brought up by her father's parents, and received a liberal education. After her grandfather's death in 1850 she was trained to teach, but her refusal to acknowledge Napoleon III. prevented her from serving in a state school. She found her way in 1866 to a school in the Montmartre quarter of Paris, where she threw herself ardently into works of charity and revolutionary politics. She became violently anti-Bonapartist, and is said to have meditated the assassination of Napoleon. During the siege of Paris she joined the ambulance service, and unstirringly resisted preachment to the Prussians. On the establishment of the Commune she joined the National Guard. She offered to shoot Thiers, and suggested the destruction of Paris by way of vengeance for its surrender. She was with the Communards who made their last stand in the cemetery of Montmartre, and was closely allied with Théodore Ferré, who was executed in November 1871. This ardent attachment was perhaps one of the sources of the exaltation which marked her career, and gave many handles to her enemies; but when she was brought before the 6th Committee of war in December 1871 she defied her judges and defended the Commune. She was sent as a convict to New Caledonia, among her companions being Henri Rochefort, who remained seven months in prison. After a short period of freedom she was again arrested for making inflammatory speeches. She was soon liberated, but, hearing that her enemies hoped to intern her in a lunatic asylum, she fled to England. She returned to France in 1895, and in 1902 was back in London. She was touring France and lecturing on behalf of anarchist propaganda when she died at Marseilles on the 10th of January 1905.

Her Mémoires (Paris, 1886) contain accounts of her trials. See also La Bonne Louise (Paris, 1909), by E. Girault.

MICHEL FRANCISCO XAVIER (1800–1887), French anti-monarchist, was born in Lyons on the 28th of October 1800. He became known for his editions of French works of the middle ages, and the French Government, recognizing their value, sent him to England (1833) and Scotland (1837) to continue his researches there. In 1839 he was appointed professor of foreign literature in the Faculté des lettres at Bordeaux. Between 1834 and 1842 he published editions of a large number of works written between the eleventh and fourteenth centuries in French, English and Saxon, including the Roman de la rose and the Chanson de Roland. Subsequently he published French translations of Goldsmith, Sterne, Shakespeare and Teneney. He died in Paris on the 18th of May 1887.

His original works include Histoire des races maudites de la France et de l'Espagne (1847); Recherches sur le commerce pendant le moyen âge (1852–1854); Les Ecsossais en France et les français en Ecosse still Vérités du peuple Basque (1856); Histoire du commerce et de la navigation à Bordeaux (1867–1871); and, in conjunction with Edouard Fournier, Histoire des hôtellerie, cabarets, hôtels garnis (1851–1854).

MICHELANGELO (MICHELAGNIOLLO BUONARROTTI (1475–1564), the most famous of the great Florentine artists of the Renaissance, was the son of Lodovico Buonarroti, a poor gentleman of that city, and of his wife Francesca dei Nerli. The Buonarroti Simoni were an old and pure Florentine stock of the Guelf faction: in the days of Michelangelo's fame a connexion of the family with the counts of Canossa was imagined and admitted on both sides, but has no foundation in fact. Ludovico was barely able to live on the income of his estate, but made it his boast that he had never stopped to add to it by mercantile or mechanical pursuits. The favour of the Medici procured him temporary employment in minor offices of state, among them that of podestà of Prato (1470–1471) and of that of Massa Marittima (1474–1475) and Castello di Chiusi and Caprese in the Casentino. At Caprese, on the 6th of March 1475, his second son Michelagniolo or Michelangelo was born. Immediately afterwards the family returned to Florence, and the child was put to nurse with a marble-worker's wife of Settignano. His mother's health had already, it would seem, begun to fail; at all events in a few years from this time, after she had borne her husband three more sons, she died. While still a young boy Michelangelo determined, in spite of his father's opposition, to be an artist. He had sucked in the passion, as he himself used to say, with his foster-mother's milk. After a sharp struggle his stubborn will overcame his father's pride of gentility, and at thirteen he got himself articled as a paid assistant in the workshop of the brothers Ghirlandaio. Domenico Ghirlandaio, bred a jeweller, had become by this time the foremost painter of Florence. In his service the young Michelangelo laid the foundations of that skill in fresco with which twenty years afterwards he confounded his detractors at Rome. He studied also, like all the Florentine artists of that age, in the Brancacci chapel, where the frescoes of Masaccio, painted some sixty years before, still held their own; and here, in reply, to a taunt he had flung at a fellow-student, Torrigiano, he received the blow on the nose which disfigured him to his dying day.

Though Michelangelo's earliest studies were directed towards painting, he was by nature and predilection much more inclined to sculpture. In that art he presently received encouragement and training under the eye of an illustrious patron, Lorenzo dei Medici. On the recommendation, it is said, of Ghirlandaio, he was transferred, before the term of his apprenticeship as
Michelangelo's stay in Rome at this time lasted five years—from the summer of 1506 till that of 1507. The interval had been one of extreme political distraction at Florence. The excitement of the French invasion, the mystic and ascetic regimen of Savonarola, the reaction which led to his overthrow, and finally the external wars and internal dissidences which preceded a new settlement, had all created an atmosphere unfavourable to art. Nevertheless Ludovico Buonarroti, who in the loss of the life of Lorenzo, the oldest and best friend he had, had come to regard his son Michelangelo as the mainstay of his house, had been repeatedly urging him to come home. A spirit of family duty and family pride was the ruling principle in all Michelangelo's conduct. During the best years of his life he submitted himself sternly and without a murmur to pinching hardship and almost superhuman labour for the sake of his father and brothers, who were ever sufficiently ready to be fed and helped by him. Having now, after an illness, come home in 1501, Michelangelo was requested by the cardinal Francesco Piccolomini to adorn with a number of sculptured figures a shrine already begun in the cathedral of Siena in honour of the most distinguished member of his house, Pope Pius II. Four only of these figures were ever executed, and those not apparently, or only in small part, by the master's hand. A work of greater interest in Florence itself had diverted him from his engagement to his Sienese patrons. This was the execution of the famous colossal statue of David, popularly known as the Giant. It was carved out of a huge block of marble on which another sculptor, Agostino d'Antonio, had begun unsuccessfully to work forty years before, and which had been lying idle ever since. Michelangelo had here a difficult problem before him. Without much regard to the traditional treatment of the subject or the historical character of his hero, he carved out of the vast but cramped mass of material an adolescent, frowning colossal, tensely watchful and self-balanced in preparation for his great action. The result amazed every beholder by its freedom and science of execution and its victorious energy of expression. All the best artists of Florence were called in council to determine on what site it should be set up, and after much debate the terrace of the palace of the Signory was chosen, in preference to the neighbouring Loggia del Lanzi. Here accordingly the colossal "David" of Michelangelo took, in the month of May 1504, the place which it continued to hold until in 1882 it was removed for the sake of protection to a hall in the Academy of Fine Arts, where it inevitably looks crushed and cabined. Other works of sculpture belong to the same period: among them a second "David," in bronze and on a smaller scale, commissioned by the maréchal Pierre Rohan and left by the young master to be finished by Benedetto da Maiano, which was returned to Florence in 1508; a great rough-hewn "St Matthew" begun but never completed for the cathedral of Florence; a "Madonna and Child" executed on the commission of a merchant of Bruges; and two unfinished bas-reliefs of the same subject.

Neither was Michelangelo idle at the same time as a painter. Leaving disputed works for the moment out of sight, he in these days at any rate painted for his and Raphael's common patron, Angelo Doni, the "Holy Family" now in the Ufizi at Florence. In the autumn of 1504, the year of the completion of the statue, he received the Florentine state's commission for a work of monumental painting on a heroic scale. Leonardo da Vinci had been for some months engaged on his great cartoon of the "Battle of Anghiari," to be painted on the wall of the great hall of the municipal council. The gonfaloniere Piero Soderini now procured for Michelangelo the commission to design a companion work. Michelangelo chose an incident at the battle of Cascina during the Pisan war of 1364, when the Florentine soldiery had been surprised by the enemy in the act of bathing. He dashed at the task with his accustomed fiery energy, and had carried a great part of the cartoon to completion when in the early spring of 1505, he had to set off for France in order to obey a call to Rome which reached him from Pope Julius II. His unfinished cartoon, in its power over the varieties and contrasts...
MICHIELANGELO

of energetic and vitally significant action, showed how greatly Michelangelo had profited by the example of his elder rival, Leonardo, little as, personally, he yielded to Leonardo's claims, or could bring himself to respond to his courtesy. The work of Michelangelo's youth is for the most part comparatively trivial in character. His early sculpture, showing a degree of science and perfection unequaled since the antique, has also something of the antique serenity. It bears strongly the stamp of intellectual research, but not by any means that of storm or strain. In the cartoon of the "Bathers" the qualities afterwards proverbially associated with Michelangelo—his furia, his terrificità, the tempest and hurricane of the spirit which accompanied his unequalled technical mastery and knowledge—first find expression. With Michelangelo's departure to Rome early in 1505 the first part of his artistic career may be said to end. It will be convenient here to recapitulate its principal results in sculpture and painting, both those preserved and those recorded but lost.

SCULPTURE—
Florence, 1499–1504—"Head of a Faun," marble; lost.
Condivi describes Michelangelo's first essay in sculpture as a head of an aged faun with a front tooth knocked out, this latter point of the three (in an afterthought) by the Etruscan model; stated. The head is sometimes identified with one in the National Museum at Florence, which however bears no marks of Michelangelo's early style and is in all probability a work of the Madonna di San Sisto. The authentic head has been lost, Florence. This bas-relief, executed in imitation of the technical style of Donatello, is a genuine example of Michelangelo's early work in the Medici school under Bertoldo. The "Head of a Faun," marble; lost. It was a genuine work in full relief, of probably somewhat later date than the last-mentioned. The subject occurs often in ancient sarcophagus reliefs; Michelangelo has followed the antique in his treatment of the nude and the arrangement of the subject is his own.
Bologna, 1493–1495—Statuettes of "St. Petronius," "St. Proculus," and a "Kneeling Angel," marble; part of the decorations of the shrine of St. Dominic in the church of that saint at Bologna; the style of all three much influenced by the work of Jacopo della Quercia in the same church; the attitude of the kneeling angel with the candelabrum imitated from an ancient bas-relief.
Rome, 1495–1501—"St John the Baptist," executed for Lorenzo de' Medici, marble; probably lost. Declared in 1874 to have been found again in the possession of Count Guidalotti-Rospigliosi at Pisa. Velentine and prolonged discussion arose as to the authenticity of this newly-found S. Giovanni, and at last it was bought for the Berlin Museum, where its genuineness is still stoutly maintained. But the finicky and affecting elegance of the conception denote a different temperament from Michelangelo's and probably a later date. With this figure must be given up also the restoration of an antique group of "Bacchus and Ampelus" at the Uffizi, which is attributed by S. of the Palazzo Vecchio, and is claimed by many as a work of Michelangelo—"Recumbent Cupid," bought by the cardinal San Giorgio as an antique, marble; lost. The attempts to recognize it in certain extant copies or servile imitations of the antique are, as a rule, in vain. In Turin there are twelve marble statues in an evident confusion, and not of Michelangelo. The "Bacchus and Ampelus" at the Uffizi, which is attributed by S. of the Palazzo Vecchio, and is claimed by many as a work of Michelangelo—"Recumbent Cupid," bought by the cardinal San Giorgio as an antique, marble; lost. The attempts to recognize it in certain extant copies or servile imitations of the antique are, as a rule, in vain. In Turin there are twelve marble statues in an evident confusion, and not of Michelangelo. The "Bacchus and Ampelus" at the Uffizi, which is attributed by S. of the Palazzo Vecchio, and is claimed by many as a work of Michelangelo—"Recumbent Cupid," bought by the cardinal San Giorgio as an antique, marble; lost. The attempts to recognize it in certain extant copies or servile imitations of the antique are, as a rule, in vain. In Turin there are twelve marble statues in an evident confusion, and not of Michelangelo.
Rome, 1504–1506—"Virgin lamenting the dead Christ," commissioned by the abbot de la Grolaie; marble, St Peter's, Rome. "Bacchus and young Faun," commissioned by Jacopo Galli; marble, National Museum, Florence. (Of these two masterpieces of Michelangelo's youth enough has been said above).—"Cupid," commissioned by the abbot de la Grolaie; marble, lost; has been commonly identified as the "Kneeling Cupid" of the Victoria and Albert Museum, but this, if by Michelangelo at all, which is not quite certain, must in all likelihood belong to a later time.
Florence, 1504–1505—Five Saints, in niches decorating the shores of Piti; two after Bosio and two after the Pietromini family; cathedral of Siena. The contract for the sculptured decoration of this shrine was one of those which the pressure of other work prevented Michelangelo from taking up. In hand were the saints in niches, traditionally reputed to be his work, the St Peter alone shows any clear marks of his style; the other four were probably designed, and certainly carried out, by weaker hands.—"David" (the so-called "Rohan"; commissioned for the city of Florence by Piero Soderini; marble; Florence Academy. Besides what has been said above, it has only to be added that a wax model in the Casa Buonarroti may be the same design with a different movement of the legs, it is probably Michelangelo's).—"David," commissioned by Piero Rahan; bronze; lost; a clay model in the National Museum, Florence, may probably be a sketch for this statue. The bronze has been generally considered to be the original, but none has stood the test of criticism.
"Virgin and Child," commissioned for Taddeo Taddei; circular relief, unfinished, in the Palazzo Lomn, Royal Academy. The motive of the Christ-child frightened by the flight of the bird is one that John is the most playful in all Michelangelo's work; the whole design shows the influence of Leonardo in his gentler, as much as the cartoon of the "Bathers" shows it in his more violent, mood.
"Virgin and Child with St John," commissioned by Bartolommeo Pitti; nearly circular relief, unfinished, marble; Florence, National Museum: a more tranquil and very charming presentation of the Madonna and Child. The life-like figure of Messenger, known as Simonetta della Scala, and by them presented to the church of Notre Dame in that city; group in the round, marble; church of Notre Dame, Bruges. A meditative seated Virgin with upright mantle (known locally as the "Virgin of the Catz") marble, National Museum, Florence. Unfinished (only roughly blocked out), the other figures of the set never having been so much as begun; the contract was signed in 1503 and cancelled in 1514. There is an early drawing by Raphael from this statue.
"Holy Family," painted for Angelo Doni; tempera, circular: Florence, Uffizi. The only perfectly well-attested panel painting of Michelangelo which exists. His love of restless and somehow strained actions is illustrated by the gesture of the Magdalene who kneels on the ground holding up the child on her right shoulder; his love of the nude by the introduction (wherein he follows Luca Signorelli) of some otherwise purposeless undraped figures in the background.
"Virgin and Child with Four Angels"; tempera, National Gallery, London. This unfinished painting, strongly marked by the influence of Michelangelo in his work at this period, has been confidently claimed for him, but lacks his strength and mystery, and is far more probably the work of his imitator and intimate associate, Francesco Granacci. "Cartoon of the Bathshea"; lost and utterly perished. The only authentic records of it are found in a few contemporary reports of the alleged existence of a cartoon by Michelangelo, and in a description of a miniature from Venice and a certain number of sketches and studies by the master himself, chiefly at the Albertina, Vienna, the British Museum and the University of Oxford. Among the many drawings and prints of the Bathshea, there are many figures at Holkham Hall, well known and often engraved, seems to be a later cento destitute of real authority.

Michelangelo had not been long in Rome when Pope Julius devised fit employment for him. That capacious and headstrong Pope, fired by the spirit of the age, and resolved to meet the idea of a sepulchral monument to commemorate his glory, for which he should be dead, and to be executed according to his own plans while he was still living. He entrusted this congenial task to Michelangelo. The design being approved, the artist spent the winter of 1505–1506 at the quarries of Carrara, superintending the excavation and shipment of the necessary marbles. In the spring he returned to Rome, and when the marbles arrived fell to with all his energy at the preparations for the work. For a while the pope followed their progress eagerly, and was all kindness to the young sculptor. But presently his disposition grew quite capricious. In a letter to a friend of his, Bramante of Urbino, he had been selected by Julius to carry out a new architectural scheme, commensurate with the usual vastness of his conceptions, viz., the rebuilding of St Peter's church. To the influence and the malice of Bramante Michelangelo attributed the unwelcome invitation he now received to interrupt the great work of sculpture which he had just begun in order to decorate the Sixtine chapel with frescoes. Soon, however, schemes of war and conquest interposed to divert the thoughts of Julius, not from the progress of his own monument merely, but from artistic enterprises altogether. One day Michelangelo heard him say at table to his jeweller that he meant to spend no more money on pebbles, either small or great. To add to the artist's discomfiture, when he went to apply for personal payments due, he was first put off from day to day, and at last actually with scant courtesy dismissed. At this his dark mood got the mastery of him. Convinced that not his employment only but his life was threatened, he suddenly took horse and left Rome, and before the messengers of the pope could overtake him was safe on Florentine territory. Michelangelo's flight took place in April 1506. Once among his own people he turned a deaf ear to the conception of a monument for his return, and stayed throughout the summer at Florence, when occupied we are not distinctly informed, but apparently, among other things, on the continuation of his great battle cartoon.

During the same summer Julius planned and executed the victorious military campaign which ended with his unopposed entry at the head of his army into Bologna. Thither, under strict safe-conduct and promises of renewed favour, Michelangelo
MICHELANGELO
was at

last

persuaded to betake himself.

Julius received the
these two volcanic

truant artist kindly, as indeed between
natures there existed a natural affinity, and ordered of him
his own colossal likeness in bronze, to be set up, as a symbol
of his conquering authority, over
the principal entrance
of the church of St Petronius.
For the next fifteen months

Michelangelo devoted his whole strength to this new task.
The price at which he undertook it left him, as it turned out,
hardly any margin to subsist on. Moreover in the technical
art of metal casting he was inexperienced, and an assistant
whom he had summoned from Florence proved insubordinate
and had to be dismissed. Nevertheless his genius prevailed
over every hardship and difficulty, and on the 2ist of February
1508 the majestic bronze colossus of the seated pope, robed and
mitred, with one hand grasping the keys and the other extended
in a gesture of benediction and command, was duly raised to
its station over the church porch.
Three years later it was
destroyed in a revolution. The people of Bologna rose against
the authority of Julius; his delegates and partisans were cast
out, and his effigy hurled from its place. The work of Michelangelo, after being trailed in derision through the streets, was
broken up and its fragments cast into the furnace.
Meanwhile the artist himself, as soon as his work was done,

had followed

his reconciled master back to Rome.
The task
that here awaited him, however, was after all not the resumption
of the papal monument, but the execution of the series of
paintings in the Sixtine chapel which had been mooted before

departure.
Painting, he always averred, was not his
business; he was aware of his enemy's hopes that a great enterhis

prise in fresco-painting would prove beyond his powers; and he
entered with misgiving and reluctance upon his new undertaking.
Destiny, however, so ruled that the work thus thrust upon him
remains his chief title to glory. His history is one of indomitable
will and almost superhuman energy, yet of will that hardly ever
had its way, and of energy continually at war with circumstance.
The only work which in all his life he was able to complete as
he had conceived it was this of the decoration of the Sixtine
ceiling. The pope had at first desired a scheme including figures
of the twelve apostles only.
Michelangelo began accordingly,
but could rest content with nought so meagre, and soon proposed
instead a design of many hundred figures embodying the story
of Genesis from the Creation to the Flood, with accessory
personages of prophets and sibyls dreaming on the new dispensation to come, and, in addition, those of the forefathers of Christ.
The whole was to be enclosed and divided by an elaborate
framework of painted architecture, with a multitude of nameless
human shapes supporting its several members or reposing among
them shapes mediating, as it were, between the features of
the inanimate framework and those of the great dramatic and
prophetic scenes themselves. The pope bade the artist do as
he pleased. By May 1 508 the preparations in the chapel had
been completed and the work begun. Later in the same year
Michelangelo summoned a number of assistant painters from
Florence.
Trained in the traditions of the earlier Florentine

school, they were unable, it seems, to interpret Michelangelo's
designs in fresco either with sufficient freedom or sufficient

uniformity of style to satisfy him. At any rate he soon dismissed
them, and carried out the remainder of his colossal task alone,
except for the necessary amount of purely mechanical and
subordinate help. The physical conditions of prolonged work,
face upwards, upon this vast expanse of ceiling were adverse
and trying in the extreme. After four and a half years of toil
the task was accomplished.
Michelangelo had during its
progress been harassed alike by delays of payment and by

doubts on his capacity,
and vaunting the superior powers of Raphael. That gentle
spirit would by nature have been no man's enemy, but unluckily
Michelangelo's moody, self-concentrated temper prevented the
two artists being on terms of amity such as might have stopped
the mouths of mischief-makers.
Absolute need of funds for
the furtherance of the undertaking constrained him at one
moment to break off work and pursue his inconsiderate patron
hostile intrigue, his ill-wishers casting

365

as far as Bologna. This was between September
1510, by which
time the whole of the great series of subjects along the centre
of the vault were completed, and
January 1511, when the master
set to work again and
lateral
began filling the

complicated

spaces of his decorative scheme.

The main

field of the Sixtine ceiling
in form a depressed barrel
divided in Michelangelo's scheme into four larger, alternaThe following is the order of the

drunkenness
of
deluge (9)
Noah. The figures in the last three of
these scenes are on a smaller scale than those in the first six. In
numbers I, 3, 5, 7 and 9 the field of the picture is reduced by the
encroachments of the architectural framework with its seated pairs
of supporters, commonly known as " Slaves " or " Atlases." FUnking these smaller compositions, along the lateral spaces between
the crown of the vault and the walls on either side, are seated
figures of prophets and sibyls alternately; two other prophets are
introduced at each extremity of the series
making seven prophets
and five sibyls in all. In the triangles to right
and left of the prophets at the two extremities are the death of Goliath, the death
of Holofernes, the brazen serpent and the
punishment of Haman.
In the twelve lunettes above the windows are
groups of the ancestors
of Christ, their names designated by inscriptions, and in the twelve
above
them
triangles
(between the prophets and sibyls) other
kindred groups crouched or sitting. These last are all shown
in relatively simple
human actions and household relations,
heightened but not falsified by the artist's genius, and rising
into majestic significance from roots deep in daily human nature.
The work represents all the powers of Michelangelo at their best.
Disdaining all the accessory allurements of the painter's art, he has
concentrated himself upon the exclusive delineation of the human
form and face at their highest power. His imagination has conceived,
and his knowledge and certainty of hand have enabled him to realize,
attitudes and combinations of unmatched variety and
grandeur,
and countenances of unmatched expressiveness and power. But
he has not trusted, as he came later to trust, co science and acquired
knowledge merely; neither do his personages, so far as they did
afterwards, transcend human possibility or leave the facts of actual
life behind them.
The profoundest knowledge and the most searching realism serve to embody all this inspiration and sustain all this
sublimity; the sublimity, moreover is combined with the noblest
elements of grace and even of tenderness. As for the intellectual
meanings of his vast design, over and above those which reveal
themselves at a first glance or by a bare description, they are
from the nature of the case inexhaustible, and can never be perWhatever the soul of this great Florentine, the

spiritual heir of Dante, with the Christianity of the middle ages
not shaken in his mind, but expanded and transcendentalized, by
the knowledge and love of Plato; whatever the soul of such a man,
full of suppressed tenderness and righteous indignation, and of
anxious questionings of coming fate could conceive that Michelangelo has expressed or shadowed forth in this great and significant
scheme of paintings. The powers of the artist seem to have expanded
with the progress of his work. He seems to have begun (as the
spectator entering the chapel has to begin) with what is chronologically the last subject of the series, the drunkenness of Noah, and
to have worked backwards, increasing the scale of his figures for
their better effect from the fourth subject (the Temptation and
Expulsion), and rising in ascending scale of majesty through the
successive acts of creation from the last to the first.

vault

is

;

The Sixtine chapel was no sooner completed than Michelangelo
resumed work upon the marbles for the monument of Julius.
But four months only had passed when Julius died. His heirs
immediately entered (in the summer of 1513) into a new contract
with Michelangelo for the execution of the monument on a
reduced scale. What the precise nature and extent of the original
design had been we do not know, only that the monument
was to be detached from the wall, and to stand four-square
and free a thing hitherto unknown in Renaissance sepulchral
architecture in one of the chapels of St Peter's. But the new
design was extensive and magnificent enough. It was to consist
of a great three-sided structure, two courses high, projecting
from the church wall, and decorated on its three unattached
On the upper course was to be placed the
sides with statues.
colossal recumbent figures of the pope, with a vision of the
Virgin and Child above him, angels mourning at the sides,
and prophetic and allegoric personages at the angles sixteen
figures in all. The lower course was to be enriched with twentyfour figures in niches and on projecting pedestals: in the
niches, Victories; in front of terminal pilasters between them,


slaves or captives denoting, it would seem, either conquered provinces or arts and sciences in bondage after their patron’s death. Much injured and undeveloped was the sketch by the master, and with a copy of the same by Sacchetti, are supposed to show the design at this stage of its reduction. The entire work was completed in nine years’ time. During the next three years, it would seem, Michelangelo brought to completion three at least of the promised figures, for which the blocks had reached Rome from Carrara as early as July 1508; and they are among the most famous of all existing works of the sculptor’s art—namely, the “Moses,” now in the church of S. Pietro in Vincoli at Rome and the two “Slaves” at the Louvre.

The “Moses,” originally intended for one of the angles of the upper course, is now placed at the level of the eye, in the centre of the principal face of the monument as it was at last finished, on a deplorably reduced and altered scale, by Michelangelo and his assistants in his old age. The prophet, supposed to have just come down from Mount Sinai and found the Israelites worshipping the golden calf, sits, heavily bearded and draped, with only his right arm bare, his left foot drawn back, his head raised and turned to the left, his left hand laid on his lap and his right grasping the tables of the law—an incarnation of majestic indignation and menace. The work, except in one or two places, is of the utmost finish, and the statue has been called by the Sixtine prophets the Sixtine ceiling done in marble. The “Slaves” at the Louvre are youthful male figures of equally perfect execution, nude but for the band which passes over the breast of one and the right leg of the other. One, with his head drooping and his right arm resting on his bosom, his eyes almost closed, seems succumbing to the agonies of death; the other, with his arms bound behind his back, looks upward still hopelessly struggling. All three of these figures were finished between 1513 and 1516.

By 1516 Michelangelo’s evil star was again in the ascendant. Julius II., had been succeeded on the papal throne by Cardinal Giovanni de’ Medici under the title of Leo X. The Medici, too, had about the same time by force and fraud re-established their sway in Florence, overthrowing the free institutions that had prevailed there since the days of Savonarola. Now, on the one hand, this family were the hereditary friends and patrons of Michelangelo; on the other hand he was a patriotic son of republican Florence; so that henceforward his personal allegiance and his political sympathies were in conflict. Over much of his art, as has been thought, the pain and perplexity of this conflict have cast their shadow. For the present the artist was content to him of the rise to power of the Medici was a fresh interruption of his cherished work on the tomb of Julius. Leo X. and his kinsmen were full of a vast new scheme for the enrichment and adornment of the façade of their own family church of Sant Lorenzo in Florence. Michelangelo, carried away by the idea and forgetful of his other still great and onerous task, offered his services for the new façade. They were eagerly accepted, although for a moment the idea had been entertained of entrusting the work to Leonardo da Vinci. The heirs of Julius on their part showed an accommodating temper, and at the request of Leo allowed their three-years’old contract to be cancelled in favour of another, whereby the scale and sculptured decorations of the Julian monument were again to be reduced by nearly a half. Michelangelo soon produced for the San Lorenzo façade a design of combined sculpture and architecture as splendid and ambitious in its way as had been that for the original monument of Julius. The contract was signed in January 1518, and the artist went to Carrara to superintend the excavation of the marbles.

Michelangelo was now in his forty-fourth year. Though half his life was yet to come, yet its best days had, as it proved, been spent. All the hindrances which he had encountered hitherto were as nothing to those which began to beset him now. For the supply of materials for the façade of San Lorenzo he had set a firm of masons to work, and had himself, it seems, entered into a kind of partnership with them, at Carrara, where he knew the quarries well, and where the industry was hereditary and well understood. When all went well in progress there under his own eye, reasons of state induced the Medici and the Florentine magistracy to bid him resort instead to certain new quarries at Pietrasanta, near Serravalle in the territory of Florence. Hither, to the disgust of his old clients at Carrara and to his own, Michelangelo accordingly had to transfer the scene of his labours. Presently he found himself so impeded and enraged by the mechanical difficulties of raising and transporting the marbles, and by the disloyalty and incompetence of those with whom he had to deal, that he was fain to throw up the commission altogether. The contracts for the façade of San Lorenzo were rescinded in March 1518, and the whole magnificent scheme came to nothing. Michelangelo then returned to Florence, where the materials of work poured in from many quarters. The king of France desired something from his hand to place beside the two pictures he possessed by Raphael. The authorities of Bologna wanted him to design a façade for their church of St Petronius; those of Genoa to cast a statue in bronze of their great commander, Andrea Doria. Cardinal Grimani begged hard for any picture or statue he might have to spare; other amateurs importuned him for so much as a pencil drawing or sketch. Lastly his friend and partisan Sebastian del Piombo at Rome, ever eager to keep up the feud between the followers of Raphael and those of Michelangelo, sought him out and pressed his efforts to return at once to Rome, and take up the hands of the dead master’s pupils the work of painting still remaining to be done in the Vatican chambers. Michelangelo complied with none of these requests. All that we certainly know of his doing between 1518 and 1522 is the blocking out in the rough of four more of the “Slaves” for the tomb of Julius, and carrying out a commission, which he had received from three citizens of Rome as early as 1514, for a statue of the risen Christ. The roughed-out “Slaves” now stand immersed in a grotto in the Boboli Gardens, Florence. Pope Adrian VI. was the first patron finished by the master, but with the last touches added by pupils, stands in the church, for which it was destined, of Sta Maria sopra Minerva at Rome; there is little in it either of devotional spirit or imaginative power, although, in those parts which Michelangelo himself finished, there is extreme accomplishment of design and workmanship.

The next twelve years of Michelangelo’s life (1522–1534) were spent at Florence, and again employed principally in the service of his capricious and ungenial patrons—the Medici. The plan of a great group of monuments to deceased members of this family, first broached to Michelangelo in 1520 by Cardinal Giulio de’ Medici. No practical impulse, however, was given to the work until Giulio, after the death of Leo X. and the brief pontificate of the puritanical and iconoclastic Adrian VI., had in his turn become pope in 1523 under the title of Clement VII. Even then the impulse was a wakening one. First Clement proposed to associate another artist, Sansovino, with Michelangelo in his task. This proposal being on Michelangelo’s peremptory demand abandoned, Clement next distracted the artist with an order for a new architectural design—that, namely, for the proposed Medicen or “Laurentian” Library. When at last after many changes of scope and scheme the plans for the sepulchral chapel of “Sagrestia nuova” took shape, they did not include, as had been at first intended, memorials to the founders of the house’s greatness, Cosimo (pater patriae) and Lorenzo the Magnificent, or even to Pope Leo X. himself, but only to two younger members of the house lately deceased, Giuliano, duke of Nemours, and Lorenzo, duke of Urbino. Michelangelo brooded long over various designs for this work, and was still engaged on its execution when his time being partly also taken up by the building-plans for the Medicen library—when political revolutions interposed to divert his industry. In 1527 came to pass the sack of Rome by the Austrians, and the apparently irretrievable ruin of Pope Clement. The Florentines seized the occasion to expel the Medici from their city, and set up a free republican government once more. Naturally no more funds for the works in San Lorenzo were forthcoming, and Michelangelo, on the invitation of the new signory, occupied himself for a while with designs for a group of Hercules and Cacus, and another of Samson
and the Philistines—the latter to be wrought out of a block of marble which had been rough-hewn already for another purpose by Baccio Bandinelli. Soon, however, he was called to the assistance of the citizenry by a direct order from his enemy Charles V. having become reconciled, both alike were now bent on bringing Florence again under the rule of the Medici. In view of the approaching siege, Michelangelo was appointed engineer-in-chief of the fortifications. He spent the early summer of 1533 in strengthening the defences of San Miniato; from July to September he was absent on a diplomatic mission to Ferrara and Venice. Returning in the middle of the latter month, he found the cause of Florence hopeless from internal treachery and from the overwhelming strength of her enemies in the shape of the Sultan’s Fleete, and he was appointed again suddenly for Venice. There for a while he remained negotiating for a future residence in France. Then, while the siege was still in progress, he returned once more to Florence; but in the final death-struggle of her liberties he bore no part. When in 1530 the city submitted to her conquerors, no mercy was shown to most of those who had taken part in her defence. Michelangelo believed himself in danger with the rest, but on the intervention of Baccio Valori he was presently taken back into favour and employment by Pope Clement. For four years he now laboured on the works connected with the Medici monuments, with the help from 1532 of Giovanni Montorsoli and other pupils, and on the building of the Lauren- tian library. In 1531 he suffered a severe illness; in 1532 he made a long stay at Rome, and entered upon yet another contract for the completion of the Julian monument, to be reduced now to a still more shrunken scale and to be placed not in St Peter’s but in the church of San Pietro in Vincoli. In the autumn of 1534 he left Florence for good. What remained to be done in the Medici chapel was done by pupils, and the chapel was not finally completed until 1545.

The statues of the Medici monument take rank beside the "Moses" and the "Slaves" as the finest work of Michelangelo’s central time in sculpture. They consist of a Madonna and Child and of the two famous monumental groups, each composed of an armed and seated portrait-statue in a niche, with two emblematic figures reclining on each side of a sarcophagus below. The "Madonna and Child" (left unfinished because the marble was short in bulk) combines astonishingly the divers qualities of realistic motive and natural animation with learned complexity of design and imposing majesty of effect. It was set up finally—not at all in accordance with the artist’s first intention—against a blank wall of the chapel, and flanked at wide intervals by two groups of figures, the work of pupils. The portraits are treated not realistically but typically. In that of Lorenzo seems to be typified the mood of crafty brooding and concentrated inward thought; in that of Giuliano, the typical style of a man of action. To this contrast of the meditative and active characters correspond, a contrast in the emblematic groups accompanying the portraits. At the right of the chapel St Florence reigns with the "Day"—the former a female, the latter a male, personification; the former sunk in an attitude of deep but uneasy slumber, the latter (whose head and face are merely blocked out of the marble) lifting himself in one of wistful and disturbed awakening. For Michelangelo’s unfulled grandeur of style, and for the sense which his works convey of a compulsive heat and tempest of thought and feeling in the spirit that thus conceived them, both these attitudes might be charged with extravagance. As grand, but far less violent, are those of the two companion figures that recline between sleep and waking on the sarcophagus of the penive Lorenzo. Of these, the male "Night," son of "Earth" and "Heaven," is "Morning," male ("Mornin- cuto and Aurora"). In Michelangelo’s original idea, partly founded on antique precedent in pedimental and sarcophagus groups, figures of "Earth" and "Heaven" were to be associated with those of "Day" and "Night" as they are now, and with "Sun" and "Moon," and with a doubt of a corresponding nature, with those of the Morning and Evening Twilight on that of Lorenzo. These figures afterwards fell out of the scheme and the figures designed for them remain empty. Michelangelo’s original fundamental idea was, as some words of his own record, to exhibit the elements and the powers of earth and heaven lamenting the death of the princes. River-gods were to recline in the sidelong case but at the feet of the monument. These too are lacking. They were never finished, but a bronze cast from a small model of one of them, and the torso of a large model, have lately been identified, the former in the National Museum and the latter in the Academy at Florence. Michelangelo’s other fundamental idea was, as some words of his own record, to exhibit the elements and the powers of earth and heaven lamenting the death of the princes. River-gods were to recline in the sidelong case but at the feet of the monument. These too are lacking. They were never finished, but a bronze cast from a small model of one of them, and the torso of a large model, have lately been identified, the former in the National Museum and the latter in the Academy at Florence.

Other works of 1532-1534. — "Victory" marble (National Museum, Florence). A youthful conqueror standing over a bearded enemy, whose shoulders he crushes down with his left knee. Fine and interesting work; whether the detail was added later in the making of the Julian monument, or having some connexion with the "Hercules and Cacus" and "Samson and the Philistine," subjects undertaken for the Signory in 1528, must remain uncertain. For the formation of these figures was to be continued at the Albert Museum, for the latter a plaster model at the Casa Buonarroti, are claimed, perhaps rightly, as original. "David" (formerly "Apollo"), marble, unfinished (National Museum, Florence). Both the authenticity and the approximate date of this fine work are beyond doubt: of its origin and destination we are uninformcd. "Crouching boy," marble, unfinished (the Hermitage, Petersburg), another masterly sketch in marble; the seated lad stoops forward between his parted knees, having both hands occupied with his left foot; the figure blocked out of the marble, with the least possible regard to the masses, shows the same subject and motive enigmatical. "Cupid," knapping, apparently newly unrolled, was placed on the altar of a bow, marble (Victoria and Albert Museum). Probably, but not quite certainly, authentic; if so, then of 1530 or thereabouts; its identification with the early Cupid done for Jacopo Galli at Rome in 1496 is untenable. "Leda," painting, done for the duke of Ferrara, but withheld because of the misconduct of his messenger, and given by the master to his pupil Antonio Mini in 1531; lost. A fine injured tempera painting of the subject in the store-rooms of the National Gallery in London may presumably be an early copy.

Michelangelo had fully purposed, as soon as he could get free of his task on the Medici tombs, to devote all his powers to the completion of the Julian monument in accordance with the next-to-the-last will of 1532. But his intention was again frustrated by Pope Clement insisted that he must complete his decorations of the Sixtine Chapel by painting anew the great east wall above the altar, adorned until then by frescoes of Perugino. The subject chosen was the Last Judgment; and Michelangelo began to prepare sketches. In the autumn of 1534, in his sixtieth year, he settled finally, and for the remainder of his life, at Rome. Immediately afterwards Clement died, and was succeeded by a Farnese under the title of Paul III. Even more than his predecessors Paul insisted on claiming the main services of Michelangelo for himself, and proceeded his ambitious projects.

As the first seven years after the artist’s return to Rome, his time was principally taken up with the painting of the colossal and multitudinous "Last Judgment." This being completed in 1541, he was next compelled to undertake two more great frescoes—one of the Conversion of Paul and another of the Martyrdom of Peter—in a new chapel which the pope had caused to be built in the Vatican, and named after himself—"Capella Paolina.

The frescoes of the Sixtine Chapel are probably the most famous single picture in the world. In it Michelangelo shows more than ever the omnipotence of his artistic science, and the fiery daring of his conceptions. But the work, so far as its deplorably deteriorated condition admits comparison, is hardly comparable in the qualities of colour and decorative effect to the earlier and far more nobly inspired frescoes of the ceiling. It is to these and not to the "Last Judgment" that the student must turn if he would realize what is best and greatest in the art of Michelangelo.

The frescoes of the Pauline Chapel are on their part so injured as to be hardly susceptible of useful study or criticism. In their ruined state they bear evidence of the same tendencies that made the art of Michelangelo in its latest phase so dangerous an example to weaker men—the tendency, that is, to seek for unqualified energy and violence of action, both in place and out, for "terribleness" quiem" et cetera.

"Other Work of the years 1534-1540. Sculpture. During the fifteen years when Michelangelo was mainly engaged on these "unities," he alone has been enabled to acquit himself, although in a manner that can have been satisfactory to none concerned, of his engagements to the heirs of Julius. Once more the influence of the "unities" had produced a change, not to their disadvantage. By a final contract dated 1542, it was agreed that the "Moses" executed thirty years before, seated on a low plinth in a central recess, should be the chief figure of the new
scheme; in niches at either side of him were to be standing figures of "Leah" and "Rachel." These Michelangelo himself executed hastily with the help of assistants. To pupils of the workshop there was left, as an evident proof of the caryatid effigy of the pope occupying the centre of a wide and incongruous architectural scheme, a Madonna and Child in a niche above, and a prophet and a sibyl in niches below. Meantime, the figures or any of the "Slaves" in the new design had been completely abandoned. The master gave the two that had been finished in 1513-1516 to Robert Strozzi, who gave them the title of "Vittoria." The frames of 1518 and 22 remained at Florence. "Brutto," marble (National Museum, Florence) Probably executed soon after 1539, in memory of the tyrannicide Lorenzo de' Medici. "Gioconda," marble (National Museum, Florence) The most pathetic unfinished sketch in marble of a life-size "Pieta" (Palazzo Rondini, Rome)—the mourning mother standing on an elevation behind her son, holds his body upright in her arms. Moved by a master's sympathy for the faithful builders of this old Florentine church, Michelangelo, after 1550, filled the numerous complicated and more finished group of the "Pieta," with the corpse of Christ collapsing in utter relaxation through the arms of those who try to uphold it: this Michelangelo destines for his own sepulchre; it stands now in the cathedral of Florence.

Painting.—"The Entombment of Christ" (National Gallery London). This unfinished painting bears all the marks of Michelangelo's design, and must have been begun from a cartoon by him, probably of about 1535-1540. The touch of his own hand seems evident in some parts, particularly the body of Christ; other parts, in various degrees of incompletion, are apparently the work of various pupils.

For nearly all his great life-works mentioned above, preparatory sketches and studies by the master's hand exist. These, with a large number of other drawings, are to be found, together with their own sakes and not for any other use, of are infinite value and interest to the student. Michelangelo was the most learned and scientific as well as the most inspired and daring of draughtsmen, and his drawings are of extreme old age never ceased to practice with pen, chalk or pencil. He is said to have burned vast numbers of his drawings with his own hand and caused others to be burned by friends and pupils to whom he had given them, so that the present possess must be less than a tithe of what he executed. But there are some 250 genuine sheets—enough to let us follow and understand his modes of conceiving, preparing and maturing his subjects. In some cases, these drawings are scarcer, and in other various collections, chiefly public; those in England (at the British Museum, the University Galleries, Oxford, and the Royal Library, Windsor), are quite half the whole number; other important examples remain still at what was formerly the home of his friends, the Casa Buonarroti at Florence; others at the Uffizi, Florence; the Venice Academy; the Albertina, Vienna; the Louvre; the Conde Museum at Chantilly; the Berlin Museum; and, not least, the Teylers Museum at Haarlem. By means of these drawings and the many published facsimiles we are best able to trace the progress of the master's genius and its secrets. We see him diligently copying in yet another and other more finished studies; and studies thus drawn with the pen, for the "David," the "Bathers Surprised," the accessory figures for the tomb of Julius as first conceived, and the great series of the Sixtine Chapel decorations. But it is still, to be found in the Sistine Chapel, chapels and elsewhere, that the master's mind was always in use along with the pen, and many, if not the finest studies for the "Slaves" or "Atlases" and other decorative figures of the ceiling are in the latter material (many more studies are preserved for these subordinate figures than for the main compositions). After the Sixtine Chapel period the pen gives way to red or black chalk almost entirely. Sketches are rare for the great abortive scheme of the Julius monument; almost non-existent for the equally abortive San Lorenzo façade; fairly abundant for the various stages of the Medici monument scheme in its architectural parts, but not for the great figures. About the time of Michelangelo's final change of domicile from Florence to Rome (1537) he began the subject of making highly finished and fully shaded drawings of classic or symbolic subjects in red or black chalk for presentation to his friends. Especially to young Tommaso Cavassa, the subject of his passionate Platonie affection, from about 1532. The "Phaeton," the "Tityos," the "Ganymede," the "Men shooting at a Mark," are well-known examples; in this class of work the Windsor collection is both rich and choice. At the same time the master's son, Michelangelo, was producing drawings little less powerful and finished of Christian subjects, especially the "Crucifixion," "Entombment," "Resur- rection," and the greatest conception of the "Last Judgment," for which there exist both general sketches and particular studies. Many few extant drawings for the Cappella Paolina a faltering both of the imagination and of the hand become discernible. To the same or rather similar end the master's daughter, Maddalena, was making some abortive drawings done either directly for, or nearly in the spirit of, the famous "Crucifixion" which is recorded to have painted with so much devotion for Vittoria Colonna. About many of these, for their intensity of feeling, there is a wavering thought betraying the approach of infirmity; so there is about many of the architectural studies done for the buildings which he had charge in his later years at Rome, but with the old impressive power and penetration we are not wanting in some even of the latest drawings that have come down to us.

During his later years the long-pent human elements of fervor and tenderness in Michelangelo's nature had found vent and utterance such as they had never found before. He had occasioned a prejudice in the young, and there are signs of the same love-passages during his life at Bologna. But it was not until towards his sixtieth year that the springs of feeling were fairly opened in this new medium of self-assertion and self-expression. This noble and sometimes life-worn and labour-hardened man, about 1533-1534 we find him beginning to address impassioned sonnets—of which the sentiment is curiously comparable to that expressed in some of Shakespeare's—to a beautiful and gifted youth, the young Roman noble Tommaso Cavassa. Sooner afterwards he made the acquaintance of the pious, accomplished, and high-souled lady, Vittoria Colonna, widow of the Marquess Pescara. For ten years until her death, which happened in 1547, her friendship was the great solace of Michelangelo's life. On her, in all loyalty and reverence, he poured out all the treasures of his mind—his mellow wisdom, his tenderness and affection, his love of beauty, his passionate adoration, his early and last. She, the young Roman noble Tommaso Cavassa. Sooner afterwards he made the acquaintance of the pious, accomplished, and high-souled lady, Vittoria Colonna, widow of the Marquess Pescara. For ten years until her death, which happened in 1547, her friendship was the great solace of Michelangelo's life. On her, in all loyalty and reverence, he poured out all the treasures of his mind—his mellow wisdom, his tenderness and affection, his love of beauty, his passionate adoration, his early and last. She, the chief of his inspirers of his poetry—of which, along with her praises, the main themes are the Christian religion, the joys of Platonic love, and the power and mysteries of art. Michelangelo's poetical style is strenuous and concentrated like the man. He wrote with labour and much self-correction; we seem to feel him hinging himself on the material of language with the same overwhelming energy and vehemence with which contemporaries describe him as flinging himself on the material of marble—the same impetuosity of creative effort combined with the same fierce desire of perfection, but with far less either of innate instinct for the material or of trained mastery over its difficulties.

And so the mighty sculptor, painter, and poet reached old age. An infirmity which settled on him in 1544, and the death of Vittoria Colonna in 1547, left him broken in health and heart. But his strength held on for many a year longer yet. His father and brothers were dead, and his family sentiment concentrated itself on a nephew, Leonardo, to whom he showed unremitting practical kindness, coupled with his usual suspiciousness and fitfulness of temper. In almost all his relations the old man was continually and bitterly inclined to manifest the same loyal and righteous heart, accompanied by the same masterful, moody, and estranging temper, as in youth. Among the artists of the younger generation he held a position of absolute ascendancy and authority; nor was his example, as we have said, by any means altogether salutary for them. To artists, and to a certain number of chosen friends, belonging chiefly to the lettered, diplomatic, and secretarial classes, he was more accessible and affable than he had been to any one in earlier days, though still formidable in moods of scorn and scoffing. His great age and fame made him the most honoured citizen of Rome, to whom the highest, both of his fellow countrymen and foreigners, were eager to do homage. During the last years of his life he made but few more essays in sculpture, and those not successful, but was much employed in the fourth art in which he excelled—that of architecture. A succession of popes demanded his services for the embellishment of Rome. Between 1536 and 1546 he was engaged on plans for the rearrangement and reconstruction of the great group of buildings on the Capitol—plans which were only partially and imperfectly carried out during his lifetime and after his death. At the end of the year 1564 the pope died and the throne fell, the prince of the Tiber, who was by the pope of the same family, the Farnese. On the death of Antonio de San Gallo he succeeded to the onerous and coveted office of chief architect of St Peter's church, for which he remodelled all the designs, living to see some of the main features, including the supports and lower portion of the great central dome, carried out in spite of all obstacles, according to his plans. The dome as it stands is his most conspicuous and one of his noblest monuments: the body of the church was completed in a manner quite different from his devising. Other
MICHELET, JULES

great architectural tasks on which he engaged were the reconstruction of the Porta Pia, and the conversion of a portion of the baths of Diocletian into the church of Sta Maria degli Angeli; the great cloister with its hundred columns, now used as the Museo delle Terme, is the only part of this reconstruction which has been preserved. He died in the midst of these vast schemes and responsibilities, the heroic old man's last remains of strength gave way. He died on the threshold of his nineteenth year, on the 18th of February 1854.

Authorities.—For the earlier bibliography of Michelangelo, which is extensive, see the useful though very imperfect compilation of Passerini, Bibliografia di Michelangelo Buonarroti, &c. (Rome, 1827); or the admirable work of order, are the following: P. Giovi, supplement to the fragmentary Dialogu de vivis literis illustratis, written about 1527, first published by Vitale della Porta in Italiano (Florence, 1671); G. Vasari, in Vite degli più eccellenti architecti, pittori, e scultori, &c. (Florence, 1550); A. Condovi, Vite di Michelangelo Buonarroti (1553); this account, for which the author, a pupil and friend of the master's, had long been collecting materials, was much fuller than that of Vasari, who made use of it in rewriting his own life of Michelangelo for his second edition, which appeared after the master's death (1859). The best edition of Vasari is that by Milanesi (Florence 1878–1883; of Condovi, that by Gerini and Mariette (Paris, 1746); for English readers there is a useful translation with notes, by Sir Charles Holroyd. The first additions of importance were made by Milanesi in his own Vite di Michelangelo, ed. di Toccoli, Milano, 1822); the next, by Cavalcaselle (in the pages 307, 395, 495, 591), important are the portions of correspondence preserved in the Buonarroti archives were published by Guasti in his notes to the Il Greco, and in the Memorie storiche, etc., of Daudet, and lastly by the great complete biographies of Michelangelo had been meanwhile attempted by J. Harford (London, 1840), which was followed by the more careful work, by Lebreich, I. Michelangelo (Hanover, 5th ed., 1879). A great increment of biographical material was at length obtained by the publication, in the four-hundredth year after Michelangelo's birth, of the whole body of his letters in the Memorie della vita di Michelangelo Buonarroti, ed. G. Milanesi (Florence, 1875). This material was first employed in a connected but too trivial narrative by A. Gottii, Vite di Michelangelo (Florence, 1875). Next followed C. Heath Willett, Michelangelo (Florence, 1880); this is followed by the Impressions of the Cinquecento, which in the technical remarks in which, especially as concerns the frescos, are still valuable. Other lives of Michelangelo are by Anton Springer, in his Michelangelo u. Raphaël (Leipsic, 1843); J. A. Symonds, The Life of Michelangelo (London, 1893), full of valuable matter on the history and spirit of Michelangelo's times, but not trustworthy in the criticism of his works; H. Mackowsky, Michelangelo (Berlin, 1908), excellent in all respects, his art, his character, his morals, his art; Emile Gebhardt, Michel-Ange, sculpteur et peintre (1868) is a handsome volume of reproductions with text. Michelangelo, by Fritz Knapp, in the Klassiker der Kunst series (Stuttgart, 1906) is a valuable addition to the literature. For the art and architecture works of Michelangelo the standard is authority is H. Wölflin, Die Jugendwerke Michelangelo (Munich, 1881, and later editions), a masterly work, though as a whole it does not give a complete view of his genius. Among the works of the Sixtine frescos, magnificently illustrated, is that by E. Steinmann, Die Sixtinische Kapelle, vol. ii. (Munich, 1905). Consult also C. Justi, Michelangelo (Leipsic, 1903), and with caution H. Thode, Michelangelo u. das Ende der Renaissance (Berlin, 1902–1903). Of the poems of Michelangelo the first sound edition is that already referred to, G. Guasti, Rime di Michelangelo Buonarroti (1842); in earlier editions the text had been recklessly tampered with, and the rugged individuality of the master's style smothered. An edition with German translations was published by Hasenclever (Leipzig, 1873); and a thorough critical edition by Karl Frey (Berlin, 1878); for the English student the translation of J. A. Symonds, in his A History of Art (London, 1878, and later editions) is the best. In the French language, the invaluable. On the drawings of Michelangelo see especially B. Berenson, The Drawings of Italian Painters (London, 1903). A most interesting critical work on the same subject is that of the important examples are reproduced and discussed, unfortunately not arranged chronologically, is Karl Frey, Die Zeichnungen Michelangelo (Berlin, 1908 seq.), still in progress. An elaborate life by the Emperor Napoleon III., published in French, Michelangelo, et ses œuvres) is also in progress, but is more to be prized for documentary fullness and accuracy than for critical insight.

MICHET, JULES (1798–1874), French historian, was born at Paris on the 21st of August 1798, of a family which had Huguenot traditions. His father, an ecclesiastic, was a man of very prosperous, and the son at an early age assisted him in the actual work of the press. A place was offered him in the imperial printing office, but his father was able to send him to the famous Collège or Lycée Charlemagne, where he distinguished himself. He passed the university examination in 1821, and was shortly after appointed to a professorship of history in the Collège Rollin. Soon after this, in 1824, he married. The period of the restoration and the July monarchy was one of the most favourable to rising men of letters of a somewhat similar period; the events that has ever been known in France, and Michet had powerful patrons in Villemain, Victor Cousin, and others. But, though he was an ardent politician (having from his childhood embraced republicanism and a peculiar variety of romantic free-thought), he was first of all a man of letters and an inquirer into the history of the past. His earlier works were school-books, and they were not written at a very early age. Between 1825 and 1837 he produced divers sketches, chronological tables, &c., of modern history. His Histoire de la France, published in the last-mentioned year, is a sound and careful book, far better than anything that had appeared before it, and written in a sober yet interesting style. In the same year he was appointed maître de conférences at the École normale. Four years later, in 1831, the Introduction à l'histoire universelle showed a very different style, exhibiting no doubt the idiosyncrasy and literary power of the writer to greater advantage, but also displaying the peculiar visionary qualities which made Michet the most stimulating, but the most untrustworthy (not in facts, which he never consciously falsifies, but in suggestion) of all historians. The year 1835, the year of 1830. He had assisted and amused him, and had put him in a better position for study by being put on the Record Office, and a deputy-professorship under Guizot in the literary faculty of the university. Very soon afterwards he began his chief and monumental work, the Histoire de France. But he accompanied this with numerous other books, chiefly of erudition, such as the Oeuvres choisies de Victor de Laplace, the Mémoires de Laugier écris par lui-même, the Origines du droit français, and somewhat later the Proces des templiers. 1838 was a year of great importance in Michet's life. He was in the year 1830, and the events of the Revolution, and its consequences, have had his natural aversion to the principles of authority and ecclesiasticism, and at a moment when the revived activity of the Jesuits caused some real and more pretended alarm he was appointed to the chair of history at the Collège de France. Assisted by his friend Edgar Quinet, he began a violent polemic against the unpopular order and the principles which it represented, a polemic which made their lectures, and especially Michet's, one of the most popular resorts of the day. He published, in 1839, Histoire romaine, but this was in his graver and earlier manner. The results of his lectures appeared in the volumes Le Prêtre, la Femme, la Famille, and Le peuple. These books do not display the apocalyptic style which, partly borrowed from Lamennais, characterizes Michet's later works, but they contain in miniature almost the whole of his curious ethico-political-theological creed—a mixture of sentimentalism, communism, and anti-sacerdotism, supported by the most eccentric arguments, but urged with a great deal of eloquence. The principles of the outbreak of 1848 were in the air, and Michet was not the least important of those who condoned and propagated them; indeed his original lectures were of so incendiary a character, and the compounds of the later works depended so much on the actual revolution broke out Michet, unlike many other men of letters, did not attempt to enter on active political life, and merely devoted himself more strenuously to his literary work. Besides continuing the great historical, he undertook and carried out, during the years between the downfall of Louis Philippe and the final establishment of Napoleon III., an enthusiastic Histoire de la révolution française. Despite or because of its enthusiasm, this was by no means Michet's best book. The events were too near and too well known, and hardly admitted the picturesque sallies into the blue distance which make the charm and the danger of his larger work. The actual picturesqueness as well as in general veracity of picture, the book cannot approach Carlyle's; while as a mere chronicle of the events it is inferior to half a dozen prosaic histories older and younger than itself.
MICHETE, K. L._MICHETE

The coup d’État lost Michelet his place in the Record Office, as, though not in any way identified with the republic administratively, he refused to take the oaths to the empire. But the new régime only kindled afresh his republican zeal, and his second marriage (with Mlle Adèle Malaret, a lady of some literary capacity, and of republican belongings) seems to have further stimulated his powers. While the history steadily held its way, a crowd of extraordinary little books accompanied and diversified it. Sometimes they were expanded versions of its episodes, sometimes what may be called commentaries or companion volumes. In some of the best of them natural science, a new subject with Michelet, to which his wife is believed to have introduced him, supplies the text. The first of these (by no means the best) was *Les Femmes de la révolution* (1834), in which Michelet’s natural and inimitable faculty of dithyrambic too often gives way to tedious and not very conclusive argument and preaching. In the next, *L’oiseau* (1836), a new and most successful vein was struck. The subject of natural history was treated, not from the point of view of mere science, nor from that of sentiment, nor from anecdote nor of gossip, but from that of the author’s fervent democratic pantheism, and the result, though, as was to be expected, unequal, was often excellent. *L’Insecte*, in the same key, but duller, followed. It was succeeded by *L’Amour* (1839), one of the author’s most popular books, and not unworthy of its popularity, but perhaps hardly his best. These remarkable works, half pamphlets half moral treatises, succeeded each other as a rule at the twelve months’ interval, and the succession was almost unbroken for five or six years. *L’Amour* was followed by *La Femme* (1860), a book on which a whole critique of French literature and French character might be founded. Then came *La Mer* (1861), a return to the natural history class, which, considering the powers of the writer and the attraction of the subject, is perhaps a little disappointing. The next year (1862) the most striking of all Michelet’s minor works, *La Sorcière*, made its appearance. Developed out of an episode of the history, it has all its author’s peculiarities in the strongest degree. It is a nightmare and nothing more, but a nightmare of the most extraordinary verisimilitude and poetical power.

This remarkable series, every volume of which was a work at once of imagination and of research, was not even yet finished, but the later volumes exhibit a certain falling off. The ambitious *Bible de l’humanité* (1864), an historical sketch of religions, has but little merit. In *La Montagne* (1868), the last of the natural history series, the tricks of staccato style are pushed even farther than by Victor Hugo in his less inspired moments, though— as is inevitable, in the hands of such a master of language as Michelet— the effect is frequently grandiose if not grand. *Nos fils* (1860), the last of the string of smaller books published during the author’s life, is a tractate on education, written with ample knowledge of the facts and with all Michelet’s usual sweep and range of view, if with visibly declining powers of expression. But in a book published posthumously, *Le Baguet*, these powers reappear at their fullest. The picture of the industrious and famishing populations of the Riviera is (whether true to fact or not) one of the best things that Michelet has done. To complete the list of his miscellaneous works, two collections of pamphlets, which were partly published at different times, may be mentioned. These are *Les Soldats de la révolution* and *Légendes démocratiques du nord.*

The publication of this series of books, and the completion of his history, occupied Michelet during both decades of the empire. He lived partly in France, partly in Italy, and was accustomed to spend the winter on the Riviera, chiefly at Hyères. At last, in 1867, the great work of his life was finished. In the usual edition it fills nineteen volumes. The first of these deals with the history up to the death of Charlemagne, the second with the flower time of feudal France, the third with the 13th century, the fourth, fifth, and sixth with the Hundred Years’ War, the seventh and eighth with the establishment of the rural power under Charles VII. and Louis XI. The 16th and 17th centuries have four volumes apiece, much of which is very distantly connected with French history proper, especially in the two volumes entitled *Renaissance* and *Réforme.* The last three volumes carry on the history of the 18th century to the outbreak of the Revolution. Michelet was perhaps the first historian to devote himself to anything like a picturesque history of the middle ages, and his account is still the most vivid that exists. His inquiry into manuscript and printed authorities was most laborious, but his lively imagination, and his strong religious and political prejudices, made him regard all things from a singularly personal point of view. Critics, who partly find in his work the convenient texts for his polemic, have alternately held it further than Waterloo, and the best criticism of it is perhaps contained in the opening words of the introduction to the last volume—"l’âge me presse." The new republic was not altogether a restoration for Michelet, and his professorship at the Collège de France, of which he contended that he had never been properly deprived, was not given back to him. He died at Hyères on the 4th of February 1874.

Almost all Michelet’s works, the exceptions being his translations, compilations, &c., are published in uniform size and in about fifty volumes, partly by Marpon and Flammarion, partly by Calmann Lévy. He has not received much recent attention from critics and monographers, but his *Origines du droit français,* *cherchées dans les symboles et formules du droit universel* was edited by Emile Faguet in 1890 and went into a second edition in 1900. See G. Monod, *Jules Michelet; Études sur la vie et ses œuvres* (Paris, 1908). (G. S.)
MICHEL OF NORTHGATE—MICHIGAN

Elected a fellow of the Royal Society in the same year as Henry Cavendish (1760). In 1730 he published at Cambridge a work of some eighty pages entitled *A Treatise of Artifical Magnets*, in which is shown an easy and expeditious method of making them superior to the best natural ones. Besides the description of the method of magnetization which still bears his name, this work contains a variety of accurate magnetic observations, and is distinguished by a lucid exposition of the nature of magnetic induction. He was the original inventor of the torsion balance, which afterwards became so famous in the hands of its second inventor Coulomb. Micheli described in his proposal of a method for obtaining the mean density of the earth. He did not live to put his method into practice; but this was done by Henry Cavendish, who made, by means of Michell's apparatus, the celebrated determination that now goes by the name of Cavendish's experiment (Phil. Trans., 1768). His most important geological essay was entitled *Conjectures concerning the Cause and Observations upon the Phaenomena of Earthquakes* (Phil. Trans., ii. 1768), which showed a remarkable knowledge of the strata in various parts of England and abroad.

Michell's other contributions to science are: "Observations on the Comet of January 1760 at Cambridge, Phil. Trans. (1760); "A Recommendation of Hadley's Quadrant for Surveying," ibid. (1765); "Proposal of a Method for measuring Degrees of Longitude upon the Theory of the Ellipsoid of the Equator," ibid. (1766); "An Inquiry into the Probable Parallax and Magnitude of the Fixed Stars," ibid. (1767); "On the Twinkling of the Fixed Stars," ibid. (1767); "On the Mean Longitude, Dissecting the Distance, Magnitude, &c., of the Fixed Stars," ibid. (1784).

MICHEL OF NORTHGATE, DAN (fl. 1340). English writer, the author of the *Ayensute of Invyst*. Nothing is known of him except what can be gathered from his work. It is a literal translation in the Kentish dialect of a French treatise entitled *Le Somme des vices et des vertues* (also known as *Le Miroir du monde ou Le Livre des commandemens*, &c.), which was written in 1279 by Laurentius Gallus, a Dominican monk and confessor to Philip III, of France. This work was translated into Flemish, Catalan, Spanish and Italian, and appears in no less than six English translations. Dan Michel's autograph MS. is preserved in Arundel MS. 57, which states that the work was completed in the year 1340 on the eve of the apostles Simon and Jude by Dan Michel of Northgate, a brother of the cloister of St Austin of Canterbury. The value of the book is chiefly philological as an authenticated and dated example of the southern dialect.

The *Ayensute of Invyst* was edited for the Roxburghe Club by the Rev Joseph Stevenson in 1835, and for the Early English Text Soc. by Richard Morris in 1876.

MICHELLOZZO DI BARTOLOMMEO (1391-1472?), Italian sculptor, was a Florentine by birth, the son of a tailor, and in early life a pupil of Donatello. He worked in marble, bronze and silver. The statue of the young St John over the door of the Duomo at Florence, opposite the Baptistery, is by him; and he also made the beautiful silver statuette of the Baptist on the altar-front of San Giovanni. Michelozzo's great friend and patron was Cosimo dei Medici, whom he accompanied to Venice in 1433 during his short exile. While at Venice, Michelozzo built the library of San Giorgio Maggiore, and designed other buildings there. In 1426, together with Donatello, he erected an open-air pulpit at an angle of the cathedral of St Stephen at Prato. The magnificent Palazzo Medici in Florence, built c. 1440, was designed by him; it is one of the noblest specimens of Italian 15th-century architecture, in which the great taste and skill of the architect has combined the delicate lightness of the earlier Italian Gothic with the massive stateliness of the classical style. With great engineering skill Michelozzo shored up, and partly rebuilt, the Palazzo Vecchio, then in a ruinous condition, and added to it many important rooms and staircases. When, in 1437, through Cosimo's liberality, the monastery of San Marco at Florence was handed over to the Dominicans of Fiesole, Michelozzo was employed to rebuild the domestic part and remodel the church. For Cosimo I. he designed numerous other buildings, mostly of great beauty and importance. Among these were a guest-house at Jerusalem for the use of Florentine pilgrims, Cosimo's summer villa at Careggi, and the strongly fortified palace of Cafaggiolo in Mugello. For Giovanni dei Medici, Cosimo's son, he built a very large and magnificent palace at Fiesole. In spite of Vasari's statement that he died at the age of sixty-eight, he appears to have lived till 1472. He is buried in the monastery of San Marco, Florence. Though chiefly noted as a sculptor and engineer, Michelozzo's fame rests partly on his architectural works, which claim for him a position of very high honour even among the greatest names of the great 15th-century Florentines.

See Hans Stegmann, Michelozzo di Bartolommeo, eine kunstgeschichtliche Studie (1888); Fritz Wolff, Michelozzo di Bartolommeo (1906); cf. also Hans Semper, Donatello (1887).

MICHIGAN, a north central state of the United States, situated between latitudes 41° 44' and 47° 30'. N. and longitudes 88° 25' and 90° 31' W., and consisting of two peninsulas—the upper or northern and the lower or southern—separated by a strait. The upper or northern peninsula is bounded N. by Lake Superior; E. by lakes Superior, George, Huron, and Michigan, and by St Mary's River, which separates it from the Province of Ontario, Canada; S. by lakes Huron and Michigan and the Straits of Mackinac, which separate it from the lower peninsula; and S. and W. by Wisconsin, and the Menominee, Montreal and Brulé Rivers, which separate it in part from Wisconsin. The lower or southern peninsula is bounded N. by lakes Michigan and Huron and the Straits of Mackinac, E. by Lake Huron, S. by Lake Erie, and W. by the Detroit Rivers, which separate it from Ontario; S. by Ohio and Indiana, and W. by Lake Michigan. In size Michigan ranks eighteenth among the states of the Union, its total area being 57,080 sq. m., of which 500 sq. m. are water surface.

**Physical Features.**—Physiographically the history of the state is similar to that of Minnesota. The northern part is rugged moun
tainous and marshy, not completely worn down by erosion; and the southern part is a portion of the old coastal plain, whose layers contain salt, gypsum and some inferior coal. Lake Huron on the east and Lake Michigan on the west of the lower peninsula are each 581 ft. above sea-level, and Lake Superior on the north of the upper peninsula is 602 ft. above sea-level. For the most part the surface of the state is gently undulating and at a slight elevation above the lake level. The marshy plains of southwestern Michigan are a part of the lower peninsula is occupied by a plateau of considerable dimensions, and the north-west part of the upper peninsula is rugged. hills, covering most of the peninsula.

Lake Huron is a body of water 57 miles wide and 256 miles long. It extends north and south from 45° 47' to 47° 56' N. Lat. and from 83° 15' to 88° 19' W. Long. The northern part of the lake is 16,653 sq. m. The lake is divided into three sections, that to the north-east of this depression a water-parting with summits varying from about 400 to 600 ft. above the lakes extends from a point between Saginaw Bay and Lake Huron south by west to the south border of the state and beyond. The east slope descends quite rapidly to a low flat belt from 5 to 40 m. wide along the east border of the state south from Lake Huron. From Lake Huron to the south-east shore of Saginaw Bay a wide sandy beach is followed northward by precipitous shores abounding in rocks and bluffs. West of the divide and south of the depression, south-west Michigan is occupied by the valleys of the St Joseph, Kalamazoo and Grand Rivers, by the gently rolling upland—from form the northern tier of counties before the Glacial Dunes, which here and there rise to a height of from 100 to 200 ft. or more along the shore of Lake Michigan, and are formed on this side (but not on the Wisconsin side) of the lake by the retreating ice. The northern portion of the lower peninsula—including the counties of Roscommon and Missaukee, parts of Wexford and Ogemaw, and those to the north and north-west of Bay County, which on an elevation at its highest point, north of its centre, of upwards of 1100 ft. above Lake Michigan; to the south of this plateau the land slopes gently down to the depression and to the lakes from Lake Michigan and Saginaw Bay. The surface of the upper

1 This is the northernmost point of the mainland; the most northerly of the islands north-east of Isle Royal and belonging to Michigan, is more than five miles north.

2 In addition, within the boundaries of Michigan, are approximately 16,653 sq. m. of Lake Superior, 12,992 sq. m. of Lake Michigan, 6925 sq. m. of Lake Huron and 460 sq. m. of lakes St Chir and Erie.
peninsula is more irregular than that of the lower peninsula. A peninsula extending through the middle from east to west and south, from west of the centre to Green Bay, is either flat and even swampy or only gently undulating. Eastward from Green Bay are two ranges of hills, the southern range of the sandstone formation, extend for several miles along the coast, rise almost perpendicularly from the water's edge, and display an interesting diversity of flora and habitat. There is a great variety of both trees, herbs, especially of gray, blue, green and yellow. The most rugged portion of the state is farther west. South and south-west of Keweenaw Bay, in the Marquette iron district, is an irregular area of mountains, hills, and boulder fields; the range of the Huron Mountains (in Marquette county) rising to an elevation of 1,400 ft. or more above the lake. These and a peak in the Porcupine Mountains (2032 ft. above the lake) in the north-west part of Ontonagon county are the highest in the state. To the south of this is the Menominee iron district, marked somewhat regularly by east and west ridges. Extending in a general north-east and south-west direction through Keweenaw peninsula to the Wisconsin border and reaching in places an elevation of 600 ft. above Lake Superior. The famous Pictured Rocks in Alger county on the lake shore, east of Munising, are a part of this range. The two-thirds of the state, that are south of 45° are in the south-east corner of the state, that is nearly a straight line along the coast, the sandy shores, or bluffs, with their cliffs and bristles, are reflected more than half the length of the peninsula. On the other hand, the prevailing winds of the upper peninsula being westward, the lakes have little effect on the temperature there; and so, with the exception of the bogs and boulder fields, the mean temperature of the rest of the state they have ranged within two years from 104° F. at points in the south-east to 49° F. in the north-west. Throughout the state July is invariably the warmest month, February the coldest, the mean annual temperature is about 45° F. The mean annual precipitation is not far from 31 in., a little more than one-half of which falls during the five growing months from May to October; in the north it is exceptionally heavy along the north shore of the upper peninsula.

**Soil.**—The soil of south-west and south-east Michigan is for the most part a dark clay loam or mud; in the north central part of the lower peninsula it is a light sandy loam, along the Huron shore it is heavy with clay, in the mining districts of the north-west the soil is coarse and sandy. The ranging from 10 to 20 per cent.; in other words the soil is generally rich in a variety of mineral elements, and varies chiefly in the proportions of vegetable loam, sand, or gravel, and clay. Although the temperature of the entire lower peninsula is considerably influenced by the lakes, yet, the prevailing winds being westerly, it is in the west portion of that peninsula that the most severe climate is found. The snowfall there is reflected more than half the length of the peninsula. On the other hand, the prevailing winds of the upper peninsula being north-westward, the lakes have little effect on the temperature there; and so, with the exception of the bogs and boulder fields, the mean temperature of the rest of the state they have ranged within two years from 104° F. at points in the south-east to 49° F. in the north-west. Throughout the state July is invariably the warmest month, February the coldest, the mean annual temperature is about 45° F. The mean annual precipitation is not far from 31 in., a little more than one-half of which falls during the five growing months from May to October; in the north it is exceptionally heavy along the north shore of the upper peninsula.

** Productions.**—Of the total land surface of the state in 1904 48.08 % was in farms and 67.92 % in 1904, 48.08 % in 1904, 46.96 % in 1904. Of these remaining farms, 104,766 farms, with 580,300 acres, contain 600 acres or more, of 3,443,300 acres in 1904. Of these, 203,261 farms, of which 143,688 contained less than 100 acres, 54,550 others contained less than 250 acres, and 203,261 farms, in 1894, 1907, and 1917, or 104,766 of the owners (in 1904, 161,073 by owners and 914 by managers), 22,482, in 1904, 19,525 by tenant farmers. In 1907, 41,075 farms, containing 1,700,999 acres, were owned by tenants; 34,986 by the owners; 275,369 by tenants, of the state, of 54.5 % of all who were engaged in gainful occupations, were farmers. Of the total acreage in 1900 of all crops 38.3 % was in cereals and 28.5 % in hay and forage; of the acreage of cereals, 7,000,000 acres were in wheat, 3,200,000 in oats and 1,600,000 in rye. In 1907 the buckwheat crop was 850,000 bushels; rye, 5,452,000 bushels; the hay crop, 3,246,000 tons; oats, 35,934,000 bushels; barley, 1,496,000 bushels; wheat, 12,731,000 bushels; and corn, 57,190,000 bushels. The number of the most numerous (2,139,000 in 1907), and Michigan's wool clip in 1907 was 14,080,500. The number of meat cattle in 1907 was 1,852,000,000; and of horses 704,000.

Michigan produces the bulk of the peppermint crop of the United States, and it is in the front rank as a fruit-producing state. Barley and buckwheat are grown chiefly in the east part of the lower peninsula south of Saginaw Bay. Potatoes are grown in considerable quantities in the north-west part of the lower peninsula in the vicinity of Grand Traverse Bay as well as throughout the southern part of the state; they are grown in the north central part of the lower peninsula, and of peats in the counties bordering on Lake Huron, Kalamazoo, Jackson, Washtenaw, Lenawee, Ingham, Bay and Muskegon are the leading celery-producing districts; the leading potato districts are Marquette and Keweenaw. The region of the upper peninsula south of this area for about 40 miles along the southern boundary was a part of the great hardwood forest of the Ohio Basin with woods varying with soil and drainage, on the drier gravel lands were oak forests consisting of red, black and white oak, hickory, ash, cherry, basswood and walnut; in depressions there were maple, elm, ash, beech, sycamore, poplar and willow; and in the south-eastern part of this area there were a few chestnuts and tulip trees. On the sandy lands were a few chestnuts and tulip trees. On the sandy lands were oaks, especially in the vicinity of Muskegon, Grand St. Joseph, Manistee and Kalamazoo. The southern hardwood forest had pine trees on the sandier land, mixed hardwoods and conifers on the loam and clay, and tamaracks and cedar in the swamps. The sandy lands were in part burnt over by Indians, and now a growth of alders, aspens and huckleberry bushes. The tamarack and cedar swamps now have a growth, especially on their edges, of spruce, balsam, white pine, and maple. From 1900 to 1909 about 20% of the area was "cut over" or "burned over" lands, mostly the old pine woods, the region of the old hardwood forest was almost entirely farmland, but about 40 % of the state was still in woods. Red oak, birch, elm, ash, white cedar, hemlock, basswood, spruce, poplar, balsam, fir and several other kinds of trees are found in many sections; but a large portion of the merchantable timber, especially in the lower peninsula, has been cut. Some of the larger groves of shrubs are the willow, hazel, alder, shrub maple, birch, hawthorn, elderberry, viburnum and snowberry. Yews are common in the north, and dwarf juniper in the south. In 1900 the woodland area, including 310,000,000 acres of state owned land, was estimated at 130,000,000 acres, or about two-thirds of the entire state. Huckleberry, blackberry and rasperry bushes are common in the north sections. Smilax, elatinus, honeysuckle and woodbine are the common forest vines.

* Under the revised constitution of 1908 the legislature is authorized to provide for the reforestation of state lands.
MICHIGAN

about $107,850,000 in dividends. Copper mining in the state began about the same time as iron mining, and the quantity mined increased from 12 long tons in 1845 to 109,543 in 1906. In 1900, 97,475 long tons were produced, and the production for the years 1860 of any other state; from 1847 to 1883 its copper product was more than one-half that of all the states, but after 1887 (except in 1889) more was produced in Michigan than in any other state. In 1906 and in 1907 the yield in both Arizona and Montana was greater than in Michigan. Fields of bituminous coal extend over an area of over 10,000 sq. m. in the central portion of the lower peninsula and over 4,000 sq. m. in the southern part of the lower peninsula. Michigan is noted for its limestone, which is found in Saginaw, Bay, Eaton, Jackson, Huron and Shiawassee counties. Salt wells are numerous in the middle and south-east section of the state, and in 1880 the mining industry was increased by the discovery of a salt deposit in Saginaw county in 1859 and 1860. For a number of years prior to 1893 Michigan was the leading salt-producing state, and, though her output was subsequently (except in 1901) exceeded by that of New York, it continued to increase up to 1906, when it was 4,062,173 barrels; in 1907, the product was 10,786,630 barrels. Gypsum is obtained from deposits along the banks of the Grand river in Kent county and in the vicinity of Alabaster along the shore of Lake Huron in Iosco county. Operations on deposits of Carpenetian Rapidas were begun in 1841, and although that near Alabaster was opened in 1852, it was not until 1902 that it became of much importance; in 1900 the mine produced 1,915,392 short tons of the product; in 1907 3,717,291 short tons were mined. Marl is found in the south part of the state; limestone most largely in the north part of the lower peninsula, and the east part of the upper peninsula; and sandstone largely on the lower peninsula. In 1887, 77,000 barrels in 1898 to 3,572,668 in 1907. Besides limestones and dolomites, the only building stone of much commercial importance in the state is granite. Original iron is produced in considerable quantity in Huron county. A small quantity of petroleum is obtained from thirteen wells in St Clair county in the east part of the state. Oil is found at Alcona and Saginaw counties. Michigan has all the elements requisite to a great petroleum products industry. Clements, Benton Harbor and Alma are of considerable commercial value for medicinal purposes.

Manufactures.—In 1900 the value of the manufactory products of Michigan was $59,944,082, an increase of 28.4% over that of 1890, and by 1904 there was a further increase of 20.19%. During the same period, however, the value of the products of the lumber and timber industry, which in 1879, 1880 and 1890 was greater than that of any other state, and in 1900 was still more than twice as great as that of the products of any other manufacturing industry in the state and was exceeded only by that of the product of Wisconsin, decreased from $83,121,668 in 1890 to $51,915,647 (35.1%) in 1900, and to $40,569,335 in 1904, this decrease being due in part to the large quantities of raw material (both hard wood and pine) formerly found in the forests of Michigan no longer available. The value of manufactory products brought in from other states and from Canada. The value of the products of the furniture factories and of the planing mills, nevertheless, is still very large. The furniture factories, or, as they are called in Michigan, Grand Rapids is the leading centre not only in Michigan but in the United States) rising from $10,767,038 in 1890 to $14,614,506 in 1900 and $18,421,735 in 1904, and that of the planing mills from $10,007,603 in 1890 to $12,450,532 in 1900 and $14,375,467 in 1904. The total value of the lumber and timber products, the furniture products, and the planing-mill products amounted in 1900 to $86,099,683; the value of these manufactures based upon minerals mined or quarried amounted to $83,750,062. Another important class of manufactures is that based on agriculture: the value of flour and gist mill products amounted to $21,643,547 in 1900, and $26,512,027 in 1904; that of fruit products, which is a new industry, is $819,691,856, and that of woolen and worsted manufactures, which in 1904 was $4,512,027, in 1904, to $5,691,315 in 1900 and to $6,753,699 in 1904; that of agricultural implements to $6,330,508 in 1900 and $8,716,719 in 1904; and of malt liquors to $5,295,625 in 1900 and $10,901,906 in 1904.

Among other manufactures in which the state ranks high and in which there was a large increase during the same period are: leather, carriages and wagons, chemicals, paper and wood pulp and beet sugar. In 1904 Michigan manufactured automobiles valued at $6,876,708. The leading manufacturing centres are, in the order of the value of their products in 1904: Detroit, Grand Rapids, Kalamazoo, Battle Creek, Saginaw, Jackson, Lansing, Muskegon, Bay City and Port Huron, all in the south half of the lower peninsula.

The manufacturing industry of Michigan began in 1830, but little progress had been made in 1837 when the state began the construction of three railways and two canals across the south-west part of the lower peninsula. The Michigan Central was completed from Detroit to Ypsilanti in 1837, while the Michigan Southern was in operation in November 1840, and considerable work was done on the proposed Michigan Northern and Michigan Western. Labor was not abundant, and the manufacturers were frequently incompetent to carry on the work and sold its interests to private companies. In 1850 there were 342 m. completed, and from then until 1880 the mining industry was increased to 3938; but the great period of railway building in Michigan was in the decade from 1880 to 1890, when the mileage was increased to 7108.48. By the close of 1896 it had increased further to 8629.35. The principal lines were the Michigan Central, the Pere Marquette, the Lake Shore & Michigan Southern, the Grand Rapids & Indiana, the Ann Arbor, the Grand Trunk, the Chicago & North-Western, the Duluth South Shore & Atlantic, the Minneapolis, St Paul & Sault Ste. Marie, and the Chicago, Milwaukee & St Paul. Members of railway commissioners, who in 1870 succeeded a commissioner (whose office was created in 1873) hears complaints, has power to suspend the operation of orders of minor importance to railway companies, and reports annually to the governor. There is empowered to appoint a commission to fix transportation rates for railways and express companies. Besides railway communication, Michigan has a coast line of about 1600 m., along which vessels of 2000 tons can sail and find several good harbours, the water communication having been extended and improved by several of the state. The state undertook to construct the canal at Sault Ste. Marie, which passes the rapids of St Mary's River; the St Clair Flats, at the north end of Lake St Clair, by which a deeper channel is made through shallow water; and the Portage Lake, in the copper district, which connecting lake with Lake Superior. The state undertook to construct the canal at Sault Ste. Marie in 1837 but little had been accomplished in 1852 when the national government granted 750,000 acres of land to the state in aid of the enterprise, and three years later the state was incorporated to complete it. The national government has enlarged its locks so as to make it navigable for vessels drawing 21 ft. of water. The national government completed the canal at the St Clair Flats in 1871 and contributed land for aid in the construction of that connecting lakes Portage and Superior, which was completed in 1873 and passed under national control in 1891.

Population.—The population of Michigan in 1880 was 1,636,037; in 1890 it was 2,093,889, an increase of 27.5% within the decade; in 1900 it was 2,426,882, a further increase of 14.7%. According to the census of 1890 the state included 1,799,321 whites, 18,561 negroes, 5354 Indians, 240 Chinese and 9 were Japanese. 1,879,329 or 77.6% were native born and 541,653 were foreign-born, 184,398 of the foreign-born being natives of Canada (151,915 English; 32,483 French), 125,074 of Germany, 43,839 of England, and 30,466 of Holland. In 1900 682,479 communicants of different denominations were reported: of these 492,135 were Roman Catholics, 128,675 Methodists, 105,803 Lutherans, 30,166 Presbyterians, 28,345 members of Reformed bodies, and 26,349 members of the Protestant Episcopal Church. In 1900 39.3% of the total population lived in places having at least 2500 inhabitants.

Administration.—The constitution under which Michigan is now governed was first adopted in 1850, when it was felt that the powers which the first, that of 1835, conferred upon the executive and the legislature were too unrestricted. In 1908 it was revised, and many changes were made. The constitution admits of amendment by an affirmative vote of two-thirds of the members of each house of the legislature, and which was lowered at the next succeeding spring or autumn election by an affirmative vote of a majority of the electors voting upon the question; or an amendment may be proposed by a petition signed by members of the legislature or by a majority of the total number of electors who voted for secretary of state at the preceding election, and such an amendment (unless disapproved by a majority vote in a joint meeting of the two houses of the legislature) is submitted to popular
vote at the next election and comes into effect only if it receives a favourable majority of the popular vote. Amendments suggested by the legislature have been frequently adopted, and one, adopted in 1862, provided that the question of a general revision of the entire code of laws be submitted to the voters once every sixteen years and at such other times as may be provided by law. When this question was so submitted for the first time, in 1866, the vote was in favor of a revised code; a convention was appointed, but the purpose was rejected at the polls. The revision by the Constitutional Convention of 1907-1908 was adopted by popular vote in 1908.

In its present form the constitution confers suffrage upon every male citizen of the United States who is twenty-one years of age or over, and has resided in the state six months and in his township or ward twenty days immediately preceding an election; and any woman may vote in an election involving the direct expenditure of public money or the issue of bonds if she has the qualifications of male electors and if she have property assessed for taxes in any part of the district or territory affected by the election in question. At the head of the executive department is the governor, who is elected for two years, and who at the time of his election must be at least thirty years of age and who have hitherto been a citizen of the United States for at least six years, and for the two years immediately preceding a resident of the state. A lieutenant-governor, for whom the same qualifications are prescribed, is elected at the same time for the same term. Under the first constitution the secretary of state, treasurer, auditor-general, attorney-general, commissioner of the land office, superintendent of public instruction and the judges were all appointed by the governor, but under the present one they are elected and only minor officers are appointed. In 1853 the legislature created a board of four members to be appointed by the governor, one of whom must be a physician, another an attorney, and made it its duty to investigate the case of every convict for whom a petition for pardon is received and then report and recommend to the governor what it deem expedient. The governor's salary is fixed by the revised constitution of 1908 at $5000 a year. The lieutenant-governor succeeds the governor in case of vacancy, and next in order of succession comes the secretary of state.

The legislature, consisting of a Senate of 32 members, and a House of Representatives of 100 members (according to the constitution not less than 64 and not more than 100), meets biennially, in odd-numbered years, at Lansing. Both senators and representatives are elected for a term of two years by single districts, except that a township or city which is entitled by its population to more than one representative elects its representatives on a general ticket. Beginning in 1913 and at each subsequent tenth year, the legislature, under the revised constitution of 1908, rearranges the senatorial districts and reapportions the representatives among the counties and districts, using as a basis the returns of the last preceding decennial census; the taking of a state census between the decennial periods is discontinued.

No bill can pass either house except by an affirmative vote of a majority of the members elected to that house, and on its third reading the ayes and noes must be taken and recorded; for appropriation bills a two-thirds majority of all members elected to each house is required. All legislation must be by bill, legislation by joint and concurrent resolutions thus being prevented. No bill may be passed at a regular session until it has been printed and in possession of each house for five days; no bill may be passed at a special session on any subject not expressly stated in the governor's proclamation or submitted by special message. The governor has ten days (Sundays not being counted) in which to exercise his veto power (which may be applied to any item or items of any bill making appropriations of money and embracing distinct items), and an act shall not become a law unless the two-thirds majority of all the members elected to each house of the third of the members elected is required to pass a bill over his veto. Under the revised constitution of 1908 any bill passed by the legislature and approved by the governor, except appropriation bills, may be referred by the legislature to the district courts; and all such referred shall be considered as good law unless approved by a majority of the electors voting thereon; no local or special act, passed by the legislature, takes effect until it is approved by a majority vote of the electors in the affected district.

The administration of justice is entrusted to a supreme court, a continually increasing number of circuit courts (thirty-eight in 1900), one probate court in each county, and not exceeding four justices of the peace in each township. The supreme court is composed of one chief justice and seven associate justices, all elected for a term of ten years, not more than two retiring every two years; it holds four sessions annually, exercises a general control over the inferior courts, may issue, hear and determine any of the more important writs, and has appellate jurisdiction only in all other important cases. There is only one circuit court judge for a circuit, unless the legislature provides more; the term of office is six years. The three circuit court judges have original jurisdiction in most matters of civil and criminal, hear appeals from the lower courts, and must hold at least four sessions annually in each county of the circuit. Each county elects a judge of probate for a term of four years; he has original concurrent jurisdiction with the circuit court in matters of probate, and has original jurisdiction in all cases of juvenile delinquents and dependents. The legislature may provide for the election of more than one judge of probate in a county with more than 100,000 inhabitants. Justices of the peace are elected by the townships for a term of four years, and in more than one-fourth of the townships for a term of six years. The justices of the peace, four in each township, in civil matters have exclusive jurisdiction of cases in which the demand does not exceed $100 and concurrent jurisdiction with the circuit courts in contract cases in which the demand does not exceed $300.

For purposes of local government the state is divided into eighty-three counties, each of which is in turn divided regularly by N. and S. and E. and W. lines into several townships. In the more sparsely inhabited counties of the upper peninsula and in the N.E. section of the lower peninsula the townships are much larger in extent than in other parts of the state. The officers of the township are a supervisor, clerk, treasurer, highway-commissioner, one overseer of highways for each highway district, a justice of the peace, and not more than four constables, all of whom are elected at the annual township meeting in April. The supervisor, two of the justices of the peace and the clerk constitute the township board, whose duty it is to settle claims against the township, audit accounts, and publish annually an itemized statement of receipts and disbursements. The supervisor is also the township assessor, and the several township supervisors constitute the county board of supervisors who equalize property valuations as between townships, authorize townships to borrow money with which to build or repair bridges, are entrusted with the care and management of the property and business of the county, and may borrow or raise by tax what is necessary to meet the more common expenses of the county. Other county officers are a treasurer, clerk, sheriff, register of deeds, attorney, surveyor and two coroners, each elected for a term of two years, a school commissioner elected for a term of four years, and one or more notaries public appointed by the governor.

Under the revised constitution of 1908 the former classification of cities into four classes and the practice of granting special charters were abolished, and the legislature is required to provide by general laws for the incorporation of cities and villages; "such general laws shall limit their rate of taxation for municipal purposes and restrict their powers of borrowing money and contracting debts." Cities and villages are permitted—upon authorization by the affirmative vote of three-fifths of the electors voting on the question—to own and operate, even outside their corporate limits, public utilities for supplying water, gas, heat, power and transportation, and may sell and deliver, outside their corporate limits, water, heat, power and light to an amount not more than one-fourth that furnished by them in each case within their corporate limits; but no city or village of less than 25,000 inhabitants may own or operate transportation facilities. Under the revision of 1908 corporate franchises cannot be granted for a longer term than thirty years.

Law.—A wife in Michigan has the same right to her property acquired either before or after marriage as she would have if single, except that she cannot under ordinary circumstances give, grant or
sell it to another without her husband's consent. Grounds. Courts of divorce are adulatory, physical incapacity at the time of marriage, sole maintenance for three years or more, desertion for two years, habitual drunkenness, extreme cruelty, or, in cases of the refusal of the husband to provide for her maintenance when sufficiently able to do so; but in case the parties were married outside of the State, the court shall not dissolve such marriage if the plaintiff resides in the State at least one year before petitioning for the same. An insolvent debtor's homestead—consisting of not more than 40 acres of land with a house thereon, or a house and lot in a city or village not exceeding $800 value, not mortgaged or incumbered with any other property—is exempt from execution. For several years previous to 1876 a clause of the constitution prohibited the sale of intoxicating liquors within the State. At this time, the liquor business has been subjected to a heavy tax, and since 1887 the age limitation has been left to the option of each of the several counties. A state court of mediation and arbitration, consisting of three members appointed for two years by the legislature, was created in 1889 to inquire into the cause of grievances threatening or resulting in any strike or lock-out and to endeavour to effect a settlement.

Charitable and Penal Institutions.—The state supports the Michigan Asylum for the Insane (opened 1859), at Kalamazoo; the Eastern Michigan Asylum for the Insane (opened 1875), at Pontiac; the Northern Michigan Asylum for the Insane (opened 1886), at Traverse City; the Michigan Asylum for the Dangerous and Criminal Insane (established 1885), at Ionia; the Upper Peninsula Hospital for the Insane, at Newberry; a Psychopathic Hospital (established 1907), at Alpena; the Michigan Lunatic Asylum (established 1864), at Lansing; the Michigan State Prison (established 1839), at Jackson; the Michigan Reformatory (established 1887), at Ionia; the State House of Industry (organized 1837), at Lansing; the Michigan Industrial School for Boys, at Lansing; the Industrial School for Girls (established 1879), near Adrian; the State Public School (opened 1874), at Coldwater, a temporary home for dependent children; the Michigan Soldiers Home (established 1885), at Jackson; the Michigan School for the Deaf (established 1854), at Flint; the School for the Blind, at Lansing; an Employment Institution for the Blind (established 1903), at Saginaw; the Home for the Feeble Minded and Epileptic (established 1893), at Lapeer; and the Michigan Soldiers' Home (established 1885), at Grand Rapids. Each of these institutions is under the control of a board of three or more members appointed by the governor, of which one is appointed by the governor and at the head of the department is the State Board of Corrections and Charity, consisting of the governor and four other members appointed by him, with the approval of the Senate, for a term of eight years, one retiring every two years. This board is required to visit each of the institutions at least once a year to ascertain its condition and needs, and all proposed appropriations for their support, plans of buildings, proposed systems of sewerage, ventilation and heating must be submitted to it.

Education.—Michigan was a pioneer state in creating the American educational system; she began the organization of it at the time of her admission into the Union in 1837, and has since been noted for the high standard of her schools. Each township operating under the District Act has two school inspectors—one being elected at each town meeting for a term of two years—who with the township clerk constitute the township board of education, select the school inspectors, and to this board is given authority to divide the township into districts and to exercise a general supervision over the several schools within their jurisdiction; a township may be organized as a single district, called a “township unit district.” The qualified electors of each district having an ungraded school elect a moderator, a director and a treasurer—one at each annual school meeting—for a term of three years, who constitute the district school board, and this board is entrusted with ample power for directing the affairs of the school. In a district having more than 100 children of school age a graded school under the control of five trustees is formed whenever two-thirds of the electors vote for it at a town meeting, and the trustees of a graded school may establish a high school whenever a majority of the electors authorize them to do so. A high school may also be established in any township in which there is no incorporated village or city if when the question is submitted to the electors of that township a majority of the votes cast are in the affirmative. Each county has a county school commissioner, elected for a term of four years, who exercises a general supervision over the schools within his jurisdiction, and a board of examiners, consisting of three members (including the commissioner) and appointed by the several boards of county supervisors, from whom teachers receive certificates. Finally, at the head of all the public elementary and secondary schools of the state is the state superintendent of public instruction, elected for a term of two years; he is ex officio a member and secretary of the state board of education, and a member, with the right to speak but not to vote, of all other boards having control of public instruction in any state institution. In every district having as many as 800 children between the ages of five and twenty the state requires that the school be taught not less than nine months a year; and a compulsory education law requires the attendance of all children between the ages of eight and fifteen for four months in every year, the same being the same for the full school year, and between the ages of eight and twenty if found frequenting public places without lawful occupation.

The higher state institutions of learning consist of a university, to which graduates of high schools on an accredited list are admitted without examination, four normal schools, an agricultural college, and a school of mines. The university (at Ann Arbor) was established in 1837, and is under the control of a board of regents elected by the people for a term of eight years, two every two years; the president of the institution and the superintendent of public instruction are members of the board but without the right to vote. The state normal schools are: the Michigan State Normal College at Ypsilanti (organized in 1839); the Central Michigan Normal School at Mount Pleasant (established in 1857); the Northern State Normal School at Marquette (organized 1853); and theNormal School at Kalamazoo (established in 1904). All of them are under the state board of education, which consists of the state superintendent, and five other members elected, one every two years, for a term of six years. The agricultural college at East Lansing, 3 m. east of Lansing, is the oldest in the United States; it was provided for by the state constitution of 1850, organized in 1855 and opened in 1857, and is under the control of the state board of agriculture, consisting of the president of the college and six other members elected by popular vote for a term of six years, two every two years. Provision for the school of mines, at Houghton, was established in 1855 and is under the control of a board of six members appointed by the governor with the approval of the Senate, two every two years. In 1908 it had 32 instructors, 253 students, and a library containing 35,938 volumes. Other grant institutions include the University of Detroit, at Detroit; the University of Michigan, at Ann Arbor; Hillsdale College (Baptist, 1843), at Hillsdale; Kalamazoo College (Baptist, 1855), at Kalamazoo; Adrian College (controlled by the Methodist Protestant Church since 1867), at Adrian; Olivet College (Congregational, 1859), at Olivet; Hope College (Reformed, 1886), at Holland; Detroit College (Roman Catholic, 1872), at Detroit; Alma College (Presbyterian; incorporated 1886), at Alma; and some professional schools at Detroit (q.v.).

Finance. The revenue of the state is derived almost wholly from taxation, about 87% from a direct or general property tax, the rest from various specific or indirect taxes, such as the liquor tax and the inheritance tax. The direct tax, other than on the property corporations, is assessed by the county supervisors, or, in cities and incorporated villages by the officer named therein for that service, on what is supposed to be the full cash value of the property. The assessment roll thus prepared is reviewed by a local board of review; an equalization officer reports the value of each within the state but not maintained by it are: Albion College (Methodist Episcopal; opened in 1834), at Albion; Hillsdale College (Free Baptists, 1853), at Hillsdale; Kalamazoo College (Baptist, 1855), at Kalamazoo; Adrian College (controlled by the Methodist Protestant Church since 1867), at Adrian; Olivet College (Congregational, 1859), at Olivet; Hope College (Reformed, 1886), at Holland; Detroit College (Roman Catholic, 1872), at Detroit; Alma College (Presbyterian; incorporated 1886), at Alma; and some professional schools at Detroit (q.v.).

the last decade of the century. The present constitution (as revised in 1908) forbids the contraction of a state debt exceeding $250,000, except for repelling an invasion or repelling an insurrection; the remaining power of the minor civil divisions is restricted by a general law.

The early experience of the state with banks was scarcely less serious than that of the public in the United States. Although there were already fifteen banks in the state in 1837 yet the cry against monopoly was loud, and so in that year a general banking law was passed whereby any ten or more freeholders could establish a bank with a capital of less than fifty thousand nor more than three hundred thousand dollars and begin business as soon as 30% of the capital was paid in specie. Only a few provisions were made, and those included in the charter of the public in the form of many restrictions. In the following year the legislature passed an act for the suspension of specie payments until the 6th of May 1838, and the consequence was that the state was flooded with irredeemable paper currency. But most of the acts cut banks out of existence by 1839, and in 1844 the bank act of 1837 was declared unconstitutional. Profiting by this experience, the framers of the constitution of 1850 inserted a provision in that document whereby no general banking law can have effect until it has been submitted to the people and has been approved by a majority of the votes cast on the question. This provision is included in the revised constitution adopted in 1850, with an additional provision that no amendment shall be made to any banking law unless it shall receive an affirmative two-thirds vote of both branches of the legislature. The present banking law provides that the state shall not issue notes to the amount of less than 25,000 in the city of not more than 1500 inhabitants, not less than $25,000 in a city of not more than 5000, not less than $30,000 in a city of between 5000 and 20,000, not less than $100,000 in a city of between 20,000 and 50,000, and not less than $250,000 in any city of over 50,000, and the state banks and savings banks are required to keep on hand at least 33% of their total deposits. Every stockholder in a bank is made individually liable for the amount of all debts of the bank at any time in addition to the said stock. And all banks are subject to the inspection and supervision of the commissioner of the state banking department, who is appointed by the governor with the approval of the Senate for a term of four years.

History.—From 1613 until 1760 the territory now within the borders of Michigan formed a part of New France, and the first Europeans to found missions and settlements within those borders were Frenchmen. Two Jesuits, Raymbault and Jougis, visited the site of Sault Sainte Marie as early as 1641 for the conversion of the Chipewas; in 1668 Marquette founded there the first permanent settlement within the state; three years later he had founded a mission among the Hurons at Michilimackinac; La Salle built a fort at the mouth of the Saint Joseph in 1679; and in 1701 Cadillac founded Detroit as an important point for the French control of the fur trade. But the missionaries were not interested in the settlement of the country by Europeans, the fur traders were generally opposed to it, there was bitter strife between the missionaries and Cadilac, and the French system of absolutism in government and monopoly in trade were further obstacles to progress. Even Detroit was so expensive to the government of the mother country that there was occasional talk of abolishing it, and so during the last fifty-nine years that Michigan was a part of new France there were no new settlements, and little if any growth in those already established. During the last war between the English and the French in America the Michigan settlements passed into the possession of the English, Detroit in 1760 and the others in 1761, but the time had not yet come for much improvement. The white inhabitants, still mostly French, were subjected to an English rule that until the Quebec Act of 1774 was chiefly military, and as a consequence many of the English fought homes elsewhere, and many of whom had been allies of the French, were so ill-treated, both by the officers and traders, that under Pontiac, chief of the Ottawas, a simultaneous attack on the English posts was planned. Detroit was besieged for five months and both Michilimackinac and Saint Joseph were taken. Moreover, the English policy, which first of all was concerned with the profits of trade and manufacture, gave little more encouragement to the settlement of this section of the country than did the French. By the Treaty of Paris, in 1783, which concluded the American Revolutionary War, it was provided that the territory now included in the United States, and in 1787 this territory became a part of the North-West Territory; but it was not until 1796 that Detroit and Mackinac (Michilimackinac), in accordance with Jay's Treaty of 1794, were surrendered to Great Britain. In 1800, on the division of the North-West Territory, the west portion of Michigan became a part of the newly-established Indiana Territory, into which the entire area of the present state was embodied in 1802, when Ohio was admitted as a state; and finally, in 1803, Michigan Territory was organized, its south boundary being then described as a line drawn east from the south extremity of Lake Michigan until it intersected Lake Erie, and its west boundary a line drawn from the same starting point through the middle of Lake Michigan to its north extremity and then due north to the north boundary of the United States. In 1812, during the second war between Great Britain and the United States, General William Hull, first governor of the Territory, although not greatly outnumbered, surrendered Detroit to the British without a struggle; in the same year also Mackinac was taken and Michigan again passed under British rule. This period of short duration, however, for soon after Commodore Oliver H. Perry's victory on Lake Erie, in September of the next year, Detroit and the rest of Michigan except Mackinac, which was not recaptured until July 1815, were again taken into the possession of the United States. Up to this time the Territory still had remained for the most part a wilderness in which the fur trade reaped the largest profits, its few small settlements being confined to the borders; and the inaccurate reports of the surveyors sent out by the national government described the interior as a vast wilderness with little timber and fit for cultivation. The large number of hostile Indians was also a factor in making the Territory unattractive. But during the efficient administration of Lewis Cass, governor of the Territory from 1813 to 1831, the interference of the British was checked and many of the Indians were removed to the west of the Mississippi; printing presses, established during the same period at Detroit, Ann Arbor, Monroe and Pontiac, became largely instrumental in making the country better known; the first steamboat, the "Walk-in-the-Water," appeared at Detroit in 1818; the Erie canal was opened in 1825; by 1830 a dry-belt line was running between Detroit and Buffalo, and the population of Michigan, which was only 476,218 in 1810 and 889,631 in 1820, increased to 31,639 in 1830 and 212,267 in 1840. In 1819 the Territory had been empowered to send a delegate to Congress. By 1832 the question of admission into the Union had arisen, and in 1835 a convention was called in Detroit, a constitution was framed in May, that constitution was adopted by popular vote in October, state officials were elected, and application for admission was made; but a dispute with Ohio over the boundary between the two caused a delay in the admission by Congress until early in the year 1837. There had been both internal and external arguments; the North-West Territory fixed the boundary line as claimed by Michigan, yet that line was found to be farther south than was at the time expected and when the constitution of Ohio was adopted it was accompanied with a proviso designed to secure to that state a north boundary that was north of the mouth of the Maumee River. The territory between the two proposed lines was unquestionably of greater economic importance to Ohio than to Michigan, and, besides, at this particular time there were forcible political reasons for not offending the older state. The consequence was that after the bloodless "war" between the two states for the possession of Toledo, Congress settled the dispute in Ohio's favor and gave to Michigan the territory since known as the upper peninsula. The boundaries as fixed by Congress were rejected by a convention which met on the 4th of September at Ann Arbor, but they were accepted by the convention of the Jackson party, which met, also at Ann Arbor, on the 6th of December; the action of this latter convention was considered authoritative by Congress, which admitted Michigan into the Union as a state on the 26th of January 1837. Since admission into the Union the more interesting experiences of the Territory Independent with only one larger town, the county, which together resulted in serious financial distress; in the utilization of its natural resources, which have been a vast source of
wealth; and in the development of its educational system, in which the state has exerted a large influence throughout the Union. From the beginning of its government under its first state constitution in 1835 until 1835 Michigan had a Democratic administration, with the exception of the years 1840-1852, when opposition to the financial measures of the Democrats placed the Whigs in power. But it was in Michigan that the Republican party received its first official recognition, at a state convention held at Jackson on the 6th of July 1857, and from the beginning of the following year the administration has been Republican with the exception of two terms from 1883 to 1885, and from 1891 to 1893, when it again Democratic.

GOVERNORS OF MICHIGAN

Territorial.

William Hull 1805-1813
Lewis Cass 1813-1831

Steven Thompson Mason (acting) 1831-1834
George Bryan Porter 1831-1834
Steven Thompson Mason (acting) 1834-1835
John Scott Horner (acting) 1835

Steven Thompson Mason 1835-1840
William Woodbridge Whig 1840-1841
Charles A. Goodrich (acting) 1841
John Steward Barry 1842-1843
Alpheus Felch 1843-1847
William L. Greenly (acting) 1847-1849
Ephraim W. Chrysler 1849-1851
John Steward Barry 1850-1851
Robert McClelland 1851-1853
Andrew Parsons (acting) 1853-1854
Kimble S. Bangham 1854-1855
Moses Wiesner 1855-1856
Austin Blair 1856-1857
Henry T. Childs Crapo 1857-1858
Henry Porter Baldwin 1859-1861
John Judson Bagley 1862-1863
Charles Miller Closswell 1863-1864
David Howell Jerome 1864-1868
Josiah W. Beigele 1868-1869
Russell Alexander Alger 1869-1871
Cyrus C. Clay Luce 1871-1873
Edwin Baruch Winters 1873-1893
John T. Rich 1893-1895
Hazen Smith Pingree 1895-1901
Aaron Thomas Bliss 1901-1905
Fred M. Warner 1905-1911

Chase S. Osborn 1911

AUTHORITIES.—The Publications of the Michigan Geological Survey (1856-1905), New York, 1898 seq.) deal largely with the mining districts of the upper peninsula. Alexander Winchell, Michigan: Being Condensed Popular Sketches of the Topography, Climate and Geology of the State (1873), is a large measure a work of reference. W. J. Beal and C. F. Wheeler, Michigan Flora (Lansing, 1892), contains the results of an extensive study of the subject. See also the Twentieth Census of the United States (Washington, 1901); S. S. Van Renssen, Michigan Fighting: A State Cyclopaedia with Sectional County Maps (Detroit, 1901); Bela Hubbard, Memorials of a Half-Century (New York, 1887), a well written account of observations, chiefly upon scenery, fauna, flora and climate; Webster Cook, Michigan: its History and Government (New York, 1903), written primarily for use in schools and containing a reference bibliography; A. C. Maclaughlin, History of Higher Education in Michigan, in Circulars of Information of the United States Bureau of Education (Washington, 1891), being an account of the origin of the public school system and an individual account of each higher institution of learning; T. M. Cooley, Michigan: a History of Government (Ann Arbor, 1896); J. V. Campbell, Outlines of the Political History of Michigan (Detroit, 1876), also by a jurist of the state; Henry M. Utley and Byron M. Cutcheon, Michigan as a Province, Territory and State (1891-1900); Michigan Pioneer and Historical Collections: Collections and Researches (Lansing, 1877 seq.): and Publications of the Michigan Political Science Association (Ann Arbor, 1893).

MICHIGAN, LAKE, the only one of the great lakes of North America wholly within the boundaries of the United States, and the largest body of fresh water in the world. It lies S. of Lake Superior and W. of Lake Huron, between 41° 37' and 46° 55' N. and 84° 45' and 88° W.; is bounded on the N. and E. by the state of Michigan, on the W. by Wisconsin, while Illinois and Indiana touch its S. end. It is 320 m. long, and has an average width of 65 m. The maximum depth recorded by the United States Lake Survey is 875 ft.; the mean level of the surface is 581 ft. above mean sea-level, being the same as that of Lake Huron and 27 ft. below that of Lake Superior. Its area is 22,400 sq. m., and it has a basin of 68,100 sq. m. in area.

The shores of Lake Michigan are generally low and sandy, and the land slopes gradually to the water. The northern shore of the lake is irregular and more rugged and picturesque than the other shores, the summit of the highest peak being about 1,400 ft. above the sea. On the eastern side are numerous sand hills, formed by the wind into innumerable fantastic shapes, sometimes covered with stunted trees and scanty vegetation, but usually bare and rising to heights of from 150 to 250 ft. The south-western shore is generally low, with sand hills dotted with shrivelled pines and birch oaks. Along the western shore woods and prairies alternate, interspersed with a few high peaks. The cliffs on the east shore of Green Bay form a bold escarpment, and from this ridge the land slopes gradually to the lake. With the exception of Green and Traverse bays, Lake Michigan has few indentations of the coast line, and except at the north end it is free from islands. The waters near shore are shoal, and as there are few harbours of refuge of easy access navigation is dangerous in heavy storms. Around the lake the climate is equable, for, though the winter months are cold, the summer hot, the waters of the lake modify the climate to an extent, and the average temperature varies from 40° to 54° F.

The average annual rainfall is 33 in. The finest agricultural land in the United States is near the lake, and there is an immense trade in all grains, fruits, livestock and lumber, and in products such as flour, pork, hides, leather goods, furniture, &c. Rich lead and copper mines abound, as also salt, iron and coal. Abundant water power promotes manufactures of all kinds. Beer and distilled liquors are largely manufactured, and fine building stone is obtained from numerous quarries.

The state is practically tideless, though true tidal pulsations amounting to 3 ft. have been observed. In the lake there are a great variety of salt-water and fresh-water fishes, and many of the smaller species are abundant. Many of the larger species, however, have disappeared since the time when the lake was inhabited by American Indians, and the smaller species are seldom now found in any great number. The state of Michigan is also remarkable for the great number of birds that frequent its shores and waters. The lake is peculiarly noted for its grebes, which are abundant on its shores; and it is also the favourite resort of the double crested cormorant, which is found in great numbers. The lake is also a favourite resort of the beluga, or white whale, and many of these animals are found in the lake during the summer months. The lake is also a great breeding ground for the ichneumon fly, which is the enemy of the black fly, and many of these animals are found in great numbers on its shores. The lake is also a great breeding ground for the ichneumon fly, which is the enemy of the black fly, and many of these animals are found in great numbers on its shores. The lake is also a great breeding ground for the ichneumon fly, which is the enemy of the black fly, and many of these animals are found in great numbers on its shores. The lake is also a great breeding ground for the ichneumon fly, which is the enemy of the black fly, and many of these animals are found in great numbers on its shores. The lake is also a great breeding ground for the ichneumon fly, which is the enemy of the black fly, and many of these animals are found in great numbers on its shores.
MICHIGAN UNIVERSITY—MICHIGAN CITY

Chicago, the principal port on the lake, is at its south-west extremity, and is remarkable for the volume of its trade, the number of vessels arriving and departing exceeding that of any port in the Union, except New York, and the commerce is conducted more than one hundred miles into the interior. It is a large railway centre, and the number and size of the grain elevators are noticeable. The port is protected by breakwaters enclosing a portion of the lake front, below the level of the high water mark, half a mile land in, and only 14 ft., much difficulty arose in draining it. A sanitary and ship canal 34 m. long was therefore completed in 1900 to divert the Chicago river, a small stream that flows into the lake, into the head waters of the Des Plaines River and the river Joliet into the Mississippi at St Louis. The discharge of water is by law so regulated that the maximum flow shall not exceed 250,000 cub. ft. per second. The diversion of the lakes of the withdrawal of water through this artificial outlet is receiving much attention. Milwaukee, situated on the shore of Lake Michigan, Bay, on the western side of the lake, is, next to Chicago, the largest city on the lake, and has a large commercial harbour of refuge. Escanaba, on Little Bay de Noc (Noquette), in the northern part of the lake, is a natural harbour and a large iron shipping port. Green Bay and Lake Michigan are connected by a canal extending from the lake to the head of Sturgeon Bay. Lake Michigan is connected at its north-east extremity with Lake Huron by the strait of Mackinac, 48 m. long, with a minimum width of 6 m.; the water is generally deep and the shoals lying near the usually travelled routes are well marked.

MICHIGAN UNIVERSITY, one of the principal educational institutions of the United States, situated at Ann Arbor, 20 m. from Detroit. It embarks a department of literature, science and the arts (including industry and commerce), opened in 1841, and including a graduate school, organized in 1852; a department of medicine and surgery, opened in 1853; a department of law, opened in 1859; a school of pharmacy, opened as a separate department in 1876; a homoeopathic medical college, opened in 1875; a college of dental surgery, opened in 1875; and a department of engineering, separately organized in 1893, which includes courses in marine engineering, architecture, and architectural engineering. The university was one of the first to admit women, having opened its doors to them in 1870 as a natural consequence of its receiving aid from the state (since 1867), and since 1900 they have constituted nearly one-half of the student body in the department of literature, science and the arts. In 1907–1908 there were in all departments 350 instructors and 5013 students (1706 in the department of literature, science and the arts; 1355 in the department of engineering; 931 in the department of medicine and surgery; 782 in the department of law; 82 in the school of pharmacy; 82 in the homoeopathic medical college; 168 in the college of dental surgery; and 1070 in the summer session). Besides the several main department buildings there is a library building, a museum building, several laboratories, a gymnasium for men, and a gymnasium for women. The general library in 1908 contained 172,940 volumes, 3,800 pamphlets, and 3,370 maps, and the several department libraries brought the total up to 277,000 volumes and 5,000 pamphlets. The general museum embraces natural collections, geological and anthropological collections, including the exhibit of the Chinese government at the New Orleans Exposition, which was purchased by the government to the university in 1885; there are besides several special collections in some of the laboratories. The astronomical observatory is surmounted by a movable dome in which is mounted a refracting telescope having a thirteen-inch object glass. The several laboratories are equipped for use in instruction in physics, chemistry, mineralogy, geology, zoology, botany, forestry, actuarial work, engineering, histology, physiology, hygiene, electrotherapeutics, pathology, anatomy and dentistry.

The university is governed from without by a board of eight regents elected by popular suffrage, two biennially, at the same time as the election of judges of the supreme court; from within the government is to a large extent in the hands of a university senate, in which the faculty of each department is represented. The university is maintained by a permanent annuity of $30,000, derived from the land set apart for it by the Ordinance of 1787, by the proceeds of a three-eighths mill tax, and by small fees paid by the students.

Its organic relation to the other public schools of the state was well established in 1870, when it was provided that graduates from such high schools as had been examined and approved by a committee of the university should be admitted without examination; one of the most important functions of the university is to prepare students for teaching in the high schools.

The first charter for a university within what is now the state was granted by the governor and judges of the Territory of Michigan in 1817, for a “Catholopolitians,” or University of Michigania, with a remarkable “Greek” system of nomenclature for its courses and faculties; this institution did practically no teaching. A second charter was granted in 1821 for a University of Michigan in Detroit; but this was accomplished, until the admission of Michigan into the Union as a state in 1837, when by the third charter the aim was to model the institution after the German university minus the theological department, and the university was entrusted to a board of regents and a chancellor appointed by the governor. Branches to correspond to the German gymnasium were established in the principal towns before any money was spent on the University proper, but the question of the constitutionality of their establishment and maintenance arose, and they were soon discontinued. An act establishing the university in general in 1836.

The first class graduated in 1845. The department of literature, science and the arts was at first much like a New England college. For some time the prospects did not seem promising; but in 1851 a new state constitution provided that the regents should be elected, and directed them to choose a president; and it was under the administration (1852–1865) of the first incumbent of that office, Henry Philip Tappan (1805–1881), that the present broad and liberal basis was established. Although he was a Presbyterian clergyman, he endeavoured at the outset to substitute the term of scholarship for those of religion; at the same time a scientific course was introduced, courses in pedagogy followed, and in 1878 the elective system, which has since rapidly expanded, was established. President Tappan was succeeded in 1863 by Erastus Otis Haven (1820–1881), who resigned in 1866, and was succeeded temporarily (1869–1871) by Professor Henry S. Frieze (1817–1886), and in 1871 by James Burrill Angell (b. 1829), who resigned in 1890. In 1871–1872 the German seminar method was introduced in graduate work in history, by Prof. Charles Kendall Adams (1835–1902), afterwards president of Cornell University (1883–1892) and of the University of Wisconsin (1892–1902). See B. A. Hinsdale and I. N. Denman, History of the University of Michigan (Ann Arbor, 1906); Elizabeth M. Farrand, History of the University of Michigan (Ann Arbor, 1885); and The Quarter Centennial of the Presidency of James Burrill Angell (Ann Arbor, 1890).

MICHIGAN CITY, a city of Laporte county, Indiana, U.S.A., on the S.E. shore of lake Michigan, about 40 m. E. by S. of Chicago. Pop. (1890) 14,776; (1900) 14,829, of whom 3602 were foreign-born; (1910 census) 16,007. Michigan City is served by the Chicago, Indianapolis & Louisville, the Lake Erie & Western, the Michigan Central and the Pere Marquette railways, by interurban electric lines, and by several lines of lake steamships. The city contains a United States Life Saving Station and the Indiana State Prison, and is the seat of a Protestant Episcopal bishop. Its transportation

President Angell graduated in 1849 at Brown University, where he was assistant librarian in 1848. He went to Europe in 1853, studied in London, and in 1855 returned to the United States, where he was professor of modern languages in 1853–1860; was editor of the Providence Journal in 1860–1866; was president of the University of Vermont in 1866–1871, was United States minister to China in 1880–1881, was a member of the joint commission of 1887–1888 to settle fisheries disputes between the United States and Great Britain, was chairman of the international deep waterways commission in 1896, and in 1897–1898 was United States minister to Turkey.
advantages make it one of the principal commercial cities in the state. Its shipments of lumber are of special importance, and it has also a transshipment trade in salt and iron ore. The total factory product in 1905 was valued at $6,314,226.

The municipality owns and operates its water-works system. Michigan City is situated on the White River, which in turn empties into Lake Michigan. It was established as a village in 1837, and was first chartered as a city in 1867.

**MICHMASH**, a place in Benjamin, about 9 Roman miles north of Jerusalem (Onom, ed. Lag., p. 280), the scene of one of the most striking episodes in Old Testament history (1 Sam. xiv.). Though it did not rank as a city (not being mentioned in Joshua xviii. 21 seq.), Micmash was reconstituted after the exile (Neh. x. 31), and, favoured by the possession of excellent wheat-land (Mishna, Men. viii. 1), was still a very large village (Max. 1. 7) in the time of Eusebius. The modern Mukhmas is quite a small place.

The historical interest of Micmash is connected with the ecclesiastical importance of the position, commanding the north side of the Pass of Micmash, which made it the meeting place of the Philistines and the centre of their forays in their attempt to quell the first rising under Saul, as it was also at a later date the headquarters of Jonathan the Hasmonaean (1 Macc. ix. 73). From Jerusalem to Mount Ephraim there are two main routes. The present caravan road keeps the high ground to the west near the watershed, and avoids the Pass of Micmash. This is the poorer road, and in antiquity may be judged of from Isa. x. 28 seq., led southwards from Ai over an undulating plateau to Micmash. Thus far the road is easy, but at Micmash it descends into a very steep and rocky gorge, the precipitous sides of which can be crossed before the use of iron tools is known.

At the bottom of the valley is the Pass of Micmash, a noble gorge with precipitous craggy sides. On the north the crag is crowned by a sort of plateau sloping backwards into a round-topped hill. This little plateau, about a mile east of the present village of Mukmash, seems to have been the post of the Philistines, lying close to the centre of the insurrection, yet possessing unusually good communications with their establishments on Mount Ephraim by the way of Ai and Bethel, and at the same time commanding the routes leading down to the Jordan from Ai and from Micmash itself.

**MICHOACÁN,** or MICHOACÁN DE OCAMPO, a state of Mexico touching on the Pacific, bounded N. by Jalisco and Guanajuato, E. by Mexico and Guerrero, S. by Guerrero and the Pacific, and W. by the Pacific, Colima, and Jalisco. Pop. (1900), 935,808, chiefly Indians and mestizos. Area, 22,874 sq. m. Its territory is divided into two nearly equal parts by the eastern branch of the Sierra Madre Occidental, the northern part belonging to the great central plateau region, and the southern to an extremely broken region formed by the diverging branches of the Sierra Madre, with their wooded terraces and slopes and highly fertile valleys. The general slope of the southern part is toward the Pacific, and contains two beautiful plateaux, which are bounded by the boundary-line with Guerrero. The narrow coastal zone on the Pacific is only 101 m. long and has no ports or towns of importance, the slopes of the Sierra Madre del Pacífico being precipitous and heavily wooded and the coastbelt sandy, hot and malarial. The Lerma, on the northern frontier, and the Balsas on the southern, are the only rivers of importance of the state, their tributaries within its boundaries being small and swift-flowing. There are several large and beautiful lakes in the state, the best known of which are Patzcuaro and Cuítzaco. Lake Chapala lies on the northern boundary. Michoacán lies within the most active volcanic region of Mexico; Jorullo (4262 ft.) is near its southern line, and Colima (12,750 ft.) is northwest of it in the state of Jalisco. Earthquake shocks are numerous, and Colima was in violent eruption in 1898-1900. The highest summit in the state is Tancitaro (12,660 ft.). The climate is for the most part temperate and healthy, but it is hot and unhealthy on the coast. Michoacán is essentially a mining region, producing gold, silver, lead and cinnabar, and having rich deposits of copper, coal, petroleum and sulphur. The natural products include fine cabinet and construction woods, rubber, fruit, palm oil and fibres. The soil of the valleys is highly fertile, and produces cereals in the higher regions, and sugar-cane, tobacco, coffee and tropical fruits in the lower. Though the plateau region was settled soon after the arrival of the Spaniards in Mexico, there are large districts on the southern and Pacific slopes that still belong almost exclusively to the Indians. Besides Morelia, the capital and largest city, the principal towns of the state are: La Piedra (pop. 5,523), an important commercial town on the Lerma river; on the Mexican railway between N.N.W. of Morelia, Zamora (10,373), 75 m. W.N.W. of Morelia; and Puruandiro (21,372), 12 m. N.W. of Morelia; on the Mexican National, 55 m. S.W. of Morelia in a mountainous district celebrated for the fine quality of its coffee; Puruandiro (2782), a commercial and manufacturing town 40 m. N.W. of Morelia; Patzcuaro (7621), on Patzcuaro lake, with a station on the Mexican National, 7550 ft. above sea level; Sahuayo (7408), 105 m. W. by N. of Morelia near Lake Chapala; Zitacuaro (6052), 60 m. S.E. of Morelia on a branch of the Mexican National, which also passes through the mining town of Angangueo (912) in the same district; and Tacambaro (5070), 46 m. S.S.W. of Morelia in a fertile valley of the Rio de las Balsas basin.

**MICKIEWICZ, ADAM** (1798–1855), Polish poet, was born in 1798, near Nowogrodek, in the present Russian government of Minsk, of which his father, who belonged to the schlichter or less noble, had a small property. The poet was educated at the university of Vilna; but, becoming involved in some political troubles there, he was forced to terminate his studies abruptly, and was ordered to live for a time in Russia. He had already published a school manual with some miscellaneous poetry at Vilna, which had been favourably received by the Slavonic public, and on his arrival at St Petersburg he found himself admitted to the leading literary circles, where he was a great favourite both from his agreeable manners and his extraordinary talent of improvisation. In 1825 he visited the Crimea, which inspired a collection of sonnets in which we may admire both the elegance of the rhythm and the rich Oriental colouring. The most beautiful are The Storm, Balchysierat, and Songs of the Country Fathers.

In 1828 appeared his Konrad Wallenrod, a narrative poem describing the battles of knights of the Teutonic order with the heathen Lithuanians. Here, under a thin veil, Mickiewicz represented the sanguinary passages of arms and burning hatred which had characterized the long feuds of the Russians and Poles. The objects of the poem, although evident, are made by the poet to escape the Russian censors, and it was never permitted to appear, although the very motto, taken from Machiavelli, was significant: "Dovete adunque sapere come sono due generazioni da battere... bisognar essere volpe e leone." This is a summary of the poem, and contains two beautiful lyrical lines. After a five years' exile in Russia the poet obtained leave of absence, and he had secretly made up his mind never to return to that country or Poland so long as it remained under the government of the Muscovites. Wending his way to Weimar, there he made the acquaintance of Goethe, who received him cordially, and, pursuing his journey through Germany, he entered Italy by the Splügen, visited Milan, Venice, and Florence, and finally took up his abode at Rome. There he wrote the third part of his poem Dziady, the subject of which is the religious commemoration of their ancestors practised among Slavonic nations, and Pan Tadeusz, his longest work, by many considered his masterpiece. A graphic picture is drawn of Lithuania on the eve of Napoleon's expedition to Russia in 1812. In this village idyll, as Brückner calls it, Mickiewicz gives us a picture of the homes of the Polish magnates, with their somewhat boisterous but very genuine hospitality. We see them before us, just as the knell of their nationalism, as Brückner says, seemed to be sounding, and therefore there is something melancholy and dirge-like in the poem in spite of the pretty love story which forms the main incident. Mickiewicz turned to Lithuania with the loving eyes of an exile, and gives us some of the most delightful descriptions of Lithuanian cities and Lithuanian forests. He describes the weird sounds to be heard in the primeval woods in a country where the trees were sacred. The cloud-pictures
are equally striking. There is nothing finer in Shelley or Wordsworth.

In 1832 Mickiewicz left Rome for Paris, where his life was for some time spent in poverty and unhappiness. He had married a Polish lady, Selina Seymourska, who became insane. In 1840 he was appointed to the newly founded chair of Slavonic languages and literature in the Collège de France, a post which he was especially qualified to fill, as he was now the chief representative of Slavonic literature, Pushkin having died in 1837. He was, however, only destined to hold it for a little more than three years, his last lecture having been given on the 28th of May 1844. His mind had become more and more disordered under the influence of religious mysticism. He had fallen under the influence of a strange fanatic named Towkowski. His lectures became a medley of religion and politics, and thus brought him under the censure of the Government. A selection of them has been published in four volumes. They contain some good sound criticism, but the philological part is very defective, for Mickiewicz was no scholar, and he is obviously only well acquainted with two of the literatures, viz. Polish and Russian, the latter only till the year 1830. A very sad picture of his declining days is given in the memoirs of Herzen. At a comparatively early period the unfortunate poet exhibited all the signs of premature old age; poverty, despair and physical affliction had wrought their worst. In 1840 he founded a French newspaper, La Tribune des peuples, but it only existed a year. The restoration of the French Empire seemed to kindle his hopes afresh; his last composition is said to have been a Latin ode in honour of Napoleon III. On the outbreak of the Crimean War he was sent to Constantinople to assist in raising a regiment of Poles to take service against the Russians. He died suddenly there in 1855, and his body was removed to France and buried at Montmorency. In 1900 his remains were disinterred and buried in the cathedral of Cracow, the native city of Poland, where rest, besides many of the kings, the greatest of her worthies.

Mickiewicz is held to have been the greatest Slavonic poet, with the exception of Pushkin. Unfortunately in other parts of Europe he is but little known; he writes in a very difficult language, and one which it is not the fashion to learn. There were both pathos and irony in the expression used by a Polish lady to a foreigner, "Nous avons notre Mickiewicz à nous." He is one of the best products of the so-called romantic school. The Poésies de France and the Poésies of Poland were full of legends and picturesque stories which only awaited the coming poet to put them into shape. Hence the great popularity among his countrymen of his ballads, each of them being connected with some national tradition. Besides Konrad Wallenrod and Pan Tadeusz, attention may be called to the poem Grasyza, which describes the adventures of a Lithuanian chieftainess against the Teutonic knights. It is said by Ostrowski to have inspired the brave Emilia Plater, who was the heroine of the rebellion of 1830, and after having fought in the ranks of the insurgents, found a grave in the forests of Lithuania. A fine vigorous Oriental piece is Fariz. Very good too are the odes to Youth and to the historian Lelewel; the former did much to stimulate the efforts of the Poles to shake off their Russian conquerors. It is enough to say of Mickiewicz that he has obtained the proud position of the representative poet of his country; her customs, her superstitions, her history, her struggles are reflected in his works. It is the great voice of Poland appealing to the nations in her agony.

His son, Ladislas Mickiewicz, wrote Vie d'Adam Mickiewicz (Posen, 1890-1895, 4 vols.), also Adam Mickiewicz, sa vie et son œuvre (Paris, 1808). Translations into English (1881-1885) of Konrad Wallenrod and Pan Tadeusz were made by Miss Biggs, also Œuvres politiques de Mickiewicz, trans. by Christien Ostrowski (Paris, 1843). (W. R. M.)

MICKLE, WILLIAM JULIUS (1735-1788), Scottish poet, son of the minister of Langholm, Dumfries-shire, was born on the 28th of September 1735. He was educated at the Edinburgh high school, and in his fifteenth year entered business as a brewer. His father purchased the business, and on his death William Mickle became the owner; but he neglected his affairs, devoting his time to literature, and before long became bankrupt. In 1763 he went to London, where in 1765 he published "a poem in the manner of Spenser" called the Conceivings (afterwards Syr Martyn); was appointed corrector to the Clarendon Press, and translated the Lusiad of Camoens into heroic couplets (specimen published 1771, whole work, 1775). So great was the repute of this translation that when Mickie—appointed secretary to Commodore Johnstone—visited Lisbon in 1779, the king of Portugal gave him a public reception. On his return to London he was appointed one of the agents responsible for the distribution of pamphlets, and this employment, in addition to the sums brought him by his translation of the Lusiad, placed him in comfortable circumstances.

It has been suggested that the Scottish poem "There's nae luck about the hoose" was Mickie's. It is more likely, however, that Jean Adams was the author. Scott read and admired Mickle's poems in his youth, and founded Kennethworth on his ballad of Clunmor Hall, which appeared in Thomas Evans's Old Ballads... with some of Modern Date (1784).

MICMAC, a tribe of North American Indians of Algonquian stock. They formerly occupied all Nova Scotia, Cape Breton and Prince Edward islands, and part of New Brunswick and Newfoundland. They fought on the French side in the colonial wars. They are now civilized and almost all profess Catholicism. They number some 4000 in settled communities throughout their former territory.

There is an excellent account of the Micmac Indians in J. G. Millais's Newfoundand and its Untrodden Ways (1905).

MICON, a Greek painter of the middle of the fifth century B.C. He was closely associated with Polygnotus of Thasos, in conjunction with whom he adorned the Painted Stoa, at Athens, with paintings of the battle of Marathon and other battles. He also painted the Amaceum at Athens.

MICROCLINE, a rock-forming mineral belonging to the feldspar group (see FELSPAR). Like orthoclase it is a potash-feldspar with the formula KAlSi3O8, but differs from this in crystalizing in the anorthic system. The name (from Greek μικρός, small, and κλίνω, to incline), was given by A. Breithaup in 1830, and has reference to the fact that the angle (86° 30') between the two perfect cleavages differs but little from a right angle: the species was, however, first definitely established by A. Des Cloizeaux in 1876. The crystals and cleavage masses are of the same kinds as those of orthoclase. The optical constants and specific gravity (2-56) are the same for the two minerals; there are, however, important differences in the twinning and in the optical characters. In addition to being twinned according to the same laws as orthoclase, microcline is repeatedly twinned according to the albite-law and the pericline-law, producing a very characteristic grating or cross-hatched structure which is especially prominent when thin sections of the mineral are examined in polarized light. This lamellar structure is often on a very minute scale, sometimes so minute as to be almost indistinguishable: it has therefore been suggested that orthoclase is really a microcline in which the twin-lamellae are ultra-micoscopic. In a section parallel to the basal plane c (001) of a microcline crystal the lamellae do not extinguish optically parallel to the edge bc as in orthoclase, but at an angle of 15° 30'; further, the obtuse bisectrix of the optic axes in microcline is inclined to the normal of the plane b (101) at an angle of 15° 26'. Green microcline is distinctly pleochroic.

Microcline occurs, usually with orthoclase, as a constituent of pegmatites, granites and gneisses; it is rare in porphyries and is not known in volcanic rocks. A beautiful crystalized mass of greenish-blue analcite-of-lithia (Co Al2SiO6) is known as amazonite (q.v.). Chesterlite is a variety occurring as crystals on dolomite in Chester county, Pennsylvania.

Closely allied to microcline is the anorthic soda-potash-feldspar known as anorthoclase or natron-microcline. Here sodium predominates over potassium and a little calcium is also often present, the formula being (Na, K) Al2SiO6. It resembles microcline in having a cleavage angle of very nearly 90° and in the cross-hatched structure, the latter being usually very minute and giving rise to a mottled
extinction. It is the characteristic feldspar of volcanic rocks which are termed andesite, and is typically developed in the lavas of Pantelleria near Sicily and those of Kilimanjaro and Mount Kenya in East Africa: the rhomb-shaped porphyritic feldspars of the "rhomb-porphory" of southern Norway also belong here.

**MICROCOM**—**MICROMETER**

MICROCOM, a term often applied in philosophical and in general literature to man regarded as a "little world" (Gr. μικρός εἶδος) in opposition to the "macrocorm," greatest world, in which he lives. From the dawn of speculative thought in Greece the analogy between man and the world has been a common-place, and may be traced from Heractitus and Empedocles, through Plato, Aristotle, the Stoics, the Schoolmen and the thinkers of the Renaissance down to the present day. Thus Lotez's comprehensive survey of mental and moral science is characterized by his systematic expression of the tendency indicated by the term is the monadology of Leibnitz, in which the monad is regarded as containing within its own sphere a complete expression of the universe, the typical created monad being the human soul.

MICRO COSMIC SALT, or ammonium sodium hydrogen orthophosphate, NaNH₂HPO₄. 4H₂O, so named by the alchemists because it is contained in the decomposing urine of man (the "microcosm"). It is interesting historically as being the raw material from which Brand prepared phosphorus, whence it is now derived in all its salts. It has been used as a salt in the treatment of many diseases, and in large transparent crystals from a mixture of solutions of sal-ammoniac and disodium phosphate, or by saturating a solution of monosodium phosphate with ammonia. When heated to redness, it leaves a transparent glass of sodium metaphosphate, NaNPO₄, which like borax dissolves most metallic oxides, with formation of glasses that often exhibit characteristic colours, and which may be used in the qualitative analysis of substances.

See Chemistry, § Analytical.

MICROMETER (from Gr. μικρός, small, μέτρον, a measure), an instrument applied to telescopes and microscopes for measuring small angular distances with the former or the dimensions of small objects with the latter.

Before the invention of the telescope the accuracy of astronomical observations was necessarily limited by the angle that could be distinguished by the naked eye. The angle between two objects, such as stars or the opposite limbs of the sun, was measured by directing an arm furnished with fine "sights" (in the sense of the "sights" of a rifle) first upon one of the objects and then upon the other (q.v.), or by employing an instrument similar to the first two arms, each furnished with a pair of sights, and directing one pair of sights upon one object and the second pair upon the other. The angle through which the arm was moved, or, in the latter case, the angle between the two arms, was read off upon a finely graduated arc. With such means no very high accuracy was possible. Archimedes concluded from his measurements that the sun's diameter was greater than 29° and less than 32°; and even Tycho Brahe was so misled by his measures of the apparent diameters of the sun and moon as to conclude that a total eclipse of the sun was impossible.

Michael Maestlin in 1579 determined the relative positions of eleven stars in the Pleiades (Historia coelestis Lucii Borelli, Augsburg, 1666), and A. Winnecke has shown (Monthly Notices R. A.S., xxix. 146) that the probable error of these measures amounted to about 30″.

The invention of the telescope at once extended the possibilities of accuracy in astronomical measurements. The planets were shown to have visible disks, and to be attended by satellites whose distance and position angle relative to the planet it was desirable to measure. It became, in fact, essential to invent a 1 micrometer 2 for measuring the small angles which were indeed the first time rendered measurable. There is now no doubt that William Gascoigne, a young gentleman of Yorkshire, was the first inventor of the micrometer. William Crabtree, a friend of his, taking a journey to Yorkshire in 1639 to see Gascoigne, writes thus to his friend Jeremiah Horrocks. "The first thing Mr Gascoigne showed me was a large telescope amplified and adorned with inventions of his own, whereby he can take the diameters of the sun and moon or any small angle in the heavens or upon the earth, most exactly and ingeniously... The micrometer so mentioned fell into the possession of Richard Towlely of Lancashire, who exhibited it at the meeting of the Royal Society held on the 25th of July 1667.

The principle of Gascoigne's micrometer is that two pointers having parallel edges at right angles to the measuring screw, are moved up opposite sides of a symmetrical disk, and at right angles to the axis of the telescope. The micrometer screw at zero when the two edges are brought exactly together. The edges are then separated till they are tangent to the opposite limbs of the disk of the planet to be measured, or till they respectively bisect two stars, the angle between which is to be determined. The symmetrical separation of the edges is produced and measured by a single screw; the fractions of a revolution of the screw are obtained by an index attached to one end of the screw, reading on a dial divided into 100 equal parts. The whole arrangement is elegant and ingenious. A steel cylinder (about the thickness of a goose-quill), which forms the micrometer screw, has two threads cut upon it, one having one-half pitch and the other double the pitch of the other. This screw is mounted on an oblong box which carries one of the measuring edges; the other edge is mounted on the coarser part of the screw relative to the edge attached to the box, whilst the whole itself is moved directly to the axis of the telescope by the finer screw. This produces an opening and closing of the edges symmetrically with respect to the telescope axis. Flamsteed describes in his first volume of "Historia coelestis," the results of measurements made by Gascoigne extending from 1638 to 1643.

These include the mutual distances of some of the stars in the Pleiades, a few observations of the apparent diameter of the sun, others of the distance of the moon from neighbouring stars, and a great number of measurements of the diameter of the moon. Dr John Bevis (Phil. Trans. 1774), p. 190) also gives results of measurements by Gascoigne of the diameters of the moon, Jupiter, Mars and Venus with his micrometer.

Delambre gives the following comparison between the results of Gascoigne's measurements of the sun's semi-diameter and the computed results from modern determinations:—

  - October 25 (o.s.)  16°11'  or 10°16'0"  
  - November 2  16°14'  or 16°14'8"  

Gascoigne, from his observations, deduces the greatest variation of the apparent diameter of the sun to be 35", according to the Connaissance des temps it amounts to 32°3". These results prove the enormous advance attained in accuracy by Gascoigne, and his invention of the micrometer deserves the highest praise.

Huygens, in his Systema Saturnium (1659), describes a micrometer with which he determined the apparent diameters of the principal planets. He inserted a slip of metal, of variable breadth, at the focus of the telescope, and observed at what part it exactly covered the object under examination; knowing the focal length of the telescope and the width of the slip at the point observed, he thence deduced the apparent angular breadth of the object. The Marquis Malvasia in his Ephemerides (Bologna, 1662) describes a micrometer of his own invention. At the focus of his telescope he placed fine silver wires at right angles to each other, which, by their intersection, formed a network of small squares. The mutual distances of the intersecting wires he determined by counting, with the aid of a pendulum clock, the number of seconds required by an equatorial star to pass from web to web, while the telescope was adjusted so that the star ran parallel to the wires at right angles to those under investigation. In the Phil. Trans. (1667), No. 21, p. 373, Adrien Auzout gives the results of some measures of the diameter of the sun and moon made by himself, and this communication led to the letters of Townley and Bevis above referred to. The micrometer of Auzout and Picard was provided with silk fibres or silver wires instead of the edges of Gascoigne, but the silk fibres remained fixed while the other was moved by a screw.

It is beyond doubt that Huygens independently discovered that an object placed in the plane of the focus of the two lenses of a Kepler telescope appears as distinct and well-defined as the 1 Delambre, Hist. ast. moderne, ii. 590. 2 Méém. acad. des sciences (1717), pp. 78 seq.
image of a distant body; and the micrometers of Malvasia, Auzou and Picard are the natural developments of this discovery. Gascoigne was killed at the battle of Marston Moor on the 2nd of July 1644, in the twenty-fourth year of his age, and his untimely death doubled the curse that the public lamentation of discovery which anticipated, by twenty years, the combined work of Huygens, Malvaison, Auzout and Picard in the same direction.

As the powers of the telescope were gradually developed, it was found that the finest hairs or filaments of silk, or the thinnest silver wires that could be drawn, were much too thick for the refined purposes of the astronomer, as they entirely obliterated the image of a star in the more powerful telescopes. To obviate this difficulty Felice Fontana, of Florence, (Pogg. Brui d'Italia e di storia naturale, 1755) first proposed the use of spider webs in microtometers, but it was not till the attention of Troughton had been directed to the subject by Rittenhouse that the idea was carried into practice. In 1813 Wollaston proposed fine platinum wires, prepared by surrounding a platinum wire with a cylinder of silver, and drawing out the cylinder with its platinum axis into a fine wire. The surrounding silver was then dissolved by nitric acid, and a platinum wire of extreme fineness remained. But experience soon proved the superiority of the spider web; its perfection of shape, its lightness and elasticity, have led to its universal adoption.

Beyond the introduction of the spider web it is unnecessary to mention the various steps by which the Gascoigne micrometer assumed the modern forms now in use, or to describe in detail the suggestions of Hooke, Wren, Smeaton, Cassini, Bradley, Maskelyne, Herschel, Arago, Pearson, Bessel, Struve, Dawes, and, or the successive productions of the great artists Ramsden, Troughton, Fraunhofer, Ertel, Simms, Cooke, Grubb, Clarke and Repsold. It will be sufficient to describe those forms with which the student will be most familiar, as they have been done, or which have survived the tests of time and experience.

Before astronomical telescopes were mounted parallactically, the measurement of position angles was seldom attempted. Indeed, in those days, the difficulties attached to such measures, and to the measurement of distances with the filament micrometer, were exceedingly great, and must have taxed to the utmost the skill and patience of the observer. For, on account of the diurnal motion, the direction of the axis of the telescope when pointed to a star is always changing; so that, to follow a star with the filament micrometer, the observer requires to move continuously the two handles which give slow motion in altitude and azimuth.

Sir T. C. The first astronomer who measured position angles; the instrument he employed is described in Phil. Trans. (1781), lxxi, 500. It was used by him in his earliest observations of double stars (1779-1783); but, even in his hands, the measurements were not very accurate, because of the difficulty of mounting the spider web in such a way that he had to encounter from the want of a parallactic mounting. In the case of close double stars he estimated the distance in terms of the disk of the components. For the measurement of wider stars he invented his lamp-micrometer, in which the components of a double star observed with the right eye were made to coincide with two lucid points placed 10 ft. from the left eye. The distance of the lucid points was the tangent of the magnified angles subtended by the stars to a radius of 10 ft. This angle, therefore, divided by the magnifying power of the telescope gives the real angular distance of the centres of a double star. With a power of 400 the scale was a quarter of an inch for every second.

The Modern Filar Micrometer.

When equatorial pendulums for telescopes became more general, no filar micrometer was considered complete which was not fitted with a position circle. The use of the spider line or filar micrometer is described in the section on the first instruments. In 1782 (Phil. Trans. lxxii. 163) Sir W. Herschel writes:—

"I have in vain attempted to find lines sufficiently thin to extend them across the centres of the stars, so that their thickness might be neglected." It is a matter of regret that Fontana's suggestion was unknown to him.

J. T. Quetlet in his Treatise on the Micrometer ascribes to Ramsden the practical introduction of the spider web in microtometers. The evidence appears to be in favour of Troughton.

Dr. Hooke makes the important improvement on Gascoigne's micrometer of substituting parallel hairs for the parallel edges of its original construction (Hooke's Posthumous Works, p. 497).

Herschel and South (Phil. Trans., 1824, part iii. p. 10) claim that became universal; the methods of illumination were improved; and micrometers with screws of previously unheard of fineness and accuracy were produced. These facilities, coupled with the wide and fascinating field of research opened up by Sir William Herschel's discovery of the binary character of double stars, gained an impulse to micrometric research which has continued unabated to the present time. A still further facility was given to the use of the filar micrometer by the introduction of clockwork, which caused the micrometer to move automatically with the motion of a star, and left the observer's hands entirely at liberty.

The micrometer represented in figs. 1, 2, 3 is due to Troughton. Fig. 1 is a horizontal section in the direction of the axis of the telescope. The eyepiece ab consists of two plano-convex lenses a, b, of nearly the same focal length, and draws the two convex sides facing each other. They are placed at a distance apart less than the focal length of a, so that the wires of the micrometer, which must be distinctly seen, are beyond b. This is known as Ramsden's eye-piece, and is recognized in almost every micrometer. One of the spider slides is inserted into the tube cd, which screws into the brass ring ef, through two openings in which the oblong frame, containing the micrometer slides, slides. These slides are shown in fig. 2, and consist of brass or brass-plated wires, and move to and fro in the forks k, l, which are rigidly fitted. The slides are accurately fitted so as to have no sensible lateral shake, but yet so as to move easily in the direction of the greatest length of the micrometer box. Motion is communicated to the forks by female screws tipped in the heads m and n acting on the screws o and p respectively. Two pins q, r, with spiral springs coiled round them, pass loosely through holes in the forks k, l, and keep the bearings of the heads m and n firmly pressed against the ends of the micrometer box. Thus the smallest rotation of either head communicates to the corresponding slide motion, which, if the screws are accurate, is proportional to the amount through which the head is turned. Each head is graduated into too equal parts on the curves u and v, so that, by estimation, the reading can easily be carried to 1/25 of a revolution. The total number of revolutions is read off by a scale attached to the side of the box, but not seen in the figure.

Two spider webs are stretched across the forks, one (t) being cemented in a fine groove cut in the inner fork k, the other (s) in a similar groove cut in the outer fork l. These grooves are simultaneously cut in situ by the maker, with the aid of an engine capable of ruling fine straight lines, so that the webs when accurately laid in the grooves are perfectly parallel. A wire sf is stretched across the centre of the field, perpendicular to the parallel wires. Each movable web must pass the other without coming in contact with it or the fixed wire, and without rubbing on any part of the brass-work. Should either be caught (termed called "fiddling") it is fatal to accurate measurement. One of the most essential points in a good micrometer is that all the webs shall be so nearly in the same plane as to be well in focus together under the highest powers used, and at the same time absolutely free from "fiddling." For measuring position angles a brass circle gh (fig. 3), fixed to the telescope by the screw s, has rack teeth on its circumference that receive the teeth of an endless screw ss, which, being fixed by the arms xx to the oblong box gh, gives motion to a motor which revolves the axis of the telescope; an index upon this point is out on the graduated circle gh the angular rotation of the instrument.

The micrometer by Troughton, fitted to their 5 ft. equatorial telescope, is the first position micrometer constructed capable of measuring position angles to 1/1000 of a second. So far as we can ascertain, the first telescope of large size driven by clockwork was the 9-in. equatorial made for Struve at Dorpat by Fraunhofer; it was completed in 1825. The original idea appears to be due to Claude Louis Picard of the Ecole d'Artillerie in Paris. In 1757 he presented a telescope to the king, so accurately driven by clockwork that it would follow a star all night long.
The English micrometer still retains the essential features of Troughton's original construction as described. The later English artists have somewhat changed the mode of communicating motion to the slides, by attaching the screws permanently to the micrometer head and tapping each micrometer screw into its slide. Instead of making the slides of the so-called fixed hollow cone (fig. 4), attached to the end of the screw, the French artists still retain Troughton's form.

Fraunhofer's micrometer is shown in fig. 5, which is the original Merz micrometer of the Cape Observatory, made on Fraunhofer's model. S is the head of the micrometer screw proper, and that of the screw mounting the micrometer, and fixed. S is attached, so that a screw which moves the eyepiece E. C is the clamp and M the slow motion in position angle. L, L are tubes attached to a larger tube N; the latter fits loosely on a strong hollow cylinder, which terminates in the screw. This screw the whole apparatus is attached to the telescope. The nozzles of small lamps are inserted in the tubes L, L, for illumination. The other end of the tube is furnished with internal threads; these threads are admitted through apertures in the strong hollow cylinder above mentioned (for illumination, see p. 385). In this micrometer the three slides moved by S, S, S' are simple dovetails. The lowest of these slides repose upon a foundation-plate 60, into one end of which the screw is tapped. In the middle of this slide a stiffly fitting brass disk is inserted, to which a small turn-table motion may be communicated by an attached arm, acting on it by two fine opposing screws accessible to the astronomer; and by their means the fixed web may be rendered strictly parallel with the movable one. Another web is fixed parallel to the axis of the screw, as nearly as possible in the same plane with it and passing through the axis of rotation of the micrometer. For the internal structural details of the micrometer the reader is referred to the article "Micrometer" in the 9th edition of the Encyclopaedia Britannica.

To use the instrument, it is well first to adjust the web moved by the screw S, so that its point of intersection with the web (commonly called the "position-web"), which is parallel to the axis of the screw, shall be nearly coincident with the axis of rotation of the micrometer box. For this purpose it is only necessary to direct the telescope to some distant object, bisect that object with the movable wire, and read the number of revolutions and parts of a revolution of the screw, now reverse the micrometer box 180° and repeat the observation; the mean of the two readings will be the point required. Now direct the telescope to a star near the equator and so that the star's image in its diurnal motion shall pass across the intersection of the two webs which mark the axis of rotation of the micrometer box. Then, as the diurnal motion causes the star-image to travel away from the axis of rotation, the micrometer box is rotated till the image of the star when at a considerable distance from the axis is bisected by the position-web. The micrometer is now clamped in position-angle by the clamp C, the star again brought back to the axis, and delicate adjustment given in position-angle by the slow-motion screw M, till the star-image remains bisected whilst it traverses the whole length of the position-web by the diurnal motion only. This determines the reading of the position-circle corresponding to position-angle 90° or 270°.

1 When it is remembered that the measurements of the Struvees, Dombowski, Secchi, the Bonds, Magellanic, and the majority of most of the European meridiana and micrometers that have been made with Fraunhofer or Merz micrometers it is not too much to say that fig. 5 represents the instrument with which a half of the astronomical measurements of the 19th century were made.

2 For the corrections applicable to measures of position-angle in different hour angles, on account of errors of the equatorial instrument and of refraction, see Chauvenet's Practical and Spherical Astronomy, ii. 392 and 450.

The position-angles of double stars are reckoned from north through east, the brighter star being taken as origin. To observe the position-angle of a double star it is only necessary to turn the position-web so that it shall be in the direction of joining the centres of the components of the double star. To test this parallelism the single web must be made to bisect the images of both components simultaneously, as in fig. 6, because it is evident that if the two components of the double star are not exactly in line, there will be a great tendency to systematic error if the web is placed on one side or other of the stars.

To avoid such error Dawes used double wires, not spider webs, placing the image of the star symmetrically between the two micrometer wires, placed a distance apart, for position-wires. This plan has the advantage of permitting easy adjustment of the webs to such a distance apart as may be found most suitable for the particular observation, but has the disadvantage that it does not permit the zero of the position-circle to be determined with the same accuracy; because, whilst by means of the screw s' (fig. 7) the eyepiece can be made to move the distance parallel to the other web, the star-image of the other component of the double is determined by the distance of the wires. If the star-image is not exactly in line with the micrometer, the image of the latter will be seen to be out of line with the lines of the components of the double. Whether the star is moving by right or by left, the error is in the same direction, and the error is the distance of the micrometer away from the position-circle center. The position-circle can then be made to bisect the image of the star by turning the micrometer box to bring it to the intersection of the micrometer wires. The result is that the micrometer wires lie between the position-circle center and the image of the star.

The micrometer is now clamped as before, and the position-angle read by bisecting each web with the star-image. The micrometer wires will then be in line with the position-circle center and the star-image, as indicated in fig. 8.

To measure distances with the Fraunhofer micrometer, the position-circle is clamped at the true position-angle, which is the same as the angular distances of the stars. The micrometer is used, as in fig. 7, and the graduated head S. The micrometer box is now moved so that the micrometer wires are parallel to the position-circle center and the star-image. The micrometer wires will then be in line with the position-circle center and the star-image.
micrometer with the upper side of the box removed. The letters in the description refer to both figures.

\( S \) is the head of the micrometer screw, \( z \) that of the screw by which the micrometer box is moved relative to the plane \( f \) (fig. 8), \( s \) that of the screw which moves the eyepiece slide. \( K \) is the clamp in position angle, \( R \) is the movable screw in position-angle. \( \theta \) is the position circle, \( R, R \) its two readers. The latter are in fact little microscopes carrying a vernier etched on glass, in lieu of a filar micrometer. These verniers can be read to \( 1 \), and estimated to \( 0.2 \). \( D \) is the drum-head which gives the fraction of a revolution, \( d \) that gives the whole number of revolutions, \( I \) is the index or pointer at which both drums are read. This index is shown in fig. 9, but only its mode of attachment (\( X \), fig. 9) in fig. 8. The teeth of the pinion \( z \), fig. 9, are cut on the axis of the micrometer screw. The drum \( d \) and

necessary always to bisect the preceding star with the fixed web. But this measures index error by bisecting both stars with the same web (or different webs of known interval fixed on the same frame), and not employing the fixed web at all. The discordance in zero, when known to exist, is really of no consequence, because the observations can be so arranged as to eliminate it.

The box is mounted on a strong hollow steel cylinder \( CC \) (fig. 9) by holes \( \eta, \theta \) in the ends of the box, which fit the cylinder closely and smoothly. The cylinder is rigidly fixed in the studs \( C, C \), and these are attached to the foundation plate \( f \). The cylinder contains towards \( \eta \) a sliding rod, and towards \( \theta \) a compressed spiral spring. There is thus a thrust outwards of the spring upon the hollow cap \( Z \) on a projection attached to the side of the box. The amount of this pressure is regulated by the screw \( z' \).

The short screw whose divided milled head is \( \sigma \) shifts the zero of the micrometer by pushing, without turning, the short sliding rod whose flat end forms the point \( d \) d'appui of the micrometer screw at \( \gamma \). The pitch of the screw \( \varphi \) is the same as that of the measuring screw (50 threads to the inch), and its motion can be limited by a stop to half a revolution.

The five fixed webs are attached to the table \( TT \), which is secured to the bottom of the box by the screws \( p \). The three movable webs are attached to the projections \( \lambda \lambda \) on the frame \( aa \). The plane surfaces \( TT \) and \( \lambda \lambda \), composed of a bronze of very close texture, which appears capable of receiving a finish having almost the truth and polish of an optical surface. It seems also to take a very clean \( V \) cut, as the webs can be laid in their furrows with an astonishing ease and precision. These furrows have apparently been cut \( \text{in situ} \) with a very accurate engine; for not the slightest departure from parallelism can be detected in any of the movable webs relative to the fixed webs. Extraordinary care has evidently been bestowed in adjusting the parallelism and distance of the planes \( \tau \) and \( \lambda \), so that the movable wires shall almost, but not quite, touch the surface \( \tau \). The varnish to fix the webs applied, not on the surface \( \tau \) as is usual, but on a bevel for the purpose, the position of the webs depending on their tension to keep them in their furrows. The result is that no trace of "fiddling" exists, and the movable and fixed webs come sharply together in focus with the highest powers. Under such powers the webs can be brought into apparent contact with such precision and delicacy that the uncertainty of measurement seems to lie as much in the estimation of the fraction of the division of the head as in the accuracy of the contact. It is

its attached tooth wheel are ground to turn smoothly on the axis of the screw. The pinion \( z \) and the toothed wheel \( d \) are connected by an intermediate wheel and pinion \( Y \); the numbers of teeth in the wheels and pinions are so proportioned that twenty-four revolutions of the micrometer screw produce one revolution of the drum and wheel \( d \). The divisions of both drums are conveniently read, simultaneously, by the lens \( e \); at night the lamp which illuminates the webs and the position-circle also illuminates the drum-heads (see on illumination p. 385). \( aaaa \) is the web-frame (fig. 9), \( by \) is a single rod consisting of two cylinders accurately fitting in the ends of the micrometer box, the larger cylinder being at \( \beta \). There is a hole in the web-frame which smoothly fits the larger cylinder at \( \beta \), and another which similarly fits the smaller cylinder at \( \gamma \). A spiral spring, coiled round the cylinder \( \gamma \), rests one end on the shoulder formed by the difference of the diameters of the cylinder \( \beta \) and \( \gamma \) and the other on the inside of the web-frame, presses the latter continuously towards \( \gamma \). Contact of the web-frame of the micrometer with the side of the box at \( \gamma \) would therefore take place, were it not for the micrometer screw. This screw fits neatly in the end of the box at \( e \). It passes loosely through the web-frame at \( e' \), is tapped into the frame at \( e'' \), and its end rests on a flat hardened surface at \( e' \).

Rotation of the web-frame about \( \beta y \) is prevented by the heads of the screws at \( m \); the head of the screw on the lower side of the frame projects on the plane \( m \), that on the upper side (fig. 9) touches lightly on the inner surface of the lid of the box. Such rotation can obviously be controlled within limits that need not be further considered. But freedom of rotation in the plane of the paper (fig. 9) is only prevented by good fitting of the holes \( \beta' \gamma' \); and, since the weight of the side is on one side of the screw, this may have the effect of changing the reading for coincidence of the movable with the fixed web in reverse positions of the micrometer. With the Cape micrometer a systematic difference has been found in the coincidence point for head above and head below amounting to \( \pm 0.14 \). This corresponds, in the Cape instrument, with an excess of the diameters of the holes over those of the cylinders of about \( \pm 0.0001 \) of an inch—quantity so small as to imply good workmanship, though it involves a value which is much larger than the probable error of a single determination of the coincidence point. The obvious remedy is to make all measures on opposite sides of the fixed web before reversing in position-angle—a precaution, however, which no careful observer would neglect. In measuring differences of declination, where the stars are brought up by the diagonal motion, this precaution cannot be adopted, because it is

a convenient feature in Repsold's micrometer that the webs are very near the inner surface of the top of the box, so that the eye is not brought inconveniently close to the plate when high powers are used.

Another excellent micrometer, originally based on a model by Clark of Cambridge, Massachusetts, has been largely used by Burnham and others in America. The form, as constructed by Warner and Swasey for the 60-inch refractor telescope, is shown in figs. 10 and 11. The micrometer box, and of course with it the whole system of spider webs, is moved by the screw \( z' \); the measuring web is independent and moved by the box \( b b \). The micrometer will be readily understood from the figure without further explanation. The method of counting the total number of revolutions gives more friction and is less convenient than Repsold's, and no reduction of this kind is employed in the practical and convenient plan adopted by Repsold.

Repsold's more recent form of the spider-line micrometer (since

1The marks of varnish so applied will be seen in fig. 9.
1893) for large telescopes is shown in fig. 12. Quick motion in position-angle for rough setting or for the measurement of close double stars is given by the large ring R. The micrometer is clamped in position-angle for his movable webs with the same accuracy as he formerly could only do for the so-called position-angle webs. Repsold also provides two insulated sliding contact rings instead of the single ring g, so that the electric current for illuminating the lamps does not pass through the instrument itself but may come to the micrometer from the storage battery through two insulated leads. The same firm is also constructing a micrometer in which the readings of the head are printed on a band of paper instead of being read off at the time of observation.

Instruments have been invented by Alvan Clark and Sir Howard Grubb for measuring with the spider-leg micrometer angles which are larger than the field of view of the eyepiece. In both cases two eyepieces are employed, one to view each separate web. One drawback to this form of instrument is that the two webs cannot be viewed simultaneously, and therefore the observer must rely upon the simultaneity of rate of the clockwork and uniformity in the conditions of refraction whilst the eye is moved from one eyepiece to the other.

Clark's micrometer was exhibited at the June meeting of the Royal Astronomical Society in 1889 (Monthly Notices, R.A.S., vol. xix.). Grubb's duplex micrometer is described in the 9th edition of the Encyclopaedia Britannica. Some examples of use of the latter are given by Professor Pritchard (Mem. R.A.S. xlvii. 4–12), who estimates the accuracy attainable with the duplex micrometer as equal to that of the heliometer; but as few measures of permanent value have been made with the instrument, and those made exhibited an accuracy far inferior to that of the heliometer, it is unnecessary to describe the instrument here in greater detail.

The Reading Micrometer-Microscope. — Micrometers used for subdividing the spaces on graduated circles and scales have, in general, only a single pair of crosswebs or parallel webs moved by a single screw. The normal form of the apparatus is shown in figs. 13 and 14. On the objective, D, the micrometer is E, the graduated head of the screw, G the milled head by which the screw cc is turned, A an eyepiece sliding in a tube B, aa (fig. 14) the slide, and b, b the spiral springs. The focal length of the objective and the distance between the optical centre of the lens and the webs are so arranged that images of the divisions are formed in the plane of the webs, and the pitch of the screw is such that one division of the scale corresponds with some whole number of revolutions of the screw.

There is what is technically called a "comb" inserted in the micrometer box at d (fig. 14)—its upper surface being nearly in the plane of the wires. This comb does not move with reference to the box, and serves to indicate the whole revolution of which a fraction is read on the head. In fig. 14 a division is represented bisected by cross webs, and five divisions of the screw correspond with one division of the scale. In all modern reading micrometers the cross webs of fig. 14 are replaced by parallel webs embracing the division (fig. 15). The means for changing the length of the tube and the distance of C from the scale are as used in the figure. These appliances are required if the "run" has to be accurately adjusted. By "run" is meant the difference between the intended whole number of screw-revolutions and the actual measures of the space between two adjacent divisions of the scale in turns of the screw fig. 15, divided by the number of intended revolutions. In delicate researches two divisions of the scale should always be read, not merely for increased accuracy but to obtain the corrections for "run" from the observations themselves.

Repsold employ for the micrometers of their reading microscopes the form of construction shown in fig. 9, omitting, of course, the motion of the whole micrometer box given by the screw s for those cases in which the axis of the micrometer is supposed to remain constant in position, as, for example, in the case of the reading micrometers of transit circles (see TRANSIT CIRCLE).

But when the relative positions of two adjacent objects or scale-divisions have to be determined (as, for example, in the case of heliometer scales), much time is saved by retaining the motion of the micrometer box. One double web, fixed in the box, is pointed symmetrically, as in fig. 15, on one of the scales, by moving the whole micrometer box by means of the screw s; the pair of webs, moved by the screw S, is then pointed upon an adjacent division on the other scale. If the reading for coincidence of the movable with the fixed webs is known, we then obtain from the single reading of S the difference from coincidence of the divisions of the two scales.

FIG. 14.

parts of the micrometer screw in order to eliminate the effects of periodic error of the screw. The electric lamp a gives illumination of the webs in a dark field, nearly in the manner described for the Cape transit circle micrometer; the intensity of illumination is regulated by a carbon-resistance controlled by the screw b. The lamp c illuminates the drum-head and also, by reflection, the portions of the position-circle which come under the microscopes d and e. The head f is a switch which enables the observer to illuminate lamp c at pleasure. These lamps, although shown in the figure, are in reality covered so as not to shine upon the observer's eye. The illumination of the field is given by a lamp near the object glass, controlled by a switch near the micrometer.

Repsold in more recent micrometers under construction give a second motion to the eyepiece at right angles to the axis of the micrometer screw; this enables the observer to determine the zero
MICROMETER

It is generally possible so to arrange the method of observation as to eliminate the effect of an error in "the reading for coincidence of the webs" from the results. This excellent time-saving convenience has also been used in Gill's apparatus for measuring astrographic plates (see below).

Ghost Micrometer.—C. E. Burton and Sir Howard Grubb (Monthly Notices, xli, 89), after calling attention to J. von Lamont's paper (Jahrbuch der K. S. b. München, p. 187) and K. L. von Littrow's paper (Proc. of Vienna Acad. of Sciences, xx. 253) on a like subject, proceed to describe a most ingenious form of "Ghost Micrometer," in which the fine line or lines ruled in (or rather cut through) a silver film deposited on glass is formed at the common focus of an object-glass and eyepiece of a telescope. A faint light being thrown on the outside of the ruled plate, there will result a bright line of view. We have not had an opportunity of testing this, nor Grubb's more recent models; but, should it be found possible to produce such images satisfactorily, without distortion and in an apparatus convenient and rigid in form, such micrometers may possibly supersede the filar micrometer. Their absolute freedom from diffraction, the perfect control of the illumination and thickness of the lines, and the accuracy with which it will be possible to construct scales for zone observations will be important features of the new method.

The Astrographic Micrometer or Measuring Machine.—The application of photography to exact astronomy has created the necessity for new forms of apparatus to measure the relative positions of stellar and planetary images on photographic plates, and the relative positions of lines in photographic spectra.

Especially important has been the problem of measuring the "catalogue plates" of the international Carte du ciel—a work that implies the determination of the positions of some millions of stars—that is to say, of all stars to the 11th and 12th magnitudes. The problem has been how to accomplish this work with the minimum of labour consistent with the desired accuracy. The adoption of a réseau photographed upon the plate has greatly facilitated the procedure.

A plate of parallel-surfaced glass has a film of silver deposited upon it. On this film is ruled a system of lines 5 mm. apart, and another similar system of lines at right angles to the first, thus dividing the silvered surface of the plane into squares 5 mm. on each side. The cutter employed to rule these lines removes the silver in fine lines from the surface of the glass. Thus, if a photographic plate, before it is exposed in the telescope, is placed with its sensitive surface nearly in contact with the silvered surface of this réseau, and the parallel light, normal to the surface of the plate, is allowed to fall on the silvered film through the glass on which the film has been deposited, that light will pass through the fine lines in the silver film where the silver has been removed by the cutter, but will otherwise be intercepted by the silver film. Thus a latent image of the réseau-lines will be formed on the photographic plate, and, when this latter has been exposed to the sky in the telescope, we obtain, on development, a negative of the images both of the stars and of the réseau-lines. If the errors of the rectangular co-ordinates of these lines are known, the problem of determining the co-ordinates of any star-image on the plate becomes reduced to the comparatively simple one of interpolating the co-ordinates of the star relative to the sides of the 5 mm. square within which that image is included. This interpolation can, of course, be accomplished with the aid of a micrometer-microscope whose optical axis is normal to the plate, provided that the plate is mounted on slides which enable the observer to bring the réseau-squares successively under the microscope.

This system has an additional advantage beyond its convenience, viz., that if any distortion of the film takes place during development the same distortion will be communicated both to the star-images and to the réseau-lines, and consequently its effect will be eliminated from the resulting star co-ordinates, except in so far as the distortion with which it is connected is of an irregular character; this exception is hardly worth consideration. An originally anticipated difficulty has arisen from the fact that the réseau-lines have not been ruled on parallel-surfaced glass with optical surfaces, and consequently on passage of light refraction in the glass plate, the rays do not always pass through the silver film in a direction strictly normal to the silvered surface; therefore, if the sensitive surface of the photographic plate is not in contact with the silvered film of the réseau, the undeveloped photographic copy of the réseau may in such a case not be an exact reproduction of the silvered réseau. It is practically impossible to work with the sensitive film in contact with the réseau-film, not only because dust particles and contact would injure the silver film, but also because the plate-glass used for the réseau is seldom a perfect plane. The discrepancies produced in this way are, however, very small, if care is taken to minimize the distance between the silver film and the photographic plate and to select a reasonably good piece of glass for the réseau. For very refined work, however, the irregularities in the reproduction of the réseau may be studied by comparing the images of the original réseau with the mean of corresponding measures of a number of photographic copies of it.

At Greenwich, Oxford and several other observatories, instead of measuring the distances of the star's image from the opposite sides of the 5 mm. réseau-square by means of a spider-line micrometer, a scale of 25 has been employed. The plate shown in fig. 16, is employed in the common focus of the objective and the eyepiece. The image of the star is set upon the intersections of the lines of the central cross, and the positions of the réseau-lines are recorded by a conveniently graduated scale.

At 5 Greenwich Astronomic Catalogue, vol. i, by permission of the Controller of H.M. Stationery Office.

FIG. 16.—Diagram of the diaphragm in eyepieces of the micrometer used for measuring the plates of the Astrographic Catalogue.

of arc, the nearest estimate corresponds with a nominal accuracy of 0.3". This involves a loss of accuracy because, with a spider-line micrometer, the accidental error of pointing is of the order of 0.1" of arc.

In the measuring machines in general use the field of view, as in the case of the glass-scale micrometer, is sufficiently large to include the image of the 5 mm. square. The microscope or viewing telescope is fitted with a spider-line micrometer having two screws at right angles to each other, by means of which readings can be made first on one réseau-line, then on the star, and finally on the opposite for the photographic plates. This form of micrometer is of course capable of giving results of higher precision, but the drawback is that the process involves a minimum of six pointings and the entering of six screw-head readings in order to measure the two co-ordinates of the star.

Gill's Measuring Machine.—Sir David Gill (Monthly Notices, R.A.S. lix. 61) devised a measuring machine which combines the rapidity of the glass-scale type of micrometer with the accuracy of the spider-line micrometer and simplifies the reductions of the observations at the same time. The essential conditions of the instrument are:

1. The object glass of the micrometer-microscope is placed midway between the plane of the photographic plate and the plane of the micrometer webs.

2. The micrometer is provided with a "fixed square" 5 mm. X 5 mm., the sides of this square being parallel spider webs 4° of arc apart; the size of the square is reckoned from centre to centre of these double webs.
The apparatus has been used with complete success at the Royal Observatory, Cape of Good Hope, and at Melbourne, Sydney and Córdoba.

**Effects of Wear on the Micrometer Screws.**—The accuracy of this apparatus has frequently been criticized on the ground that errors are produced in the screws by the effect of wear. One reply to this is that it is not difficult to determine from time to time the errors of the screws and to apply the necessary corrections to the observations. But a little consideration will show that when the plate is reversed 180° the effects of errors of the screws produced by wear are practically eliminated.

In discussing the effect of wear upon a screw, it will be convenient to imagine the thread unrolled and forming a wedge, of which we can represent the unworn bearing-side by a straight line AB (fig. 18),

![Fig. 18](image)

FIG. 18.

on which rubs the block CD, which represents the female screw or bush, and moves between the points E and F, sometimes towards E, sometimes forwards F, but having as often to measure short distances as long distances from the middle point of this range, and these as often towards E as towards F. Now, if CD is pressed by its weight or by a spring on the surface of the block AB, the effect of wear will be to produce a symmetrical grinding away of both surfaces, which may be represented thus, fig. 19. That is to say, the screw-errors will be identical for revolution π and for 10−π, and thus will disappear in their effect in the mean of observations made in reversed positions of the plate. At the Cape of Good Hope, after more than 200,000 readings had been made, the screw-errors were redetermined; the results proved the truth of the above conclusions, viz. the absolute freedom of the derived co-ordinates from the effects of wear of the screws in the mean of measures made in reversed positions of the plate.

**Hinks's Measuring Machine.—**A very refined modification of the Cape machine is described by A. Hinks (Monthly Notices, R.A.S., vol. 61, p. 444), and the instrument contains many elegant mechanical and optical details due to Horace Darwin and Messrs Zeiss respectively.

Its fundamental principle is that, by a combination of glass scales with a micrometer screw, "the chief part of the distance to be measured is read off on the scale; the fractional part of the scale-space is not estimated but measured by the screw." Hinks claims that thus never more than one- or two-tenths of a revolution of the screw need be used in making the measurement, and little time is lost in running the screw backwards and forwards. All this is true, but three readings instead of one for each pointing, much more figure-work in computation (especially if corrections have to be applied to the single readings to reduce them to exact normal screw readings), are factors which involve a far greater expenditure of time than making a few additional turns of a screw in the process of measurement. Hinks's further claim that, in consequence of the small motion of the screw, less error is produced in the screw by wear is not true; for, although large movements of the screw produce a large amount of wear, that wear is spread over longer parts of the screw but remains the same for any particular part of its motion; the readings of the screws are exaggerated towards the extremity of the range of screw employed (see Monthly Notices, R.A.S., vol. 45, p. 83), and are therefore more likely to produce errors which are not eliminated on reversing all the plate in cases where the screw range is not strictly limited, and the wear therefore not strictly symmetrical.

The excellent manner in which the scales and micrometers are mounted, the employment of a compound microscope for viewing the scales, with its ingeniously arranged and admirably efficient reversing prism, and the perfection of its slow motions for focusing and reading, combine to render this a most accurate and rapid instrument for very refined measures, although too slow for work in which the measures must depend on single pointings in each of two reversed positions of the plate, and where speed of working is essential.

**Apparatus for Measuring Star-Spectra, &c.—**These machines may be divided into three classes, viz. A, in which the motion of the projector which carries the photographic plate is measured entirely by a screw; B, in which that motion is measured by combination of a scale and screw; and C, in which the
MICROMETER

photographic plate is fixed and the measuring microscope is moved.

The chief drawback to type A is that the errors of the screw are liable to change by wear, otherwise the apparatus, as made and used in the Potsdam form, is of the most inaccurate one. In determining the errors of the screws of the Potsdaman form of machine it is necessary to have regard to the fact that the screw is placed at one side of the slide, as in fig. 20.

The result is that, if the screw is bent—if, for example, the end of the frame next the screw-head is raised and that next the end left is lowered in the diagram—a twist will be given to the web-frame, and the centre of the web will be moved nearer to the micrometer-drum than it should be, whilst the reverse effect will follow when the screw is bent in the opposite direction. As a result, when the micrometer is at any particular point (say the middle) of the web, but which would be nearer the axis of the web and greater for a point farther from that axis. In the Potsdaman form of this apparatus the micrometer is, for convenience, provided with a motion at right angles to the axis of the screw, and it has been found at the Cape Observatory that the periodic errors in this apparatus do vary very sensibly according as the micrometer is directed to a point more or less distant from the measuring screw. Since the discovery of this fact all measurements have been made in that form of the micrometer with respect to the axis of the screw for which the errors of the screw have been determined.

In the apparatus of type B as made by Zeiss there are two microscopes attached to one plate, one of which views the spectrum-plate (or other object) to be measured, while the other views a scale that moves with the slide on which the spectrum-plate is mounted. In this way the scale can be viewed by a microscope of much higher magnifying power than can be employed for the photographed spectrum. Indeed, if the scale were subdivided into 10 μm, the power employed might only be limited by the sharpness of the division-lines. But for refined work the power would imply the investigation of too many divisions of the scale; it is therefore more usual to divide the scale into single millimetres or half-millimetres and to provide a micrometer which subdivides the millimetre into 1000 or, by estimation, into 10,000 parts. For very accurate work it is desirable that the base-plate, the slide and the scale should be of nickel steel, having the same thermal coefficient of expansion as glass.

The forms of measuring machines of type C, often seen in physical laboratories, should be at once rejected for refined measurements, because it is impossible to construct slides of such perfection that the axis of the microscope will remain absolutely normal to the surface of the slide (assumed to be a plane) throughout the range of measurement. Even if the slide itself is mechanically perfect, the irregularity in the thickness of the lubricating oil between the bearing surfaces of the slide is apt to produce a variable error.

Bakhuyzen (Bulletin de Com. perm. congress. astrof. i. 164) described a measuring-machine by Repsold, in which the micrometer-screw is not the axis of the microscope but the arc of the circular slit. This is shown in the accompanying transverse section. The form of the arc is such that the observer imparts motion to the slide on which the travelling wire micrometer is placed, and that the observer can use the thumb and finger of both hands in rotating it, there is no difficulty, after a little practice, in keeping the web constantly bisecting the star in transit, and that with a little more attention the greater part of the absolute errors in following the star becomes nearly zero.

In the Astron. Nach., No. 3377, Repsold gives a detailed description of two forms of oscillating circles, fitted with means of observing in this manner, to which he has given the name of "the impersonal micrometer." This method of observation was very successfully employed, under Seeliger at Munich, in an extended series of measurements, under the auspices of the Geodetic Institute at Potsdam, in telegraphic longitude operations. Still more recently the method has been largely employed at the Cape of Good Hope and elsewhere. On the date March 17, Dr H. Stuve published an account of the application of clockwork as an aid in Repsold's method; and, later, Dr Cohn published a more elaborate paper on the same subject in the Astron. Nach., Vol. 127. The method consisted in using a motion transmitted to the micrometer screw from an axis on which is mounted a disk that presses with friction-contact upon a cone that revolves uniformly by clockwork. The velocity of rotation of the micrometer-screw could therefore be varied for stars of different declination by varying the distance from the apex at which the revolving disk presses upon the revolving cone. In the Königberg transit instrument used by Stuve and Cohn, the disk is at a fixed distance from a fixed cone, which revolves in a light-proof binnacle, the point of a pin on the axis of the transit instrument and thence through bevel-wheels in the cube of the axis to a second rod leading to the eyepiece. This rod turns a worm-wheel which is on a worm-wheel fitted "spring tight" upon the axis of the micrometer-screw.

It should be mentioned that an essential feature of the travelling wire micrometer is that the eyepiece as well as the wire shall be kept in bisection by the bire, both star and wire will appear at rest in the field of view.

The distinction between the old and new method of observation may thus be, in one sense, be described as the difference between shooting at a moving object and in shooting at one at rest. In the ease of the original Repsold plan without clockwork the description is not quite exact, because both the process of following the object and correcting the aim are simultaneously performed; whilst, if the clockwork runs uniformly and the friction-disk is set to the proper distance from the apex of the cone, the star will appear almost perfectly when started, and the observer has only to make slight corrections by differential gear—a condition which is exactly analogous to that of training a modern gun-sight upon a fixed object. It is impossible in this article to give a detailed description of the apparatus, but the following note, published by Repsold in 1887, for an illustrated account of the original Repsold's instrument and to the History and Description of the Cape Observatory for a complete description of the apparatus. It will be found in the article to the Cape transit circle, with and without clockwork.

The Hartmann Spectro comparator.—For accurate measurement of the displacements of lines of stellar spectra which are produced by the relative motion of star and observer in the line of sight, a very beautiful instrument has been devised by Dr J. Hartmann of Potsdam, and is described by him in the Publicationen des astrophysikalen Observatoriums zu Potsdam, Bd. 18, Stück 53 (1887). An English translation of this paper is given in the Astrophysical Journal, Vol. 2, No. 1, 1890. The method is used originally by Huggins, who first conceived and proved the possibility of measuring stellar velocities in the line of sight, was to measure with a filar micrometer the displacement of some well-known line in a stellar spectrum relative to the corresponding line of a terrestrial spectrum. Vogel of Potsdam introduced the method of photographing stellar and terrestrial spectra on the same plate, and in this way obtained an immense advance in the ease and precision of observation. Vogel and his successors employed either a new form of measuring machine, provided with a micro- scope to see the single object, which could be successively pointed on the photograph lines of the star spectrum and the lines of the terrestrial spectrum. To derive the stellar velocity in the line of sight relative to the observer it was then necessary to assume that the normal wave-lengths of the stellar and terrestrial spectra are accurately known. But in the
complex spectra of stars of the solar type this is by no means the case; for, as Dr. Hartmann remarks, "in the first place the lines in these spectra are so numerous that their complete measurement and reduction would require many days, and in the second place a rigorous reduction of such material has hitherto not been at all possible because the wave-lengths of the lines are not known with sufficient accuracy. On this account, observers have until now limited themselves to a partial treatment of such spectra, measuring only a small number of lines, whereby the major part of the rich material present in the plate remains unutilized." But the spectroscopes that can be employed for stellar spectrographs are not sufficiently powerful to separate fully lines which are very closely adjacent, and therefore a line, assumed to be of a known wave-length, may be apparently displaced by the near neighbourhood of an unknown line. Hartmann overcame these and many other difficulties by directly superposing the image of the spectrogram of a star, having iron comparison lines, upon the image of a spectrogram of the sun taken also with iron comparison lines.

The apparatus for this purpose is shown in fig. 21. its principle of construction is shown in figs. 22 and 23. The solar spectrograph is attached by clamps to the plate A; the stellar spectrograph to the plate A₂. The plate A₂ is mounted on the dove-tailed slide B₃, upon the metallic stage T, and can be moved to right or left relative to T by the micrometer-screw S; whilst the plate A₂ is mounted on the dove-tailed slide B₃ and can be moved at right angles to its greatest length by the screw G. The micrometer-screw S has a pitch of 0.5 mm., its head is divided into 100 parts. Two spiral springs underneath press the plate B₃ with its agate end-bearing against the rounded end of the screw S. The whole number of revolutions of the screw is read by the scale X (fig. 23). The whole stage T, carrying both spectrograms, can be moved from right to left on the steel cylinder Z, by turning the head K, on the axis of which is a pinion that gears into a toothed rack attached to the lower side of the cylinder Z. A scale N on the cylinder Z serves for setting the slide to any required position. The preliminary conditions of measurement are:

1. The centre of both spectrographs shall be parallel to the axis of the cylinder Z.
2. The distance between the centres of the two spectrographs shall be equal to the distance between the optical axes of the two viewing microscopes.
3. The scales of the images formed in the focus of the eyepiece common to both microscopes shall be identical.

To fulfil condition (1) the plates A₁ and A₂ are mounted in circular slides, whose centres are E₁ and E₂ respectively, so that by means of the screws D₁, D₂, with their corresponding opposing springs F₁ and F₂, the operation can be very easily accomplished. To fulfil condition (2) the two microscopes whose object glasses are O₁ and O₂ (fig. 22) are attached to the plate L, their optical axes being normal to the stage T. The screw Q serves to adjust the axis of O₂ to coincidence with the centre of the lines of the solar spectrograph, and the screw G then serves to move the slide B₃ till the optical axis of O₂ is coincident with the centre of the lines of the stellar spectrograph. Suppose now the solar spectrogram to be viewed in the focus of O₂, and the converging rays to be reflected by the prisms P₁ and P₂, till an image is formed in the focus of the eyepiece at the point where the axis of the eyepiece intersects...
the upper face of the prism $P_2$. Then if the prism $P_1$ is cemented to $P_2$, a sharp image of such lines of the solar spectrograph as are visible in the field of view will be seen in the eyepiece. If the stellar spectrograph is viewed in the focus of $P_3$ and the rays are reflected by the prism $P_3$ to $P_4$, no image would be seen in the eyepiece, for the rays would pass out directly through the parallel glass plate which is formed by the cementing together of the prisms $P_3$ and $P_4$. But if the cemented face of $P_4$ is silvered, then the lines of the stellar spectrogram would be seen in focus of the eyepiece and the image of the solar spectrogram would be obliterated. Therefore, if one-half of the cemented face of $P_4$ is silvered, it becomes possible to view, side by side, one-half of the image of the solar spectrograph formed by $O_1$ and one-half of the image of the stellar spectrograph formed by $O_2$. A prism half silvered in this way is provided, which enables the observer to compare the equality of scale of both photographs. If, for example, it is found that the image of the solar spectrograph is the larger of the two it becomes necessary to adjust the object glass $O_1$ farther from the stellar spectrograph. This has the effect of forming the image of the latter farther from the observer's eye, and so it becomes necessary to turn the handle of the rack-pinion $V$ in such a way as to move the prisms $P_3$ and $P_4$ nearer to $P_2$ till the lines of the stellar spectrograph are again sharply in focus. The effect of turning the pinion $V$ is, of course, to displace the focus both of the solar and stellar spectrographs in the field of the eyepiece, but this displacement is easily restored by the focusing screws $O_1$ and $O_2$. By successive adjustments of this kind condition (3) can be accurately realized.

These three adjustments having been made, the prisms $P_3$ and $P_4$ are removed and replaced by another prism in which the silverying is arranged as in fig. 24, where the hatched lines denote the silvered surfaces. The narrow tongues of the silvered surface will now reflect corresponding parts of the star-spectrograph, and will obliterate corresponding parts of the solar spectrograph—as shown in figs. 25 and 26. Fig. 25 shows the stellar and solar lines of the two spectrographs in coincidence, whilst the metallic lines of comparison are non-coincident. Fig. 26 shows the metallic lines of comparison in coincidence whilst the solar and stellar lines are non-coincident. It is obvious that these two conditions can be produced at the will of the observer by simply turning the screw $S$, and that the difference of the readings of the screw-head, which are required to reproduce the two conditions in question, gives a measure of the displacement of the stellar lines relative to the solar lines. If then the screw-value in kilometres per second is known for the neighbourhood of each of the comparison lines employed, the radial velocity of the star can be independently derived directly from coincidences made in above manner in the neighbourhood of each comparison line. For the special purpose of determining the solar parallax this instrument has been used in a most refined and perfect manner by Dr Halm at the Cape of Good Hope (Annals of the Cape Observatory, vol. x. part 3).

**MICRONESIA**

Double Image Micrometers are described in the article **Heliometer** (q.v.).

**MICRONESIA** (from Gr. μικρός, small, and νησίς, island), one of the three great divisions of the oceanic islands in the central and western Pacific. Lying to the north of Melanesia, it embraces the following groups: Mariana, Pelew, Carolines, Marshall and Gilbert. See articles under these headings, and **Pacific Ocean** (section on Islands).

The Micronesian islands form in the main a branch of the Polynesian race, but distinguished from it by well-marked differences in appearance, language and institutions. Many of the islanders, however, show signs of hybridism. The proximity of Japan and the Philippines on the west, and of the Papuan race on the east, has been instrumental in producing these mixed elements in the Micronesian population.

There are authenticated instances of Japanese junks, with living people in them, having been found in various parts of the North Pacific. In 1814 the British brig "Forrester" met with one off the coast of California (about 30° N. lat.), with three living men and fourteen dead bodies on board. In December 1832 a Japanese junk arrived at the Hawaiian Islands with four of the crew living. If these junks could cross the Pacific in the latitude of Hawaii, it is not at all unlikely that others running in a south-easterly direction would reach some of the many atolls which stretch over about 35° of longitude, forming the Caroline and Marshall archipelagoes.

The traditions of the Gilbert Islanders tell us that their islands
and South Polynesian islands on the south and south-east, suggests, what in fact is found, a combination of races. In some places the oblique Mongolian eye is noticed, and (together with certain Indo-Chinese customs) there is often a scantiness of beard and general "Malay" look, which increases westwards, and seems to imply relations with the archipelago subsequent to the departure thence of the pure Polynesians. In the Gilberts the traces of Polynesian (Samoan) influences are evident, and are confirmed by tradition. Among the Carolines and the Marshalls darker and more savage communities are found, suggesting a Melanesian element, which is further traceable in the north-west of the Caroline Islands.

Each of the four main groups, viz. the Caroline, Marshall, Gilbert and Ladrone (Mariana), from long isolation, has developed ethnological peculiarities of its own. The most advanced folk were the "Chamorros" of the Ladrones, owing to the greater natural resources of the islands, and perhaps more frequent contact with influences from the west; but as a separate people they no longer exist, having been nearly exterminated by the Spanish in the 17th century. Next in advancement come the Caroline islands. These islands are inhabited by a well-settled people, rather slightly built figure, with small and regular features; head high and well proportioned, but forehead rather receding and narrow at the temples; cheek bones and chin slightly prominent; straight black hair, longer than that of the Polynesians, colour somewhat darker than the Polynesians, the Marshalls being darker and more vigorous than the Carolines, while the Gilbert type, though smaller than the latter, is still darker and coarser. The upper class greatly surpasses the common people in physique and intelligence.

There is a division of society into septs or clans, the membership of which is regarded as sacred, and the birthright of the oldest son must not intermarry, and when two islands or communities meet in war the members of one sept, however widely separated by distance of space or time, will not injure or fight with each other. Each sept is subdivided into smaller and smaller groups (families of kin), of which the head is known as "tamuol or tros"; (2) a lower but still noble class; and (3) common people, mostly without rights of property. These last are only allowed one wife. Here and there as traces, as in Tonga, in the great sovereign, the descendants probably of a conquered dynasty. Succession is through the female side, which assures to women a certain position, and leads besides to some curious results (see paper by J. S. Kurbay in "Das Ausland," 1880, No. 27). The upper class are the keepers of traditions, boat-builders, leaders of expeditions; tattooing is generally done by them, the amount being in inverse proportion to their wealth and status, and there still has definite religious associations. Both sexes are tattooed. The Marshall Islanders are the boldest and most skilful navigators in the Pacific, and voyage many months in groups of canoes, sailing with outrigger to windward, well-provisioned, and depending on the skis for fresh water, help to show how the Pacific was colonized. They have a chart, medo, of small sticks tied together, representing the positions of islands and the directions of the winds and currents. A two-edged weapon, of which the blade is of sharks' teeth, and a defensive armour of braided sinnet, are also peculiar to the islands; a large axed, made of the shell of the Turbinella gigas (the largest bivalve known), was formerly used in the Carolines, probably by the old builder race.

The dialects of Micronesia, though grammatically alike, differ widely in their vocabularies. Chief characteristic of the languages is the influence of Malay inflexions on the nouns, and the affixes on which the inflexions are inseparable or not; and, as in Tagal, or the infix to denote changes in the verb; in the west groups there is a tendency to use closed syllables and double consonants, and not to write the palatals ch, sh, the dental th, and s (the last perhaps only in foreign words), which is alien to the Polynesians. These letters are wanting in the Gilbert language, which differs considerably from all others, and has the suffix for the third person singular, as in "th", "th", "th", and "th". Most words take the accent on the penult. In some of the dialects there appears to be no true article, but in the Gilbert Islands the Polynesian it is used for both definite and indefinite articles. Gender is not indicated in the noun, but the noun is either gathered from the was operated upon from the west and also from the east. Those who came from the east are expressly said to be from Samoa. Those who came from the west were more numerous than those from the east. There are also traditions of the arrival of other strangers at some of the Carolines and Marshalls.

The fourth group is the Micronucleus-Plagiopyllumic acid. In 1859 there was still the remnant of a large prophase which, from the description given, appears to have been like those used in the Indian Archipelago.
may be so disposed that the two minerals have a definite relation between their crystallographic axes (parallel growth). The quartz typically occurs as angular patches; at other times it forms club-shaped, curved or vermiliform threads (vermicular microgmatite, myrmekite), and then some authors consider that the felspar has been corroded and the quartz fills up the spaces thus produced (quarts de corrosion of French petrographers). Microgmatite is often so fine grained that even in the thinnest sections and with high powers it cannot be resolved into its components. This fine microgmatite resembles threads, having a divergent arrangement. In some rocks the whole ground mass consists of such spherical growths of fibrous microgmatite (see Quartz—Porphyry); in their centres there is often a quartz or felspar crystal; the outer boundaries of the spherulites are not usually circular but irregular owing to the interlocking of adjacent spherulites at their margins ("granophyric structure"). Micrographic structures may occur in other minerals, e.g. quartz and garnet, cordierite, epidote or hornblende, augite and felspar, but are less common, and the name microgmatite is usually reserved for aggregates of quartz and felspar.

In rocks where microgmatite frequently occurs (e.g. granite, porphyry and granophyre, quartz-diorite) it is usually the last to consolidate, and may replace the most exposed parts of the rock, especially if the other minerals had separated out in more or less perfect crystals. Hence it has no definite form of its own, but fills up the irregular interstices between the earlier crystallizations. The microgmatite is not in direct contact with the felspar; it is often to be the mixture of quartz and felspar which has the lowest fusion point. Eutectics are common in alloys and often have a very perfect micrographic structure. The eutectic mixture of quartz and orthoclase has been estimated to contain 70-75% of the latter. This theory, however, is not without its difficulties; analyses of microgmatite prove that its composition is by no means constant (this may, perhaps be due to small admixtures of soda and lime (felspars)); and experimental researches on the fusion points of mixtures of quartz and felspar have not yet shown that there is a definite mixture which melts at a lower temperature than any other.

A microgmatite terrane, which always takes the form of an eutectic, is made up of quartz and orthoclase, and a perfect mixture of quartz and orthoclase has been estimated to contain 70-75% of the latter. This theory, however, is not without its difficulties; analyses of microgmatite prove that its composition is by no means constant (this may, perhaps be due to small admixtures of soda and lime (felspars)); and experimental researches on the fusion points of mixtures of quartz and felspar have not yet shown that there is a definite mixture which melts at a lower temperature than any other.

**Microscope** (Gr. μικρός, small, σκοπέω, to view), an optical instrument for examining small objects or details of such objects; it acts by making the angles of vision under which the images appear greater than when the objects themselves are viewed by the naked eye.

Microscopes are distinguished as simple and compound. A simple microscope consists of a single positive lens, or of a lens combination acting as a single lens, placed between the eye and the object so that it presents a virtual and enlarged image. The compound microscope generally consists of two positive lens systems, so arranged that the system nearer the object (termed the objective) projects a real enlarged image, which occupies the same place relatively to the second system (the eyepiece or ocular) as does the real object in the simple microscope. An image is therefore projected by the ocular from the real magnified image produced by the objective with increased magnification.

**History of the Simple Microscope.**—Any solid or liquid transparent medium of lenticular form, having either one convex and one flat surface or two convex surfaces whose axes are coincident, may serve as a "magnifier," the essential condition being that it shall refract the rays which pass through it so as to cause widely diverging rays to become either parallel or but slightly divergent. Thus if a minute object be placed on a slip of glass, and a convex surface be placed upon it, the drop will act as a magnifier in virtue of the conformity of its upper surface to that of the eye, so that when the eye is brought sufficiently near it (the glass being held horizontally) the object will be seen magnified. Again if a small hole be made in a thin plate of metal, and a minute drop of water be inserted in it, this drop, having two convex surfaces, will serve as a still more powerful magnifier. There is reason to believe that the magnifying power of transparent media with convex surfaces was very early known. A convex lens of rock-crystal was found by Layard among the ruins of the palace of Nimrud; Seneca describes hollow spheres of glass filled with water as being commonly used as magnifiers.

The perfect gem-cutting of the ancients could not have been attained without the use of magnifiers; and doubtless those who executed these wonderful works also made them. Convex glass lenses were first generally used to assist ordinary vision as "spectacles"; and not only were spectacle-makers the first to produce glass magnifiers (or simple microscopes), but by them also the telescope and the compound microscope were first invented. During the Thirty Years’ War the simple microscope was widely known. Descartes (Dioptrique, 1637) describes microscopes wherein a concave mirror, with its concavity towards the object, is used, in conjunction with a lens, for illuminating the object, which is mounted on a point fixing it at the focus of the mirror. Antony van Leeuwenhoek appears to be the first to succeed in grinding and polishing lenses of such short focus and perfect figure as to render the simple microscope a better instrument for most purposes than any compound microscope then constructed. At that time the "compass" microscope was in use. One leg of a compass carried the object, and the other the lens, the distance between the two being regulated by a screw. Stands were also in use, permitting the manipulation of the object by hand. Robert Hooke shaped the minutest of the lenses with which he made many of the discoveries recorded in his Micrographia from small glass globules made by fusing the ends of threads of spun glass; and the same method was employed by the Italian Father Di Torre. Early optimicians and microscopists gave their chief attention to the improvement of the simple microscope, the principle of which we now explain.

**Simple Microscope**

**Position and Size of the Image.**—A person with normal vision can see objects distinctly at a distance varying from ten inches to a very great distance. Objects at different distances, however, are not seen distinctly at the same distance; this is affected by the power of accommodation of the eye, which can so alter the focal length of its crystalline lens that images of objects at different distances can be produced rapidly and distinctly one after another upon the retina.

The angle under which the object appears depends upon the distance and size of the object, or, in other words, the size of the image which the retina is capable of viewing depends upon the distance and the dimensions of the object. The ratio between the real size of the object y (fig. 1) and the distance l, which is equal to the tangent of the visual angle ω, is termed the "apparent size" of the object. From the figure, which represents vision with a motionless eye, it is seen that the apparent size increases as the object under observation is approached. The greater the visual angle, the more distinctly are the details of the object perceived. On the other hand, as the observer recedes from the object, the apparent size, and also the image on the retina diminishes; details become more and more confused, and, after a while, disappear altogether, and ultimately the external configuration of the object as a whole is no longer recognizable. This case arises when the visual angle, under which the object appears, is approximately a minute of arc; it is due to the physiological construction of the retina, for the ends of nerve fibres, which receive the impression of light, have themselves a definite size. The lower limit of the resolving power of the eye is reached when the distance is approximately 34.5 times the size of the object. If the object be represented by two separate points, these points would appear distinct to the normal eye only so long as the distance between them is at the most one-tenth of the distance from the eye. When the latter distance is increased still further, the two appear as one. Therefore if it is desired to distinctly recognize exceedingly small objects or details of such, they are brought as near as possible to the eye. The eye is aided in bringing its focal length to the smallest possible amount, and when this strain is long continued it may cause pain. When the shortest distance obtained by the highest strain of accommodation is insufficient to recognize small objects, distinct vision is possible at even a shorter distance by placing a very small diaphragm...
between the eye and the object, the pencils of rays proceeding from the object, which otherwise are limited by the pupils of the eye, being thus restricted by the diaphragm. The object is then projected with such acute pencils on the plane focussed for, in this case on the plane on which the eye can just accommodate itself, that the optical confusion arising there is still so small that it is below the limit of angular visual distinctness and on that account appears as a sharp point. However, the loss of light in this procedure is very large, so that only most intensely illuminated objects can be investigated.

A naked short-sighted eye, which would be corrected for distant objects by a spectacle glass of \(-10\) diopters, may approach the object up to about 4 in. and have sharp image upon the retina without any strain whatever. For the observation of small objects, a myopic eye is consequently superior to a normal eye; and the converse is true for vision with the magnifying glass or the simple microscope. As a rule, large magnification is not demanded from the former, but a larger field of view, whilst the simple microscope should ensure powerful magnification even when the field is small. The simple microscope enlarges the angle of vision, and does not tire the eye when it is arranged so that the image lies in the farthest limit of distinct vision (the punctum remotum). A normal eye will tolerate an image formed by the magnifying glass most conveniently when it is produced at a great distance, i.e., when the object is in its front focal plane. If \(f\) (fig. 2) be the object the image appears to a normal eye situated behind the system \(L\) with passive accommodation at a very great distance in the air.

Since \(H'P'\) is the focal length of the simple microscope, the visual angle \(\omega\) is given by

\[ \tan w'w = yf'f/V \]

in which \(f' = H'P'\) is the image-side focal length (see LENS). Since the lens is bounded by air, the image- and object-side focal lengths \(f'\) and \(f\) are equal. The value \(y/f' = f/V\) in (1), is termed the power of the lens. In most cases the number of diameters of the simple microscope is required; i.e., the ratio between the apparent sizes of the object when observed through the microscope and when viewed by the naked eye. When a person of normal vision views a small object, he brings it to the distance of distinct vision, which would average about 10 in. The apparent size is then (fig. 1) \(\tan w = y/\omega\), where \(\omega = 10\) in., whilst the apparent size of the object viewed through the magnifying glass would result from the formula (1) \(\tan w'w = y/yf'f/V\); consequently the number of diameters will be

\[ N = \frac{\tan w}{\tan w'} = \frac{y}{y'f'} \cdot \frac{f}{f'} = \frac{y}{y'} = \frac{V}{V'} \]

it is thus equal to the magnifying power multiplied by the distance of distinct vision, or the number of times that the focal length is contained in 10 in.

Since this value for the distance of distinct vision is only conventional, it is understood that the capacity of the simple microscope given in (2) holds good only for eyes accustomed to examine small objects 10 in. away; and observation through the magnifying glass must be undertaken by the normal eye with passive accommodation. A lens of 1 in. focal length must be spoken of, according to this notation, as a \(\times 10\) lens, and a lens of \(\frac{1}{10}\) in. focal length as a \(\times 100\) lens. Obviously the position of a normal eye free from accommodation is immaterial for determining the magnification. A \(\times 10\) magnification, however, by no means guarantees to a myopic eye of \(-10\) D by a lens of 1 in. focus. Since this short-sighted observer can view the object with the naked eye with no inconvenience, his image, in this case, is formed at infinity. If, however, the apparent size is \(w = y/4\), and to secure convenient vision through the lens the short-sighted person would bring the object to such a distance that a virtual, magnified image would be projected in his punctum remotum. In addition it will be supposed that the centre of the pupil of the observer coincides with the back focal point of the system. The apparent size of the object seen through the lens is then \(\tan y = y/4\). The magnification, resulting from the simple microscope of the above, is here \(N = \tan w/\tan w' = y/yf'f'/f'f = 4/4/4 = 4\). Thus, while a lens of 1 in. focal length assures to the normal-sighted person a \(\times 10\) magnification, it affords to the short-sighted individual only \(\times 4\). On the other hand, it is evident that the view is hypermetropic than to the observer of normal sight. From this it appears that each observer obtains specific advantages from one and the same simple microscope, and also the individual observer can obtain different magnifications by either using different accommodations, or by viewing in passive accommodation.

**Regulation of the Rays.**—In using optical instruments the eye is considered as a system of lenses, moved just in free vision, that is to say, the attention is fixed upon the individual parts of the image one after another, the eye being turned in its cavity. In this case the eye is always directed so that the part of the image which is wished to be viewed exactly falls upon the most sensitive portion of the retina, viz. the **macula lutea** (yellow spot). Corresponding to the size of the yellow spot only a small fraction of the image appears particularly distinct. The other objects which are represented on the retina on the regions surrounding the yellow spot will also be perceived, but with reduced definition. These external and less sensitive parts of the retina, therefore, merely give information as to the general arrangement of the objects and to a certain extent act as guide-post in order to show quickly and conveniently, although not distinctly, the places in the image which should claim special attention. Such a general view gives a general view over the whole object with particular definition of a small central portion. Vision with a movable eye, or "direct vision," gives exact information as to the parts of the object one after another.

The simple microscope permits such vision. If the instrument has a sensible lens diameter, and is arranged so that the centre of rotation of the eye can coincide with the intersection of the principal rays, the lens can then form with the eye a centred system. Such lenses are termed "lenses for direct vision." By moving the eye about its centre of rotation M the whole field can be examined. The position of the image of the lens serves as the diaphragm of the field of view. The selection of the rays emerging from the lens and actually employed in forming the image is undertaken by the pupil of the eye which, in this case, is consequently the exit pupil of the instrument. In fig. 3 \(PP_L\) designates the exit pupil of the lens, and the image of \(PP_L\), i.e., \(PP_M\), which is formed by the lens, limits the aperture of the pencils of rays on the object-side; consequently it is the entrance pupil of the instrument. Since the exit pupil moves in observing the whole field, the entrance pupil also moves. The principal rays, which on the object-side connect the object-points with the centre of the entrance pupil, intersect the axis on the image-side at the centre of rotation M of the eye. M, in the intersection of the principal rays.

So long as the exit pupil is completely filled the brightness of the image will be approximately equal to that of free vision. If, however, we fix the points lying towards the margin of the field of view, the diaphragm gradually cuts out more and more of the rays which were necessary to fill the pupil, and in consequence the brightness gradually falls off to zero. This vignetting can be observed for all lenses.

In most cases, and also in corrected systems, the intersection of the principal rays is no longer available for the centre of rotation of the eye, and this kind of observation is impossible. In some instruments observation of the whole available field is only possible when the head and eye are moved at the same time, the lens retaining its position. Dr M. von Rohr terms this kind of vision "peep-hole observation." It has mainly to be considered in connection with powerful magnifying glasses. In most cases a diaphragm regulates the rays. Fig. 4 shows the position of the entrance pupil, \(PP_M\), to be considered in this kind of observation. PP is the entrance pupil, \(PP_L\), is the exit pupil, and \(PP_L\) is the diaphragm. The intersection of the principal rays in this case lies in the middle of the entrance pupil or of the exit pupil. By head and eye motion the various parts of the whole field can be viewed one after another. The distance of the eye from the lens is here immaterial. In this case also the illumination must fall to zero by the vignetting of the pencils coming from objects at the margin of the field of view. C and D are the outermost rays which can pass through the instrument.

Magnifying glasses are often used for viewing three-dimensional objects. Only points lying on the plane focused for can be sharply reproduced in the retina, which acts as object-plane to the retina.

1 See also LENS.
All points lying out of this plane are reproduced as circles of confusion. The central projection, of which the centre is the middle point of the entrance pupil on the plane focused for, will show in weaker systems a somewhat dispersed round of points, as a remainder of definition; that is to say, the totality of points, which lie out of the plane focused for, and which are projected with circles of confusion so small that they appear to the eye as sharply focused. This is considered as relief, and determines the depth of definition of the lens. With increasing magnification the depth of definition diminishes, because the circles of confusion are greater in consequence of the shorter focal length of the objectives. Many powerful simple lenses have hardly any depth of definition so that in fact only points lying in one plane can be seen sharply with one focusing.

**Forms of the Simple Microscope.**—If the ordinary convex lens be employed as magnifying glass, great aberrations occur even in moderate magnifications. These are: (1) chromatic aberration, (2) spherical aberration, and (3) astigmatism (see ABBERRATION). When the pupil reflects the image of the object, the images of the ordinary lenses increase considerably with the magnification, or, what amounts to the same thing, with the increase in the curvature of the surfaces. For lenses of short focus the diameter of the pupil is too large, and diaphragms must be employed which strongly diminish the aperture of the pencils, and so reduce the errors, but with a falling off of illumination. To reduce the aberrations Sir David Brewster proposed to employ in the place of glass transparent materials of high refractive index and low dispersion. In this manner lenses of short focus can be produced having lower curvatures than glass lenses necessitate. This was based on the assumption that the index of refraction being about 1·6 times as large as that of ordinary glass. The spherical aberration of a diamond lens can be brought down to one-ninth of a glass lens of equal focus. Apart, however, from the cost of the mineral and its very difficult working, a source of error lies in its want of homogeneity, which often causes a double or even a triple image. Similar attempts made by Pritchard with sapphires were more successful. With this mineral also spherical and chromatic aberration are a fraction of that of a glass lens, but double refraction, which involves a doubling of the image, is fatal to its use. Improvements in glass lenses, however, have rendered these experiments with sapphires obsolete.

The simplest was a sphere of glass, the equator of which (i.e. the mount) formed the diaphragm. Wollaston altered this by taking two plano-convex lenses, placing the plane surfaces towards each other and clearing the diaphragm by the new principle (figs. 5 and 6). Wollaston.

Sir David Brewster found that Wollaston’s form worked best when the two lenses were hemispheres and the central space was filled up with a transparent cement having the same refractive index as the glass; he therefore used a sphere and provided it with a groove at the equator (see fig. 7). Coddington achieved the same con-struction, and for this reason this device is frequently called the Coddington lens; although he brought the Wollaston-Brewster lens into existence, he did not patent it. The Brewster-Wollaston (fig. 5) lens reproduced all points of a concentric spherical surface simultaneously sharp. A construction also employing one piece of glass forms the so-called Stanhope lens (fig. 7), which was really due to Brewster. This is a glass lens, the two parts of which are spherical surfaces. The more strongly curved surface is placed next the eye, the other serves at the same time as specimen carrier. This lens is employed when articles are found in too small a size for a magnifying glass for miniature photographs of the locality.

**Doublets, &c.**—To remove the errors which the above lenses showed, particularly when very short focal lengths were in question, lens combinations were adopted. The individual components required weaker curvatures and permitted of being more correctly manufactured, and, more particularly, the advantage of reduced aberrations was the predominant factor.

Wollaston’s doublet (fig. 8) is a combination of two plano-convex lenses, the focal lengths of which are in the ratio of 3:1; the plane Wollaston. Fraunhofer. Wilson. Steinheil. Chevalier (Brickell).

---

**FIG. 8.**

**FIG. 9.**

**FIG. 10.**

**FIG. 11.**

**FIG. 12.**

Sides are turned towards the object, and the smaller of the two lenses is nearer the object. This construction was further improved (1) by introducing a diaphragm between the two lenses; (2) by altering the distance between the two lenses; and (3) by splitting the lens into two lenses. Triplet lenses are employed when the focal length of the simple microscopes was less than 1½ in. When well made such constructions are almost free from spherical aberration, and the chromatic errors are very small. Similar doublets are composed of two plano-convex lenses by Fraunhofer (fig. 9) and the Wilson (fig. 10). Axial aberration is reduced by distributing the refraction between two lenses; and by placing the two lenses farther apart, the rays passing through apertures lying from points lying outside the axis are reduced. The Wilson has a greater distance between the lenses, and also a reduction of the chromatic difference of magnification, but compared with the Fraunhofer it is at a disadvantage with regard to the size of the free working distance, i.e. the distance of the object from the lens surface nearer it.

By introducing a dispersive lens of flint the magnifying glass could be corrected for both chromatic and spherical aberrations. Browning’s “platyscope” lens and the Steinheil “aplanatic” lens (fig. 11) are of this type. Both yield a field of good definition free from colour employment.

The manner in which the eye uses such a lens was first effectively taken account of by M. von Rohr. These anastigmatic lenses, which are manufactured up to X 40, are chromatically and spherically corrected, and for a middle diaphragm the errors of lateral pencils, distortion, astigmatism and coma are eliminated. “Peep-hole” observation is employed, observation being made by moving the head and eye while the lens is held steady. Even in powerful magnifications a good image exists in all parts of a relatively large field, and the free working distance is fairly large.

For especially large free working distances the corrections proposed for the Halsted—Browning claim to be used. The stones must be noticed (fig. 12). To an achromatic collective lens, which is turned towards the object, a dispersive lens is combined (this type to a certain extent belongs to the compound microscope). By altering the distance of the collective and dispersive members the magnification can be widely varied. Through the large free working distance, which for certain work offers great advantages, the size of the field of view is diminished.

In magnifying glasses for direct vision the eye must always be considered. The lens is brought as close as possible to the eye so as to view as large a field as possible. The watchmaker’s glass is one of the earliest forms of this kind. Galland showed how to correct these lenses for direct vision, i.e. to eliminate distortion and astigmatism when the centre of rotation of the eye coincided with the point where the principal rays crossed the axis. Von Rohr fulfills this condition by constructing the Veran lens, which is low power systems intended for viewing a large flat field.

**Stands.**—For dissecting or examining objects it is an advantage to have both hands free. Where very short focus simple microscopes are employed for producing high magnifications, it is imperative to employ a stand which permits exact focusing and the use of a special illuminating apparatus. Since, however, only relatively low powers are now employed, the ordinary rack and pinion motion is sufficient for focusing purposes, and for illuminating the object only a mirror below the stage is required when the object is transparent, and a condensing lens above the stage when opaque.

Dissecting stands vary as to portability, the size of the stand, and the manner in which the arm rests are arranged. A stand is shown in fig. 57 (Plate). On the heavy horseshoe foot is a column carrying the stage. In the column is the guide for the rack-and-pinion movement. Lenses of various magnifications can be adapted to the carrier and moved about over the stage. The rests can be attached to the stage, and when done with folded together. Illumination of transparent objects is effected by the universally adapted mirror. By turning the knob A, placed at the front corner of
the stage, a black or white plate, forming a dark or light back-
ground, can be swung underneath the specimen.

The eye-piece, the arrangement of the space of small objects
is desired a stereoscopic lens can be used. In most cases refracting
and reflecting systems are arranged so that the natural inter-
space of the objects is retained. Most lenses of any power
are powerful systems, for the main idea is the recognition of the depth
of objects, so that only systems having a sufficient depth of definition
can be utilized. Very often such stereoscopic lenses, owing to faulty
corrections, double images and eye-sides, and also magnification
are due to the alteration of the inter-pupillary distance and the
visual angles belonging to the principal rays at the object-side (see
Binocular Instruments).

**Compound Microscope**

The view held by early opticians, that a compound microscope
could never produce sufficiently good images, although as a simple
type, has proved erroneous; and the principal attention
of modern opticians has been directed to the compound instru-
ment. Although we now know how the errors of lenses may
be corrected, and how the simple microscope may be improved,
this instrument remains with relatively feeble magnification,
and to obtain stronger magnifications the compound form is necessary.

By compounding two lenses or lens systems separated by a definite
inter-space, the system found having focal length contained
less than the focal lengths of the separate systems. If \( f_1 \) be
the focal lengths of the combination, \( f_1' f_1'' \) and \( f_2, f_2'' \) the focal lengths
of the two components, and \( \Delta \) the distance between the inner foc
disks of the system (see LENS). \( \Delta \) is also equal to the distance \( f_1', f_2'' \).
The accepted \( f's \) are always on the image side, whilst the unaccented are on the object side.
From this form of expressions, for example, that one obtains a system of \( \frac{1}{2}; \)
focal length by joining two positive systems of \( \frac{1}{2}; \) in. each, whose
focal planes, turned towards one another, are separated by \( 8 \) in.

A microscope objective being made in essentially the same way as a simple system, the compound system
when being situated before the front focus of the objective, the magnifica-
tion due to the simple system makes the free object distance greater
than that obtained with a simple microscope of equal magnification.
Moreover, this distance between the object and eye is substantially
increased in the compound microscope by the stand; the incon-
veniences, and in certain circumstances also the dangers, to the eye
which may be shown for example by warming the object, are also
avoided. The conversion of the rapid change in the magnification
obtained by changing the eyepiece or the objective is also a special
advantage of the compound form.

In the commonest compound microscopes, which consist of two
positive systems, a real magnified image is produced by the objective.
This permits researches which are impossible with the simple micro-
scope. For example, the real image may be recorded on a photo-
graphic plate; it may be measured; it may be physically altered by
polarization, by spectrum analysis of the light employed by absorp-
tion layers, etc. The greatest advantage of the compound microscope is
that it is not limited to a larger area, and this much more completely
than is possible in the simple form. According to the law of oblique,
it is only possible either to portray a small object near one of the
foci of the system with wide pens, or to produce an image from a real
object, so that the correction to the image side becomes impracticable.
The simple microscope is subject to either limitation. As we shall see
later, one of the principal functions of the microscope objective is
the representation with wide pens. In that case, however, in the
compound microscope a small object may always be represented
by means of wider pens, one of the foci of the objective (not of
the compound) being near it. For the eyepiece the other rule
holds; the object is represented by narrow pens, and it is hence
possible to subject the relatively great object, viz. the magni-
fied real image, to a further representation.

**History of the Compound Microscope.**—The arrangement
of two lenses so that small objects can be seen magnified followed
soon after the discovery of the telescope. The first compound
microscope (discovered probably by the Middelburg lens-grinders,
Johan and Jacob Janssen about 1590) was a combination of a
strong biconvex with a still stronger biconvex lens; he had
thus, as well as the first telescope, a negative eyepiece. In 1656
Fontana described a microscope which had a positive eyepiece.
The development of the compound microscope essentially
depends on the improvement of the objective; but no distinct
improvement was made in its construction in the two centuries
following the discovery. In 1668 the Italian Divini employed
several doublets, i.e. pairs of plano-convex lenses, and his
example was followed by Giordani von Aeb. But even with such
magnification as these instruments permitted many faults
were apparent. A microscope, using concave mirrors, was proposed in 1672 by Sir Isaac Newton; and he was succeeded
by Barker, R. Smith, B. Martin, D. Brewster, and, above all,
Amic. More recently these catadioptric microscopes were
disregarded because they yielded unfavourable results. From
1850 onwards many improvements were made in the microscope
objective; these may be best followed from a discussion of the
faults of the image.

**Position and Size of Image.**—In most microscopic observations
the object is mounted on a plate glass slide or about 0-06 in.

The tube, embedded in a liquid such as water, glycerine or Canada balsam, and
covered with a plate glass plate of about 0-006 in. thick called
the cover-slip. If we consider the production of the image of an object
the 2 systems by the two positive systems of a compound microscope
shown in fig. 13, the objective \( L_1 \) forms a real magnified image \( O' O' \);
the object \( O O \), the focal distance of the image \( F' O' \Delta \), and the image-side focal length \( f' \); then the magnification

\[
M = \frac{y}{y'} = \frac{f' y}{y'} = \frac{f' \Delta}{\Delta}
\]

The distance \( \Delta \) is called the "optical
tube length."

Weak and strong microscope objectives act differently. Weak systems
act like photographic objectives. In this case the optical tube
length cannot be altered within fixed limits without spoiling the image; at the same time
the objective magnification \( M \) is also
affected. This change is brought about by mounting the objective and eyepiece
on two telescoping tubes, so that
by drawing apart or pushing in the tube length is increased or diminished
at will. For strong objectives there is, however, only one optical tube length
in which it is possible to obtain a good image by means of wide pens,
any alteration of the tube length involving a considerable spoiling
of the image. This limitation is examined below.

When forming an image by a microscope objective it often happens that the
transformation of the image-forming system have different optical proper-
ties. A series of objectives with short focal lengths are available which permit
the placing of a liquid between the cover-slip and the front lens of the objective; such lenses are known as immersion objectives and are covered on both sides by air called "dry systems." The
immersion liquids in common use are water, glycerine, cedar-wool oil, monochro-
naphthalene, etc. Immersion systems in which the embedding liquid, cover-
slip, immersion-lens and front lens have equal refractive indices are called
"homogeneous immersion systems." In immersion systems the objective-side
focal length remains the same as the aperture; the front focus is retained,
and the employment of the immersion means that the value of \( f' \) is unaltered.

If we assume that a normal eye observes the image-side
of the eyepiece, the eyepiece must project a distant image from the real
image produced by the objective. This is the case if the image-side foci lie
in the front focal plane of the eyepiece. In this case the optical tube
length equals the distance of the adjacent focal planes of the two
objectives which equals the distance of the image-side foci of the objective \( F' \) from the object-side foci of the eyepiece
\( F_p \). The image viewed through the eyepiece appears then to the
observer under the angle \( \psi \), and as with the single microscope

\[
tan \frac{\psi}{2} = \frac{f'}{y'} = \frac{f'}{f'} = \frac{f'}{f'}
\]

where \( f' \) is the image-side focal length of the eyepiece.
To obtain the magnification of the complete microscope we must combine the objective magnification \( M \) with the action of the eyepiece. If we replace \( y' \) in equation (4) by the value given by (3), we obtain

\[
\tan w' = \frac{2af'}{f''} = \frac{V}{N}
\]

the magnification of the complete microscope. The magnification

\[
N = \tan w' = \frac{w}{2af'} = \frac{V}{L}
\]

The magnification number increases then with the optical tube-length and with the diminution of the focal lengths of objective and eyepiece, distinctively in the same compound microscope; and hence the magnification varies with the power of accommodation.

The image produced by a microscope formed of two positive systems (fig. 13) is inverted, the objective \( L_1 \) tracing the object \( O_0 \), a real inverted image \( O'_0 \), and the eyepiece \( L_4 \), maintaining this arrangement. For many purposes it is immaterial whether the image is inverted or upright; but in some cases an upright image lightens the work, or may be indispensable.

The simplest microscope is negative lens as eyepiece.

**Fig. 14.**—Ray transmission in compound microscope with a negative eyepiece.

**Fig. 15.**—Entocentric transmission through a microscope objective.

\( E = \) plane focused for; \( O_1s, O'_s = \) projections of \( O_0s \) on \( E \); \( Z = \) centre of projection; \( P_1P_1' = \) virtual image of real diaphragm \( PP_1' \varepsilon \) with regard to the preceding part of the objective is the entrance pupil.

The entrance pupil lies behind the focal plane, and consequently nearer objects appear larger, and farther objects smaller ("entocentric transmission," see below). If a diaphragm lying in the back focal plane of the objective forms the exit pupil for the objective, as in figs. 13 and 14, so that its image, the entrance pupil, lies at infinity, all the principal rays in the object-space are parallel to the axis, and we have on the object-side "telecentric" transmission. The size of the image on the focal plane is always equal to its actual size, and is independent of the distance of the object from the plane focused for. This representation acquires a special importance if the objective be microscopically measured, for an inaccuracy in focusing does not involve an alteration of the size of the image. To ensure the telecentric transmission, the diaphragm in the back focus of the objective may be replaced by a diaphragm in the front focal plane of the condenser, supposing that uniformly illuminated objects are being dealt with; for in this case all the principal rays in the object-space are transmitted parallel to the axis.

With uniformly illuminated objects it may happen that the penci in the object-space must be limited before passing the object, either through the size of the source of light employed or through a diaphragm connected with the illuminating system.

**Fig. 16.**—Hypocentric transmission in a microscope objective.

\( O_1s, O'_s \) and \( Z \) as in fig. 15. \( P_1P_1' = \) exit pupil of objective.

As with the microscope, the intersection of the principal rays lies in front of the object, and consequently objects in front of the plane focused for will be projected on \( E \) magnified and the objects lying behind it diminished ("hypocentric transmission"). It produces a perspective representation entirely opposed to ordinary vision. As objects lying nearer than those having the same apparent size show an increase of hypocentric transmission than those lying farther from the eye, we have a false impression of the spatial arrangement of the object.

Whether the entrance pupil be before or behind the object, in general it is only in the case of a point object that the principal rays will have in the object space only trifling inclinations towards one another or are strictly parallel. This is specially important, for otherwise pencils from points placed somewhat laterally to points arrive at the objective plane almost parallel.
proceeding from the eyepiece. This image $P'P''$ is then the exit pupil of the combined system, and consequently the image of the entrance pupil of the combined system. As the exit pupil $P'P''$ for the objective lies before the front focus of the eye-piece, generally at some distance and near the objective, the eyepiece projects a real image from it behind its image-side focus, so that if this point is on the axis it is the real image of the object; the object space the objective has telecentric transmission, the exit pupil must coincide with the back focal plane of the combined system, and it always lies behind the image-side focus of the eyepiece. The exit pupil, often called Ramsden's circle, is thus accessible to the observer, who by head- and eye-movements may survey the whole field.

We can now understand the ray transmission in the compound microscope, shown in fig. 13. Points of a small object (compared with the double aperture) may be said to be accessible. The diaphragm limiting them, i.e., the entrance pupil, is placed so that the principal rays are either parallel or slightly inclined. The pencils producing the real image are very much more acute angles; their inclination is the smaller the stronger the magnification. The eyepiece, which by means of narrow pencils represents the relatively large real image at infinity, transmits from all points of this real image parallel pencils, whereby the inclination of the principal rays becomes further increased. The point of intersection, i.e., the centre of the exit pupil, is accessible to the eye of the observer. In the case of the negative eyepiece, on the other hand, the divergence of the principal rays through the eyepiece is also further augmented, but their point of intersection is not accessible to the eye. This property shows the superiority of the collective eyepiece over the dispersive.

The increase of the inclination of the principal rays, which arises with the microscope, influences the perception of the relief of the object. In centrocentric transmission this phenomenon appears in general as in the case of the concentric lens, as perspicuity in perspective at a too short distance, the objects appearing flattened. Although in the case of the spatial comprehension of a perspective representation experience plays a large part, in observing through a microscope it does not count, or only a little, for the object is presumably quite unknown. In telecentric and hypercentric transmission we obtain a false conception of the spatial arrangement of the object, but the details of this can be made visible by focusing on the different sides, and so obtains an approximate idea of their spatial arrangement.

While the limiting of the pencil is almost always effected by the objective, the limit of the field of view is effected by the eyepiece; and indeed it is carried out by a real diaphragm DD arranged in the plane of the real image $O'Y'$ (fig. 13) projected from the objective. The image-side focus of this pencil projection is evidently the objective; the image-side focus of the image projected by the objective is, in the present case, the objective. Hence the oblique pencils, as in the case of the dispersive eyepiece, on the contrary, no sharply limited field can arise, but vignetting must occur.

**Illumination.**—The dependence of the clearness of the image on the aperture of the system, i.e. on the angular aperture of the image-producing pencil, holds for all instruments.

The clearness of image points in a median section of the pencil are directly proportional to the cosine of the semi-aperture of the pencil, if semi-aperture is defined as the angle which the rays make with the axis. The clearness of image points is then a maximum when the pencils are parallel. This is valid so long as the pen is in air; but, if on the other hand, the pen passes from air through a plane surface into an optically denser medium, e.g. water or glass, the pen becomes more acute and the aperture smaller. But since no rays are lost in this transmission (apart from the slight loss due to reflection) the brightness of the image point in the water is as large as that in air, although the apertures have become larger. Fig. 17 shows a pencil in air, A, dispersing in water, W, from the semi-aperture $\mu_1$, or a pencil in water dispersing in air from the semi-aperture $\mu_2$. If the value of the clearness in air be taken as $\sin \theta_0$, then the law of refraction $N = \frac{1}{n_1}$, the value of the clearness in water is $N \sin \theta_0$. This rule is general. The value of the clearness of an image-point in a median section is the sine of the semi-aperture of the pencil multiplied by the refractive index of the medium.

The embodiment of this principle is the immersion experiment. A view taken under water from the point O (fig. 18) sees only the whole horizon, but also a part of the bed of the sea. The whole field of view in air of 180° is compressed to one of 97.5° in water; the rays from O which have a greater inclination to the vertical than 48.75° cannot come out into the air, but are totally reflected. If pencils proceed from media of high optical density to media of low density, and have a semi-aperture greater than the critical angle, the refractive index of the immersion-lens, or the object space can be employed, hence front lenses have small radii of curvature in order to permit the wide pencils to reach the air (see fig. 19, in which $O$ is the preparation, $A$ the object-point in it, $D$ the cover slip, I the immersing fluid). The function $\sin \theta = A$, for the microscope, has been called by Abbe the numerical aperture. In dry-systems only the sine of the semi-aperture is concerned; in immersion-systems it is the product of the refractive index of the immersion-fluid and the sine of the object-side semi-aperture. In the case of the brightness of large objects obviously the whole pencil is involved, and hence the clearness of the squares of these objects is very superior to that of a pencil of a dry-system proceeding from an object point cannot exceed 90°, the numerical aperture of a dry-system cannot be greater than 1. On the other hand, system, the numerical aperture can almost amount to the refractive index for $\lambda = n u = n^2$. Dry systems of 0.98 numerical aperture, water immersion ($n = 1.53$), oil immersion ($n = 1.40$), and even a-bromnaphthalene immersions ($n = 1.65$) from $A = 1.40$, are available. In immersion-systems of such considerable aperture no medium of smaller refractive index than the immersion liquid may be placed between the surface of the front lens and the object, as otherwise total reflection would occur. This is especially important in the case of oil immersion because in this case, the embedding and immersing liquids must have equal refractive indices, one must use a-bromnaphthalene for embedding; but this substance destroys organic preparations, so that one can employ this immersion-system only for examining inorganic materials, e.g. fine diatoms.

In immersion-systems a very much greater aggregate of rays is represented by a single ray as compared with a dry system. In addition to a considerable increase in brightness the losses due to reflection are avoided; losses which arise in passing to the back surface of the cover-slip and to the front surface of the front lens.

**The Physical Theory.**

In order to fully understand the representation in the microscope, the process must be investigated according to the wave-theory, especially in considering the representation of objects or object details having nearly the size of a wave-length. The ray-line, rays, which we have considered above, have no real existence, are nothing but the paths in which the light waves are transmitted. According to Huygens's principle (see Diffraction) each aether particle, set vibrating by an incident wave, can itself act as a new centre of excitation, emitting a spherical wave; and similarly each particle on this wave itself produces wave systems. All systems which are emitted from a single source can by a suitable optical device be directed that they simultaneously influence one and the same aether particle. According to the phase of the vibrations at this point, the particle is displaced to the right or left, its speed, its action, and there arises greater clearness or obscurity. This phenomenon is called interference (q.v.). E. Abbe applied the Fraunhofer diffraction phenomena to the explanation of the representation in the microscope of uniformly illuminated objects.

If a grating is placed as object before the microscope objective, Abbe showed that in the image there is an intermittent clear and dark banding only, if at least two consecutive diffraction spectra enter into the objective and contribute towards the image. If the illuminating pencil is parallel to the axis of the microscope objective, the illumination is said to be direct. In this case the aperture of the objective must be so small that $\sin \theta = A < 0.2$, so that the maximum of the first order is admitted, the banding is distinctly seen, although the image does not yet accurately resemble the object. The resemblance is greater the more diffraction spectra enter into the objective.

The Abbe formula can immediately deduce the limit to the diffraction constant $\delta$, so that the banding by an objective of fixed numerical aperture can be perceived. The value $\sin \theta = A$ equals the numerical aperture $A$, which is the refractive index of the immersion-lens, and $n$ is the semi-aperture on the object-side. For microscopy the Fraunhofer formula is best written $\delta = A + n$. This expresses $\delta$, as the resolving power of the objective, as the sum $A + n$ of the magnification in the objective and the semi-aperture of the objective. In this case if two diffraction maxima are resolved are perceived, if two diffraction maxima can be passed through the objective, so that the character of the object is seen in the image, even if an exact resemblance has not yet been attained. 

The Fraunhofer diffraction phenomena, which take place in the
back focal plane of the objective, can be conveniently seen with the naked eye by removing the eyepiece and looking into the tube. and better by focusing a weak auxiliary microscope on the back focal plane of the objective. If one observes, by the case of a grating, the telecentric transmission on the object-side, and in the front focal plane of the illuminating system a small circular aperture is arranged, then by the help of the auxiliary strikeingly is the phenomenon of the back focal plane the round white image O (fig. 20) and to the right and left the diffraction spectra, the images of different colours partially overlapping. If a resolvable grating is considered, the diagram portrays the appearance shown in fig. 21.

It is possible to almost double the resolving power, as in the case between spectral and real marks. To determine the utility of an objective for resolving fine details, one experiments with definite structures of diatoms such as Surirella gemma and Amphipleura pulicic or artificial fine structures, then an objective of fixed numerical aperture will only represent details of a definite fineness. All smaller details are not portrayed. The Fraunhofer formula permits the determination of the most useful magnification of such an objective in order to utilize its full resolving power.

As we saw above, the apparent size of a detail of an object must be greater than the wavelength of the spectrum, then we can assume that a detail which appears under an angle of 2θ can be surely perceived. Supposing, however, there is oblique illumination, then formula (7) can always be applied to determine the magnifying power attainable with a least 0.93 objective. By substituting y, the size of the object, for d, the smallest value which a single object can have in order to be analysed, and the angle y by 2θ, we obtain the magnifying power and the magnification number:

\[ V_m = 2A \tan \theta / 2; N_m = 2A \tan \theta / A; \]

where l equals the sight range of 10 in.

Even if the details can be recognized with an apparent magnification of 2θ, the observation may still be inconvenient. This may be improved when the magnification is so increased that the angle upper limit of the object is still just resolvable.

The magnification and magnification number which are most necessary for a microscope with an objective of a given aperture can then be calculated from the following:

\[ V_m = 2A \tan \theta / 4; N_m = 2A \tan \theta / 4 \]

If 0.55 μ is assumed for daylight observation, then according to Abbe (Journ. Roy. Soc., 1882, p. 403) we have the following table for the limits of the magnification numbers, for various microscope objectives, in μ - 0.001 mm.

---
0.10 2.75 53 106
0.30 0.92 139 317
0.60 0.41 317 516
0.90 0.31 476 952
1.20 0.23 635 1279
1.40 0.17 914 1841
1.60 0.14 1257 2460

From this it can be seen that, as a rule, quite slight magnifications suffice to bring all representable details into observation. If the magnification is below the given numbers, the details can either not be seen at all, or only very indistinctly; if on the contrary, the given magnification is increased, there will still be no more details visible. The table shows at the same time the great superiority of ultra-violet light, in which the object can be resolved by the microscope, as in a Noblet's grating. The resolving power. With the best immersion-system, having a numerical aperture of 1.6, details of the size 0.17 μ can be seen, while the theoretical maximum of the resolving power is 0.167 μ, so that the theoretical maximum has already been practically attained.

Still smaller particles cannot be portrayed by using ordinary daylight.

In order to increase the resolving power, A. Kölh er (Zeit. f. Mikros., 1904, 21, pp. 129, 273) suggested employing ultra-violet light, of a wavelength 275 μ; he thus increased the resolving power to about double that which is reached with day-light, of which the mean wave-length is 550 μ. Light of such short wave-length is, however, not visible, and therefore a photographic plate must be employed. Since glass does not transmit the ultra-violet light, quartz is used, but such lenses can only be spherical-corrected, and cannot be corrected for this purpose; for this reason the objectives have been called monochroms, as they have only been corrected for light of one wave-length. Further, the different objectives, which usually play the two rays render it unnecessary to dye the preparations. Glycerin is often used as immersion fluid. M. v. Rohr's monochroms are constructed with apertures up to 1.25. The smallest resolving detail with oblique illumination is 1.7 μ. The determined magnifications usually render it unnecessary to dye the preparations. Glycerin is often used as immersion fluid. M. v. Rohr's monochroms are constructed with apertures up to 1.25.
the exit pupil of the microscope is about 0.04 in., with the magnification N, and about 0.02 in. with the magnification N'. Moreover, with such exceptionally narrow pencil shadows are formed on the retina of the observer's eye, from the irregularities in the eye itself. These disturbances are called "entoptical phenomena." From the section Regulation of the Rays (above) it is seen that the resolving power is opposed to the depth of definition, which is measured by the reciprocal of the numerical aperture, 1/A.

Dark-field Illumination.—It is sometimes desirable to make minutenet objects in a preparation specially visible. This can be done by cutting off the chief maximum and using only the diffraction spectra for producing the image.

At least two successive diffraction maxima must be admitted through the objective for there to be any image of the objects. With this device these particles appear bright against a dark background, and can be easily seen. The cutting off of the chief maximum can be effected by a suitable diaphragm in the back focal plane of the objective. But, owing to the various partial reflections which the illuminating cone of rays undergoes when traversing the surfaces of the lenses, a portion of the light comes again into the preparation, and into the eye of the observer, thus veiling the image. This defect can be avoided (after Abbe) if a small central portion of the back surface of the front lens be ground away and blackened; this portion should exactly catch the direct cone of rays, while the edges of the lens let the deflected cone of rays pass through (fig. 28).

![Diagram of a microscope objective](By permission of C. Zeiss.)

FIG. 28.

The large loss of light, which is caused in dark-field illumination by the cutting off of the direct cone of rays, must be compensated by employing exceptionally strong sources. By dark-field illumination it is even possible to make such small details of objects perceptible as are below the limits of the resolving power. It is a similar phenomenon to that which arises when in a ray of sunlight falls into a darkened room. The extremely small particles of dust (motes in a sunbeam) in the rays are made perceptible by the diffracted light, whilst by ordinary illumination they are not visible. The same observation can be made with the cone of rays of a reflector, and in the same way the fine rain-drops upon a dark background and the fixed stars in the sky become visible. It is not possible to recognize the exact form of the minute objects because their apparent size is much too small; only their presence is observable. In addition, the particles can only be recognized as separate objects if their apparent distance from one another is greater than the angular definition of sight.

Ultramicroscopy.—This method of illumination has been used by H. Siedentopf in his ultramicroscope. The image consists of a diffraction disk from whose form and size certain conclusions may be drawn as to the size and form of the object. It is impossible to get a representation as from an object. Very finely divided sub-microscopic particles in liquids or in transparent solids can be examined, and the method has proved exceptionally valuable in the investigation of colloidal solutions.

Siedentopf employed two illuminating arrangements. With the orthogonal arrangement for illuminating and observing the beam of light traverses an extremely fine slit through a well-corrected system, whose optic axis is perpendicular to the axis of the microscope; the system reduces the dimensions of the beam to about 2 μ. When the focal line of the objective is turned, by observation it is the same as if a thin section of a thickness of 2 to 4 μ had been shown. In this optical way it is possible to show thin sections of preparations in liquid or in solids, and even to obtain an illumination, which certainly gives better results, is avoided in the coaxial apparatus. Care must here be taken, by using suitable dark-field screens, that no direct rays enter the observing system. The only sources of illumination are the angular parts of the diffraction pattern. The limit at which sub-microscopic particles are made visible is dependent upon the specific intensity of the source of light. With suitable screens particles can be made visible to a distance of about 0.004 μ.

Production of the Image.—As shown in LENS FORMATION, for reproduction through a single lens with spherical surfaces, a combination of the rays is only possible for an extremely small angular aperture. The aberrations of the spherical lenses are very rapidly with the aperture. If it were not possible to recombine in one image-point the rays leaving the object and derived from one object-point, i.e. to eliminate the spherical and chromatic aberrations, the large angular aperture of the objective, which is necessary for its resolving power, would be valueless. Owing to these aberrations, the fine structure, which in consequence of the large aperture could be resolved, could not be perceived. In other words, a sufficiently good and distinct image as the resolving power permits cannot be arrived at, until the elimination, or a sufficient diminution, of the spherical and chromatic aberrations has been brought about.

The objective and different functions and also as a rule it is not possible to correct the aberrations of one system by those of the other. Such a compensation is only possible for one single defect, as we shall see later. The demands made upon the eyepiece, which has to represent a relatively large field, by narrow cones of rays, are not very considerable. It is therefore not very difficult to produce a usable eyepiece. On the other hand, the correction of the objective presents many difficulties.

We will now examine the conditions which must be fulfilled by an objective, and then how far these conditions have been realized.

Consider the aberrations which may arise from the representation by a system of wide aperture with monochromatic light, i.e. the spherical aberrations. The rays emitted from an axial object-point are not combined into one image-point by an ordinary biconvex lens of convex surfaces, but those rays which are deflected more than the outer rays. The so-called "caustic" occupies a definite position in the image-space. The spherical aberrations, however, can be overcome, or at least so diminished that they are quite harmless, by forming appropriate combinations of lenses.

The aberration of rays in which the outer rays intersect the axis at a shorter distance than the central rays is known as "under-correction." The reverse is known as "over-correction." By selecting the radii of the surfaces and the kind of glass the under- or over-correction can be regulated. Thus it is possible to correct a system by combining a convex and a concave lens, if both have aberrations of the same kind but of opposite sign, and such that the power of the crown lens must preponderate so that the resultant lens is of the same sign, but of a little less power. Correction of the spherical aberration in strong systems with very large aperture can not be brought about by means of a single combination of lenses, but several partial systems are necessary. Further, undercorrected systems must be combined with over-corrected ones. Another way of correcting this system is to alter the distances. If, by these methods, a point in the optic axis has been freed from aberration, it does not follow that a point situated only a very small distance from the optic axis can also be represented without spherical aberration. The representation, free from aberration, of a small surface-element, is only possible, as Abbe has shown, if the objective simultaneously fulfills the "sine-condition," i.e. if the ratio of the sine of the angle at the objective-side to the sine of the corresponding angle at the image-side, is a constant.

If u/sin u'/sin u = C, in which C is a constant. The sine-condition is in contrast to the tangent-condition, which must be regarded as an over-corrected representation of the whole object-space in the image-space (see LENS FORMATION). The sine-condition u tan u'/tan u = C must exist. These two conditions are only compatible when the representation is made with quite narrow pencils, and when the aperture is so small that the sines and tangents are of about the same value.

Very large apertures occur in strong microscope objectives, and hence the two conditions are not compatible. The sine-condition is then not fulfilled as far as the condition of resolution is concerned, because it must be possible to represent a surface-element through the objective by wide cones of rays. The removal of the spherical aberration and the sine-condition can be accomplished by a wide-aperture objective with a wide aperture therefore can only represent, free from aberrations, one object-element situated on a definite spot on the axis. As this is the object-element which is most important, the representation is quite useless. Hence the importance of observing the length of the tube in strong systems. If the sine-condition is not fulfilled but the spherical aberrations in the
axis have been removed, then the image shown in fig. 19 results. The cones of rays issuing from a point situated only a little to the
side, which traverse different zones of the objective, have a different magnification. The sine-condition can therefore also be understood as follows: that these two zones must have the same magnification for the plane-element.

According to Abbe, a system can only be regarded as aplanatic if it is spherical corrected for not only one axial point, but when it also fulfils the sine-condition and thus magnifies equally in all zones a surface-element situated vertically on the axis at this point.

A second method of correcting the spherical aberration depends on the notion of aplanatic points. If there are two transparent substances separated from one another by a spherical surface, free from error by monochromatic light, and these are called "aplanatic points." The first is the centre of the sphere. All rays issuing from this point pass unrefracted through the dividing surface; its image-point coincides with it. Besides this there is a second point on the axis, from which all issuing rays are so refracted at the surface of the sphere that, after the refraction, they appear to originate from one point—the image-point (see fig. 30). With this, the objective O', and consequently the image-point O" also, will be at a quite definite distance from the centre. If however the object-point does not lie in the medium with the index n, but before it, and the medium is, for example, like a front lens, still limited by a plane surface, just in front of which is the object-point, then in traversing the plane surface spherical aberrations of the under-corrected type again arise, and must be removed. By homogeneous immersion the object-point can readily be reduced to an aplanatic point. By experiment Abbe proved that old, good microscope objectives, which by mere testing had become so corrected that they produced usable images, were not only free from spherical aberrations, but also fulfilled the sine-condition, and were therefore really aplanatic systems.

The second aberration which must be removed from microscope objectives are the chromatic. To diminish these a collective lens of crown-glass is combined with a dispersing lens of flint; in such a system the red and blue rays intersect at a point (see aberration). In systems employed for visual observation (to which class the microscope belongs) the red and blue rays, which include the physiologically most active part of the spectrum, are combined; but rays other than the two selected are not united in one point. The transverse sections of these cones of rays diverge more or less from the transverse section of the chosen blue and red cones, and produce a secondary spectrum in the image, and the images still appear to have a slightly coloured edge, mostly greenish-yellow or purple; in other words, a chromatic difference of aberration arises (see fig. 31). This refers to systems with small apertures, but still more so to systems with large ones; chromatic aberrations are exceptionally increased by large apertures.

The new glasses produced at Schott's works, Jena, possessed in part optical qualities which differed considerably from those of the older kinds of glass. In the old crown and flint glass a high refraction index was always connected with a strong dispersion and the reverse. Schott succeeded, however, in producing glasses which with a comparatively low refraction have a high dispersion, and with a high refraction a low dispersion. By using these glasses and employing minerals with special optical properties, it is possible to correct objectives so that three colours can be combined, leaving only a quite slight tertiary spectrum, and so to abate for two colours. Abbe called such systems "apochromats." Good apochromats often have as many as twelve lenses, whilst systems of simpler construction are only achromatic, and are therefore called "chromatic.

By an apochromat it is not possible to entirely remove the chromatic difference of magnification, i.e. the images produced by the red rays are somewhat smaller than the images produced by the green rays. A white object is represented with blue streaks and a black one with red streaks. This aberration can, however, be successfully controlled by a suitable eyepiece (see below).

A further aberration, which can only be overcome with difficulty, and which then only partially, is the "curvature of the field," i.e. the points situated in the middle and at the edge of the plane object can not be seen clearly at the same focusing.

**Historical Development.** The first real improvement in the microscope objective dates from 1830 when V. and C. Chevalier, at first after the designs of Selligse, produced objectives, consisting of several achromatic systems arranged one above the other. The systems could be used separately or in any combination. A second method for diminishing the spherical aberration was to alter the distances of the single systems, a method still used. Selligse had no particular comprehension of the problem, for his achromatic single systems were simply telescope objectives corrected for an infinitely distant point, and were placed so that the same surface was turned towards the object in the microscope objective as in the telescope objective; although contrary to the telescope, the distance of the object in the microscopical objective is of the same order as the diameter of the objective. It would have been more correct to have employed these objectives in a reverse position.

These circumstances were considered by Chevalier and Lister. Lister showed that a combination of lenses can be achromatic for only two points on the axis, and therefore that the single systems must be so arranged that the aplanatic (virtual) image-point of the first (fig. 32) of the five objectives coincided with the object-point of the next system. This system will always be aplanatic. These objectives are put together in a larger aperture than a single achromatic system. Although such systems have been made recently for special purposes, this construction was abandoned, and a more complex one adopted, which also made the production of better objectives possible in this is the production of the compensation of the aberrations produced in the different parts of the objective. The system thus is divided into two. The first proceeded on quite different lines, hinted at the possibility of such a compensation. This method makes it specially possible to reduce the chromatic aberrations of higher orders and to fulfill the sine-condition, and the chief merit of this improvement belongs to Amici. He had recognized that the good operation of a microscope objective depended essentially upon the size of the aperture, and he therefore endeavoured to produce systems with wide aperture and good correction. He used chiefly a highly curved plano-convex front lens, which has since always been employed in strong systems. Even if the object-point on the axis cannot be reproduced quite free from aberration through such a lens, because aberrations of the type of an under-correction have been produced by the first plane outer limiting surface, yet these defects with the strong lens are not liable to be well compensated by other systems. Amici chiefly employed cemented pairs of lenses consisting of a plano-convex flint lens and a biconvex crown lens (fig. 33) and constructed objectives with an aperture of 1.7. He also showed the influence of the over-slip on pencils of such wide aperture. The lower surface of the slip causes under-correction on being traversed by the pencil, with over-correction when it leaves it; and since the aberration of the surface lying farthest from the object, i.e. those caused by the upper surface preponderate, an over-corrected cone of rays enters the objective. The over-correction increases when the glass is thickened.

In order to counteract the complications, the whole objective must be correspondingly under-corrected. Objectives with definite under-correction can however only produce really good images with glass apertures of 0.90-0.95. Differences of even 0.004-0.008 in. in the glass covers can be noticed by the deterioration of the image. In systems with smaller apertures variations of the thickness of the glass cover are not so
noticeable. For this reason Amici constructed objectives of a similar aperture and focus for different thicknesses of glass covers.

This expensive method was simplified in 1837 by Andrew Ross by making the upper and lower portion of the objective variable by means of a so-called correction-collar, and so giving the objective a corresponding under-correction according to the thickness of the glass cover. The alteration of the focus and the aperture are little influenced.

The correction-collar was improved by Wenham and Zeiss, by working the upper system upon the lower, and not the reverse; for in this way the preparation remains almost exactly focused during the operation (see fig. 34). The injurious influence of the glass cover is substantially lessened if no air is admitted to the space between the glass cover and the

front lens (as in the dry-system) but if the intervening space is filled with an immersion-liquid, Amici was likewise the first to produce practical and good immersion-systems. The slight difference of the refractive indexes of the glass cover and the immersion-liquid involves a diminution of the aberrations, by which the objective will become less sensitive to the differences in thickness of the glass covers and admits of a more perfect adjustment. Water-immersion was introduced by Amici in 1840, and was improved by E. Hartnack in 1855.

The advantages of the immersion over the dry-systems are greatest when the embedding-liquid, the glass cover, the immersion-liquid and the front lens have the same refractive index. Such systems with a so-called homogeneous immersion were first constructed after the plan of E. Abbe in 1858 in the Zeiss workshops at the instigation of J. W. Stephenson. Cedarwood oil (Canada balsam), which has a refractive index of 1.515, is the immersion-liquid. The structure of a modern system of this type, with a numerical aperture of 1.50, is shown in fig. 35.

The most perfect microscope objective was invented by E. Abbe in 1886 in the so-called apochromatic objective. In this, the secondary spectrum is so much lessened that for all practical purposes it is used directly. In the apochromats the chromatic difference of the spherical aberrations is eliminated, for the spherical aberration is completely avoided for three colours. Since in these systems the sine-condition can be fulfilled for several colours, the quality of the images of points beyond the axis is better. There still remains a slight chromatic difference in magnification, for although the magnification consequent upon the fulfilment of the sine-condition is the same for all zones for one colour, it is impossible to avoid a change of the magnification with the colour. Abbe overcame this defect by using the so-called compensation ocular, made with Jena glasses. Fig. 36 shows an apochromat of a numerical aperture of 1.40.

**THE EYEPIECE OR OCULAR**

The eye-piece is considerably simpler in its construction than the objective.

Its purpose in a microscope is by means of narrow cones of rays to represent at infinity the real magnified image which the objective produces. As, however, the object represents a real image, the problem is to project a transparent diapositive. It is therefore impossible to observe this image through an ordinary lens. Since many of the rays coming from the exit-pupil of the objective would not reach the eye of the observer at all, it is necessary, in order to make use of all of them, to direct the diverging rays forming the real image so that the whole of the light enters the eye of the observer. This is effected by a collective lens; it may be compared with the second part of the condenser system of a projection lantern. The two most customary eye-pieces consist in two simple plano-convex lenses, whose distance one from the other is equal to half the sum of the two focal lengths. One of these is the Ramsden eye-piece (fig. 37). If the real image produced by the objective coincides with the collective lens, only the inclination of the principal rays is altered, the form of the cone being affected only to a very small extent. The lens nearer the eye, which has about the same focal length as the collective lens, is distant from it by about its focal length. The eye-lens converts diverging pencils into parallels. Both lenses together form the exit-pupil of the objective behind the eye-lens, so that this image, the exit-pupil of the total system or the Ramsden circle, is accessible to the eye of the observer. It is possible to see the whole field through this pupil by slightly moving the head and eye. In practice the real image is formed not directly on the collective lens but a little in front of it, because otherwise all the particles of dust on the collective would also be seen magnified.

In the other type, the Huygenian eye-piece (fig. 38), which is much more widely used, the objective lens is in front of the real image; it alters the direction of the principal rays and somewhat diminishes the real image. In this type the eye-lens is about twice as powerful as the collective lens, and makes the rays parallel. Here also the exit-pupil is accessible to the eye and through it the whole field can be seen by moving the head and eye. In both eye-pieces microscopes or cross-wires are used for measuring in the plane of the real image. The Ramsden eye-piece is the most convenient for this because this plane lies in front of the collective lens, and the objective image has not yet been influenced by the eye-piece. As both eye-pieces are used with very small apertures (about f/20) no attempt has been made to overcome the spherical aberrations, which are usually very slight; neither, as a rule, are the eye-pieces chromatically corrected, care has only to be taken by a suitable choice of the distance of one lens from the other, that the coloured images derived from a colourless object should have the same apparent size. Since, however, the difference of chromatic magnification cannot be overcome in powerful objectives, this error is still further increased by the eye-piece. The difference of chromatic magnification cannot even be overcome in apochromats, and to cancel this aberration Abbe devised the compensating ocular (fig. 39).

**Fig. 37.** Ramsden Eye-piece.

**Fig. 38.** Huygenian Eye-piece.

---

These eye-pieces are very convenient in use, for when they are changed the lower focus always falls in about the same plane. In German and French microscopes the optical length of the tube, when apochromats and compensation-eye-pieces are used, is 180 mm. By multiplying the magnification of the objective by the number...
on the eyepiece the total magnification of the microscope is obtained. By the magnification of the objective is meant the ratio of the distance of distinct vision to the focal length of the objective. As powerful achromatic objectives show differences of chromatic magnification in the same way as apochromats, compensation eyepieces can be used in combination with these objectives.

**ILLUMINATING SYSTEMS**

Most microscopic observations are made with transmitted light; an illuminating arrangement is therefore necessary and as the plane of the object is nearly always horizontal or only slightly inclined, the illuminating rays must be directed along the optical axis of the microscope.

To fully utilize the aperture of the system all dispersing rays in the object-space of the objective must be retained in the image-space of the illuminating system. When this occurs the greatest brightness will be obtained. That the rays must fill up the objective, it must not be too small, and should be as near as possible to the stage plate, and the source of light must be considerably extended (fig. 40). Diffused daylight is very suitable. If the aperture of the objective is increased, the diameter of the illuminating surface must also be increased so that the system is quite filled up, from which it follows that this method of illuminating soon fails. The possibilities of illuminating with a concave mirror appear to be less favourable. As a rule a concave mirror of similar aperture is fixed on the side of the plane mirror. With the concave mirror an image of the source of light can be obtained on the object. The distance of the concave mirror from the stage plate is of equal importance. This is also the most suitable distance when diffused daylight is used, but it is too short with artificial light; the distance between the stage plate and the mirror should then be increased, so that an image of the source of light can be thrown upon the object. It is simpler to place an illuminating lens at the source of the light; but the source falls approximately at the front focus of this lens and consequently is represented at infinity through the illuminating lens. By a correct choice of the focal length of the illuminating lens in relation to the focal length of the mirror, it is possible to choose the size of the image of the source of light so that the whole object-field is uniformly lighted.

Too much light is useless for observing delicately coloured or colourless preparations, whose parts only become visible as a result of slight differences of diffraction. Then it is necessary to use the concentrated cones of light. The apparatus must be such that the apertures of the illuminating rays can be easily altered, e.g. by inserting diaphragms in the course of the rays of the illuminating cone below the stage plate (fig. 40, PP). This concentration is most easily produced by sliding or revolving diaphragms. A series of holes of different sizes perforate a revolving disk below the stage plate at an equal radial distance from the axis of the disk, so that the rays can be brought under the preparation in turn, the centre of the diaphragms always being a continuation of the optical axis of the microscope.

The so-called cylinder diaphragms (fig. 41) are used especially in German microscopes. A changeable diaphragm is placed at the upper end of a short tube which can be moved in a case below the stage in the direction of the optical axis. By bringing the diaphragm nearer the object the aperture of the objective is increased; if the diaphragm is removed the cone of rays is diminished (cf. fig. 40). These diaphragms are sometimes fitted in a slide, so that it is possible to move the diaphragm sideways as well as the object (see below).

With very powerful objectives these methods are insufficient; and a condenser is fitted below the stage plate. As a rule an iris diaphragm, which can be moved sideways, is now fitted below this condenser; below is the mirror which can be moved in all directions. The Abbe apparatus consists of a condenser, movable iris diaphragm, and mirror (fig. 42). The whole apparatus can be focused by a rack and the button s. The iris diaphragm can be regulated by the lever p; it can also be turned to one side round the pivot s, so that the condenser k can be removed or changed. The correct direction can be given to the illuminating cone by the mirror m. It is often desirable to pass from direct to oblique lighting. The Abbe apparatus makes this easy. The iris diaphragm i is pushed to the side by the rack and pinion r n. The chief cone of rays then enters obliquely into the objective, the angle between the direct cone of rays and the diffraction spectrum of the first order can then become as large as possible, and the diffraction angle is always in the objective. Oblique lighting, however, can only be in an azimuth, so that the object must be turned in order that the details may be observed. Hence a condenser, for lighting with very oblique cones, must have about the same aperture as the objective, and therefore be of very wide aperture; they therefore closely resemble microscope objectives in construction. Especially powerful achromatic condensers are really only magnified microscope objectives, with the difference that they are not corrected for the thickness of the cover slip, but for the thickness of the glass on which the object is placed. For exceptionally accurate work microscope objectives are sometimes used as condenser systems. When using immersion objectives, an immersion condenser must also be used if rays of extreme obliquity are wanted, for, in immersion with total reflections, rays can only come from the upper plane surface of the condenser, which have a larger inclination to the axis than about 41°, varying according to the refractive index of the glass. In order to get inclined rays pass out from the condenser, some immersion liquid must be placed between the upper surface of the condenser and the object slide. Condensers are for this reason also constructed with apertures up to 1 40.

**Vertical Illuminators.**—Opaque objects can only be seen by reflected light. With low magnifying systems and a large free object distance, ordinary good daylight is sufficient. If the objects have a low reflecting power, or if a slightly higher magnification is needed, the lighting can be improved by optical system.

To examine small opaque objects with a high magnification the Lieberkühn mirror, so named after its inventor, was formerly much used. This was a concave mirror, pierced in the middle, fixed to the object, and directed towards the object and with such a
focal length that rays parallel to the axis falling upon it were united exactly upon the object. In this case the object lay upon a stage plate, whose centre had so far been made opaque, so that the rays coming from the illuminating plane mirror could not reach the objective, but only the rays passing the stage plate to the side of this blackened portion reached the Lieberkühn mirror, and were used in lighting. The disadvantage of this method was that only small objects could be examined. Much more easily manipulated is the paraboloid side-illuminator invented by R. Beck, which can be conveniently fitted in and used for objectives with different focal lengths. A paraboloid surface exists half in a short focal length, which concentrates all the light coming from the one side on to the object. To examine objects with objectives of high power and low free object distance, the apparatus for side-illumination is not sufficient. A side-illuminator is used. In Zeiss's form (fig. 43) a small prism \( p \), which also revolves upon a horizontal axis, is placed as near as possible to the back wall of the object, in the way that the separating line of the horizontal and hypothesis surfaces of the prism, lies approximately over the middle of the system, so that the rays entering through the opening in the side after having been reflected by the hypothesis surface are concentrated through one half of the object on to the object. When observing only the other half of the objective is used. The sources of light used should be arranged so that the objective throws an image of the light-source upon the object. It is best if the image of the light is not larger than the object examined, and to effect this, an illuminating lens with an iris diaphragm is placed between the source of light and the illuminator. By suitable adjustment and changing the iris diaphragm the size of the opening can be controlled. The objects observed with the vertical illuminator must not have a glass cover if the dry system is employed, because the upper surface of the glass cover would send so much light back into the objective by reflection, that the image would be indistinct. It is more convenient to examine covered objects with the vertical illuminator, if the immersion system is employed. Owing to the slight difference of illumination between the immersion liquid and the cover, the portion of light reflected on the cover is not noticeable.

**Dark Field Illumination.**—As was seen when discussing the physical theory, the minute details of the object cause diffractions, and can only be examined if the objective can take up at least two consecutive diffraction spectra. These diffractions become especially distinct if the direct lighting cone of rays, the spectrum of zero order or the chief maximum, is not allowed to enter the objective and instead only two or more diffraction maxima are taken into the details then appear bright on a dark background. In dark field illumination care has to be taken that no direct rays reach the objective, and hence a good dark field illumination can be produced if the condenser system has a larger aperture than the objective. If an Abbe lighting apparatus is used a dark field diaphragm (fig. 44) can be placed in the iris diaphragm case. The central diaphragm darkens the light which the stage otherwise falls directly into the objective, and the open zones send so many oblique rays through the object that they cannot all get taken up by the objectives. Exactly the same effect is reached when, as is shown in fig. 45, a more powerful system \( D \) is used for a condenser, which has a blackened section on the back of the front lens of such a size that no light can enter the objective \( A \). In this way it is only possible for diffracted rays to enter the objective.

Apparatus for a good dark field illumination has received much attention, because in this way ultra-microscopic particles can be made visible. This depends on the good combination of the entering cones of rays, which should be as oblique as possible; this is most easily done by mirror condensers. A number of early investigations have been revived for this purpose.

Wenham's paraboloid illuminator (fig. 46) is made entirely of glass, and is in the form of a paraboloid, having on the top a spherical hole, of such a curvature that all entering rays, \( r', r'' \), parallel to the axis, after their reflection in the sphere, pass through the spherical surface perpendicularly and unite in \( F \), the centre of the sphere. A diaphragm \( s \) is placed in the middle of the spherical surface, and this keeps back the central rays. This diaphragm is sometimes used instead of a diaphragm piercing the condenser, and which can be moved up and down, so that the aperture of the oblique entering cones of rays can be altered. Another form of the paraboloid condenser also due to Wenham, has a plane surface on the upper side. Some immersion fluid must then be placed between the stage plate and the condenser in order to allow all the rays to pass out; otherwise only those rays would be able to pass out which are close to the axis of the condenser in the inside of the condenser, and are smaller than the limiting angle of the total reflection.

**Fig. 45.—Path of Rays for dark-ground illumination with fixed diaphragm in the objective.**

(Convective \( D \) can also be used as a condenser (Zeiss).)

Th. Ross's "spot lens," invented in 1855, and J. W. Stephenson's catoptric illuminator (1879), may also be mentioned. A certain condenser of very high illuminating power is due to H. Siedentopf (fig. 47). It is a double mirror system, whose reflecting surfaces are a sphere and a paraboloid. The combination of rays is also sufficient in practice if the cardioid surface is replaced by a spherical one.

**FIG. 46.—Wenham's Paraboloid Condenser.**

A supplementary spherical surface \( e \) is necessary for the completion of the condenser.

**FIG. 47.—Siedentopf's Cardioid Condenser.**

The stereoscopic microscope is the most suitable for finding out the space taken up by the separate parts of a preparation. (See also Binocular Instruments and Stereoscopic.) The observer has a stereoscopic impression of an object, when different perspective representations are presented to both eyes, which, through the action of the central nerve system, resolve into one impression.

One way of receiving a stereoscopic impression through a microscope is by fixing an apparatus as directly as possible above the last lens of the microscopic objective, which divides the rays passing out and directs half into each eye-piece. The half cones of rays have now semicircular sections, the diaphragms having the same form. The cones must be so directed through the divided system that the two exit pupils correspond to the interpupillary distance of the observer. The distance of the centres of the semicircular entrance pupils and their distance from the objective, regulate the distance of the two perspective representations, which are presented one to the right eye and one to the left. If the perspective centres lie too near one another in the object-space, as may happen with slightly opened and weak systems, the difference of the perspective is then too slight to make any real stereoscopic impression. On the other hand, a very much exaggerated stereoscopic effect can be derived from short focused...
systems of wide aperture. On account of the slight depth definition, short focused systems of wide aperture are not at all specially suitable for stereoscopic observation, because the possibility of observing objects taking up a good deal of space is too limited when such systems are used.

Professor J. L. Riddell (Quart. Journ. Micro., 1853, p. 236; 1854, pp. 18–24) published an arrangement of prisms, which, however, imparted a pseudomorphous impression if image-forming oculars were not used, and in 1854 a second system (fig. 48), essentially a Wheatstone pseudoscope, appeared, just above the objective. This gave an orthoscopic image even in ordinary eyepieces. By adopting right-angled reflection-prisms and adjusting the eyepiece he erected the image. Stephenson’s stereoscopic microscope (fig. 58, Plate) resembles this apparatus in all essentials. A construction of prism eyepieces is now almost forgotten, while on the contrary an extremely simple dividing prism published by Wenhon (Land. Micro. Soc., 1881, i. 190) has been exceptionally well attested in practice. It is more easily used than any other apparatus (see Binocular Instruments, fig. 8). A reflection-prism (fig. 49) in a setting placed above the last surface of the objective and divides the exit rays. The group of rays coming from the right half of the objective can continue its way without hindrance to the right eye. The group of rays coming from the left half of the objective can continue its way without hindrance to the left eye. The group of rays coming from the right half of the objective is reflected twice in the prism eyepiece, while the left objective ray containing the left eye-piece is a little inclined towards the right tube, which is perpendicularly. It can be adapted to the interpupillary distance by changing the tube slide. If it is desired to use the instrument as a monococular, the setting with the prism at the lower end of the tube is taken away.

A second manner of making stereoscopic observations employs stereoscopic eyepieces. The first of such eyepieces was proposed by R. B. Tolles. He realized that the division of the cones of rays by prisms could only be satisfactorily performed if the prism was placed in the position of the exit pupil of the objective or in the position of the real image of the exit pupil. He employed a Nador conical and placed the prism at the object where a system of reversing mirrors formed a real image of the exit pupil of the objective. A new stereoscopic eyepiece was devised by A. Przemozowski who substituted a Wenhon diffracting division prism at the position of the real image of the exit pupil of the objective formed by the reversing system. The newest form of a stereoscopic microscope resembles the oldest in so far as two completely separate microscopes are used. In the oldest microscope by Cherubin d’Orleans the observer receives a pseudoscopic impression in consequence of the image defect which has been avoided in the instruments constructed in the Zeiss Factory (fig. 50, Plate) by the instigation of the American zoologist H. S. Greenough. The system of Forrò prisms employed affords a convenient method of adapting the ends of the eyepieces to the interpupillary distance.

The two tubes are inclined to one another at an angle of about 14°. The microscope is only intended for slight magnifications. The possibility has already been suggested of using both eyes for observing without having a stereoscopic impression as afforded by a binocular microscope. Binocular microscopes have therefore been constructed on this plan. Such a combination of prisms was used by Wenhon, who placed it directly behind the left objective lens. As a rule this arrangement of prisms can be exchanged for the Wenhon stereoscopic reflection-prisms.

A second kind of dividing prism which directs the entire course of rays to both eyes, and thus produces identical images, was proposed by Powell and Lealand (fig. 50). Every ray is divided into a reflected and a refracted portion on the front side of a plane mirror. Whilst one column of the refracted portion after leaving the plate continues its way in the same direction, displaced a little to one side, the reflected portion is directed into the side tube by a reflection-prism. With these microscopes, which are not stereoscopic, objectives of any power can be used. The surfaces of the dividing prisms must be very exact, and no distortion of the image may arise from them. A microscope with three columns of rays can be obtained by employing the Abbe stereoscopic eyepiece.

By the supplementary use of one of Wenhon’s prisms the ray is an image divided into two parts, a refracted and a weaker reflected one. The same image can be presented to each eye by using this eyepiece stereoscopic impression is then felt. It is brought about by placing two semi-transparent diaphragms in the plane of the exit pupil of the microscope by.

Although the optical system is the first consideration in a microscope, the system is valueless if the fittings do not allow its correct use. The optical system must be kept at a certain distance and well centred, and a correct position for the object in relation to the system must be assured.

In fig. 60, Plate, the microscope is seen to consist of the heavy metal foot A, which rests on the table at three points. The whole microscope is fitted to this foot. The object can be held firmly on the stage plate B by three screws. The stage plate are the condenser and the diaphragms, and the illuminating mirror J is held by a rod D fixed to the stage plate. Likewise on the stage plate is the eyepiece. The rough adjustment of the microscope can be made by a rack and pinion F, and the fine adjustment by the screw G. The tube containing the eyepiece and the objective is double. The inner tube H is movable, making a change in the length of the tube possible. As a rule this inner tube has a mark which allows the length of the tube to be set.

It is most important the stand should be free of vibration. A fine adjustment is also necessary, in order to perform conveniently and with certainty the slightest motion of the microscope in relation to the object. In cheap stands the rough adjustment was worked by moving the inner tube by hand, but the more convenient rack and pinion now used almost exclusively.

For slight magnifications rough adjustment is sufficient, but with objectives of a focus below ¼ in., a fine adjustment is wanted. Very different constructions are in use. Almost all are such that the whole microscope is thrown on a given spot by the mechanism of the fine adjustment, and not only the objective. The most used is the micrometer screw adjustment (fig. 51). The tube carrier B turns the diaphragms 180° round the optical axis, the orthoscopic impression can be changed into the pseudoscopic. The mechanical arrangement of the eyepiece is such that the distance of the two exit pupils can be adjusted to the interpupillary distance.

MECHANICAL ARRANGEMENTS

Fig. 59.—GREENOUGH'S BINOCULAR MICROSCOPE (ZEISS).

Fig. 61.—PETROGRAPHICAL MICROSCOPE (ZEISS).
an essential in all rough and fine adjustments is that the motion must always be parallel to the optical axis of the microscope, so that the same portion of the object remains in the centre of the field.

Another condition which must be fulfilled by a good stand is the elimination of all vibration, especially when it will take a long time, it is of great assistance if the microscope can be inclined, so that the upper portions can be kept in a natural position. The apparatus for inclining the microscope is such that the microscope can be placed in all positions between the vertical and the horizontal. The horizontal position is sometimes necessary if photographs are to be taken by the microscope.

Many devices are available for controlling the objective. It is essential that the objective is always brought before the lower stage is brought to a position in such a way that the microscope and the revolving stage are in line, and the revolving stage has a central position C to keep this condition fulfilled. In many stands the objective can be centred instead of the plate. For measuring this angle, an eye piece with cross hairs is used. In the lower focal plane of the eyepiece, at the spot where the real image which the objective forms of the object arises, a glass plate is introduced on which are two fine cross lines or even two very thin threads. The eye piece can be adjusted for the thread-plate, so that different observers can see the cross clearly. The cross is always adjusted first. When observing with such an eyepiece, care must be taken that the real image of the object lies in the plane of the cross threads, i.e., that there is no parallax. The adjustment is easily controlled. If the eye is moved to and fro over the eyepiece and the image makes apparently similar movements in relation to the cross threads, then the image does not lie in the plane of the cross threads.

To measure the angle, the images of the crystal edges are covered in turn by one of the threads by turning the table, and the angle of rotation is read from the scale. A cross-table is very convenient for this calculation, for with the aid of the two movable slidi ng threads in the plane of the plate and at right angles to one another, the point where the two crystal edges intersect can be quickly and correctly brought into the revolving axis of the plate. This measurement can also be made with a goniometer eyepiece, in which a row of parallel double - marks are used instead of the cross threads. The fitting of the eyepiece at the upper end of the tube is provided with a graduated circle. The eyepiece proper with the graduated circle is adjustable, and the rotation be read from the graduated circle. In carrying out this calculation the marks of the thread-plate have only to be placed exactly parallel to the crystal edge.

For examining preparations in polarized light a polarizer D is introduced in the illuminating apparatus below the diaphragm and an analyser E above the eyepiece. The analyser can be rotated, and the angle being read by a divided circle. The device is set in such a way that it always points to the objective; it is then generally in a case G, which can be put into the tube. The placing of the analyser near the objective has the advantage that the field of view is not restricted, as is the case if the analyser is used above the eyepiece. Nicol's, Glan-Thomson prisms or similar polarization apparatus are used as polarizers and analyser. Below the analyser C a plate H of selected Nicol's may be put in the course of the rays. This small plate can also be laid above the polarizer in the illuminating apparatus or in the eyepiece.

To examine crystals, especially in converging light a condenser, movable in the optic axis, is needed at the lower side. The image produced by the microscope objective M in its back focus plane is then observed through a supplementary microscope. The objective of the supplementary microscope, the Bertrand lens, can be applied through a window I at the lower end of the inner tube K. By using a rack and pinion movement L the supplementary microscope can be adjusted for the images. There is nearly always an arrangement for the condenser first in converging light and then in parallel polarized light. This change can often be brought about by taking away or adding parts of the condenser.

**MICROMETRY**

It is often required in microscopic work to determine the size of objects or parts of objects.

There are three essential ways of performing this. The first method uses the objective screw micrometer. The object is placed on a slide in the plane of the stage plate and able to be finely moved by the micrometer screw, which has an fine worm as possible. A divided cylinder is fixed to the turning knob, which thus makes it possible to measure fractions of the revolution. The revolutions of the cylinder are registered by a calculator. The use of an eyepiece with a cross thread is essential to this measurement. After the microscope has been so adjusted that the image of the object to be measured falls exactly in the plane of the cross threads, the object is moved by the micrometer until one edge of the object is exactly covered by a thread. The micrometer is now read. Then the object is moved by the micrometer till the image of the other edge is covered by the thread in the eyepiece, and the micro meter is again read. The difference between the two positions gives the size of the object. The objective screw micrometer is, however, not sufficiently delicate, and is only used when comparatively large objects are to be measured, and especially for objects whose edges do not appear at the same time in the field of view.

The second and most widely used method employs a micrometer eyepiece. In this case not the object itself but a real image which has already been magnified by the objective is measured, and obviously much more accurate results are possible. The most accurate calculations are obtained by using the screw micrometer ocular (fig. 54). Directly below the collective lens of a Ramadan eyepiece a slide can be moved by a micrometer screw a; the slide carries a little glass plate c provided with a graduation. With the help of this scale the total revolutions of the screw can be read; fractions of the revolution can be read from the divided cylinder d of the scale is generally divided into hundredths of millimetres or thousandths of inches. A fixed mark which serves as an index is placed on the lower side of the collective lens and is seen clearly at the same time as the graduation of the movable slide. The to observe the object at zero if the zero mark of the cylinder coincides with the index and the fixed mark is at a known division. The calculation is most convenient if the micro meter is left in the position of zero and the object is moved till one of its edges corresponds to the zero mark of the eyepiece scale. If the micrometer is then moved till another graduation corresponds to the other edge of the image the size of the image can be read off. As this method measures...
the image correctly to a few thousandths of millimetres, the object itself is measured accurately to some hundred-thousandths of millimetres, if it has been graduated in that way; and the object is measured even more accurately if the measurements be repeated many times by the same operator. To keep up this degree of exactitude the magnification of the objective must be carefully ascertained, e.g., by using an objective micrometer. A fine scale with known intervals is drawn on the stage plate, and by determining the distance between the graduations of the objective micrometer formed through the same objective, by means of the screw micrometer ocular, the magnification of the objective is determined. As the errors in the determination of the length of the micrometer are also magnified, very exact scales are necessary. When determining the magnification the microscope must be used under exactly the same conditions: neither the length of the tube nor the focal length of the objective can be altered.

A fixed eyepiece micrometer is simpler and more popular. This consists of a scale on a little glass plate, which, instead of a cross wire, is placed in the eyepiece. The adjustment of the micrometer must be such that the image produced by the objective falls exactly in the plane of the scale. The size of the image is determined by calculating the entire interval taken up by it. By using an objective micrometer in place of the object, the magnification of the objective can be ascertained and from this the actual size of the object. As fractions of intervals can only be estimated in this manner, a measurement with such an eyepiece scale can of course only be as exact as with a screw micrometer ocular. However, such a determination of size is often quite accurate enough.

A third method employs a drawing prism. The object and the drawing plane are seen at the same time, and the lines can be readily drawn. If, as before, an objective micrometer is placed below the microscope in the place of the object, and the size of a special micrometer-interval is drawn on the same plane of the board, the addition of the length of the object to be ascertained, and of the length of the visible piece of the scale to its distance from the eyepiece, the size of the object, and the objective micrometer, they can of course be projected at the same moment on a scale on the drawing board.

The errors attending the determination of the size of a microscopic object depend chiefly on the accuracy of the objective micrometer; any errors in the micrometer being magnified by the objective. These may be diminished by using different parts of the objective micrometer for the correction of the eyepiece. The calculation of the size is based on the found mean value. A second error can arise through the inaccuracy of the eyepiece micrometer, and also in the case of drawing through the eye of the screw, and through dead motion. The eyepiece micrometer allows its errors to be diminished, if one measures at different points and then fixes a mean value. The dead motion of a micrometer screw is best avoided by working the screw always from one and the same side. The thickness of the cross wire may also occasion a fault. For this reason there is sometimes employed two very narrow threads lying beside one another, and which limit the image as nearly as possible.

The Testing of the Microscope

The excellence of a microscope objective depends on its definition and its resolving power.

The definition is better according as the chromatic and spherical aberrations are removed there although the remains in every microscope constructions some slight aberration. In consequence of these residual aberrations, every object-point is not reproduced in an ideal image, and is surrounded by a small circle or ring of different brightness, which is the circle of confusion.

The lower figure shows the plan of the transmission of the iris diaphragm. The entrance pupil is in this way reduced to two small separate fields, which nevertheless contain rays of all zones. It is necessary that the outside edge of the diaphragm coincides with the edge of the entrance pupil. This can be attained by drawing the iris diaphragm so far as to form the entrance pupil. The double diaphragm is then in such a position that the edge of the outer diaphragm coincides with the edge of the iris diaphragm.

The object employed must have distinct boundaries. Abbe’s tube determines the objective carrier on which six cover glasses of exactly determined thickness (between 0.09 mm. and 0.24 mm.) are cemented. The cover glasses are silvered on their under surfaces, and in the silvering fine lines are drawn; these lines form the test objective. This plate admits at the same time of a correct determination of the thickness of the cover glass, for which the best correction exists. So long as the object is not sharply focused two separate dispersion figures will be seen. The defects of the objective are revealed, e.g., two adjacent sharp images are formed, which become indistinguishable when an object having two adjacent figures, i.e., a sharp image is produced. To the curvature of the image, all parts of the object are not seen distinctly at one and the same time.

The resolving power of an objective depends on its numerical aperture. The numerical aperture can be determined in two ways. A diaphragm with a very narrow hole is placed on the stage, and the microscope sharply focused on the edges of the hole. The illuminating mirror is turned aside and a graduated scale is laid on the foot of the microscope. Strong systems produce in the proximity of their back focal plane an image of the scale, which can be inspected with a weak auxiliary microscope, and the length of the visible piece of the scale seen at different points divided by the length of the visible piece of the scale to its distance from the diaphragm on the stage gives the tangent of half the angular aperture.

The size of the objective may be determined by the apertometer. With weak systems no auxiliary microscope is necessary, because the eyepiece being removed and the scale viewed directly in the tube.

Abbe constructed a simple instrument for the determination of the aperture, termed the apertometer (fig. 55). A semi-circular glass plate bears two scales, over which two black thin metal plates bent back at right angles may be moved. A little hole in the silvered plate marks the centre of this circle. Through this hole the points of the metal plates can be observed by total reflection on the surface of the mirror (Zeiss). The apertometer is laid on the stage, so that the hole lies in the axis of the microscope, and the hole is sharply focused. The eyepiece being removed the image of the metal plates b is projected on the eyepiece, the angle of which is known to be equal to the central position, there is fixed on the upper part of the eyepiece a disk of pasteboard or metal with an axial hole, The metal plates b are then moved till the points just cut off the edge of the disk are seen. The angle can then be read off. With strong systems the vanishing of the points is observed with an auxiliary microscope, formed by means of the inner tube. In immersion systems the immersion liquid is placed between the front lens and apertometer.

If the numerical aperture be known the resolving power is easily found. The resolving power can also be determined by using different fine test objects. Norbert’s test plates, which bear graduated groups of extremely fine and narrow divisions are very useful, while the tests of Amphilinella pellucida and Sturiella gemma are often employed.

The magnification of a microscope is determined from the focal lengths of the two optical systems and the optical tube length, for $N = \frac{250}{\Delta f_s \mu}$, $\Delta f_s$ to determine the optical tube length $\Delta$, it is necessary to know the position of the focal planes of the objective and of the ocular. If one focuses the object in the inner tube, on the image situated in the back focal plane of the objective of a distant object, and then on the dust particles lying on the surface of the objective, the displacement of the auxiliary objective gives the distance of the back focal plane of the objective from the end of the outer tube. To determine the position of the anterior focal plane of the eyepiece, the eyepiece is placed on the eye-lens downwards. An auxiliary microscope is now focused first on the image of a distant object and then on the plane of the edge of the setting. This plane can be seen under a cover glass on the edge of the paper. This gives the distance of the anterior focal plane of the eyepiece from the edge of the setting of the eyepiece and consequently also of the edge of the eyepiece carried by the upper end of the tube. These measurements determine the optical tube length $\Delta$. 
MICROTOMY

There are many methods for determining the focal length of the objective. The objective to be examined is placed on the stage, and in the manner just shown, the distance of the focal plane from the eye-piece is determined. Any plane object a few yards distant can be used. If the object can be seen by using the mirror, the plane mirror must be used; then the actual size of the object and of the image produced by the objective can be measured with a micrometer scale. The distance of the object from the nearer focus of the objective is next determined. This distance is composed of the distance of the object to the plane of the focal length that is determined, and of the distance of the focus of the objective on the stage plate from the image plane mirror. Let the size of the object be $y$, the size of the image $y'$, the distance of the object from the focus $x$, then $y'/y = x/f$. If the image (seen by light) is $x'$, then $y'/x' = y/f$. It is used to determine the focal length of the eye-piece. These are the dimensions necessary for determining the magnification of the microscope, viz., the optical length of the tube $\Delta$, the focal lengths of the objective $f_1$, and of the eye-piece $f$. The focal length of an objective can be more simply determined by placing an objective micrometer on the stage and reproducing on a screen some yards away by the objective which is to be examined. If the size of the image of a known interval of the objective micrometer is determined by an ordinary scale, and the distance of the image from the focal plane of the objective belonging to it is measured, then the focal length can be calculated from the ratio $\Delta/y = f_1$. In $y$ is the size of the object, $y'$ that of the image, and $x'$ the distance of the image from the focal plane belonging to it.

The method of determining the magnification there is also a direct one, in which it is necessary to use first measure $f_2$, $f_3$ or $\Delta$. If a drawing prism is used above the eye-piece, and an objective micrometer is inserted, then if a scale is laid on the drawing board, marking each group of $15^\circ$ cm, distant from the exit pupil, one or more intervals of the objective micrometer can be seen projected on the scale lying on the board. The comparison of the two scales gives directly the magnification. The course of the light within the drawing prism must be taken into account when determining the distance of the scale from the exit pupil. Although this method does not give very accurate results, it is more convenient and simple than the indirect method.

MICROTOMY (Gr. μηροτόμειν, to cut), the term applied to the preparation of thin sections of organic tissue for the microscope. In 1875 the methods were introduced in the Zoological Laboratory; their development has enabled observers to achieve the exact study of minute anatomy, in the case of small objects, which without these methods could only be investigated by the unsatisfactory process of focusing with the microscope through the solid object. It is not necessary here to detail at length the wet method of preparing sections. Briefly, the tissue is soaked in a solution of gum, or of gum and syrup, and after being frozen by ether spray, or by a mixture of ice and salt, is cut into sections either by the Rutherford, Cathcart or some similar section-cutter, or by apparatus which can be fitted to the more modern types of micrometer referred to below. This method, which is to-day used mainly by pathologists, has two main disadvantages: the prolonged action of watery fluids on the tissues, and the impossibility of getting ribbons, each section having to be picked up separately.

The general processes of the dry method employed in zoological and botanical microtomy are, up to a certain point, practically identical with those used for the preservation of animals and the objects, for the cutting process, of non-volitile microscopical substances, in the first place the tissue must be fixed, i.e. the protoplasm must be set or coagulated as far as possible in the condition in which it appears in life; and in the third, they must be hardened, i.e. in most cases dehydrated. Killing may be effected by asphyxiation or narcotization (nicotine, cocaine, chloral hydrate, &c.) in special cases, but is generally achieved by fixing reagents, of which corrosive sublimate and other chlorides, picric, acetic, osmic and chromic acids, alone or in combination, chromates and strong alcohol are the most usual. These serve to a great extent also as hardening agents, but alcohol, used after them, completes this process effectively, and when not too strong (70%) is the best storage fluid. The second set of processes relates to the staining, without which transparent sections are almost invisible. The stains are divisible into general stains, which dye the tissue practically uniformly and indifferently; and selective stains, which have affinity for special tissues or cell elements. Of the latter group some fasten on nuclei, others only on the chromatins of the nuclei; some on connective tissues, others on muscle fibres and so on. It is probable that the action of all these stains is produced by definite chemical combination with compounds originally present in, or introduced into, the tissue selected.

The most generally useful stains for ordinary work belong either to the cochineal series (borax-carmin, carmalum, &c.), or to the logwood series (haematoxylin, haemalum, iron haematoxylin, &c.); in both of these great improvements have been introduced of late years by Dr Paul Mayer. The activity of these stains apparently depends upon the presence of alumina or of some similar base. For more special researches, such as cytology, neuropathology, neurology, and so forth, greater dependence is placed on the so-called 'coal-tar', or the names which it is composed of such as safranine or gentian violet, are regressive stains; that is to say, the tissues are overstained uniformly, and the superfuous colouring matter washed out either by alcohol or by weak hydrochloric acid from the unselected parts. Others, such as methyl green, are progressive—that is, the colour is brought up to the pitch required and the reaction promptly stopped. The coal-tar stains can be used singly, or in combinations of two or three. Some of the best, unfortunately, are not permanent. A third group of stains is furnished by such reagents as silver nitrate, gold chloride, and the like (impregnation stains), which can be made not only to stain, but also to deposit a fine metallic precipitate on certain structures. In the case of small and delicate objects, the staining is done in the mass before any further preparation for sections, but with larger animals, or large pieces of resistant tissue, the stain is applied to the sections only. The processes so far mentioned are applicable to many branches of microscopic work.

When preparing tissues for sections the first step is complete dehydration, wrought off by bringing the object into absolute alcohol. It is then transferred to one of a group of reagents, which are miscible with absolute alcohol, but would form an emulsion with water, and are solvents of the embedding medium. The embedding mass in most general use is paraffin wax, melting at a temperature of $54^\circ$ to $60^\circ$ C., according to the character of the object and the thickness of section required. The object is transferred from absolute alcohol to benzol, chloroform, cedar oil, or similar fluid to the melted paraffin; the fluid diffuses and evaporates, leaving the tissues to be completely permeated by the paraffin. This process can be greatly hastened by the use of a partial vacuum. When impregnation is complete the paraffin is cooled rapidly, so as to assume a homogeneous non-crystalline condition, and the tissue thus comes to form part of a block of soft but tenacious material, which protects it from damage by air or damp, and can be readily cut by a razor. The block is then trimmed to the form of a triangle or rectangle, and fixed by a clamp or by local melting in the holder of the micrometre.

The first automatic micrometre suitable for cutting a block of tissue into a continuous series of sections was made in 1883 in the university workshops of Cambridge, from a design by Caldwell and R. Threlfall. Only a single machine was made, but in 1884 twelve machines were made by the Cambridge Scientific Instrument Company from a design by Caldwell. Since then numerous excellent and simpler forms of micrometre have been evolved. Some of these have distinctive advantages over others, but with micrometres as with other tools—the success of the results depends very largely on the manipulator, for every one works best with his accustomed instrument. In one type of micrometre the razor is attached at one end only to a heavy
block, sliding backwards and forwards in a horizontal V-groove; the paraffin block is fed to this either up a vertical guide (Schanze, Reichert, &c.) or up an inclined plane (Thoma-Jung). In another type the razor is firmly clamped at both ends, to diminish vibration, and the paraffin block advances to it at the end of a long lever on trunnion bearings (Cambridge rocker) or up a vertical guide (Mino types).

In the selection of a microtome, apart from its steadiness, rigidity, accuracy of workmanship, and so forth, it must be borne in mind that, in general, simplicity of working parts means longer life, and that an elaborate "automatic" mechanism, by which a single movement is translated into several in different directions, not only complicates the machine, but robs the operator of those alterations of pace, rigidity, pressure, &c., which are often necessitated by the varying texture in different parts of the object cut. For general use by less skilled students in a laboratory, price, simplicity and rapidity of work recommend the rocking-micromotome of the Cambridge Scientific Instrument Company, but it tends to fail at large or hard objects. For the all-round work of an investigator, its simplicity and finish have made Jung's sliding micromotome with the Naples improvements deservedly popular for many years; it can be fitted with special apparatus for cutting celloidin and frozen objects, and it can be relied upon to cut any tissue, however difficult; but it cannot be worked as rapidly as some others, nor produce long ribbons of large objects. For this latter purpose the Minot-Becker, Minot-Zimmermann and Reinhold-Gilliat have been strongly recommended; these, however, are all of more complicated construction, with corresponding liability to uneven wear and damage; they are highly "automatic," leaving nothing but pace under control of the operator, and they are (particularly the last) expensive.

In 1910 the Cambridge Scientific Instrument Company issued a new micromotome designed primarily for cutting larger sections than was possible in their earlier forms, which respectively dealt with sections 12×30 mm. and 30 mm. in diameter; the new instrument cuts sections measuring 150×120 mm. (6×4 in.) embedded in paraffin or celloidin and of a thickness varying from 0-002 to 0-006 mm., each division of the scale being equal to 0-002 mm., and the total distance of automatic feed being 21 mm. The construction and action of the instrument can be understood by referring to the figure; a detailed description is given, since the same principles are utilized to a greater or less extent in all sliding micromotomes.

The object to be cut, having been embedded in a suitable preparatory A, is fixed to a wooden block which is attached by clamps to the object-holder B. The object-holder is provided with mechanism by means of which the height of the block is determined; this is effected by mounting the holder in a cup-shaped socket at the extremity of a brass pillar E, which can be raised or lowered and fixed in any position by a clamp. In addition, the direction in which a section is cut can be varied by adjusting the four screws, one of which is shown at C, which orientate the block. The object-holder and feeding mechanism are rigidly combined, which rests at three points on two guides in the frame M, N, of the instrument; and in order to secure easy running the necessary lubrication of the bearing surfaces is provided for by a groove in which oil is placed. The motion for the cut is produced by means of three screws, which, operating through the ratchet M, cause a toothed wheel to revolve, which in turn raises the pillar K; the amount of the motion can be read off from the index. On the return stroke the sliding carriage the stoppin is again actuated in such a manner that just before the knife R reaches the object-holder the mechanism depresses this part of the instrument so that the knife is not fouled; when the cutting is over, the object-holder is fully raised, and the motion appropriate for taking the next section. The knife is rigidly set in two heavy brass clamps adjustable by the screws S, and these clamps are attached to the frame of the instrument by the screws T. The angle which the cutting edge makes with the frame is also adjustable, and by means of a small angular scale engraved on the knife-holders any setting can be easily determinet or repeated. The knife is flat on one side and hollow-ground on the other. In using the micromotome it is essential that the cutting edge of the knife points towards the end of the instrument where the handle is placed; the hollow-ground face should be uppermost, and the flat surface should on a sliding block cut, so that the lower facet of the cutting edge is parallel to the frame.

As to the relation of the position of the knife to the direction of motion, it is the usual practice, when paraffin sections are to be taken, to have the cutting edge at right angles to the movement of the carriage when on the other hand, celloidin preparations are being cut, the knife must be set obliquely across the frame, an angle of 30° being convenient. This obliquity makes the cutting of the sections. In addition it must be remembered that celloidin preparations always require lubricating when being cut, and it is also necessary to keep both the knife and the preparation constantly moistened with either 50% alcohol or with cedarwood oil.

The sections, when cut by the micromotome with the knife straight and the two sides of the rectangular paraffin block parallel to it, in most cases can be got off in a continuous ribbon, each sticking to its predecessor. This very desirable result generally can be insured by a coating of softer paraffin; but if the object be large, or brittle, or of varying texture, it is safer to cut the sections singly from a triangular block with an oblique knife. The sections or ribbon are often not quite flat, but rolled, creased or compressed; they must be flattened before being attached to the slide. It is possible to carry out these two processes simultaneously by covering the carefully cleaned slide with plenty of a very dilute solution of Mayer's glycerine and albumen, and laying the sections on the fluid and the slide on a hot-plate; as the water becomes warm the sections flatten out, and as it evaporates they settle down on the slide, and are held there by the albumen (many other methods are in use). The slide is then warmed to melt the paraffin, and plunged into benzol, or some similar fluid, which removes the paraffin; thence into absolute alcohol, which dehydrates and coagulates the albumen. If the tissue has not been stained en bloc the sections can now be stained on the slide. After staining they are fully dehydrated, rendered transparent by oil of cloves, and mounted in xylol-dammar or Canada balsam. W. Giesbrecht was the first to fix sections on the slide, using a solution of shellac in cresote in 1881; and also in the same year and in the laboratory of the Naples aquarium, W. H. Caldwell first cut and fixed ribbons of sections.

For ordinary work the paraffin method excels all others for rapidity, certainty and cleanliness; but for large and hard objects, or crumbling tissues (such as ova with a large quantity of yolk), some manipulators prefer to embed in celloidin. By this method, after dehydration, the tissue is soaked in a mixture of absolute alcohol and ether; thence transferred either to increasingly strong solutions of celloidin in the same mixture or to a thin solution which is then boiled down till strong. The celloidin mass is then hardened: at first, if necessary, by drying; afterwards by a bath of chloroform or its vapour. It can then be cut in the micromotome, either wet, or if
previously cleaned with cedar oil) dry like a paraffin block. The method is more tedious and more messy than the paraffin process; but amongst its advantages must be reckoned that little or no heat is required, and that the embedding mass is transparent, though it does not allow of such thin sections as paraffin.

The above accounts present an outline of the complex processes employed to-day, by which, on the one hand, sections 30 μ in thickness may be made through the entire human brain; and, on the other, diagram to be cut into a long ribbon of consecutive sections 1 μ (one-thousandth of a millimetre) thick, every minute test fragment being retained in its proper place.

The standard book on the subject is Bolles Lee's Microtomist's trade-museum. Other works are G. Mann, Methods and Theory of Practical Microtomy (London, 1905); and A. Flatt, Examination and Microscopical Research (London, 1905) (G. H. Fo.)

MIDAS, the name of several Phrygian kings. The first of these was said to have been the son of Gordius and Cybele, whose first priest he was, and in whose honour he founded a temple at Pessinus. Having taken the drunken Silenus back to his youthful charge Dionsius, he was rewarded by the god with the power of transforming everything he touched into gold. Finding himself in danger of starvation, even his food and drink being changed by his touch, Mides entertained Dionysus to take back the gift. By the command of the god he bathed in the river Pactolus, which henceforth became auriferous (Ovid, Metam. xi. 85-145; Hyginus, Fab. 191). Another story connects him with the musical contest between Apollo and Marsyas (or Pan). Having decided against the god, his ears were changed into those of an ass. He concealed them under a Phrygian cap; but the story was discovered by his barber, who, being unable to keep it, dug a hole in the ground and whispered into it "Midas has the ears of an ass." He then filled up the hole, thinking his secret safe; but the reeds which grew up over the spot proclaimed it to all the world. Mides with the ass's ears was a frequent subject of the Attic satyr-drama. There is no doubt that Mides was the name of one or more real persons around whom religious legends have grown up. The name "Midas the king" occurs on a very ancient tomb in the valley of the Sangarius, the legendary seat of the Phrygian kingdom. The Phrygian monarchy was destroyed by the Cimmerians about 670 B.C., and the name Mides became in Greek tradition the representative of this ancient dynasty.

MIDDELBURG, the ancient capital of the province of Zeeland, Holland, in the middle of the island of Walcheren, 4 m. by rail N. by E. of Flushing, with which it is also connected by steam tramway and by ship canal (1873), which continues to Veere on the Scheldt. It contains a large market and is a seat of manufacturing (men's wearing clothes, cloth, beer, glass, paper). Pop. (1903), 19,002. Middelburg contains many splendid old houses, which recall the prosperity which distinguished it until the end of the 18th century. The beautiful town-hall, built by Anton Keldermans about 1512, with a square tower 180 ft. high, and a façade adorned with statues of the counts and countesses of Zeeland and Holland, contains the valuable city archives and antiquarian and historical collections. The old abbey of St Nicholas, founded in 1130, and now occupied by the provincial council, has some fine old tapestry of the end of the 16th century. The building was added to in the 14th and 15th centuries, and partly rebuilt after a fire in 1492. It was the scene in 1503 of a meeting of the knights of the Golden Fleece, and was frequently the residence of royal visitors, including Maximilian, Philip the Fair and Charles V. The abbey of Middelburg formerly possessed a vote of his own in the Provincial States. What was formerly the nave of the abbey church is now the New Church, and the ancient choir constitutes the Choir Church. These churches are interesting for the monuments of William II., count of Holland, king of the Romans (d. 1250), the 16th century scholar Hadrian Junius, and Jan Pieterszoon Coen (1587-1629), the founder of the East India Company of the usual periodizing. It is only after having traced these one by one that we can properly review the process as a whole.

contains a good chime of bells. The corn exchange, the hofs St Joris and the hof St Sebastian (formerly buildings belonging to the gilds of archers, and now places of amusement) also deserve mention. The museum of antiquities belonging to the Zeeland Society of Arts and Sciences (founded at Flushing in 1769, and transferred to Middelburg in 1801) contains a complete collection of the fauna and flora of the province, many maps, plans and drawings relating to Zealand, the first telescope made by Hans Lips and Zacharias Jensen in Middelburg in 1608, and some provincial Roman antiquities.

The extensive trade which Middelburg formerly carried on with the East and West Indies and with England and Flanders, was ruined by the war with England and the French occupation. But the construction of the railway in 1872, followed by the opening of the ship canal and the large dock (1876), as well as the establishment, by the aid of the chamber of commerce, of certain manufacturing industries (iron, machinery, furniture, oil and cigars), lifted it out of its isolation.

MIDDELBURG, a town of the Transvaal, 98 m. E. by rail of Pretoria, and 317 m. W. of Lourenço Marques. Pop. (1904), 5085—of whom 2343 were whites. It is prettily situated on the high veld, 5000 ft. above the sea, on one of the head streams of the Olifants River. Middelburg is the chief town of an administrative division of the same name, and is a trading centre for a large district. It is also the centre of one of the richest coal-fields in South Africa. From some of the adjacent collieries excellent steam coal is obtained. Copper and cobalt are found in the neighbourhood.

Middelburg was chosen in 1901 as the place of conference for peace negotiations between the British and the Boers. After the occupation of Pretoria in June 1900 by Lord Roberts the Boer forces had been reduced to guerrilla warfare, and Lord Kitchener, learning that the Transvaal commandants were despondent, invited General Botha to enter into negotiations, on the basis of the recognition of British sovereignty. The conference between Lord Kitchener and General Botha was opened on the 28th of February and the negotiations, which ended in failure, were protracted until the 16th of March (see TRANSVAAL: History, § The War of 1899-1902).

Middelburg is also the name of a town in the Cape Province, South Africa, 250 m. N. by W. of Port Elizabeth. Pop. (1904), 6137.

MIDDLE AGES, THE. This name is commonly given to that period of European history which lies between what are known as ancient and modern times, and which has generally been considered as extending from about the middle of the 5th to about the middle of the 15th centuries. The two dates adopted in old textbooks were 476 and 1453, from the setting aside of the last emperor in the West until the fall of Constantinople. In reality it is impossible to assign any exact dates for the opening and close of such a period. The trend of recent historical research leads one even to doubt the validity of the very conception of any definite medieval period. The evolution of modern European society has been continuous. Progress has not been uniform. There was much retrogression with the intrusion of new barbarian races; but from their absorption by the 11th century until the 20th there is not a century in which some notable gain was not made towards the attainments of modern civilization. The correct perspective places between the summits of modern and ancient times, not a long level stretch of a thousand years, with mankind stationary, spell-bound under the authority of the Church, absorbed in war or monastic dreams, but a downward and then a long upward slope, on both of which the forces which make for civilization may be seen at work.

It is clear that a survey of the history of these so-called middle ages—long use makes the term inevitable—must include not only the political phase, but also economics, religion, law, science, literature, &c., since all are involved in the concept. A hurried outline of each of these vital branches of our civilization will at least reveal the dimensions of the usual periodizing. It is only after having traced these one by one that we can properly review the process as a whole.
In political history, the epochal fact which marks the close of ancient times is the decline of the Roman Empire. This was a process extending over three or four centuries, in which no one date lends itself to the historian. The deposition of Romulus Augustus, the last Roman emperor in the West, in 476, was certainly not one of those events upon which the history of the Western world depends. Outwardly it did not mark the end of the Empire, but the restoration of imperial unity. The throne in Italy had been vacant, and the restoration of unity was realized in fact under Justinian. There is no reason why the date 476 should stand out in European history more strongly than half a dozen other such dates. Yet we may say that the 5th century did witness the actual dismemberment of the Roman Empire. The new nations in Spain, Gaul, parts of Italy and Britain were forming the rude beginnings of what were to become national states in the centuries following. Western Europe was taken out of the imperial mould and broken up. This is a revolution of sufficient magnitude to be regarded as politically the opening of a new era. It had been long preparing in the economic and administrative decline of the Empire, and in the steady influx of Germanic peoples into Roman territory for over two centuries; but the power of the old civilization to absorb the new races was exhausted by the 5th century, and the political history of Europe was turned into a different path. That path, however, was not destined to end blindly in a "middle age." The line of political development marked out in the 5th century—that of the national state—still continues. The revolution in which Alaric, Theodoric, and Clovis figured did not set students of the middle ages only, as is frequently stated; its full meaning did not appear until the Peninsula War, the Prussia of Stein and Scharnhorst, and even Solfierino and Sedan. Thus the 5th century politically introduces not so much the history of the middle ages as that of modern Europe.

The immediate introduction, however, was a long one—so long and so distinct from the later development as to constitute in itself a distinct phase. For five or six centuries—from the 5th until about the 11th—comparatively little permanent progress was made. The Germanic tribes were still adjusting themselves and slowly learning to combine their primitive institutions with the remains of those of Rome; the premature union under Charlemagne gave way before new invasions, and anarchy became crystallized in feudalism. It was not until the 12th and 13th centuries that modern national states really took shape: England with its trial by jury, circuit courts, Magna Charta and parliament; France under the strong hand of the Capetians. A political middle age certainly lay between Theodosius and William the Conqueror, or at least between Justinian and Henry II. It is difficult to grasp its vastness. Few students of history realize that the period from the Saxo to the Norman Conquest of England would take us as far back as from George V. to Edward I.; or that from Theodosius to Philip Augustus there is an interval equal to that between the accession of Hugh Capet and the French Revolution.

This, however, is not the period most frequently termed the middle ages in political histories. It does not include those two institutions which more than any others stand in popular imagination as genuinely medieval—the papal monarchy and the Holy Roman Empire. The papacy, it is true, while having its fullest development under Hildebrand (Gregory VII.) in the middle of the 11th century; its political decline set in suddenly after the pontificate of Boniface VIII. at the opening of the 14th. The great age of the Empire began slightly earlier, and continued until the fall of the Hohenstaufens in the middle of the 13th century. One cannot now deny the term middle ages to the period of these two institutions. It has been consecrated to this use too long. Yet when we include under a common name two eras so distinct as this and that preceding, our term becomes so vague as to be almost valueless. Moreover, it is doubtful if this second period is really as "medieval" as it has seemed. Papal monarchy and Holy Roman Empire were not the only political phenomena of their age, and it is possible that their vast pretensions have somewhat blinded historians as to their real importance. While they were struggling to enforce their claims to universal sovereignty, the royal power, less extravagant but more real, was welding together the feudal states of France and moulding the England of to-day. Compared with this obscure process—this spread of the king's peace along the highways and through the distant forest lands of the 12th and 13th centuries—papal interdicts and jubilees, however impressive their spectacles, are but fleeting shows. The chivalry of Germany pouring through Alpine passes for an Italian campaign, or a coronation, left little trace in history except the lesson of their futility. There is much in the imperial and papal histories that is merely spectacular and romantic; much that appeals to the imagination and lends itself to myth; and since the sources are abundant—the papal archives inexhaustible and the German chronicles easily accessible—an undue emphasis has been placed upon them. It is at least evident that the political middle ages were already in process even during the period of papal monarchy and Holy Roman Empire.

In economic history there is a more definite line traceable. The one great economic change brought about by the decline of the Roman Empire was the lessening of urban life throughout the greater part of Europe, the closing up of avenues of communication and the predominance of isolated agricultural communities. This phase began to give way in the 11th century to a commercial and industrial renaissance, which received a great impetus from the crusading movements—theirself largely economic—and by the 14th century had made the Netherlands of Europe, the Rhine a vast artery of trade, and north Italy a hive of busy cities. The discovery of America and the expansion of commerce merely readjusted conditions already highly developed. The period of isolated economy which we may term medieval lasted only from about the 5th to the 12th centuries. As for manufactures, the antique methods survived until the 18th and 19th centuries.

In religious history—to be distinguished from that of the political organization referred to above as the papal monarchy—the official recognition of the Christian Church by Galerius in 311 serves as a convenient starting-point for what we know as universal Christendom, though the slow disappearance of paganism, as distinct from Christian only, stretches over at least a century more. The Reformation of the 16th century has long been regarded as the close of the period. The real close, however, is the present day—as the result of the rationalism and science of the 18th and 19th centuries. The heroes of the Reformation, judged by modern standards, were reactionaries. Unconsciously in to its own ultimate damage the Reformation forged the weapons of progress; but it was itself in no sense, except in the institutions it created, political. History has seen its highest stage at the Conference of Nicaea. The real change in attitude which marks the dawn of a new era came in the generation of Voltaire. And "medievalism" is only now on the defence against "modernism," both Catholic and Protestant.

In legal history there was a distinct medieval period, when Germanic customs superseded Roman law, that most splendid of Rome's legacies. But the renaissance of law began relatively early; by the 12th century it had created a university, by the 13th it was helping to organize national states and laying the lines that order which the economic renaissance was already demanding.

In science there was no great product in antiquity to be lost. Compared with art or law, literature or philosophy, ancient science (in our sense) was almost insignificant. The promise in Aristotle of such production remained unfulfilled. The 17th century is not so much a renaissance here as a mere beginning. No one can deny the general unsatisfactory, uncritical nature of "medieval" thought. A single Roger Bacon does not relieve his age of the charge. But the middle age in science must include much of antiquity, including Pliny.

Philosophy was the one subject which had, clearly, and definitely, a medieval period. Scholasticism, which absorbed the attention of most thinkers from about the 11th to about the
15th centuries, is so easily marked off and played so considerable a rôle in the academic history of that time, that historians often refer to it as the only intellectual interest of "medieval" men. Then, selecting some of the later and less virile scholastics as victims, they ask how men could be seriously interested in their trivialities. But these men were not all busy over the problem of how many angels could stand on a needle-point; nor were they all dominated by the religious spirit of faith or intellectual cowardice. They were searching for truth with scientific eagerness. Their very failure made possible the modern era. It is perhaps unnecessary to point out how small a proportion of the "intellectuals" were scholastics even in the 13th century.

In the realm of art the "middle ages" had already set in before Constantine robbed the arch of Titus to decorate his own, and before those museums of antiquity, the temples, were plundered by Christian mobs. The victory of Christianity—iconoclastic in its primitive spirit—was but a single chapter in the story of decline. The process was completed by the misery of the decaying empire, and by the Germanic invasions. The barbarians, however, destroyed less than has been commonly supposed. Destruction was more the product of necessity than of wantonness. Thus public monuments became fortresses, and antique sculpture was built into city walls. Such art as continued was almost wholly religious; for in the wilderness of the times the churches formed oases of comparative prosperity and peace, and, even in the darkest times, wherever such oases existed there the seeds of art took root. The Church architecture of the "middle ages," then developed naturally and without a break, through the Byzantine and Romanesque styles, out of the secular and religious architecture of Greece and Rome. And, with the return of comparatively settled and prosperous conditions, not only architecture but the other arts also blossomed under the influence of what was later stigmatized as the "Gothic" spirit into new and original forms. Down to the Reformation the churches continued to be, as the temples of the ancient world had been, the main centres of the arts; yet the arts were not confined to them, but flourished wherever, as in castles or walled cities, the conditions essential to their development existed. With the revival of civilized conditions in secular life, secular ideals in art also revived; the ecclesiastical traditions in painting and sculpture, which always tend to become stereotyped, began in the West to be encroached upon long before the period of the "Renaissance." The 12th and 13th centuries, which witnessed the great struggle between the secular and spiritual powers in the state, witnessed also the rise of a literature inspired by the lay spirit, and of an art which was already escaping from the thraldom of the stereotyped ecclesiastical forms. Gothic sculpture was not incidentally decorative, it was an essential element in the harmony of the architectural design. The elongated kings that guard the door of Chartres Cathedral, or the portals with the Last Judgment, are a necessary element in the facade. Thus lettered, even the realism of the Gothic sculptors failed, except in rare instances, of its full expression. The plastic arts were left for Italy, where antique models were at hand, and the glory of its achievement in the 15th and 16th centuries was so great as to obscure in men's eyes what had been done before.

But this Italian renaissance was not the only one. It was but one of many; and it was concerned with the two subjects which perhaps least deeply influence the lives of the mass of men—literary humanism and art. It is obviously absurd, in the face of that glowing fact, to regard it as the end of a middle age in anything but in its own field.

When one studies the history of Europe subject by subject, as indicated above, and not merely in a monastic chronicle of things in general, chosen according to the author's point of view, one sees the old-time framework passing away. The traditional idea of a barren middle age and a single glorious renaissance proves false. An organic study of the past reveals a more rational picture of the process which produced the Europe of to-day. Cataclysm and special creation here as elsewhere give way to evolution. The new synthesis reveals a universal decline from the 5th to the 10th centuries, while the Germanic races were learning the rudiments of culture, a decline that was deepened by each succeeding wave of migration, each tribal war of Franks or Saxons, and reached its climax in the disorders of the 10th and 11th centuries when the half-formed civilization of Christendom was forced to face the migration of the Northmen by sea, the raids of the Saracen upon the south and the onslaught of Hungarians and Slavs upon the east. That was the dark age. It left Europe bristling with feudal castles, and already alert for the march of progress. At once the march begins. Henry the Fourth sets back the Slavs and places the outposts of Christendom along the Elbe and the Oder. Otto III, his son, drives the Magyars from southern Germany and establishes the East Mark (Austria) to guard the upper Danube. The restoration of the Empire in 962 marks the first milestone on the pathway of recovery. Already scholarship had found a home in monasteries planted in the heart of the German forests. The succeeding century brought the Empire to the acme of its power, until Henry III. in the Synod of Sutri, sat in judgment on the impotent and demoralized papacy. Meanwhile France had been learning something even in its feudal anarchy. The monks of Cluny were at work. The Cappelans were at work. The great monastery of Bec was drawing the sons of northern sea-robbers to the service of that greatest civilizing force, the Church. The progress made through even this darkest age may be measured by the difference between the army of Rollo and that which William the Conqueror gathered for the invasion of England.

There is a legend, current among historians from the days of Robertson and Hallam, that as the year 1000 approached mankind prepared for the Last Judgment; that the earth "clothed itself with the white mantle of churches" and like a penitent watched in terror and in prayer for the fatal dawn. Contemporary sources fail to bear out this beautiful conception. Apart from the fact that reckoning from the birth of Christ was by no means universal, and consequently the mass of men were ignorant that there was such a thing as the year 1000, one wonders how that most enduring type of architecture, the Romanesque, reached its maturity among men who thought that the earth itself was so soon to "shriivel like a parched scroll." Recent scholarship has absolutely disproved this legend, founded on a few trite phrases in monastic chronicles, and still to be heard in similar contexts. The year 1000 marks no epoch in medieval history.

The latter half of the 11th century witnessed the most remarkable political creation in Europe since the days of Caesar, the papal monarchy of Hildebrand. The great scholastic controversies had already begun in the schools of France; the revival of Roman law had called for the university of Bologna, and the canonists had begun the codification of the law of the Church. The way was already cleared for the busy 12th century, the age of Louis VI. and Henry II., of Glanvill and Suger, of Abelard and Maimonides, of Frederick Barbarossa and Alexander III., of the emancipation of French communies and cities and the independence of those of Lombardy, of the growth of guilds and the extension of commerce, of trouvère and troubadour and the beginnings of vernacular literature, of the creation of Gothic art, of trial by jury and the supremacy of royal justice. Such are but a fraction of its achievements. The 12th century stands beside the 18th as one of the greatest creative centuries in human history. The 13th like the 12th applied these creations in the transformation of society. The century of Dante was also that of the first English parliament; its vast economic expansion enabled the national state to triumph in both England and France, and furnished the grounds for the overthrow of Boniface VIII. Into the complex history of this momentous age it is impossible to go in any detail. Sufficient to say that in the opening quarter of the 14th century England and France at least stood on the brink of "modern times." Then these two nations entered upon that long tragedy of the Hundred Years' War, a calamity absolutely immeasurable to both. But during its massacres, jacobecies, plagues and famines, the cities of Italy, growing rich with trade and manufactures, were in their turn
the centres of progress, this time in a new direction, toward the recovery of the antique past and the development of art.

This is the so-called Renaissance (q.v.). The humanists which it produced, interested only in its splendid revelations, forgot or ignored the achievements of the period which intervened between Cicero and Petrarch. Then by the genius of their work they fastened their mistaken perspective upon historians and the cultured world at large. They struck upon the unfortunate and opprobrious term "middle ages" for that which stood between them and their classic ideals. The term was first used by Flavio Biondo, whose "decades" was an attempt to block out the annals of history from 410 to 1410. His treatment fell in admirably with the ideas of his age and of that following. To Protestants the age of the papal monarchy was like the reign of Anti-Christ. Then, after the indifference of humanists and Protestant polemic, came the disgust of men of science at the scholastic philosophy— an attitude best exhibited in Bacon's *Advancement of Learning*. The 18th century was thus trebly barred from a knowledge of genuine medieval history. A Romanticism, that reaction in which Sir Walter Scott, the Schlegels and Victor Hugo so largely figured, was as far from understanding what it admired as classicism had been from what it hated. Its extravagant praise of all that savoured of the middle ages was still blind to their real progress and work. They were, for it, the ages of romance and chivalry. The view of the romanticists was as one-sided as any that had gone before. It is only with the introduction of a wider outlook in the scientific study of history that it has been possible to straighten the perspective and modify the traditional schemes.

In the purely intellectual sphere it is certainly true that the recovery of the ancient world was of great importance; that it made possible genuine criticism by presenting new points of contrast and opening up fields that led away from theological quibbles. But it did not mean the "double discovery of the outer and inner world." Mankind did not, as Burckhardt and J. A. Symonds lead one to imagine, suddenly throw off a cowl that had blinded the eyes for a thousand years to the beauty of the world around, and awaken all at once to the mere joy of living. If any one was ever awake to the joys of living it was the minnesinger, troubadour or goliard, and the world had to wait until Rousseau and Burns before its external beauty was discovered, or at least deeply appreciated, by any but a few Dutch artists. Even Goethe crossed the Alps with his carriage shutters closed. Mont Blanc is not mentioned by travellers until after the middle of the 18th century. The discovery of the outer world is a recent thing in art as well as in science. As for the claim that the "Renaissance" delivered men from that blind reliance upon authority which was typical of "medieval" thought, that is a fallacy cherished by those who themselves rely upon the authority of historians, blind to the most ordinary processes of thought. In this regard, indeed, in spite of the advance of scientific method and the wealth of material upon which to base criticism, we are still for the most part in the middle ages. The respect for anything in books, the dogma of journalistic inerrancy which still numbers its devotees by millions, the common acceptance of even scientific conceptions upon the dicta of a small group of investigators, these are but a few of the signs of the persistence of what is surely not a medieval but a universal trait. The so-called Renaissance did much; but it did not do the things attributed to it by those who see the "middle ages" through humanist glasses.

Upon the whole, therefore, it would seem that not only was there no one middle age common to all branches of human evolution, except the period more definitely marked as the dark age, but that those characteristics which are generally regarded as "medieval" were by no means limited to a single epoch of European history. In short, the dark age was a reality; but the traditional "middle ages" are a myth. (J.T.S.)

**MIDDLEBORO,** a township, N. of Plymouth, about 10 sq. m. The principal village also is named Middleboro; it is 35 m. S. of Boston, is served by the New York, New Haven & Hartford railroad and by electric lines connecting with Taunton, Boston, New Bedford and Cape Cod, and has a town-house, a soldiers' monument, and a public library housed in a building erected from a fund (part of which is used as a permanent endowment) bequeathed by Thomas Sprout Peirce (1823-1901), a merchant of the township, who, in addition, bequeathed about $500,000 as a special trust-fund for the use and benefit of the township of Middleboro; the income has been spent largely in the construction of macadam roads, the erection of an almshouse and the installation of special courses in the high school. The village, a place of considerable natural beauty, is a summer resort, and has various manufactures. Other villages in the township are North, East and South Middleboro, and Rock. The township had important herring fisheries in early times and manufactured straw hats (from 1838) and ladies' dress goods. Middleboro was settled about 1662 under the Indian name Middelborough, and in 1673 was changed to Middleborough. The town is picturesquely situated near the Green Mountain range, and is the seat of Middlebury College (chartered, 1800; co-educational since 1883), which offers a classical course and a Latin-scientific course, and had in 1907-1908 1,298 students from 50 states and 10 foreign countries. There are a public library and a public school. The Sheldon art museum and a public library are among the public institutions of the village, and the principal buildings include the court-house and the opera-house. The principal industrial establishments are marble quarries, "Italian" marble works, iron foundries, lime-kills, flour-mills, and, door, sauh and lumber mills. About 1 m. north of the village, in the forest of Weybridge, there is a large United States government breeding station for Morgan horses; and merino sheep are raised in the vicinity.

The township of Middleborough was incorporated in 1761, and the first settlement on the site of the present village was made in 1773. At the outbreak of the War of Independence the settlement was deserted, and all except two or three of the houses were destroyed by British troops; but the settlers returned soon after the close of the war, and the township was formally organized and sent a member to the state assembly in 1788. Middleborough was incorporated as a borough in 1813, and as a village in 1832.

**MIDDLESBROUGH,** a municipal, county and parliamentary borough and seaport in the North Riding of Yorkshire, England, 238 m. N. by W. from London, on the North Eastern railway. Pop. (1891), 75,532; (1901), 91,302. It lies on the south bank of the Tees, 5 m. from its mouth in the North Sea, and is the centre of one of the most important iron-working districts in the world. It is wholly of modern growth, having been incorporated in 1833. Its chief buildings are a fine town-hall with lofty clock-tower and spire (1850), containing the municipal offices, free library, &c.; a large and handsome county court, a coining and memorial museum, and a Roman Catholic cathedral. Besides iron and steel works, the first of which was that of Messrs. Bolckow, Vaughan & Co., there are rolling-mills, tube works, wire-mills, engineering works, oil works, chemical works, salt works and a considerable ship-building industry. The district abounds in blast furnaces. The docks are accessible to large vessels, the entrance having a depth of 32 ft. Extensive dredging operations are carried on in the river. The accommodation for shipping includes two grading docks, two patent slips, &c. The entrance to the river is protected by two breakwaters named respectively the North and South. The furnaces within the port produce some
MIDDLESEX, 1st EARL OF—MIDDLESEX

2,500,000 tons of pig iron annually. Middlesbrough is the seat of a Roman Catholic bishop. The parliamentary borough falling within the Cleveland division of the county, returns one member. The county borough was created in 1888. The town is governed by a mayor, ten aldermen and thirty councillors. Areaa, 2,823 acres.

The earlier history of the place is meagre. Where Middles-

i

brough now stands there were at one time a small chapel and priory founded by Robert de Brus of Skelton Castle. These were dedicated to St Hilda, and with some lands were given by de Brus to the abbey of St Hilda at Whitby in 1130. The priory fell with the time of the Reformation, and no trace now remains beyond some stones built into the wall of a bakery. The Oak Chair in the town-hall also is made from a fragment. In 1801 there were upon the site of Middlesbrough only four farm-

houses. In 1829 a company styling itself the Middlesbrough Owners bought 500 acres of land, and began building in the town. In 1830 the Stockton & Darlington railway was extended to Middlesbrough; four years later the town was lighted with gas; and after six years more a public market was established. The census of 1851 showed the population to be 154; that of 1841 showed the town to be increasing. The importance of the town. From the year 1851, when John Vaughan discovered the presence of ironstone in the Eston hills, the town advanced rapidly.

MIDDLESEX, LIONEL CRANFIELD, 1st EARL OF (1575-1649), was a successful London merchant, who was introduced to King James I, by Henry Howard, earl of Northampton, and entered the royal service in 1605. In 1613 he was knighted and was appointed surveyor-general of customs; in 1616 he became one of the masters of requests, and in 1619 master of the court of wards and liverys and chief commissioner of the navy. He was returned to parliament as member for Hythe in 1624 and for Arundel in 1621. Cranfield, who was also a member of the ward-

robe, was responsible for many economies in the public service, and his business acumen was very useful to the king. He took part in the attack on Bacon in 1621, and although, contrary to general expectation, he did not succeed Bacon as lord chancellor, he was created Baron Cranfield in July of this year. In 1621 also he became lord high treasurer, and in September 1622 was created earl of Middlesex, losing his positions and influence shortly afterwards because he opposed the projected war with Spain, and had incurred the displeasure of the earl of Oxford and George Villiers, 1st duke of Buckingham. Impeached by the House of Commons for corruption, he was found guilty by the House of Lords in May 1624 and was sentenced to lose all his offices, to pay a heavy fine and to be imprisoned during the king’s pleasure. However, he was released from prison in a few days, was pardoned in the following year, and was restored to his seat in the House of Lords in 1640. The earl’s second wife was Anne Brett (d. 1670), a cousin of Buckingham’s mother, whom he married somewhat reluctantly in 1621 in order to ensure Buckingham’s support. Middlesex died on the 6th of August 1645, leaving with others a son James (1621-1651), and earl of Middlesex, who was a partisan of the parliamentary party during the Civil War. James was succeeded by his brother, Lionel, and when this earl died in October 1674 his titles became extinct. The first earl’s daughter Frances married Richard Sackville, 5th earl of Dorset, and their son Charles was created earl of Middlesex in 1675. Two years later he became earl of Dorset, and the title of earl of Middlesex was borne by the earls and dukes of Dorset until 1834.

MIDDLESEX, a south-eastern county of England, bounded N. by Hertfordshire, E. by Essex, S.E. by the county of London, S. by Surrey, and W. by Buckinghamshire. The area is 883 sq. m., and, excepting Rutland, the county is the smallest in England. The area outside the county of London, or extra-

metropolitan area, with which this article is mainly concerned, is 233 sq. m. It lies entirely in the basin of the river Thames, which forms its southern boundary. On the east it is separated from Essex by the Lea, the largest northern tributary of the Thames. The other rivers, in order westward, are the Brent, the Crane or Yelling Brook, and the Colne. The waters of several streams are collected in the artificial Brent reservoir near Hendon, from which the Brent flows with a circuitous course to the Thames at Brentford. The Crane, rising in the high ground near Harrow-on-the-Hill, joins the Thames at Iffleyworth; and the Colne, which rises on the elevated plain between Hatfield and St Albans (Hertfordshire), traverses a flat valley on the western boundary of the county, where it divides into several channels, and joins the main river at Staines. The highest ground, exceeding 400 ft. at several points, and reaching 503 ft. above Stannaraw, is found along the northern boundary, in a line from Stanmore through Elstree, Chipping Barnet and Potter’s Bar (Hertfordshire) on the south, and a line of hills to the west of the main line, project southward, the eastern from Whetstone through Finchley and Highgate to Hampstead, where, within the county of London, a height of 443 ft. is found on Hampstead Heath; the western being the isolated elevation on which stands Harrow-on-the-Hill. The hills skirts the Lea valley, in the neighbourhood of Enfield, are abrupt, though of no great elevation. Elsewhere the country is very slightly undulating or quite flat, as along the banks of the Thames and Lea. The Thames, however, beautifies its immediate neighbourhood, and the Lea, which has its origin in the mound of Chalk, the greater part of the county was formerly densely forested and sparsely populated, and the name of Enfield Chase, a royal preserve in the north-east, still recalls this condition. In modern times the visible influence of London has spread over practically the entire county. Villages have grown into populous suburbs; large institutions, for which sites adjacent to rather than within the metropolis have been found preferable, are numerous, and the development of suburban railway communications has brought fresh ground within reach of builders.

The county lies entirely within the structural basin of the Thames, and, as in the neighbouring counties, the general slope of the ground and dip of the strata is towards the south-east. South of an irregular line passing from Uxbridge, north of Hayes, and between Park Royal and Ealing, towards the upper side of the Park to Tottenham and on from that point to Enfield, the only visible deposits are the gravels, loams, brick-

earth and sands laid down in former times by the Thames, with contributions by the Lea and the Colne. These alluvial deposits rise gradually northward from the Thames and westward from the Lea, in a series of gentle terraces. The earliest portions of London were built upon these terraces, because while they were dry at the surface, water could be obtained by sinking shallow wells. The alluvium has yielded many flint implements and the bones of the mammoth, bear and rhinoceros, great elk and other extinct forms. Loose deposits of modern origin are dug and sold as ballast, &c., about West Drayton, Southall, Enfield and Tottenham.

The London clay, a marine deposit, is bluish where it has not been altered by brown weathering. To the westward the river deposits and rises to the surface north and east of the alluvial boundary indicated above. It gives rise to the undulating grassy country round Harrow, Chipping Barnet and Elstree. Below the London clay are the sandy and gravelly Reading beds, which may be seen at Harrow and at South Mimms; inliers occur at Pinner and Ruislip. Chalk is only visible on the side of the Colne valley at Harfield, where it is quarried, and at South Mimms. Formerly, the sandy and pebbly Bagshot beds covered all the clay on the clay area, but now only isolated patches remain, such as those on the top of Harrow, Hampstead and Highgate hills. Long after the Bagshot beds were covered down the chalk was removed by a variety of physical processes; such are the pebble gravels of Stanmore Heath and the district north of Barnet; the clay and sand of Finchley, Muswell Hill and Southgate. The chalky boulder clay to be seen at Finchley, Southgate and Potter’s Bar is not confined to the London basin, but extends far down into Hertfordshire and Essex, and is probably the result of the wearing away of the London clay and the deposition of the material thus removed. The chalky boulder clay in Southgate and Highgate is also probably of the same character.

The Chalk is found also in the county of Middlesex, and there are several deposits of flinty chalk, especially at Stanmore and in the Hatfield Heath district, as well as at Enfield which are worked in the manufacture of fire bricks. The clay is the source of a variety of manufactures, especially the manufacture of bricks and glass. The famous East End of London was formerly a large district of brickworks, and the manufacture is still extensive. The county is the home of the London and Home Counties Stonemasons’ and Carpenters’ Association. A large model of the geology of London is exhibited in the Museum of Practical Geography, Jermyn Street, London.

MIDDLETON, EARLS OF

is heavy, poor clay; but the rich alluvial soil of the Thames Valley is specially suitable for market gardens. On the outskirts of London many nail yards were formed, devoted to market gardening. The intolerance of livestock decreases; in fact, agriculture as a whole has slowly to give place to extension of building. Industries are extensive and varied. The county is traversed, in various directions, by the following companies, from east to west and south, affording communications: Great Eastern, Great Northern, Midland, London & North-Western, London & North, Metropolitan, Great Western, London & South-Western. Moreover, in some parts the tramway system has been extended over a wide area from London; thus Uxbridge, in the extreme west of the county, is served. The principal canals are the Grand Junction, running west from Brentford to the Colne Valley, and thence northward; with a branch (the Paddington Canal) connecting it with the Regent's Canal and the Thames. To this and, in the extreme west of Middlesex, which includes part of Essex, is mentioned in 1751, but the Middlesex portion was not subordinated into rural deaneries until 1857, when the deaneries of Fullham, Ealing, Uxbridge, Staines, Hampton, Enfield, Harrow and St Pancras were created. The deaneries of Chelsea, Hammersmith, Hampstead, Hornsey, Kensington, Paddington, St Marylebone, Westminster and Willesden were created later, but Staines was abolished.

In 1213 Middlesex was ravaged by William, earl of Salisbury, and Falkes de Breauté, and in the same year at Runnymede near Staines John went his way to the Barons. After the death of the 17th century Middlesex supported the Parliamentary cause, joining in 1642 with Hertfordshire and Essex in a petition that the votes of the bishops and popish lords might be disallowed in the House of Lords, and that the forts and castles of the kingdom might be placed in such hands as the Parliament could confide in. Sir Denzil Hollis was defeated by the Royalists at Brentford in 1642, and in 1645 a fruitless treaty between Charles I. and the Parliament was concluded at Uxbridge. Brentford had famous election contests in 1768 and 1769.

The woolen and leather industries flourished in Middlesex in early times; the place of slaughter, and hides were tanned at Enfield. Bricks were also manufactured from early times, and Heston was noted for its wheat. Paper was extensively manufactured in the 17th century, and much distress was caused in 1636 by a decree prohibiting the purchase of old rags for the Middlesex paper-mills for fear of the plague. In 1630 the manufacturers of mohair yarn in Middlesex appealed against a bill prohibiting the wearing of material made of the said yarn during the winter season. In 1655 a certificate of a hundred master tanners and other traders of Middlesex approved for their present mode of converting hides into leather by means of new liquor, with or without oak-barrel. Middlesex returned two members to parliament in 1695. (For the representation of London, see LONDON.)

See John Norden, Speculum Britanniae: the first part, an historical and chorographical description of Middlesex (London, 1593; reprinted 1637 and 1723); Daniel Lysons, The Environments of London (1792-1796); Victoria County History, Middlesex.

MIDDLETON, EARLS OF. John Middleton, 1st Earl of Middleton (c. 1619-1674), belonged to a Kincardineshire family which had held lands at Middleton since the 12th century. In early life he served as a soldier in France; later he fought against Charles I. both in England and in Scotland, being especially prominent at the battle of Philiphaugh and in other operations against the great Montrose. He held a high command in the Scottish army which marched to rescue the king in 1648, and he was taken prisoner after the battle of Preston. He joined Charles II. when that monarch reached Scotland in 1650, but he was soon at variance with the party which at that time was dominant in church and state; and was only restored to favour after doing a public penance at Dundee. He was a captive for the second time after the battle of Worcester, where he commanded the Royalist cavalry, but he escaped from the Tower of London to Paris. In 1655 Middleton was chosen by Charles II. to head the projected rising in Scotland. He reached that country in February 1654, but the insurrection was a complete failure. Its leader, who cannot be held responsible for this result, remained in Scotland until 1655, when he rejoined Charles II., who made

farm for £300, with power to elect a sheriff from among their number, and by charter from John the shrievalty of both London and Middlesex was granted to the mayor and citizens in fee. By charter of 1344 common plans for the county of Middlesex were ordered to be held at the stone cross in the Strand. Under a charter of 1447 the lord mayor was authorized to nominate one of the city aldermen as justice of the peace for Middlesex. The six modern hundreds of Edmonton, Elthorne, Gore, Isleworth, Osulston, and Spelthorne have been scarcely changed since the Domesday Survey, except that Islworth was then Honeslaw (Hounslow), while in the 12th century hidge a hundred of "Mimes" is mentioned, corresponding with the Domesday hundred of Edmonton. Middlesex has always been included in the kingdom of Kent. Middlesex, which includes part of Essex, is mentioned in 1571, but the Middlesex portion was not subordinated into rural deaneries until 1857.

MIDDLETON, EARLS OF. John Middleton, 1st Earl of Middleton (c. 1619-1674), belonged to a Kincardineshire family which had held lands at Middleton since the 12th century. In early life he served as a soldier in France; later he fought against Charles I. both in England and in Scotland, being especially prominent at the battle of Philiphaugh and in other operations against the great Montrose. He held a high command in the Scottish army which marched to rescue the king in 1648, and he was taken prisoner after the battle of Preston. He joined Charles II. when that monarch reached Scotland in 1650, but he was soon at variance with the party which at that time was dominant in church and state; and was only restored to favour after doing a public penance at Dundee. He was a captive for the second time after the battle of Worcester, where he commanded the Royalist cavalry, but he escaped from the Tower of London to Paris. In 1655 Middleton was chosen by Charles II. to head the projected rising in Scotland. He reached that country in February 1654, but the insurrection was a complete failure. Its leader, who cannot be held responsible for this result, remained in Scotland until 1655, when he rejoined Charles II., who made
MIDDLETON, A.—MIDDLETON, C.

him an earl in 1636. He returned to England with the king in 1660 and was appointed commander-in-chief of the troops in Scotland and lord high commissioner to the Scottish parliament, which he opened in January 1661. He was an ardent advocate of the restoration of episcopacy, this being one reason which led to serious dissensions between the earl of Lauderdale and himself, and in 1663 he was deposed of his office. He was Afterwards (1667) governor of Tangier, where he died in June 1674.

His eldest son CHARLES, 2nd Earl of MIDDLETON (c. 1640-1710), held several offices under Charles II. and James II., being envoy extraordinary at Vienna and afterwards joint secretary for Scotland. In 1684 he became an English secretary of state, and with Richard Graham, Viscount Preston, he had the difficult task of managing the House of Commons for James II. He was loyal to James after the king fled to France, although he remained in England. Where, as the leader of the moderate Jacobites, he sought to bring about a restoration by peaceful means. In 1693 the earl joined the exiled king at St Germaines, where he became his secretary of state; afterwards he held the same office at the court of James Edward, the old pretender, in Flanders and in Lorraine. He was partly responsible for the unsuccessful expedition of the Jacobites to Scotland in 1707, and he resigned his office as secretary in 1713. MIDDLETON, who had been created Earl of Monmouth by the pretender, died in 1719. His titles had been declared forfeited in 1695, but they were claimed by his son John, who died unmarried about 1746. The earl was a Protestant, and it is said that he made the dying wish of James II. and joined the Roman Catholic Church.

One of MIDDLETON's kinsmen was Sir CHARLES MIDDLETON, Bart. (1726-1813). Having served in the navy MIDDLETON was comptroller of the navy from 1778 to 1790, "standing out through that period of inertia administration as the pillar of the service." In April 1805, at a most critical time, he was, although eighty years of age, appointed first lord of the admiralty by Pitt and was created Lord Barham. It has been usual to regard Barham as a cipher at the admiralty board, but more recent research, especially an examination of the Barham Papers, has proved this to be the reverse of the truth. He enjoyed the absolute confidence of Pitt, and it was his experience, industry and energy which made possible the great campaign which ended at Trafalgar. He resigned office in January 1806 and died on the 17th of January 1813. His barony passed through his daughter Diana (1762-1823) to the Noels, earls of Gainsborough, by whom it is still held. The *Barham Papers* are being edited by Sir J. K. Laughton (vol. i. 1907; vol. ii. 1910). See also J. S. Corbett, *The Campaign of Trafalgar* (1910).

MIDDLETON, ARTHUR (1742-1787), American politician and signer of the Declaration of Independence, was born at MIDDLETON Place on the Ashley river, South Carolina, on the 26th of June 1742. His family was one of the most prominent in the colony. The grandfather, Arthur Middleton (1681-1737), was president of the Council in 1721-1730 and as such was acting governor in 1725-1730, and the father, Henry Middleton (1717-1784), was speaker of the Assembly in 1745-1747 and again in 1754-1755, a delegate to the Continental Congress in 1774-1776, and its president. The Middletons must have been on the Carolina Committee of Safety, and in 1775 president of the South Carolina Provincial Congress. Like most wealthy South Carolinians of the 18th century, Arthur Middleton was educated in England—at Hackney, at Westminster School, and at St John's College, Cambridge. He then returned to South Carolina, but soon afterwards went back to England to live, and travelled on the Continent. In 1773 he again returned to South Carolina, and in the controversies between the colonists and the home government became a leader of the Whigs. He was a member of the provincial Council of Safety in 1775-1776, and a delegate to the Continental Congress in 1776-1777. In 1778 he was elected governor of South Carolina, but owing to his dissatisfaction with the new state constitution he declined to serve. He was captured by the British at Charleston in May 1780, was exchanged in July 1781, was again a delegate to Congress in 1781-1783, and later served in the state legislature. He died on the 1st of January 1787 at MIDDLETON Place, near Charleston.

His eldest son, HENRY MIDDLETON (1770-1846), was an orator of ability, was governor of South Carolina in 1810-1812, a representative in Congress in 1813-1819, and the United States minister to Russia from 1820 to 1830, negotiating in 1824 a convention "relative to navigation, fishing and trading in the American Ocean, and to the establishments on the North-West Coast.

This was the first treaty between the United States and Russia.

MIDDLETON, CONYERS (1683-1750), English divine, was born at Richmond in Yorkshire on the 27th of December 1683. He graduated at Cambridge, took orders, and in 1706 obtained a fellowship, which he soon resigned upon contracting an advantageous marriage. In 1717 a dispute with Richard Bentley, who made an extortiionate demand on the occasion of MIDDLETON's being created D.D., involved him in an acrimonious controversy. He wrote several trenchant pamphlets, among them the "Remarks" and "Further Remarks" on Bentley's Proposals for a New Edition of the Greek Testament, an endeavour to visit his grievances upon the text of the New Testament. In 1723 he was involved in a lawsuit by personalities against Bentley, which had found their way into his otherwise judicious tract on library administration, written on the occasion of his appointment as university librarian. In 1726 he offended the medical profession by a dissertation contending that the healing art among the ancients was only exercised by slaves or freedmen. Between the dates of these events MIDDLETON had been the first printer to publish the pagan origin of church ceremonies and beliefs which he subsequently embodied in his Letter from Rome (1729). This cogent tract probably contributed to prepare the storm which broke out against him on his next publication (1731). In his remonstrance with Daniel Waterland on occasion of the latter's reply to Matthew Tindal's Christianity as Old as the Creation, MIDDLETON takes a line which in his day could hardly fail to expose him to the reproach of infidelity. He gives up the literal truth of the primeval Mosaic narratives; and, in professing to indicate a short and easy method of confuting Tindal's principal stress on the indispenasblessomeness of Christianity as a mainstay of social order. This was to resign nearly every thing that divines of the Waterland staff thought worth defending.

MIDDLETON was warmly assailed from many quarters, and retreated with some difficulty under cover of a sheaf of apologetic pamphlets and a more regular attendance at church. His next important publication was a Life of Cicero (1741), largely told in that statesman's own words. Though MIDDLETON's reputation was much enhanced by this piece of work, there is no doubt that he drew largely from the scarce book of Wilmot Bellenden, De tribus luminibus Romanorum. The work was undertaken at the instance of Lord Hervey, in correspondence with whom also originated his disquisition on The Roman Senate, published in 1747. The same year and the following produced the most important of all his writings, the Introductory Discourse and the Free Inquiry "concerning the miraculous powers which are supposed to have subsisted in the church from the earliest ages." In combating this belief MIDDLETON indirectly established two propositions of capital importance. He showed that ecclesiasticism was an experiment and that every religious doctrine must be distinguished between the authority due to the early fathers' testimony to the beliefs and practices of their times, and their very slender credibility as witnesses to matters of fact. Some individual grudge seems to have prompted him to expose, in 1750, Bishop Sherlock's eccentric notions of antediluvian prophecy, which had been published 25 years before. On the 28th of July 1750 he died at Hildersham, near Cambridge.

MIDDLETON's most ambitious work is obsolete from no fault of his, but his controversial writings retain a permanent place in the history of opinion lately from the scarce sphere of what is not inappropriately be compared with Lessing. Like Lessing's, the character of his intellect was captious and iconoclastic, but redeemed from mere negation by a passion for abstract truth, too apt to slumber until called into activity by some merely personal stimulus. His diction is generally masculine and
harmonious. Pope thought him and Nathaniel Hooke the younger the only prose writers of the day who deserved to be cited as authorities on the language. Samuel Parr, while exposing his plagiarisms, heaps encomiums on his style. But his best qualities, his importance of superstition and disdain of mere exactness of expression, are rather moral than literary.

The best general view of his intellectual character and influence is to be found in Sir Leslie Stephen's English Thought in the Eighteenth Century, ch. vi. A handsome edition of his works, containing several posthuma...
Authorities.—His works were edited by Alexander Duce (5 vols.) in 1840, and more fully introduced by many others. He was born and by A. H. Bullen (8 vols.) in 1885. The Best Plays of Thomas Middleton were edited for the Mermaid series (1887) by Havelock Ellis with an introduction by A. C. Swinburne. See also Miss P. C. Wiggin's Index to the Authorship of the Middleton-Range Plays (Boston, 1897), and the notice on Middleton in Professor A. W. Ward's Hist. of Engl. Dram. Lit. (ed. 1899; ii., 493–540), which contains a full account of Middleton's Contenent. A careful examination of the parallelisms between the plays of Shakespeare and Middleton is made by D. Hugo Jung in "Das Verhältnis Thomas Middletons zu Shakespare" (Münchener Beiträge zur roman. u. engl. Phil. vol. xxix., 1904).

MIDDLETON, a market town and municipal borough in the Middleton parliamentary division of Lancashire, England, on the Irk, near the Rochdale Canal, and on the Lancashire & Yorkshire railway, 6 m. N.N.E. from Manchester. Pop. (1901), 25,178. The church of St Leonards is of mixed architecture, with a low square tower. The oldest portion of the building (the tower arch) dates from the 12th century, but the main portion from 1412, and the south aisle from 1524. Two chapels in it contain memorials of, and are named after, two ancient Lancashire families, the Asshetons and the Hopwoods. The Queen Elizabeth grammar-school, a building in the Tudor style, was founded in 1572 by Nowell, dean of St Paul's, London. There are a handsome town-hall and municipal technical schools. An extensive system of tramways and electric light railways connects the town with the suburbs and adjacent industrial centres. The prosperity of the town dates from the introduction of manufactures at the close of the 18th century. The staple trade is the spinning and weaving of cotton, and the other industries include silk weaving, calico-printing, bleaching, dyeing, iron-founding and the manufacture of soap and chemicals. There are collieries in the neighbourhood. The town was incorporated in 1886, and the corporation consists of a mayor, 6 aldermen and 18 councillors. Area, 4775 acres.

MIDDLETOWN, a city and the county-seat of Middlesex county, Connecticut, U.S.A., in the township of Middletown, in the south-central part of the state, on the west bank of the Connecticut river, about 30 m. from its mouth, and about 15 m. south of Hartford. Pop. (1890), 9013; (1900), 9589, of whom 2316 were foreign-born; (1910 census) 11,831. Within a radius of 2 m. from the city hall there was found in 1910 most of the township's population of 20,749. The city is served by two branches of the New York, New Haven & Hartford railroad, by a line of coast steamers, and by electric lines connecting with neighbouring cities and villages. The city is connected by a long highway bridge with the village of Portland & adjacent industrial centres. The prosperity of the town dates from the introduction of manufactures at the close of the 18th century. The staple trade is the spinning and weaving of cotton, and the other industries include silk weaving, calico-printing, bleaching, dyeing, iron-founding and the manufacture of soap and chemicals. on the London & North Western railway. Pop. (1901), 4,669. It lies in open country near the river Dane, having water communications by the Trent and Mersey canal, and a branch giving access to the Shropshire Union canal. The church of St. Michael and All Angels is of various periods and contains numerous monuments. In the streets not a few old buildings remain, making for picturesqueness, and a number of the fine timbered houses in which Cheshire abodes are seen in the immediate neighbourhood. Middlewich shares in the salt industry common to several towns, such as Northwich and Winsford, in this part of the county; there are also chemical works and a manufacture of condensed milk.

**Midhat Pasha** (1822–1884), Turkish statesman, the son of a civil judge, was born at Constantinople in 1822. His father, a declared partisan of reform, trained him for an administrative career, and at the age of twenty-two he was attached as secretary to Falk Effendi, whom he accompanied in Syria for three years. On his return to Constantinople Midhat was appointed chief director of confidential reports, and after a new financial mission in Syria was made second secretary of the grand council. His enemies, however, succeeded in ostracizing him from this post, and caused him to be entrusted with the apparently impossible task of settling the revolt and brigandage rampant in Rumelia. His measures were drastic and his success was startling. The government made him an official of the first rank and restored him to his place in the grand council. In similar vigorous fashion he restored order in Bulgaria in 1857. In 1860 he was made vizier and pasha, and entrusted with the government of Nisch, where his reforms were so beneficial that the sultan charged him, in conjunction with Fuad Pasha and Ali Pasha, to prepare the scheme for adapting them to the empire which was afterwards known as the law of the vilayets. After further administrative work in his province, he was ordered to organize the council of state in 1866, and was made governor of Bagdad, where his success was as complete, he having attended with much greater difficulties. In 1871 the anti-reform influence of the grand vizier, Mahmoud Nedim, seemed to Midhat a danger to the country, and in a personal interview he boldly stated his views to the sultan, who was so struck with their force and entire disinterestedness that he appointed Midhat grand vizier in place of Mahmoud. Too independent, however, for the court, Midhat remained in power only three months, and after a short governorship of Salonica he lived apart from affairs at Constantinople until 1875.

From this time forward, however, Midhat Pasha's career resolved itself into a series of strange and almost romantic adventures. While sympathizing with the ideas and aims of the "Young Turkey" party, he was anxious to restrain its impatience, but the sultan's obduracy led to a coalition between the grand vizier, the war minister and Midhat Pasha, which deposed him in May 1876, and he was murdered in the following month. His nephew Murad V. was in turn deposed in the following August and replaced by his brother, Abdul Hamid II. Midhat Pasha now became grand vizier, reforms were freely promised, and the Ottoman parliament was inaugurated with a great flourish. In the following February, however, Midhat was dismissed and banished for supposed complicity in the murder of Abdul Aziz. He then visited various European capitals, and remained for some time in London, where he carefully studied the procedure in the House of Commons. Again recalled in 1878, he was appointed governor of Syria, and in August exchanged offices with the governor of Smyrna. But in the following May the sultan again ordered him to be arrested, and although he effected his escape and appointed the powerful Vizier subsequently saw fit to surrender, claiming a fair hearing. The trial accordingly took place in June, when Midhat and the others were sentenced to death. It was, however, generally regarded as a mockery, and on the intercession of the British government the sentence was commuted to banishment. The remaining three years of his life were consequently spent in exile at Taif in Arabia, where he died, probably by violence, on the 8th of May 1884. To great ability, wide sympathies, and undoubted patriotism he added absolute honesty, that rare quality in a vizier, for he left office as poor as when he entered it.

**Midhurst** is a market town in the north-western portion of the county, 12 m. N. by E. of Chichester by the London, Brighton & South Coast railway; served also by the London & South Western railway. Pop. (1901), 7,674. It is pleasantly situated on slightly rising ground near the river Rother. The church of St Mary Magdalene and St Denis is a large Perpendicular building. The town retains several picturesque old houses, and in the vicinity, by the river, are the ruins of the 16th century mansion of Cowdray, burnt down in 1793. A grammar-school was founded at Midhurst in 1672 and attained some eminence. After being closed for many years it was re-opened in 1858. In 1860 the first specimens of the cotton manufacture were opened about 4 m. from Midhurst; it bears the name of King Edward VII., who laid its foundation stone and opened it.

The name of Midhurst (Middeherset, Mudhurst) first occurs in the reign of Henry I. when Savaric Fitz-Cana held it of the honour of Arundel, then presumably in the king's hands. The charter of Henry I., although no longer extant, is quoted in later confirmation charters of Richard I., Henry III., Edward III. and Richard II., and in the reign of Edward III. the town was released from taxation by the order of the king, and in consequence a new charter was granted by the shire of the same name, and the burgesses were further favoured by it. In the reign of Henry VI. a market was held by the burgesses every Thursday, and a fair on Whit-Tuesday, by grant from Sir John Bohun. In 1888 the fair-days were the 6th of April, the 9th of May and the 29th of October. The market-day was Thursday. Pleasure-fairs are still held on the 6th of April and the 29th of October, but there is no market.

**Midian** (properly Madyan, so Sept., in the Bible, one of the peoples of North Arabia whom the Hebrews recognized as distant kinmen, representing them as sons of Abraham's wife Keturah (Gen. xxv. 1-2). Thus the sons of Keturah are the "incense-men," not indeed inhabitants of the far south incense-land, but presumably the tribes whose caravans brought the incense to Palestine and the Mediterranean ports. So the Midianites appear in connexion with the gold and incense trade from Yemen (Isa. lx. 6), and with the trade between Egypt and Syria (Gen. xxxvii. 28, 36). They appear also as warriors invading Canaan from the eastern desert, and ravaging the land as similar tribes have done in all ages when Palestine lacked a strong government (see GIDEON). Again, they are described as peaceful shepherds, and the pastures of the Midianites, or of the branch of Midian to which Moses's father-in-law (Jethro or Reuel, or Hobab) belonged, lay near Mount Horab (Exod. iii. 1). The Kenites who had friendly relations with Israel, and are represented in Judg. i. 16, iv. 11, as the kin of Moses's father-in-law, appear to have been but one fraction of Midian which took a separate course from their early relations to Israel.1 Balaam, according to one version of the story, was a Midianite (Num. xxii. seq.) and his association with Moab has been connected with the statement in Gen. xxxvii. 35, that the Edomite king Hadad defeated Midian in the land of Moab; see Balaam, Edom.

1 The admixture of Midianite elements in Judah and the other border tribes of Israel is confirmed by a comparison of the names of the Midianite clans in Gen. xxv. 4 with the Hebrew genealogies (1 Chron. ii. 46, Ephah; iv. 17, Ephah; Gen. xlviii. 19, Hancho). Ephah is also associated with "Of near Ijarkiyya (Hancho), three miles from Medinah, with Medinah a Bedouin locality mentioned by Assur-bani-pal. Ephah probably is the Hayaya transported by Sargon to Beth-omni (Samaria).
A place Midian is mentioned in 1 Kings xi. 18, apparently between Edom and Paran, and in later times the name lingered in the district east of the Gulf of 'Akaba, where Eusebius knows a city Miamis in the country of the Saracens and Potlemy (v. 7) places Midiana. Still later Madiyan was a station on the pilgrim route from Egypt to Mecca, the second beyond Aila (Elath). Here in the middle ages was shown the well from which Moses watered the flocks of Shoaib (Jethro), and the place is still known as “the caves of Shoaib.” It has considerable ruins, which have been described by Sir R. Burton (Land of Midian, 1879).

This district which has on its east Taímá, a centre of civilization in the 9th century B.C., and on its south-east El-'Ola which existence as a seat of culture is possibly even older, is identified some scholars with the Madinat al-Mamari, the Madinat al-Mamari or Madinat al-Mamari of the Arabian geographers, and the Madinat al-Mamari or Madinat al-Mamari of the Saracens, Yemen. This part of north-west Arabia had frequent intercourse with Palestine appears, certainly from its commercial relations with Gaza; and the association of the Madianite Jethro with early Hebrew legislation, as also the possibility that Miamis (“Egypt”) in the Old Testament should be taken in some cases to refer to this district, have an important bearing upon several Old Testament questions. See MIA MI A.

MIDLETON, WILLIAM ST JOHN FREM ANTE B RODRICK, 9TH VISCOUNT (1856- ), English politician, was the son of the 8th viscount (1830-1907). He came of a Surrey family who in the 17th century, in the persons of Sir St John Brodrick and Sir Thomas Brodrick, obtained grants of land in the south of Ireland. Sir St John Brodrick settled at Midleton, between Cork and Youghal in 1641; and his son Alan Brodrick (1660-1728), speaker of the Irish House of Commons and lord chancellor of Ireland, was created Baron Brodrick in 1715 and Viscount Midleton in 1717 in the Irish peerage. In 1796 the title of Baron Brodrick in the peerage of the United Kingdom was created. The English family seat at Peper Harow, near Godalming, Surrey, was designed by Sir William Chambers. The 8th viscount was a Conservative in politics, who for a few years had a seat in the House of Commons, and who was responsible in the House of Lords for carrying the Infants Protection Act. His brother, the Hon. G. C. Brodrick, was for many years warden of Menton College, Oxford. As Mr St John Brodrick, the 9th viscount had a distinguished career in the House of Commons. After being at Eton and Balliol, Oxford, and serving as president of the Oxford Union, he entered parliament as conservative member for one of the Surrey divisions in 1880. From 1886 to 1892 he was financial secretary to the war office; under secretary for war, 1893-1898; under secretary for foreign affairs, 1898-1900; secretary of state for war, 1900-1903; and secretary of state for India, 1903-1905. He lost his seat for the Guildford division of Surrey at the general election of January 1906. In March 1906 it was announced that he had been created a viscount. He married, first in 1880, Lady Hilda (d. 1901), daughter of the 9th earl of Wemyss, by whom he had a family; and secondly in 1903, Madeleine Stanley, daughter of Lady St Helier by her first husband.

MIDLETON, or MIDDLET ON, a market town of Co. Cork, Ireland, on the river Owenacurra, 13 m. E. of Cork by the Youghal branch of the Great Southern & Western railway. Pop. (1901), 3,361. The river here enters a branch of Cork harbour. The surrounding hilly country is pleasant and fertile, and furnishes the town with a good agricultural and dairy produce, and also whisky-distilleries. Ballinscurrach, 13 m. south on the estuary, serves as a small port. The grammar school was founded in 1696, and here among its students were John Philip Curran and Isaac Butt. Midleton is governed by an urban district council.

MIDNAPORE, a town and district of British India, in the Burdwan division of Bengal. The town is 68 m. W. of Calcutta; it has a station on the Bengal Nagpur railway. Pop. (1901), 33,140. It is an important centre of trade, being the terminus of a navigable canal to Calcutta, and also the junction for the Sini branch of the Bengal-Nagpur railway. There are manufactures of brass and copper wire. It has an American mission, a municipal college, and a public library founded in 1852.

The district of Midnapore has an area of 5,866 sq. m. The general appearance is that of a large open plain, of which the greater part is under cultivation. In the northern portion the soil is poor, and there is little wood. The country along the western boundary, known as the Jungle Mahals, is undulating and picturesque; it is almost uninhabited. The eastern and south-eastern portions are swampy and richly cultivated. The chief rivers of the district are the Hugli and its three tributaries, the Rupnarayan, the Haldi and the Rasulpur. The Midnapore high-level canal used also for irrigation runs almost due east and west from the town of Midnapore to Ulubaria on the Hugli 16 m. below Calcutta, and affords a continuous navigable channel 53 m. in length. There is also a tidal canal for navigation, 26 m. in length, extending from the Rupnarayan river. The district is traversed as well by the Bengal-Nagpur railway towards Orissa, with a branch to Chota Nagpur. The jungles in the west of the district yield lac, tussur, silk, wax, resin, fire-wood, chinchalik, &c., and give shelter to large and small game. The principal exports are rice, silk and sugar; and the chief imports consist of cotton cloth and twist. Salt, indigo, silk, mats and brass and copper utensils are manufactured. Both silk and indigo are decaying industries. The population in 1901 was 2,759,114, showing an increase of 6% in the decade.

The early history of Midnapore centres round the ancient town of Tamulk, which in the beginning of the 5th century was an important Buddhist settlement and maritime harbour. The first connexion of the English with the district dates from 1760, when Mir Kasım ceded to the East India Company Midnapore, Chitta- nagar, and Burdwan (then estimated to furnish one-third of the entire revenue of Bengal) as the price of his elevation to the throne of Bengal on the deposition of Mir Jafar.

MIDRASH, a very common term in Jewish writings for "exposition" and a certain class of expository literature. The word also occurs twice in the Old Testament (2 Chron. xiii. 22, xxiv. 27; R.V. rather poorly "commentary").

1. Introduction.—The term (Heb. midrash from διαραβ "to search out, enquire") denotes some explanation or exposition, which, in contrast to the more literal exegesis (technically called peshat or "simple"), endeavours to reach the spirit lying behind the text. It may be defined as a didactic or homiletic development of some thought or theme, characterized by a more subjective, imaginative and ampliative treatment. Jewish Midrash falls broadly into two classes: Halakha (q.v.) or Halakah (walking, way, conduct) and Haggadah (narrative with a purpose, homily; Aramaic equivalent Aggadah; the incorrect form Agadoh rests upon a mistaken etymology). The former dealt with legal and ritual matters; it flourished in the schools and developed into the most subtle casuistry. The latter covered all non-halakic topics, and was essentially founded in the Haggadah (narration with a purpose), which, although it complicates the interpretation of the Old Testament, and it had a more spiritual and ethical tone than the Halakha. In both classes, accepted tradition (written or oral) was reinterpreted in order to justify or to deduce new teaching (in its widest sense), to connect the present with a hallowed past, and to be a guide for the future; and the prevalence of this procedure, the immense number of examples of its working, and the particular application of the term Midrash to an important section of Rabbinical literature complicates both the study of the subject and any attempt to treat it concisely. Apart from the popular paraphrastic translations of the Old Testament (see Targum), the great mass of orthodox Rabbinical literature consists of (1) the independent Midrashim, and (2) the Mishnah which, with its supplement the Gēmara, constitutes the Talmud. Both contain Halakha and Haggada, although the Mishna itself is essentially Halakha, and the Midrashim are more especially Haggadic; and consequently further information bearing upon Midrash must be sought in the art, Talmud. These two articles...
MIDRASH

2. midrash or Midrash.—Of the three different kinds of historical writing—the genetic or scientific, the purely narrative and the pragmatic—it is the last which has prevailed among religious historians. It is extremely difficult to avoid the subjective element in dealing with matters of fact, and the religious treatment of history is influenced, however unconsciously, by the mental environment of the writers. In giving greater prominence to events of religious importance and to their bearing upon the spiritual needs of contemporaries they view and interpret the past in a particular light, and will see in the past those growths which only in their own time have become mature. A latent significance is found, a particular connexion is traced, and a continuity is established, the true nature of which must be tested by critical students. Now, it is subjective history which we find in the earliest references to Midrash. The Midrash of the prophet Iddo (2 Chron. xxii) like the Visions and the Histories of Idde and Shemariah (lx. 29, xii. 15) which are quoted for the lives of Solomon, Abijah and Jeroboam, are evidently quite distinct from the sources which are in the parallel portions of the earlier compilation, and the entire spirit of the narratives is different. Similarly, there is a conspicuous difference of treatment of the life of Joash in 2 Kings xi seq., compared with 2 Chron. xxiii seq., which refers to some Midrash of the Book of the Kings (xxiv. 27). Although it is uncertain whether this comprehensive Midrash also included the "books of the Kings" (xvi. 11, xxvii. 7, &c.), and the Midrash of Iddo and other related works, it is clear that the Book of Chronicles (q.e.) marks a very noteworthy advance upon the records in the (canonical) Books of Kings (q.e.). It is now recognized that the compiler of the former has used many novel narratives of a particular edifying and didactic stamp, and scholars are practically unanimous that these are subsequent to the age of the Israelite monarchy and present a picture of historical and religious conditions which (to judge from earlier sources) is untrustworthy. At the same time various details (as comparison with the Book of Kings shows) are relatively old and, on a priori grounds, it is extremely unlikely that the unhistorical elements are necessarily due to deliberate imagination or perversion rather than to the development of habits of thought. The religious significance of the Book of the earlier compilation, and the past is idealized from a later standpoint; and whether the narratives in Chronicles are expressly styled Midrash or not, they are the fruit of an age which sought to inculcate explicitly those lessons which, it conceived, were implied in the events of the past. The value of the book lay not in history for its own sake, but in its direct application to present needs. But the tendency to reshape history for the edification of later generations was no novelty when Chronicles was first compiled (about 4th cent. B.C.). Pragmatic historiography is exercised most continuously in the "apocalyptic" or "apocryphal" writers, i.e. allied to Deut., especially the secondary portions; and there are many relatively early narratives in which the details have been modified, and the heroes of the past are the mouthpiece for the thought of a later writer or of his age. Numerous instructive examples of the active tendency to develop tradition may be observed in the relationship between Genesis and the "Book of Jubilees," or in the embellishments of Old Testament history in the Antiquities of Josephus, or the filling gaps in the diverse traditions of the famous figures of the Old Testament, Adam, Noah, Enoch, Abraham, Moses, Isaiah, Ezra, &c., as they appear in non-canonical writings. In such cases as these one can readily perceive the different forms which the same material elements have assumed, and one may distinguish the unreliable accretions which are clearly later and secondary. Accordingly, when there are narratives which cannot be tested in this manner, they show all the internal marks of didactic expansion and date from an age much later than the times with which they deal, their immediate value is not necessarily lost in the details which appear to be both historical and literary, but in their context with the traditions and phases of thought. So far then, Midrash tends to include moralizing history, whether we call it narrative or romance, attached to names and events, and it is obviously exemplified whenever there are unmistakable signs of untrustworthy amplification and of some explicit religious or ethical aim colouring the narrative. This, however, is only one of the aspects which have to be taken into consideration when one advances to the Rabbinical Midrash.

3. Continuity of Literature and Material.—Amid obscure vicissitudes in the 7th to 5th centuries, B.C., the Canonical books of the Old Testament gradually began to assume their present shape (see Palestine: History). The internal peculiarities show that the compilations are much edited remains of a larger body of literatures, and it may reasonably be supposed that the older sources did not at once perish. There is literary critical evidence for late insertions by exilic or later compilers;¹ the compiler of Chronicles apparently refers to accessible works; and there is a close material relationship between the Old Testament and later literature. All this suggests that Old Hebrew writings, apart from those preserved in the Canon, persisted to a relatively late period. No a priori distinction can be made, and no precise chronological line can be drawn between the books of the Canon (Canticles, Ecclesiastes, Esther, Ezekiel, and Proverbs had been at one time or other subjects of debate among the Rabbis), and the Apocrypha (Ethiopic, Judith, Maccabees and Tobit, were "allowed"); and the intimate relation between them appears in the character of the "Wisdom Literature" (e.g. Proverbs, and the Wisdom of Solomon), in the treatment of the stories of Esther and Daniel (the history of Susanna), and also in the twofold recensions Ezra and 1 Eadras. Historical or narrative Midrash is exemplified in the "canonical" books Daniel, Esther, Jonah and Ruth, and in the "apocryphal" stories of Daniel (viz. Susanna, where the point lies in the name Daniel God is judge "); Esther, Judith, Tobit (and the Ahitig 1 Eadras); and in the "Mishna" (see History of Jew. and Christian Literature, iii. 37 seq. and commentaries on Chronicles). This, however, is not the place to notice the course of Jewish literary activity in Palestine or anywhere else. Whether the more rigid lines of Pharisianism (the development of the canonical "priestly" law) or the popular and less scholastic phases, which recall the earlier apocalyptic tendencies of the Old Testament and were cultivated alike by early Jewish and Christian writers. But after the fall of Jerusalem, partly through the need for systematising the traditional post-biblical law, and partly through disputes among the Christians, orthodox Rabbinism received the stamp which has since characterized it. The traditional or oral law was codified in the Mishna (see Talmud, §1 seq.), the Canon was

¹ E.g. Judg. i. (see G. F. Moore, Enzy. Bib. "Historical Lit.", col. 2085, middle), 2 Sam. ix.-xx., &c.
fixed, and the fluctuations in the MSS. of the Old Testament (which, like the numerous variations in the Septuagint, complicated exact exegesis) gave way to what was virtually a single text. Moreover, the important body of apocryphal and pseudopigraphical literature, with all its links between Christianity and Judaism, fell into disfavour on both sides. This literature was especially valuable because it illustrates contemporaneous Hellenistic Jewish thought, and indicates the degree of Hellenistic thought with which Jesus and his followers were familiar; it thus fills the gap between the Old Testament and the authoritative Rabbinical Midrashim which, though often in a form several centuries later, not rarely preserve older material.

A few miscellaneous examples of related Midrashic details may be quoted.

i. The book of Jubilees (a haggadic and halakic Midrash on Genesis, about 2nd century a.c.), contains the story of the war between Amorite Kings and Jacob (ch. xxxiv). This is known to the probably contemporary Testament of Judah and to much later Midrashim (Mid. Wayyiqtol, Vayiqtol Shemiotei, also the apocryphal "Book of Jashar"). It is evidently connected with the cryptic allusion to the capture of Shechem in Gen. xxviii. 22 (R.V. marg.). Unless we suppose that the latter was suddenly appended into the stories which thenceforth persisted, it may be inferred that an old extra-canonical tradition (for which a case can be made) continued to survive the compilation of Genesis (c.q.) and ultimately abridged, incorporated, and exaggerated to extend the probability of such a tradition—the merest hint of which happens to be preserved in Gen. loc. cit.—does not prejudice the problem of its origin or accuracy; in Jub. the story is useless for Jacob's history, and seems to have been composed by a recollection of more recent events in the Maccabean age.

ii. A curious account of war between Egypt and Canaan after Josephus (Jew. ed. x., viii., and xii., is connected with details (burial of Jacob's sons at Hebron) recorded by Josephus (Ant. ii. 8). Josephus in turn has another story in which Moses leads the Egyptians against Ethiopia (Ant. ii. 10) which parallels Hosea, Ex. i. 27, and this is found in the late chronicles of Jerahmeel and the Book of Jashar (cf. also Mid. Dibrah ha-yarmim shel-Moshke; see Jub. Ency. vi. 573 seq.). This narrative is first attributed to Moses (v. 9) (whereof certain charlatans and historians would invite speculation), and the latter with the Cushite wife; but although one may grant that the canonical sources do not by any means preserve all the older current traditions, the contents of the latter cannot be recovered from the later persisting Midrashim.

iii. The allusion in Jude v. 9 to the contention of the archangel Michael for the body of Moses belongs to a group of traditions which have been collected by K. I. Charles (Assumption of Moses, pp. 165 seq.), and it appears that the incident was familiar to Clement of Alexandria, Origen and other early writers. Moreover, Jude v. 13, referring to the story of the Transfiguration of Moses, which has other parallels in Matt. xxv. 29; Acts vii. 36, 38 seq. (ibid. pp. lixii. seq.). Here may be added Jannes and Jambres, who withstood Moses (2 Tim. iii. 8); these or related names were used by Philo in the first century (Jub. vii. 537 seq.), Origen (who refers to a book of Jannes and Mambres), and various earlier and later Jewish sources; see I. Abrahams, Ency. Bib. col. 3277 seq.; H. St. J. Thackeray, Religation of St Paul to Controversial Jewish Thought (London, 1900), pp. 75; MS. in Acts vii. 50 seq. The legends of his escape from a fiery furnace may have a philo-historical air (interpreted as "fire"), but the allusion to the redemption of Abraham xxii 22 seems to indicate that older tradition was fuller than the present account; and what is another example of the link connecting the Old Testament with Rabbinical thought.

v. Not to multiply examples further, it may suffice to refer to (a) the apparent belief that the serpent tempted Eve to unchastity (Gen. iii. 14 seq.); (b) the flight of the angels upon earth (Gen. vi. 1 seq.; Jude 6, 14 seq.); (c) the semblance of the angels upon earth (Gen. vi. 1 seq.; Jude 6, 14 seq.); Clermont-Ganneau, Quarti. Statements of the Pal. Explor. Fund, 1903, pp. 233 seq. and the later Ab. See; and (d) the numerous parallels to the in Midrashim, the development of the story of Esther in Josephus, the Greek and Old Latin Versions, the Targums and later Jewish sources (see L. B. Paton, Comm. on Esther, pp. 106 and passim); and finally (e) the numerous miscellaneous parallels noticed in recent annotated editions of the

pseudopigraphical literature (especially those of R. H. Charles). (See further Talmud, § 5.)

4. Midrashic Exposition.—The Talmud poetically describes Midrash as a hammer which wakens to shining light the sparks which slumber in the rock; and the simile is a happy one when one considers the exegetical implements, the workmen and their workmanship. For the expository or interpretative Midrash was bound up with rules and methods which often appear crude and arbitrary, they are nevertheless those of the age and they helped to build up lasting monuments. It was believed that the Western War had an infinite fulness; according to the Midr. Bemidbar Rabh every word of the Law had seventy different aspects, and Philo of Alexandria held that there are no superfluous words in Scripture. Consequently an exaggerated emphasis is often laid upon single words; as, for example, in the school of Rabbi 'Aqiba, where even individual letters were forced to reveal their meaning. Thus, since the Hebrew dh, which marks the accusative, is also the preposition with, Deut. x. 20 ("thou shalt fear [eth] Yahweh thy God") was interpreted to include the veneration of the doctors of the law along with Yahweh. Such examples of literal interpretation can of course be found, but arbitrary cases of the kind just noticed are due either to an obviously far-fetched interpretation or to the endeavour to find some authoritative support for teaching which it was desired to inculcate. Thus faulty proof rather than faulty inference is illustrated when the word "in—number" (Ex. x. 4) was used to confirm the Halakha that the man who killed the Passover Lamb must know how many people were about to share it (Jew. Ency. viii. 570). Often the biblical text cannot be said to supply more than a hint or a suggestion, and the particular application in Halaka or Haggada must be taken on its merits, and the teaching does not necessarily fall because the exegesis is illegitimate. To take another specimen: the Mekillo on Ex. xx. 25 infers from the unusual form of the word "it," that the prohibition of iron applies only to it, i.e. the altar, and not to stones used in building the temple. This Halakha is followed by a haggadic explanation of the prohibition: "iron abridges life while the altar prolongs it; iron causes destruction and misery, while the altar produces reconciliation between God and man; and therefore the use of iron cannot be allowed in making the altar." Such were the sparks that could be hammered out of the rock, and it is instructive to observe similar exegetical methods in the New Testament. Emphasis upon a single word is illustrated by Gal. iii. 16, where the argument rests upon the word "seed" (and not the plural "seeds") in the proof-text, and the same word in Rabbinical writings is used to support other arguments. By identical kinds of exegesis Lev. xii. 14 (not to put a stumbling block before the blind) is the ground for cautioning a father against striking an adult child, and Deut. xxiv. 4 (the law of the muzzled ox) is used to show that God's labourer is worthy of his hire. Again, since through Eve sin entered into the world, woman must be subordinate to man (1 Tim. ii. 11-14), or, she who has thus extinguished "the light of the world" should alone by lighting the festal candles on the sabbath (Talm. Skabb. 56).

By the allegorical method Isa. lxvi. is interpreted as applying to Jesus (Luke iv. 16-22), and frequently passages which originally had another application have a Messianic reference in

Mish. Sanhed. iv. 5, see A. Geiger, Zeit. f. morgenländ. Geschicht. 1858, pp. 307 seqq.; S. R. Driver, Expositor, ix. (1889), p. 18 seq. See also the Talmud Mō'ad Qatan, 7a, and New Testament (1 Cor. ix. 9, 1 Tim. vi. 18) respectively.
Christian and Rabbinical teaching. Similarly the application of Hos. ii. 23, not to the scattered tribes of Israel, but to the Gentiles, is common to the Mishna and to Romans ix. 25 seq. (Sanday and Headlam, Comment. ad loc.) The Apostle Paul, once a disciple of the famous Rabbi Gamaliel, uses in 1 Cor. x. 4 ("the spiritual rock that followed them in the desert") a famous Rabbinic Philo who had identified it with Wisdom or the Word of God. Moreover, not only are passages thus taken out of their context, but they are combined, especially when they contain the same words or phrases, or appear to have the same or similar thoughts or aims. The Talmud, with a reference toProv. xxxi. 14 ("she bringeth her food from afar"), says "the words of the Torah are poor (or deficient) in one place but rich in another." Hence in the Mid. Sifre on Numbers xv. 39, "ye shall not see after...your own eyes" is explained to refer to adultery, after the words of Samson "she is pleasing in my eyes" (Judg. xiv. 3); and on Deut. vi. 5 it charges man to love the Lord "with all thy soul...even if he should take away thy soul," the teaching being based upon Ps. xlv. 22. Similarly, in the New Testament, after the same method, Mal. iii. 1 and Is. xl. 3 (linked by the phrase "to prepare the way") are combined in Mark i. 2 seq.; Abraham’s faith (Gen. xv. 6) and temptation (xxxii. 1) are associated in James ii. 21-23, as also in contemporary Jewish thought, and by other quotations Paul enunciates the universality of sin (Rom. iii. 28 sq.) and the doctrine that Christians are God’s temple (2 Cor. vi. 16 sqq.). Proceeding upon such lines as these, the Jews wove together their Midrashic homilies or sermons where, though we may find much that seems commonplace, there are illuminating parables and proverbs, metaphors and similes, the whole affording admirable examples of the contemporary thought and culture, both of the writers and—what is often overlooked—the level of their hearers or readers. Like many less ancient discourses, the Midrashim are apt to seem when read in cold print, and they are sometimes judged from a standpoint which would be prejudicial to the Old Testament itself. But they are to be judged as Oriental literature and if they contain jarring extravagances and puerilities, one may recall that even in modern Palestine it was found that the natives understood Robinson Crusoe as a religious book more readily than the Pilgrim’s Progress (J. Robertson, Early Rel. of Israel, 1892, p. 66). In making allowances for the defects (without which they would probably not appeal to the age) it must be remembered that some of the Rabbinic teaching had been recognized that the Midrashic Haggada was not always estimable.

An interesting example of combined quotation is illustrated in Matt. xii. 4-8, where the teaching of Jesus on the law of the Sabbath rests upon 1 Sam. xxvi. 1-6, Num. xxviii. 9 seq. and Hos. vi. 6. Approps of this law the Rabbinic arguments are worth noticing. Apparently the severe rules laid down in Judæa (Matt. 12; 8-12 (sec R. H. Charles, ad loc.) were exceptional. It was allowed that the Sabbath need not be too rigorously kept, and this was justified by Exod. xxxi. 13, where the singular use of the restrictive particle ak (Ex. “verily”) supported the teaching that other Sabbaths need not be observed. Also, from the words “holy unto you” (v. 14) it was taught that the Sabbath is given to you to desecrate in case of need, but thou art not given to desecrate it. (Talm. Sabb. 199a). Also, the Passover Lamb could be sacrificed on the Sabbath, and justification for this was found in Num. ix. 2 “in its season” (Pesah, 606a). See further on this subject, and on the evasions of the Sabbath law S. Schechter, Studies in Judaism, pp. 297 seq.; ibid. in C. A. Monetofice, Hibbert Lectures (for 1892), Appendix; ibid. Hastings’ Dict. Bib., v. 63, and also S. R. Driver, Hastings’ Dict. iv. 320 seq. With regard to other quotations, cf. A. H. McNeile on Matt. xii. 5; John xii. 23; “the à priori elements in the Sifre...these verses were due to later reflection on the part of Christians who had realized the inadequacy of the law.” (Swete’s Camb. Bibl. Exeg. ii. 643 seq.) For other illuminating Rabbinical methods of exegesis in the New Testament, see McNeile, Camb. Bibl. Exeg. ii. 643 seq. (“Our Lord’s use of the Old Testament”); Briggs, op. cit. pp. 436.

5. The Jewish Midrashim.—The earlier stages in the growth of the extant Rabbinical Midrashim cannot be traced with any certainty. Although there are several allusions to early written works, other references manifest an objection to the writing down of Haggada and Halaka. Perhaps it was felt that to preserve uniformity of teaching in the schools it was undesirable to popularize the extant collections, or perhaps the references must be reconsidered in the light of those significant changes after the fall of Jerusalem which have been mentioned above (§ 3). However this may be, the independent Hâlâkôth (where the oral decisions are interpreted or discussed on the basis of the Old Testament, etc.) were grouped together and arranged according to their subject in the Mishnâh and Tôsaphôth (Talm., § 1), and in the halakic Midrashim (where the decisions are given in connection with the biblical passage from which they were derived) they follow the sequence of the text of the Old Testament. The Haggada was likewise collected according to the textual sequence of the Old Testament. But the sermons or discourses of the homiletic Midrashim are classified according to the reading of the Pentateuch in the Synagogue, either the three year cycle, or else according to the sections of the Pentateuch and Prophetic books assigned to special and ordinary Sabbaths which in course of time the latter are sometimes styled Pesiqta (“section”). The homiletic Midrashim are characterized by (a) a proem, an introduction based upon some biblical text (not from the lesson itself), which led up to (b) the exposition of the lesson, the first verse of which is more fully discussed than the rest. They conclude (c) with Messianic or consolatory passages on the future glory of Israel. A feature of some Midrashim (e.g. nos. 4, 5d, e, and 7 below) is the halakic exordium which precedes the proems.

Among the more important Midrashim are:—1. Maḥbûla (Aram. “measure,” i.e. “rule”) best known as the name of a now imperfect halakic Midrash on Exod. xii.–xxiii. 19 (also xxxi. 12-17 and xxxv. 1-3). It represents the school of R. (Rabbi) Ishmael, is a useful source for old Haggados (especially on the narrative portions of Exodus), and is interesting for its variant readings of the Canonical Text. E.g. Uloguins, Thes. Anto. Sacr. xiv. (Venice, 1744, with a poor Latin translation) by J. H. Weiss (Vienna, 1865) and M. Friedmann (ibid. 1870), German. trans. by J. Winter and A. Wunsche Leipzig, 1909). See further J. Z. Lauterbach, Jev. Ency. viii. 444 seq.

ii. Siphreh (Aram. “the book”) or Tôrath Kôdîmîm (“the law of the priests”), a commentary on Leviticus, mainly halakic, the text being a source for various maxims. On Lev. vii. 17 seq. neighbourly love and abstinence from vengeance constitute, according to R. Aqiba, the great principle of the Torah. It is useful for the interpretation of the Mishnah treatises Qodshim and Tahârûth. Latin. trans, by J. H. Weiss (Vienna, 1862), and with the commentary of Shimshon (Samson) of Siens (Warsaw, 1868); see Jev. Ency. xi. 350 sqq.

iii. Sêphêr (Aram. “the books”), an old composite collection of Halaka on Numbers, after R. Ishmael’s school; and on Deut. after that of R. Aqiba, although the haggadic portions belong to the former. Latin in Ulogi. xii.; recent edition, with good introduction by A. Elman (Vienna, 1864); see Jev. Ency. xi. 352 seq.

The above works, although of 5th century or later date in their present form, contain much older material, which was perhaps first redacted in the earlier part of the 2nd century, A.D. They are of

1. See on this point, Jev. Ency. viii. 549 seq., 552, 576; Schechter, op. cit. p. 62; Strack, op. cit. 62 seq. etc. In one case we need not doubt that the latter are sometimes stated.

2. See more fully Jev. Ency. viii. 553. Cf. for the structure, the helpful conclusively notes in the prophecies (e.g. Amos) and the discussion of the reading of the lesson from the prophets in Luke iv. 17 seq. Acts ii. 13 seq.

Palestinian origin, although the main reduction was made in Baby-
lonia.1

IV. Tanhûmâ, one of the oldest on the lessons of the Pentateuch, with the addition of R. Tanhûmâ, one of the most famous haggadists of Palestine (4th century), who systematized and fixed the haggadic literature. This collection of works is known as "Tânûmâ" (or "Tânûmâ") and the opening words, Yd. Râbhônâ ("our Rabbi teachers") on the questions connected with the titles and the present reduction (probably 3rd century), see Ḥun. Eyn. viii. 560 sqq., xii. 44 sqq. Extract edition by Buber (Wilna, 1886).

v. Midrash Rabbônâ (or Rabba), a large collection of very diverse origin, probably not completed before the 13th century. It covers the Pentateuch (tsi ed., Constantinople, 1512) and the Tanhûmâ, with the addition of R. Tanhûmâ, the first at Venice, 1545). Ger. trans. by A. Wûnsche, Bibliotheca rabbinica (Leipzig, 1880-1885). The several portions are named after the ordinary Jewish titles of the Old Testament books with the addition of Rabbônâ ("great"). These are (a) Bûdshôth ("in the beginning," Gen. 1. 1) Rabbônâ, on Genesis, the oldest and most valuable of aggadic Midrashim. Traditionally ascribed to R. Hôshakah (3rd century), but in the main a reduction of 6th century. Ed. J. Trexler see Ḥun. Eyn. vii. 626 sqq.; viii. 557 sqq. (K. Sinaih, "names" Exod. i. 1) R., a composite and incomplete work of 11th and 12th century, but valuable nevertheless for its Tanhûmâ. This is further divided into the continuation of (a). See Ḥun. Eyn. viii. 562 (c) Wûyyârî (and he called) R., on Leviticus, perhaps 7th century, based upon sources in a 2 and 56 ab. It is characterized by its numerous proverbs (e.g. Exod. ii. 6: "If a man lender to his fellow, he is not for the sake of a bad pup of a bad dog") See Ḥun. Eyn. viii. 560, xii. 476 sqq. (bii. Bûmidâr ("in the desert of ..") R., 33 homilies on Kings (including 24 above (though in an earlier text), with a later aggadic exposition, perhaps of 12th century, on Num. i.-vii. See Ḥun. Eyn. ii. 669 sqq., viii. 562. (c) Dîdrîm ("words") R., independent homilies on Deuteronomy, of about 10th century, a collection of Tanhûmôsh and excerpts from the old sources. See Ḥun. Eyn. iv. 487 sqq. (f) Shîr ("song") R., or (after the opening words) Aggadât Haût, a late compilation of haggadah on Canticles, illustrating the allegorical interpretation of the Song of Songs and the connection of the book with the 7th century. See Ḥun. Eyn. viii. 561, (d) Mînîrâh Rabbônâ, a compilation including an exposition of i. Chron. iv. 21-23, xiii. 15-15 and interesting Messianic references. For this and similar Mid. or Ruth, see Ḥun. Eyn. viii. 555, x. 577 sqq. (b) Etûtah ("how") Rabbônâ, a compilation of the 7th century on Lametations, from sources cited also in the Palestinian Talmud. Thirty-six proems precede the commentary. See Ḥun. Eyn. v. 85 sqq. (d) Mîbidaleh or Rok. Rabbônâ, on Ecclesiastes; see Ḥun. Eyn. viii. 593 sqq. (e) Mî螺h, Rabbônâ, dating, though related to the 10th century. On this and other similar works dealing with this ever-popular book, see Ḥun. Eyn. v. 241, viii. 566, and Fatôn's comment. On Ḥun. Eyn. vi. 101 sqq.

vi. Piēṣîṭâ ("section") or P. de-Rab Kâhôna, contains 33 or 34 homilies (on the principal festivals), the first of which opens with a section of R. Kâhôna ben (son of) Abâh, less for the bad pup of a bad dog). See Ḥun. Eyn. viii. 560, xii. 476 sqq. (bii. Bûmidâr ("in the desert of ..") R., 33 homilies on Kings (including 24 above (though in an earlier text), with a later aggadic exposition, perhaps of 12th century, on Num. i.-vii. See Ḥun. Eyn. ii. 669 sqq., viii. 562. (c) Dîdrîm ("words") R., independent homilies on Deuteronomy, of about 10th century, a collection of Tanhûmôsh and excerpts from the old sources. See Ḥun. Eyn. iv. 487 sqq. (f) Shîr ("song") R., or (after the opening words) Aggadât Haût, a late compilation of haggadah on Canticles, illustrating the allegorical interpretation of the Song of Songs and the connection of the book with the 7th century. See Ḥun. Eyn. viii. 561, (d) Mînîrâh Rabbônâ, a compilation including an exposition of i. Chron. iv. 21-23, xiii. 15-15 and interesting Messianic references. For this and similar Mid. or Ruth, see Ḥun. Eyn. viii. 555, x. 577 sqq. (b) Etûtah ("how") Rabbônâ, a compilation of the 7th century on Lametations, from sources cited also in the Palestinian Talmud. Thirty-six proems precede the commentary. See Ḥun. Eyn. v. 85 sqq. (d) Mîbidaleh or Rok. Rabbônâ, on Ecclesiastes; see Ḥun. Eyn. viii. 593 sqq. (e) Mî螺h, Rabbônâ, dating, though related to the 10th century. On this and other similar works dealing with this ever-popular book, see Ḥun. Eyn. v. 241, viii. 566, and Fatôn's comment. On Ḥun. Eyn. vi. 101 sqq.

vi. Piēṣîṭâ ("section") or P. de-Rab Kâhôna, contains 33 or 34 homilies (on the principal festivals), the first of which opens with a section of R. Kâhôna ben (son of) Abâh, less for the bad pup of a bad dog). See Ḥun. Eyn. viii. 560, xii. 476 sqq. (bii. Bûmidâr ("in the desert of ..") R., 33 homilies on Kings (including 24 above (though in an earlier text), with a later aggadic exposition, perhaps of 12th century, on Num. i.-vii. See Ḥun. Eyn. ii. 669 sqq., viii. 562. (c) Dîdrîm ("words") R., independent homilies on Deuteronomy, of about 10th century, a collection of Tanhûmôsh and excerpts from the old sources. See Ḥun. Eyn. iv. 487 sqq. (f) Shîr ("song") R., or (after the opening words) Aggadât Haût, a late compilation of haggadah on Canticles, illustrating the allegorical interpretation of the Song of Songs and the connection of the book with the 7th century. See Ḥun. Eyn. viii. 561, (d) Mînîrâh Rabbônâ, a compilation including an exposition of i. Chron. iv. 21-23, xiii. 15-15 and interesting Messianic references. For this and similar Mid. or Ruth, see Ḥun. Eyn. viii. 555, x. 577 sqq. (b) Etûtah ("how") Rabbônâ, a compilation of the 7th century on Lametations, from sources cited also in the Palestinian Talmud. Thirty-six proems precede the commentary. See Ḥun. Eyn. v. 85 sqq. (d) Mîbidaleh or Rok. Rabbônâ, on Ecclesiastes; see Ḥun. Eyn. viii. 593 sqq. (e) Mî螺h, Rabbônâ, dating, though related to the 10th century. On this and other similar works dealing with this ever-popular book, see Ḥun. Eyn. v. 241, viii. 566, and Fatôn's comment. On Ḥun. Eyn. vi. 101 sqq.

vii. Piēṣîṭâ Kâhônah. —A very similar but larger collection of 51 homilies, of which 28 have a halakic exordium prefixed to the Tanhûmôsh—proems, perhaps of 9th century. Edited by M. Fried- man (Vienna, 1880). Quite another and later work is the Pi'éṣîṭa or Lëqât Tôb of Tobiah b. Eliezer of Mainz. (trans. Ugaluson, xv. sqq., xvi. 1866; ed. Buber, 1880); see Ḥun. Eyn. viii. 561 sqq. 

viii. Midrashim ascribed to Rabbônâ, are mentioned above there are numerous self-contained works of greater or less interest. Some are connected with Old Testament books; e.g. Aggadât Bereishîth, 83 homilies on Genesis, each in three parts connected with a section from the collection of the Prophets, and one from the Prophecies, and a Psalm (ed. Buber, Cracow, 1903; see Ḥun. Eyn. viii. 563); the Mid. Tehillim on the Psalms (German, translated by Buber, 1885); others—e.g. Pîrgâ or Baratshâ de-Rabbi Eliyâh—of much similar interest.

1 They contain (as I. Abrahams has point out to the present writer) a redaction and deal of haggadah, but far more enigmatic material which for the latter part (post 560) also contain halakha, but the chief contents are haggadic and homiletical.

2 I. Abrahams points out to the writer that the rest is more suspected ago as academical and, the fact xii. onwards and the rest of the Pentateuch have independent Midrashim: the Law proper was held to the Rabbis to begin at Exod. xii.
preliminary schools and has been appointed to a ship. The French equivalent is aspirant, and other European navies use that name for midshipmen. MIDSOMER NORTON, an urban district in the northern parliamentary division of Somersetshire, England, 12 m. S.S.W. of Bath, on the Somerset & Dorset and the Great Western railways. Pop. (1901), 5890. The town is pleasantly situated in a hilly district, between two branches of the small river Somer. The church of St John the Baptist, principally Perpendicular, has in its tower three bells presented by Charles II. Both this town and the adjacent villages and towns of RADSTOCK (pop. 3355) have considerable trade in coal, which is shipped by virtue. The coalfield extends northward-westwards to Bristol, and is of great importance to the manufactures of that city.

MIDWIFE (Mid. Eng. midwif, mydylif or mederwine, from preposition mid, with, and wife, i.e. woman, in the sense of one who is with the mother, or from adjective mid, one who is the means of delivering the mother, a woman who assists other women in childbirth.) As a class, midwives were recognized in Egypt in the time of the fourth captivity; in Greece in the 13th century; in Rome until the middle of the 16th century, as it is to-day in the East, that women should be attended in confinement only by those of their own sex. From that period more attention was given to the practice of midwifery by the medical profession (see Obstetrics), while in continental Europe, towards the close of the 17th century, special schools were instituted for the proper training of midwives. But it was not until well on in the 19th century that any supervision or regulation was imposed on those who acted as midwives. Now in practically every European country midwives are under strict state control, they are required to undergo a course of thorough training, and their practice is carefully regulated by legislation.

In France midwives (sages femmes) are divided into a first and a second class. Those qualifying for both classes go through a two years' course of training and examination both in the theory and practice of midwifery, as well as in anatomy, physiology and pathology. A midwife of the first class has a superior status and can practise in any part of France, while those of the second class are restricted in their practice to the department for which the certificate was issued. Their qualifications allow them also to vaccinate and to prescribe certain antiseptic preparations. They are not allowed to use instruments and must call in a qualified doctor in all cases involving maternal or infant death. In Germany midwives are appointed, recognized and authorized by the state. They can conduct confinements independently and without the aid of a medical man. They must be provided with a certificate from the police authorities, and must reside in special districts assigned to them by the authorities. In Austria midwives before they are allowed to practise must pass a strict examination, after having followed a six months' course at one of the state schools of midwifery. They are subject to elaborate "instructions for midwives" issued from time to time by the ministry of the interior. In Italy a midwife must pass an examination and obtain a diploma from a recognized authority; but in order to obviate the difficulty which the poorer classes in the smaller communities would find in obtaining properly-authorized midwives, a certificate of permission to perform all midwifery duties may be granted to a certain number who have practised without the sanction of the law satisfactorily during a term of five years. These certificates are distributed by the prefect. In Russia matters pertaining to the appointment, transfer, dismissal and pay of midwives are under the charge of the medical department of the ministry of the interior. In each town of a province or region there is stationed one senior midwife and a number of junior apprentices in a number of districts in the province. The examination of midwives by the issue of such a certificate of competency is carried out by the Medico-Chirurgical Academy and certain of the universities. A duly-licensed midwife, on presentation of her diploma, is at once placed on the register of the medical department of the province to which she may have belonged. The general code of Russian laws lays down extensive rules for the carrying out of the duties of midwives. In Norway all midwives are licensed after examination and are allowed and insured by the government. Provision is made for infirm and aged midwives. They are usually paid by the parish, but also receive fees according to the means of the person attended. In Sweden a certificate of competency and of having passed an examination does not give a midwife a right to practise unless a note has been made on the certificate that the oath of office has been duly taken. All midwives are under the control of the board of health. In Holland a midwife takes up her practice on presentation of a certificate of competency, which must be renewed every two years. She must not say in her certificate that she has anything but a general knowledge of midwifery. The law further provides that she must sign her name as at where she may be found and at what hour she will probably return. In the country a midwife may be paid out of the poor rate. In Denmark midwives are allowed to practice. In the main of the practice of midwifery is almost entirely in the hands of women. In Holland a number of candidates are given free training by the state in return for their practising midwifery in scattered counties. In Austria midwifery has been considered an essential of the profession, and in the United States have also passed laws for the registration of midwives.

In England alone there was no regulation of any kind so late as 1870. Many ignorant and untrained, could describe herself as a midwife and practise for gain. Several societies made continuous efforts towards the close of the 19th century to obtain legislation. A select committee on midwives' registration reported in 1872 that the evidence they had taken showed that there was at this time "serious and unnecessary loss of life and health and permanent injury to both mother and child in the treatment of childbirth, and that some legislative provision for improvement and protection was desirable." A similar committee reported to the same effect in 1893. Eventually a bill was drafted with the object of securing the examination and registration of midwives, but, although it was introduced into both Houses of Parliament in 1898, it was not unsuccessful until 1902. The Midwives Act 1902 forbids any woman after the 1st of April 1905 to call herself midwife without a certificate, and also as a midwife after the 1st of April 1910. Existing midwives (those who held certificates in midwifery from certain recognized institutions, or produced satisfactory evidence at the passing of the act that they had been qualified for at least one year) in bona fide practice as midwives, and bore good characters) were allowed to claim certificates within two years from the 1st of April 1903. The act created a central midwives' board, whose duties are, inter alia, to regulate the power of suspension and report convictions. They must supply the central board with the names and addresses of those practising within their area, and notify any death. The local authority has to report any case of a midwife performing any act under the act, and may, if it think fit, delegate its powers to a lesser local authority, such as a district council. The act provides for penalties for obtaining a certificate by false representation or for the utterance of any false certificate. The act does not apply in Ireland or Scotland.

MIRÉVELT (Miereveld, or Mirevelt), MICHEL JANsz VAN (1567-1641), Dutch painter, was born at Delft, the son of a goldsmith, who apprenticed him to the copperplate engraver J. Vischer. He subsequently became a pupil of Willem Willemsz and Augustyn of Delft, until Anthony van Montfoort (Blocklandt), who had seen and admired two of Mirevelt's early engravings, "Christ and the Samaritan" and "Judith and Holofernes," invited him to enter his school at Utrecht. Devoting himself first to still life, he eventually took up portraiture, in which he achieved such success that many commissions entrusted to him necessitated the employment of numerous assistants, by whom hundreds of portraits were turned out in factory fashion. The works that can with certainty be ascribed to his own brush are remarkable for their sincerity, severe drawing and harmonious colour, but comparatively few of the two thousand or more portraits that bear
his name are wholly his own handiwork. He settled down in his native town, but went frequently to The Hague, where he entered the gild of St Luke in 1625. So great was his reputation that he was patronized by royalty in many countries and acquired great wealth. The king of Sweden and the count palatine of Neuburg presented him with golden chains, Archduke Albrecht gave him a pension, and Charles I. vainly endeavoured to induce him to visit the English court. Though Mierevelt is chiefly known as a portrait painter, he also executed some mythological pieces of minor importance. Many of his portraits have been reproduced in line by the leading Dutch engravers of his time. He died at Delft on the 27th of June 1647.

The RKYS Museum in Amsterdam has the richest collection of Mierevelt's works, chief of them being the portraits of William, Philip William, Maurice, and Frederick Henry of Orange, and of the count palatine Frederick V. At The Hague Museum are the portraits of four princes of the house of Orange, of Frederick V., king of Bohemia, and of Louise de Coligny as a widow. Other portraits by him are at nearly all the leading continental galleries, notably at Brunswick (3), Gotha (2), Schwerin (3), Munich (2), Paris (Louvre, 3), Dresden (4), Berlin (2), and Darmstadt (3). The town hall of Delft also has numerous examples of his work.

Many of his pupils and assistants rose to fame. The most gifted of them were Paulus Moreelse and Jan van Ravesteyn. His sons Pieter (1596–1632) and Jan (d. 1633), and his son-in-law Willem Jacobz Delft, probably painted many of the pictures which are his name. His portrait was painted by Van Dyck and engraved by Delff.

MIERIS, the name of a family of artists who practised painting at Leiden for three generations in the 17th and 18th centuries.

1. Frans van Mieris, the elder (?1635–1681), son of Jan van Mieris, a goldsmith and diamond-setter, was born, according to Houbraken, at Leiden on the 16th of April 1635, and died there on the 12th of March 1681. His father wished to train him to his own business, but Frans preferred drawing to chasing, and took service with Abraham Torevenvelt, a glazier who kept a school of design. In his father's shop he became familiar with the ways and dress of people of distinction. His eye was fascinated in turn by the sheen of jewelry and stained glass; and, though he soon gave up the teaching of Torevenvelt for that of Gerard Douw and Abraham van den Tempel, he acquired a manner which had more of the finish of the exquisite of the Dutch school than of the breadth of the disciplines of Rembrandt. It should be borne in mind that he seldom chose panels of which the size exceeded 12 to 15 in., and whenever his name is attached to a picture above that size we may surely assign it to his son Willem or to some other imitator. Unlike Gerard Douw when he first left Rembrandt, or Jan Steen when he started on an independent career, Mieris never ventured to design figures as large as life. Characteristic of his art in its minute proportions is a shining brightness and metallic polish. The subjects which he treated best are those in which he illustrated the habits or actions of the wealthier classes; but he sometimes succeeded in homely incidents and in portrait, and not unfrequently he ventured on allegory. He repeatedly painted the satin skirt which Ter Borch brought into fashion, and he often rivalled Ter Borch in the faithful rendering of rich and highly-coloured woven tissues. But he remained below Ter Borch and Metsu, because he had not their delicate perception of harmony or their charming mellowness of touch and tint, and he fell behind Gerard Douw, because he was hard and had not his feeling for effect by concentrated light and shade. In the form of his composition, which sometimes represents the framework of a window enlivened with greenery, and adorned with bas-reliefs within which figures are seen to the waist, his model is certainly Gerard Douw.

It is a question whether Houbraken has truly recorded this master's birthday. One of his best-known pieces, a party of ladies and gentlemen at an oyster luncheon, in the Hermitage at St Petersburg, bears the date of 1650. Celebrated alike for composition and finish, it would prove that Mieris had reached his prime at the age of fifteen. Another beautiful example, the "Doctor Feeling a Lady's Pulse" in the gallery of Vienna, is dated 1656; and Waagen, in one of his critical essays, justly observes that it is a remarkable production for a youth of twenty-one. In 1657 Mieris was married at Leiden in the presence of Jan Potheuck, a painter, and this is the earliest written record of his existence on which we can implicitly rely.

Of the numerous panels by Mieris, twenty-nine at least are dated; the latest being an allegory, long in the Ruhl collection at Cologne, illustrating that he considered the kindred vices of drinking, smoking and dicing, in the year 1680. Mieris had numerous and distinguished patrons. He received valuable commissions from Archduke Leopold, the elector-palatine, and Cosimo III., grand-duke of Tuscany. His practice was large and lucrative, but never engendered in him either carelessness or neglect. If there be a difference between the painter's earlier and later work, it is that the former was clearer and more delicate in flesh, whilst the latter was often darker and more vivid in the shadows. When he died his clients naturally went over to his son Willem, who in turn bequeathed his painting-room to his son Frans. But neither Willem nor Frans the younger equalled Frans the elder.

2. Willem van Mieris (1662–1747), son of Frans. His works are extremely numerous, being partly imitations of the paternal subjects, or mythological episodes, which Frans habitually avoided. In no case did he come near the excellence of his sire.

3. Frans van Mieris, the younger (1669–1763), also lived on the traditions of his grandfather's studio.

The pictures of all the generations of the Mieris family were successfully imitated by A. D. Snaphaan, who lived at Leipzig and was patronized by the court of Anhalt-Dessau. To those who would study his deceptive form of art a visit to the collection of Worlitz near Dessau may afford instruction.

MIFFLIN, THOMAS (1744–1800), American soldier and politician, was born in Philadelphia, Pennsylvania, on the 10th of January 1744, of Quaker parentage. He graduated at the college of Philadelphia (now the university of Pennsylvania) in 1760. As a member of the Pennsylvania house of representatives in 1777–1775, he was an ardent Whig, and in 1774 was a member of the first Continental Congress. After the outbreak of the War of Independence he devoted himself chiefly to the enlisting and drilling of troops, and was chosen major of a regiment. In June 1775 he entered the continental service as Washington's first aide-de-camp, and in August was chosen quartermaster-general. He became a brigadier-general in May 1776 and a major-general in February 1777. On the 9th of June 1776 he was succeeded as quartermaster-general by Stephen Moylan. Moylan, however, proved incompetent, and Mifflin resumed the office on the 1st of October. In the autumn of 1777 Mifflin was a leader in the obscure movement known as the Conway Cabal, the object of which was to replace Washington by General Horatio Gates. On the ground of ill health Mifflin tendered his resignation on the 8th of October, and on the 7th of November Congress accepted his resignation as quartermaster-general, but continued him in rank as major-general without pay. On the same day he was appointed a member of the new board of war, and on the following day was asked to continue as quartermaster-general until his successor should be appointed. On the 21st of November he urged before the old board of war and ordinance that Gates should be made president of the new board of war "from a conviction that his military skill would suggest reformation in the different departments of the army essential to good discipline, order and economy, and that his character and popularity in the army would facilitate the execution of such reformation when adopted by Congress." The attacks on Washington failed, and in March 1778 Mifflin was finally superseded as quartermaster-general by General Nathanael Greene. In October of the same year he was removed from the board of war. The sufferings of the troops at Valley Forge having been charged to his mismanagement as quarter-
MIGNARD, MIGNET

master-general, Congress, in June 1778, ordered an investigation; but before this inquiry had proceeded far, Congress granted him $1,000,000 to settle all claims against the office during his administration. In February 1779 he resigned his commission as master-general. During the war his eloquence was repeatedly of assistance to Congress in recruiting soldiers. He was a delegate in Congress in 1782-1784, and from November 1783 to November 1784, was president, in which office he received Washington's resignation of the command of the army and made a congratulatory address. In 1785-1788 he was speaker of the Pennsylvania general assembly (then consisting of only one house); he was a member of the Federal Constitutional Convention of 1787; and president of the state supreme executive council (or chief executive officer of the state) in 1788-1790. He was president of the Pennsylvania Constitutional Convention of 1788-1790; was the first governor of the state, from 1790 to 1799, after the adoption of the new state constitution; and during the Whisky Insurrection assumed personal command of the Pennsylvania militia. Towards the close of his last term as governor he was elected a member of the state assembly, but died during the first session, at Lancaster, on the 20th of January 1800.

MIGNARD, PIERRE (1610-1693), called—to distinguish him from his brother Nicholas—Le Romain, French painter, was born at Troyes in 1610, and came of a family of artists. In 1630 he left the studio of Simon Vouet for Italy, where he spent twenty-two years, and made a reputation which brought him a summons to Paris. Successful with his portrait of the king, and in favour with the court, Mignard pitted himself against Le Brun, declined to enter the Academy of which he was the head, and made himself the centre of opposition to its authority. The history of this struggle is most important, because it was identical, as long as it lasted, with that between the old gilds of France and the new body which Colbert, for political reasons, was determined to support. Shut out, in spite of the deserved success of his decorations of the cupola of Val de Grace (1664), from any great share in those public works the control of which was the attribute of the new Academy, Mignard was chiefly active in portraiture. Turenne, Molière, Bossuet, Maintenon (Louvre), La Vallière, Sévigné, Montespan, Descartes (Castle Howard), all the beauties and celebrities of his day, sat to him. His readiness and skill, his happy instinct for grace of arrangement, atoned for want of originality and real power. With the death of Le Brun (1660) the situation changed; Mignard deserted his allies, and succeeded to all the posts held by his opponent. These late honours he did not long enjoy; in 1695 he died whilst about to commence work on the cupola of the Invalides. His best compositions have been engraved by Audran, Edelinck, Masson, Poyli and others.

MIGNE, JACQUES PAUL (1800-1875), French priest and publisher, was born at St Flour, Cantal, on the 25th of October 1800. He studied theology at Orleans, was ordained priest in 1824 and placed in charge of the parish of Puiseaux, in the diocese of Orleans. In 1833 he went to Paris, and started L'Univers religieux, which afterwards became Louis Veuillot's ultramontane organ. On severing his connexion with the paper three years later, he opened at Petit Montrouge, near Paris, the great publishing house which brought out in rapid succession numerous religious works at popular prices. The best known of these are: Scripturae sacræ cursus completus, and Theologiae cursus (each in 28 vols., 1840-1845); Collection des auteurs sacres (100 vols., 1846-1848); Encyclopédie théologique (171 vols., 1841-1860); Patrologiae cursus completus, Latin series in 24 vols., 1844-1853; 2nd edition, 1878 seq.; Greek series, first published in 1844, 10 vols., 1848-1855, 2nd edition, 16 vols., 1857-1866. Unfortunately these editions, bought out in great haste and often edited by supercilious scholars, do not come up to the requirements of modern criticism. By far the most noteworthy is the Patrology, which was superintended by the learned Benedictine J. B. Pitra. Its vast scope leaves it still unique and valuable, where other editions of special works do not exist. The indices in 3 vols. are arranged so that one may easily find any reference in the patristic writings. In February 1868 a great fire destroyed the whole of Migne's printing premises, but he established a new house in Paris, which was purchased in 1876 by the publishers Garnier Frères, who still own all the works brought out by Migne. He died in Paris on the 16th of October 1875.

For a more complete account of Migne's life, see the article in the Catholic Encyclopedia (New York, 1906 seq.).

MIGNET, FRANÇOIS AUGUSTE ALEXIS (1796-1834), French historian, was born at Aix in Provence on the 8th of May 1796, and died at Paris on the 24th of March 1884. His father, a Vendean by birth, was an ordinary locksmith, who enthusiastically accepted the principles of the French Revolution and roused in his son the same love for liberal ideas. François had brilliant successes when studying at Avignon in the lycée where he was afterwards professor (1813); he returned to Aix under the Consulat, and in his capacity of chairman of the staff which carried on a fierce pen-and-ink warfare against the Restoration. He acquired his knowledge of the men and intrigues of the Napoleonic epoch from Talleyrand. He wrote a Histoire de la révolution française (1824) in support of the Liberal cause. It was an enlarged sketch, prepared in four months, in which more stress was laid on fundamental theories than on the facts, which are more rigidly linked together than their historical sequence warrants. In 1830 he founded the National with Thiers and Armand Carrel, and signed the journal's manifesto, the Ordonnances de juillet, but he refused to accept his share of the spoil after his party had won. He was satisfied with the modest position of director of the archives at the Foreign Office, where he stayed till the revolution of 1848, when he was dismissed, and retired permanently into private life. He had been elected a member of the Académie des Sciences Morales et Politiques, re-established in 1832, and in 1837 was made the permanent secretary; he was also elected a member of the Académie Française in 1836, and sought no further honours. He was well known in fashionable circles, where his witty conversation and his pleasant manners made him a favourite. The greater part of his time was, however, given to study and to his academic duties. Eulogies on his deceased fellow-members, the Academy reports on its work and on the prizes awarded by it, which it was part of Mignet's duty as secretary to draw up, were literary fragments thoroughly appreciated by connoisseurs. They were collected in Mignet's Notices et portraits. He worked slowly when in his study, and willingly lingered over research. With the exception of his description of the French Revolution, which was chiefly a political manifesto, all his early works refer to the middle ages—De La féodalité, des institutions de Saint Louis et de l’influence de la législation de ce prince (1823); La Germanie au viii et au ix siècle, sa conversion au christianisme, et son introduction dans la société civilisée de l’Europe occidentale (1834); Essai sur la formation territoriale et politique de la France depuis la fin du vii au x siècle jusqu’à la fin du xix ème (1836); all of these are rough sketches showing only the outlines of the subject. His most noted works are devoted to modern history. For a long time he had been taken up with a history of the Reformation, but only one part of it, dealing with the Reformation at Geneva, has been published. His Histoire de Marie Stuart (2 vols., 1851)
is well worth reading: the author made liberal use of some important unpublished documents, taken for the greater part from the archives of Simancas. He devoted some volumes to a history of Spain, which had a well-deserved success—Charles Quint, son abdication, son séjour, et sa mort au monastère de Yuste (1843); Antonio Perez et Philippe II. (1843); and Histoire de la rivalité de François I. et de Charles Quint (1873).

At the same time he had been commissioned to publish the diplomatic acts relating to the War of the Spanish Succession for the centre of the court and to the whole group of flowers of these Négociations were published (1835-1842), and they do not go further than the peace of Nijmegen; but the introduction is celebrated, and Mignet reprinted it in his Mélanges historiques.

See the eulogy of Mignet by Victor Duruy, delivered on entering the Académie Française on the 18th of June 1885, and the notice by Jules Simon, read before the Académie des Sciences Morales et Politiques on the 7th of November 1885.

MIGNON, ABRAHAM (1649-1697), Dutch painter, was born at Frankfort. His father, a merchant, placed him under the still-life painter Jacob Merrol, by whom he was taken to Holland about 1660. He then worked under de Heem at Utrecht, where in 1675 he married the daughter of the painter Cornelis Willearts. Sibylle Merian (1647-1717), daughter of the engraver Matthew Merian, became his pupil and achieved distinction as a flower painter. He died at Wetzlar. Mignet devoted himself almost exclusively to flowers, fruit, birds and other "still life," though at times he also attempted portraiture. His flower pieces are marked by careful finish and delicate handling. His favourite scheme was to introduce red or white roses in the centre of the painting, and to set the whole group of flowers against a dark background. Nowhere can his work be seen to better advantage than at the Dresden Gallery, which contains fifteen of his paintings, twelve of which are signed. Six of his pictures are at the Louvre, four at the Hermitage, and other examples are to be found at the museums of Amsterdam, The Hague, Rotterdam, Brussels, Munich, Karlsruhe, Brunswick, Cassel, Schwerin, Copenhagen and Turin.

MIGNONETTE, or MIGNONETTE (i.e. "little darling"), the name given to a popular garden flower, the Reseda odorata of botanists, is "fragrant weed," as Cuvier called it, highly esteemed for its delicate but delicious perfume. The mignonette is generally regarded as being of annual duration, and is a plant of diffuse decadent twiggly habit, scarcely reaching a foot in height, clothed with bluntish lanceolate entire or three-lobed leaves, and bearing longish spikes—technically racemes—of rather insignificant flowers at the ends of the numerous branches and branchlets. The plant thus naturally assumes the form of a low dense mass of soft green foliage studied over freely with the racemes of flowers, the latter unobtrusive and likely to be overlooked until their diffused fragrance compels attention. It is probably a native of North Africa, and was sent to England from Paris in 1742; and ten years later it appears to have been sent from Leiden to Philip Miller at Chelsea. Though originally a slender and rather straggling plant, there are now some improved garden varieties in which the growth is more compact and vigorous, and the inflorescence holier, though the odour is perhaps less pungent. The small six-petalled flowers are somewhat curious in structure: the two upper petals are larger, concave, and furnished at the back with a tuft of club-shaped filaments, which gives them the appearance of being deeply incised, while the two lowest petals are much smaller and uniedited; the most conspicuous part consists of the anthers, which are numerous and of a brownish red, giving the tone of colour to the inflorescence. In the varieties named Golden Queen and Golden Machtet the anthers have a decided tint of orange-yellow, which imparts a brighter golden hue to the plants when in blossom. A handsome prolific or double-flowered variety has also been obtained, which is a very useful decorative plant, though only to be propagated by cuttings; the double white flowers grow in large massive panicles (proliferous racemes), and are equally fragrant with those of the ordinary forms.

What is called tree mignonette in gardens is due to the skill of the cultivator. Though practically a British annual, as already noted, since it flowers abundantly the first season, and is utterly sterile in the autumnal frosts, and though recorded as being annual in its native habitat in Persia and the Flora Alpina, the mignonette, like many other plants treated in England as annuals, will continue to grow on if kept in a suitable temperature. Moreover, the life of certain plants of this expression, character may be prolonged into a second season if their flowering and seedings are persistently prevented. In applying these facts to the propagation of tree mignonette, the gardener grows on the young plants under glass and prevents their flowering by nipping off the flowering tips of the shoots, so that they continue their vegetative growth into the second season. The young plants are at first supported in an erect position, the laterals being removed so as to secure clean upright stems, and then at the height of one or two feet on, as may be desired, a head of branches is encouraged to develop itself. In this way very large plants can be produced.

For ordinary purposes, however, other plans are adopted. In the open borders of the flower garden mignonette is usually sown in spring, and in great part takes care of itself; but being a favourite subject of decorative art, and particularly of the window or balcony culture, and on account of its fragrance a welcome inmate of town conservatories, it is also very extensively grown as a pot plant, and for market purposes with this object it is sown in pots in the autumn, and thinned out to give the plants room for air. There, since it is transplanted, it is specially grown in pots protected from frosts, and marketed when just arriving at the blooming stage. In this way hundreds of thousands of pots of blooming mignonette are raised and disposed of year by year.

In classifying the odours given off by plants Rimmel ranks the mignonette in the class of which he makes the violet the type; and Fee adopts the same view, the laters being removed so as to secure clean upright stems, and then at the height of one or two feet on, as may be desired, a head of branches is encouraged to develop itself. In this way very large plants can be produced.

MIGNON, LES. In a general sense the French word mignon means "favourite," but the people of Paris used it in a special sense to designate the favourites of Henry III. of France, frivolous and fashionable young men, to whom public malignity attributed dissolve morals. According to the contemporary chronicler Pierre de l’Estoile, they made themselves "exceedingly odious, as much by their foolish and haughty demeanour, as by their effeminate and immodest dress, but above all by their prodigious gifts the king made to them, and of which it is said to have stirred up the ill will of the Parisians against them.

From 1576 the mignons were attacked by popular opinion, and historians accredited without proof the scandalous stories of the time. The best known of the mignons were the dukes of Joyeuse and of Épernon.

MIGNOT, CLAUDINE FRANÇOISE (commonly called MARE) (c. 1617-1711), French adventurer, was born near Grenoble, at Meylan. At the age of sixteen she attracted the notice of the secretary of Pierre des Portes d’Amblézieux, treasurer of the province of Dauphiny, and Amblézieux promised to promote their marriage. He married the girl himself, however, and left her his fortune. Her will was disputed by his family, and Claudine went to Paris in 1653 to secure its fulfilment. She sought the protection of François de l’Hôpital, marshal of France, then a man of seventy-five. He married her within a week of their first meeting, and after seven years of marriage died leaving her part of his estate. By a third and morganatic marriage in 1672 with John Casimir, ex-king of Poland, a few weeks before his death, she received a third fortune. Immediately after her marriage with Amblézieux she had begun to educate herself, and her wealth and talents assured her a welcome in Paris. She retired in her old age to a Carmelitite convent in the city, where she died on the 30th of November 1711. Her history, very much modified, was the subject of a play by Bayard and Paul Duport, Marie Mignot (1829).

MIGRATION. Under this title will be considered movements of men with intention of changing their residence or domicile. Such migration (Lat. migrare) may be either external—that is, from one country to another, including emigration from mother country to colony; or it may be internal—that is, within
428

MIGRATION

the limits of a single country. Under external migration are comprised emigration and immigration, denoting simply direction from and to. The emigrants never at the same time the immigrants; that is, the material of the movement is the same, but the effect upon the country giving up and the country receiving the migrant requires separate treatment. Hence it is proper to separate emigration from immigration. Temporary migration, or travel for purposes of business, enterprise or pleasure, will be considered only incidentally, and because in some cases it is difficult to distinguish between such movements and permanent migration.

Migration in general may be described as a natural function of social development. It has taken place at all times and in all regions, and under a great variety of circumstances. It has been tribal, national, class and individual. Its causes have been political, economic, religious, or mere love of adventure. Its causes and results are fundamental for the study of ethnology (formation and mixture of races), of political and social history (formation of states and survival of institutions), and of political economy (mobility of labour and utilization of production forces). Under the form of conquest it makes the grand epochs in history (e.g. the fall of the Roman Empire); under the form of colonization it has transformed the world (e.g. the settlement of America); under free initiative it is the most powerful factor in social adjustment (e.g. the growth of urban population). It must suffice here to indicate the character of the principal movements in the past, and then describe certain aspects of modern migration. The early movements may be grouped as follows: (a) Prehistoric migrations. Among savage and nomadic nations the whole tribe often moves into new territory, either occupying it for the first time or exterminating or driving out the indigenous inhabitants. We have only vague knowledge of these early movements, laboriously gleaned from archaeology, anthropology and philology. The cause has been commonly said to be the pressure of population on the food-supply. A more probable explanation is the love of booty and the desire of the stronger to take possession of the lands of the weaker. (b) Greek and Roman colonization. Both of these ancient civilizations extended their influence through migration of individual families and the planting of colonies. The motive seems to have been primarily commercial—that is, the love of gain. It may have been partly a sort of "swarming" process, caused by pressure of population at home. In some cases it had a political motive, as the planting of military colonies or providing new homes for the proletariat. The consequenes were of course momentous. (c) The German Conquest. Beginning about the 5th century, the Roman empire was overthrown by German tribes from the north of the river Danube and cast of the river Rhine. This Volkerwanderung, as it is called by German historians, again transformed the face of Europe, resulting in the establishment of independent kingdoms and a great mixture of races and institutions. It was coincident with the building-out of the feudal system. The conquered in many cases could be left as serfs and tillers of the soil, while the conquerors seized the higher positions of administration and power. (d) The later middle ages saw many minor migratory movements, such as those accompanying the crusades, the pushing of German colonization among the Slavs, and the introduction of Flemish weavers into England. The religious reformation caused a considerable amount of expatriation, culminating in the expulsion of the Huguenots from France. (e) The period of discovery and colonization opened up a new era for migration. The first expeditions were for adventure and booty, especially the discovery of gold and silver. Then came the establishment of commercial posts or factories for the purposes of trade. Finally came colonization proper—that is, the settlement of new countries by Europeans intending to remain there permanently, but still retaining their connexion with the mother country. This meant the opening up of the world to commerce and the extension of European civilization to vast areas formerly peopled by savages or half-civilized peoples. It meant a great outlet for the spirit of enterprise and adventure, relief from over-population, an enormous increase in wealth and power, and a struggle for supremacy among the nations of Europe. Colonization and colonial policy excited immense attention in Europe; and this extended into the 19th century (E. G. Wakefield’s plans for colonization, and the various colonization societies of modern times). The colonial policy proper was broken down by the revolt of the North American colonies from Great Britain, and later of Mexico and Central and South America from Spain. (f) The movement of population, however, has continued under the form of emigration. This movement is characterized firstly by its magnitude; secondly, by the fact that the emigrant changes his political allegiance, for by far the greater part of modern emigration is to independent countries, and even where it is to colonies the colonies are largely self-governing and self-regarding; and thirdly, it is a movement of individuals seeking their own good, without state direction or aid. This is 20th-century emigration, differing from all preceding forms and having an importance of its own.

Statistics of Emigration.—The direction of the modern movement is from Europe to America, Australia and South Africa, as shown in the following table:

2 Exclusive of emigrants to Spanish colonies.
3 Russian emigrants from German ports.
MIGRATION

Since 1820 over twenty million persons have emigrated from Europe to countries beyond the sea. The greater part of this emigration has been to the United States of North America. The history of emigration is well shown in the following table of emigration from Great Britain and Ireland. Down to 1853 the figures include all emigrants from British ports; after 1853 emigrants of British and Irish origin only.

Emigration from Great Britain and Ireland, 1815-1905.

The greater part of this emigration has been to the United States of North America. The history of emigration is well shown in the following table. It was speedily resumed on an enlarged scale owing especially to the improved means of ocean transportation. It culminated in the decade 1880-1890, and declined after the commercial crisis of 1893. Later there was another increase.

The relative movement of nationalities is best presented by the statistics of the United States. The nationality (country of origin of immigrants coming to the United States, 1871-1895) is shown in the following table—

It was speedily resumed on an enlarged scale owing especially to the improved means of ocean transportation. It culminated in the decade 1880-1890, and declined after the commercial crisis of 1893. Later there was another increase.

The relative movement of nationalities is best presented by the statistics of the United States. The nationality (country of origin of immigrants coming to the United States, 1871-1895) is shown in the following table—

Prior to 1820 there was no official record of immigration, but it is estimated that the total number of immigrants from the close of the Revolutionary War was 250,000. During the decade from 1820 to 1830 the movement was very moderate. From 1830 to 1840 it steadily increased, but never reached 100,000 per annum. In 1846 came the Irish potato famine, and an enormous emigration began, followed by a very large German emigration from similar causes. The civil War of the United States interrupted the movement, but

1 Of those, 77,409 went to the Cape of Good Hope and Natal.
2 Of those, 12,797 went to the Cape of Good Hope and Natal.
3 Of those, 60,082 went to the Cape of Good Hope and Natal.
MIGRATION

A very important transformation has taken place in the proportionate number coming from different countries during the last half of the 19th century. At first the Irish and Germans were most prominent. Of later years, the Italians, Czechs, Hungarians and Russians were, as will be seen from the following table, numerously represented.

Nationality of Immigrants to the United States, 1901-1905.

</table>

Those "without occupation" are mostly women and children. The "miscellaneous" are day labourers. It is probable that about 20% of the adult males are "skilled."

Immigration to Other Countries.—In no other country is immigration conducted on so important a scale as in the United States. The statistics are very imperfect. The main figures have already been given in the table of emigration. Australia has an annual immigration by about 20,000, which is of British origin, and the United States has a very heavy emigration, which sometimes exceeds the immigration in certain of the states. The immigration to Canada for the year 1905 was put down as 146,666, but a part of this was due to the emigration from the United States. Brazil has had a large immigration (in 1895 equal to 160,524, but in 1904 only 14,447). The Argentine is credited with an immigration in 1905 of 177,117, and Uruguay with more immigration of 62,477. In the South American immigration the countries principally represented are those of southern Europe, especially Italy. The majority of the immigrants are adult males and farm labourers.

Balance of Emigration and Immigration.—Even in the case of immigration from Europe to countries beyond the seas there is some return movement. Emigrants who have been successful in business return in order to end their days in the old country. Those who have not succeeded return in order to care for friends and relatives, or simply from homesickness. Thus, for Great Britain and Ireland while the emigration of persons of British and Irish origin was, in 1905, 262,077, the immigration of persons of the same category was 122,712, leaving a net emigration of only 139,365. In the United States' statistics we cannot distinguish in the outgoing passenger emigrant from other persons. But if for a period of years we take the total inward passenger movement and subtract from it the total outward passenger movement, we ought to have the net immigration. By this method we arrive at the conclusion that while the gross immigration during the five years 1901-1905 was 3,833,076, the net immigration was only 1,719,076, showing an outward movement of 2,114,000, or about 71.3% of the total number of immigrants.

Temporary Emigration.—In many European countries there is not only emigration beyond seas, but a very considerable movement to neighbouring countries in search of work, and generally with the intention of returning. Thus in Italy, the "permanent" emigration (i.e. to countries beyond seas) numbered, in 1905, 447,083; the "temporary" emigration to European or Mediterranean countries amounted to 379,248. This temporary emigration is strongest in the spring, and consists principally of adult males (agriculturists, farm and day labourers, bricklayers and merchants) in search of work. It resembles somewhat the movement of Irish labourers into Great Britain at harvest time. It is notorious that the Italians who emigrate to the United States largely return.

Effects of Emigration.—There are two views with regard to emigration: one unfavourable, viz., that it is a drain on population, reducing its economic strength and disturbing social and political relations. The second is looking upon emigration different. Of later years, the importance of the problem increased. It is estimated that the number of emigrants from Great Britain to the United States is about 1,000,000 per annum. The intensity of emigration is measured not by the absolute number of emigrants, but by the number of emigrants to the total population. Its effect is shown by comparing the number of emigrants with the excess of births over deaths per 1000 of the population. This is shown in the following table (1905):—
MIGRATION

Excess of births over deaths per 1000 Inhabitants. Emigrants per 1000 Inhabitants.

Great Britain and Ireland 11.4 6.66
England and Wales 12.0 4.96
Scotland 12.0 4.96
Ireland 6.3 11.42
Germany 13.2 4.5
Switzerland 9.1 1.45
Sweden (1903) 10.6 6.89
Norway 12.6 9.11
Denmark 13.5 3.12
Italy 10.5 14.11
Austria-Hungary 12.2 2.69

It will be observed that, with the exception of Ireland and Italy, where there is a heavy emigration there is usually a considerable excess of births over deaths, i.e. natural increase, set up for the loss by emigration. Even taking Great Britain and Ireland together, the emigration by per annum has not been very large, as is shown by the following table:

Annual Emigration per 1000 of the Average Population of Great Britain and Ireland.

1853-1855 8.4 1881-1890 7.1
1856-1860 4.3 1891-1895 5.1
1861-1870 5.2 1896-1900 3.7
1871-1880 5.1 1901-1905 5.5

Even in particular districts where emigration is heavy the loss is made up by births. For instance, in 1891 the emigration from the provinces of West Prussia and Posen was extraordinarily heavy—10-9 per 1000 of the population. But the excess of births over deaths was 19.6 per mille. Emigration may give temporary relief to congested districts, but it is not in itself a remedy for so-called over-population.

It is difficult to analyse closely the economic effect of emigration, because so much depends upon the character of the emigrants and the condition of the labour market. The following considerations have been urged at different times. Although emigration does not diminish population, yet, as the emigrants are in the most productive period of life (15 to 45), the country of emigration loses adults and replacement with children. It thereby loses the cost of rearing the number of people to adult age, and is left with a disproportionate number of children and old people. The age distribution of the population of Ireland lends some support to this view. In the same vein it is urged that voluntary emigration takes away the cream of the working-classes. It is the man of energy, some of means, of ambition, who takes the chances of success in the new country, leaving the poor, the indolent, and the weak and crippled at home. It is maintained that such emigration reduces the standard of living through a process of selection which is unfavourable to the home country.

On the other side, it is said that the men who are doing well at home are the least likely to emigrate, because they have least to gain. Modern means of transportation have made the voyage so cheap that almost any one is able to go. It is therefore the restless, the unsuccessful, or at least those not fitted for the strenuous conditions of the old country, who is tempted to go. Emigration affords a natural outlet for the superfluous labour force of a country. The supply of labour is somewhat reduced, but wages are kept up for those who remain. Those who go find means of bettering their own condition beyond the seas, where they become producers of food and raw material for the home country, and at the same time consumers for her manufactured products. Emigration is therefore an economic gain, both directly and indirectly. It is evident from these arguments that no general answer can be given to the question. In some cases it may be an evil; in most, when conducted under normal conditions, it would seem to offer little danger.

The same remark would hold true in regard to the social and political effects of emigration. In some cases, by taking away the strong, self-reliant and energetic, it may result in the deterioration of the home population. In other cases it allows restless spirits who have failed at home to try again elsewhere. Often in cases of political revolution the members of the defeated party have sought refuge in the new country, as after the revolutions of 1848. In case of conquest the conquered nationality takes to emigration on an extensive scale, as after the absorption of Alsace-Lorraine by Germany in 1871. The movement may be aided indirectly by other means through partial associations. Of such have been the state-aided emigration from Ireland, and the assisted emigration of paupers, criminals and other persons in the effort to relieve a congested population or in order to create a new home for members of the community. Such efforts fail if the new countries are unwilling to admit these persons. Finally, we have the expulsion of the Jews from Russia as an example of the effort of a community to get rid of an element which has made itself obnoxious to the local sentiment.

Effects of Immigration.—The effects of emigration are negative in character; those of immigration are positive. (a) On population: immigration, of course, is the increase of the population of new countries, and greatly accelerates the growth by natural increase, especially as the immigrants are in the most productive ages of manhood. In the United States, for instance, out of a population of 76,834,000 in 1890, 12,873,731 were immigrants who were either foreign-born or who had one or both parents foreign-born. This does not mean that the population would have been twenty-six millions less had there been no immigration; for the rate of natural increase among the native-born might have maintained itself. Nevertheless, immigration has probably stimulated the growth of the population. (b) Economic effects: The economic gain of immigration to a new country depends on two elements: the gain derived from their available labour force, that is, to the number of adults engaged in the work of producing wealth.

According to the United States census of 1900, out of 29,273,731 (1900) persons engaged in gainful occupations, 5,851,399 or 20.1% were of foreign birth. If we add to these the native whites of foreign extraction (5,300,924) we have 11,152,323 persons of foreign extraction or 39.4% of the total labour force. The foreign whites alone constituted 10.4% of the total number of persons engaged in agricultural pursuits; 11.4% of those in professional services; 25.7% in domestic and personal services; 19.2% in trade and transportation; and 30.6% of those engaged in manufacturing and mechanical industries. In addition to these, the native whites of foreign parentage constituted, in agriculture, &c., 10.6%; in professional service, 20.6%; in domestic and personal services, 15.6% in trade and transportation, 25.7% in manufacturing and mechanical, 25.4% of all those engaged in those occupations. The labour force of the United States is thus made up very largely of immigrants and the children of immigrants.

Attempts have sometimes been made to put a money value on the economic gain by immigration. The amount of money brought into the country by immigrants is probably less than the money sent back by immigrants for the support of families and friends at home or to aid them in following. The valuable element is the able-bodied immigrant himself as a producer of production. It is said, for instance, that an adult slave used to be valued at from $800 to $1000, so that every adult immigrant may be looked upon as worth that sum to the country. Or, it has been said that an adult immigrant represents what it would cost the country to rear an immigrant from infancy to the age, say, of 15. This has been estimated by Ernst Engel as amounting to $550 for a German child. The most scientific procedure would probably be to determine the probable earnings of the immigrant during the rest of his lifetime, and to discount his expenses of living. The remainder represents his net earnings which he will contribute to the well-being of the new country. W. Farr reckoned this to be, in the case of unskilled English emigrants, about £175. Multiplying the total number of adult immigrants by any one of these figures, we get the annual value of immigration. Such attempts to put a precise money value on immigration are futile. The question of quality among the immigrants is so great that an immigrant is worth what it has to cost to bring him up only if he is able-bodied, honest and willing to work. If he is diseased, crippled, or incapable of work, he is a net drain on the community instead of a gain. So, too, the immigrant is worth his future earnings to the community only if there is a demand for his labour.

Economic and Political Effects of Immigration.—The influx of millions of persons of different nationality, often of a foreign language and generally of the lower classes, would seem to be a danger to the health of a community. The United States, for instance, has felt some inconvenience from the constant addition of foreigners to its electorate and its population. The foreign-born are more numerous represented among the criminal, delinquent and dependent classes than their numerical strength would justify. They also tend to segregate more or less, especially in large cities. Nevertheless, the process of assimilation goes on with great facility, and with a considerable extent. The influence of the physical environment leads to the adoption of the same mode of life. The most powerful influences, however, seem to be social. These are common school education and the adoption of the same national language in political life, which is granted to all adults after five years' residence; and the general influence of social standards embodied in laws, institutions and customs already established. Doubtless the assimilation of the English, with their long history of modifying effect on American life; but on the whole the power of a modern civilized community working through individual freedom for the assimilation of elements differing from it too radically has been displayed to a remarkable degree.

Restriction of Immigration.—New countries have sought to escape certain evils of indiscriminate immigration. These evils were ascribable to the crime of negro slavery. The negro, if diseased in mind or body, and persons unable to support themselves. By the Acts of 1821 and 1893 such persons were refused admission to the United States, and, when rejected, the steamship companies debarring from 1896 to 1905 is shown in the following table:
MIGRATION

Causes. 1896 1897 1898 1899 1900 1901 1902 1903 1904 1905
Insane . 10 6 12 19 32 16 27 23 33 92

Diseased — — — — — 258 348 593 799 1773 1500 2198
Assisted — 3 79 82 2 50 — 9 38 19
Convict — 1 2 8 4 7 9 31 35 39
Prostitutes — — — — — 3 7 — — — —
Contract Labourers 776 328 417 741 833 327 275 1086 1501 1164
All other 1 1 1 1 1 6 7 2 20 445
Total debarked 2799 1617 3030 3798 4246 3516 4974 8769 7994 11879

No law of international comity is violated by the refusal to receive these unfortunate immigrants. They should be taken care of at home. The English legislature in 1905 passed an act to prevent the landing of undesirable aliens, and the number refused admission in 1906 was 493. (b) Immigration sometimes increases the competition in the labour market, and thus lowers wages. One case is particularly aggravating, viz. when employers import foreign labourers in order to take the place of their men who are on strike. In 1886 the United States passed what is called the Contract Labor Law, forbidding the landing of any person who is under contract to perform labour in the United States. It is very difficult to discover such cases, but the number rejected is fairly large (see table above).

(c) The immigration of men of alien race who refuse to assimilate with the natives is said sometimes to be a danger to the country. This at least is the excuse for the entire exclusion of Chinese labourers from the United States since 1882 (provisions made more stringent in 1888 and 1892) (see also the article Coolies).

Internal Migration.—In modern times there is constant movement of population within national lines, from section to section, and especially from rural districts to the cities. No record is kept of this, and we can trace it only through the census statistics of birthplace. In the United States, for instance, it was shown in 1890 that more than 21.5 per cent. of the native-born inhabitants were living in a state other than that in which they were born. Still further, it appears that about one-half of the native-born inhabitants had moved out of the county in which they were born. In 1890 there were 1,233,629 natives of the State of New York living in other states. The movement is principally westwards in direction and along parallels of latitude. For instance, New York has made large contributions to the population of Ohio, Michigan, Illinois, Wisconsin, Iowa and so on. Virginia has contributed largely to the population of West Virginia, Kentucky, Ohio, Indiana, Illinois and Missouri.

In Europe there is a similar movement; but it is difficult to make comparisons, because of the differences in the administrative areas. In England in 1891, 71.6 per cent. of the population were residing in their native county; in Prussia, 69.7 per cent. in the kreis; in France, 81.7 per cent. in the department; in Austria, 80.5 per cent. in the Bezirk; in Switzerland, 82.1 per cent. in the canton where they were born (Weber, Growth of Cities, p. 249). The most important phase of internal migration is the movement from rural districts to the cities. The statistical results are shown in the following table extracted from the admirable work of Weber, just quoted—

Percentage of Population living in Towns of 10,000 and over at Three Periods.

In England and Wales the rural population increased in the aggregate during the first half of the 19th century, but at a gradually diminishing rate; in the second half of the century the population declined with varying regularity, until the census of 1891, when there was an increase. But notwithstanding this aggregate increase there are many rural districts which still show a slowly declining population. The urban population is increasing, as shown in the following table—

Decennial Rate of Increase or Decrease.

Somewhat the same phenomenon is seen in France. According to the census of 1891 not less than 55 out of the 87 departments had decreased in population; and out of the 32 that had increased, 7 showed a decrease in their rural parts when the large towns were deducted. In Germany the towns of 10,000 and over show a much more rapid increase than the rural districts; and the same fact is generally true of the smaller countries of Europe. This more rapid increase of population in cities is due only in part to migration from the country. Until the 19th century deaths generally exceeded births in cities, so that if it had not been for constant immigration the cities would not only not but have grown, but would have decreased in population. Cities grow more rapidly now than formerly, because the excess of deaths over births has been turned into an excess of births over deaths. Thereby the cities are becoming less dependent upon immigration for increase of population than formerly, but the migration still goes on. The causes of migration from country to city are mainly economic. In early stages of culture men are scattered over the country, or at most gathered together in hamlets and villages. Each of these is self-sufficing, having its own farms and handicraftsmen, and producing what it needs. With the beginning of exchange commercial centres spring up, situated on navigable streams and especially at points where land and water journeys are broken. With the growth of manufactures, industrial centres spring up where the division of labour can be fully provided for. In modern times two factors have accelerated this process, viz.: (1) the building of railways, which have developed community to a very great degree and favoured the large towns at the expense of the small; and (2) the invention of machinery, which has greatly increased the possibility of division of labour and manufactures on a large scale. The old handicraftsman has been superseded by machine labour and the village artisan by the factory hand. At the same time improvements in agriculture and the opening up of new countries have enabled the modern community to gain its food and raw material with a less expenditure of labour force, and the surplus agricultural population has gone to the city. The attractive influences upon individuals have been higher wages, greater scope for the ambitious, and the social advantages of city life.

The general laws of internal migration may be summarized (according to Ravenstein) as follows:

1. The great body of migrants proceed only a short distance.
2. The process of absorption goes on as follows: The inhabitants of the country immediately surrounding a town of rapid growth flock into it; the gaps thus left in the rural population are filled up by migrants from more remote districts, until the attractive force of one of the rapidly-growing cities makes its influence felt, step by step, to the most remote corner of the land. Migrants enumerated in one town the centre of absorption will consequently grow less with the distance, proportionately to the native population which furnishes them.
3. The process of dispersion is the inverse of that of absorption, and exhibits similar features.
4. Each main current of migration produces a compensating countercurrent.

5. Migrants proceeding long distances generally go by preference to one or the great cities of commerce or industry.

6. Migration patterns of humans are less migratory than those of the rural parts of the country.

7. Females are more migratory than males.

**AUTHORITIES.—**The statistics of migration are to be found in the official returns of different countries, especially the statistical tables relating to emigration and immigration published by the British Board of Trade, and the Reports (annual) of the Commissioner-General of Immigration of the United States. For general discussion see Philippovich, Auseinandersetzung und Aussenwanderungspolitik (Leipzig, 1892). An exhaustive bibliography will be found in an article by the same author, "Aussiedlung," in HANDWURTBEBJICHEL DER STATISTIKER, p. 282; also in "Inter-Deutsche Migration," with bibliography (New York, 1890). For the internal migration of the population see A. F. Weber, Growth of Cities (New York, 1890). See also Ravenstein, "The Laws of Migration," in Journal of Royal Statistical Society (1885 and 1886). Professor Flinders Petrie, in his Huxley Lecture for 1906 on Migrations (reprinted by the Anthropological Institute), deals with the mutations and movements of races from an anthropological standpoint with profound knowledge and originality.

(R. M. S.; T. A. l.)

**MIGRATION**, in Zoology. In zoology considerable importance attaches to the problems of migration, by which is meant the wandering of living creatures into another, usually distant, locality in order to breed there; this implies a return, and the double phenomenon is annual. All other changes of the abode are either sporadic, epidemic, or fundamental, and are within lesser limits. Further, migration should not be confused with "spreading," which proceeds steadily, and in epicyles, with a totally different result. It need not be emphasized that hard and fast lines between these phenomena do not exist; they are often a question of degree. For instance, when the common toad, which is a strictly terrestrial creature, wanders every spring to a frequently distant pool in order to spawn there, this is a true migration. The same applies, strictly speaking, to those insects which hibernate in the ground, at the root of the tree on which they feed and breed. The grey plover breeds in the arctic circle and winters in equatorial countries. To complicate matters further, it is not necessary that the migration be undertaken periodically, more than once, by the same individual. For instance, the common eel ascends the rivers as an elver in its youth; years after it returns to the sea, there to breed and to die, whilst other fishes come and go, year after year. Further, some of the larger birds, for instance swans and cranes, are still immature in their second year, and yet they migrate with their older relations. It seems permissible to use this fact as an indication that the breeding as such is not the prime reason of the inter-tropical migration. The most impelling agent must have been the want of food, and what we usually understand by migration cannot suddenly have sprung into existence to its full extent, but is more likely the cumulative effect of the doings of countless generations. The faculty of shifting the abode was of course always there, the necessity of moving forward on was also present, and those which went in the wrong direction came to grief, while the others flourished and returned with their progeny. They did not at first cover enormous distances, but just enough to find unoccupied ground. The annual repetition became an established habit, at last the instinct. There can be but little doubt that the prime impulse was want of food. The new growing grass on the prairie or on the veldt attracts every year those creatures which live upon pasture. The inter-tropical belt of the world is so crowded with creatures that there is keenest competition, whilst in the temperate and cold regions is a long winter quiescence unfit for the support of many creatures, whereas in the summer these same regions are covered with new vegetation, with its concomitant abundance of insects and other invertebrates. The tables are decked again, and these opportunities are not wasted.

The process of migration, in its most striking cases, is now very complicated. Many a bird goes actually to the arctic regions for the shortest of summers, but spends most of the year within the tropics. On the other hand there are many species which do not go so far north, but stop to breed in the intermediate regions. We must not take the extremes when trying to unravel the development of the problem. The periodical migrations of mammals, with their more limited extent and greater leisure, are less perplexing.

It has been argued with some show of reason that the real home of a bird is that country in which it was born, in other words where the species breeds, but this by no means is a case a valid conclusion. It applies to most creatures, but it can well bear exceptions if we leave sentiment aside. When it comes to a question of domicile, the ten weeks' sojourn of the swift, Cypselus, in England are more than weighed down by the nine months or more which these birds spend in southern countries, although we do not know whether they are resident there or roam about. The breeding time is the busiest period of a bird's life; then the numbers of each species are suddenly multiplied, and so is the stress of providing food, and the particular food which is best for the young may not be available in every country. The idea that the arctic circle is the original home of the numerous kinds of birds which breed in it, whence they are now periodically driven away by stress, has been coupled with the glacial epoch, that supposed solution of so many difficulties. We have only to assume that the old, permanent home of these migrants was in the arctic region, that the progressing glaciation drove them away, of course towards the equator, and then, when times improved again, the birds returned to their old home. This sounds very plausible, but it involves huge assumptions. The birds, not the individuals, but the species, are supposed to have inherited such a loving reminiscence of their old home, that after thousands of years—with most of the small birds meaning as many generations—they returned at the first opportunity. It implies that their long continued sojourn in foreign lands, where—under this assumption—thousands of generations must have been bred and have spent all their lives, was not sufficient to naturalize them, so to speak, in other words to supplant the instinctive love of the primary ancient home. That the last glacial epoch has driven the limit of many kinds of animals and plants farther south is as certain as that many have recovered the lost ground after the reversion of the glaciation, but it must have been a very slow and steady process of spreading. It may, and probably does, account for the present annual visitations of arctic lands, as a phenomenon which has been evolved de novo, which would have come to pass even if no birds had existed in pre-glacial times.

How do birds manage to find their way, thousands and thousands of miles across land and water? This question has been extolled as a mystery of mysteries. It has been stated that the old birds show the way to the young, a speculation which does not apply to those many cases in which old and young notoriously travel at different times. It has been assumed that they travel by sight, taking advantage of certain landmarks; another untenable idea, since—experience having to be excluded in a flock of birds which made the journey for the first time—it implies that the young must have inherited the reminiscence of those landmarks! Others have likened the bird to a kind of compass, because in eastern Europe von Middendorff found some migration routes to coincide with the direction of the magnetic pole. The whole question reduces itself to a sense of direction, a faculty which is possessed by nearly all animals; in some it is present to an astonishing extent; but the manifestations of this sense vary only in degree. The cat which escapes out of the bag finds its way back, directly or after many adventures. The bee, after having loaded itself with pollen, returns by the proverbial line to the hive which may be a mile away, but, move the small creature a foot in the meantime, an inch to the right or left, and the bee will knock its head against the hive and blunder about; move the hive a few yards and bee after bee returning will be puzzled to find its hive again. They, maybe, with the help of landmarks, have accustomed themselves to steer a course. Such instances need not be multiplied. The principle is the same whether
the journey be one of a few yards or of many miles. Given the sense of direction, it is no mystery to steer a course due north than it is to lay on south-east by east, provided always the impetus to be on the move. There is no mystery except that we, the most intellectual of mankind, have lost the necessary skill which, well nigh have lost this sense, and why?

It is, perhaps, an instance of the mental cruelty through long-continued disuse. A. Newton's article "Birds" in *Encyc. Brit.,* 9th ed.)

In almost all countries there are some resident species which arrive in spring, and others in autumn; others which arrive in autumn, stop for the winter and depart in spring; and others again—and these are strictly the "birds of passage" which show themselves in spring, or in the northward migration of the species within, staying long in it, and their transient visits take place about spring and autumn. These three apparently different categories of migrants are all acted upon by the same impulsion and the same cause. The species which resort to Britain and to other temperate countries in winter are simply those which have their breeding quarters much nearer the poles, and in returning to them on the approach of spring are but doing exactly as do those species which, having their winter abode nearer the equator, come to us with the spring.

The birds of passage, proper, like our winter visitants, have the more northern hemisphere, and whilst the more northern species, if any species, seek their winter abode nearer the equator, and thus perform a somewhat larger migration.

In England the song-thrushes receive in the autumn a considerable accession in numbers from the birds which arrive from the north, though the migration is by no means so well marked as it is on the continent. We have the arrival of several species of butterflies at work. In most localities in Britain the newcomers depart after a short sojourn, and are accompanied by so many of the home-bred bands of the north, that it is often found that not a single song-thrush can be found from the end of November to the end of January, while in others examples can always be seen. Much the same may be said of the redbreast. Undoubtedly resident as a species, attentive scrutiny will reveal the fact that many numbers are subject to very considerable variation, according to the season of the year. At no time do our redbreasts collect in bands, but towards the end of summer they may be seen in the south of England successively passing onward, the travellers being mostly—if not wholly—young birds of the year; and so the great majority disappear, departing it may be safely presumed for more southern countries—and these species form the so-called "partial migrants", by which we mean that even if such necessities are not absolutely wanting yet that the regions in question would not supply sufficient food for both parents and offspring—the latter being at the lowest possible rate of consumption. The migration of the species of both were diminished by the casualties of travel. But on the other hand we must remember what has above been advanced in regard to the pertinacity with which birds return to their accustomed breeding-places, and the force of this passionate need for the old home cannot but be taken into account, even if we do not allow that in it lies the whole stimulus to undertake the perilous voyage.

It is for the phenomenon as it appears to be explainable that here, as in so many other cases, 'survival of the fittest' will be found to have had a powerful influence. Let us suppose that in any species of migratory bird, breeding can as a rule be only safely accomplished in a given area; and further, that during a great part of the rest of the year sufficient food cannot be obtained in that area. It will follow that those birds which do not leave the breeding area at the proper season will never breed at all. Of course, this is not the case. But it will also be the fate of those which do not leave the feeding area at the proper time. Now, if we suppose that the two areas were (for some remote ancestor of the existing species) coincident, but by geological and climatic changes the one has been separated from the other, we stand ready to consider how the habit of incipient and partial migration at the proper seasons would at last become hereditary, and so fixed as to be what we term an instinct. It will probably be found that every great migration exists in complete coincidence to a complete separation of the breeding and the subsistence areas; and when the natural history of a sufficient number of the trees in the country worked out we may find every link between species which never leave a restricted area in which they breed and live the whole year round, to those other cases in which the two areas are absolutely separated.

If more particulars respecting migration are all that can here be given, and it is doubtful whether much can be built upon them. It has been ascertained by repeated observation that in the spring-movement of most species of the northern hemisphere, the birds always in their migrations are driven onwards by hunger; and that they appear some days, or perhaps weeks, before the hens. It is not difficult to imagine that, in the course of a journey prolonged throughout some 50° or 60° of latitude, the stronger individuals

---

*1* If the relative proportion of land to water in the southern hemisphere was at all as it is in the northern, we should not doubt find the birds of southern continents beginning to press upon the tropical and equatorial regions of the globe at the season when they were thronged with the emigrants from the north. The question of the former's winter quarters, and the latter should be acted upon by the force of the former, according to the explanation given of the southward movement of northern migrants. But, if the proportion of land to water were much more than in the other hemisphere, yet, when we regard the comparative deficiency of land in southern latitudes all round the world, it is obvious that the feathered population of such as nowadays exists can exert but little influence, and its effects may be practically disregarded.

MIGRATION

should outstrip the weaker by a very perceptible distance, and it can hardly be doubted that in most species the males fly more as they are bigger than the females. Some observers assert that the same thing takes place in the return journey in autumn—Seemen, for instance, says that, first of all, the young, then the males, having finished their moult of autumn, are seen to be everywhere by the females—but on this point others are not so sure, which is not surprising when we consider that the majority of observations have been made on the flying of birds from the island of the rectangular room Passeres, to which the remark is especially applicable—in the British islands, France, North Germany and the Russian empire—for it is well known that the journey any inequality in the speed of travelling will not have become apparent. There is another matter to be noticed. It has been suspected that there is any difference in the size of birds of the same species, particular in the case of the indigo bunting. It is true that the birds which perform the most extensive journeys would be naturally those those with the largest and broadest remiges, and in support of this view it certainly appears that in some of the smaller migrants—such as the whitethroat (Sylvia communis) and the yellowhammer—the examples which reach the extreme north of Europe and there pass the summer possess greater mechanical powers of flight than those of the same species which stop short on the shores of the Mediterranean. It may perhaps be inferred, though precise evidence is wanting, that these individual differences push further to the southward in winter than those which are less favoured in this respect, and that some individuals no at the some species, and it may well be so with individuals. H. B. Tristram has remarked (Ibis, 1863, p. 77) that, in many genera of birds, “the specimens first arrived northerly have also the most extended southerly range; and the closest of them to the highest latitudes for nidification also pass further than others to the southward in winter,” fortifying his opinion by examples added at a later stage. These two are two major factors.

For many years past a large number of persons in different countries have occupied and amused themselves by carefully registering the dates on which various migratory birds first make their appearance, and there is now an abundance of records so compiled. Still it does not seem that they have been able to determine what connexion, if any, exists between the arrival of birds and the weather. The only point at which it comes to have been made about the weather in the places whence the travellers are supposed to have come. As a rule it would seem as though birds were not dependent on the weather to any great extent. Occasionally there have been reports of birds among them in the valleys of rivers having been found, but very much delayed, but most sea-fowls may be trusted, it is said, as the almanac itself. Foul weather or fair, heat or cold, the puffins (Fratercula arctica) repair to some of their stations punctually on a given day as if their movements were regulated by clock-work. Whether they have come from far or from near we know not, but other birds certainly come from a great distance, and yet many of them do not arrive till the time which has been allotted for them by nature without much tardiness. It is up to the time of its summer-home—in most parts of Europe is one of the days of August—and how rarely it is seen after that time is past.

It must be allowed, however, that, with few exceptions, the mass of statistics above spoken of has never been worked up and digested so as to make it easy to compare. Therefore it would be premature to say that little would come of it, but the result of those exceptions is not very encouraging. E. von Moltke has fully coped with the whole matter of the birds throughout the Russian Empire, but the insight into the question afforded by his published labours is not very great. His chief object has been to trace what he has termed the isepisses (lines = acqualis, Trenses = adovale) or the lines of simultaneous arrival, and in the case of seven species these are laid down on the maps which accompany his treatise. The lines are found by taking the average date of arrival of each bird, and the road that joins the two points is then finally drawn. They are out of the isepisses, or rather the points formed by each of them, the whole course of the migration is thus most accurately made known with regard to the changes going on in their progressive advance at intervals of a few days, and the issue of the whole investigation, according to him, proves that in the middle of Siberia the general direction of all the does-lows lies almost the same from south-east to north-west, and in European Russia from south-west to north-east. Thus nearly all the migrants of the Russian empire tend to converge upon the Crimea, where there are more mountains of the peninsula, but it is almost needless to say that few of them reach anything like so far, since the country in those high latitudes is unusually unfit to support the majority. With the exception of some swallows and martins the results of these journeys by migratory birds have been the subject of a very exhaustive memoir by J. A. Palméen, but it would be beyond our limits to do justice to the pertinence of his results concisely. He enters very fully in to this part of the question, and lays down the probability the chief roads taken by the most migratory birds of the palearctic region in their return autumnal journey, further dividing them into the latitudes and lines of flight. Some of these do not usually occur. Broadly speaking, the birds of Russia and Western Siberia go for the winter to Africa, those of Mongolia, and those of Siberia east of the Lena go towards the extreme south. But lay down the paths of migratory birds, observe their comings and goings, or strive to account for the impulses which urge them on, and we find that the result of any consideration the most marvellous thing of all—how do the birds find their way from so many immeasurable distances? This seems to be by far the most inexplicable part of the matter. Year after year the migratory wagtail will come back. year after year the migratory cuckoo will deposit her eggs in that nest, and yet in each interval of time the former may have passed the route they take away to the Mediterranean, and the latter, absent for a still longer period, may have wandered into the heart of Africa. That particular form of bluethroat which yearly repairs to breed upon the mosaics of the subalpine and northern parts of Scandinavia (Cyanecula suecica) is hardly ever seen in Europe south of the Baltic. Throughout Germany it may be said to be quite unknown, being replaced by a conspicuously different form of the same species. For instance, it is among the collectors of that country, a numerous and well-instructed public of keen interest, we are in a position to declare that it is not known to stop in its transit from its winter haunts, which we know to be much farther south, to the northern British isles. Other instances, though none so crucial as this, could be cited from among European birds were there room here for them. In New Zealand again there are many species which are annual visitors; one, a species of Chroicocephalus, is supposed to come from the other, Eudynamis taliensis is widely spread throughout Polynesia, yet both these birds yearly make two voyages over the enormous waste of waters that surrounds the country to which they return to breed. But space would utterly fail us were we to attempt to recount all the examples of these wonderful flights. Yet it seems that the route of sight should be the faculty whereby they are so guided to the destination, and they have the ability of those which travel in the dark. J. A. Palméen asserted (op. cit. p. 193) that migrants are led by the older and stronger birds, which are the leaders of the group, and those which stray from their right course are yearlings that have never before taken the journey, as he ascribed the due performance of the flight to experience. There are many birds which cannot be said to migrate in company. While swallows, to take a sufficiently evident example, conspicuously congregate in vast flocks and go and leave their shores in large companies, the majority of our summer-visitors are alone, although not altogether apparently without concert with others. Experience here can only signify the knowledge acquired on former occasions and obtained by sight. Now it was stated by C. J. Temminck (Manuel d'ornithologie, III. Introduction, p. 191) that there would appear the statement has not been invalidated, that among migrants the young and the old always journey apart and most generally by different routes. The former can have no experience, the latter may have had. The experience of those that have the haven where they would be. The sense of sight, essential to a knowledge of landmarks, is utterly insufficient to account for the success that attend the birds which travel by night, or in a single flight span oceans or continents. Yet without it the idea of "experience" cannot be substantiated. We may admit that inherited but unconscious experience, which is really all that can be meant by instinct, is a factor in the whole matter—certainly, as Wallace seems to have proved, in originating the migratory impulse, but yet every aspect of the question is fraught with difficulty. For instance we know nothing about the different unobscured birds fly during their long stretches of migration. Gaede, in his otherwise very interesting book, has startled ornithologists by various statements, but his calculations were based upon such crude observations that the results are farcical. The author, in fact, acknowledged his satisfaction that the grey or hooded crow, Corvus cornix, which notoriously is not a fast bird, flies from Hedegland to the coast of Lincolnshire in only one night, and that at a rate of 70 miles an hour. To the little bluethroat he assigned a velocity of two hundred and forty miles an hour, a statement as silly as that made by some fanciful observer in Portugal who convinced himself by instinct, or sense. It is a very good thing we may in the very few hours later were skimming over the Portuguese pine forests on their way to Central Africa. Fifty miles an hour would be a high average speed, and it well tell how long such birds can continue their flight without interruption. All we seem to know is that not a few kinds manage, in various parts of the world, to cross enormous distances without the chance of a break. It was Gaede's notion that migration was for the most part carried on at such a height in the air as to be beyond our ken, and that what...
comes to our perception consists chiefly of the abortive or unsuccessful attempts, when birds are checked in their course, and being unable to proceed further, again return to the place where they started. Now, for obvious reasons birds could notwell fly at very great heights in very thin air, as experiments with pigeons released from balloons have shown, and the condor seems far above the bison in this respect. The few remarkable instances in which birds have been observed through a telescope passing across the face of the moon have naturally yielded but vague calculations as to distances, and in most cases G. M. Voigl in the very. The sky above the clouds the migration proceeds beyond our ken, and if for some reason or other they are below the clouds the phenomenon becomes to us very noticeable. It is well known that birds roam overhead, while onights that are overcast, misty and dark, especially if slight rain be falling, flocks may often be heard almost continuously. It is in such weather, continues Newton, that birds while migrating are most vociferous, doubtless with the result that thereby the company of fellow-travellers is kept together.

These yet remain a few words to be said on what may be termed Exodromous migration, that is when from some cause or other the ordinary practice is broken through. The erratic movements of the various species of crossbill (Loxia) and some allied forms afford a striking example. For instance, during the winter of 1843 we were informed that none of the species occurring in the part of the country or at what season of the year he may not fall in with a company of the common crossbill (L. curvirostra), and the like may be said of many other birds. The birds at this season shut up the seed caches, and as its supply in any one locality is intermittent or precarious, we may with reasonably be expected that they will from place to place in its quest, and may that they will be found in all parts of the country. There is no accounting for their uncertain appearance. The great band of nutcrackers (Nucifraga caryocatactes) which in the autumn of 1844 pervaded western and central Europe (Bull. Acad. Bruxelles, xi. 296), may also have been actuated by the same motive, but we can hardly explain the roving of all other birds so plausibly. The inroads of the waxwing (Amelius garrulus) have been the subject of interest for more than 300 years, and by persons erroneously superstitious auguries were regarded as fore-runners of dire calamity. Sometimes years have passed without the bird being seen in central, western or southern Europe, and then perhaps for two or three seasons in succession vast flocks have suddenly appeared. Later observations have made it quite certain that this is as inconstant in the choice of its summer as of its winter-quarters. One of the most extraordinary events known to ornithologists is the irruption of birds into Europe in 1863 of Pallas's sand-grouse (Syrrhaptes paradoxus). Of this bird, hitherto only as an inhabitant of the Tatar steppes, a single specimen was obtained at Starepta on the Volga in the winter of 1845. In May 1859 a pair is said to have been observed at low altitudes in the western part of the Russian empire, and a few weeks later five examples were procured, and a few others seen, in western Europe—one in Jutland, one in Holland, two in England and one in Wales. In 1860 another was seen in Sweden, and in 1861 four examples were adduced to consist of at least 700 individuals overran Europe—reaching Sweden, Norway, the Faeroes and Ireland in the north-west; Quebec in the north; and descending to the Mediterranean and the Straits of Dover in the south of Spain. On the sandhills of Jutland and Holland some of these birds bred, but they were all killed off. A much greater visitation took place in 1886, which met with the same fate. The number of birds was quite incalculable, the wave extending from Norway to southern Spain.

In comparison with the periodic annual migrations of so many birds, those of other creatures are scarce and insignificant, excepting fishes.

Mammals.—Few trustworthy observations have been recorded. The most regular and least limited migrations seem to be those of the Pacific salmon. At a given time almost the whole of the Russian empire, and a few weeks later five examples were procured, and a few others seen, in western Europe—one in Jutland, one in Holland, two in England and one in Wales. In 1860 another was seen in Sweden, and in 1861 four examples were adduced to consist of at least 700 individuals overran Europe—reaching Sweden, Norway, the Faeroes and Ireland in the north-west; Quebec in the north; and descending to the Mediterranean and the Straits of Dover in the south of Spain. On the sandhills of Jutland and Holland some of these birds bred, but they were all killed off. A much greater visitation took place in 1886, which met with the same fate. The number of birds was quite incalculable, the wave extending from Norway to southern Spain.

At a given time almost the whole of the Russian empire, and a few weeks later five examples were procured, and a few others seen, in western Europe—one in Jutland, one in Holland, two in England and one in Wales. In 1860 another was seen in Sweden, and in 1861 four examples were adduced to consist of at least 700 individuals overran Europe—reaching Sweden, Norway, the Faeroes and Ireland in the north-west; Quebec in the north; and descending to the Mediterranean and the Straits of Dover in the south of Spain. On the sandhills of Jutland and Holland some of these birds bred, but they were all killed off. A much greater visitation took place in 1886, which met with the same fate. The number of birds was quite incalculable, the wave extending from Norway to southern Spain.

In comparison with the periodic annual migrations of so many birds, those of other creatures are scarce and insignificant, excepting fishes.

Mammals.—Few trustworthy observations have been recorded. The most regular and least limited migrations seem to be those of the Pacific salmon. At a given time almost the whole of the Russian empire, and a few weeks later five examples were procured, and a few others seen, in western Europe—one in Jutland, one in Holland, two in England and one in Wales. MIGUEL—MILAN

437

MIGUEL, MARIA EVA RIST (1802-1866), usually known as Doña Miguel, whose name is chiefly associated with his pretensions to the throne of Portugal, was the third son of King John VI. of Portugal, and Carlota Joaquina, one of the Spanish Bourbon princesses; he was born at Lisbon, 25 July 1802. In 1807 he accompanied his parents in their flight to Brazil, where he grew up an uneducated and fanatical debauchee; in 1821, on his return to Europe, it is said that he had not yet learned to read. In 1822 his father swore fidelity to the new Portuguese constitution which had been proclaimed in his absence; and this led Carlota Joaquina, who was an absolutist of the extreme Bourbon type, and hated her husband, to seek his dethronement in favour of Miguel her favourite son. The insurrections which ensued (see PORTUGAL) resulted in his being deposed and exiled by the English, who restored him to Portugal, in March 1823, with the title of Prince of the House of Braganza. On the sudden death of John VI. in May 1826, Pedro of Brazil, his eldest son, renounced the crown in favour of his daughter Maria da Gloria, on the understanding that she should become the wife of Miguel. The last named accordingly swore allegiance to Pedro, to Maria, and to the constitution which Pedro had introduced, and on this footing was appointed regent in July 1827. He arrived in Lisbon in February 1828, and, regardless of his promises, dissolved the Cortes in March; having called a new Cortes, with the title of the House of October, of which his mother was the ruling spirit, he got himself proclaimed sole legitimate king of Portugal in July. His private life was characterized by the widest excesses, and he used his power to oppose all forms of liberalism.

The public opinion of Europe became more and more actively hostile to his reign, and after the occupation of Oporto by Dom Pedro in 1832, the destruction of Miguel's fleet by Captain (afterwards Sir Charles) Napier off Cape St Vincent in 1833, and the victory of Saldanha at Santarem in 1834, Queen Cristina of Spain recognized the legitimate sovereignty of Maria, and in this was followed by France and England. Dom Miguel capitulated at Evora on the 26th of May 1834, renouncing all pretensions to the Portuguese throne. He lived for some time at Rome, where he enjoyed papal recognition, but afterwards retired to Bronnach, in Baden, where he died on the 14th of November 1866.

MIHRAB, a term in Mahomedan architecture given to the niche which in a mosque indicates the direction of Mecca, towards which the Moslems turn when praying.

MIKADO (Japanese for "exalted gate"), the poetical title associated by foreign countries with the sovereign of Japan; the Japanese title, corresponding to "emperor," is tenno, the term kōtei being used of his function in relation to external affairs. By the constitution of 1889, the emperor of Japan transferred a large part of his former powers as absolute monarch to the representatives of the people, but as head of the empire he appoints the ministers, declares war, makes peace and concludes treaties, acting generally as a constitutional sovereign but with all the personal authority attaching to his august position. The history of the mikado goes back to very early times, but from 1600 to 1868 the real power was in the hands of the shoguns, who nevertheless were in ceremonial theory subjects successively invested with their authority by the mikado. The revolution of 1867 restored the real power into the mikado's hands. (See JAPAN: History; and MIYAZAWA, HIROSHI.)

MIKIRS, a hill tribe of India, occupying two or three detached tracts in Newgong and Sibasagar districts of Eastern Bengal and Assam, known as the Mikir hills. In 1901 their total number was returned as 87,056. Mikir is the name given to them by the Assamese; they call themselves Arleeng, which means "man" in general. They have long settled down to agriculture, and are distinguished from the tribes around them by the absence of savagery. Their language, which has been studied by missionaries, seems to connect them with the Kuki-Chin stock on the Burmese frontier.

MILAN (Ital. Milano, Ger. Mailand, anc. Mediolanum, q.v.), a city of Lombardy, Italy, capital of the province of Milan, 93 m. by rail E.N.E. of Turin. Pop. (1881), 327,839; (1900), 366,615. It is the seat of an archbishop, with its cathedral, the Duomo, the bishopric of Monza, the former abbey of Bicocca, the new university, the Polytechnic Institute, the Faculties of Law and of Science, the Academy of Science, the National Library, the Technical School, the National Technical Polytechnic Institute, the National School of Veterinary Medicine, the National School of Fine Arts, and the School of Music. It is the head quarters of the army corps, the chief financial centre of Italy and the wealthiest manufacturing and commercial town in the country. It stands on the little river Olona, near the Lombard plain, 400 ft. above sea-level.

The plain around Milan is extremely fertile, owing at once to the richness of the alluvial soil deposited by the Po, Ticino, Olona and Adda, and to the excellent system of irrigation. Seen from the top of the cathedral, the plain presents the appearance of a vast garden divided into square plots by rows of mulberry or poplar trees. To the east this plain stretches in an unbroken level, as far as the eye can follow it, towards Venice and the Adriatic; on the southern side the line of the Apennines from Bologna to Genoa closes the view; to the west rise the Maritime, Cottian and Graian Alps, with Monte Viso as their central point; while northward are the Pennine, Helvetic and Rhätian Alps, of which Monte Rosa, the Saasgrat and Monte Leone are the most conspicuous features. In the plain itself lie many small villages; and here and there a larger town like Monza or Sarzano, or a great building like the Certosa of Pavia, makes a white point upon the green. The climate is changeable and trying; in the intense hot, in winter very cold. Snow is often seen, and the thermometer is frequently below freezing-point.

In shape Milan is a fairly regular polygon, and its focus is the splendid Piazza del Duomo, from which a number of broad modern streets radiate in all directions. These streets are connected by an inner circle of boulevards, constructed just outside the canal, which marks the site of the town moat. The
milan

arches of Porta Nuova are almost the last trace of the inner circuit, constructed after the destruction of the city by Frederick Barbarossa, to which also belonged the Porta del Fabbric, demolished in 1678. Curious reliefs from the Porta Romana are to be seen in the museum. Within this circle the majority of the streets are narrow and crooked, while those between it and the bastions, though broader on the whole, have but little regularity. An outer circuit of boulevards, planted with trees and containing the view of the suburbs, lies just beyond the remaining walls of the city, erected by the Spaniards in the 16th century; the entire length of these boulevards is traversed by an electric tramway 7 m. long.

Occupying the site of the Piazza del Duomo is the famous cathedral. It is built of brick casel in marble from the quarries which Gian Galeazzo Visconti gave in perpetuity to the cathedral chapter. It was begun in 1386. The name of the original architect is unknown, but it is certain that many German masons were called to Milan to assist the Tuscan builders. It was then the largest church in existence, and now, after St Peter's at Rome and the cathedral of Seville, the Duomo of Milan is the largest church in Europe; it covers an area of 14,000 sq. yds. and has 400 columns of people. The interior is 456 ft. long, 180 ft. wide; the nave is 157 ft. high, and the distance from the pavement to the top of the tower is 356 ft. The style is Gothic, very elaborately decorated, but it shows many peculiarities, for the work was continued through several centuries and after many designs by many masters, notably by Amadeo, who carried out the octagonal cupola (the pinnacle of which dates from 1774), and by Tibaldi, who laid down the pavement and designed a baroque façade. This last feature was begun after Tibaldi's design in 1615, but was not finished till 1805, when Napoleon caused the work to be resumed. With its Renaissance windows and portals this façade, though good in itself, was utterly out of keeping with the general style of the church, and in 1900 the removal of the inharmonious features was begun, to be replaced in a style strictly in accordance with the Gothic style of the rest of the building from the designs of Giuseppe Bareno. In shape the church is cruciform, with double aisles to the nave and aisles to the transepts. The roof is supported by fifty-two pillars with canopied niches for statues instead of capitals; the great windows of the choir, reputed to be the largest in the world, are filled with stained glass of 1844. To the right of the entrance is the tomb of Archbishop Herbier, the champion of Milanese liberty, while beside him rests Archbishop Otto Visconti, the founder of that family as a reigning house. The large bronze candelabrum in the left transept is said to be 15th century work. In a crypt under the choir lies the body of the cardinal saint Carlo Borromeo, who consecrated the cathedral in 1577. It is contained in a rock-crystal shrine, encased in silver, and is vested in full pontifical robes blazing with jewels. The roof of the cathedral is built of blocks of marble, and the various levels are reached by staircases carried up the buttresses; it is ornamented with a profusion of turrets, pinnacles and statues, of which last there are said to be no fewer than 4,440, of very various styles and periods. In front of the cathedral rises a colossal bronze equestrian statue of Victor Emmanuel II.

There are two noteworthy palaces in the Piazza del Duomo. The first is the Palazzo Reale dating from 1774, but occupying the site of the earliest mansion of the Viscontis and the Sforzes. Its great hall is a handsome chamber with a gallery supported by caryatides. Built into the palace is the ancient church of San Gottardo, a Romanesque building which was built by Azzzone Visconti in 1328-1339, and was the scene of the murder of Giovanni Maria Visconti in 1472. Its campanile is a beautiful example of early Lombard terra-cotta work. The second palace is that of the archbishops, the fine façade of which is the work of Fabio Magione. It has an older north colonnade, by some attributed to Bramante, but, lacking fine buildings without sufficient evidence, and a fine court with double colonnades by Tibaldi, to whom the back façade is due. The Palazzo della Ragione, erected in the Piazza dei Mercanti, just west of the Piazza del Duomo, the central point of the medieval city, in 1223-1238 by the podestà, Oldrado da Treseno, whose equestrian portrait in high relief adorns it, still exists in fine preservation. It is a brick edifice with a portico, of which the top is supported by a large hall on the upper floor. It is connected to the square by an archway which was built by Ambrogio early in the 14th century (on the site of a temple of Bacchus it is said), but as it stands it is a Romanesque basilica of the 12th century, recently well restored (like many other works of Milan and Lombardy, curious galleries over the façade, and perhaps the most perfectly preserved atrium in existence. The wooden door belongs to the original 4th century church, but it was extensively restored very recently with scenes from the life of David. In a great silver reliquary (modern) in the crypt lie the bones of St Ambrose, above which rises the high altar, which retains its original decorations, the only intact example. Its pillars are gold and silver and enriched with enamel and gems, and are the work of one UgoVilvius, a German. The baldacchino, with sculptured sculptures of the 12th or early 13th century, is borne by four ancient columns of porphyry, erected in the 12th century, at the corners of the nave and the aisles; the capitals are of the 9th century, which, Burniehardt remarks, completely breaks with Byzantine tradition. In the side chapel of S. Satiro are even earlier mosaics (5th century); they can also be found in the gallery by Borgognone (15th century). The lofty brick campanile (789-824) is among the earliest in Italy, and is decorated with coloured majolica disks. The court of the neighbouring canonica is by Bramante, who also restored the cloisters of the monastery of S. Ambrogio, now the military hospital. S. Lorenzo, in the south portion of the town, dates from before A.D. 538, thus being practically contemporary with S. Vitale at Ravenna. Though it is not certain it is to be a part of the thermæ or palace of Maximian, but was burnt down and restored in 1071 (in the restoration Cornian capital were used as bases). Thirty years after its building, and a second fire followed in 1124. It was restored, but collapsed again in 1573, and a great part of it had to be re-constructed, including the dome (1574-1591). (The chapel of S. Aquilino, possibly a part of the original structure, contains frescoes of the 5th or 6th century.) In plan the church is an octagon, supported at the corners by four square towers in brickwork, which belong to the original structure. The interior with its white columns is a very fine example, and its architectural features and statues have been very considerable. S. Eustorgio, one of the largest Gothic churches in Milan, with some Romanesque survivals, dates, as it stands, with its campanile, to the present time, and has a much older old style. It has some interesting medieval sculptures, and a fine chapel (Cappella Portinarl), with a good dome and a beautiful frieze of angels, built by Michelozzo in 1464. The choir of the chapel (though covered with a marble sarcophagus with reliefs, supported by statues) of Peter Martyr (q.v.), the masterpiece of Giovanni di Balduccio of Pisa (1359); the walls of the chapel are decorated with important frescoes by Vincenzo Foppa of Brescia. S. Simpliciano, too, originally Romanesque, is now in the main Gothic, and has been much altered. S. Vincenzo in Prato (835), now restored to its basilican form, with nave and two aisles divided by columns and three apses, and with small, flat arching on the exterior, which is in brickwork; S. Satiro, founded in 879; S. Babila, also restored to its original form, &c., &c. The most interesting feature of the church is the domical structure on the left of S. Satiro is earlier than the church, while the campanile is part of the original structure, though Preceded in date by that of S. Ambrogio, which is one of the finest genuine campaniles of the time. The erection of the church of S. Satiro was Bramante's earliest work in Milan (after 1476). The choir is painted in perspective (there was no room to build one), the earliest examples of this device, which was so frequently used in both architecture. The octagonal sacristy (before 1488), with niches below and a gallery above, with stucco decorations by Bramante himself (the frieze with putti and medallions are believed to be his best). The Cisterian abbey-church of Chiaravalle, 53 m. south of Milan, is a fine brick building in the plan of a Latin cross, with nave and two aisles with round pillars, with a lofty domed tower, the alternate slender round pillars and cross vaulting, while the exterior is still quite Romanesque. It was founded in 1135 by St Bernard and consecrated in 1221. It is interesting as the model of many other churches in Lombardy, e.g. S. Maria del Carmine and
S. Francesco in Pavia. S. Marco, modernized inside, still retains a beautiful façade of 1254 and a tower—in brick as elsewhere—and the Sala della Scala. Its original palace was destroyed in the 13th century and the present one erected by Galeazzo II Visconti (1355-1378) and demolished in 1861. This was the site of the famous Library of the Papi. The Sala della Scala, the chief hall of the palace, is 144 ft. long and was the scene of the last struggle between the Lombard and Roman republics. In 1868, the Library was moved to a new building in the town.

The Castello Sforzesco, or Castle of Milan, stands in the Parco Sempione. It was built in 1490 by Francesco Sforza on the site of one erected by Galeazzo Visconti (1335-1378) and destroyed in 1861. The construction of this famous royal residence was begun in 1490 and completed in 1522. The Castle houses a museum of modern art and contains many of the most important works of art in Italy. The most notable of these are the works of Pietro da Cortona, Antonio da Correggio, and Filippo Maria Visconti. After suffering many vicissitudes and being partially destroyed more than once, it was restored—including especially the splendid entrance tower by Antonio da Correggio—and opened to the public in 1522—in the 15th-century style.

MILAN

By Lord Rowton in 1894. Sport and athletics are provided by a number of clubs, notably the Touring Club Italiano, founded in 1864.

The modern industrial development of Milan, with its suburbs and neighbouring towns, such as Monza, Gallarate, Sarzano, Busto Arsizio and Legnano, has been noteworthy. Machine-making on a large scale is carried on by firms that have celebrated 50- and 100-year anniversaries. Minor industries are represented by workshops for the manufacture of wooden utensils, of ornamental metalwork, of cotton goods, of leather goods, of paper, of ceramics, of textiles, of bronze and zincotype establishments. There is, besides, a large carriage-making industry. In textile industries silk is often produced in very great quantities. Some of these firms have been carried on by Englishmen and Americans. The Milanese manufacturers of articles in caoutchouc and of electric cables have acquired a world-wide reputation. In typography Milan is renowned principally for its musical editions and for its heliotype and zincotype establishments. There is, besides, a large production of posters for advertisement. The manufacture of furniture of all kinds is very extensive; the furniture being made by workmen almost entirely hired for the purpose and supplied by the Milanese buyers, who also advance the capital necessary for working expenses. Theatrical costumes and appliances are also made in Milan, which is an important centre of furriers. Milan is still well supplied with fur clothes, in Italy, especially as regards working in gold, silver, vulcanite, bronze and leather. The motive power for much of the house industry is supplied by electricity; the electrification of the canal was completed by the Pinerole in 1924 m. from Milan; the horse-power is continually being increased owing to new needs. Gas is also much used. Milan is also a centre of the export trade in cheese, chocolate, biscuits, &c., and are also manufactured.

The municipal schools of Milan are as well organized as any in Italy, and the exhibit in connexion with them at the great international exhibition of 1906 was of interest. There were, in 1907, 76 miles of no. 1 and 47,093 of no. 2 lines and 131 miles of tramways and holiday classes there were 10,724 older pupils; 2,109,960 free rations and 215,135 paid rations were distributed to 16,526 pupils, and douches were supplied. Pizzoli's manual for examining the mental qualities of the pupils is of interest. The international exhibition of 1906 held in Milan was of considerable importance, all the leading states of the world taking part in it. The retrospective exhibition of means of transport was interesting in view of the recent opening of the Simplon tunnel, the occasion of the exhibition. Among the most noteworthy exhibits were those of machinery, of automobiles and bicycles, of agriculture, of transport by sea. The Universal Exposition, being held at Milan, was the centre of the city of Milan; besides which, all the countries exhibiting had their own separate pavilions.

In 1889 the bicentenary of St Ambrose was celebrated. The bicentenary did not extend beyond the walls; but in that year it was found necessary, owing to the growth of the city and of municipal expenditure, to include the external quarters or Corpi Santi (a name also applied to the extramural portions of Cremona and Pavia), with their large industrial population. Since that time municipal finance has been in a prosperous condition.

The water supply, from wells some 150 ft. deep in the sub-soil, is fairly good; one of the towers of the Castello Sforzesco is used as a distributing centre, while the sewerage system consists of 48 m. of sewers on the single channel principle, with collectors discharging into the Vettabia, a tributary of the Lambro.

In 1886, the Cinema Monumentale, was opened, but found to be insufficient, it is reserved for important monuments, that of Musocco, 3 m. from the city, being used for general purposes.

History.—(For earlier history see Mediolanum.)—After the establishment of the Lombard capital at Pavia in 569 Milan remained the centre of Italian opposition to the foreign conquest. The Lombards were Arians, and the archbishops of Milan from their early days had been adherents of the orthodox faith. The conflict of the two creeds was unequal, their attitude of resolute opposition to the Lombards gained for them great weight among the people, who felt that their archbishop was a power around whom they might gather for the defence of their liberty and religion. All the innate hatred of the foreigner went to strengthen the hands of the archbishops, who slowly acquired, in addition to their spiritual authority, powers military, executive and judicial. These powers they came to administer through their delegates, called vicarcounts. When the Lombard kingdom fell before the Franks under Charles the Bald in 774, the archbishops of Milan were still further strengthened by the close alliance between Charles and the Church, which gave a sort of confirmation to their temporal authority, and also by Charles's policy of breaking up the great Lombard fiefs and dukedoms, for which he substituted the smaller counties. Under the confused government of Charles's immediate successors the archbishop was the only real power in Milan. But there were two classes of difficulties in the situation, ecclesiastical and political; and their presence had a marked effect on the development of the people and the growth of the commune, which was the next stage in the history of Milan. The archbishop was obliged to contend against the heretics or against fanatical reformers who found a following among the people; and on the other, since the archbishop was the real power in the city, the emperor, the nobles and the people each desired that he should be of their party; and to whichever party he did belong he was certain to find himself violently opposed by the other two. From these causes it sometimes happened that there were two archbishops, and therefore no central control, or no archbishop at all, or else an archbishop in exile. The chief result of these difficulties was that a spirit of independence and capacity of judging and acting for themselves, which was developed in the people of Milan. The terror of the Hunnish invasion, in 896, further assisted the people in their progress towards freedom, for it compelled them to take arms and to fortify their city, rendering Milan more than ever independent of the feudal lords who lived in their castles in the country. The tyranny of these nobles drove the peasantry and smaller vassals to seek the protection for life and property, the equality of taxation and of justice, which could be found only inside the walled city and under the rule of the archbishop. Thus Milan grew populous, and learned to govern itself. Its inhabitants became for the first time Milanese, according to the standard of St Ambrose—no longer subjects of a foreign conqueror, but a distinct people, with a municipal life and prospects of their own.

For the further growth of the commune, the action of the great archbishop, Heribert (1018–1045), the establishment of the carriocco, the development of Milanese supremacy in Lombardy, the destruction of Lodii, Como, Pavia and other neighbouring cities, the exhibition of free spirit and power in the Lombard league, and the battle of Legnano, see the articles Italy and Lombards. In 1137 an almost circular moat, still preserved in the inner canal or caponiere, was constructed round the town; but in 1172 Frederick Barbarossa took and almost entirely destroyed the city, only a few churches surviving. The city with its walls was, however, rebuilt five years later by the allied cities of Bergamo, Brescia, Mantua and Verona.

After the battle of Legnano, in 1174, although the Lombard cities failed to reap the fruit of their united action, and fell to mutual jealousy once more, Milan internally began to grow in material prosperity. After the peace of Constance (1183) the city walls were extended; the arts flourished, each in its own quarter, under a syndic who watched the interests of the trade. The manufacture of armour was the most important industry. During the struggles with Barbarossa, when freedom seemed on the point of being destroyed, many Milanese vowed themselves, their goods and their families to the Virgin should their city come safely out of her troubles. Hence arose the powerful fraternity of the "Umiliati," who established their headquarters at the Brena, and began to develop the wool trade, and subsequently gave the first impetus to the production of silk. From this period also date the irrigation works which render the Lombard plain a fertile garden. The government of the city consisted in a parlamento or consiglio grande, including all who possessed bread and could maintain a free household. But this state was deemed to be unmanageable owing to its size, and reduced first to 3000, then to 1500 and finally to 800 members; (b) a crenza or committee of 12 members, elected in the grand council, for the despatch of urgent or secret business; (c) the consuls, the executive, elected for one year, and compelled to report to the great council at the term of their office.

The bitter and well-balanced rivalry between the nobles and the people, and the endless danger to which it exposed the city
owing to the fact that the nobles were always ready to claim the protection of their feudal chief, the emperor, brought to the front two noble families as protagonists of the contending factions—the Torriani of Valsassina, and the Visconti, who derived their name from the office of delegates which they held under the archbishops. After the death of the Visconti in 1237, when Frederick II defeated the Guelph army of the Milanese and captured their carroccio, Pagano della Torre rallied and saved the remnants of the Milanese. This act recommended him to popular favour, and he was called to the government of the city—but only for the distinct purpose of establishing the “catasta,” a property tax which should fall with equal incidence on every citizen. This was a democratic measure which marked the party to which the Torriani belonged and rendered them hated for the nobility. Pagano died in 1241. His nephew Martino followed as podestà in 1256, and in 1259 as Sigismondo, who the first time such a title was heard in Italy. The nobles, who had gathered round the Visconti, and who threatened to bring Ezzelino da Romano, the Ghibelline tyrant of Pavia, into the city, were defeated by Martino, and 900 of their number were captured. Martino was followed by two other Torriani, Filippo his brother (1263-1265) and Napoleon his cousin (1265-1277), as lords of Milan. Napoleon obtained the title of imperial vicar from Rudolph of Hapsburg. But the nobles under the Visconti had been steadily gathering strength, and Napoleon entered Milan in 1277. He ended his life in a wooden cage at Castel Baradello above Como.

Otto Visconti, archbishop of Milan (1262), the victor of Desio, became lord of Milan, and founded the house of Visconti, who ruled the city—except from 1320 to 1310—till 1447, giving twelve lords to Milan. Otto (1277-1295), Matteo (1310-1322), Galeazzo (1322-1328), Azzone (1328-1339), Lucchino (1339-1349) and Giovanni (1349-1354) followed in succession. Giovanni left the lordship to three nephews—Matteo, Galeazzo and Bernabò. Matteo was killed (1355) by his brothers, who divided the Milanese, Bernabò reigning in Milan (1354-1385) and Galeazzo in Pavia (1354-1378). Galeazzo left a young cousin, Gian Galeazzo, who became sole lord of Milan by seizing and imprisoning his uncle Bernabò. It was under him that the cathedral of Milan and the Certosa of Pavia were begun. He was the first duke of Milan, having obtained that title from the emperor Wenceslaus. His sons Giovanni Maria, who reigned at Milan (1402-1412), and Filippo Maria, who reigned at Pavia (1402-1447), succeeded him. In 1412, on his brother’s death, Filippo united the whole duchy under his sole rule, and attempted to carry out his father’s policy of agrandizement, but without success.

Filippo was the last male of the Desio house. He Conti house. At his death, a republic was proclaimed, which lasted only three years. In 1450 the general Francesco Sforza, who had married Filippo’s only child Bianca Visconti, became duke of Milan by right of conquest if by any right. Under this duke the castello was rebuilt and the canal of the Martesana, which connects Milan with the Adda, and the Great Hospital were carried out. Francesco was followed by five of the Sforza family. His son Galeazzo Maria (1466-1476) left a son, Gian Galeazzo, a minor, whose guardian and uncle Lodovico (il Moro) usurped the duchy (1479-1500). Lodovico was captured in 1500 by Louis XII. of France, who ruled for three years for the house of Sforza. In 1508 Gian Galeazzo, who became duke of Milan by right of succession, was restored to the throne of Milan, and held it by the help of the Swiss till 1515, when Francis I. of France reconquered the Milanese by the battle of Marignano, and Massimiliano resigned the sovereignty for a revenue from France. This arrangement did not continue. Charles V succeeded the emperor Maximilian, and at once disputed the possession of the Milanese with Francis. In 1522 the imperialists entered Milan and proclaimed Francesco Sforza (son of Lodovico). Francesco died in 1535, and with him ended the house of Sforza. From this date till the War of the Spanish Succession (1714) Milan was a dependency of the Spanish crown. At the close of that war it was handed over to Austria; and under Austria it remained till the Napoleon campaign of 1796. For the results of that campaign, and for the history of Italian progress towards independence, in which Milan played a prominent part by opening the revolution of 1848, with the insurrection of the Cinque Giornate (March 17-22), by which the Austrians were driven out; the reader is referred to the article ITALIA.

The Lombard campaign of 1859, with the battles of Solferino and Magenta, finally made Milan a part of the kingdom of Italy.

LITERATURE.—Pietro Verri, Storia di Milano; Corio, Storia di Milano; Canto, Illustrazione grande del Lombardo Veneto; the Milanese chroniclers in Muratori’s Rer. Ital. scriptores; Sismondi, Italian Republicans; Ferrari, Rosaziones di Italia; Litta, Fomiglie celebri, s.s. “Torriani,” “Visconti,” “Sforza.” During the Revolution, Muratori, Annali d’Italia; Hallam, History of the Middle Ages; and Mediolanum (4 vols., 1881); L. Beltri, Il Castello di Milano (Milan, 1892); L. della Torriana, Famiglie Milano (Milan, 1894); F. Malaguzi Valeri, Milano, 2 vols. (Bergamo, 1906); and C. M. Ady, A History of Milan under the Sforza (1909). (H. F. B.; T. A.)

MILANESI, GAETANO (1873-1895). Italian scholar and writer on the history of art, was born at Siena, where he studied law, and in 1888 he obtained an appointment in the public library. In 1886 he was elected member of the Accademia della Crusca, in which capacity he took part in the compilation of its famous but still unfinished dictionary, and two years later was appointed assistant keeper of the Tuscan archives, in Florence; then he took charge of the famous Medici archives, whence he collected a vast body of material on the history of Italian art, not all of which is yet published. In 1889 he became director of the archives, but retired in 1892, and died three years later. His posthumous and posthumously published is his edition of Vasari’s works in nine volumes, with copious and valuable notes (Florence, 1878-1885). Of his other writings the following may be mentioned: Il diario inedito di Alessandro Sazinni (in the Archivio storico Italiano, 1842); Documenti per la storia dell’ arte senese, 3 vols. (Siena, 1854-1856) and Discorsi sulla storia civile ed artistica di Siena (Siena, 1892). He also edited a number of Italian classics.

See E. Ridolfi’s article in the Nuova antologia (May 15, 1895); and A. Virgili’s article in the Atti della regia Accademia della Crusca (Florence, 1896).

MILAN OBRENOVIĆ IV. (1854-1901), king of Servia, was born on the 22nd of August 1854, at Jassy. He was the grand-nephew of the famous Milosh, whose brother Jefrem (d. 1856) had a son, Milosh (1829-1861), who married Maria Kataridis, a Moldavian. Milan was their son. While still very young, he lost both his parents, and was adopted by his cousin, Michael Obrenovich, who returned to Servia on the expulsion of the Karageorgeviches in 1858 and became ruling prince on the 20th of October 1858. In the reign of young Milosh, Milan was educated in Paris, at the Lyceè Louis-le-Grand, where he displayed considerable precocity, but he was only fourteen years of age when in 1868 his cousin was assassinated and he succeeded to the throne under a regency. In 1872 he was declared of age, and taking the reins of government into his own hands, soon manifested great intellectual power, coupled with a passionate headstrong character. Eugene Schuyler, who saw him about this time, found him “a very remarkable young man . . . singularly intelligent and well-informed.” By a careful raising and education, and with a judicious leaning towards the former, Prince Milan was enabled in 1878, at the end of the Turkish War, to induce the Porte to acknowledge his independence, and was proclaimed king in 1882. (The history of his reign is told in detail under SERVIA.) Acting under Austrian influence, King Milan devoted all his energies to the improvement of means of communication and the development of natural resources, but the cost, which was unduly increased by reckless extravagance, led to proportionately heavy taxation. This, coupled with increased military service, rendered King Milan and the Austrian party most unpopular; and political troubles were further increased by the defeat of the Servians in the war against Bulgaria, 1885-86. In 1885 (Sept.) the union of Rumelia and Bulgaria caused widespread agitation in Servia, and Milan precipitately declared war upon his kinsman Prince Alexander on the 15th of November. After
a short but decisive campaign, the Servians were utterly routed at the battles of Stívinska and Pipot, and Milan's throne was only saved by the direct intervention of Austria. Domestic difficulties now arose which rapidly assumed a political significance. In October 1875 King Milan had married Natalia, the sixteen-year-old daughter of Peter Ivanovich Ketchko, a Moldavian Boyar, who was a colonel in the Russian army, and whose wife, Pulcheria, was by birth Princess Sturza. A son, Alexander, was born in 1876, but the king and queen showed signs of friction. Milan was anything but a faithful husband. Queen Natalia was greatly influenced by Russian sympathies, and the couple, ill-assorted both personally and politically, separated in 1886, when the queen withdrew from the kingdom, taking with her the young prince, Alexander, afterwards king, then ten years of age. While she was residing at Wiesbaden in 1888, King Milan succeeded in recovering the crown prince, whom he undertook to educate; and in reply to the queen's remonstrances, he exerted considerable pressure upon the metropolitan, and procured a divorce, which was afterwards annulled as illegal. King Milan now seemed master of the situation, and on the 3rd of January 1889 promulgated a new constitution which was formally adopted by the existing code of 1869. Two months later (March 6) he suddenly abdicated in favour of his son, a step for which no satisfactory reason was assigned, and settled as a private individual in Paris. In February 1891 a Radical ministry was formed, Queen Natalia and the ex-metropolitan Michael returned to Belgrade, and Austrian influence began to give way to Russian. Fear of a revolution and of King Milan's return led to a compromise, by which in May 1891 the queen was expelled, and Milan was allowed a million francs from the civil list, on condition not of returning to Servia during his son's minority. Milan in March 1892 renounced all his rights, and even his Servian nationality. The situation altered, however, after the young King Alexander in April 1893 had effected his coup d'etat and taken the reins of government into his hands. Servian politics began to grow more complicated, and Russian intrigue was rife. In January 1894 Milan suddenly appeared at Belgrade, and his son gladily availed himself of his experience and advice. On the 29th of April a royal decree reinstated Milan and Natalia, who in the meantime had become ostensibly reconciled, in their position as members of the royal family. On the 21st of May the constitution of 1869 was restored, and Milan continued to exercise considerable influence over his son. The queen, who had been residing chiefly at Biarriz, returned to Belgrade in May 1895, after four years' absence, and was greeted by the populace with great enthusiasm. In 1897 Milan was appointed commander-in-chief of the Servian army. In this capacity he did some of the best work of his life, and his success in improving the Servian military system was very marked. His relations with the young king also remained good, and for a time it seemed as though all Russian intrigues were being checked. The good relations between father and son were interrupted, however, by the latter's marriage in July 1900. Milan violently opposed the match, and resigned his post as commander-in-chief; and the young king banished him from Servia and threw himself into the arms of Russia. Milan retired to Vienna, and there he died unexpectedly on the 11th of February 1901. Milan was an able, though headstrong man, but he lived a scandalously irregular life, and was devoid of moral principle. In considering his relations with his young son, it must be remembered that in the dynastic and political condition of Servia natural feeling was inevitably subordinated in Milan to other considerations.

H. Ciu.)

MILÀ Y FONTANALS, MANUEL (1818–1884), Spanish scholar, born at Villafranca del Panadés, near Barcelona, on the 4th of May 1818, was educated first at Barcelona, and afterwards at the university of Cervera. In 1845 he became professor of literature at the university of Barcelona, and held this post till his death. In 1848 he married Vilafranca del Panadés on the 16th of July 1884. The type of the popular recluse, Milà y Fontanals was almost unknown outside the walls of the university till 1859, when he was appointed president of the juegues florales at Barcelona. On the publication of his treatise, De los trovadores en España (1866), his merits became more generally recognized, and his monograph, De la poesía heróico-popular castellana (1873) revealed him to foreign scholars as a master of scientific method.

MILAZZO, a seaport on the north coast of Sicily, in the province of Messina, 22 m. W. of Messina by rail. Pop. (1901), 16,422. It is mainly built on the low isthmus of a peninsula, which stretches some 3 m. farther north and forms a good harbour: but the old town, which contains a castle, mainly the work of Charles V., lies on a hill above. Milazzo is the ancient Mylae, an outpost of Zancle, occupied before 648 b.c., perhaps as early as 716 b.c. (E. A. Freeman, History of Sicily, I., pp. 395, 587). It was taken by the Athenians in 426 B.C. The people of Rhegium planted here the exiles from Naxos and Catania in 353 b.c. as a counterpoise to Dionysius' foundation of Tyrandis; but Dionysius soon took it. In the bay Dullius won the first Roman naval victory over the Carthaginians (260 B.C.).

MILDENHALL, a market town in the Stowmarket parliamentary division of Suffolk, England, 764 m. N.E. from London by railway, north of the Great Eastern railway from Cambridge. Pop. (1901), 3567. It lies on the edge of Mildenhall Fen, the great Fen district stretching northward and westward from here. The church of St Andrew has an Early English chancel with fine east window and chancel arch. The remainder is principally Perpendicular with a magnificent carved oak roof, ornate north porch and lofty tower with fan tracery within. There is a wooden market cross of the 15th century; the manor house is a picturesque gabled building of the 17th century, and there is a modern public hall. Flour milling is an industry. The diversity of Old English remains indicates a small settlement.

MILDEW (O. Eng. meldezw or mildezw, explained as "mealdew," cf. Ger. Meltbou, with more probability, as "honey-dew," Goth. melih, honey, cf. Lat. mel, Gr. μέλι), a popular name given to various minute fungi from their appearance, and from the sudden, dew-like manner of their occurrence. Like many other popular names of plants, it is used to denote different species which possess very small botanical affinity. The term is applied, not only to species belonging to various systematic groups, but also to such as follow different modes of life. The corn-mildew, the hop-mildew and the vine-mildew are, for example, parasitic upon living plants, and the mildews of damp linens and of paper are saprophytes (Gr. σαπρόβιο). Rotten, that is, they subsist on matter which is already dead. As regards mildews in general, the conditions of life and growth are mainly suitable nutrition and dampness accompanied by a high temperature. The life history of the same species of mildew frequently covers two or more generations, and these are often passed on hosts of different kinds. In some cases again the same generation confines its attack to the same kind of host, while in others the same generation grows on various hosts (see Fung; Hop; and Whet.).

MILES, NELSON APPLETON (1839– ), American soldier, was born in Westminster, Massachusetts, on the 8th of August 1839. He was engaged in mercantile pursuits in Boston when the Civil War began, and he entered the army in September 1861 as a lieutenant in the 22nd Massachusetts volunteer infantry. He served with distinction in the Peninsula campaign, and at Antietam, Frederickburg and Chancellorsville, where he received a wound which incapacitated him up to the opening of Grant's Virginia campaign of 1864. He had been commissioned in September 1862 colonel of the 61st New York volunteers, commanded a brigade at the Wilderness and Spottsylvania, and in May 1864 was rewarded for his gallant leadership by the grade of brigadier-general of volunteers. He fought in the Cold Harbor and Petersburg operations in 1864–65, was brevetted major-general of volunteers for his conduct at Reams Station, and at the close of the war was in temporary command of an army corps. In July 1866 he was made colonel of a regular infantry regiment, and in 1867 he was brevetted brigadier-general in the regular army for his services at Chancellorsville and major-general for his services at Spottsylvania. He was promoted to be brigadier-general U.S.A. (Dec. 1890), and to be
major-general (April 1890), and in 1895 succeeded General John McA. Schofield as commanding general of the United States army. He was conspicuously successful (1889-1886) in dealing with Indian outbreaks, fighting the Cheyenne and Arapaho, Comanche on Llano Estacado (1873) and the Sioux in Montana (1876), capturing the Nez Percé under Chief Joseph (1877), and defeating the Chiricahua Apaches under Geronimo (1886), and he commanded the United States troops sent to Chicago during the railway riots in 1894. He was in nominal direction of military operations during the war with Spain in 1898, though his personal share of the operations was confined to directing the almost unopposed Porto Rico expedition. He was raised to the rank of major-general, June 1900, and retired from active service in August 1903. In 1904 he was appointed Engineer-in-Chief and chief-of-staff under Governor William L. Douglas in Massachusetts. He wrote Personal Recollections (1866), Military Europe (1868) and Observations Abroad (1899).

MILETUS (mod. Palatia), an ancient city of Asia Minor, on the southern shore of the Latmos Gulf near the mouth of the Maeander. Before the Ionic migration it was inhabited by Carians (IIiad i. 676; Hom. i. 140), and pottery, found by Th. Wiegand on the spot proves that the site was inhabited, and had relations with the Aegaean world since the latest Minoan age. The Greek settlers from Pylos under Nestor were the first to have a habitation on the site. The men in the old city, and built for themselves a new one on the coast. Miletus occupied a very favourable situation at the mouth of the rich valley of the Maeander, and was the natural outlet for the trade of southern Phrygia (Hipponax, Fr. 45). It had four harbours, one of considerable size, and its power extended inland for some distance up the valley of the Maeander, and along the coast to the south, where it founded the city of Iasus. Its enterprise extended to Egypt, where it had much to do with the settlement of Naukratis (q.v.). Very little of Naukratis or the Naukratis pottery, however, was found on the site by Wiegand, and only in the Athena temple. The Black Sea trade, however, was the greatest source of wealth to the Ionian cities. Miletus, like the rest, turned its attention chiefly to the north, and succeeded in almost monopolizing the traffic. Along the Hellespont, the Propontis and the Black Sea coasts it founded more than sixty cities—among them Abydus, Cyzicus, Sinope, Dioscurias, Panticapaeum and Olbia. All these cities were founded before the middle of the 7th century; and before 500 B.C. Miletus was decidedly the greatest Greek city. During the time when the enterprise of the seafaring population raised Miletus to such power and wealth its chief industries were the building and repair of ships. As a result, though the analogy of all Greek cities, and some casual statements in later writers, suggest that the usual struggles took place between oligarchy and democracy, and that tyrants sometimes raised themselves to supreme power, Miletus was equally distinguished at this early time as a seat of literature. The Ionian epic and lyric poetry indeed had its home farther north; philosophy and history were more akin to the practical race of Miletus, and Thales, Anaximander, Anaximenes and Heraclitus all belonged to this city. The poet Timotheus and the famous Aspasias were its inhabitants. The theory of the Ionian cities of Caria was a Pythagorean, and the Ionian was a poetic version of the Ptolemaic. The Mermaid kings of Lydia found in Miletus their strongest adversary. War was carried on for many years, till Alyattes III. concluded a peace with Thryasybulus, tyrant of Miletus; the Milesians afterwards seem to have acknowledged peaceably the rule of Croesus. On the Persian conquest Miletus passed under a new master; it headed the Ionian revolt of 500 B.C., and was taken by storm after the battle of Lade (see IONIA). Darius massacred most of the inhabitants, transported the rest to Ampe at the mouth of the Tigris, and give up the city to the Carians. This disaster was long remembered in Greece and made the theme of a tragedy by Phrynichus. Henceforth the history of Miletus has no special interest. It revived indeed when the Persians were expelled from the coast in 479 B.C., became a member of the Delian League (q.v.), revolted to Sparta in 411, passed into Carian hands, and opposed Alexander on his southward march, succumbing only to a siege in form (334 B.C.). It was a town of commercial importance throughout the Graeco-Roman period, and received special attention from Trajan. Its harbours, once protected by Lade and the other Tragassaean islands, were gradually silted up by the Maeander, and Lade is now a hill projecting from the coast. Ephesus took its place as the great Ionian harbour in Hellenistic times. It then became the seat of a Christian bishopric and was strengthened by a Byzantine castle (κάστρον τοῦ Πελατίων) built above the town; but its decay was inevitable, and its site is now a marsh.

Since 1899 Miletus has been the scene of extensive excavations directed by Dr Th. Wiegand for the Berlin academy. The ruins lie on the base of a hill projecting north-east into a bend of the Maeander. On the eastern side stand the ancient remains on the site of an older Greek building. When complete it had 54 rows of seats. It was as large as any theatre in Asia Minor, and is still imposing, the auditorium, though derived of its upper ranks and colonnade, rising nearly 100 ft. Cyriacus of Ancona described the building as practically complete in his day (1446). The front is over 150 yds. long. East of this was the ancient north harbour, now silted up, and on the hillside above stood a large heroön of Hellenistic time remarkable for being, like the tomb of Brasidas at Amphipolis, within the walls. South of the harbour, and lies the so-called agora with ruins of large magazines of Doric style. South of these so-called agora is a grot of Titus, and a senate-house of theatrical form. On the east opens a great hall surrounded by porticoes and enclosing a high altar of Athena. Peacefully adorned with ruins. The agora lies beyond this again. A straight street leads south-west from the north harbour to the Didyma Gate in the wall, which runs across the peninsula and was rebuilt by Trajan, when he under took to raise the last great outer quadrilateral and all streets cross this at right angles in the geometric Hellenistic manner. A Sacred Way lined with tombs, led to Didymo. Two temples have been discovered by Th. Wiegand, one, on the southeast, being a large sanctuary of Apollo Delphinus with triple colonnade enclosing a court with central tripod. This seems to have been the chief temple of the city and the place where public records, treaties, &c. were engraven. The temple, an Athenian temple, an archaic sanctuary of Athena, lies west of the stadium.

See O. Rayet and A. Thomas, Milet et le golfe Latomique (1877); Th. Wiegand, "Vorlaufige Nachrichten ueber die Ausgrabungen in Milet," in Sitzungsberichte der Berliner Akademie (1900, fol.); A. von Salis, "Die Ausgrabungen in Milet und Didyma" in Neue Jahrb. f. d. k. Ak. xxv, 2, 1910. (D. G. H.)

MILFORD, a township of New Haven county, Connecticut, U.S.A., on Long Island Sound, separated from the township of Stratford on the W. by the Housatonic river, and about 10 m. S.W. of New Haven. Pop. (1890), 3611; (1900), 3783, including 541 foreign-born and 173 negroes; (1910), 4366. Area, about 16 square miles. The New York, New Haven and Hartford railroad, and by an electric line connecting with Bridgeport and New Haven. Within its borders are various popular beaches, including Woodmont (incorporated as a borough in 1893), Pond Point, Bay View, Fort Trumbull Beach (where a fortification, called Fort Trumbull, was erected in 1776), Myrtle Beach, Meadow's End, Walnut Beach and Milford Point. The township is traversed by the Wepowaug river, which here empties into the Sound. Milford is a typical old New England town, and many of the permanent inhabitants are descendants from the first settlers. The burying-ground includes the tomb of Robert Treat (1622-1710), commander of the Connecticut troops in King Philip's War, leader of the company that founded New Netherland, and the site of the town. Milford has a beautiful green of about four acres, containing a soldiers' monument. It has also the Taylor Library (founded in 1894), and along the Sound are many summer residences. Named after Milford, England, it was founded in 1639 by Rev. Peter Prudden and his followers from New Haven and Wethersfield. The land was purchased from the Indians for 6 coats, 10 blankets, 1 kettle, 12 hatchets, 12 hoes,
24 knives and 12 small mirrors. A "church-state" was imme-
diately organized after the model of that of New Haven, but two or three years later the town bestowed suffrage on six of its inhab-
itants who were not church members. These citizens were an
obstacle to the town's admission to the New Haven Jurisdiction,
which was formed in 1643, but in the following year a compromise
was effected and Milford was admitted on condition that, in the
future, suffrage should be granted only to church members and
that none of the objectionable six should be elected to any office
of the Jurisdiction. In 1646 Milford, with the other members of
the Jurisdiction, was absorbed by Connecticut; this caused con-
siderable dissatisfaction and some of the inhabitants under
the lead of Robert Treat removed to New Jersey and assisted in
the founding of Newark. The regicides Whalley and Goffe were
concealed in Milford from 1661 to 1664.

See M. Louise Greene, "Early Milford," in the Connecticut

MILFORD, a township of Worcester county, Massachusetts,
U.S.A., about 16 m. S.E. of Worcester. Pop. (1890) 8,970;
(1900) 13,176, of whom 33,42 were foreign-born; (1910 census)
13,365. With its area of about 15 sq. m. are a large rural
population and the village of Milford, on the Charles river, about
33 m. S.W. of Boston, served by the Boston & Albany, the New
York, New Haven & Hartford and the Grafton & Upton railways
(the last named having its passenger department operated by
electricity and its freight by steam, and connecting Milford with
North Grafton), and by inter-urban electric lines. The village
has a memorial hall, housing the public library, and in the town-
ship there is an excellent hospital, the gift of Edwin L. Eben.
The village is a stopping point for an agricultural and manufac-
turing district. In 1905 the value of the township's factory
products was $3,300,504 (32.8% more than in 1900). The most
important manufactures are boots and shoes; the industry was
established in 1795, and for many years the special product was
brogans for Southern negroes. In 1908 there were 12 large
granite quarries in the township (north and north-east of
the village). Milford granite is the typical stone of an area reaching
in Rhode Island south of the southern boundary of Providence
county; it is a biotite granite of post-Cambrian age, is generally
pinkish-gray in colour (owing to the large proportion of feldspar
among its constituents), and is widely useful for building purposes.
The township was the east precinct of Mendon until 1780, when
it was incorporated; in 1835 parts of Holliston and Hopkinton
were annexed; in 1886 a part was separated as Hopedale.

See Adin Ballou, History of Milford (Boston, 1882); and T.
Nelson Dale, The Chief Commercial Gravities of Massachusetts,
New Hampshire and Rhode Island (Washington, 1908), Bulletin

MILFORD HAVEN, a market town, seaport, urban district
and contributory borough of Pembroke
Wales, situated on the north shore of the celebrated harbour
of the same name. Pop. (1901), 5,102, including the adjacent
village of Hakin. Milford Haven is the terminus of a branch-line
of the South Wales section of the Great Western railway. The
town possesses a pier and important dock accommodation, in-
duding a graving-dock 600 ft. long, and is the centre of a valuable
and increasing fishing industry. The promenade of Milford
Terrace commands a fine view of the broad expanse of the Haven
with its various towns and forts.

The present town of Milford Haven, originally a hamlet in
the parish of Steynton, is of modern growth, and was first called
into existence by the exertions of the Hon. R. F. Greville,
nephew of Sir William Hamilton, who in 1790 laid out a town on
this spot, the advantages of which as a convenient port for the
Irish traffic he clearly recognized. In the opening years of
the 19th century a royal dockyard was established here, but in 1814
dockyard and arsenal were removed to Paterchurch near Pembroke.
The growth of the town was further checked twenty years later
by the development of Neyland, or New Milford, further east
than the Haven, whither the Irish packet service was trans-
ferred; but towards the close of the 19th century the town
recovered much of its former prosperity. The importance of the
place is wholly due to its excellent situation on the splendid
land-locked harbour, which is here 2 m. broad.

Milford Haven itself, designated by the Welsh Aberdauleddu,
as the estuary of the united East and West Cleddy rivers, has
played an important part on several occasions in the course of
history. Throughout Plantagenet times it formed the chief
point of embarkation for Ireland. It was from Milford Haven
that Henry II. set sail for the conquest of Ireland in 1170, and to
this harbour he made his return journey. In 1390 Richard II.
landed at Milford Haven from Ireland, shortly before his
surrender to Henry of Lancaster, afterwards Henry IV., in his
reign a French fleet with 12,000 men on board sailed to the Haven
and disembarked with the object of assisting the rebellion of
Owen Glendower. In 1485 Henry, Earl of Richmond, disem-
barred here on his return from France, and was welcomed on
landing by Sir Rhys ap Thomas and many of the chivalry of
Wales. In 1538 the leading persons of Pembroke, with Bishop Anthony Rudd of St. David's at their head, petitioned
Queen Elizabeth to fortify the Haven against the projected
Spanish invasion, upon which the block-houses of Dale
and Nangle at either side of the mouth of the harbour were accord-
ingly erected. During the 19th century numerous forts have
been constructed for the protection of the Haven and of the
royal dockyard at Pembroke Dock.

MILICZ, or MILITZ (d. 1374), Bohemian divine, was the
most influential among those preachers and writers in Moravia
and Bohemia who, during the 14th century, in a certain sense paved
the way for the reforming activity of Huss. The date of his
birth is uncertain; he was in holy orders in 1340, and in 1360
he was attached to the court of the emperor Charles IV., whom
he accompanied into Germany in that year, and about the same
time also held a canonry in the cathedral of Prague along with
the dignity of archdeacon. About 1363 he resigned all his
appointments that he might become a preacher pure and simple;
he addressed scholars in Latin, and (an innovation) the laity in
their native Czech, or in German, which he learnt for the purpose.
He was conspicuous for his apostolic poverty and soon roused
the enmity of the mendicant friars. The success of his labours
made itself apparent in the way in which he transformed the
notorious "Bematik" street of Prague into a benevolent institu-
tion, "Jerusalem." As he viewed the evils inside and outside
the church in the light of Scripture, the conviction grew in his
mind that the "abomination of desolation" was now seen in the
temple of God, and that antichrist had come, and in 1367 he
went to Rome (where Urban V. was expected from Avignon)
to expound these views. He affixed to the gate of St Peter's a
placard announcing his sermon, but before he could deliver it
was thrown into prison by the Inquisition. Urban, however,
on his arrival, ordered his release, whereupon he returned to
Prague, and from 1369 to 1372 preached daily in the Tyn
Church there. In the latter year the clergy of the diocese com-
plained of him in twelve articles to the papal court at Avignon,
whither he was summoned in Lent 1374, and where he died in
the same year, not long after being declared innocent and authorized
to preach before the assembly of cardinals. He was the author of
a Libellus de Antichristo, written in prison at Rome, a series of
Postilliæ and Lectiones quadragesimales in Latin, and a similar
series of Postilliæ (devotional tracts) in Czech.

pp. 279-282.

MILITARY FRONTIER (Ger. Militärgrenze, Slav. Granitza),
a narrow strip of Austrian-Hungarian territory stretching along
the borders of Turkey, which had for centuries a peculiar military
organization, and from 1849 to 1873 constituted a crown-land.
As a separate division of the monarchy it owed its existence to
the necessity of maintaining during the 16th and 17th centuries
a strong line of defence against the invasions of the Turks, and
may be said to have had its origin with the establishment of the
capitany of Zengg (a coast town about 35 m. south-east of
Fiume) by Matthias Corvinus and the introduction of Uskoks
(g.) into Croatia. By the close of the 17th century there were
three frontier "generalates"—Carlstadt, Warasdin and Petržina
or Petrinja (the last also called the Banal). After the defeat of the Turkish power by Prince Eugene it was proposed to abolish the military constitution of the frontier, but the change was successfully resisted by the inhabitants of the district; in 1764, with a new Slavonian frontier district was established in 1772, and Maria Theresa extended the organization to the March-lands of Transylvania (the Szekler frontier in 1764, the Wallachian in 1760). As a reward for the service it rendered the government in the suppression of the Hungarian insurrection in 1748, the Military Frontier was erected in 1840 into a crown-land, with a total area of 15,152 sq. m. and a population of 1,220,503. In 1851 the Transylvanian portion (1,172 sq. m.) was incorporated with the rest of Transylvania; and in 1871 effect was given to the imperial decree of 1869 by which the districts of the Warasdin regiments (St George and the Cross) and the towns of Zengg, Belovar, Ivanic, &c., were “provincialized” or incorporated with the Croatian-Slavian crown-land. In 1872 the Banat regiments followed suit; and in 1873 the old military organization was abolished in the rest of the frontier. Not till 1881, however, were the Croatian-Slavian March-lands completely merged in the kingdoms to which they naturally belonged. The social aspect of the military frontier régime is interesting. The military system is so closely intertwined with the life and customs of the population, that the towns, with their watch-towers and the beacons which flashed the alarm along the whole frontier in a few hours are still features in the landscape. MILITARY LAW, “the law which governs the soldier in peace and in war, at home and abroad. At all times and in all places the conduct of officers and soldiers as such is regulated by military law.” The above is the definition as given in the opening chapter of the Manual of Military Law, which is issued under the authority of the English War Office, and which is the textbook used by all English courts martial. The definition is, however, somewhat too wide, as the British system does not exclude in time of peace the action of the civil courts. In time of peace all persons who belong to the military class in most European continental countries are judged by military law and by military courts. There is also in most continental countries an intermediate stage between war and peace, known as in État de siège, which may be declared for a fixed period for a district, or even a city, by reason of domestic insurrection or the presence of an enemy. It requires legislative enactment. Thirdly comes a state of war, when the military authorities are supreme; and whilst they can call upon the civil courts for support that such courts are in fact, therefore, under the military régime, is found. This is a brief summary of the system of military law that prevails in most countries of the continent. The cardinal point of difference between the British and the continental systems lies in the fact that in the United Kingdom the soldier is not only a soldier, but a citizen also; and although he may be tried for civil offences by a military tribunal, the power is not exercised in all cases. Thus treason, treason-felony, murder, manslaughter, rape, are brought before a civil court in times of peace, if the offence is committed in the United Kingdom, or if it is committed anywhere else in the king’s dominions, except Gibraltar, with a hundred miles from that place in which the offender can be tried by a civil court. Minor civil offences, when not committed within military lines, or when the person affected by the offence is a civilian, or when it is a case for a jury, or where intricate questions of law may arise, may also be brought before a civil tribunal. But the offence, of whatever nature, committed on active service would be brought before a military tribunal. The military law of England in early times existed, like the

1 By 1848 the following had come to be the division of the Military Frontier: (1) The Carlsstadt (Carlотов), Warasdin and Banal Generalate; corresponding to the original three generalates. (2) The Slavonian Generalate; (district of Mitrovica). (3) The Banal Generalate; south and east of Temesvar, and (4) The Transylvanian Generalate. Twelve towns, known as “military communities,” had communal constitutions not unlike those of the free towns of Hungary-Carlopolago, Zengg, Petrinja, Kostajnica, Belovar, Ivanic, Brod, Peterwardein, Carlowitz, Semlin, Pancsova and Weiisckichen, forces to which it applied, in a period of war only. Troops were raised for a particular service, and were disbanded upon the cessation of hostilities. The crown, of its mere prerogative made laws known as Articles of War, for the government and discipline of the troops while thus embodied and serving. Except for the punishment of desertion, which offence was made a felony by statute in the reign of Henry VI., these ordinances or Articles of War remained almost the sole authority for the enforcement of discipline until 1689, when the first Mutiny Act was passed and the military forces of the crown were brought under the direct control of parliament. Even the Parliamentary forces in the time of Charles I. and Cromwell were governed, not by an act of the legislature, but by a body of small powers similar to those issued by the king and authorized by an ordinance of the Lords and Commons, exercising in that respect the sovereign prerogative. This power of law-making by prerogative was, however, held to be applicable during a state of actual war only, and attempts to exercise it in time of peace were ineffectual. Subject to this limitation it existed for considerably more than a century after the passing of the first Mutiny Act. From 1689 to 1803, although in peace time the Mutiny Act was occasionally suffered to expire, a statutory power was given to the crown to make Articles of War to operate on territories and elsewhere beyond the seas in the same manner as those made by prerogative. In 1817, in consequence of the rebellion, this power was created in respect of the forces in the kingdom. But these enactments were apart from and in no respect affected the principle acknowledged all this time—that the crown of its mere prerogative could make laws for the government of the army in foreign countries in time of war. The Mutiny Act of 1803 effected a great constitutional change in this respect: the power of the crown to make any Articles of War became altogether statutory, and the prerogative merged in the act of parliament. So matters remained till the year 1879, when the last Mutiny Act was passed, by which Articles of War were promulgated. The Mutiny Act legislated for offences in respect of which death or penal servitude could be awarded, and the Articles of War, while repeating those provisions of the act, constituted the direct authority for dealing with offences for which imprisonment was the maximum punishment as well as with many matters relating to trial and procedure. The act and the articles were found not to harmonize in all respects. Their general arrangement was faulty, and their language sometimes obscure. In 1869 a royal commission of inquiry was ordered, and made certain recommendations as to the way in which the task should be performed. In 1879 the government submitted to parliament and passed into law a measure consolidating in one act both the Mutiny Act and the Articles of War, and amending their provisions in certain important respects. This measure was called the “Army Discipline and Regulation Act 1879.” After one or two years' experience of its working it also was found capable of improvement, and was in its turn superseded by the Army Act 1881, which now forms the foundation and the main portion of the military law of England. It contains a proviso saving the right of the crown to make Articles of War, but in such a manner as to render the power in effect a nullity; for it enacted that no crime made punishable by the act shall be otherwise punishable by such articles. As the punishment of every conceivable offence is provided for by the act, any articles made thereunder can be no more than an empty formalism having no practical effect. Thus the history of English military law up to 1879 may be divided into three periods, each having a distinct constitutional aspect: (1) that prior to 1689, when the army, being regarded as so many personal retainers of the sovereign rather than servants of the state, was mainly governed by the will of the sovereign; (2) that between 1689 and 1803, when the army, being recognized as a permanent force, was governed within the realm by statute and without it by the prerogative of the crown; and (3) that from 1803 to 1879, when it was governed either directly by statute or by the sovereign under
an authority derived from and defined and limited by statute. Although in 1879 the power of making Articles of War became in effect altogether inoperative, the sovereign was empowered to make rules of procedure, having the force of law, which regulate the administration of the act in many matters formerly dealt with by the Articles of War. These rules, however, must not be inconsistent with the provisions of the Army Act itself, and must be made before parliament immediately after they are made. Thus in 1879 the government and discipline of the army became for the first time completely subject either to the direct action or the close supervision of parliament.

A further notable change took place at the same time. The Mutiny Act had been brought into force on each occasion for one year only, in compliance with the constitutional theory that the maintenance of a standing army in time of peace, unless with the consent of parliament, is against law. Each session therefore the text of the act had to be passed through both Houses clause by clause, in line by line. The Army Act, on the other hand, is a fixed permanent code. But constitutional traditions are fully respected by the insertion in it of a section providing that it shall come into force only by virtue of an annual act of parliament. This annual act recites the illegality of a standing army in time of peace unless with the consent of parliament, and the necessity nevertheless of maintaining a certain number of land forces (exclusive of those serving in India) and a body of royal marine forces on shore, and of keeping them in exact discipline, and it brings into force the Army Act for one year.

Military law is thus chiefly to be found in the Army Act and the rules of procedure made thereunder, the Militia Acts, the Reserve Forces Acts and the Volunteer Acts, together with certain acts relating to the yeomanry, the Territorial and Reserve Forces Act 1907, and various royal warrants and regulations. In the Army (Annual) Act 1906 important amendments were made to the Army Act for the purpose of preventing soldiers convicted of offences against discipline under the act, and not discharging with ignominy, being subjected to the stigma attaching to imprisonment. This was effected by creating a new punishment, termed detention, the places in which soldiers under detention being termed detention barracks. The change, while principally one of nomenclature, removed an undoubted grievance. The Army Act itself is, however, the chief authority. Although the complaint has been sometimes made, and not without a certain amount of reason, that it does not accomplish much that it might in point of brevity, simplicity and clearness of expression, it is a very comprehensive piece of legislation, and shows some distinct improvements upon the old Mutiny Acts and Articles of War.

When a person subject to military law commits an offence he is taken into military custody, which means either arrest in his own quarters or confinement. He must without unnecessary delay be brought before his commanding officer, who upon investigating the case may dismiss the charge, if in his discretion he thinks it ought not to be proceeded with, or may take steps to bring the offender before a court martial. Where the offender is not an officer he may dispose of the case summarily, the limit of his power in this respect being seven days’ imprisonment with hard labour not exceeding 180. For drunkenness, certain deductions from pay, confinement to barracks for twenty-eight days, this involving severe extra drills, deprivations of rights, and other minor punishments. Where the offence is absence without leave for a period exceeding seven days, the commanding officer may award a day’s imprisonment in respect of each day of such absence up to twenty-one. It is only in the case of the imprisonment exceeding seven days that the evidence before the commanding officer is taken on oath, and then only in the event of the accused so desiring it. The commanding officer is enjoined by regulation not to punish summarily the more serious kind of offences, but his legal jurisdiction in this respect is without limit as regards any soldier brought before him, and where he has dealt summarily with a case the accused is free from any other liability in respect of the offence thus disposed of. In any instance where the commanding officer has summarized awarded imprisonment, fine or deduction from pay, the accused may claim a district court martial instead of submitting to the award.

Ordinary courts martial are of three kinds, viz. (1) a regimental court martial, usually convened and confirmed by the commanding officer of the regiment or detachment, presided over by an officer not ranking in the rank of captain, composed of at least three officers of the regiment or detachment with not more than one year’s service, and having a maximum power of punishment of forty-two days’ detention; (2) a district court martial, usually convened by a general officer having authority to do so, consisting of not less than three officers, each with not less than two years’ service, and having a maximum power of punishment of two years’ imprisonment; (3) a general court martial, the only tribunal having authority to try a commissioned officer, and with a power of punishment extending to death or penal servitude, for offences for which these penalties are authorized by statute; imprisonments in the United Kingdom, India, Malta and Gibraltar and of five elsewhere, each of whom must have had over three years’ service, five being not under the rank of captain. There is another kind of tribunal, viz. a field general court martial. It is convened (1) by any officer in command of a detachment or portion of troops beyond the seas when not on active service, or by any officer in immediate command of a body of forces on active service where it appears to him on complaint or otherwise that a person subject to military law has committed an offence. The officer must be satisfied that the facts alleged are practicable, and that the person is available for public service, to try the person by an ordinary court martial. The quorum of the court is three, if consistent with military exigencies, and each member must have held a commission for not less than a year. The quorum may be reduced when the public service requires it. The procedure of ordinary courts martial is observed as far as possible, and the proceedings always should be in writing when possible. But in the circumstances in which these courts are assembled, it is not always possible to adhere to the technical rules which obtain in the ordinary tribunals, although the broad principles are not violated. The evidence on a field general court martial is taken on oath. The prisoners in the United Kingdom, India, Malta and Gibraltar, and of five elsewhere, each of whom must have had over three years’ service, five being not under the rank of captain. The prisoner is allowed to address the court in his own defence.

The Army Act prescribes the maximum punishment which may be inflicted in respect of each offence. That of death is incurred by various acts of treachery or cowardice before the enemy, or by, with wilful intention or being drunk, rupture or就是unlawful authority, leaving without orders a guard or post, or when contrary order or being drunk on a post, plundering or committing an offence against the person or property of an inhabitant, intentionally causing false alarm or deserting his post. Whether desertion or other penal acts other also becomes liable to the punishment of death who mutinies or incites to or joins in or connives at a mutiny, who uses or offers violence to or defiantly disobeys the lawful command of his superior officer when in the execution of his office. Penal servitude is the maximum punishment for various acts and irregularities upon active service not distinctly of a treacherous or wilfully injurious character, for using or offering violence or insubordinate language to a superior, or disobeying a lawful command when upon active service. The same punishment is applicable when not upon active service to a second offence of desertion or fraudulent enlistment (i.e. enlistment without a character of desertion or attempted desertion or aiding or conniving at desertion, or of fraudulent enlistment, absence without leave, failure to perform his duty at his post or performing any of the circumstances of such discharge, or any other offence which, according to the ordinary criminal law of England is punishable with penal servitude.) Imprisonment for two years is the maximum punishment for minor desertions, deserting without leave of absence, or of any act committed upon active service would involve death or penal servitude, such as offering violence or insubordinate language to a superior or disobeying a lawful command, and for the following offences; resisting an officer’s arrest, being negligent or neglectful in his duties, desertion of the ranks or attempted desertion or aiding or conniving at desertion, or of fraudulent enlistment, absence without leave, failure to perform his duty at his post or performing any of the circumstances of such discharge, or any other offence which, according to the ordinary criminal law of England is punishable with penal servitude. It is only in the case of the imprisonment exceeding seven days that the evidence before the commanding officer is taken on oath, and then only in the event of the accused so desiring it. The commanding officer is enjoined by regulation not to punish summarily the more serious kind of offences, but his legal jurisdiction in this respect is without limit as regards any soldier brought before him, and where he has dealt summarily with a case the accused is free from any other liability in respect of the offence thus disposed of. In any instance where
allowing him to escape, being concerned in the unreasonable detention of a person awaiting trial, escaping or attempting to escape from lawful custody, committing or conspiring to commit perjury, or wilfully injuring military clothing or equipment, ill-treating a horse, or preparing for, procuring or assisting in the preparation of, or fraudulently representations in public documents, making a willfully false accusation against an officer or soldier, making a false confession of guilt or complicity, the statement that the prolongation of a court martial or contempt of such court, giving false evidence on oath, any offence specified in relation to billeting or the impressment of officers, making a false statement or answer to a question put in relation to any of the forces of His Majesty's forces as to produce effects upon His Majesty, or the destruction of his clothes, or the furnishing of materials or the production of false evidence, or the use of force or fraud in connection with any of these. The court martial or contempt of such court, giving false evidence on oath, any offence specified in relation to billeting or the impressment of officers, making a false statement or answer to a question put in relation to any of the forces of His Majesty's forces as to produce effects upon His Majesty, or the destruction of his clothes, or the furnishing of materials or the production of false evidence, or the use of force or fraud in connection with any of these.

An acting non-commissioned officer may be ordered by his commanding officer for an offence or for inefficiency or otherwise to take the punishment of his permanent grade—in other words, to forfeit his acting rank.

It will have been observed that persons subject to military law are liable to be tried by court martial for offences which if committed in peace, according to the law of England, are not considered criminal. The case of desertion, for example, is a punishment which is imposed on active service or in a place more than 100 miles from a civil court having jurisdiction to try the offence. With regard to all civil offenses committed by a military person, he is to be submitted to the ordinary laws of the country. The same is true of desertion. If a criminal offence against his property or person does not for his own good and without further reference to the court, refuse confirmation to the whole or any portion of the finding or sentence, and he may mitigate, commute or entirely remit the punishment. The said punishment may be confirmed or the sentence may be reduced by the judge advocate general, who submits to the sovereign his opinion as to the legality of the trial and sentence. If they are legal in all respects he sends the proceedings to the Army Council, upon whom rests the duty of advising the sovereign regarding the exercise of clemency. In addition to confirmation, however, every general or district court martial held out of India has another ordeal to go through. It is reviewed and examined in the office of the judge advocate general, and any illegality that may be disclosed is corrected and the prisoner is relieved of the consequences. To a certain extent a protection against illegality also exists in the case of regimental courts martial. In this country the court martial is laid before the general commanding, by whom any question that might appear to him doubtful would be referred to the adjutant general or the judge advocate general for decision. It is also provided, however, that the judge advocate general, in fulfilling the duties which are in their nature judicial, is only an adviser. He is not actually a judge in an executive sense, and has no authority directly to interfere with or correct an illegal conviction. In many cases the law thus provides no remedy for an officer or soldier who may have been wronged by the finding or sentence of a court martial—for instance, through a verdict not justified by the evidence or through a non-observance of the rules and practice prescribed for these tribunals. A person who has suffered injustice may appeal to the king's bench division of the high court of justice. But, speaking generally, that tribunal would not interfere with a court martial, no matter how gross its errors. As respects the crimes of desertion, mutiny, or other offenses against the security of the state, the power of the military authorities that the law shall be complied with (see JUDGE ADVOCATE GENERAL).

The Army Act applies to European officers and soldiers serving in India, and is the same as to the rest of the country. In the case of India are governed by their own Articles of War, and in the case of civil offenses they are dealt with according to the provisions of the Indian penal code. There are judge advocates general for each of the military commands of the different military centres.

Important changes were made in the system of courts of inquiry by an Army Order of the 12th of February 1902. A court of inquiry is and has been an assembly of officers directed by a commanding officer to collect evidence and report with respect to a transaction into which he cannot conveniently
himself make inquiry. But now, whenever any inquiry affects the character or military reputation of an officer or soldier, full opportunity must be given him of being present at the inquiry and of giving any evidence or making any statement, or cross-examining adverse witnesses, or producing witnesses, on his own behalf. Evidence may now be ordered to be taken on oath if the assembling of the court as such requires it. No proceedings of a court of inquiry, no confession, statement or answer, is admissible in a court martial. But an officer or soldier tried by court martial in respect of matter which has been the subject of a court of inquiry is entitled to a copy of the proceedings on payment of the cost of the copy. The finding and sentence are only valid after confirmation by the proper military authority. A sentence of death or penal servitude can only be confirmed by the general or field officer in command of the forces with which the prisoner is present. The rule which allows the prisoner and his wife to tender their evidence on oath under the Criminal Evidence Act 1868 as regards evidence is applicable to field general courts martial. It is useful to note that the Army Act, sec. 70, enables His Majesty to make new provisions under the hand of a secretary of state for, amongst other things, the assembly and the procedure of courts of inquiry. The power to make changes by Army Order or rule is only limited by the principle that the rules must not be contrary to or inconsistent with the act.

In an authoritative report published by the Norwegian government and compiled by a trained Norwegian lawyer who visited the various countries, the systems of twenty-two states are reviewed. The earliest military law still in force is found in Norway and Denmark, and dates from 1683, while England and Sweden date from 1881. Sweden has a military penal code, and England is ruled by the Army Act. There are two kinds of military courts of first instance: (1) those belonging to separate military bodies, such as divisions, brigades, regiments; (2) those having jurisdiction in a certain territory, and their seat determined. In times of war the courts must follow the military bodies. In Bavaria and Switzerland a military jury is attached to a court martial. In several states "auditors," i.e. judicial guides, are attached to courts martial. In some a military jurisconsult (lawyer) is attached as judge, always a fixed post. This obtains in Sweden, Finland, Austria-Hungary, Switzerland and Portugal. In Norway, Denmark, Sweden, Finland, Belgium, Great Britain, Germany, Austria, United States, Spain, Württemberg and Switzerland the presiding officer is chosen for the single trial. In other states the military judges are appointed for a certain term, usually six months. The quorum of judges on the courts martial on the continent differs. Seven judges sit in Belgium, Holland, France, Spain, Portugal, Greece, Turkey and Württemberg; three only, in cases of ordinary offences committed by non-commissioned officers and soldiers in Switzerland, Russia, the United Kingdom, United States and Bavaria. In grave cases in the United Kingdom five to nine sit, nine in Russia, five to thirteen in the United States. In Norway and Denmark the court is of thirteen up to twenty-five, unless replaced by a commission and a military lawyer.

In Norway, Denmark, Sweden, Finland, and Bavaria and other places in Germany, special summary courts martial are held when necessary. Certain forms and legal guarantees are then dispensed with. Such are held in Belgium and Holland "in a town or place in state of siege." La Préâtre is a special court of a judge assisted by a registrar, for vagabonds, servants, sutlers, and with a very limited competence over soldiers who have committed a petty offence, before him in France, Rumania and Greece.

The United Kingdom has a summary court martial when the regular court martial cannot be held without injuring the military service. In the United States there are the "field officers' court martial" and "military commission," consisting of three officers. The second is for judging spies and some other matters that escape the jurisdiction of the regular courts martial. A special military tribunal in Germany judges the officials attached to the army. Courts of honour exist in Russia, Germany, Bavaria, Württemberg, Austria-Hungary and Spain. Great Britain and the United States have the system of a "court of inquiry." This was only a commission of inquiry, but it is now public, the accused is present, and the witnesses are examined.

Soldiers not on active service, says the Swedish report, should be answerable for infractions of common law under the jurisdiction of the civil courts. All infractions of military order or discipline committed by soldiers, whether on active service or no, should be judged by military courts. In time of war, it is equally admitted, military courts must judge all offences, even offences at common law, committed by soldiers forming part of an army on campaign. The difference lies in regard to offences committed in the course of peace. In Sweden, Tjänsteforordnare who directs, Italy and the United States, as a general rule, place offences against the common law (infractions de droit commun) in time of peace under the jurisdiction of the civil courts.

In the United States offences against good order, in Great Britain personal offences (such as drunkenness), are judged by courts martial. In most other states the general rule is that soldiers, even in time of peace, if on actual service are judged by courts martial. In the case of complicity between a soldier and a civilian, sometimes one is judged by a military and the other by a civil court (in Germany, Spain and Switzerland), sometimes both by a military court (Belgium, Italy, Sweden, Rumania and Greece); sometimes it depends on the nature of the crime—in the United Kingdom, United States, Sweden, Finland, Holland and Portugal. In Norway a mixed tribunal judges them.

The procedure in military courts differs according to the countries. In some systems (a) the examination and preparation of evidence are confined to a juge d'instruction; (b) in other systems they are confined to a special commission of inquiry; (c) in other states there is a special enquiry; (d) in great cases he must be a military jurisconsult. In Italy, Spain, Rumania, Greece and Turkey an officer acts as juge d'instruction.

The proceedings before a court martial are usually public, except in Sparta and other states when courts martial of small importance, or where publicity is considered injurious to the interests of the service (cases of discipline, disclosing the secrets of the service). This difference is usually applied (except in Great Britain and the United States) to the proceedings before a court martial when there is a preliminary investigation. In several states, i.e. Norway, Denmark, Holland, Austria, Servia, Germany and Württemberg, the public prosecutor is also the court martial in the first instance. In other states the court of inquiry fills these offices (except in cases of small importance in Germany and Württemberg). In other states there is a special office of public prosecutor. In Spain, Portugal, Rumania, Greece and Turkey he is an officer. In Russia, Belgium, Bavaria, Switzerland and Italy he is a military lawyer. In these countries the accused has the right to choose a counsel, or one is assigned him by the United Kingdom, United States, when the matter is grave, the direction of the case is given by a judge advocate. In the United States the judge advocate is the public prosecutor.

There is no superior tribunal to which to appeal in Denmark, Great Britain and the United States. In Denmark the cases are sent to the auditor-general, who can annul if there is error, and then send back the case to be tried anew. In Great Britain and the United States, extraordinary cases of ordinary cases must be confirmed by the commanding officer by whose order the court was called. He can however sentence. In certain cases of great gravity it must go to the head of the state, after passing the revision of the judge advocate general, who in Great Britain is the constitutional adviser of the crown as regards courts martial from the view of legality. There are in these courts martial sometimes additional judges in the judge advocate general's office. This revisorial power is the safeguard of military justice, as all decisions are reviewed, and if any illegality is pointed out the proceedings are consequently quashed. The effect of the disapproval is not merely to annul the
proceedings, but it also prevents the accruing of any disability or forfeiture. The British judge advocate's office has been much strengthened. It now consists of: (1) The judge advocate general (formerly the queen's advocate general, who is a trained lawyer); (2) a deputy judge advocate, also a trained lawyer; (4) a military officer of the rank of colonel who has been called to the bar; (5) in Scotland since 1899, and on a five-years' appointment retail, a colonel who has been called to the bar.

In Germany there is no appeal, except for officials attached to the army. In Austria-Hungary the sentence can be lightened by the commander of the person's own division. Officers can also be tried by court if it appears to him too light. In Spain all judgments have to be confirmed, and if confirmation is refused, it is carried before the supreme court of the navy and army. The condemned has no power of appeal himself, but all cases are sent to that court. Russia only requires the confirmation of the commanding officer. In Rumania and Greece all condemned prisoners in time of peace can demand a court of revision, composed of a general and four superior officers. In time of war the court may be composed of three.

Certain forms of punishment, in all countries but the United States, can be given by the superior officer, without judicial intervention, for small purely military offences, where a summary procedure is required. The offender, if he prefers, may be carried before court-martial. The punishment is immediately carried into force, but the person punished can complain to higher military authority. In that case, if the complaint is not admitted, the punishment is enhanced. The condemned in the United States is punished by imprisonment or by confinement to barracks, arrests and prison. Certain special punishments obtain in certain countries—for instance, imprisonment in Turkey may be accompanied by a bread-and-water diet; and officers of the United States navy are deprived of their rank.

In 1908 France took steps to abolish courts-martial in time of peace, all common law offences to be judged by the ordinary courts, and breaches of military discipline such as rebellion, insubordination, desertion, and desertion under the flag by mixed courts composed of civil and military magistrates.

See Clode, Military Forces of the Crown; T. Gram, Fonctionnement de la justice militaire dans les différents États de l'Europe. (JNO. S.)

MILITIA (Fr. milice, Ger. Miliz, from Lat. miles, soldier, militia, military service), a term used generally for organized military forces which are not professional in character and not permanently embodied. All ancient armies, with the exception of the personal guards of their leaders, were militias or national levies, remaining under arms for the war or the campaign and returning to their ordinary occupations at the close of each military episode. Militias such as those of the Greek city-states and that of Rome were of course highly trained to the use of arms; so were the barbarian "nations in arms"; which overcame the professionalized Roman armies of the Empire; and although in the Eastern Empire these new fighting elements were absorbed into a fully organized regular arm, in the West the tribal militia system gradually developed into feudalism. The noble and the knight indeed spent the greater part of their lives in the field and devoted themselves from their youth to the cult of arms, but the feudal tenantry, who were bound to give forty days' war service and no more, and the burghers who, somewhat later in the history of civilization, formed the efficient garrisons of the walled towns were true militias. The English Yeomanry indeed almost ruled the battlefield.

In the 15th century the introduction of firearms began to weigh down the balance in favour of the professional soldier. Artillery was always the arm of the specialist. The development of infantry, "fire-power," with the early arquebus and musket, called for the highest skill and steadiness in the individual soldier, and cavalry too adopted the new weapon in the form of long and expensive spears and lances. In the new military order there was no place for the unprofessional soldier. The rôle of the unprofessional combatant, generally speaking, was that of an insurgent—harassing small detachments of the enemy, cutting off stragglers, and plundering convoys. Towards the end of the first civil war in England (1642–1645) the country-folk banded themselves together to impose a peace on the two warring armies, but their menace was without effect, and they were easily disarmed by Fairfax and Cromwell, who did not even trouble to hold them as prisoners. The calling out of the arrière ban of Franche-Comté in 1675 displayed its ludicrous inefficiency, and thereafter in France, which set the fashion to Europe in all military matters, the "provincial militia," which Louvois and Barbezieux placed in raised in the place of the discredited arrière ban, was employed partly to find drafts for and partly to augment the regular army.

When a first line army was large enough to absorb the fighting strength of the country there was neither room nor need for a true militia force. This was the case with France under Napoleon's régime, but things were different elsewhere. In Great Britain the county militia (whose special history is briefly sketched below) was permanently embodied during much of the Napoleonic Wars. Destitute as it was of technical and administrative services, of higher staffs and organization, and even of cavalry, this militia was a regular army in all but name. Combining continuous service with territorial recruiting as it did, it consisted of men of a better stamp than the casually recruited regular forces. In those days, the militia was a county force commanded by the lords-lieutenant and officered by men of influence; it was not administered by the War Office.

In other countries, Napoleon's invading armies had only to deal with regular troops for their initial resistance, and thereafter nothing remained for the beaten side but to make peace with the conqueror on such terms as could be obtained. Militias existed in name as organizations, for the production of more or less unwilling drafts for the line, but the fundamental militia obligation of defending the fatherland as distinct from defending the state, produced only local and occasional outbursts of guerrilla warfare. In the Crimean War, the 1859 war in Italy, the 1866 war in Germany, and other wars (the Hungarian War of 1849–49 excepted) the forces, other than the regular troops, engaged in first line were guerrilleros, insurgents, Garibaldians, &c., and behind the forces in first line there were draft-supplying agencies, but no true militia. Only the British militia and the Prussian landwehr represented the self-contained army of second line, and of these the former was never put to the test, while the latter, responding feebly to a political call to arms in 1850, was in consequence so entirely reorganized that it formed a mere rear rank to the line troops. This latter system, consecrated by the German successes of 1870, became the universal model for the continent of Europe, and organized and self-contained militias to-day are only to be found in states maintaining first line armies of "general service" professionals, or in states which maintain no first line troops whatever. In the first class are the auxiliary forces of the British Empire and the United States, in the second the Swiss, Norwegian, Dutch and Swedish forces.

Militia of the United Kingdom

The title of "militia" disappeared from the list of the British forces in 1908, on the conversion of the existing self-contained militia into an army of "special reserve," which is restricted to the rôle of providing drafts for the first line.1 The "self-contained" second line army of the present day is the Territorial Force (see United Kingdom: Army). The county organization of England, with which throughout the militia was closely associated, began with the advent of the Saxons. The prototype of the militia was the fyrd. In this force as reorganized by Alfred liability of service was general on the part of every free, land-bodied male between the ages of 16 and 60. Although the title of "the Fyrd" survived until long after the Norman Conquest, the force established by King Alfred was known as the general levy, which was bound to appear armed when ordered to aid in suppressing domestic riots as well as in defending the realm against invasion by foreign foes. Service was restricted to the counties, except in case of invasion, when it was extended to the whole kingdom. In 1660, the centuria became the demerit list, the new title little altering the principles governing the national forces of the kingdom, and in form in effect with certain developments the basis of the modern militia system. The Norman Conquest was immediately followed by a great production of local levies in response to the need of the levy, the distinction between these forces being that while obligation to serve in the latter rested upon every male within certain limits of

---

1 Various dominions and colonies of the British Empire have militias, for which see United Kingdom: Army. For the Swiss Militia System, which is in many respects the archetype of modern militias, see Switzerland; and for the organized militia of the United States see United States.

XVIII. 15
MILITIA

age, service in the feudal levy depended upon tenure of land under the king as feudal lord. The general levy was not in any case liable for service other than that for which he was assessed, but the service of all men for long times in war, and of units of feudal tenants in continental wars until they, too, successfully resisted the demand. Personal service formed the basis of both levies, but service by deputy, or payment in lieu of personal service, was recognized, and was called "scutage". The feudal levy was not reserved to the early centuries. The feudal levy was discontinued during the Commonwealth and abolished at the Restoration; but liability to serve in the general levy has never been abolished, and in some states it still exists in the statutory form of liability to serve both in the general and local militia. Even at the abolition of these forces the statutory liability to serve in them was not done away with. Inspectors and other officers were needed, and the militia raised under this national system were secured from time to time by means of "assizes of arms", "views of armour", "commissions of array", and "commissions of muster", founded on the feudal system of the 12th century. The machinery employed to carry out the law formed the basis of the existing procedure for the enforcement of the ballot for the militia, which thus bears a strong resemblance to the means adopted from ancient times. These constitutional powers were frequently abused by "electing" or impressing men to serve out of the kingdom, or to serve abroad, and that was the case which in the year 1627 by an Act of Parliament, which strictly regulated the scope and limits of military service within the kingdom in the charge of the parishes or counties, but provided for service abroad at the charge of the Crown. "Commissions of muster" were a development of preceding methods of levying and maintaining a militia, and the militia which the commissioners registered and mustered persons liable to serve, sorted them into bands and trained and exercised them at the charge of the county. These bands became known as troops or training bands. With the introduction of the counties, and the creation of the professional forces, the militia was divided into the counties, and the Hampshire, respectively, in 1759. In these districts, it was freeing of the militia from the control of the county. The process of the organic reform was started in 1757 was the disclosure of the inefficiency of the militia during the Rebellion of 1745. The act of 1662 followed the old law by requiring owners of property to furnish men, horses and arms in proportion to the value of their property, and the liability of persons of small property was to be discharged out of a rate levied on the parish. This was entirely altered in 1757, a liability on the county being substituted for that on the individual, with a gradual raising of the liability on the part of individuals. Each county was required to furnish a quota apportioned among the various parishes; men were to be chosen by lot to serve for three years (this being the first provision of a fixed term of service) or to replace those who failed or laid themselves liable to be called out, or to serve; substitutes, and vacancies were to be filled from time to time by a like process of ballot. The ages of liability were from 18 to 45. The system thus legalized is practically the existing though supplemented system. The forces were to be called out and exercised during a limited period, and in case of invasion or danger thereof, or in case of rebellion, the Crown could order it or any portion of it to be called out and ordered to be moved or put in motion in such a manner and to such a place as it might think fit (which was if nothing else being summoned for the purpose). During the eminently or annual training it was the subject of the Mutiny Act, except that no punishment during training was to extend to the officer or man. The period of the rifle was reduced by the Crown, the estimate for its training was framed each year, not by an executive minister of the sovereign, but by the House of Commons itself. Upon the introduction of a commission of the line, an act was passed providing for the pay and clothing of the militia for the year. The king directly appointed the permanent staff and was given a veto on the appointment and promotion of the officers who were to have a property qualification.

Under this act 30,000 militia were raised by ballot and embodied from 1759 to 1763. This force was exclusively "Protestant", and remained so until 1802. The service of the militia as thus arranged remained nearly in the same state until 1789. Pitt's reform, however, was followed by numerous amendments, new enactments, and other changes, of which the following is a summary:

1758. Men volunteering to serve recognized as counting towards the quota.
1761. Raising of quota made compulsory on counties under penalty of fines.
1775. (American War.) Act passed empowering emigration of militia in case of colonial as well as domestic rebellion.
1786. Charge on parishes for storage of arms, &c., transferred to counties.
1795. Enlistment into regulars encouraged.
1796. Supplementary militia formed, consisting of 63,878 men.
1798. (Irish Rebellion.) English militia volunteered for service in Ireland.
1799. Irish militia volunteered to serve in Great Britain.
1803. 45,492 men raised for militia by ballot, but of these 40,998 were substitutes.
1805. Militia affiliated to line for purposes of recruiting for regulars.

Militia to Scotland 1549 - 1809...
1806. Training Act to raise by ballot 200,000 men to be trained for one whole year, and then to discharge them from training for two years.

1808. Military Act (Enrolled above under Local, Act local militia (which is in effect the old general levy) established in addition to general militia then embodied.

27,000 militiamen volunteered to regular army during previous 1854. Certain restrictions, which were subsequently (in 1859) removed.

1811. English militia, hitherto not liable to serve out of the kingdom, now made liable to serve in any part of the United Kingdom under certain restrictions, which were subsequently (in 1859) removed.

Method of obtaining men from militia for regulars further systematized.

1813. During years from 1803 to 1813, nearly 100,000 militiamen joined the regular army.

Act passed to enable militia to serve abroad as militia with their own officers. Three strong battalions joined the British army in France.

1815. Militiamen recruited in great numbers the army which fought at Waterloo.

Local militia ceased to be raised.

Industrial Ballot Act suspended.

General militia disembodied.

1820-21-25. Militia called out for training.

1824. Act passed suspending ballot for general militia.

1831. Militia Act of 1821 re-enacted with Order in Council, 27th of December 1830. This was the last occasion on which the ballot was put in force.

In the latter stages of the great French war the tendency of the government in the general was to keep the militia in the producing drafts (in the end whole units) for service abroad, and the local militia as the real defensive force. During the height of the war the army was embodied, and various branches of the army were as follows: First line, the standing army; second line, the general or regular militia, which as the war went on were more and more used abroad; third line, the local militia, with the survivors of the volunteer force, who from being numbered about 60,000 men.

After the peace of 1815 the militia was allowed practically to fall into abeyance, and although the permanent staff was maintained, it had no duties to perform. In 1848 the Prime Minister intimated in private conversation to re-establish the militia, but it was not until 1852, after an unsuccessful attempt to resuscitate the local militia, that the general militia of England was reorganized under a system of voluntary enlistment with the ballot in reserve, Scotland and Ireland being included in 1854.

The proper qualification of officers which had hitherto existed (with exception in favour of ex-officers of the army and navy) was reduced, and after a further reduction in 1866, in 1868 large powers respecting the militia were conferred upon the Crown, and during the Crimean War the queen was authorized to embody the militia whenever a state of war existed with any foreign power. In that war the militia was embodied and did all that was required not only in the United Kingdom, but in the Mediterranean garrisons, thus enabling the authorities to send most of the available regular troops to the scene of hostilities. It further added to the strength of the militia that when the Indian Mutiny it filled scarcely less useless functions when again called out. The acceptance of voluntary offers of service in the Channel Islands and Isle of Man was definitely authorized in 1858, and extended to service in Malta and Gibraltar in 1875.

In 1871 an important constitutional change was made. It was part of the new army system inaugurated in that year that the control of the militia should be removed from the lord-lieutenant of the county and vested wholly in the Crown. It now virtually ceased to exist as a distinct body, and in 1881 it became a part of the regular forces with a limitation as to the time and area and other conditions of service. Once more, was it the line of battalions to form territorial regiments, the artillery and engineers being also closely associated with the regular services. Various amendments and new enactments followed, all in the direction of increasing the usefulness of the militia, rendering it more efficient and ready for service, though at the same time making it more and more a means for supplying recruits, both officers and men, to the regular army.

The officers, who were commissioned by the Crown, were in 1877 made similar to the other national service officers. No militia officers and men were only so subject when embodiment or for training, with extension in the case of men convicted of offences committed while training until two years after the term of the punishment. Enlistment was voluntary, compulsory service by ballot remained legal, but suspended. The period of engagement was for six years, re-engagements for periods of four years, and then for six years, if permitted. Bounties were paid to militiamen at various rates upon enlistment, conclusion of training, re-engagement, enlistment for special reserve or usual enlistment, and other special circumstances. Recruit training, maximum six months, and able did not exceed three months. Recruits were either drilled immediately on joining or enlisted at any time of the year, which is now the most usual system, or else the recruits were drilled immediately preceding the annual training of the corps. The annual training varied with the different branches of the service. The usual training of the infantry was 33 days, and other restrictions, with the exception of the militia reserved to the local authority, were generally extended to 34 days, 56 days being the legal maximum.

The militia occupied an important position in the mobilization scheme for national defence. The permanent staff (adjutant, quartermaster, and an establishment of non-commissioned officers and buglers or drummers, all regulars) was engaged during the non-training period of the year in recruiting, care of arms, clothing &c., and in drilling recruits. The general lines of the system, as regards recruiting are still followed with the Special Reserve, though the constitution of the new force is very different.

The militia ordinarily was liable only for service in the United Kingdom, but by legislation in 1899 may voluntarily serve in any part of the world, in the colonies, or in the military expeditions. The militia were thus accepted for service abroad, the bulk of them proceeding to the seat of war in South Africa.

MILK

MILK (O. Eng. melior; from a common Indo-European root, cf. Lat. melius, Gr. ἰ监督检查), the fluid secreted by the mammary glands of the division of vertebrate animals called Mammalia (see Mammal). It is produced by the female of the species, and in most cases is used by the young animal and the parent. The milk of various domesticated animals is more or less used by man for food. The milk of the cow, which may be taken as typical of all others, and is indeed by far the most important and valuable of all (see DAIRY and DAIRY FARMING), is, when newly drawn, an opaque white fluid, with a yellowish tinge, soft, bland and sweetish to the taste, and possessed of a faintly animal odour. This odour, according to Schreiner, is due to the presence of sulphuretted hydrogen, and disappears after a short exposure. The specific gravity of milk ordinarily ranges from 1-029 to 1-033, very seldom reaching 1-035 or falling so low as 1-027. In chemical constitution it consists of an emulsion

1. This, though here mentioned as part of a process of "regularizing," it may be more correctly referred to as that which was advisable under any conditions. The new Territorial Force when created out of the Volunteer Force (which had no such liabilities except when training from serving with regulars) was made subject to military law, officers at all times, men whenever under instruction.
of fatty globules (cream) in a watery alkaline solution of casein, and a variety of sugar, peculiar to milk, called lactose. The fat (which when separated we know as butter) and the lactose constitute the carbonaceous portion of the milk regarded as food. The casein, which forms the principal constituent of cheese, and a certain proportion of albumen which is present, form the nitrogenous, while the complex saline substances and water are the mineral constituents. These various substances are present in the proportions which render milk a perfect and typical food suitable to the wants of the young of the various animals for whom it is provided by nature. The milk of animals, so far as is known, contains them, although they are present in somewhat different proportions. It is probable that the milk of ruminants possesses certain physical and physiological distinctions from that of non-ruminant animals, which will account for the virtues attributed to the milk of the ass and mare.

The following table exhibits the chemical constitution of the kinds of milk most frequently used by man:

In addition to these constituents milk contains small proportions of the gases carbonic acid, sulphuretted hydrogen, nitrogen and oxygen, and minute quantities of other principles, the constant presence and essential conditions of which have not been determined. These consist of galactin and lactochrome, substances peculiar to milk, discovered by Winter Blathy, with certain animal principles such as leucin, pepton, kreatin, tyrosin, &c. The salts in milk consist, according to the average of numerous analyses by Fleischmann, of the following constituents:

- Phosphoric acid: 28.31
- Chlorine: 16.34
- Lime: 27.00
- Soda: 10.00

Potash: 17.34
Magnesia: 4.07
Ferric oxide: 0.62

Milk thus is not to be regarded as a definite chemical compound nor even as a mixture of bodies in fixed and invariable proportions. Not only does the milk vary in different races and breeds of cows vary within comparatively wide limits; the milk of the same animal is subject to extensive fluctuations. The principal causes of variation in the individual are age, period of lactation, nature and amount of food, state of health, and treatment, such as frequency of milking, &c. The following table indicates the range of normal variations:

| Water     | 90.00 to 83.65 |
| Fat       | 2.80 to 4.80  |
| Casein and albumin | 3.30 to 5.55 |
| Sugar     | 3.00 to 5.80  |
| Ash       | 0.70 to 0.80  |

The average quantity of milk yielded by cows is also highly variable, both in individuals and breeds.

**Milk and Disease.**—Although the milk of a perfectly healthy cow may be absolutely sterile, it is difficult to obtain it in that condition. In the report of the joint committee appointed for the purpose by the county boroughs of Bradford, Hull, Leeds, Rotherham and Sheffield in 1908, the following conclusions were drawn: (a) Cows' milk freshly drawn from the udder by ordinary methods contains bacteria. They are more numerous in the first flow of the milk. (b) There is a great increase in contamination in the milk at each stage of the process only reaching the customer. This is due to (a) the dirty condition of the cows' udders, (b) the imperfect cleansing of the cans and of the hands of the milkers. The committee recommend:

1. Ewe's milk is exceedingly variable, especially in its percentage of fat. The above analysis is one of nine by Dr Arthur Voelcker, in which the fat was found to range from about 2 to 12 1/2%.

**452**

"(1) The washing of the udder and flanks with soap and water, and similar attention to the hands of the milkers. (2) Efficient sterilization of all vessels by steam if possible, or by immersion of boiling water. (3) Rejection of the first draw of the milk from each teat. (4) Advantages of milk received from the dairy immediately after milking. (5) Removal of the milk of each cow immediately from the shed. (6) Ventilation and cleanliness of the cowsheds." This provides for the result of these practices, the following remarks, during the past weighing process itself. As any bacteria present in the milk will multiply rapidly on the way to the consumer, it is mainly a question of the time which elapses before consumption. It is, therefore, better recommended that the milk be cultivated or chilled, as the lower the temperature the less do the bacteria multiply, (b) that contamination during transit may be avoided by dustproof locked milk cans.

The heating milk at a temperature of 60° C. for one hour, 70° C. for ten minutes, and 95° C. for one minute; tubercle bacilli, if present, will certainly be killed. Cholera and typhoid organisms are less resistant, and are killed more quickly than tubercle bacilli by the above temperatures. Only a single pathogenic species can withstand the short boiling to which milk is ordinarily treated in domestic management, and this is the anthrax bacillus containing spores. The danger from this source is remote, as the microbe does not form spores within the animal body. Even in the worst cases, therefore, only vegetable forms, easily destroyed by boiling, can find their way into the milk from the cow. The lactic acid bacillus, always present in unboiled milk (to which the souring of milk is due), is easily destroyed by heat; but the bacillus mesentericus, often found in it, forms spores, which are not destroyed by ordinary boiling, and germinate in the milk if it is kept at a moderately warm temperature, producing a brisk fermentation whereby a large volume of gas is liberated. The fundamental idea of Soxhlet's method for sterilizing milk is to boil it for a few minutes in just the same vessels, and, closing the same with an impervious stopper, which is only removed just before use. Milk so treated will keep well at the ordinary room temperature, and will acquire the B. mesentericus. To render milk sterile in the strict sense of the word it is necessary to raise it to a temperature of about 120° C. for twenty minutes. Under these conditions the lactic decomposes into dark-brown fission products, the fat loses its natural character, and the cream which cannot be made to diffuse again even by shaking, and the albuminoids are converted into a form very difficult of digestion. In short, there is the greatest difficulty in freeing milk on a large scale from forms without at the same time seriously prejudicing its flavour and nutritive value. Since, then, the destruction of the hardy germ is so difficult, the greater care should be taken, by washing, brushing, and sponging, hands and udders, to secure the best possible preparation of milk intended for infant consumption. Sterilization then becomes an easier task, the milk drawn under these conditions being very poor in spore-forming bacteria. It is imperative that milk intended for elution or infant's milk, &c., should be treated with all possible care.

Since Metchsikoff's introduction (see Longevity) of the use of soured milk for dietic purposes—the lactic acid bacillus destroying pathogenic bacteria in the intestine—a great impetus has been given to the multiplication of laboratory preparations containing cultures of the bacillus; and in recent years much benefit to health has, in certain cases, been derived from the discovery. For further articles: ADULTERATION AND DAIRY FARMING; INFANCY: DIETICS; Food and Food Preservation; in the last of which the preparation of condensed milk is described.

**MILKWORT.** In botany, the common name for plants of the genus Polygala (natural order Polygalaceae), a large genus widely dispersed in temperate and tropical regions and represented by a few species in Britain. The common species, P. vulgaris, is an annual herb, and the perennial P. canariensis is abundant throughout the British Isles. The stems are 2 to 10 in. long and bear narrow rather tough leaves and small, 1/4 to 1 1/2 in. long, white, pink, blue, lilac or purple flowers. The flowers (see fig.) are peculiar in form and arrangement of parts; they have five free sepal the two inner of which (b) are large petaloid and winglike, forming the most conspicuous part of the flower; the petals are united below with the sheath of the eight stamens forming a tube split at the base behind; their form recalls that of the pea family. The name Polygala is from the Greek polygala, much,
and yāla, milk, the plant being supposed to increase the yield of milk in cows. Some species with showy flowers are known in cultivation as greenhouse, or hardy annual or perennial, herbs, or shrubs. The root of P. Senega, snake-root, a North American species is officinal. Sea milkwort is the common name for Glycos maritima, a small succulent herb found on seashores and in estuaries in the British Isles; it belongs to the primrose order (Primulaceae).

MILL, JAMES (1773–1836), historian and philosopher, was born on the 6th of April 1773, at Northwater Bridge, in the parish of Logie-Pert, Forfarshire, the son of James Mill, a shoemaker. His mother, Isabel Fenton, of a good family which had suffered from connexion with the Stuart rising of 1745, resolved that he should receive a first-rate education, and sent him first to the parish school and then to the Montrose Academy, where he remained till the unusual age of seventeen and a half. He then entered the university of Edinburgh, where he distinguished himself as a Greek scholar. In October 1798 he was licensed as a preacher, but met with little success. From 1799 to 1802, in addition to holding various tutorships, he occupied himself with historical and philosophical studies. Finding little hope of a career in Scotland, in 1802 he went to London in company with Sir John Stuart, then member of parliament for Kin-cardineshire, and devoted himself to literary work. From 1803 to 1806 he was editor of an ambitious periodical called the Literary Journal, which professed to give a summary view of all the leading departments of human knowledge. During this time he also edited the St James’s Chronicle, belonging to the same proprietor. In 1804 he wrote a pamphlet on the corn trade, arguing against a bounty on the exportation of grain. In 1805 he published a translation (with notes and quotations) of C. F. Villers’s work on the Reformation, an unsparring exposure of the alleged vices of the papal system. In 1805 he married Harriet Burrow, whose mother, a widow, kept an establishment for lunatics in Hoxton. He then took a house in Pentonville, where his eldest son, John Stuart Mill (q.v.), was born in 1806. About the end of this year he began his History of India, which he took twelve years to complete, instead of three or four, as he had expected.

In 1808 he became acquainted with Jeremy Bentham, and was for many years his chief companion and ally. He adopted Bentham’s principles in their entirety, and determined to devote all his energies to bringing them before the world. Between 1806 and 1818 he wrote for the Anti-Jacobin Review, the British Review and the Electric Review; but there is no means of tracing his contributions. In 1808 he began to write for the Edinburgh Review, to which he contributed steadily till 1813, his first known article being “Money and Exchange.” He also wrote on Spanish America, China, General Miranda, the East India Company, and the Liberty of the Press. In the Annual Review for 1808 two articles of his are traced—a “Review of Fox’s History,” and an article on “Bentham’s Law Reforms,” probably his first published notice of Bentham. In 1811 he co-operated with William Allen (1770–1843), quaker and chemist, in a periodical called the Philantropist. He contributed largely to every number—his principal topics being Education, Freedom of the Press, and Prison Discipline (under which he expounded Bentham’s “Panopticon”). He made powerful onslaughts on the Church in connexion with the Bell and Lancaster controversy, and took a prominent part in the discussions which led to the foundation of London University in 1825. In 1814 he wrote a number of articles, containing an exposition of utilitarianism, for the supplement to the fifth edition of the Encyclopaedia Britannica, the most important being those on “Jurisprudence,” “Prisons” and “Government.”

In 1818 the History of India was published, and obtained a great and immediate success. It brought about a change in the author’s position. The year following he was appointed an official in the India House, in the important department of the examiner of Indian correspondence. He gradually rose in rank till he was appointed, in 1830, head of the office, with a salary of £1000, raised in 1836 to £2000. His great work, the Elements of Political Economy, appeared in 1821 (3rd and revised ed. 1826).

From 1824 to 1826 Mill contributed to the Westminster Review, started as the organ of his party, a number of articles in which he attacked the Edinburgh and Quarterly Reviews and ecclesiastical establishments. In 1829 appeared the Analysis of the History of India, From 1826 to 1830 Mill was largely occupied on the defence of the East India Company, during the controversy attending the renewal of its charter, he being in virtue of his office the spokesman of the court of directors. For the London Review, founded by Sir William Molesworth in 1834, he wrote a notable article entitled “The Church and its Reform,” which was much too sceptical for the time, and injured the Review. His last published book was the Fragment on Mackintosh (1835). He died on the 23rd of June 1836.

Mill had a thorough acquaintance with Greek and Latin literature, general history, political, mental and moral philosophy. His intellect was logical in the highest degree; he was clear and precise, an enemy of loose reasoning, and quick to refute prevailing fallacies. All his work is marked by original constructive thought, except in a few subjects, in which he confessedly expounded Bentham’s views. At a time when social subjects were as a rule treated empirically, he brought first principles to bear at every point. His greatest literary monument is the History of India. The materials for narrating the acquisition by England of its Indian Empire were put into shape for the first time: a vast body of political theory was brought to bear on the delineation of the Hindu civilization; and the conduct of the actors in the successive stages of the conquest and administration of India was subjected to a severe criticism. The work itself, and the author’s official connexion with India for the last seventeen years of his life, effected a complete change in the whole system of governing that country.

Mill played a great part also in English politics, and was, more than any other man, the founder of what was called ‘philosophic radicalism.’ His writings on government and his personal influence among the Liberal politicians of his time determined the change of view from the French Revolution theories of the rights of man and the absolute equality of men to the claiming of securities for good government through a wide extension of the franchise. Under this banner it was that the Reform Bill was fought and won. His Elements of Political Economy, which was intended only as a textbook of the subject, shows all the author’s precision and lucidity. As Dr J. K. Ingram said, it has the “character of a work of art.” It followed up the views of Ricardo, with whom Mill was always on terms of intimate friendship; interest is mainly historical, as an annual summary of views which are now largely discarded. Among the more important of its theses are: (1) that the chief problem of practical reformers is to limit the increase of population, on the assumption that capital does not naturally increase at the same rate as population (ii. § 2, art. 3); (2) that the value of a thing depends entirely on the quantity of labour put into it; and (3) that what is now known as the “uneared increment” of land is a proper object for taxation. The work as a whole is a striking example of the weakness of treating
MILL, JOHN—MILL, JOHN STUART

Ecclesiastical History, M'Crie's Knox, and two histories of the Quakers. A contemporary record of Mill's studies from eight to thirteen is published in Bain's sketch of his life. It shows that the Autobiography rather understates the amount of work done. At the age of eight he began Latin, Euclid, and algebra, and was appointed schoolmaster to the younger children of the family. His main reading was still history, but he went through the Latin and Greek authors commonly read in the schools and universities, besides several that are not commonly read by undergraduates. He was not taught to compose either in Latin or in Greek, and he was never an exact scholar; it was for the subject matter that he was required to read, and by the age of ten he could read Plato and Demosthenes with ease. His father's History of India was published in 1818; immediately thereafter, about the age of twelve, John began a thorough study of the scholastic logic, at the same time reading Aristotle's logical treatises in the original. In the following year he was introduced to political economy and studied Adam Smith and Ricardo with his father.

Not unnaturally the training which the younger Mill received has aroused amazement and criticism; and it is reasonable to doubt whether the material knowledge which he retained in the result was as valuable to him as his father imagined. It is important, however, to note that the really important part of the training was the close association which it involved with the strenuous character and vigorous intellect of his father. From his earliest days he spent much time in his father's study and hospital, and was much influenced by his philosophical and political views. Much therefore of what he acquired was assimilated without difficulty, and the accuracy of his impressions was tested by his subsequently drafting a resume of their conversations. He thus learned early to grapple with difficulties and to accustom himself to the necessity of precision in argument and expression. It was an inevitable result of such an education that Mill acquired many of his father's speculative opinions, and his father's way of defending them. But he did not receive the impress passively and mechanically. "One of the great objects of education," according to the elder Mill, "should be to generate a constant and anxious concern about evidence. The duty of collecting and weighing evidence for himself was at every turn impressed upon the boy; he was taught to accept no opinion on authority. He was deliberately educated as an apostle, but it was as an apostle of reasoned truth in human affairs, not as an apostle of any system of dogmatic tenets. It was to prevent any falling off from this high moral standard till it should become part of his being that his father kept the boy so closely with himself. Mill expressly says that his childhood was not unhappy. It seems unhappy only when we compare it with the normal life of a boy, and decline to imagine its peculiar enjoyments and aspirations. Mill complains that his father often required more than could be expected of him, but his tasks were not so severe as to prevent him from growing up a healthy and high-spirited boy, though he was not constitutionally robust, and his pursuits were so different from those of other boys of the same age.

From May 1820 till July 1821 Mill was in France in the family of Sir Samuel Bentham, brother of Jeremy Bentham. Away from his father he maintained his laborious habits. Copious extracts from a diary kept by him at this time are given by Bain; they show how methodically he read and wrote, studied chemistry and botany, tackled advanced mathematical problems, made notes on the scenery and the people and customs of the country. He also gained a thorough acquaintance with the French language. On his return in 1821 he added to his work the study of psychology, and that of Roman law, which he read with John Austin, his father having half decided on the bar as the best profession open to him. In 1822, however, when he had just completed his seventeenth year, this intention was abandoned, and he entered as a clerk in the examiner's office of the India House, "with the understanding that he should be employed from the beginning in preparing drafts of despatches and be thus trained up as a successor to those who then filled the highest departments of the office."
Mill's work at the India House, which was henceforth his livelihood, did not come before the public; hence some have suspected his political writings as the work of an abstract philosopher, entirely unacquainted with affairs. From the first he was more than a clerk, and after a short apprenticeship he was promoted, in 1828, to the responsible position of assistant-examiner with a salary of $600 a year. The duty of the so-called examiners was to examine the letters of the agents of the Company in India, and to draft instructions in reply. The character of the Company's government was almost entirely dependent upon their abilities as statesmen. For twenty years, from 1836 (when his father died) to 1856, Mill had charge of the Company's relations with the native states, and in 1856 he became chief of the office with a salary of $1000. In the hundreds of despatches that he wrote in this capacity much, no doubt, was done in accordance with established routine, but few statesmen of his generation had a wider experience of the responsible application of the principles of government. About this work he said little in the Autobiography, probably because his main concern there was to expound the influences that effected his moral and mental development.

About the time of his entering the India House Mill read Dumont's exposition of Bentham's doctrines in the Traité de Legislation, which made a lasting impression upon him. When he laid down the last volume at a half-year's notice, he took up the notion of being. It gave unity to the detached and fragmentary parts of his knowledge and beliefs. The impression was confirmed by the study of the English psychologists, as well as Condillac and Helvetius, and in 1822-1823 he established among a few friends the "Utilitarian" Society, taking the word as he tells us, from Galt's Annals of the Parish. Two newspapers were open to him—the Traveller, edited by a friend of Bentham's, and the Morning Chronicle, edited by his father's friend Black. One of his first efforts was a solid argument for freedom of discussion, in a series of letters to the paper in support of the prosecution of Richard Carlile. But he watched all public incidents with a vigilant eye, and seized every passing opportunity of exposing departures from sound principle in parliament and courts of justice. Another outlet was opened up for him (April 1824) by the starting of the Westminster Review, and still another in the following year in the Parliamentary History and Review. This year also he found a congenial occupation in editing Bentham's Rationale of Judicial Evidence. All the time, his mind full of public questions, he discussed eagerly with the many men of distinction who came to his father's house, and engaged in a supernumerary, a reading society formed at Grote's house in 1823, and in set debates at a speculative society formed in the same year.

From the Autobiography we learn that in 1826 Mill's enthusiasm was checked by a mitigating as to the value of the ends which he had set before him. This expression was the result, no doubt, of his strenuous training and the comparative lack of congenial friendships. His father was reserved, undemonstrative even to the pitch of chilling sternness, and among young Mill's comrades contempt of feeling was almost a watchword. Himself absorbed in abstract questions and projects of general policy, he had no need of even casual matters of personal attachment. On the other hand without experience he could not have been prepared for the actual slowness of the reformer's work. In 1826 he looked back to four years of eager toil. What were the results? He had become convinced that his comrades in the Utilitarian Society, never more than ten, had not the stuff in them for a world-shaking propaganda; the society itself was dissolved; the Parliamentary Review was a failure; the Westminster did not pay its expenses; Bentham's Judicial Evidence produced little effect on the reviewers. His own reception to his first volume of the Speculative Debating Society, where he first measured his strength in public conflict, was calculated to produce self-distrust. He found himself looked upon with curiosity as a precocious phenomenon, a "made man," an intellectual machine set to grind certain tines. The outcome of this period of depression was a broadening of his outlook on the problems which he had set himself to solve. He now saw that regard for the public good was too vague an object for the satisfaction of a man's affections. It is a proof of the dominating force of his character that it cost the younger Mill such an effort to shake off his stern creed about poetry and profitable emotion. Like Plato, the elder Mill would have put poetry under ban as enemies of truth, and he subordinated private to public affections. Landor's maxims of "few acquaintances, fewer friends, no familiarities" had his cordial approval. These doctrines the younger Mill now felt himself forced in reason to abandon. Too much in awe of his father to make him a confidant, he wrestled in the gloomy solitude of his own mind. He gained from the struggle a more catholic view of human happiness, at delight in the poetry of nature and the affections as well as the philosophy of heroic unsentimentality, a disposition to study more sympathetically the point of view of opponents, a more courteous style of polemic, a hatred of sectarianism, an ambition, no less noble and disinterested, but moderated to practical possibilities.

In the course of the next few years he wrote comparatively little, but he continued his reading, and also derived much benefit from discussions held twice a week at Grote's house in Threadneedle Street. Gradually also he had the satisfaction of seeing the debates in the Speculative Society becoming famous enough to attract notice, and of his own interchange of opinions, among others Maurice and John Sterling. He ceased to attend the society in 1829, but he carried away from it the strengthening memory of failure overcome by persevering effort, and the important doctrinal conviction that a true system of political philosophy was "something much more complex and many-sided than he had previously had any idea of, and that its office was to supply, not a set of model institutions but principles from which the institutions suitable to any given circumstances might be deduced."

The practical philosophy that Mill attacked appeared in a series of contributions to the Examiner in the autumn of 1830 entitled "Prospects in France." He was in Paris soon after the July Revolution, and made the acquaintance of the leading spirits among the younger men; in his discussion of their proposals we find the germs of many thoughts afterwards more fully developed in his Representative Government. It is from this time that Mill's letters supply a connected account of his life (see Hugh Elliott, Letters of John Stuart Mill, 1910).

The letters in the Examiner may be taken as marking the close of his speculative period. He returns to speculative work after his return to hopes of aspired to activity. It was characteristic of his nature that he should be stirred to such delight by the Revolution in France, and should labour so earnestly to make his countrymen understand with what gravity and sobriety it had been effected. Their own Reform Bill came soon after and it is again characteristic of Mill—at once of his enthusiasm and of his steady determination to do work that nobody else seemed able or willing to do—that we find him in the heat of the struggle in 1831 writing to the Examiner a series of letters on "The Spirit of the Age," which drew from Carlyle the singular exclamation, "Here is a new mystic." How little this criticism was justified may be seen from the fact that Mill's inductive logic was the direct result of his aspirations after political stability as determined by the dominion of the wisest (Examiner letters). "Why is it," he asked, "that the multitude accept implicitly the decisions of the wisest, of the specially skilled, in physical science?" Because in physical science there is all but complete agreement in opinion. "And why this agreement?" Because all accept the same methods of investigation, the same tests of truth. Is it possible then to obtain unanimity as to the methods of arriving at conclusions in social and political matters, so as to secure similar agreement of opinion among the specially skilled, and similar general respect for their authority? The same thought appears in a review of Herschel's Natural Philosophy, written about the same time. Mill remarks that the uncertainty hanging over the very elements of moral and social philosophy proves that the means of arriving at the truth in those sciences are not yet
MILL, JOHN STUART

properly understood. "And whither," he adds, "can mankind so advantageously turn, in order to learn the proper means, and to form their minds to the proper habits, as to that branch of knowledge in which by universal acknowledgment the greatest number of truths have been ascertained, and the greatest possible degree of certainty arrived at?"

By 1831 the period of depression had passed; Mill's enthusiasm for humanity had been somewhat thoroughly roswakened, and had taken the definite shape of an aspiration to supply an unimpeachable method of search for conclusions in moral and social science. No mystic ever worked with warmer zeal than Mill. But his zeal encountered a check which baffled him for several years, and which left its mark in various inconsistencies and incoherences in his completed system. He had been bred by his father in a great veneration for the syllogistic logic as and antidote against confused thinking. He attributed to his early discipline in this logic an impatience of vague language which in all likelihood was really fostered in him by his study of the Platonic dialogues and of Bentham, for he always had in himself more of Plato's fertile ingenuity in canvassing the meaning of vague terms than the schoolman's rigid consistency in the use of them. Be this as it may, enthusiastic as he was for a new logic that might give certainty to moral and social conclusions, Mill was no less resolute that the new logic should stand in no antagonism to the old. In his Westminster review of Whately's Logic in 1828 (invaluable to all students of the genesis of Mill's logic) he appears, curiously enough, as an ardent and constant champion of the syllogistic logic against hiftiers such as the Scottish philosophers who talk of "superseding" it by "a supposed system of inductive logic." His inductive logic must "supplement and not supersede." But for several years he searched in vain for the means of concatenation.

Meantime, while recurring again and again, as was his custom, to this cardinal difficulty, Mill worked indefatigably in other directions where he saw his way clear. The working of the new order in France, and the personalities of the leading men, had a profound interest for him; he wrote on the subject, in the Examiner. He had ceased to write for the Westminster in 1828; but during the years 1832 and 1833 he contributed many essays to Tait's Magazine, the Jurist, and the Monthly Repository. In 1835 Sir William Molesworth founded the London Review with Mill as editor; it was amalgamated with the Westminster (as the London and Westminster Review) in 1836, and Mill continued editor (latterly proprietor also) till 1840. Much of what he wrote then was subsequently incorporated in his systematic works. Two of his essays were reprinted in his first two volumes of Dissertations and Disquisitions (1839). The essays on Bentham and Coleridge constituted the first manifesto of the new spirit which Mill sought to breathe into English Radicalism. But the reprinted papers give no just idea of the immense range of Mill's energy at this time. His position in the India Office, where alone he did work enough for most men, cut him off from entering parliament; but he laboured hard though ineffectually to influence the legislature from without by combating the disposition to rest and be thankful. In his Autobiography he admits that the attempt to form a Radical party in parliament at that time was chimerical.

It was in 1837, on reading Whewell's Inductive Sciences and re-reading Herschel, that Mill at last saw his way clear both to formulating the methods of scientific investigation and joining on the new logic as a supplement to the old. The Logic was published in 1843. In 1844 appeared his Essays on Some Unsolved Questions in Political Economy. These essays were worked out and written many years before, and show Mill in his first stage as a political economist. Four out of the five essays are clear and powerful solutions of perplexing technical problems—the distribution of the gains of international commerce, the influence of consumption on production, the definition of productive and unproductive labour, the precise relations between profits and wages. Though Mill appears here purely as the disciple of Ricardo, striving after more precise statement, and reaching forward to further consequences, we can well understand in reading these essays how about the time when he first sketched them he began to be conscious of power as an original and independent thinker.

That originality and independence became more conspicuous as he advanced, and more and more carried him forward towards the standpoint from which his systematic work was written. It would seem that in his fits of despondency one of the thoughts that marred his dreams of human improvement was the apparently inexorable character of economic laws, condemning thousands of labourers to a cramped and miserable existence, and thousands more to semi-starvation. From this oppressive feeling he found relief in the thought set forth in the opening of the second book of his Political Economy—that, while the conditions of production have the necessity of physical laws, the distribution of what is produced among the various classes of producers is a matter of human arrangement, dependent upon alterable customs and institutions. There can be little doubt that this thought, whether or not in the clear shape that it afterwards assumed, was the germ of all that is most distinctive in his system of political economy. This system, which for many years subsequently was regarded as authoritative, has been subjected to vigorous criticism by later economists, and it is perhaps not too much to say that it now possesses mainly an historical interest. Its chief importance is perhaps the stress which it laid on the vital connexion between the two. This he has called his third stage as a political economist, and he says that he was helped towards it by the lady, Mrs Taylor, who became his wife in 1831. It is generally supposed that he writes with a lover's extravagance about this lady's powers—when he compares her with Shelley and Carlyle. But a little reflection will show that he wrote with his usual accuracy and sobriety when he described her influence on him. He expressly says that he owed none of his technical doctrine to her, that she influenced only his ideals of life for the individual and for society; the only work perhaps which was directly inspired by her was the essays on the marriage of working women (Dissertations, vol. ii.). It is obvious from what he says that his inner life became very different after he threw off his father's authority. This new inner life was strengthened and enlarged by Mrs Taylor.

During the seven years of his married life Mill published less than in any other period of his career, but four of his most

1 Mrs Taylor (Harriet Hardy) was the wife of John Taylor, a wholesale druggist in the city of London. She was a confirmed invalid, and lived in the country, where Mill visited her regularly for twenty years, with the full consent of her husband, a man of limited mental powers, but of high character and unselfishness. Mill's friendship with Mrs Taylor and their marriage in 1851 involved a breach with his family (apparently due to his resentment at a fancied slight, not to any bitterness on their part), and his practical disappearance from society. (On these points see Mary Taylor, Mrs Mill's grand-daughter, in Elliot's edition of the Letters.)
closely reasoned and characteristic works, the _Liberty_, the _Utilitarianism_, the _Thoughts on Parliamentary Reform_, and the _Subjection of Women_, besides his posthumously published essays on _Nature_ and on the _Utility of Religion_, were thought out and partly written in collaboration with his wife. In 1836 he became head of the examiner's office in the India House, and for two years, till the dissolution of the Company in 1838, his official work, never a light task, kept him fully occupied. It fell to him as head of the office to write the defence of the Company's government of India when the transfer of its powers was proposed. The necessity of providing checks against uneducated democracy, and the circumstances, have attempted so much for the good of their subjects or carried so many of their attempts to a beneficial issue," and exposed the defects of the proposed new government, are models of trenchant and dignified pleading.

On the dissolution of the Company Mill was offered a seat in the new council, but declined, and retired with a pension of £1,500. His retirement from official work was followed almost immediately by his wife's death at Avignon, whether they had contrived to see each other during the last year of her life, it is not certain. She spent the rest of his life he spent most of his time at a villa at St Vérain, near Avignon, returning to his Blackheath residence only for a short period in each year. He sought relief in active literary occupation, in politics, sociology and psychology. He published, with a touching dedication to his wife, the treatise on _Liberty_, which they had wrought out together. He then turned to politics, and published, in view of the impending Reform Bill, a pamphlet on parliamentary reform. The chief feature in this was an idea concerning which he and Mrs Mill often deliberated—the necessity of providing checks against uneducated democracy. His suggestion of a plurality of votes, proportioned to the elector's degree of education, was aboved poultry put forward only as an ideal; he admitted that no authentic test of education could for the present be found. An anonymous Conservative caught at the scheme in another pamphlet, proposing income as a test. Soon after Mill supported in _Fraser's_, still with the same object, Hare's scheme for the representation of minorities. In the autumn of the same year he turned to psychology, reviewing Bain's works in the _Edinburgh Review_. In his _Representative Government_ (1860) he systematized opinions already put forward in his _System of Logic_. His _Utilitarianism_ (published in _Fraser's_ in 1861) was a closely-reasoned systematic attempt to answer objections to his ethical theory and remove misconceptions of it. He was especially anxious to make it clear that he included in "utility" the pleasures of the imagination and the gratification of the higher emotions, and to show how powerfully the good of mankind as a motive appealed to the imagination. His next treatise, the _Subjection of Women_, was not published till 1869. His _Examination of Hamilton's Philosophy_ published in 1865, had engaged a large share of his time for three years before. While mainly occupied in those years with philosophical studies, Mill did not rejoin his interest in current politics. He supported the North in the American crisis of 1862, using all his strength to explain what has since been universally recognized as the issue really at stake in the struggle, the abolition of slavery. It was characteristic of the closeness with which he watched current events, and of his zeal in the cause of "lucidity," that when the _Reader_, an organ of science and unpartisan opinion, fell into difficulties in 1865 Mill joined with some distinguished men of science and letters in an effort to keep it aloof. He supplied part of the money for carrying it on, contributed several articles, and assisted the editor, Fraser Rae, with his advice.

The effort was vain, though such men as Herbert Spencer, Huxley, Tyndall, Cairnes, Mark Pattison, F. Harrison, Sir Frederick Pollock and Lockyer were among the contributors. In 1865 he agreed to stand as parliamentary candidate for Westminster, on conditions strictly in accordance with his principles. He would not canvass, nor pay agents to canvass for him, nor would he engage to attend to the local business of the constituency. He was with difficulty persuaded even to address a meeting of the electors. The story of this remarkable election has been told by James Beal, one of the most active supporters of Mill's candidature. In parliament he adhered to the "long principle of doing only work that needed to be done, and that body else ever equally able will be that may have been a consciousness of this fact which prompted a remark, made by the Speaker, that Mill's presence in parliament elevated the tone of debate. The impression made by him in parliament is in some danger of being forgotten, because he was not instrumental in carrying any great measure that might serve as an abiding memorial. But, although his first speech on the bill for the prevention of cattle diseases excited the opposition of country members, and a subsequent speech against the suspension of the Habeas Corpus Act in Ireland was very favorably received, he was not so prominent in the debates. He retired to the ear of the House. The only speech made by him during his three years in parliament that was listened to with impatience was, curiously enough, his speech in favour of counteracting democracy by providing for the representation of minorities. His attack on the conduct of Governor Eyre in Jamaica (q.v.) was listened to, but with repugnance by the majority, although his action in this matter in and out of parliament was far from being ineffectual. He took an active part in the debates on Disraeli's Reform Bill (moving an amendment to omit the word "man" and insert "person"), and helped to force from the government several useful modifications of the Bill for the Prevention of Corrupt Practices. The reform of land tenure in Ireland, the representation of women, the reduction of the national debt, the reform of London government, the abrogation of the Declaration of Paris, were among the topics on which he spoke with marked effect. He took occasion more than once to enforce what he had often advocated in writing, England's duty to intervene in foreign politics in support of the cause of freedom. As a speaker Mill was somewhat hesitating, pausing occasionally as if to recover the thread of his argument, but he showed great readiness in extemporaneous debate. As a member a candidate for ministerial office, he might be regarded as a failure in parliament, but there can be no doubt that his career there greatly extended his influence.

Mill's subscription to the election expenses of Bradlaugh, and his attitude towards Governor Eyre, are generally regarded as the main causes of his defeat in the general election of 1868. But, as he suggests himself, his studied advocacy of unfamiliar projects of reform had made him unpopular with "moderate Liberals." He retired with a sense of relief to his cottage and his literary life at Avignon. His parliamentary duties and the quantity of correspondence brought upon him by increased publicity had absorbed nearly the whole of his time. The scanty leisure of his first recess had been devoted to writing his _St Andrews_ rectorial address on higher education and to answering attacks on his criticism of Hamilton; of the second, to annotating in conjunction with Bain and Findlater, his father's _Analysis of the Mind_. Now he looked forward to a literary life, and his letters show how much he enjoyed the change. His little cottage was filled with books and newspapers; the beautiful country round it furnished him with a variety of walks; he read, wrote, discussed, walked, botanized. He was extremely fond of music and was himself a fair pianist. His step-daughter, Miss Taylor (d. January 1907), was his constant companion after his wife's death. "Helen," he wrote to W. T. Thornton, an old colleague in the India House, "has carried out her long-cherished scheme (about which she tells me she consulted you) of a vibratory for me, and has made a pleasant covered walk, some 30 ft. long, where I can vibrate in cold or rainy weather. The terrace, you must know, as it goes round two sides of the house, has got itself

XVIII. 15 a

[1] He was one of the founders, with Mrs P. A. Taylor, Miss Emily Davies and others, of the first women's suffrage society, which developed into the National Union of Women's Suffrage Societies, and his writings are still the most important theoretical statements of the case for women's suffrage. He presented to Parliament the first petition on the subject (see further Blackburn, _Women's Suffrage Record_).
MILL, JOHN STUART
dubbed the 'semi-circumstantial.' In addition to this, Helen
has built me a herbarium, a little room fitted up with closets
for my plants, shelves for my botanical books, and a great
table which to manipulate them all. Thus, you see, with my
herbarium, my vibratory, and my semi-circumstantial, I am
in clover; and you may imagine with what scorn I think of
the House of Commons, which, comfortable club as it is said to be,
could offer me none of these comforts, or, more perfectly speak-
ing, these necessaries of life." Mill was an enthusiastic botanist
all his life long, and a frequent contributor of notes and short
papers to the *Physiologist.* One of the things that he looked
forward to during his last journey to Avignon was seeing
spring flowers and completing his herbarium. His delight in
summer frequently appears in letters written to his
friends during his summer and autumn tours.

Yet he did not relax his laborious habits nor his ardent out-
look on human affairs. The essays in the fourth volume of his
*Dissertations*—on endowments, on land, on labour, on meta-
physical and psychological questions—were written for the
*Fortnightly Review* at intervals after his short parliamentary
career. One of his first tasks was to send his treatise on the
*Subjection of Women* (written 1856, published 1869, many
months of hesitation) to his friend Mrs. Taylor. The book was
written soon after. The last public work in which he engaged was
the starting of the Land Tenure Reform Association. The Inter-
ception by the state of the unearned increment, and the promo-
tion of co-operative agriculture, were the most striking features
in his programme. He wrote in the *Examiner* and made a public
speech in favour of the association a few months before his
death. The secret of the ardour with which he took up this
question probably was his conviction that a great struggle was
impending in Europe between labour and capital. He regarded
his project as a timely compromise.

Mill died at Avignon on the 8th of May 1873. He was a man
of extreme simplicity in his method of life. Though occasionally
irritable in speech, in his written polemics he was remarkable
for courtesy to opponents and a capacity to understand their
point of view. His references to his friends were always generous,
and he was always ready to assist those whose work needed help.
For example, he desired to guarantee the cost of the first books
of Bain and Herbert Spencer. A statue in bronze was placed
on the Thames Embankment, and there is a good portrait by
Watts, who was, I fancy (by which, by Watts himself, was hung in the
National Gallery).

The influence which Mill's works exercised upon contemporary
English thought can scarcely be overestimated. His own writings
and those of his successors (e.g. J. E. Cairnes and Alexander
Smith) were powerful, and hold their own still in the last quarter of
the 19th century and even later. In philosophy his chief work was to
systematize and expound the utilitarianism of his father and Bentham
(see UTILITARIANISM). He may, in fact, be regarded as the founder
of that empirical school of philosophy which owed its impulse to
John Locke, and is generally spoken of as being typically English. Its
fundamental characteristic is the emphasis laid upon human
reason, i.e. upon the duty incumbent upon all thinkers to investigate
for themselves rather than to accept the authority of others.
Knowledge must be based upon experience. In reasserting and amplifying
the empirical conclusions of his predecessors, especially in the
field of ethics, Mill's chief function was the introduction of the humanist-
element. This was due, no doubt, to his revulsion from the sternness of
his upbringing and the period of stress through which he passed in
his early manhood. Yet it must be noted that the socialism he espoused and
the social policy of which he was the leader and the architect were
entirely consistent with his early training.

We have seen, for example, that he was led to investigate the subject of
logic because he found in attempting to advance his humanitarian
themes in politics an absence of that fundamental agreement which he recog-
nized as the basis of scientific advance. Both his logical and his
metaphysical studies were thus undertaken as the pre-requisites of a
project for developing political and economic thought. The
lower classes were not yet ripe for socialism, with the principles
of which he (unlike James Mill and Bentham) was in general agree-
ment, his whole life was devoted to the amelioration of the conditions
of the working classes. This fact, no doubt, should be taken into
account in any detailed criticism of the philosophic work; it was taken
up not as an end but as ancillary to a social and ethical system.
Regarding himself as a philosopher, &c., will show that
subsequent criticism, however much it has owed to way of
stimulus to Mill's strenuous rationalism, has been able to point
out that much is inconsistent, inadequate and even superficial in his
writings. Two main intellectual movements from widely different
standpoints have combined to diminish his influence. On the one
hand there has arisen a school of thinkers of the type of Thomas
Hilf, who have met the problem of the alleged pessimism of
the idealism of modern German thinkers. On the other hand are the
revolutionaries, who have substituted for the utilitarian ideal of the
greatest happiness those of 'race preservation' and the 'sur-
viving of the fittest,' both of which dominant currents of modern
psychology, likewise—e.g. in connexion with Mill's doctrine of
Association of Ideas (q.v.) and the phrase 'Mental Chemistry,' by
which he sought to meet the problems of modern criticism and the
experimental methods of the psycho-physiological school have set up wholly new criteria,
with a new terminology and different fields of investigation (see REFORM
PSYCHOLOGY).

A similar fate has befallen Mill's economic theories. The title
of his work, *Principles of Political Economy,* with some of their
Applications to Social Philosophy, though open to criticism, indicated
that he had to meet the problems of the field of the science which
had been common amongst his predecessors. He aimed at
fact in producing a work which might replace in ordinary use the
*Wealth of Nations,* which in his opinion was "in many parts obsolete and
in danger of becoming little more than a collection of the most general
principles of the subject with their applications, and in
all the consequences which had been derived from them, without
the natural development of the subject as a whole, unable to
keep pace with the progress of society, or to stand up to the
competition of the more modern writers, whose method is to
expound the principles of their system in the light of the
most advanced science of the day." His book, by which he
endeavoured to project the more modern criticism and the experimental methods of the
psychical-sociological school have set up wholly new criteria,
new terminology and different fields of investigation (see
*ECONOMIC PHILOSOPHY*).

But the title of his systematic work implies a doubt whether political
economy is a part of "social philosophy" at all, and not rather a
study preparatory and auxiliary to it. Thus, on the logical as
well as on the sociological side, his work has been attacked
by many, and, notwithstanding his misgivings and even the
many attempts at its understanding (especially in his
elaborate book *The Principles of Political Economy*), it seems likely to
remain as a monument of his knowledge and insight.

(W. M.: J. M. M.)

MILL (O. Eng. myln, later myl, or mill, adapted from the late Lat. molina, cf. Fr. moulin, from Lat. molis, a mill, molere, to grind; from the same root, mol, is derived "meal;" the word appears in other Teutonic languages, cf. Du. molen, Ger. mühle), the device for grinding corn, is a wooden wheel hewn out of a single log, and used either in the horizontal or the vertical plane; the horizontal wheel is called "mill," the vertical wheel "water-mill, &c. It was not the early word used of the actual grinding mechanism. The old hand-mill was known as a "quern," a word which appears in this sense in many Indo-European languages; the ultimate root is kar-, to grind. "Quern" (see Corn) is generally remiamed today, but the word is also applied to many mechanical devices by which raw material is transformed into a condition ready for use or into a stage preparatory to other processes, e.g. saw-mill, rolling-mill, &c., or still more widely to buildings containing machinery used in manufactures, e.g. cotton-mill. In mining it is applied to various machines used in breaking and crushing the ore (see Ore-Dressing).

In the engineering industries milling machines constitute a very important class of machine tools, the characteristic of which is that rotary cutting or percussion is employed. The theory of milling is the "milling" is the serrated edge, called "cncleming" by John Evelyn (Discourse on Metals, 1607, p. 223), which is formed on them to prevent slipping and filing. Coins made by the old process of hammering were apt to have irregular edges which invited mutilation; but the introduction of the screw press, which came to be known as a mill (cf. W. Lowndes, Amendm. Silver Coinage, 1605, p. 92), permitted the production of a regular edge with serrations, which in consequence were termed milling. This machine also enabled legends to be impressed round the edges of coins, such as "Vix, Vix," and "Goodman," and "Good Women," and "Naughty Women," as well as other inscriptions (see Hocking, Catalogue of the Coins, &c., in the Museum of the Royal Mint, 1906). It was invented about the middle of the 16th century, and has generally been attributed to Guyot Brucher (d. 1556), who was succeeded at the Paris mint by his brother Antoine. Introduced into England by one Eloye Mestril in 1561, it was used for twelve years, and was then abandoned owing to the opposition of the mint officials to Mestril, who was executed for counterfeiting and striking money outside the precincts of the Tower of London; but it was again introduced by one Peter Blondieu in 1625, when it penetrated into the grinding machinery employed in the United States of America under the term "milling" or "milled" is applied to the raised edge on the face of the coin; this is known in the British mint as "marking" (see MINT).

MILLAS, SIR JOHN EVERETT (1829-1896), English painter, was born at Southampton on the 8th of June 1829, the son of John William Millais, who belonged to an old Norman family settled in Jersey for many generations, and Emily Mary, née Evamy, the widow of a Mr Hodgkinson. After his birth the family returned to Jersey, where the boy soon began to sketch. At the age of eight he drew his maternal grandfather. He went to school for a short time, but showed no inclination for study, and was afterwards educated entirely by his mother. In 1835 the family removed to Dinan in Brittany, where he sketched the French officers, to their great amusement, and in 1837, on the family's return to Jersey, he was taught drawing by a Mr Bissel. In 1838 he came to London, and on the strong recommendation of Sir Martin Archer Shee, P.R.A., his future was decided. He was sent at once to Sass's school, and entered the Academy schools in 1840. He won a silver medal from the Society of Arts in 1839, and carried off all the prizes at the Royal Academy. He was popular amongst the students, and was called "the child," because he wore his boyish costume till long after the usual age. In 1840 and the immediately succeeding years he made the acquaintance of Wordsworth and other interesting and useful people. He was at this time painting small pictures, &c., for a dealer named Thomas, and defraying a great part of the household expenses in Gower Street, where his family lived. In 1846 he exhibited "Pizarro seizing the Inca of Peru" at the Royal Academy, and in 1847 "Elgiva seized by the Soldiers of Odo." In the latter year he competed unsuccessfully at the exhibition of designs for the decoration of the Houses of Parliament, and there among a new group picture which was afterwards cut up. In the beginning of 1848 he and W. Holman Hunt, dissatisfied with the theory and practice of British art, which had sunk to its lowest and most conventional level, initiated what is known as the Pre-Raphaelite movement, and were joined by Dante Gabriel Rossetti, and afterwards by five others, altogether forming the Pre-Raphaelite Brotherhood. Rossetti was then engaged, under the technical guidance of Hunt, upon his picture of "The Girlhood of Mary Virgins," which, with Hunt's "Light of the World" and Millais's "Christ in the House of His Parents," forms what has been called the trilogy of the Pre-Raphaelite art. According to Millais, the Pre-Raphaelites had but one idea—"to present on canvas what they saw in Nature." Millais's first picture on his new principles was a banquet scene from Keats's "Isabella" (1849), and contains all the characteristics of Pre-Raphaelite work, including minute imitation of nature down to the smallest detail, and the study of all persons and objects directly from the originals. The tale was told with dramatic force, and the expression of the heads was excellent. His next important picture, "Christ in the House of His Parents," painted for the Carpenter's Shop (1851), represented a supposed incident in the childhood of our Lord treated in a simply realistic manner, and drew upon him a storm of abuse from nearly all quarters, religious and artistic. The rest of his more strictly Pre-Raphaelite pictures—"The Return of the Dove to the Ark," "The Woodman's Daughter" and the "Mariana" of 1851, "The Huguenot" and "Ophelia" of 1852, "The Prescribed Royalist" and "The Order of Release" of 1853—met with less opposition, and established his reputation with the public. Indeed, this may be said to have been accomplished by the "Order of Release" and the "Ophelia," which, with the "Isabella," was a series of pictures, the execution of which appealed to nearly all who were unprejudiced. The public were also greatly influenced by the splendid championship of Ruskin, who, in letters to The Times, and in a pamphlet called "Pre-Raphaelitism," enthusiastically espoused the cause of the Brotherhood. In 1854 Millais, who had refused to read Modern Painters, where the supposed principles of the Brotherhood were first recommended, became acquainted with Ruskin, and in 1855 went to Scotland with him and Mrs Ruskin, the latter of whom sat for the woman in The Order of Release. He made several designs for Ruskin, and painted his portrait. In 1855 Millais exhibited "The Rescue," a scene from a fire, which drew great attention, from the frantic expression of the mother and the brilliant painting of the glare. In the Paris Exhibition of this year he was represented by "The Order of Release," "Ophelia" and "The Return of the Dove." This was also the
MILLAU—MILLAR

year of his marriage with Mrs Ruskin (Euphemia Chalmers, daughter of Mr George Grey of Bowerswell, Perth), who had been deprived of the dignity of her previous marriage. The newly-wedded couple went to live at Annat Lodge, near Bowerswell, where "Autumn Leaves," described by Ruskin as "the first instance of a perfect twilight," was painted. This and "Peace Concluded" were singled out for special praise by Ruskin in his notes on the Academy Exhibition of 1866, which contained, with other works by Millais, the picture of "A Blind Girl," with a beautiful background of Icklesham and its common. The principal pictures of 1874 were "Sir Isaac Newton's Death," and another in Her Majesty's collection, both of which were violently attacked by Ruskin, who was kinder to the "Apple-blossoms" and "Vale of Rest" of 1859, extolling the power of their painting, but still insisting on the degeneracy of the artist. The "Black Brunswicker" of 1866 was in motive very like the "Huguenot," but it was less refined in expression, and a great deal broader in execution, and may be said to mark the end of the period of transition from his minute Pre-Raphaelite manner to the masterfully freedom of his mature style. From 1866 to 1869 the invention of Millais was much employed in illustration, especially in Trollope's novels, beginning with"Forster's Firs" in the Cornhill Magazine. He made altogether eighty-seven drawings for Trollope, and was the cleverest and one of the most prolific of the book illustrators of the 'sixties. He contributed to Mozon's illustrated edition of Tennyson's Poems, and made occasional drawings for Once a Week, the Illustrated London News, Good Words, and other periodicals and books. In 1863 he was elected a Royal Academician. The most important pictures of this and the next few years were "The Eve of St Agnes," remarkable for the painting of moonlight, "Romans leaving Britain" (1867), "Jephthah" (1867), "Rosalind and Celia" (1868), "A Flood," and "The Boyhood of Raleigh" (1879). All these were executed in a very broad and masterly manner. In many of his pictures of this period, such as "The Boyhood of Raleigh," his children were his models, and formed the subject of many more, like "My First Sermon," "My Second Sermon," "Sleeping," "Awake," "Sisters," "The First Minuet," and "The Wolf's Den." He now painted many single figures with more or less sentiment, like "Stella," "Vanessa," and "The Gambler's Wife," with occasionally a more important composition, like "Pilgrims to St Paul's," and "Victory, O Lord" (exhibited 1871), representing Aaron and Hur holding up Moses' hands (Exod. xvii. 12). With it he was exhibited the first and most popular of his pure landscapes, called "Chill October," which was followed at intervals by several others remarkable for literal truth to nature and fine execution. They were all from Perthsire, where he generally spent the autumn, and included "Scotch Firs" and "Winter Fuel" (painted in 1874), "Over the Hills and Far away," and "The Fringe of the Moor" (1875) and "The Sound of Many Waters" (1876). A later series was painted in the neighbourhood of Murthly, a village in the parish of Little Dunkeld, Perthshire, where he rented a house and shooting from 1881 to 1891. It was to painting nature and the world around him that he principally devoted himself for the last twenty-five years of his life, abandoning imaginative or didactic themes. To this period belong a number of pictures of children, with fancy titles, like "Cherry Ripe," "Little Miss Muffet," "Bubbles," and others well known by reproductions in black and white and in colour for the illustrated papers; and also some charming studies of girlhood, like "Sweetest eyes were ever seen," and "Cinderella." Amongst his more serious pictures were "The Princes in the Tower" (1878), "The Princess Elizabeth" (1879), two pictures from Scott—"Effie Deans" and "The Master of Ravenswood"—painted for Messrs Agnew in 1877 and 1878, and "The North-West Passage," sometimes regarded as his masterpiece, representing an old mariner (painted from Edward John Trelawney, the friend of Byron) listening to some tale of Arctic exploration in a room below decks by the sea and strewn with charts. "A Yeoman of the Guard" (1877) was perhaps his most splendid piece of colour, and was greatly admired at the Paris Exhibition of 1878, where it was sent with "Chill October, and three others of his pictures. But perhaps the works of his later years by which he will be most remembered are his portraits—especially his three portraits of Gladstone (1870, 1883 and 1890), and those of John Bright, of Lord Tennyson, and of Lord Beaconsfield, which was left unfinished at his death. He also painted the marquess of Salisbury, Lord Rosebery, the dukes of Devonshire and Argyll, Cardinal Newman, Thomas Carlyle, Sir James Paget, Sir Henry Irving, George Grote, Lord Chief Justice Russell, J. C. Hook, R.A., and himself (Uffizi Gallery, Florence). He also painted Mrs Vandyke, Count Newman, and one of his works of fiction were those of Mrs Bischoffsheim, the Duchess of Westminster, Lady Campbell and Mrs Jolting.

No very serious interruption of his usual life as a prosperous English gentleman occurred in these years, except the death of his second son, George, in 1878. In 1875 he went to Holland, one of his few visits to the Continent. In 1879 he left Cromwell Place for a house at Palace Gate, Kensington, which he built, and where he died. In 1883 he was created a baronet, on the suggestion of Mr Gladstone. In 1892 his health began to break down, and he suffered from a bad throat, which was attributed to swelling in his throat, which proved to be due to cancer. He suffered much from depression, but worked when he could, and derived much pleasure in painting several pictures, including "St Stephen," "A Disciple," "Speak! Speak!" (which was bought out of the Chantry Bequest), and "The Forerunner"—his last exhibited subject-picture. His finely-characterized portraits of Mr John Hare, the actor, and Sir Richard Quain belong also to his last years. In 1895, in consequence of the illness of Lord (then Sir Frederick) Leighton, he was called upon to preside at the annual banquet of the Royal Academy, and on the death of Lord Leighton he was elected to the presidential chair. He died on the 13th of August 1896, and was buried in St Paul's Cathedral. The Winter Exhibition of the Royal Academy in 1898 was devoted to his works. The list of his honours at home and abroad is a long one. Millais was one of the greatest painters of his time, and did more than any other to infuse a new and healthy life into British art. He had not the imagination of an idealist, but he could paint what he saw with a force which has seldom been excelled. As a man he was manly, frank and genial, devoted to his art and his family, and very fond of sport, especially hunting, fishing and shooting. He was greatly loved by a very large circle of friends. He was singularly handsome, and had a fine presence. The National Gallery of British Art possesses many of his finest works. He is also represented in the National Gallery, in the National Portrait Gallery, the Victoria and Albert Museum, and in the public galleries at Manchester, Liverpool and Birmingham.

MILLBURY—MILLENNIUM

461

rich valley 1200 ft. above the sea surrounded by the spurs of the Levezou, Causes Noir and Larzac ranges. The streets are narrow and some of the houses of great antiquity, but the town is surrounded by spacious boulevards. One of its squares is bordered on two sides by wooden galleries supported on stone columns. The only buildings of special interest are the Romanesque church of Notre Dame, restored in the 16th century, and the fine Gothic bell-tower of the old hôtel de ville. Millau is seat of a sub-prefect, and possesses tribunals of first instance and of commerce, a board of trade-arbitrators, a chamber of commerce and a communal college. The principal industry is the manufacture of gloves, and various branches of the leather industry are carried on. The chief articles of trade are skins, wool, wine and Roquefort cheese.

In the middle ages Millau was the seat of a viscounty held by the counts of Barcelon and afterwards by the counts of Armagnac. In the 16th century it became one of the leading strongholds of Calvinism in southern France. In 1569 it revolted against Louis XIII, and after its submission Richelieu caused its fortifications to be dismantled. The edict of Nantes hastened the decline of the town, which did not recover its prosperity till after the Revolution.

MILLBURY, a township of Worcester county, Massachusetts, on the Blackstone river, 5 m. S.S.E. of Worcester. Pop. (1890), 4428; (1900) 4460 (1176 foreign-born); (1905, state census) 4611; (1910) 4745. Area, 15.79 sq. m. Millbury is served by the New York, New Haven & Hartford, and the Boston & Albany railways, and by electric interurban railways. It lies for the most part in the valley of the Blackstone river, from which water-power is derived for its mills; among its manufactures are cotton, linen, felt and woolen goods, hemp thread, and foundry and machine-shop products. The municipality owns and operates the waterworks and electric-planting mill. Millbury was formed in 1813 from the North Parish of Sutton; in 1851 a part of Auburnd was annexed to the township.

MILLEDGEVILLE, a city and the county-seat of Baldwin county, in the central part of Georgia, U.S.A., on the Oconee river, at the head of navigation, 32 m. E.N.E. of Macon. Pop. (1850), 3232; (1900), 4219, of whom 2663 were negroes. It is served by the Georgia and the Central of Georgia railways. Milledgeville is situated in the Cotton Belt, and its principal industry is the preparation of cotton for the markets. The importance of the place, however, is mainly educational and historical. It is the seat of the Middle Georgia Military and Agricultural College, which occupies the old capitol building, and of the Georgia Normal and Industrial College for girls (1859; enrolment 1860-1869, 653), which is a part of the University of Georgia, and occupies the site of the old state penitentiary. Milledgeville is the seat of the state reformatory; 2 m. south of the city are the state asylums for white and negro insane; and 3 m. north-west is the state prison farm. Milledgeville was founded in 1803, and was named in honour of John Milledge (1757-1818), a representative in Congress in 1792-1793 and 1795-1802, governor of Georgia in 1802-1806, a United States senator in 1806-1809, and a benefactor of the state university. In 1854 it was made the seat of the state government in place of Louisville (capital in 1795-1804; pop. in 1800, 1809), a dignity it held until 1868. The city was first chartered in 1856. Although admirably situated for trade and manufacturing, Milledgeville was surpassed in both by Macon, which became the commercial emporium of middle Georgia; but it was a favourite place of residence for the wealthy and cultivated class of Georgians before the Civil War. It was seized by General William T. Sherman on the 23rd of November 1864. In order to remove the state documents beyond reach of the enemy, Governor Joseph E. Brown called upon the convicts in the penitentiary for aid, granting them pardons in return for their services.

MILLENNIUM (a pseudo-Latin word formed on the analogy of Messianism—Millennium, from Latin mille, a thousand, and annum, year), literally a period of a thousand years. The term is specially used of the period of 1000 years during which Christ, as has been believed, would return to govern the earth in person. Hence it is used to describe a vague time in the future when all flaws in human existence will have vanished, and perfect goodness and happiness will prevail. The attribution of a mystic significance to the millennium-period, though perhaps not prominent in that theory of Christian eschatology to which the names Millenarianism and Chiliasm (from Gr. χιλιάς, a thousand) are given, is quite common in non-Christian religions and cosmological systems.

Faith in the nearness of Christ’s second advent and the establishing of his reign of glory on the earth was undoubtedly a strong point in the primitive Christian Church. In the anticipations of the future prevalent amongst the early Christians (c. 50-150) it is necessary to distinguish a fixed and a fluctuating element. The former includes (1) the notion that a last terrible battle with the enemies of God was impending; (2) the faith in the speedy return of Christ; (3) the conviction that Christ will judge all men; and (4) will set up a kingdom of glory on earth. To the latter belong views of the Antichrist, of the heathen world-power, of the place, extent, and duration of the earthly kingdom of Christ, &c. These remained in a state of solution; they were modified from day to day, partly because of the changing circumstances of the present by which forecasts of the future were regulated, partly because the indications—real or supposed—of the ancient prophets always admitted of new combinations and constructions. But even here certain positions were agreed on in large sections of Christendom. Amongst these was the conception that the future kingdom of Christ on earth should have a fixed duration—according to the most prevalent opinion, a duration of one thousand years. From this fact the whole ancient Christian eschatology was known in later times as "chiliasm"—a name which is not strictly accurate, since the doctrine of the millennium was only one feature in its scheme of the future.

1. This idea that the Messianic kingdom of the future on earth should have a definite duration has—like the whole eschatology of the primitive Church—its roots in the Jewish apocalyptic literature, where it appears at a comparatively late period. At first it was assumed that the Messianic kingdom in Palestine would last for ever (so the prophets; cf. Jer. xxiv. 6; Ezek. xxxviii. 25; Joel iv. 20; Dan. vi. 27; Sibyll. iii. 49 sq. 766; Psalt. Salom. xviii. 4; Enoch lii. 14), and this seems always to have been the most widely accepted view (John xii. 34). But from a comparison of prophetic passages of the Old Testament learned apocalyptic writers came to the conclusion that a distinction must be drawn between the earthly appearance of the Messiah and the appearance of God Himself amongst His people and in the Gentile world for the final judgment. As a necessary consequence, a limited period had to be assigned to the Messianic kingdom. According to the Apocalypse of Baruch (xli. 3) this kingdom will last "donec finiatur mundus corruptiones." In the Book of Enoch (xcl. 12) "a week" is specified, in the Apocalypse of Ezra (vii. 28 sq.) four hundred years. This figure, corresponding to the four hundred years of Egyptian bondage, occurs also in the Talmud (Sanhedrin 99c). But this is the only passage; the Talmud has no fixed doctrine on the point. The view most frequently expressed there (see Von Otto In Hhilgenfeld's Zeitschrift, 1877, p. 527 seq.) is that the Messianic kingdom will last for one thousand (some said two thousand) years. "In six days God created the world, on the seventh He rested. But a day of God is equal to a thousand years (Ps. xci. 4). Hence the world will last for six thousand years of toil and labour; then will come one thousand years of Sabbath rest for the people of God in the kingdom of the Messiah." This idea must have already been very common in the first century before Christ. The combination of Gen. li. Dan. ix. and Ps. xc. 4 was peculiarly fascinating.

Nowhere in the discourses of Jesus is there a hint of a limited duration of the Messianic kingdom. The apostolic epistles are equally free from any trace of chiliasm (neither 1 Cor. xvi. 23 seq. nor 1 Thess. iv. 16 seq. points in this direction). In Revelation however, it occurs in the following shape (ch. xx). After
Christ has appeared from heaven in the guise of a warrior, and vanquished the antichristian world-power, the wisdom of the world and the devil. Those who have remained steadfast in the time of the last catastrophe, and have given up their lives for their faith, shall be raised up, and shall reign with Christ on this earth as a royal priesthood for one thousand years. At the end of this time Satan is to be let loose for a short season; he will prepare a new onslaught, but God will miraculously destroy him and his hosts. Then will follow the general resurrection of the dead, the last judgment, and the creation of new heavens and a new earth. That all believers will have a share in this resurrection of the body, the second kingdom, is an idea of which the author of Revelation knows nothing. The earthly kingdom of Christ is reserved for those who have endured the most terrible tribulation, who have withstood the supreme effort of the world-power—that is, for those who are actually members of the church of the last days. The Jewish expectation is thus considerably curtailed, as it is also shorn of its sensual attractions. “Blessed and holy is he that hath part in the first resurrection; on such the second death hath no power; but they shall be priests of God and of Christ, and shall reign with him a thousand years.” The ancient Jewish authors were more cautious. Accepting the Jewish apocalypses as sacred books of venerable antiquity, they read them eagerly, and transferred their contents bodily to Christianity. Nay, more, the Gentile Christians took possession of them, and just in proportion as they were neglected by the Jews—who, after the war of Bar-Cochba, became indifferent to the Messianic hope and hardened themselves once more in devotion to the law— they were naturalized in the Christian communities. The result was that these books became “Christian” documents; it is entirely to Christian, not to Jewish, tradition that we owe their preservation. The Jewish expectations are adopted for example, by Papias, by the writer of the epistle of Barnabas, and by Justin. Papias actually confounds expressions of Jesus with verses from the Apocalypse of Baruch, referring to the amazing fertility of the days of the Messianic kingdom (Papias in Iren. v. 33). Barnabas (Ep. 15) gives us the Jewish theory (from Gen. i. and Ps. xc. 4) that the present condition of the world is to last six thousand years from the creation, that at the beginning of the Sabbath (the seventh millennium) the Son of God appears, to put an end to the time of “the unjust one,” to judge the ungodly and renew the earth. But he does not indulge, like Papias, in sensuous descriptions of this seventh millennium; to Barnabas it is a time of rest, of sinlessness, and of a holy peace. It is not the end, however; it is followed by an eighth day of eternal duration—“the beginning of another world.” So that in the view of Barnabas the Messianic reign still belongs to ὁ δὲ αἰών. Justin ( Dial. 80) speaks of chiliasm as a necessary part of complete orthodoxy, although he knows Christians who do not accept it. He believes, with the Jews, in a restoration and extension of the city of Jerusalem; he assumes that this city will be the seat of the Messianic kingdom, and he takes it as a matter of course that there all believers (here is he at one with Barnabas) along with patriarchs and prophets will enjoy perfect felicity for one thousand years. That a philosopher like Justin, with a bias towards an Hellenic construction of the Christian religion, should nevertheless have accepted its chilastic elements is the strongest proof that these enthusiastic expectations were inseparably bound up with the Christian faith down to the middle of the 2nd century. And another proof is found in the fact that even a speculative Jewish Christian like Cerinthus not only did not renounce the chilastic hope, but pictured the future kingdom of Christ as a kingdom of sensual pleasures, of eating and drinking and marriage festivities (Euseb. Hist. E. iii. 28, vili. 23).

After the middle of the 2nd century these expectations were gradually thrust into the background. They would never have died out, however, had not circumstances altered, and a new method been taken up. The spirit of philosophical and theological speculation and of ethical collection, which began to spread through the churches, did not know what to make of the old hopes of the future. To a new generation they seemed paltry, earthly and fanciful, and far-sighted men had good reason to regard them as a source of political danger. But more than this, these wild dreams about the glorious kingdom of Christ began to disturb the organization which the churches had seen fit to introduce. In the interests of self-preservation against the world, the state and the heretics, the Christian communities had formed themselves into compact societies with a definite creed and constitution, and they felt that their existence was threatened by the white heat of religious subjectivity. So early as the year 170, a church party in Asia had perceived the perils of apocalyptic writings and denounced the book of Revelation as a book of fables. All the more powerful was the reaction. In the so-called Montanistic controversy (c. 160–230) one of the principal issues involved was the continuance of the chilastic expectations in the churches. The Montanists of Asia Minor defended them in their integrity, with one slight modification: they announced that Pepuzaz, the city of Montanus, would be the site of the New Jerusalem and the millennial kingdom. After the Montanistic controversy chiliasm views were more and more discredited in the Greek Church; they were, in fact, atigmatised, and esteemed as a source of danger. The Alexandrian theology that superseded them; that is to say, Neo-Platonic mysticism triumphed over the early Christian hope of the future, first among the “cultured,” and then, when the theology of the “cultured” had taken the faith of the “uncultured” under its protection, amongst the latter also. About the year 360 an Egyptian bishop, Nepos, in a treatise called ἐνιαυτοῖς ἁγίοις, endeavoured to overthrow the Origenistic theology and vindicate chiliasm by exegetical methods. Several congregations took his part; but ultimately Dionysius, bishop of Alexandria, succeeded in healing the schism and assembling the allegorical interpretation of the prophets as the only legitimate exegesis. During this controversy Dionysius became convinced that the victory of mystical theology over “Jewish” chiliasm would never be secure so long as the book of Revelation passed for an apostolic writing and kept its place among the homologomena of the canon. He accordingly raised the question of its apostolic origin; and by reviving old difficulties, with ingenious arguments of his own, he carried his point. At the time of Eusebius the Greek Church was saturated with prejudice against the book and with doubts as to its canonicity. In the course of the 4th century it was removed from the Greek canon, and thus the troublesome foundation on which chiliasm might have continued to build was got rid of. The attempts of Methodius of Tyre at the beginning of the 4th century and Apollinaris of Laodicea about 360 to defend chiliasm and assail the theology of Origen had no result. For many centuries the Greek Church kept Revelation out of its canon, and consequently chiliasm remained in its grave. It was considered a sufficient safeguard against the spiritualizing eschatology of Origen and his school to have rescued the main doctrines of the creed and the regula fidei (the visible advent of Christ; eternal misery and hell-fire for the wicked). Anything beyond this was held to be Jewish. It was only the chronologists and historians of the church who, following Julius Africanus, made use of apocalyptic numbers in their calculations, while court theologians like Eusebius entertained the imperial table with discussions as to whether the dining-hall of the emperor—the second David and Solomon, the beloved of God—might not be the New Jerusalem of John’s Apocalypse. Eusebius was not the first who dabbled in such speculations. Dionysius of Alexandria had already referred a Messianic prediction of the Old Testament to the emperor Constantius. But mysticism and political servility between them gave the deathblow to chiliasm in the Greek Church. It never again obtained a footing there; for, although, late in the middle ages, the book of Revelation—by what means we cannot tell—did recover its authority, the Church was by that time so hopelessly trammelled by a magical cultus as to be incapable of fresh developments. In the Semitic churches of the East (the Syrian, Arabian and Ethiopian), and in that of Armenia, the apocalyptic literature was preserved much longer than in the Greek Church. They were very conservative of ancient traditions in general, and hence
chiliasm survived amongst them to a later date than in Alexandria or Constantinople.

But the Western Church was also more conservative than the Greek. Her theologians had, to begin with, little turn for mystical speculation; their tendency was rather to reduce the gospel to a system of morals. Now for the moralists chiliasm had a special significance as the one distinguishing feature of the gospel, and the only thing that gave a specifically Christian character to their system. This, however, holds good of the Western theologians only after the middle of the 3rd century. The earlier fathers, Irenaeus, Hippolytus, Tertullian, believed in chiliasm simply because it was a part of the heretics as such, and because Marcion and the Gnostics would have nothing to do with it. Irenaeus (v. 28, 29) has the same conception of the millennial kingdom as Barnabas and Papias, and appeals in support of it to the testimony of disciples of the apostles. Hippolytus, although an opponent of Montanism, was nevertheless a thorough-going millenarian (see his book De Antichristo). Tertullian (cf. especially Adv. Marcion., 3) aimed at a more spiritual conception of the millennial blessings than Papias had, but he still adhered, especially in his Montanistic period, to all the ancient anticipations. It is the same all through the 3rd and 4th centuries. Latin theologians, such as Lactantius and Sulpicius Severus were all pronounced millenarians, holding by the very details of the primitive Christian expectations. They still believe, as John did, in the return of Nero as the Antichrist; they still expect that after the first resurrection Christ will reign with his saints "in the flesh" for a thousand years. Once, but only once (in the Gospel of Nicodemus), the time is reduced to five hundred years. Victorinus wrote a commentary on the Apocalypse of John; and all these theologians, especially Lactantius, were diligent students of the ancient Sybillic oracles of Jewish and Christian origin, and treated them as divine revelations. As to the canonicity and apostolic authorship of the Johannine Apocalypse no doubts were ever entertained in the West; indeed an Apocalypse of Peter was still retained in the canon in the 3rd century. That of Ezra, in its Latin translation, must have been all but a canonical book—the numbers of extant manuscripts of the so-called 4 Ezra being incredibly great, while several of them are found in copies of the Latin Bible at the beginning of the 16th century. The Apocalypse of Hermas was much read till far through the middle ages, and has also kept its place in some Bibles. The apocalyptic "Testamenta duodecim patriarcharum" was a favourite reading-book; and Latin versions of ancient apocalypses are being continually brought to light from Western libraries (e.g. the Assumptio Mosis, the Ascensio Jesuæ, &c.). All these facts show how vigorously the early hopes of the future maintained themselves in the West. In the hands of moralistic theologians, like Lactantius, they certainly assume a somewhat grotesque form, but the fact that these men clung to them is the clearest evidence that in the West millenarianism was still a point of "orthodoxy" in the 4th century.

This state of matters, however, gradually disappeared after the end of the 4th century. The change was brought about by two causes—first, Greek theology, which reached the West chiefly through Jerome Rufinus and Ambrose, and, second, the new idea of the church wrought out by Augustine on the basis of the altered political situation of the church. Augustine was the first who ventured to teach that the catholic church, in its empirical form, was the kingdom of Christ, that the millennial kingdom had commenced with the appearing of Christ, and was therefore an accomplished fact. By this doctrine of Augustine's, the old millenarianism, though not completely extinguished, was at least banished from the official theology. It still lived on, however, in the lower strata of Christian society; and in certain undercurrents of tradition it was transmitted from century to century. At various periods in the history of the middle ages we encounter sudden outbreaks of millenarianism, sometimes as the tenet of a small sect, sometimes as a far-reaching movement. And, since it had been suppressed, not, as in the East, by mystical speculation, its mightiest antagonist, but by the political church of the hierarchy, we find that wherever chiliasm appears in the middle ages makes common cause with all enemies of the secularized church. It strengthened the hands of church democracy; it formed an alliance with the pure souls who held up to the church the ideal of apostolic poverty; it united itself for a time even with mysticism in a common opposition to the supremacy of the church; nay, it lent the strength of its convictions to the support of states and princes in their efforts to break the political power of the church. It is sufficient to recall the well-known names of Joachim of Floris, of the numerous Franciscan spiritualists, of the leading sectaries from the 13th to the 16th century who assailed the papacy and the secularism of the church—above all, the name of Occam. In these men the millenarianism of the ancient church came to life again; and in the revolutionary movements of the 15th and 16th centuries—especially in the Anabaptist movements—it appears with all its old uncompromising energy. If the church, and not the state, was regarded as Babylon, and the pope declared to be the Antichrist, these were legitimate inferences from the ancient traditions and the actual position of the church. But, of course, the new chiliasm was not in every respect identical with the old. It ventured to graft its groundwork of certainties on certain innovations. The "everlasting gospel" of Joachim was in the first place a startling thing from the announcement of Christ's glorious return in the clouds of heaven; the "age of the spirit" which mystics and spiritualists expected contained traits which must be characterized as "modern"; and the "kingdom" of the Anabaptists in Münster was a Satanic caricature of that kingdom in which the Christians of the 2nd century looked for a peaceful Sabbath rest. Only we must not form our ideas of the great apocalyptic and chilismatic movement of the first decades of the 16th century from the rabble in Münster. There were pure evangelical forces at work in it; and many Anabaptists need not shun comparison with the Christians of the apostolic and post-apostolic ages.

The German and Swiss Reformers also believed that the end of the world was near, but they had different aims in view from those of the Anabaptists. It was not from poverty and apocalypticism that they hoped for a reformation of the Church. In contrast to the fanatics, after a brief hesitation they threw millenarianism overboard, and along with it all other "opinions Judaicæ." They took up the same ground in this respect which the Remonstrants held in the Catholic Church had occupied since the 3rd century. Augustine. How millenarianism nevertheless found its way, with the help of apocalyptic mysticism and Anabaptist influences into the churches of the Reformation, chiefly among the Reformed sects, but afterwards also in the Lutheran Church, how it became incorporated with Pietism, how in more recent times an exceedingly mild type of "academic" chiliasm has been developed from a belief in the verbal inspiration of the Bible, how finally new sects are still springing up here and there with apocalyptic and chilismatic expectations—these are matters which cannot be fully entered upon here.

MILLER, HUGH (1802–1850), Scottish geologist and man of letters, was born in humble circumstances at Cromarty, on the 10th of October 1802; his father, Hugh Miller, a seaman, was drowned when he was but five years old. His primary education was acquired at a dame's school and afterwards at the parochial school, and at the age of six he had learned that "the art of reading is the art of finding stories in books." At the age of twelve he began to write verses. Two of his mother's brothers, James and "Sandy" Wright, hard-working men at Cromarty,
MILLER, JOAQUIN—MILLER, W.

offered to assist him to enter the ministry, but he felt no call to the sacred office, and from 1820 to 1822 he was apprenticed to a stone-mason. During the next few years he obtained employment as a journeyman mason in Edinburgh, Inverness and various other parts of Scotland. The writing of verses occupied his leisure hours, and in 1826 he sent to the Scotman an "Ode on Greece" which was refused. It was not until 1829 that he met with his first success in the publication of Poems written in the Leisure Hours of a Journeyman Mason. These were printed and issued from the office of the Inverness Courier. Miller now turned his attention to prose and contributed many essays to the Inverness Courier. As remarked by Sir A. Geikie, "These made so favourable an impression that they were soon afterwards reprinted separately. They marked the advent of a writer gifted with no ordinary powers of narration and with the command of a pure, nervous and masculine style."

At the age of thirty-two he was still a stone-mason, but in the latter part of 1834 he was offered a post as accountant in the Commercial Bank of Scotland, and was almost immediately transferred to the Cromarty branch. His prose writings had now attracted much notice, and he next issued in 1835 Scenes and Legends of the North of Scotland, or the traditional history of Cromarty, in which he introduced some memoranda on the geology. This work met with a cordial reception. Miller, while still a stone-mason, had observed the abundant fossils in the Jurassic shales on the shores of Ethie, but it was not until 1836 that he first obtained remains of fossil fishes in the Old Red Sandstone. These for many years he collected and studied as far as he could, and in 1847 some of his specimens were brought to the notice of R. I. Murchison and Professor Agassiz. In the following year he was in communication with Murchison and his career as a geologist was definitely opened.

In 1837 Miller married Lydia Falconer Frazer (1817-1876), a lady of good position and great natural ability, whom he had met six years previously. He set up his household in Cromarty, on a salary of sixty pounds a year, aided by the small sums he then earned by literary work; and his wife took a few pupils. Mrs Miller eventually became well known under the pseudonym of Mrs Harriet Myrtle as author of the Ocean Child (1857) and other story-books for children.

Soon after his marriage, Miller became greatly stirred by the internal dissensions in the Church of Scotland, of which he was a staunch member, and he published two pamphlets which brought him to the notice of some of the prominent members of the liberal church party. In 1839 he went by invitation to Edinburgh to edit a new Whig newspaper, the Witness, which was intended to support the views of those who after the disruption in 1843 formed the Free Church. The paper rapidly attained a large circulation, and Miller thereupon devoted himself entirely to literary and scientific essays. In 1840 he contributed a series of articles on The Old Red Sandstone, and these were reprinted in book form in the following year. The charm of this work was widely appreciated, as was also the natural sagacity shown in the descriptions and restorations of some of the fossil fishes. His Footprints of the Creator was published in 1849, and My Schools and Schoolmasters in 1854. He was engaged on the final proofs of his Testimony of the Rocks on the day of his death. During the last year of his life he suffered from inflammation of the lungs; and the strain of ill-health, proving too severe, he died by his own hand in Edinburgh on the 23rd of December 1856. By request of his wife, The Cruise of the Betsey, with Rambles of a Geologist (1858) previously printed only in the Witness newspaper was published under the editorship of the Rev. W. S. Symonds.

In memory of Hugh Miller a monument was erected by public subscription in 1860 at Cromarty; and the cottage in which he was born was acquired at a later period by his son Hugh. In it have been placed part of his library, a set of the Witness newspaper, some letters addressed to him, and a number of geological specimens, including many referred to in his Old Red Sandstone. On the 22nd of August 1902 the centenary of his birth was celebrated at Cromarty, and was attended by scientific representatives from all parts of the world.

His elder son, Hugh Miller (1850-1896), passed through the Royal School of Mines and joined the Geological Survey in England in 1873; afterwards he was transferred to Scotland and surveyed the country around Cromarty and other parts of Ross-shire and Sutherlandshire. He was author of Landscape Geology, 1891.

See Life and Letters of Hugh Miller, by Peter Bayne (2 vols., 1871); Hugh Miller; his work and influence, by Sir A. Geikie, at the centenary celebration. (H. B. Wo.)

MILLER, JOAQUIN (Cincinatus Heine) (1841— ), American poet, was born in Indiana, on the 30th of November 1841, and was educated for the law. After some experiences of mining and journalism in Idaho and Oregon, he settled down in 1866 as judge in Grant county, Oregon, and during his four years' tenure of this post he began to write verse. In 1870 he travelled in Europe, and in 1871 he published his first volume of poetry, full of tropical passion, Songs of the Sierras, on which his reputation mainly rests. His Songs of the Sunlands (1873) followed in the same vein, and after other volumes had appeared, his Collected Poems were published in 1882. He also wrote plays, The Danites in the Sierras having some success as a sensational melodrama. On his return from Europe he became a journalist in Washington, but in 1887 returned to California. His pen-name, "Joaquin Miller," by which he is known, was assumed by him when he published his first book, in consequence of his having written an article in defence of Joaquin Murietta, the Mexican brigand.

Revised editions of his Complete Poetical Works appeared at San Francisco in 1902.

MILLER, JOE (Joseph or Josias) (1684-1738), English actor, first appears in the cast of Sir Robert Howard's Committee at Drury Lane in 1700 as Teague. Trinculo in The Tempest, the First grave-digger in Hamlet and Marplot in The Busybody, were among his many favourite parts. He is said to have been a friend of Hogarth. He died on the 16th of August 1738. After his death, John Mottley (1692-1756) brought out a book called Joe Miller's Jest, or Wf's Yale Mucum (1759), a collection of contemporary and ancestral Jests, of which are told of Miller. Owing to the quality of the jokes in Mottley's book, their number increasing with each of the many subsequent editions, any time-worn jest has, somewhat unjustly, to be called "a Joe Miller."

MILLER, SAMUEL FREEMAN (1816-1890), American jurist, was born in Richmond, Kentucky, on the 5th of April 1816, of Pennsylvania-German stock. He was brought up on a farm, was a clerk in a drug-store, graduated from the medical department of Transylvania University in 1838, and practised medicine in Barbourville, Kentucky, until 1847. In that year he was admitted to the bar, and entered politics as a Whig. His anti-slavery sympathies induced him to settle in Iowa, where in 1850 he freed his slaves and began to practise law in Keokuk, and he soon became a leader of the Republican party in the state. In 1862 he succeeded Justice Peter V. Daniel (1784-1860), as a justice of the U.S. Supreme Court, and served until his death in Washington, D.C., on the 13th of October 1890, when he was senior justice. Miller was a man of great mental force and individuality, and his judgments carried great weight. In 1877 he was a member of the electoral commission, which adopted his proviso that Congress could not "go behind the returns," as properly accredited by state officials. He was a prominent member of the Unitarian Church and for three years was president of its national conference. He published a volume of Lectures on the Constitution of the United States (New York, 1891).

MILLER, WILLIAM (1782-1849), leader of the Second Adventists in America, was born on the 5th of February 1782 at Pittsfield, Massachusetts. He was a recruiting officer at the beginning of the War of 1812, and after Philadelphia he was promoted captain, retiring from the army in 1815. About 1816 he settled in Low Hampton, Washington county, New York.
He now joined the Baptist Church at Low Hampton, and, after two years of minute study of the Bible, about 1818 became a Second Adventist. In 1831 he began to lecture, arguing that the "two thousand three hundred days" of Daniel viii. 14 meant 2300 years, and that these years began with Ezra's going up to Jerusalem in 457 B.C., and therefore came to an end in 1843, and urging his hearers to make ready for the final coming of Christ in that year. To his many followers, after the year 1843 had passed, he proclaimed that 1844 was the year, that his error was following. He had read of Roman chronology, and that the 22nd of October was to be the day. There was renewed excitement among Miller's followers; many of them left their business, and in white muslin robes, on house tops and hills, awaited the epiphany. In spite of disappointment, many still believed with him that the time was near. He returned to Low Hampton and died there on the 20th of December 1849. The Adventists or Millerites, who were formed into a single body in a convention called by him in April 1845, have since separated into several sects: the Evangelical Adventists (1147 in the United States in 1906), who believe in everlasting punishment; the Seventh Day Adventists (64,332), who observe the seventh day, and practise the sacrament of foot-washing; the Advent Christians (26,500), the Churches of God in Jesus Christ (2872), and the Life and Advent Union (3800). Their total number in the United States in 1900 was about 90,300. Miller published in 1843 a pamphlet which was the basis of his lectures; these were published in 1842 as Evidence from Scripture and History of the Second Coming of Christ about the Year 1843.

See Sylvester Bliss, Memoirs of William Miller (Boston, 1853); James White, Sketches of the Christian Life and Public Labors of William Miller (Battle Creek, 1875); and Edward Eggleston's novel, End of the World (1872).

Miller, William (1795–1856), British soldier, who took a prominent part in the South American Wars of Liberation, entered the British artillery service in 1811, and till 1814 he was continuously on active service with Wellington's army in the Peninsula. In the latter year he accompanied the ill-fated New Orleans expedition. After the general peace he travelled for two years about Europe, and then went to South America. The war which culminated in the expulsion of the Spaniards was just breaking out, and he took command in the Chilean artillery, with which he served during the Chilean part of the war. As a major he commanded the armies on Cochrane's vessel, the "O'Higgins." In 1821 he landed in Peru, to assist General San Martin against the Spanish General Canterac. He was made general of brigade, and became very intimate with Simon Bolivar. He rendered the most conspicuous services at Junin (Aug. 6, 1824), and his regiment, the "Hussars of Junin," covered itself with glory in the decisive victory of Ayaqucho (Dec. 9, 1824). From 1830 to 1839 he filled various high military and political offices in Peru. In the latter year he was involved in the fall of Santa Cruz, and went into exile. For some years he filled the post of British Consul-General of the Pacific Coast. He died on board H.M.S. "Naiad" at Callao, on the 31st of October 1861.

See the Memoirs published by his brother J. H. Miller (London, 1827).

Miller, William (1796–1882), Scottish line-engraver, was born in Edinburgh on the 28th of May 1796. After studying in London under George Cook, a pupil of Basire's, he returned to Edinburgh. He executed plates after Thomson of Duddingston, Macculloch, D. O. Hill, Sir George Harvey, and other Scottish landscapists, but his chief works were his transcripts from Turner. The first of these was Clovelly (1824), of The Southern Coast, a publication undertaken by George Cook and his brother William B. Cook, to which Miller also contributed the Combe Martin and the Portsmouth. He was engaged on the illustrations of England and Wales, 1827–1838; of The Rivers of France, 1833–1835; of Roger's Poems, 1834; and very largely on those of The Poetic Works of Sir Walter Scott, 1834. In The Provincial Antiquities and Picturesque Scenery of Scotland, 1826, he executed a few excellent plates after Thomson and Turner. Among his larger engravings of Turner's works may be mentioned "The Grand Canal, Venice"; "The Rhine, Oberprey and Feltzen"; "The Bell Rock"; "The Tower of London"; and "The Shepherd." The art of William Miller was warmly appreciated by Turner himself, and Ruskin pronounced him to be on the whole the most successful translator into line of the paintings of the greatest English landscapist. His renderings of complex Turnerian sky-effects are especially delicate and masterly. Towards the end of his life Miller abandoned engraving and occupied his leisure in the production of water-colours, many of which were exhibited in the Royal Scottish Academy, of which he was an honorary member. He resided at his burial-places, and produced two final series of vignettes from drawings by Birckner, illustrating the works of Hood, Poems, published by Moxon in 1871. Miller, who was a Quaker, died on the 20th of January 1882.

Miller, William Hallowes (1801–1880), British mineralogist and crystallographer, was born at Velindre near Llandovery, Carmarthenshire, on the 6th of April 1801. He was educated at St John's College, Cambridge, where he graduated in 1826 as fifth wrangler, and became a fellow in 1829. For a few years he was occupied as a college tutor and during this time he published treatises on hydrostatics and hydrodynamics. He also gave special attention to crystallography, and on the resignation of W. Whewell he succeeded in 1832 to the professorship of mineralogy, a post which he occupied until 1870. His chief work, on Crystallography, was published in 1838. He was elected F.R.S. in 1838. In 1852 he edited a new edition of H. J. Brooke's Elementary Introduction to Mineralogy. He assisted in 1843 the committee appointed to superintend the construction of the new Parliamentary standards and devices his attention to the improvement of the mercantile marine, to the development of trade, of technical education, of the postal system, and to the amelioration of the conditions of labour. Labour questions were entrusted to a separate department, the Direction du Travail, and the pension and insurance office was also raised to the status of a "direction." The introduction of trade-union representatives on the Supreme Labour Council, the organization of local labour councils, and the instructions to factory inspectors to put themselves in communication with the councils of the trades-unions, were due to his advice, and he further secured the rigorous application of earlier laws devised for the protection of the working-classes. His name was especially associated with a project for the establishment of old age pensions, which became law in 1895. He became in 1898 editor of La Lanterne. His influence with the extreme Socialists had already declined, for it was said that his departure from the true Marxist tradition had disintegrated the party.

For his administration in the Waldock-Rousseau cabinet see A. Lamy, L'Exécutif de Mille Millerand (1902); his speeches between 1889 and 1897 were published in 1907 as Travail et travailleurs.

Millerite, a mineral consisting of nickel sulphide, NIS. Crystals belong to the rhombohedral system and have the form...
MILLER'S THUMB—MILLET, J. F.

of slender needles arranged in divergent groups or of delicate fibres loosely matted together. The colour is brass-yellow and the lustre metallic. Before the chemical composition of the mineral had been determined, it had been known as "pyrite" or "hair pyrites" (Ger., Haarlikes), and was not distinguished from the capillary forms of pyrites and marcasite; the name milliere was given by W. Haidinger in 1845, in honour of W. H. Miller. The hardness is 3-3½ and the specific gravity 5-65. There are perfect cleavages parallel to the faces of the rhombohedron (100); and gliding planes parallel to the faces of the rhombohedron (110), on which second

Typical specimens of millerite are found in the coal measures in the neighbourhood of Merchilly Tydvol in South Wales, where the delicate needles and fibres occur with crystals of quartz and pearl-spar in the fissures of septarian nodules of clay-ironstone. Radiating groups of needles are found with ankerite in cavities in haematite in the Sterling mine at Antwerp in Jefferson county, New York. At the Gap mine in Lancaster county, Pennsylvania, the mineral occurs as fibrous encrusting masses with a velvety lustre. The most perfect crystals are those formerly found with calcite, dolomite and a bright green chrome-garnet in a nickel mine at Orford in Sherbrooke county, Quebec.

MILLER'S THUMB (Cottus gobio), a small fish, abundant in all rivers and lakes of northern and central Europe with clear water and gravely bottom. The genus Cottus, to which the miller's thumb belongs, is easily recognized by its broad, flat head, rounded and scaleless body, large pectoral and narrow ventral fins, with two dorsal fins, the anterior shorter than the posterior; the pseuocolum is armed with a simple or branched spine. The species of the genus Cottus are rather numerous, and are confined to the northern temperate zone of the globe, the majority being marine, and known by the name of "bullhead." Miller's thumb is confined to fresh water; and only one other freshwater species is found in Europe, C. pectorvarus, from rivers of Hungary, Galicia, and the Pyrenees; some others occur in the fresh waters of northern Asia and North America. The miller's thumb is common in all suitable localities in Great Britain, but is extremely rare in Ireland; in the Alps it reaches to an altitude exceeding 7000 ft. Its usual length is from 3 to 5 in. Generally hidden under a stone or in a hollow of the bank, it watches for its prey, which consists of small aquatic animals, and darts when disturbed. Ordinary rapidity to some other species. The female deposits her ova in a cavity under a stone, whilst the male watches and defends them until the young are hatched and able to shift for themselves.

MILLET, FRANCIS DAVIS (1846–1905), American artist, was born at Mattapoisett, Massachusetts, on the 3rd of November 1846. He was a drummer boy with the Union forces in the Civil War; graduated from Harvard College in 1869; and in 1871 entered the Royal Academy of Fine Arts, Antwerp, where he studied under Van Lerius and De Kuyser. In 1873 he was made secretary of the Massachusetts commission to the Vienna Exposition. During the Russo-Turkish War of 1877–78 he was correspondent of the London Daily News and Graphic, and of the New York Herald. On his return he was made a member from the United States of the International Art Jury at the Paris Exposition of 1878. He was director of decorations at the Columbian Exposition, Chicago, 1893, and in 1898 he went to Manila as war correspondent for The Times and for Harper's Weekly. In 1898 he became a member of the Society of American Artists. In 1885 he was elected to full membership in the National Academy of Design, New York, and in 1886 one term its vice-president; he became a member also of the American Water Color Society and of the Institute of Painters in Oil Colours, London. As a decorative artist his work may be seen at Trinity Church, Boston; the Bank of Pittsburgh; and the Capitol at St Paul, Minnesota. His pictures are in many public collections: among them are "A Cosy Corner," in the Metropolitan Museum of Art, New York; "At the Inn," in the Union League Club, New York; and "Between Two Fires," in the Tate Gallery, London. He also wrote essays and short stories, and an English version of Tolstoi's Sebastopol (1887); and among his publications are The Danube (1891), Capillary Crime and other Stories (1892), and Expedition to the Philippines (1894).

MILLET (or Milé), JEAN-FRANÇOIS (c. 1642–1709), commonly called FRANCISQUE, was born at Antwerp about 1642, and is generally classed amongst the painters of Flanders on account of the accident of his birth. But his father was a Frenchman, a turner in ivory of Dijon, who took service with the prince of Condé and probably returned after a time to his usual occupation. He remained long enough in Antwerp to apprentice his son to an obscure member of a painter family called Laurent, pupil of Gabriel Franck. With Laurent, Francisque left Antwerp for Paris, and there settled in 1660 after marrying his master's daughter. He was received a member of the Academy of Painting at Paris in 1673, and after gaining consideration as an imitator of the Poussins he died in 1709, bequeathing his art and some of his talents to one of his sons. Francisque probably knew, as well as imitated, Nicolas Poussin, Gaspar Dugeth and Sebastian Bourdon; and it is doubtful because of his isolation there are any other characteristic artists that, being himself without familiarity with the classic laws of design, in Greece, he was able to imagine and reproduce Italian and Arcadian scenery with considerable grace and effectiveness. It is indeed surprising to observe, even at this day how skilfully he executed these imaginary subjects, enlivened them with appropriate figures, and shed over them the glow of a warm yet fresh and sparkling tone. Twelve of his most important landscapes, which remained in the palace of the Tülleries, were destroyed by fire; and though many of his pieces may still be found catalogued in Continental and English collections, others in the number of which remain unknown and unacknowledged. His son JEAN FRANÇOIS MILLET, the younger (1666–1723), also called Francisque, was born in Paris, and was made a member of the Academy of Painting in 1709. He is not quite so independent in his art as his father; but he had clever friends, and when he wanted figures to his landscapes, he consulted Watteau, and other followers of the "court shepherdess" school. In the museum of Grenoble is a " Paysage" by him which is prettily adorned with Watteau's figures.

MILLET, JEAN FRANÇOIS (1814–1875), French painter, whose name of a peasant family, was born on the 4th of October 1814 in the hamlet of Gravry, near Gréville (La Manche) in the wild and picturesque district called La Hague. His boyhood was passed working in his father's fields, but the sight of the engravings in an old illustrated Bible set him drawing, and thenceforth, whilst the others slept, the daily hour of rest was spent by Millet in trying to render the familiar scenes around him. From the village priest the lad learnt to read the Bible and Virgil in Latin, and acquired an interest in one or two other works of a high class which accompanied him through life; he did not, however, attract attention so much by his acquirements as by the stamp of his mind. The whole family seems, indeed, to have been characterized by austerity and dignity, and when Millet's father finally decided to test the vocation of his son as an artist, it was with a gravity and authority which recalls the patriarchal households of Calvinist France. Two drawings were prepared and placed before a painter at Cherbourg named Mouchel, who at once recognized the boy's gifts, and accepted him as a pupil; but shortly after (1835) Millet's father died, and the eldest son, with heroic devotion, took his place at home, nor did he return to his work until the pressing calls from without were solemnly enforced by the wishes of his own family. He accordingly went back to Cherbourg, but after a short time spent there with another master (Langlois) started with many misgivings for Paris. The council-general of the department had granted him a sum of 600 francs, and the town council promised an annual pension of 400, but in spite of friendly help and introductions Millet went through great difficulties. The system of the École des Beaux Arts
MILLET

was hateful to him, and it was not until after much hesitation that he decided to enter an official studio—that of Delarocque. The master was certainly puzzled by his pupil; he saw his ability, and, when Millet in his poverty could not longer pay the monthly fees, arranged for his free admission to the studio, but he tried in vain to make him take the approved direction, and lessons ended with "Éh, bien, allez à votre guise, vous êtes si nouveau pour moi que je ne veux rien vous dire." At last, when the competition for the Grand Prix came on, Delarocque gave Millet to understand that he intended to secure the nomination of another, and then won Millet with himself, and his friends. Dejected he started in a little studio in the Rue de l'Est. He had renounced the beaten track, but he continued to study hard whilst he sought to procure bread by painting portraits at 10 or 15 francs apiece and producing small "pastiches" of Watteau and Boucher. In 1840 Millet went back to Gréville, where he painted "Sailors Mending a Sail" and a few other pictures—reminiscences of Cherbourg life.

His first success was obtained in 1844, when his "Millkwoman" and "Lesson in Riding" (pastel) attracted notice at the Salon, and friendly artists presented themselves at his lodgings only to Barby, a village on the skirts of the forest of Fontainebleau. The lodgings soon disappeared. Millet was at Cherbourg; there he remained, but having amassed a few hundred francs he went back to Paris and presented his "St Jerome" at the Salon of 1845. This picture was rejected and exists no longer, for Millet, short of canvas, painted it over "Oedipus Unbound," a work which during the following year was the object of violent criticism. He was, however, no longer alone; Diaz, Eugène Tournoux, Rousseau, and other men of note supported him by their confidence and friendship, and he had by his side the brave Catherine Lemaire, his second wife, a woman who bore poverty with dignity and gave courage to her husband through the cruel trials in which he penetrated by a terrible personal experience the bitter secrets of the very poor. To this date belong Millet's "Golden Age," "Bird Nesters," "Young Girl and Lamb," and "Bathers"; but to the "Bathers" (Louvre) succeeded "The Mother Asking Alms," "The Workman's Monday," and "The Winnowers." This last work, exhibited in 1848, obtained conspicuous success, but did not sell till Ledru Rollin, informed of the painter's dire distress, gave him 500 francs for it, and accompanied the purchase with a commission, the money for which enabled Millet to leave Paris for Barby, a village on the skirts of the forest of Fontainebleau. There he settled in a three-roomed cottage for the rest of his life—twenty-seven years, in which he wrought out the perfect story of that peasant life of which he alone has given a "complete impression." Jules Breton has coloured the days of toil with sentiment; others, like Courbet, whose eccentric "Funeral at Ornans" attracted more notice at the Salon of 1856 than Millet's "Sowers and Binders," have treated similar subjects as a vehicle for protest against social misily; Millet alone, a peasant and a miserable one himself, saw true, neither softening nor exaggerating what he saw. In a curious letter written to Sensier at this date (1850) Millet expressed his resolve to break once and for all with mythological and undraped subjects, and the names of the principal works painted subsequently will show how steadfastly this resolution was kept. In 1852 he produced "Girls Sewing," "Man Spreading Manure," "The Reapers," "Church at Gréville"; 1855—the year of the International Exhibition, at which he received a medal of second class—"Peasant Grafting a Tree"; 1857, "The Gleaners"; 1859, "The Angelus," "The Woodcutter and Death"; 1860, "Sheep Shearing"; 1861, "Woman Shearing Sheep"; "Woman Feeding Child," 1863, 1865; "Sheep"; "Pigeons"; "Woman with Hoe," "Woman Carding"; 1864, "Shepherds and Flock, Peasants Bringing Home a Calf Born in the Fields"; 1869, "Knitting Lesson"; 1870, "Buttermaking"; 1871, "November—Recollection of Gruchy." Any one of these works will show how great an influence Millet's previous practice in the nude had upon his style. The dresses worn by his figures are not clothes, but drapery through which the forms and movements of the body are strongly felt, and their contour shows a grand breadth of line which strikes the eye at once. Something of the imposing unity of his work was also, no doubt, due to an extraordinary power of memory, which enabled Millet to paint (like Horace Vernet) without a model; he could recall with precision the smallest details of attitudes or gestures which he proposed to represent. Thus he could count on presenting free from afterthoughts the vivid impressions which he had first received, and Millet's nature was such that the impressions which he received were always of a serious and often of a noble order, to which the character of his execution responded so perfectly that even a "Washerwoman at her Tub" will show the grand action of a Meden. The drawing of this subject is reproduced in Souvenirs de Barbizon, a pamphlet in which M. Piédagnel has recorded a visit paid to Millet in 1864. His circumstances were then less evil, after struggles as severe as those endured in Paris. A contract by which he bound himself in 1860 to give up all his work for three years has placed him in possession of 1000 francs a month. His fame extended, and at the exhibition of 1867 he received a medal of the first class, and the ribbon of the Legion of Honour, but he was at the same moment deeply shaken by the death of his faithful wife, who had called for a time he never completely recovered his health, and on the 20th of January 1875 he died. He was buried by his friend's side in the churchyard of Chailly. His pictures, like those of the rest of the Barbizon school, have since greatly increased in value.

See the article Barbizon; also A. Sensier, Vie et œuvre de J. F. Millet (1874); Piédagnel, Souvenirs de Barbizon, &c. (1876); D. C. Thomson, The Barbizon School (1891); Richard Mather, J. F. Millet (1903); Gessel, Millet und Roussseau (1902). (E. F. S. D.)

MILLET (Fr. millet; Ital. miglietta, diminutiv mi- glio = Lat. mille, a thousand, in allusion to its fertility, and with little definiteness to a considerable number of often very variable species of cereals, belonging to distinct genera and even subfamilies of Gramineae. Common millet is Panicum mili- ceum (German Hirse). It is probably a native of Egypt and Arabia but has been cultivated in Egypt, Asia and southern Europe from prehistoric times. It is annual, requires rich but friable soil, grows to about 3 or 4 ft. high, and is characterized by its bristle, much branched nodding panicles. One variety has black grains. It is cultivated in India, southern Europe, and northern Africa, and ripens as far north as southern Germany, in fact, wherever the climate limits the production of wine. The grain, which is very nutritious, is used in the form of groats, and makes excellent bread when mixed with wheaten flour. It is also largely used for feeding poultry, for which purpose mainly it is imported. Hungarian grass, Seteria italica (also called Panicum italicum), a native of eastern Asia is one of the most wholesome and palatable Indian cereals. It is annual, grows 4 to 5 ft. high, and requires dry light soil. German Millet (Ger. Kolbenhirse, Mohar) is probably merely a less valuable and dwarf variety of S. italica, having an erect, compact, and shorter spike. The grains of both are very small, only one half as long as those of common millet, but are exceedingly prolific. Many stalks arise from a single root, and a single spike often yields 2 oz. of grain, the total yield being five times as much as wheat. They are imported for poultry feeding like the former species and for cage-birds, but are extensively used in soups, &c., on the Continent. Numerous other species belonging to the vast genus Panicum—the largest among grasses, of which the following are among the most important—are also cultivated in tropical or subtropical countries for their grain or as fodder.

Seteria italica.
MILLIGAN—MILLIPEDE

Grasses, or both, each variety of soil, from swamp to desert, having its characteristic forms.

Polish millet is P. sanguinale; P. frumentaceum, shamal, a Decan grass, is probably a native of tropical Africa; P. decom-positus is the American P. esculentum, but has been intro-duced into California by the aborigines. P. maximum is the Guiana grass, native of tropical Africa; it is perennial, grows 8 ft. high, and yields abundance of highly nutritious grain. P. esculentum or Opisthopogona, has been acclimatized in Brazil and other tropical countries. Other gigantic species 6 or 7 ft. high form the field-crops on the banks of the Amazon. Of species belonging to allied genera, Prospone and Prosopon, sometimes also called Egyptian millet or pear millet, is largely cultivated in tropical Asia, Nubia and Egypt. Species of Paspaleum, Eleusine and Milium, are also cultivated as millets. For Indian millet, see D. L. & E.

MILLIGAN, WILLIAM (1821–1892). Scottish theologian, was born on the 15th of March 1821, the eldest son of the Rev. George Milligan and his wife Janet Fraser. He was educated at the High School, Edinburgh, and, from the age of fourteen, at the university of St Andrews, where he graduated in 1839. In 1843 at the disruption he took the side of those who remained in the Establishment, and in 1844 became minister of Cameron in Fife-shire. In 1845, his health having given way, he went to Germany, and studied at the university of Halle. After his return to Scotland and his resumption of his clerical duties he began to write articles on Biblical and critical subjects for various reviews. This led to his appointment in 1860 to the professorship of Biblical criticism in the university of Aberdeen. In 1870 he was appointed one of the committee for the revision of the translation of the New Testament. His fervent piety, and his wide interest in educational and social questions, extended his influence far beyond the circle of theologians. His contribu-tions to periodical literature for many years were numerous and valuable; but his reputation chiefly rests on his works on the Resurrection (1890) and Ascension of our Lord (1892), his Baird lectures (1886) on the Revelation of St John, and his Discussions (1893) on that book. All these volumes are distinc-ted by great learning and acuteness, as well as by breadth and originality of view. He died on the 11th of December 1892.

MILLINER, originally a dealer in goods from the city of Milan in Italy, whence the name. Such goods were chiefly steel work, including cutlery, needles, also arms and armour and textile fabrics, ribbons, gloves and "Milan bonnets." The name of Millinon, though never formed into a Livery Company, see to have been amalgamated with the "Cape" and Hurers," (q.v.), which later were amalgamated with the "Haberdashers" (q.v.). Minshew's derivation of the word from milli, thousand ("as having a thousand small wares to sell"), though a typical instance of guessing etymologies, shows the miscellaneous character of their trade in the 16th and 17th centuries. The modern use of the word is confined chiefly to one who makes and sells bonnets and hats for women; but articles of "millinery" include ribbons, laces, &c., usually retailed by haberdashers.

MILLIPEDE, the popular name of the best known members of a group of the Arthropoda, scientifically known as Diplopoda, and formerly united with the Chilopoda (see CENTIPEDE), the Pauropoda and the Symphyla as an order of the class Myriapoda. This classification, however, has of late years been abandoned on account of the recognition of closer affinity between the Chilopoda (centipedes) and the Hexapoda (insects) than between the Chilopoda and Diplopoda. By modern writers the above-mentioned groups of chilopodous Arthropoda, and also the prosoponate with the "Cape"-and Hurers," (q.v.), which later were amalgamated with the "Haberdashers" (q.v.). Minshew's derivation of the word from milli, thousand ("as having a thousand small wares to sell"), though a typical instance of guessing etymologies, shows the miscellaneous character of their trade in the 16th and 17th centuries. The modern use of the word is confined chiefly to one who makes and sells bonnets and hats for women; but articles of "millinery" include ribbons, laces, &c., usually retailed by haberdashers.

MILLIGAN—MILLIPEDE

CLASS DIPLOPODA.

Structure.—The anterior extremity is provided with a distinct head which by its general form and the nature of its appendages is as sharply marked off from the body as is the case in the Hexa-poda. It always bears at least three pairs of appendages, the eyes when present and in the Onisciforma a peculiar sense organ. The inferior edge of the head plate overhangs the thorax and is termed the frons, the head plate, and a pleural plate on each side. To the external margin of the ventral plate or sternum is articulated a pair of legs and between the leg and the pleural plate is situated the spiracle of the tracheal system. But the segmentation of the Diplo-poda presents two marked peculiarities. The first is the fact that, with the exception of a few, the anterior leg-bearing segments and perhaps one or two of those at the posterior end of the body, a single pleural plate or tergum, with its pleural plates overlies two sternal plates, two pairs of legs and two pairs of spiracles. Hence these segments appear to be double and to be furnished with twice as many legs as is normal in the Arthropoda—a peculiarity which has suggested the term "Diplo-poidea" or "double-plateued," for the group. It is generally believed that each tergal plate results from the coalescence of two original distinct adjoining segments; but the same effect would be produced by the enlargement of one of a pair of terga and the complete excision of the other. It is in favour of the latter view that there is only a single pair, and not two pairs, of stink-glands on each so-called double tergal plate. Unfortunately the history of the development of the segments does not clear up the difficulty since the terga of the double segments are single from the first, and no evidence either of fusion or excision is supplied. The second of the two peculiarities above-mentioned is the great development of the tergal scutite as compared with the sternal. Only very rarely (i.e. in Platysusmus) is there a broad plate over an area. In the majority of cases the lateral edges of the tergum are bent downwards and forwards towards the mid ventral plate; the sternum at the same time is so much reduced that the basal segments of the legs of opposite sides are almost in contact. The
as a single pair of antennae, two or three pairs of jaws and a variable number of walking-legs, of which one or more pairs may be transformed into gonapods. The antennae are short and very similar to the legs. They are prismatic in form, and usually consist of seven segments, the seventh or distal segment being small, as a rule, and furnished with a sense organ which is probably olfactory or tactile in function. In the extremitates, or jaws of the former pair are the most anterior of the pastoral appendages. They are large, powerful, and usually consist of three or two segments, a basal or

on each side a large branching nerve to other organs in the segment. In the Opisthormorpha (Julus, Spirostreptus) and the Onisco-morpha (Glomeris, Sphaerotherium) the ganglia are spaced at equal distances on the cord, but in the Meroclupidae (Polydesmus) they are grouped in pairs to correspond to the spacing of the legs. The appendages of the last ganglion of the cord, as are also the gonapods of the males of

After Vogens.

FIG. 3.—Inner view of ventral area of a single segment of Julus, much enlarged to show the structure and arrangement of the tracheal organs. The two pairs of tracheae are seen in situ, the posterior pair overlapping the anterior.

d½, Tubular chamber of tracheae. m, Ventral body muscle.

cardio, which is sometimes absent, a second or stipes, and a third or mala, the latter being supplied with a strong tooth and pectinate lamellae. In all Diplopods, with the exception of the Psephonogaster, there are only two pairs of jaws, those of the second pair, forming a large plate, the gnathochilium, which acts as a lower lip. It consists of several distinct sclerites, two external on each side, the proximal known as the cardo, the distal as the stipes, the latter being tipped with one or two lobes (mala) and far exceeding the cardo in size. Between the external plates there is a median proximal plate (mentum) generally of large size and often itself subdivided, and a pair of distal plates (linguae). Behind the base of the gnathochilium there is a single large transverse plate, the hypostoma. In the Psephonogaster, the jaws representing the gnathochilium are differently constructed and an additional pair, the maxillulae, has been recently detected between the gnathochili um and the mandibles. Behind the gnathochilium, which from embryological data appears to result from the modification of a single pair of appendages, a legless somite has been detected in some embryos. Possibly the plate referred to above as the hypostoma is its sternal element.

The heart is a median dorsal vessel composed of a series of chambers each giving off a pair of arteries and furnished with a pair of orifices or ostia. According to Newport, the anterior chamber lying in the second segment is prolonged into an aortic trunk from which arise three pairs of lateral arteries dipping down on each side of the alimentary canal and uniting beneath it in a common ventral vessel. The heart is enveloped in a delicate pericardial membrane and is supported by lateral alary muscles. The alimentary canal is a simple tube extending usually straight through the body from mouth to anus. Only in the Onisco-morphus is it looped, thus suggesting the origin of this short-bodied group of millipedes from longer, more vermiform ancestors. A pair of so-called salivary glands opens into the fore-gut near its anterior extremity and one or two pairs of malpighian tubes communicate with the hind-gut at its junction with the broad mesenteric portion of the canal. Respiration is effected by means of tracheal tubes which continue to the exterior in a manner similar to, but not of just above the bases of the walking limbs. Each spiracle leads into a longer or shorter pouch whence the tracheae, which are of two kinds, arise. In the majority of the orders the tracheae are tukted, that is to say, they form two bundles of short simple tubes springing from the innermost corners of each pouch. In the Onisco-morphus, however, each pouch gives rise to a number of long tubes which extend through the body and somewhat resemble those of the Chilopoda except that they neither branch nor are extensive. As in the Chilopoda and Hexapoda the tracheae are strengthened and kept expanded by a slender spiral filament.

The central nerve cord consists of two strands so closely approximated as to be practically fused, with a small ganglionic enlargement for each pair of legs. Hence in the double segments there are two such ganglia, which in addition to the cranial nerve give off

After G. C. Bourse, J. Linn. Soc. xix, Pl. 29, 1886.

the Onisco-morphus. The first (suboesophageal) ganglion of the cord supplies the mandibles and gnathochilium and is connected by the oesophageal commissures with the bilobed cerebral nerve whence arises the nerves for the eyes, when present, and the antennae.

Eyes are sometimes absent, as in all the genera of Meroclupidae and in many genera of other groups, as in Siphonophora, one of the Colobognatha, and several of the Juloidae (Typhlophantes). In other cases they are represented by one or two ocelli on each side (Stemmiuloides); or by a vertical series of ocelli as in the Glomerodes and Polyzonium amongst the Colobognatha. But in the majority of the orders they are represented by triangular or subcircular aggregations of ocelli recalling in a certain degree those of the Lithobiomorpha amongst the Chilopoda. They are simple in structure and consist externally of a cuticular corneal thickening or lens and internally of a reticular layer of enlarged epidermic cells, the
internal or proximal ends of which are continuous with the fibres of the optic nerve. The oviducts are the entire length of the body beneath the alimentary canal. The oviducts are sometimes separate tubes (Lysiosetaetum), sometimes confluent and divided just before terminating in the two orifices of the tail or metathoracic. The testes and seminal ducts occupy the same position and extent as the ovary and oviducts. The ducts are sometimes coiled, sometimes divided, sometimes united by transverse branches across the middle line, and are sometimes branched posteriorly. They bear short caecal diverticula in which the semen is deposited. There are no accessory glands associated with the reproductive organs, but in some cases (e.g. Polyxenus), there is a pair of receptacula seminis extending backwards alongside the ovary and opening into the oviduct.

FIG. 5.—Gonopods of Trigoniulus andersoni, one of the Opisthospermophora (Spirabolidae).

A. Anterior view, and B, lateral views of the apparatus. ant., anterior, and post, posterior portions of the cephalopod enshathing the phallopod, of which the proximal portion, ph., is shown.

C. Phallopod removed from the cephalopod.

The secondary sexual characters of the males are of great taxonomic importance. The seminal ducts, like the oviducts, open behind the legs of the second pair. Associated with them in the Limacomorpha (Gomerideresmus), there is a pair of very long spermathecal sacs. In the Spirostreptoidea and Juloidea, the spermathecal sacs are much longer than the spermathecal ducts, and there are no accessory glands. The male spermatozoa are transferred to the female reproductive organs by means of the seminal ducts, which in the Spirostreptoidea are formed into a common orifice at the hind margin of the sternum. The ducts, when joined, are termed phallopods. When the posterior legs are so modified the anterior are as a rule even more profoundly altered to form a protective sheath, or cephalopod, for the phallopod; and as a further precaution the entire apparatus is usually withdrawn within the seventh segment. In the Oniscomorpha the semen is transferred into a pair of receptacles developed upon the coxae of the legs of the last pair, which are chelate. The male apparatus of the Limacomorpha and Ascospermophora is formed to open by pores on the sides of more or fewer of the segments. They secrete a fluid with an unpleasant odour, breaking up in one case into cyande of potassium, and are practically the only means of protection, apart from the hard exoskeleton, which Diplopoda possess. In some millipede silk glands also exist, and open upon papillae upon the posterior border of the last tergal plate. They are found in Ascospermophora, Stemmiuloida and Protaspermophora, and are used for spinning nests for the eggs and protective cases for the young during euviation.

Classification.—The existing members of the class Diplopoda may be classified as follows:

Subclass I. Pselaphognatha.

Order: Penicillila (Polyxenus).

2. Chilognatha.

Order: Oniscomorpha (Gomeridensmus).

Limacomorpha (Gomeridesmus).

Colobognatha (Polyxenus, Siphonophora).

Ascospermophora (Chordomea).

Protaspermophora (Lysiotelinae).

Merochota (Polyxenus).

Opisthognathophora.

Suborder: Stemmiuloida (Stemmiulus).

Spirabolidae (Spirabolus).

Siprostriptoidae (Spirostreptus).

Juloidea (Julus, Nespermoa).

Diplopods with the soft integument strengthened by weakly chitinized sclerites and furnished above and on the head with transverse rows of short, stout, somewhat squamiform bristles; laterally, on each side of the principal segments, with a thick tuft of long bristles and with a large, silky, white tuft projecting backwards the posterior extremity. Mandibles one-jointed. Behind them a pair of small, one-jointed maxillulae, attached to a median membranous lingua. Behind the lingua are maxillae, a large, double, transverse plate with a long, external sclerite bearing distally in Polyxenus an inner short-lobate process and an outer long spiny palpaliform branch. The latter, however, is absent in Lophoproturus. These sclerites probably represent the gnathochilarium of the Diplopoda, but the formation of the skeletal elements of the jaws in question is not clearly understood. It has been suggested that they represent two pairs of jaws, but embryological proof of this does not exist.
Mandibles, two- or three-jointed; maxillulae absent, the jaws of the second pair being represented by the gnathochilarium described above.

Order Oniscoidea.

Body short and broad, hemispherical in transverse section; convex above, flat below, and capable of being spherically coiled. The exoskeleton is composed of a vaulted tergum, a pair of free pleural sclerites, two pairs of small tracheal sclerites and two pairs of legs, the latter attached to the ventral membrane, which has no sternal plates. The tergal plates are twelve or thirteen in number, whereby the first is very small, the second enormously expanded laterally, and the last, also enlarged, and probably representing at least three segments, extends laterally and posteriorly like a hood over the posterior end of the body without forming a chitinous ring round the anal valves and sternum. In the male the legs of the penultimate pair are sometimes modified as claspers; those of the last pair are always enlarged and prehensile, and bear on their coalesced basal segments a pair of sperm-carrying processes analogous to the phallopods of other groups. Apart from these organs the male has no penis, the seminal ducts perforating the coxae of the legs of the second pair. This order contains two well-marked suborders, the Glomeroida and the Zopheronididae. The Glomeroida, comprising the families Glomeridae, Gerasistidae, Onomeridae, have the antennae approximated on the head, the eyes unicorial and twelve (rarely eleven) tergal plates. To this group belong the common pill-millipedes of Europe and North Africa. In North America the Onomeridae alone are found. The Zopheronididae, with the single family Zopheronidae, have the antennae at the sides of the head, the eyes composed of a spherical cluster of ocelli, and always thirteen tergal plates. This group is common in the tropical and southern continents of the Old World, having representative genera in South Africa, Madagascar, India, Malaysia, Australia and New Zealand. They are much larger forms than the Glomeroida, large specimens reaching two or three inches in length. In addition to the characters mentioned above the Zopheronididae differ from all other Diplopoda in having long tubular trachea and the alimentary canals bent upon itself.

Order Limacormorpha.

Resembling the Oniscoidea in the shape and structure of a typical segment, except that the tracheal plates are unrepresented; in the facts that the last tergal plate does not form a complete ring round the anal area, and that the last pair of legs in the male are modified; but differing from them in that the body consists of nineteen or twenty segments, is elongate, and the appendages anteriorly and posteriorly, the second and last tergal plates being small; in the presence in the male of a pair of long hairy protrusible penes between the legs of the second and third pairs, and in the structure of the gonopods, which, instead of being chelate, terminate in a slender, tapering tergal segment. This order contains two families: Zopheronidae (Zopheronidae) and Glomeridae (Glomeridae), the former from tropical Asia, the latter from tropical America. The largest of these millipedes reach a length of only about 7 mm. Nothing special is known of their habits.

Order Coleobugnatha.

Body elongate, capable of being spirally coiled, consisting of a large and indefinite number of segments, each being furnished with a distinct oval large sternal area, and with the pleural sclerite or membrane distinct from the tergum. The last tergal plate forms a complete ring round the anal valves. Legs with coxal pouches; those of the seventh segment transformed into gonopods of a very simple type in the male, which is also furnished with a double penis completely or partially confluent with the coxae of the legs of the second pair. Head always small, frequently triangular or piriform, in the latter case the gnathites reduced in size and complexity. Repugnatorial pores present and lateral. The genera of this order are divisible into three families: the Polydesmidae (Polydesmus, Pseudeodesmus), Polyzoa (Polyzoon, Siphonella), and Staphylinidae (Siphonophora). Of these the Polydesmidae have departed least and the Siphonophora most from the typical Diplopod in the structure of the mouth parts. The group is for the most part tropical, one genus only, Polyzoon, extending as far north as Central Europe.

Order Ascospermophora.

Body elongate, consisting of from twenty-six to thirty-two segments, but not varying within specific limits; the pleural coalesced with the tergum, the sterna free. More or fewer of the anterior ten pairs of legs may be modified in the males, but no true phallopods are differentiated, the function of seminal receptacles being performed (according to C. Verhoeft) by the exsertile coxal pouches of the two pairs of legs of the eighth segment. The seminal ducts in the male perforate the coxae of the legs of the second pair. There are no repugnatorial pores, and the terga are furnished with three pairs of symmetrically placed hairs or bristles. On the posterior border of the last tergal plate there is a pair of spinning papillae. The millipedes of this order, also called Coelochaeta, are referable to several families: Chordeumidae (Chordeum), Craspedosomidae (Craspedosoma), Heterochaetidae (Heterochaeza), &c. The Heterochaetidae belong to the Oriental region, extending from India to New Zealand. The others are particularly abundant in genera and species in North and Central America and Europe; but are unknown in Africa, south of the Sahara.

Order Proteroglossiphora.

Differing from the Ascospermophora in that the number of segments is large and variable; they are furnished with repugnatorial pores, and not with the three pairs of setae. In the males the anterior appendages of the seventh segment are modified as phallopods, and the seminal ducts perforate the coxae of the legs of the second pair. This order, containing the family Lysiopetalidae (Lysiopetalum), is widely distributed in Europe and North America. Large examples of some of the species, e.g. L. saxifirum, reach a length of 4 or 5 in.

Order Meroboea.

Resembling the Proteroglossiphora in having only the anterior appendages of the seventh segment converted into phallopods and the seminal ducts perforating the coxae of the second legs in the males; but differing essentially that the sterna are...
MILLIPEDE

solidly welded to the rest of the exoskeleton of the segments, which are either nineteen or twenty in number, in the absence of eyes and of spinning papilae, and in having six-jointed legs. This order is monophyletic, and consists of a very large number of genera which by some authors are referred to the single family Polyrhachidae, to which are assigned to numerous families. Many species are brightly coloured, and some individuals of the Oriental genus

*Stemmiuloidea*

have a very distinctive appearance.

**FIG. 10.**

*Platyrhachus mirandus,* a Sumatran species of *Platyrhachidae,* to show the characteristic of the order Monochaeta.

- c. Head.
- d. Antenna.
- t. Tergal plate of first body segment.
- t."""" Ditto of seventh.
- a. Anterior pleurae next to legs.
- a. Digit of anal segment.

Platyrhachus may reach a length of 5 in. The segments are usually provided with lateral lamine or tubercular expansions bearing the repugnatorial pores, which are only very rarely absent.

Order Opisthospermophora.

Resembling the Proterospermophora in possessing a large and variable number of segments, the males lack, with the exception of the last and the anterior four or five, is furnished with a pair of repugnatorial pores, but differing essentially from them in that the posterior pair of appendages of the last segment are divided medially and an anterior into protective coleopods in the male, and that the seminal ducts in this sex do not perforate the coxae of the legs of the second pair but are usually associated with a distinct penis situated immediately behind them. The general form of this order present greater diversity of structure than is found in the other orders and are referred to four suborders, which by some zoologists are erected to ordinal rank, namely, the Stemmiuloidea (Monochaeta); the *Spiroboloidea* (Anochaeta); the *Streptostreptidea* (Diplochaeta); and the *Julioidea* (Zygochaeta).

In the Stemmiuloidea the sterna are free and the pleurae partially so; the terminal segment of the head is coalesced; the pairs of spinning papilae on the last tergite; the penis is a single long tube, and the eyes are represented by one or two large lenses on each side of the head. The genus *Stemmiulus,* constituting the *Stemmiuloidea,* is represented by species from the Oriental, Ethiopian, and Neotropical regions. In the possession of silk-glands this suborder resembles the Ascospermophora and Proterospermophora, and should perhaps rank as an order apart from the *Opisthospermophora.*

The Spiroboloidea, containing one family, the *Spirobolidae* (*Spirobolus, Rhinocrinus,* &c.), have the sterna and pleurae coalesced, the tarsal undivided; no spinning papilae, no penis, the eyes represented by an aggregation of ocelli; and the first five segments each with a single pair of legs, the sixth carrying two pairs. This group attains its maximum of development in the tropics, where species and genera are numerous and specimens of large size, i.e. 6 ins. or over, are met with.

The *Streptostreptidea* resemble the *Spiroboloidea* in many particulars, but the fourth is the smallest, and the fifth has two pairs of limbs; the male has a distinct and double penis, and in both sexes the stipes of the gnathochilium extend to the proximal end of the mentum, which is relatively small. The distribution of this order, which contains several families, *Strepistreptus,* *Rhinocricus,* *Stemmiuloidea,* *Cembalidae* (*Cembala, Julomorpha,* &c.), is practically the same as that of the *Spiroboloidea.* Specimens over 6 ins. in length are met with in the southern parts of Africa and Asia.

The Julioidea differ from the *Streptostreptidea* in having the third segment limbless, the first, second and fourth with a single pair of appendages, and the stipes of the gnathochilium much expanded and mucronate. Coarsely divided life line behind the very small pronotum.

The best marked family of this group is the *Julidae,* which is widely distributed in the northern hemisphere. Its species and genera (*Julidae, Pachydesmus*) are abundant in Europe. Another European family, the *Nemasomidae,* is founded for the genus *Nemasoma,* which is remarkable for having the sterna free.

**Habits, &c.** Millipedes are principally cryptozoic, living under

stones or logs of wood in damp, secluded localities. They feed almost wholly upon decaying vegetable matter, and drink a considerable quantity of water. Some of the tropical species emerge from their burrows during the heavy rains, and crawl over the ground and bushes in search of moisture in broad daylight. Their method of progression over level ground is quite peculiar. The body, divided into a series of wave-like movements of the legs, which are moved in groups, the groups on the right and left side exactly corresponding. Some forms, e.g. *Stemmiulus,* have been described as attempting to escape from capture by a hopping movement caused by vigorous jerking and wriggling of the body. Many of the species are very conspicuously coloured and the association of brilliant colouring with the existence of the nauseous secretion of the repugnatorial glands suggests that the colouration is aposematic or of warning significance.

Copulation between the sexes takes place before oviposition. In the *Opisthospermophora* males and females co-tell over the ventral surface of the anterior ends of their bodies opposed, the male holding the female securely by the head while the extended phallopods carrying the semen are brought into contact with her genital orifice. In the *Polydesmidae* pairing is effected in the same way except that the male and female instead of interlocking remain extended, the male clasping the female with his legs. In the *Oniscoidea* the sexes also appear to front, not head to head, however, the gonopod in the anal segment of the male can be applied to the second pair of postoral appendages in the female. Some males of this group, e.g. *Spaetherae* *i,* live in living organs of their posterior gonopods and striate while finding the females.

The method of disposing of the young, which usually have only three pairs of legs at hatching, differs in various groups. In *Julus polydesmus* the female lays her eggs in a small orifice in the surface and makes a subepithelial nest of small blocks of earth which are moistened with the saliva. These eggs are left in the nest until it is closed. The offspring, when hatched, are not capable of leaving the nest to find food, and remain with her for some time after they were hatched. Again, millipedes, like the *Stemmiuloidea* and *Ascospermophora,* possess silk-glands, spin silk cases for the protection of their eggs. Immature specimens of these groups spin similar silk cases at the time of eclosion; and cases, resembling segments, are likewise formed by the larvae of some species as a means of mouling by immature forms of some exotic species of *Polydesmidae,* e.g. the tropical African *Oxydesmus* *palmi,* which is probably related to *Sphaerodromus,* makes use of its own voided excrement in the formation of these receptacles.

A considerable number of *Chilognatha* of doubtful systematic position have been recorded from beds of the coaliferous formation. The best known are *Acanthorbes* and *Euphasmodia.* Specimens referred to existing genera have been discovered in amber beds of Oligocene age.

**CLASS PAUROPODA.**

As in the Diplopoda there is a distinct head bearing a pair of antennae and two pairs of jaws. On each side of the head there is an eye-like spot which may conceivably represent a degenerate eye, although the external cuticle shows no corneal thickening nor the presence of the eye-stalks and the minute nerves are absent from the brain. The antennae are structurally unique in the Arthropoda. There are four short basal segments from the distal of which arise two one-jointed branches, an external thinner and an internal thicker. The external or postaxial branch is tipped with a single long annulate flagelliform bristle with a rounded apical knob; and the internal or preaxial branch with two similar but shorter bristles and a globular or oval body organ between them. The two bristles or jaws of the first pair are large and one-jointed. The second pair are very short, pinniform, and attached to the ventral side of the head by a long, rod-like selerite. Between these are the jaws of the second pair, mounted on a jointed piece of the head to the mouth. The correspondence between these mouth parts and those of the Diplopoda is not understood. No doubt the mandibles are homologous in the two groups, but the larger genera (*Diplopoda, Polydesmidae*) are distinct in origin and not related to each other.
are questions to which no answer can as yet be given. Judging from the segmentation and the appendages the body is composed of twelve somites, including the last or anal, which, like the penultimate somite, is limbless. Each somite in front of the penultimate is usually six in number, excluding that of the anal segment; each of the anterior five of these overlies two limb-bearing somites, the first covering the somite of the rudimentary limbs and of the first pair of locomotor legs, the second those of the second and third pairs of locomotor legs, and so on. This condition is an adumbration of the far completed fusion of somites seen in the Diplopoda. The sixth tergal plate belongs to the limbless penultimate somite. The duplet character of the first five terga is suggested in *Pauropus* by the presence of two rows of sensory bristles; there being only one such row upon the sixth tergum. In the aberrant genus *Brachypauropus* the evidence is practically completed by the correspondence in number between the terga and pairs of legs, there being a divisional line between the two rows of setae. On each side of the body there are five long pubeose tactile setae situated on the second to the sixth terga in *Pauropus*, and on the pleural area corresponding to these terga in *Brachypauropus*.

The cerebral mass of the nervous system is large and when viewed from above is seen to consist of two lobes defined by a median groove. In the absence of eyes no optic nerves are present. These are two antennal lobes whence arise, close together, the antennal nerves. Two short commissural cords connect the cerebral mass with the suboesophageal ganglion, a composite mass formed of the nervous centres which supply the two pairs of jaws and the rudimentary legs of the first pair. Behind this large ganglion the cord, which shows superficially no trace of its double origin, presents a ganglionic swelling for each pair of legs. No circulatory or respiratory organs have been detected.

The alimentary canal consists of a short, narrow fore-gut, a large, straight mid-gut, and a moderately long hind-gut which is itself composed of two parts, an anterior narrow tube which opens into a dilated, piriform, posterior portion, narrowing gradually to terminate in the anus. Opening into the anterior extremity of the fore-gut there is a pair of "salivary" glands. Malpighian tubes have been found in some forms, i.e., females of *Eurypauropus spinosus*, but not in any examples, male or female, of *Pauropus huxleyi*. Where present they open at the point of union of the mid-
and hind-guts. The generative organs in the female are very similar in form and condition to those of the Diplopoda. In the male they are highly complex, and unlike those of any known Arthropod in certain particulars. The wide, unpaired ovary extends nearly to the posterior end of the body. Another ovary almost reaches the end of the body, but lies somewhat nearer the posterior end. The posterior portion of the duct is wide. The anterior, an abruptly narrow tube, curves round the nerve-cord and opens by a single sub-median orifice in the third segment. The ovary opening lies between the hind and the short duct of a spherical receptaculum seminis. In the male the testis is never paired. Sometimes it is single, sometimes divided into an anterior and a posterior mass, and sometimes unpaired. In the latter case the segment is divided into the posterior half of the body in the adult, but at least in the young in some cases, the mandibles or jaw-like appendages are longer than the primary ones, and may be as many as three slender short ducts which soon expand into wider tubes. These tubes, regarded as seminal vesicles, after forming a complex of loops, coils and caecal prolongations, ultimately unite beneath the intestine in a single tube which passing forwards divides on each side of the alimentary canal to terminate in the two pene situated just beneath the bases of the second pair of complete legs, that is to say, the legs of the third and fourth segments. Four at the root of the penis there is an accessory gland on the duct, and a little farther back a much larger glandular swelling.

The Pauropoda are divided into three rather sharply defined groups, each characterized by the following.

Pauropodidae.—Head covered by the first tergal plate. Anal segment not covered by the sixth tergal plate. Terga of the first ten segments fused in couples. Tactile setae situated on the lateral projection of the terga, which are neither sculptured nor spinous. (Pauropsis, Stylepondus.)

Brachyponopodidae.—Head and anal segment free and the terga simple in the last but one or two of the posterior segments. The Pauropoda is divided into an anterior and posterior plate by a transverse band of membrane and each of these into a pair of plates by a longitudinal intersegmental strip. The tactile setae arising from the pleural area of the body.

Euryponopodidae.—Body wide and onisciform, the head and the anal segment concealed dorsally by the first and penultimate terga respectively. The Pauropoda is divided into a thickly, spinous or sculptured. The tactile setae situated beyond the edge of the terga, as in the Brachyponopodidae. (Euryponops.)

The genus Pauropsis is probably world-wide in distribution, since it has been discovered in Europe, North and South America, and in Siam. The two known species of Brachyponops were found respectively in Italy and Austria. Euryponops has representatives in North America and Europe. Examples of Pauropsis are extremely agile, recalling the centipede Lithobius in their movements; those of Euryponops, on the contrary, are extremely slow and quite comparable in lack of agility to the common pill-millipede. They are also less active in feeding. They often fall among the leaves or other damp situations. They are believed to be vegetable feeders and are oviparous. The young upon hatching may have four segments and three pairs of legs representing the first three pairs of the young of the corresponding segments. The millipede first bears the first pair of legs, and the second and third pairs. The young pass through four successive moult s, and gradually acquires its full complement of segments and limbs.

**CLASS SYMPHYLA**

Prosome Arthropods, differing in many important particulars from the Diplopoda and Pauropoda. The axis of the head lies in the same straight line as that of the body, as in the Chilopoda, and not at right angles to it as in the Diplopoda and Pauropoda. There are no eyes. The antennae are very long and many-jointed. Pairs of gnathites attached to the under-side of the head have been detected. The first pair (mandibles) are two-jointed, as in many Diplopoda. The second pair (maxillae) may consist of a single segment terminating distally in two lobes; or near the distal end of the basal segment there may be a minute one or two-jointed process, regarded as a palpus. Between the maxillae lies a large, double plate (labium or maxillae of second pair) which is attached to the body by a rod-like base. The maxillae terminate in two pairs of short lobes. The body is long and narrow and bears on its dorsal side fifteen tergal plates. The first of these, immediately preceding the head, is very short; the remainder are large and stick out from the animal like a pair of antennae, the with pairs of walking legs, which, with the exception of the first pair, are alike in size and segmentation. Each consists of a pair of segments. During the last and terminates with two powerful claws. The proximal end of the body, an internally a slender, cylindrical process which may be termed the parapod is in reality a pair of long and slender basal segments, which is embedded in the ventral integument. The legs of the first and second pairs never have the parapod, but they are invariably present in the remaining ten pairs. The legs of the first pair are never more than four-jointed; they are always smaller than the others, and are sometimes reduced to mere bud-like processes. They belong to the first segment behind the head. The segment represented by the last tergal plate has no ambulatory limbs; but articulated processes of the head and the parapod border is a pair of large, laterally directed sclerites, which are perforated by the ducts of two spinning glands. The processes are regarded by some authors as the appendages of the last pair of legs.

A. Mandibles or jaws of first pair of Scolopendrella: dl, mandible; md, mandible; c, clypeus; l, lacinia; t, labium; f, femur; l, tibia; s, tarsus; c, claw. B. Jaws of second pair; md, mandible; ky, hypopharynx. C. Jaws of third and fourth pairs; mx, maxilla; c, clypeus; l, maxillary lobe; lb, first sternal plate of labium; lb, lb, first and second segments of labium. (Figs. 1A, 1B, 1C modified from Hansen, *J. M. S. 47, pl. L.)

**Fig. 15.**

angles produced and angular, whereas in *Scutigera* they are rounded. Both genera are widely distributed and are represented, in Europe, south Africa, and Australia, by a large number of species, the largest having a length of six and seven millimetres. They live in earth, beneath stones, dead leaves or fallen branches, and resemble diminutive centipedes (*Scutigera* or *Eilothorax*) both in appearance and movements. The symphylla and ctenedia, however, while the posterior segments of the Thysanurine Hexapods, the parapods with their adjacent exsertile vesicles in *Scutigera* being very similar to the abdomeal appendages and vesicles of such an insect as *Machilis* while the postero-lateral or cercal velcro line of the former bear much resemblance to the cerco-pods of *Jaegys*. It must be remembered, however, that the spinning glands of certain Diplopods occupy the same position as those of the Symphyla and open upon papilliform processes on the under side of the last plate, which are certainly not appendages. Hence, if the papillae are the homologues of the cerc in *Scutigera*, these cerc cannot be morphologically comparable, like the cercopods of *Jaegys* or other insects. Of the 23 fully formed segments it is impossible to determine the relationship between the Symphyla and the Hexapoda, as the Symphyla, nevertheless, differ essentially from the Hexapoda in the anterior position of the generative orifices, and in the presence of twelve pairs of similar ambulatory limbs. (R. I. P.)

**MILLOM,** a market town in the Egremont parliamentary division of Cumberland, England, in the extreme south-west of the county, on the Furness railway. Pop. of urban district (1901), 10,426. The church of Holy Trinity, Early Norman and Decorated in date, is chiefly of interest for its curious pillars, alternately round and octagonal, and for a window in the north aisle, which has five lights, and is known, on account of its unique shape, as the “fish-window.” A massive roodstone stands in the churchyard. Milrom Castle, dating from shortly after the Conquest, was fortified in the 14th century by Sir John (later Earl) Egremont, and was held until 1774. For centuries, they exercised the power of life and death; a stone stands where the gallows were formerly erected, and indicates that here they exercised iura regalia. Though strongly built, the castle was never of great size, and it has been largely dismantled. A fine carved staircase, however, still exists in the main chapel. In 1648 the Parliamentary forces besieged Milrom Castle, and early in the 17th century its park was converted into farmland. In the neighbourhood of Milrom there are blast furnaces and highly productive mines of red haematite ore. The deposit lies partly under the foreshore of the river Duddon, and a company has expended upwards of £150,000 upon a sea-wall and embankment to protect the mine from the sea.

**MILLS, JOHN** (d. 1750), English actor, was a member of the company at Drury Lane from 1693 almost uninterruptedly to the time of his death, playing and creating hundreds of parts. He was at his best in tragedy. His wife was an actress, and their son William—"the younger Mills"—was also an actor of some merit.

**MILLS, ROGER QUARLES** (1832— ), American legislator, was born in Todd county, Kentucky, on the 30th of March 1832. He went to Texas in 1839, studied law, and was admitted to the bar by a special act of the legislature before he was twenty-one. He entered the Confederate army in 1861, took part as a private in the battle of Wilson’s Creek, and as colonel commanded the Tenth Texas Infantry at Arkansas Post, Chickamauga (where he commanded a brigade during part of the battle), Missionary Ridge and Atlanta. He served in the national House of Representatives as a Democrat from 1873 to 1892 and in the Senate from 1892 to 1899. He made the tariff his special study, and was long recognized as the leading authority in Congress as the chairman of the Ways and Means Committee of the House of Representatives in 1887–1889 during President Cleveland’s first administration, he led the fight for reform. From his committee he reported in April 1888 the “Mills Bill,” which provided for a reduction of the duties on sugar, earthenware, glassware, plate glass, woolen goods and other articles, the substitution of ad valorem for specific duties in many cases, and the placing of lumber (of certain kinds), hemp, wool, flax, borax, tin plates, salt and other articles on the free list. This bill was passed by the Democratic House on the 21st of July, and was then so amended by a Republican majority as to be unacceptable to the President. The bill thus became the chief issue in the presidential campaign of 1888. In 1891 Mills was a candidate in the Democratic caucus for Speaker of the house, but was defeated by Charles F. Crisp (1845–1886) of Georgia. During the free silver controversy he adhered to the Cleveland section of the Democratic party, and failed to be re-elected when his term in the Senate expired in 1890. He then retired to CORSICANA, Texas, where he engaged in business and the practice of law.

**MILLSTONE GRIT,** in geology, a series of massive sandstones, grits and conglomerates with alternate shales, the whole resting disconformably on the Carboniferous Limestone or upon intervening shales (Yoredale, Lower Carboniferous Shales), generally in stratigraphical continuity. Its occasional coal-seams show that conditions of coal-formation had already begun. In Great Britain its outcrop extends from the Bristol Coalfield through South and North Wales to its fullest development in the north-midland counties, Lancashire and Yorkshire, and thence to Scotland, where the Roslin Sandstone of the Lothians and the Moor Rock of Lanark and Stirling are considered its equivalents. Characterized by grits and sandstones of the same general type, though individually variable, as sandbanks formed on the shoaling of the Carboniferous sea, yet often persistent over wide areas, the formation, estimated as 5000 ft. thick in Lancashire, contains typically the following grits in descending order: First, or Rough Rock; second, or Haslingden Flags (Lancashire); third, or Chatsworth Grit (the last two being the Middle Grits of Yorkshire); fourth and fifth, or Kingscote Grits and the Shale Grits. The first and third, the most persistent, are often coarse and pebbly, like the Kingscote Grits. In the north of England these grits lose their identity. In South Wales the Millstone Grit, immediately succeeding the Carboniferous Limestone, consists of 450 ft. of grit and shale, its upper member being the massive pebbly Farewell Rock. It extends into the Bristol Coalfield, though not recognized in the Devonshire Culm. In Ireland certain grey grits and flags are assigned to it.

In northern France and Belgium it loses its individuality and is merged in the Coal-measures. It reappears east of the Rhine, but is unrecognized in the somewhat different Carboniferous succession of eastern Europe. In America the Pottsville Conglomerate, 1500 ft. thick in the south Appalachian, with workable coals, and widely unconformable upon the Mississippian, introduces the Pennsylvania (Upper Carboniferous) system, and approximately represents the Millstone Grit of western Europe, as does the red conglomerate of Nova Scotia.

The shales of the Millstone Grit include thin beds of marine goniatites (*Glyptioceras bilinge, Gastrioceras carbonarium,* *Pterinopecten papyraceus,* and *Linguula mylitoidea,* while the grits contain *Lepidodendron, Sigmasoria* and calamites. In Scotland plants and estuarine fishes differ markedly above and below the Millstone Sandstone.

The English Millstone Grit produces a characteristic scenery of wild moorland plateaux, or alternations of shale-valleys and rugged grit-ridges. The grits furnish valuable building-stones and grinding-stones. They also afford an excellent water supply.

(C. B. W.)

**MILLVILLE,** a city of Cumberland county, New Jersey, U.S.A., on the Maurice river, 40 m. S. by E. of Philadelphia. Pop. (1890) 10,307; (1900) 19,583 (598 foreign-born; (1910) 22,549. It is served by the West Jersey & Seashore railway, by electric lines to Philadelphia, Bridgeton, Vineland and Fairton, and by schooners and small freight boats. Peaches and small fruit are cultivated extensively in the surrounding country. In the north part of the city is a large public park, in which a beautiful lake 3 m. long and about 1 m. wide has been formed by damming the river. Glass and moulding sand is found in the vicinity, and the city is engaged principally in the manufacture of glass (especially druggists’ ware). The value of the city’s factory products increased from $8,513,433 in 1900 to $9,719,417 in 1905, or 48%, and the total value in 1905, $23,324,197, of the value of the glass products. Millville was incorporated as a town in 1801, was chartered as a city in 1886, and its charter was revised in 1877.
MILMAN, HENRY HART (1791–1868), English historian and ecclesiastic, third son of Sir Francis Milman, Bart., physician to George III, was born in London on the 10th of November 1791, at a house in Bury Street, Eton and at Brasenose College, Oxford, his university career was brilliant. He gained the Newdigate prize with a poem on the Apollo Belvedere in 1812, was elected a fellow of Brasenose in 1814, and in 1816 won the English essay prize with his Comparative Estimate of Sculpture and Painting. In 1816 he was ordained, and two years later was presented to the living of St Mary's, Reading. Milman had already made his appearance as a dramatic writer with his tragedy Fazio (produced on the stage under the title Fyle) in 1814. His pastoral drama Blandula (1818) was much admired, as was his novel Yvonne de Braesne (1819), the subject of which was taken from British legend, the "bright city" being Gloucester; but he failed to invest it with serious interest. In subsequent poetical works he was more successful, notably the Fall of Jerusalem (1820) and the Martyr of Antioch (1822). The Influence of Byron is seen in his Belshazzar (1822). A tragedy, Anne Boleyn, followed in 1826; and Milman also wrote "When our heads are bowed with woe," and other hymns; an admirable version of the Sanskrit episode of Nala and Damayanti; and translations of the Apocalypse of St. John and the Eucharist. In 1826 he was elected professor of poetry at Oxford, and in 1827 he delivered the Bampton lectures on the character and conduct of the apostles as an evidence of Christianity. His poetical works were published in three volumes in 1839.

Turning to another field, Milman published in 1829 his History of the Jews, which is memorable as the first by an English clergyman who treated the Jews as an Oriental tribe, recognized sheikhs and amirs in the Old Testament, sifted and classified documentary evidence, and evaded or minimized the miracle. In consequence, the author was violently attacked and his inevitable preferment was delayed. In 1835, however, Sir Robert Peel made him rector of St Margaret's, Westminster, and canon of Westminster, and in 1849 he became dean of St Paul's. By this time his unpopularity had nearly died away, and generally revered and beloved, he occupied a dignified and enviable position, which he constantly employed for the promotion of culture and in particular for the relaxation of subscription to ecclesiastical formulaires. His History of Christianity to the Abolition of Paganism in the Roman Empire (1836) had been completely ignored; but widely different was the reception accorded to the continuation of his work, his great History of Latin Christianity (1835), which has passed through many editions. In 1838 he had edited Gibbon’s Decline and Fall of the Roman Empire, and in the following year published his Life of Gibbon. Milman was also responsible for an edition of Horace, and when he died he had almost finished a history of St Paul’s Cathedral, which was completed and published by his son, A. Milman (London, 1868), who also collected and published in 1879 a volume of his essays and articles. Milman died on the 24th of September 1868, and was buried in St Paul’s Cathedral. By his wife, Mary Ann, a daughter of Liet.-General William Cockell, he had four sons and two daughters. His nephew, Robert Milman (1816–1870), was bishop of Calcutta from 1867 until his death, and was the author of a Life of Torquato Tasso (1830).

MILNE-EDWARDS, HENRY (1800–1888), French zoologist, the son of an Englishman, was born in Bruges on the 23rd of October 1800, but spent most of his life in France. At first he turned his attention to medicine, in which he graduated at Paris in 1823; but his passion for natural history soon prevailed, and he gave himself up to the study of the lower forms of animal life. One of his earliest papers (Recherches anatomiques sur les crustacés), which was presented to the Academy of Sciences in 1829, formed the theme of an elaborate and eulogistic report by G. Cuvier in the following year. It embodied the results of two dredging expeditions undertaken by him and his friend J. V. Audouin during 1826 and 1828 in the neighbourhood of Granville, and was remarkable for clearly distinguishing the marine fauna of that portion of the French coast into four zones. Much of his original work was published in the Annales des sciences naturelles, with the editorship of which he was associated from 1834. Of his books may be mentioned the Histoire naturelle de crustacés (3 vols., 1837–1841), which long remained a standard work; Histoire naturelle des coralliaires, published in 1859–1860, but begun many years before; Leçons sur la physiologie et l'anatomie comparée de l'homme et des animaux (1857–1881), in 14 volumes, and 

MILNER, ALFRED MILNER, VISCOUNT (1854– ), British statesman and colonial administrator, was born at Bonn on the 23rd of March 1854, the only son of Charles Milner, M.D., whose wife, a daughter of Major-General Ready, sometime governor of the Isle of Man. His paternal grandfather, an Englishman, settled in Germany and married a German lady; and their son, Charles Milner, practised as a physician in London and became later Reader in English at Tübingen University. Alfred Milner was educated first at Tübingen, then at King's College, London, and under Jowett as a scholar of Balliol College, Oxford, from 1872 to 1876. He graduated in 1877, with a first class in classics, having won the Hertford, Craven, Eldon and Derby scholarships, and was elected to a fellowship of New College. At Oxford he formed a close friendship with Arnold Toynbee, and was associated with his schemes of social work; and subsequently he wrote a tribute to his friend, Arnold Toynbee: a Reminiscence (1893). In 1881 he was called to the bar at the Inner Temple and joined the staff of the Pall Mall Gazette under John Morley, becoming assistant editor under W. T. Stead. In 1885 he abandoned journalism, and became Liberal candidate for the Harrow division of Middlesex at the general election, but was defeated. In 1897 he succeeded to Mr (afterwards Lord) Goschen, and in 1887, when Goschen became chancellor of the exchequer, was appointed his principal private secretary. It was by Goschen's influence that in 1889 he was made under-secretary of finance in Egypt. He remained in Egypt four years, his period of office coinciding with the first great reforms, after the danger of bankruptcy had been avoided. Milner returned to England in 1892, and was appointed chairman of the Board of Inland Revenue, being made C.B. in 1894 and K.C.B. in 1895. Shortly after his return to England he published his England in Egypt, which at once became the authoritative account of the work done since the British occupation.

Sir Alfred Milner remained at the Board of Inland Revenue until 1897. He was regarded as one of the clearest-headed and most judicious officials in the British service, and his position as a man of moderate Liberal views, who had been so closely associated with Goschen at the Treasury, Cromer in Egypt and Hicks-Beach (Lord St Aldwyn) and Sir W. Harcourt while at the Inland Revenue, marked him out as one in whom all parties might have confidence. The moment for testing his capacity in the highest degree had now come. In April Lord Rosmead resigned his posts of high commissioner for South Africa and governor of Cape Colony. The situation resulting from the Jameson raid (see TRANSVAAL and SOUTH AFRICA) was one of the greatest delicacy and difficulty, and Mr Chamberlain, now colonial secretary, selected Milner as Lord Rosmead's successor. The choice was cordially approved by the leaders of the Liberal party, and warmly recognized at a farewell dinner presided over by Mr Asquith (March 28th, 1897).
appointment was avowedly made in order that an acceptable British statesman, in whom public confidence was reposed, might go to South Africa to consider all the circumstances, and to formulate a policy which should combine the upholding of British interests with the attempt to deal justly with the Transvaal and Orange Free State governments.

Colonel Alfred Milner reached the Cape in May 1897, and after the difficulties with President Kruger over the Aliens' Law had been patched up he was free by August to make himself personally acquainted with the country and peoples before deciding on the lines of policy to be adopted. Between August 1897 and May 1898 he travelled through Cape Colony, the Bechuanaland Protectorate, Rhodesia and Basutoland. The better to understand the point of view of the Cape Dutch and the burghers of the Transvaal and Orange Free State, Milner spent during this period both Dutch and the South African "Taal." He came to the conclusion that there could be no hope of peace and progress in South Africa while there remained the "permanent subjection of British to Dutch in one of the Republics." He also realized—as was shown by the triumphant re-election of Mr Kruger to the presidency of the Transvaal in February 1898—that the Pretoria government would never on its own initiative redress the grievances of the "Uitlanders." In a speech delivered at Graaf Reinet, a Bond stronghold, on the 3rd of March 1898, he made it clear that he was determined to secure freedom and equality for the British subjects. At the same time he sought to induce the Pretoria government to assimilate its institutions, and the temper and spirit of its administration, to those of the free communities of South Africa. The effect of this pronouncement was great, and it alarmed the Afrikanders, who at this time viewed with apprehension the virtual resumption by Cecil Rhodes of his leadership of the Progressive (British) party at the Cape. That Milner had good grounds for his view of the situation is shown in a letter written (March 12) by Mr J. X. Merriman to President Steyn of the Free State: "The greatest danger (wrote Mr Merriman) lies in the attitude of President Kruger and his vain hope of building up a State on a foundation of a narrow unenlightened minority, and his obstinate rejection of all prospect of using the materials which lie ready to his hand to establish a true republic on a broad liberal basis. Such a state of affairs cannot last. It must break down from inherent rottenness." Though this was recognized by the more far-seeing of the Bond leaders, they were ready to support Kruger, whether or not he granted reforms, and they sought to make Milner's position impossible. His difficulties were increased when at the general election in Cape Colony the Bond obtained a majority. Acting strictly in a constitutional manner, Milner thereupon (Oct. 1898) called upon Mr W. P. Schreiner to form a ministry, though aware that such a ministry would be opposed to any direct intervention of Great Britain in the Transvaal. Convinced that the existing state of affairs, if continued, would end in the loss of South Africa by Britain, Milner came to England in November 1898. He returned to the Cape in February 1899 fully assured of the support of Mr Chamberlain, though the government still clung to the hope that the moderate section of the Cape and Free State Dutch would intervene to induce the Pretoria government to assimilate the "Uitlanders." He found the situation more critical than when he had left, ten weeks previously. Johannesburg was in a ferment, while General Sir William Butler, who acted as high commissioner in Milner's absence, had allowed it to be seen that he did not take a favourable view of the Uitlander grievances. On the 4th of May Milner penned a memorable despatch to the Colonial Office, in which he insisted that the remedy for the unrest in the Transvaal was to strike at the root of the evil—the political impotence of the injured. It may seem a paradox," he wrote, "but it is true that the only way for protecting our subjects is to help them to rise to be our subjects." The policy of leaving things alone only led from bad to worse, and "the case for intervention is overwhelming." Milner felt that only the enfranchisement of the Uitlanders in the Transvaal would give stability to the South African situation. He had not based his case against the Transvaal on the letter of the Conventions, and regarded the employment of the word "suze- rainty" merely as an "etymological question," but he realized keenly that the spectacle of thousands of British subjects in the Transvaal in the condition of "helots" (as he expressed it) was undermining the prestige of Great Britain throughout South Africa, and he could not "resist" the impression that the true intention of the British government not to be ousted from its predominant position. This despatch was telegraphed to London, and was intended for immediate publication; but it was kept private for a time by the home government. Its tenor was known, however, to the leading politicians at the Cape, and at the instance of J. H. Hofmeyr a conference was held (May 31–June 5) at Bloemfontein between the high commissioner and the president of the Transvaal. Milner then made the enactment by the Transvaal of a franchise law which would at once give the Johannesburgers a share in the government of the country his main, and practically his only, demand. The conference ended without any agreement being reached, and the diplomatic discussion which followed (see TRANSVAAL) gradually became more and more contentious. When war broke out, October 1899, Milner rendered the military authorities "unfailing support and wise counsels," being, in Lord Roberts's phrase "one whose courage never faltered."

In February 1901 he was called upon to undertake the administra tion of the Transvaal and Orange Free State, both new annexed to the British Empire, though the war was still in progress. He therefore resigned the governorship of Cape Colony, while retaining the post of high commissioner. The work of reconstructing the civil administration in the Transvaal and Orange River Colony could only be carried on to a limited extent while operations continued in the field. Milner therefore returned to England to spend a "hard-begged holiday," which was, however, mainly occupied in work at the Colonial Office. He reached London on the 24th of May 1901, had an audience with the king on the same day, was made a G.C.B. and privy councillor, and was raised to the peerage with the title of Baron Milner of St James's and Cape Town. Speaking next day at a luncheon given in his honour, answering critics who alleged that with more time and patience on the part of Great Britain war might have been avoided, he asserted that what they were asked to "conciliate" was "panoplied hatred, insensate ambition, invincible ignorance." Meanwhile the diplomacy of 1899 and the conduct of the war had caused a great change in the attitude of the Liberal party in England towards Lord Milner, whom Mr Leom and Courta four even characterized as "a violent agitation for his recall, in which Sir Henry Campbell-Bannerman joined, was organized, but without success, and in August he returned to South Africa, where he plunged into the herculean task of remodelling the administration. In the negotiations for peace he was associated with Lord Kitchener, and the terms of surrender, signed at Pretoria on the 31st of May 1902, were drafted by him. In recognition of his services he was, on the 15th of July, made a viscount.

Immediately following the conclusion of peace Milner published (June 21) the Letters Patent establishing the government of the Transvaal and Orange River colonies, and exchanging his title of administrator to that of governor. The reconstructive work necessary after the ravages of the war was enormous. He provided a steady revenue by the levying of a tax of 10% on the annual net produce of the gold mines, and devoted special attention to the reparation of the Boers, land settlement by British colonists, education, justice, the constabulary, and the development of railways. While this work of reconstruction was in progress domestic politics in England were convulsed by the tariff reform movement and Mr Chamberlain's resignation. Milner, who was then spending a brief holiday in Europe, was urged by Mr Balfour to take the vacant post of secretary of state for the colonies. This offer he declined (Oct. 1, 1903), considering it more important to complete his work in South Africa, where economic depression
was becoming pronounced. He was back in Johannesburg in December 1903, and had to consider the crisis in the gold-mining industry caused by the shortage of native labour. Reluctantly he agreed, with the assent of the home government, to the proposal of the mineowners to import Chinese coolies on a three years' contract, the first batch of Chinese reaching the Rand in June 1904.

In the latter part of 1904 and the early months of 1905 Lord Milner was engaged on the elaboration of a scheme to provide the Transvaal with a system of "representative" government, a half-way house between crown colony administration and that of self-government. Letters patent providing for representative government were issued on the 31st of March 1905.1 For some time he had suffered in health from the incessant strain of work, and he determined to retire. He left Pretoria on the 2nd of April and sailed for Europe on the following day. Speaking at Johannesburg on the eve of his departure, he recommended to all concerned the promotion of the material prosperity of the country and the treatment of Dutch and British on an absolute equality. Having referred to his share in the war, he added: "What I should prefer to be remembered for is not the tremendous effort subsequent to the war not only to repair the ravages of that calamity but to re-start the colonies on a higher plane of civilization than they have ever previously attained." He left South Africa while the economic crisis was still acute and at a time when the voice of the critic was audible everywhere; but, in the words of the colonial secretary (Mr Alfred Lyttelton) he had in the eight eventful years of his administration "laid deep and strong the foundation upon which a united South Africa would arise to become one of the great states of the empire." 2 On his return home his university honoured him with the honorary degree of D.C.L.

Experience in South Africa had shown him that underlying the difficulties of the situation there was the wider problem of imperial unity. In his farewell speech at Johannesburg he concluded with a reference to the subject. "When we who call ourselves Imperialists think of the British Empire we think of a group of states bound, not in an alliance—for alliances can be made and unmade—but in a permanent organic union. Of such a union the dominions of the sovereign as they exist to-day are only the raw material." This thesis he further developed in a magazine article written in view of the colonial conference held in London in 1907. He advocated the creation of a permanent deliberative imperial council, and favoured preferential trade relations between the United Kingdom and the other members of the empire; and in later years he took an active part in advocating the cause of tariff reform and colonial preference.

In March 1906 a motion censuring Lord Milner for an infraction of the Chinese labour ordinance, in not forbidding light corporal punishment of coolies for minor offences in lieu of imprisonment, was moved by a Radical member of the House of Commons. On behalf of the Liberal government an amendment was moved, stating that "This House, while recording its condemnation of the flogging of Chinese coolies in breach of the law, desires, in the interest of peace and conciliation in South Africa, to refrain from passing censure upon individuals." The amendment was carried by 355 votes to 135. As a result of this left-handed censure, a counter-demonstration was organized, led by Sir Bartle Frere, and a public address, signed by over 370,000 persons, was presented to Lord Milner expressing high appreciation of the services rendered by him in Africa to the crown and empire.

MILNER, JOSEPH (1744–1797), English evangelical divine, was born at Leeds and educated at Leeds grammar-school and Cambridge. After taking his degree he went to Thorparch, 1 Owing to the advent of a Liberal ministry in England in 1903, this scheme remained inoperative (see TRANSVAAL: History).

Yorkshire, as curate and assistant schoolmaster. Subsequently he became head master of Hull grammar-school, and in 1768 he was chosen afternoon lecturer at Holy Trinity church, Hull. He became a strong supporter of the evangelical movement of the period, and greatly contributed to its success in Hull. In addition to his work as head master, he took charge of North Ferriby parish, about 9 m. from Hull. His published works include essays and numerous sermons, but his best known work is the History of the Church of Christ (London, 1794–1805). His other publications included the three volumes rendered by his brother, Isaac Milner (1750–1826), dean of Carlisle, who re-edited the whole work in 1810.

MILNGAVIE (locally pronounced Millguy), a police burgh of Dumbartonshire, Scotland. Pop. (1901), 3481. It lies 6 m. N.N.W. of Glasgow by the North British railway. The chief industries include bleach-fields, dye-works, a distillery and a paper mill; but the town is largely a residential quarter for Glasgow business men. Close to the town are two reservoirs, Mugdock (62 acres) and Craigmaddle (58 acres), in which is stored the water from Loch Katrine. Mugdock Castle, r. m. N.W. of Milngavie, is an old stronghold of the Grants; in Balder- nock parish, about 2 m. E., stands a cromlech, called "the Auld Wives Lift" (400 ft. high), commanding a fine view of the lands between the Forth and Clyde. Dougallston Loch, l m. S.E., contains several rare aquatic plants.

MILO, or MILON, of Crotona, Greek athlete, lived about the end of the 6th century B.C. He was six times crowned at the Olympic games and six times at the Pythian for wrestling, and was famous throughout the civilized world for his feats of strength—such as carrying an ox on his shoulders through the stadium at Olympia. In his native city he was much honoured, and he commanded the army which defeated the people of Sybaris in 511. The traditional account of his death is often used to point a moral: he found a tree which some woodcutters had partially split with a wedge, and attempted to rend it asunder; but the wedge fell out, and the tree closed on his hand, imprisoning him till wolves came and devoured him. His name became proverbial for personal strength (Diód. Sic. xii. 9; Pausanias vi. 14; Strabó vi. 263; Herodotus iii. 137).

MILO TITUS ANNUS, Roman political agitator, was the son of C. Papius Celsius, but was adopted by his mother's father, T. Annius LusCUS. He joined the Pompeian party, and organized bands of mercenaries and gladiators to support the cause by public violence in opposition to P. Clodius, who gave similar support to the democratic cause. Milo was tribune of the plebs in 57 B.C. He took a prominent part in bringing about the recall of Cicero from exile, in spite of the opposition of Clodius. In 53, when Milo was candidate for the consulship and Clodius for the praetorship, the two leaders met by accident on the Applian Way at Boviliae and Clodius was murdered (January 52). Milo was impeached; his guilt was clear, and his enemies took every means of intimidating his supporters and his judges. Cicero was afraid to speak, and the extant Pro Milone is an expanded form of the unspoken defence. Milo went into exile at Massilia, and his property was sold by auction. He joined M. Caecilius Rufus in 48 in his rising against Caesar, but was slain near Thurii in Lucania. His wife was Fausta, daughter of the dictator Sulla.

MILO OF GLOUCESTER, lord of Brecknock and earl of Hereford (d. 1143), was the son of Walter of Gloucester, who had inherited the magnate title of Milo of Cahir between 1104 and 1123. Milo succeeded his father about the latter year. He was high in the service of Henry I. between 1130 and 1135, and combined the office of sheriff with that of local justice for Gloucestershire. After the death of Henry I. he declared for Stephen, at whose court he appears as constable in 1136. But in 1139, when the empress Matilda appeared in England, he declared for her, and placed the city of Gloucester at her disposal; he was further distinguished by sacking the royalist city of Worcester and reducing the county of Hereford. In 1141, at Matilda's coronation, he was rewarded with the earldom of
Hereford. He remained loyal to the empress after her defeat at Winchester. John of Salisbury classes him with Geoffrey de Mandeville and others who were non tam comites regni quam hostes publici. The charge is justified by his public policy; but the materials for appraising his personal character do not exist.

See the Continuation of Florence of Worcester (ed. B. Thorpe, 1842-1846); the Cartulary of Gloucester Abbey (Rolls series); and J. H. Round's Geoffrey de Mandeville (1892).

MILORADOVICH, MICHAEL ANDRIJEVICH, Count (1770-1829), Russian general, saw service under Suvarov in the wars against Turkey and Poland, and in the campaign of Italy and Switzerland (1790) earned much distinction as a commander of advanced troops. In 1804, having attained the rank of lieutenant-general, he served under Kutusov in the campaign of Austerlitz, taking part in the actions of Enns and Krems and in the decisive battle of the 2nd of December, in which his column held the Pratzen heights. In the Turkish War he distinguished himself at Gjurgevo (1807). Promoted general of infantry in 1816, he commanded a corps at Borodino, and subsequently inflicted the defeat of the 2nd Consular Guard of Napoleon on Murat, king of Naples (October 18, 1812). His corps was one of those most active in the pursuit of Napoleon's Grande Armée, and in 1813 he led the rear-guard of the Allies after their earlier defeats. At the victory of Kulm he was present in command of a Russian-Prussian corps, which he led at Leipzig and in the campaign of 1814. From 1818 to the time of his death he was military governor of St Petersburg. He perished in the popular outbreak in the capital, on the 26th (14th B.S.) of December 1825.

MILORADOVIĆ, MILOŠ (1780-1826), prince of Servia, founder of the Obrenovich dynasty, was born in 1780 of poor Servian peasants. When he later became prince of Servia he used to tell how for a penny a day he drove cattle from Servia to Dalmatia. His half-brother, Milan Obrenovich, who had developed into a successful exporter of cattle and pigs into Austria, associated him in his own export trade and otherwise supported him. Partly from gratitude and partly because the family name of his half-brother was already honourably known in the country, Milosh adopted that name as his own, and called himself Obrenovich, instead of Theodorovich. Karageorge named the first of the Obrenovich (Vuković) on Turks, appointed Milosh Obrenovich in 1807 a voivode, i.e. district commander of the national army and civil administrator. As such he distinguished himself in many battles, and was reputed a wise and energetic administrator and a just judge. When in 1813 the Turks under the Grand Vizier Khurshid occupied Servia, and Karageorge and almost all his Vovodes left the country for Austria, Milosh, although strongly advised to follow their example, refused to do so. He remained in the country, surrendered to the Turks, and was recognized by them as the voivode of Rudnik (Central Servia). As he was then practically the only chief of the nation, the Turks called him to Belgrade, where he was kept through the year 1814 as a hostage. But he found means to prepare a new rising of the Servians against the Turks, and on Palm Sunday 1815 he appeared with his voivode's standard before the people round the small church of Takovo, and started the second and successful insurrection. Not so much by his victories on the battlefields as by his clever exploitation of the international difficulties of Turkey, and of the known weakness of the Turkish pashas for "takkeesh"—no doubt also by his statesmanlike moderation, he succeeded in levelling the way for the Porte through recognition of the Servian people's right to self-government. The National Assembly in 1817 elected him prince of Servia.

From that year began the organization of Servia by the Servians as an autonomous province of the Ottoman Empire. But its existence as such rested on no safe and legal basis, except on the readiness of the Servians to defend it with all their might and on the goodwill of the sultan and his "Sublime Porte." Milosh therefore worked hard to obtain some sort of international recognition of the semi-independent status of Servia. Russia came to his assistance, and by the Treaty of Adrianople of 1829 the Porte engaged formally to grant Servia full autonomy. This engagement was somewhat developed in the Hatt-i-sheykh of 1830, which added to Servia three districts (Krushevats, Alexinats, Zachar), acknowledged her, full autonomy, recognized Milosh as hereditary prince of Servia, and declared that the Turks in Servia could have properties and live only in fortified places where there were Turkish garrisons, and not in other towns and villages. Milosh won for his country the hereditary right to the throne of Servia without the co-operation of Russia. The creation of a hereditary dynasty in Servia was outside the Russian Balkan policy of that time, and this great and independent success of Milosh was the first cause of Russia's dissatisfaction with him. The second cause was that, yielding to the pressure exercised on him by his own people, he gave the country a constitution without asking "the protector of Servia," the tsar, for his approval of the step. The third cause was that Milosh consistently resented the interference of Russia in the internal affairs of the principality. The names of his misdeeds, from the Russian point of view, was that on the occasion of his visit to the Sultan Mahmud II. in 1836 he persuaded the British ambassador, Lord Ponsonby, that it would be useful to establish a British consulate in Belgrade. The first British consul in Servia, Colonel Hodges, became speedily an intimate friend of Prince Milosh, who—probably under his new friend's influence—began to agitate to replace the exclusive protectorate of Russia by the joint protectorate of all the great Powers of Europe. The cabinet of St Petersburg now decided to remove Milosh from the throne of Servia, and supported by the Russian consul-general, the leaders of the Servian opposition, who posed as champions of a constitutional system, succeeded in forcing him to abdicate in 1839. After his abdication Milosh lived mostly on his estates in Rumânia, or in Vienna. In December 1858 the National Assembly of Servia, having dethroned Prince Alexander Karageorgevich, recalled Milosh to the throne of Servia. Milosh came, accompanied by his son Michael, and began to reign in his old fashion; but death closed his activity on the 14th (27th B.S.) of September 1860. He was buried in the cathedral of Belgrade.

MILITADES, the name of two Athenian statesmen and generals of a family (the Philaidæ) of Aeginaean origin, which claimed descent from Aeacus.

1. MILITADES (6th century B.C.), the son of Cypselus, a prominent opponent of Peisistratus. According to Herodotus (vi. 36, 37) he led a colony to the Thracian Chersonese at the request of the Doloncians, who, hard pressed by the Absinthians (or Apsinthians), were advised by the Delphian oracle to invite to their country the man who should first show them hospitality after leaving the temple. Since, however, the Athenians had from c. 600-590 B.C. held Sigeum in the Troad, whence they had fought against Miletus, it is probable that the Doloncians appealed for help to Athens, and that Peisistratus took the opportunity of getting rid of one of his chief opponents by sending Militades. He became "tyrant" of the Chersonesus, which he fortified by a wall across the isthmus from Cardia to Pactia. He was captured by the people of Lampascus, but released on the intercession of Croesus of Lydia. He was succeeded by Steasagoras, son of his half-brother, Cimon.

2. MILITADES (died c. 488 B.C.), the victor of Marathon, was another of Cimon's sons. On the death of Steasagoras (probably 516-516) by Hippias—no doubt to support Hegesistratus at Sigeum (see PEISISTRATUS). He entraped and imprisoned the chief men of Chersonesus, which was then in a turbulent condition, and strengthened himself by an alliance with Hegesippyle, daughter of the Thracian prince Olorus (Herod. vi. 39). He led a contingent in the Scythian expedition of Darius Hystaspis and, according to Herodotus, advised the leaders who were left at the Danube bridge to destroy it and leave Darius to his fate. This story is improbable, as Darius left Militades in possession of the Chersonese for some
MILTON

twenty years longer, though Persian forces were frequently in the neighbourhood. Miltiades was, according to Herodotus, expelled by Scythian invaders, but was brought back by the Dolonians, and subsequently captured. All this is known is

Athens for ten years, and so-called Persian inhabitants, who were

independent. Having thus (probably) incurred the enmity of Darius, Miltiades fled to Athens on the approach of the Persians under Datis and Artaphernes, leaving his son Metiochus a prisoner in Persian hands, and was at once impeached unsuccessfully on the charge of tyranny in the Chersonese.1

Possibly the story of his having tried to destroy the Danube bridge was invented or exaggerated at this time as an argument in his favour (see Grote, History of Greece, 1 vol., ed. 1867, p. 119 note). Since, however, Herodotus says that Miltiades had

Alcmaeonid tradition, which was hostile to Miltiades, the whole story is uncertain; the statement that he fled before a Scythian invasion is especially improbable. If Miltiades really recommended the destruction of the bridge, we may infer that the Herodotean story of his flight before the Scyths is a misunderstanding of the fact that his residence in Chersonese after the Scythian invasion was insecure and not continuous.

On the approach of the Persians Miltiades was made one of the ten Athenian generals, and it was on his advice that the polemarch Callimachus decided to give them a fleet of seventy ships without any indication of his object (Herod. vi. 132-136). Cornelius Nepos (Miltiades, c. vii.), probably on good authority (2 Eph- orus), states that he had a commission to regain control over the Aegaean. No doubt his object was to establish an outer line of defence against future Persian aggression. Herodotus says that, having besieged Paros vainly for nearly a month, he made a secret visit to Timo, a priestess of Demeter in Paros, with a view to the betrayal of the island, and being compelled to flee wounded himself severely in attempting to leap a fence (but see Ephorus in Pryn. hist. gr. 197).

On his return to Athens he was impeached by Xanthippus, who was allied by marriage to the Alcmaeonids, on the ground that he had "deceived the people," and only escaped on the strength of his past services with a fine of 50 talents. The facts of the trial and the charge are difficult to recover, nor do we know why the siege was raised. Some authorities hold that he was bribed to this course, and hence that the charge was one of treason; others suggest that he retired in the belief that a Persian fleet was approaching. The Persian text states that he died of his wound (480-481), without paying the fine, which was paid subsequently by his son Cimon (q.v.). He appears to have been a man of strong determination and great personal courage, of a type characteristic of the pre-Cleisthenic constitution. His absence in the Chersonese during the first years of the new democracy (508-493?) and his patrician lineage account naturally for the difference which existed between him and the popular leaders—Themistocles and Aristides.

See the passages of Herodotus and Cornelius Nepos, quoted above, and histories of Greece. On the Parian expedition and the trial, R. W. Macan, Herodotus iv.—vi., vol. 2, appendix xi.; on the foreign policy of Miltiades see THEMISTOCLES.

(J. M. M.)

MILTON, JOHN (1608—1674). English poet, was born in Bread Street, Cheapside, London, on the 9th of December 1608. His father, known as Mr John Milton of Bread Street, scrivener, was himself an interesting man. He was a native of Oxfordshire, the son of a Richard Milton, yeoman of Stanton-St-John's, one of the sturdiest adherents to the old Roman Catholic religion in his district, and was educated at Christ Church, Oxford, where he turned Protestant. According to the poet's earliest biographer, John Milton senior was disinherited in the beginning of Queen Elizabeth's reign for reading the Bible. With a good education and good abilities, especially in music, he may have lived for some time in London by musical teaching and practice.

Dissatisfied with this story, it is difficult to believe in view of the fact that the family of Miltiades was distinctively Musophaenos. Possibly the trial is merely a horrible version of the ordinary test of a man's qualification for office (boxwaria). Not till 1595, at all events, when he must have been long past the usual age of apprenticeship, do we hear of his preparation for the profession of a scrivener; and not till February 1599-1600, when he was about thirty-seven years of age, did he become a qualified member of the Scriveners' Company. It was then that he set up his "house and shop" at the sign of the Spread Eagle in Bread Street, and began his business of drawing up wills, marriage-settlements, and the like, with such related business as that of receiving money from clients for investment and lending it out to the best advantage. It was at the same time that he married, not, as stated by Aubrey, a lady named Bradshaw, but Sarah Jeffreys, one of the two orphan daughters of a Paul Jeffrey, London scrivener, and befriended by "citizen and merchant-taylor," originally from Essex, who had died before 1582. Most of the date of her marriage she was about twenty-eight years of age.

Six children were born to the scrivener and his wife, of whom three survived infancy—Anne, who married Edward Phillips; John, the poet; and Christopher (1615—1693), who was knighted and made a judge under James II.

The first sixteen years of Milton's life, coinciding exactly with the last sixteen of the reign of James I., associate themselves with the house in Bread Street. His father, while prospering in business, continued to be known as a divine, of high reputation for scholarship and teaching ability, in the London musical world of that time. He contributed a madrigal to Thomas Morley's Triumph of Oriana (1601), four motets to Sir William Leighton's Tears and Lamentations of a Sorrowful Soul (1614), and some hymn tunes—one of which, "Yor," is still in common use—in Thomas Ravenscroft's Whole Book of Psalms (1621). Music was thus a part of the poet's domestic education from his infancy. Again and again Milton speaks with gratitude and affection of the ungrudging pains bestowed by his father on his early education. "Both at the grammar school and also under other masters at home," he says in the statement in one passage, "he brought me up with daily." When Milton was ten years of age his tutor was Thomas Young (1587—1653), a Scottish divine, who afterwards became master of Jesus College, Cambridge. Young's tutorship lasted till 1622, when he accepted the pastorship of the congregation of English merchants in Hamburg. Already, however, for a year or two his teaching had been only supplementary to the education which the boy was receiving by daily attendance at St Paul's public school, close to Bread Street. The headmaster of the school was Alexander Gill, an elderly Oxford scholar of high reputation for scholarship and teaching ability. Under him, as usher or second master, was his son, Alexander Gill the younger, also an Oxford graduate of scholarly reputation, but of blustering character. Milton's acquaintanceship with this younger Gill, begun at St Paul's school, led to subsequent friendship and correspondence. More affectionate and intimate was the friendship formed by Milton at St Paul's with his schoolfellow Charles Diodati, the son of an Italian physician, Dr Theodore Diodati, a naturalized Englishman, settled in London, and much respected, both on his own account and as being the brother of the famous Protestant divine, Jean Diodati, of Geneva and Rome. Diodati, who was destined for his father's profession, left the school for Trinity College, Oxford, early in 1623; but Milton remained till the end of 1624. In that year his elder sister, Anne, married Edward Phillips, a clerk in the Government office called the Crown Office in Chancery.

Milton had then all but completed his sixteenth year, and was as scholarly, as accomplished and as handsome a youth as St Paul's school had sent forth. We learn from himself that his exercises "in English or other tongue, prosing or versing, but chiefly this latter," had begun to attract attention even in his boyhood. Of these poems the only specimens that now remain are two copies of Latin verses, preserved in a commonplace book of his (printed by the Camden Society in 1877), and his "Paraphrase on Psalm CXIV" and his "Paraphrase on Psalm CXXXVI." At the age of sixteen years and two months, Milton was entered as a student of Christ's College, Cambridge,
in the grade of a "Lesser Pensioner," and he matriculated two months later, on the 9th of April 1625. The master of Christ's was Dr Thomas Bainbrigge; and among the thirteen fellows were Joseph Meade, still remembered as a commentator on the Apocalypse, and William Chappell, afterwards an Irish bishop. It was under Chappell's tutelage that Milton was placed when he first entered the college, between three and four years old, who entered Christ's after Milton, but during his residence, deserve mention. One was Edward King, a youth of Irish birth and high Irish connections, who entered in 1626, at the age of fourteen, another was John Cleveland, afterwards known as royalist and satirist, who entered in 1627; and the third was Henry More, subsequently famous as the Cambridge Platonist, who entered in 1631, just before Milton left. Milton's own brother, Christopher, joined him in the college in February 1630-1631, at the age of fifteen.

Milton's academic course lasted seven years and five months, bringing him from his seventeenth year to his twenty-fourth. The first four years were his time of undergraduate study. It was in the second of these—the year 1626—that there occurred the quarrel between him and his tutor, Chappell, which Mr Johnson, making the most of a lax tradition from Aubrey, magnified into the supposition that Milton may have been one of the last students in either of the English universities that suffered the indignity of corporal punishment. The legend deserves no credit; but it is certain that Milton, on account of some disagreement with Chappell, left college for a time, though he did not lose his term; and that when he did return, he was transferred from the tutorship of Chappell to that of Nathaniel Tovey. From the first of the Latin elegies one infers that the cause of the quarrel was some outbreak of self-assertion on Milton's part. We learn indeed, from words of his own elsewhere, that it was not only Chappell and Bainbrigge that he had offended by his independent demeanour, but that, for the first two or three years of his undergraduate study, he was generally unpopular, for the same reason, among the younger men, and that at his age, he had nicknamed him "the Lady,"—a nickname which the students of the other colleges took up, converting it into "the Lady of Christ's"; and, though the allusion was chiefly to the peculiar grace of his personal appearance, it conveyed also a sneer at what the rougher men thought his unusual prudishness, the haughty fastidiousness of his tastes and morals. A change in this state of things had certainly occurred before January 1628-1629, when, at the age of twenty, he took his B.A. degree. By that time his intellectual pre-eminence had come to be acknowledged. His reputation for scholarship and literary genius, extraordinary even then, was more than confirmed, and obligations required he thought it better to preserve a blameless sanctity where the spirit of indifference had already begun with servitude and forswearing. In other words, he was disgusted with the system which Laud was establishing and maintaining in the Church of England. "Church-outed by the prelates," as he emphatically expresses it, he seems to have thought for a time of the law, but he decided that the only life possible for himself was one dedicated wholly to scholarship and literature. His compunctions on this subject, expressed already in his sonnet on arriving at his twenty-third year, are expressed more at length in an English letter of which two drafts are preserved in Trinity College, Cambridge, sent by him, shortly after the date of that sonnet, and with a copy of the sonnet included, to some friend who had been corres-ponding with him on his "belatedness" and his persistence in a life of mere dream and study. There were gentle remonstrances also from his excellent father. Between such a father and such a son, however, the conclusion was easy. What it was may be learnt from Milton's fine Latin poem Ad patrem. There, in the midst of an enthusiastic recitation of all that his father had done for him hitherto, it is intimated that the agreement of the oaths and obligations required he thought it better to preserve a blameless sanctity where the spirit of indifference had already begun with servitude and forswearing.

It was part of a pastoral masque performed by the young people of the noble family of Egerton before the countess-dowager, 1

1 See the preface to Book II. of his Reason of Church Government (1641-1642), which is of great biographical interest.
MILTON

of Derby, at her mansion of Harslow, about 10 m. from Horton. That Milton contributed the words for the entertainment was, almost certainly, owing to his friendship with Henry Lawes, who supplied the music. Next in order among the compositions at Horton may be mentioned the three short pieces, "At a Solemn Music," "On Time," and "Upon the Circumcision"; after which comes Comus, the largest and most important of all Milton's minor poems. The name by which that beautiful drama is now universally known was not given to it by Milton himself. He entitled it, more simply and vaguely, "A Masque presented at Ludlow Castle 1634, on Michaelmas night, before John Earl of Bridgewater, Lord President of Wales" (1637). The earl of Bridgewater, the head of the Egerton family, had been appointed president of the council of Wales; among the festivities on his assumption of the office, a great masque was arranged in the hall of Ludlow Castle, his official residence. Lawes supplied the music and was stage manager; he applied to Milton for the poetry; and on Michaelmas night, the 29th of September 1634, the drama furnished by Milton was performed in Ludlow Castle before a great assembly. There sobriety and dignity of the writer, paity, Lawes taking part of the "attendant spirit," while the parts of "first brother," "second brother" and "the lady" were taken by the earl's three youngest children, Viscount Brackley, Mr Thomas Egerton and Lady Alice Egerton.

From September 1634 to the beginning of 1637 is a comparative blank in our records. Straggling incidents in this blank are a Latin letter of date December 4, 1634, to Alexander Gill the younger, a Greek translation of "Psalm CXIV.," a visit to Oxford in 1635 for the purpose of incorporation in the degree of M.A. in that university, and the beginning in May 1636 of a troublesome lawsuit against his now aged and infirm father. The lawsuit, which was instituted by a certain Sir Thomas Cotton, bart., nephew and executor of a deceased John Cotton, Esq., accused the elder Milton and his partner Bower, or both, of having, in their capacity as scriveners, missappropriated divers large sums of money that had been entrusted to them by the deceased Cotton to be let out at interest.

The lawsuit was still in progress when, on the 3rd of April 1637, Milton's mother died, at the age of about sixty-five. A flat blue stone, with a brief inscription, visible on the chancel-pavement of Horton church, still marks the place of her burial. Milton's testimony to her character is that she was "a most excellent mother and particularly known for her charities through the neighbourhood." The year 1637 was otherwise eventful. It was in that year that his Comus, after lying in manuscript for more than two years, was published by itself, in the form of a small quarto of thirty-five pages. The author's name was withheld, and the entire responsibility of the publication was assumed by Henry Lawes. Milton seems to have been in London when the little volume appeared. He was a good deal in London, at all events, during the summer and autumn months immediately following his mother's death. The plague, which had been on one of its periodical visits of ravage through England since early in the preceding year, was then especially severe in the Horton neighbourhood, while London was comparatively free. It was probably in London that Milton heard of the death of Edward King, who had sailed from Chester for a vacation visit to his relatives in Ireland, when, on the 28th of August, the ship in perfectly calm weather struck on a rock and went down, he and nearly all the other passengers going down with her. There is no mention of this event in Milton's two Latin "Familiar Epistles" of September 1637, addressed to his friend Charles Diodati, and dated from London; but in November 1637, and probably at Horton, he wrote his matchless pastoral monody of Lycidas. It was his contribution to a collection of octavo verses, Greek, Latin and English, inscribed to the memory of Edward King by his numerous friends in Cambridge and elsewhere. The collection appeared early in 1638. The second part contained thirteen English poems, the last of which was Milton's monody, signed only with his initials "J. M."

Milton was then on the wing for a foreign tour. He had long set his heart on a visit to Italy, and circumstances now favoured his wish. The vexatious Cotton lawsuit, after hanging on for nearly two years, was at an end, as far as the elder Milton was concerned, with the most absolute and honourable vindication of his character for probity, though with some continuation of the case against his partner, Bower. Moreover, Milton's younger brother Christopher, though but twenty-two years of age, and just about to be called to the bar of the Inner Temple, had married; and the young couple had gone to reside at Horton to keep the old man company.

Before the end of April 1638 Milton was on his way across the channel, taking one English man-servant with him. At the time of his departure the last great news in England was that of the National Scottish Covenant. To Charles the news of this "damnable Covenant," as he was calling it, was enraging beyond measure; but to the mass of the English Puritans it was far from unwelcome, promising, as it seemed to do, for England herself, the subversion at last of that system of the Inquisition for his astrological studies. While the court at Westminster had been groaning since the contemptuous dissolution of Charles's third parliament ten years before. Through Paris, where Milton received polite attention from the English ambassador, Lord Scudamore, and had the honour of an introduction to the famous Hugo Grotius, then ambassador for Sweden at the French court, he moved on rapidly to Italy, by way of Nice. After visiting Genoa, Leghorn and Pisa, he arrived at Florence, in August 1638. Enchanted by the city and its society, he remained there two months, frequenting the chief academies or literary clubs, and even taking part in their proceedings. Among the Florentines with whom he became intimate were Jacopo Gaddi, founder of an academy called the Svolgiliati, young Carlo Dati, author of "Vite de' pittori antichi, Pietro Frescobaldi, Agostino Coltellini, the founder of the Academy of the Apatisti, the grammarian Benedetto Buonmattei, Valerio Chimenti, afterwards professor of Greek at Pisa, Antonio Francini and Antonio Malatesti. It was in the neighbourhood of Florence also that he "found and visited" the great Galileo, then old and blind, and still nominally a prisoner to the Inquisition for his astrological studies.

By way of Florence and Siena, he reached Rome some time in October, and spent about another two months there, not only going about among the ruins and antiquities and visiting the galleries, but mixing also, as he had done in Florence, with the learned society of the academies. Among those with whom he formed acquaintance in Rome were the German scholar, Lucas Holstenius, librarian of the Vatican, and three native Italian scholars, named Alessandro Cherubini, Giovanni Salmi and a certain Selvaggi. There is record of his having dined once, in company with several other Englishmen, at the hospitable table of the English Jesuit College. The most picturesque incident, however, of his stay in Rome was his presence at a great musical entertainment in the palace of Cardinal Francesco Barberini. Here he had not only the honour of a specially kind reception by the cardinal himself, but also, it would appear, the supreme pleasure of listening to the marvellous Leonora Baroni, the most renowned singer of her age.

Late in November he left Rome for Naples. Here he met the aged Giovanni Battista Manso, marquis of Villa (1560–1643), the friend and biographer of Tasso, and subsequently the friend and patron of Marini. He had hardly been in Naples a fortnight, however, when there came news from England which not only stopped an intention he had formed of extending his tour to Sicily and thence into Greece, but urged his immediate return home. "The sad news of civil war in England," he says, "called me back; for I considered it base that, while my fellow-countrymen were fighting at home for liberty, I should be travelling at my ease for intellectual culture" (Defensio secunda). In December 1638, therefore, he set his face northwards; and

1 This interview forms the subject of one of W. S. Landor's Imaginary Conversations.
MILTON

483

again. His return journey, however, probably because he learnt that the news he had first received was exaggerated or premature, was broken into stages. He spent a second January and February (1638–1639) in Rome, in some danger, he says, from the judicial politics because the English Jesuits in Rome had taken offence at his habit of free speech, wherever he went, on the subject of religion. From Rome he went to Florence, his second visit to the city, including an excursion to Lucca, extending over two months; and not till April 1639 did he take his leave, and proceed, by Bologna and Ferrara, to Venice. About a month was given to Venice; and thence, having shipped for England the books he had collected in Italy, he went on, by Verona and Milan, over the Alps, to Geneva. 

In this Protestant city he spent a week or two in June, forming interesting acquaintance with new sights there, and having daily conversations with the great Protestant theologian Dr Jean Diodati, the uncle of his friend Charles Diodati. From Geneva he returned to Paris, and so to England. He was home again in August 1639, having been absent in all fifteen or sixteen months.

Milton’s Continental tour, and especially the Italian portion of it, which he describes at some length in his Defensio secunda, remained one of the chief pleasures of his memory through all his subsequent life. Nor was it without fruits of a literary kind. Besides the two of his Latin Epistolae familiares, one to the Florentine grammarian, another to the last of the family of Lucas Holstenius, there have been assigned to Milton’s sixteen months on the Continent his three Latin epigrams Ad Leonoram Romae canoneum, his Latin season Ad Salsillum poetae romanum agrotanum, his fine Latin hexameters entitled Manus, addressed to Giovanni Battista Manso, and his five Italian sonnets, with a canzone, in praise of a Bolognese lady.

His bosom friend and companion from boyhood, Charles Diodati, died in Blackfriars, London, in August 1638, not four months after Milton had gone away on his tour. The infinity of their mutual affections was never reversed. Probably not till his second stay in Florence; and, though he must have learnt some of the particulars from his friend’s uncle in Geneva, he did not know them fully till his return to England. How profoundly they affected him appears from his Epitaphium Damonis, then written in memory of his dead friend. The importance of this poem in Milton’s biography cannot be overrated. It is perhaps the noblest of all his Latin poems; and, though written in the artificial manner of a pastoral, it is unmistakably an outburst of the most passionate personal grief. In this respect two of his own Latin Epistolae familiaries perfect though that poem is, can be compared with it; and it is only the fact that Lycidas is in English, while the Epitaphium Damonis is in Latin, that has led to the notion that Edward King of Christ’s College was peculiarly and pre-eminentely the friend of Milton in his youth and early manhood.

We should not have known, but for an incidental passage in the Epitaphium Damonis, that, at the time of his return from Italy, he had chosen a subject for a great poem from the Arthurian legend. The passage (lines 160–170) is one in which, after referring to the hopes of Diodati’s medical career so suddenly dashed, Milton speaks of his distress himself and of his own projects in his profession of literature. Milton wrote that he was meditating an epic of which King Arthur was to be the central figure, but which should include somehow the whole cycle of British and Arthurian legend. This epic was to be in English, and he had resolved that all his poetry for the future should be in the same tongue.

Not long after Milton’s return the house at Horton ceased to be the family home. Christopher Milton and his wife went to reside at Reading, taking the old gentleman with them, while Milton himself preferred London. He had first taken lodgings in St Bride’s Churchyard, at the foot of Fleet Street; but, after, while probably early in 1640, he removed to a “pretty garden house” of his own, at the end of an entry, in the part of Aldersgate Street which lies immediately on the city side of what is now Maidenhead Court. His sister, whose first husband had died in 1631, had married a Mr Thomas Agar, his successor in the Crown Office; and it was arranged that her two sons by her first husband should be educated by their uncle. John Phillips, the younger of them, only nine years old, had boarded with him in the St Bride’s Churchyard lodgings; and his other nephew, Edward Phillips, only a year older, followed him. Gradually a few other boys, the sons of well-to-do personal friends, joined the two Phillipses, whether as boarders or for daily lessons, so that the house in Aldersgate Street became a small private school.

The Arthurian epic had been given up, and his mind was roving among many other subjects, and balancing their capabilities. How he wavered between Biblical subjects and heroic subjects from British history, and how many of each kind suggested themselves to him, one learns from a list in his own handwriting among the Milton MSS. at Cambridge. It contains jottings of no fewer than fifty-three subjects from the Old Testament, eight from the Gospels, thirty-three from British and English history before the Conquest, and five from Scottish history. It is curious that all or most of them are headed or described as subjects for “tragedies,” as if the epic form had now been abandoned for the dramatic. There are four separate drafts of a possible tragedy on the Greek model under the title of Paradise Lost, two of them merely enumerating the dramatic personae, but the last two indicating the plot and the division into acts. In 1641 he wrote in the Reason of Church Government that he was meditating a poem on high moral or religious subjects. But the fulfilment of these plans was indefinitely postponed. Milton became absorbed in the ecclesiastical controversies following on the king’s attempt to force the episcopal system on the Scots.

Of the first proceedings of the Long Parliament, including the trial and execution of Strafford, the impeachment and imprisonment of Laud and others, and the breakdown of the Puritan cause, Milton was references as by guarantee for parliamentary liberty, Milton was only a spectator. It was when the church question emerged distinctly as the question paramount, and there had arisen divisions on that question among those who had been practically unanimous in matters of civil reform, that he plunged in as an active adviser. There were three parties on the church question. There was a high-church party, contending for episcopacy by divine right, and for the maintenance of English episcopacy very much as it was; there was a middle party, defending episcopacy in grounds of usage and expediency, but desiring to see the powers of bishops greatly curtailed, and a limited episcopacy, with councils of presbyters round each bishop, substituted for the existing high episcopacy; and there was the root-and-branch party, as it called itself, desiring the entire abolition of episcopacy and the reconstruction of the English Church on something like the Scottish Presbyterian model. Since the opening of the parliament there had been a storm of pamphlets from these three parties. The manifesto of the high-church party was a pamphlet by Joseph Hall, bishop of Exeter, entitled “Humble Remonstrance to the High Court of Parliament.” In answer to Hall, and in representation of the views of the root-and-branch party, there had stepped forth, in March 1640–1641, five leading Puritan parish ministers, the initials of whose names, clubbed together on the title-page of their joint production, made the uncouth word “Smeactynnuas.” These were Stephen Marshall, Edmund Calamy, Thomas Young, Matthew Newcomen and William Sparrow. Thomas Young was the Scottish divine who had been Milton’s tutor in Bread Street; he had returned from Hamburg in 1628, and had been appointed to the vicarage of Stowmarket in Suffolk. The Smeactynnuas were Young’s. What is more interesting is that his old pupil Milton was secretly in partnership with him and his brother Smeactynnuas. Milton’s hand is discernible in a portion of the original Smeactynnuan pamphlet; and he continued to aid the Smeactynnuas in their subsequent rejoinders to Hall’s defences.
of himself. In May 1641 he put forth a defence of the Smeet-
ymnnian side in Of Reformation touching Church Discipline in
England and the Causes that hitherto have hindered it. He
reviewed English ecclesiastical history, with an appeal to his
countrymen to resume that course of reformation which he
considered to have been prematurely stopped in the preceding
century, and to sweep away the last relics of papacy and prelacy.
Among all the root-and-branch pamphlets of the time, it stood
out, and stands out still, as the most thorough-going and
tremendous. It was followed by four others in rapid succession,
Of Prelatical Episcopacy and whether it may be deduced from
the Apostolical Times (June 1641), Animadversions upon the
Remonstrant’s Defence against Smeatymnus (July 1641), The
Reason of Church Government urged against Prelaty (Feb.
1641-1642), A pology against a Pamphlet called a Modest Confu-
sation of the Animadversions, &c. (March and April 1641-1642).
The first of these was directed chiefly against that middle party
which advocated a limited episcopacy, with especial reply to
the arguments of Archbishop Ussher, as the chief exponent of
the views of that party. Two of the others, as the titles imply,
belong to the Smeatymnnian series, and were castigations of
Bishop Hall. The greatest of the four, and the most important
of all Milton’s anti-episcopal pamphlets after the first, is that
entitled The Reason of Church Government. It is there that
Milton takes his readers into his confidence, speaking at length
of himself and his motives in becoming a controversialist.
Poetry, he declares, was his real vocation; it was with reluctance
that he had resolved to “leave a calm and pleasing garden
fed with cheerful and confident thoughts, to embark in a
tremendous sea of noises and hoarse disputes”; but duty had
left him no option. The great poem or poems he had been
meditating could wait; and meanwhile, though in prose-
polemics he had the use only of his “left hand,” that hand
should be used with all its might in the cause of his country
and of liberty. The Apology was in answer to a Modest Confu-
sation of a Slanderous and Scurrilous Libel, the joint work
of Hall and his son, attacking Milton’s personal character.
The parliament had advanced in the root-and-branch direction
so far as to have passed a bill for the exclusion of bishops from
the House of Lords, and compelled the king’s assent to that
bill, when, in August 1642, the further struggle between Charles
and his subjects took the form of civil war. The Long Parlia-
ment moved on more and more rapidly in the root-and-branch
direction, till, by midsummer 1643, the abolition of episcopacy
had been decreed, and the question of the future non-prelatic
constitution of the Church of England referred to a synod of
divines, to meet at Westminster under parliamentary authority.
Of Milton’s life through those first months of the Civil War
little is known. He remained in his house in Aldersgate Street,
teaching his nephews and other pupils; and the only scrap
that came from his pen was the semi-jocose sonnet bearing the
title “When the Assault was intended to the City.” In the
summer of 1643, however, there was a great change in the
Aldersgate Street household. About the end of May, as his
nephew Edward Phillips remembered, Milton went away on a
country journey, without saying whither or for what purpose;
and, when he returned, about a month afterwards, it was with
a changed life, and with some of his pupils and other lovers
her company. He had, in fact, been in the very headquarters
of the king and the Royalist army in and round Oxford; and
the bride he brought back with him was a Mary Powell, the
eldest daughter of Richard Powell, of Forest Hill, near Oxford.
She was the third of a family of eleven sons and daughters,
of good standing, but in rather embarrassed circumstances,
and was seventeen years and four months old, while Milton
was in his thirty-fifth year. However the marriage came about,
it was in every respect unfortunate. The Powell family were
strongly Royalist, and the girl herself seems to have been
frivolous, and entirely unsuited for the studious life in Alders-
gate Street. Hardly were the honeymoon festivities over, when,
her sisters and other relatives having returned to Forest
Hill and left her alone with her husband, she pined for home
again and begged to be allowed to go back on a visit. Milton
consented, on the understanding that the visit was to be a brief
one. This seems to have been in July 1643. Soon, however,
the intimation from Forest Hill was that he need not look ever
to have his wife in his house again. The resolution seems to
have been mainly the girl’s own; but, as the king’s cause was
then prospering in the field, Edward Phillips was probably
right in his conjecture that the whole of the Powell family
had repented of their sudden connexion with so prominent
a Parliamentarian and assailant of the Church of England as
Milton. While his wife was away, his old father, who had
been residing for three years with his younger and lawyer
son at Reading, came to take up his quarters in Aldersgate
Street.
Milton’s conduct under the insult of his wife’s desertion
was most characteristic. Always fearless and speculative, he
converted this case into a public protest against the existing
law and theory of marriage. The Doctrine and Disci-
pline of Divorce, Restored to the good of both Sexes from the Bondage
of Canon Law and other Mistakes was the title of a pamphlet
put forth by him in August 1643, without his name, but with
no effort at concealment, declaring the notion of a sacramental
sanctity in the marriage relation to be a clerically invented
superstition, and arguing that inherent incompatibility of char-
acter, or contrariety of mind, between two married persons is
a perfectly just reason for divorce. If the date, the 1st of August,
is correct, the pamphlet must have been written almost immedi-
ately after his wife’s departure, and must in all probability
have been written at the same time in which the柄论
of divorce was returned. There was no reference to his own case, except by
implication; but the boldness of the speculation roused attention
and sent a shock through London. It was a time when the
authors of heresies of this sort, or of any sort, ran considerable
risks. The famous Westminster Assembly of Divines, called
by the Long Parliament, met on the 1st of July 1643. Whether
Milton’s divorce tract was formally discussed in the Assembly
during the first months of its sitting is unknown; but it is certain
that the London clergy, including not a few members of the
Assembly, were then angrily discussing it in private. That
there might be no obstacle to a more public prosecution, Milton
put his name to a second and much enlarged edition of the
tract, in February 1644, dedicated openly to the parliament
and the assembly. Then, for a month or two, during which
the gossip about him and his monstrous doctrine was
spreading more and more, he turned his attention to other
subjects.
Among the questions in agitation in the general ferment
of opinion brought about by the Civil War was that of a reform
of the English system of election and especially of the unpar-
eliamentary. To this Milton wrote, in a small treatise, Of Education,
in a letter to Samuel Hartlib, a German then resident in London
and interesting himself busily in all philanthropic projects and
schemes of social reform. In the very next month, however,
July 1644, he returned to the divorce subject in a pamphlet
addressed specially to the clergy and entitled The Judgment
of Martin Bucer concerning Divorce. The outcry against him
then reached its height. He was attacked in pamphlets;
and was denounced in pulpits all through London, and especially
by Herbert Palmer. In a sermon preached on the 13th of August,
before the two Houses of Parliament; strenuous efforts were
made to bring him within definite parliamentary censure. In
the cabal formed against him for this purpose a leading part
was played, at the instigation of the clergy, by the Stationers’
Company of London, which had a plea of its own against him
on the ground that his doctrine was not only immoral, but had
been put forth in an illegal manner. His first divorce treatise,
thought published immediately after the “Printing Ordinance”
of the parliament of the 14th of June 1643, requiring all publica-
tions to be licensed for press by one of the official censors, and to
be registered in the books of the Stationers’ Company, had
been issued without license and without registration. Com-
plain to this effect was made against Milton, with some others
Milton 485

liable to the same charge of contempt of the printing ordinance, in a petition of the Stationers of the House of Commons in August 1644; and the matter came before committee both in that House and in the Lords.

It is to this circumstance that the world owes the most popular and eloquent, if not the greatest, of all Milton's prose writings, his famous Areopagitica, A Speech of Mr John Milton for the Liberty of Unlicensed Printing, to the Parliament of England. It appeared on the 25th of November 1644, deliberately unlicensed and unregistered, and was a remonstrance addressed to the parliament, as if in an oration to them face to face, against their ordinance of June 1643 and the whole system of licensing and censorship of the press. Nobly eloquent of the parliament in other respects, it denounced their printing ordinance as utterly unworthy of them, and of the new era of English liberties which they were initiating, and called for its repeal. Though that effect did not follow, the pamphlet virtually accomplished its purpose. The licensing system had received its death-blow; and, though the Stationers returned to the charge in another complaint to the House of Lords, Milton's offence against the press ordinance was condoned. He was still assailed in pamphlets, and found himself "in a world of disseeme"; but he lived on through the winter of 1644/5 undisturbed in his house in Aldersgate Street. To this period there belong, in the shape of verse, only his sonnets ix. and x., the first to some anonymous lady, and the second "to the Lady Margaret Ley," with perhaps the Greek lines entitled Philosophus ad regem quendam. His divorce speculation on divorce was still occupied him; and in March 1644/5 he published simultaneously his Tetrachordon: Expositions upon the four chief places of Scripture which treat of Marriage, and his Colasterion, a Reply to a nameless Answer against the Doctrine and Discipline of Divorce. In these he repiled to his chief recent assailants, lay and clerical, with merciless severity.

Through the latter part of 1644, Milton had been saved from the penalties which his Presbyterian opponents would have inflicted on him by the general championship of liberty of opinion by Cromwell and the army Independents. Before the middle of 1645 he, with others who were on the back books of the Presbyterians as heretics, was still safer. Milton's position after the battle of Naseby may be easily understood.

Though his first tendency on the Church question had been to some form of a Presbyterian constitution for the Church, he had parted utterly now from the Scots and Presbyterians, and become a partisan of Independency, having no dread of "sects and schisms," but regarding them rather as healthy signs in the English body-politic. He was, indeed, himself one of the most noted sectaries of the time, for in the lists of sects drawn out by contemporary Presbyterian writers special mention is made of one small sect who were known as Millenists or Dissenters.

So far as Milton was concerned personally, his interest in the divorce speculation came to an end in July or August 1645, when, by friendly interference, a reconciliation was effected between him and his wife. The ruin of the king's cause at Naseby had suggested to the Powells that it might be well for their daughter to go back to her husband after their two years of separation. It was not, however, in the house in Aldersgate Street that she rejoined him, but in a larger house, which he had taken in the adjacent street called Barbican, for the accommodation of an increasing number of pupils.

The house in Barbican was tenanted by Milton from about August 1645 to September or October 1647. Among his first occupations there must have been the revision of the proof sheets of the first edition of his collected poems. It appeared as a tiny volume, copies of which are now very rare, with the title, Poems of Mr John Milton, both English and Latin, compos'd at several times. Printed by his true Copies. The songs were set in Musick by Mr Henry Lawes. . . . The title-page gives the date 1645, but the 2nd of January 1645/6 seems to have been the exact day of its publication. Whether because his pedagogic duties now engrossed him or for other reasons, very few new pieces were added in the Barbican to those that the little volume had thus made public. In English, there were only the four sonnets now numbered xi.-xiv., the first two entitled "On the Detraction which followed upon my writing certain Treatises," the third "To Mr Henry Lawes on his Airs," and the fourth "To the Religious Memory of Mrs Catherine Thomson," together with the powerful anti-Presbyterian pamphlet or "talled sonnet" entitled "On the New Forces of Conscience under the Long Parliament"; and in Latin there were only the ode Ad Joannem Rousiam, the Apologia de Rustico et Hero, and one interesting "Familiar Epistle" (April 1647) addressed to his Florentine friend Carlo Dati.

Some family incidents of importance belong to this time of residence in Barbican. The fall of Oxford in 1646 compelled the whole of the Powell family to seek refuge in London, and most of them found shelter in Milton's house. His first child, a daughter named Anne, was born there on the 29th of July that year, and on the 1st of January 1646/7 his father-in-law Richard Powell died there, leaving his affairs in confusion; and in the following March his own father died there, at the age of eighty-four, and was buried in the adjacent church of St Giles, Cripplegate.

From Barbican Milton removed, in September or October 1647, to a smaller house in that part of High Holborn which adjoins Lincoln's Inn Fields. His Powell relatives had now left him, and he had reduced the number of his pupils, or perhaps kept only his two nephews. But, though thus more at leisure, he did not yet resume his projected poem, but occupied himself rather with three works of scholarly labour which he had already for some time had on hand. One was the compilation in English of a complete history of England, or rather of Great Britain, from the earliest times; another was the preparation in Latin of a complete system of divinity, drawn directly from the Bible; and the third was the collection of materials for a new Latin dictionary. Milton had always a fondness for such labours of scholarship and compilation. Of a poetical kind there is nothing to record, during his residence in High Holborn, but an experiment in psalm-translation, in the shape of Ps. lxxx.-lxxviii.

The crushing defeat of the Scottish army by Cromwell in the three days' battle of Preston (1648) and the simultaneous suppression of the English Royalist insurrection in the south-east counties by Fairfax's siege and capture of Colchester, left King Charles at the mercy of the victors. Milton's sonnet "On the Lord General Fairfax, at the siege of Colchester," attested the exultation of the writer at the triumph of the parliamentary cause. His exultation continued through what followed when the king was beheaded (1649) and a man of mark out of parliament to attach himself openly to the new republic was John Milton. This he did by the publication of his pamphlet entitled "Tenure of Kings and Magistrates, proving that it is lawful, and hath been held so in all ages, for any who have the power, to call to account a Tyrant or wicked King, and, after due conviction, to depose and put him to death, if the ordinary Magistrate have neglected or denied to do it." It was out within a fortnight after the king's death, and was Milton's last performance in the house in High Holborn. The chiefs of the new republic could not but perceive the importance during the services of a distinguished man who had so opportunely and so powerfully spoken out in favour of their tremendous act. In March 1649, accordingly, Milton was offered, and accepted, the secretariship for foreign tongues to the council of state of the new Commonwealth. The salary was to be £288 a year (worth about £1000 a year now). To be near his new duties in attendance on the council, which held its daily sittings for the first few weeks in Derby House, close to Whitehall, but afterwards regularly in Whitehall itself, he removed at once to temporary lodgings at Charing Cross. In the very first meetings of council which Milton attended he must have made personal acquaintance with President Bradshaw, Fairfax, Cromwell himself, Sir Henry Vane, Whitelock,
Henry Marten, Haselrig, Sir Gilbert Pickering and the other chiefs of the council and the Commonwealth, if indeed he had not known some of them before. After a little while, for convenience, official apartments were assigned him in Whitehall itself.

At the date of Milton's appointment to the secretaryship he was forty years of age. His special duty was the drafting in Latin of letters sent by the council of state, or sometimes by the Rump Parliament, to foreign states and princes, with the examination and translation of letters in reply, and with personal conferences, when necessary, with the agents of foreign powers in London, and with envoys and ambassadors. As Latin was the language employed in the written diplomatic documents, his post came to be known indifferently as the secretaryship for foreign tongues or the Latin secretaryship. In that post, however, his duties, more particularly at first, were very light in comparison with those of his official colleague, Walter Frost, the general secretary. Foreign powers held aloof from the English republic as much as they could; and, while Frost had to be present in every meeting of the council, keeping the minutes, and conducting all the general correspondence, Milton's presence was required only when some piece of foreign business turned up. Hence, from the first, his employment in very miscellaneous work. Especially, the council looked to him for everything in the nature of literary vigilance and literary help in the interests of the struggling Commonwealth. He was employed in the examination of suspected papers, and in interviews with their authors and printers; and he executed several great literary commissions expressly entrusted to him by the council. The first of these was his pamphlet entitled Observations on the Articles of Peace (between Ormonde and the Irish). It was published in May 1649, and was in defence of the republic against a complication of Royalist intrigues and dangers in Ireland. A passage of remarkable interest in it is one of eloquent eulogy on Cromwell. More important still was the Eikonoklastes (which may be translated "Image-Smasher"), published by Milton in October 1649, by way of counterblast to the famous Eikon Basilike ("Royal Image"), which had been in circulation in thousands of copies since the king's death, and had become a kind of Bible in all Royalist households, on the supposition that it had been written by the royal martyr himself (see Guaden, John). In the end of 1649 there appeared abroad, under the title of Regii pro Carolo I, a Latin vindication of the memory of Charles I, and an attack on the Commonwealth. As it had been written, at the instance of the exiled royal family, by Salmusius, or Claude de Saumaise, of Leiden, then of enormous celebrity over Europe as the greatest scholar of his age, it was regarded as a serious blow to the infant Commonwealth. Milton threw his whole strength into a reply through the year 1650, interrupting himself only by a new and enlarged edition of his Eikonoklastes. His Latin Pro populo anglicano defensio (1651), ran at once over the British Islands and the Continent, and was received by scholars as an annihilation of Salmusius. Through the rest of 1651 the observation was that the two agencies which had co-operated most visibly in raising the reputation of the Commonwealth abroad were Milton's books and Cromwell's battles.

Through the eventful year 1651, in addition to the other duties of his secretaryship, Milton acted as licensor and superintending editor of the Mercurius politicus, a newspaper issued twice a week, of which Marchmont Nedham was the working editor and proprietor. Milton's hand is discernible in some of the leading articles.

About the end of 1651 Milton left his official rooms in Whitehall for a "garden house" he had taken on the edge of St James's Park in what was then called Petty France, Westminster, but is now York Street. The house, afterwards 19 York Street, was occupied by James Mill and William Hazlitt in succession, and was not pulled down till 1877. Milton had now more to do in the special work of his office, in consequence of the increase of correspondence with foreign powers. But he had for some time been in ailing health; and a discern of eyesight which had been growing upon him gradually for ten years had been settling rapidly, since his labour over the answer to Salmusius, into total blindness. Before or about May 1652, when he was in his forty-fourth year, his blindness became total, and he could go about only with some one to lead him. Hence a rearrangement of his secretarial duties. Such of these duties as he could perform at home, or by occasional visits to the Council Office near, he continued to perform; but much of the routine work was done for him by his assistant, a well-known German, George Rudolph Weckherlin, succeeded later by Philip Meadows and, eventually, by Andrew Marvell. Precisely to this time of a hull in Milton's secretaryship on account of his ill-health and blindness we have his Latin letter to the Neapolitan ambassador, the Lord General Cromwell and "To Sir Henry Vane the Younger." In 1652 died his only son, who had been born at Whitehall in the March of the preceding year. His wife died in 1653/4, just after she had given birth to his third daughter, Deborah. With the three children thus left him—Anne, but six years old, Mary, not four, and the infant Deborah—the blind widower lived on in his house in Petty France in such desolation as can be imagined. He had recovered sufficiently to resume his secretarial duties; and the total number of his dictated state letters for the single year 1652 was equal to at least the gathered materials of the preceding term of secretarialship put together. To the same date belong also three of his Latin "Familiar Epistles." In December 1652 there was published Joannis Philippi Angli responso ad apologian anonymi cujusdam tenebris, being a reply by Milton's younger nephew, John Phillips, but touched up by Milton himself, to one of several pamphlets that had appeared against Milton for his slaughter of Salmusius.

In December 1653 Cromwell's formal sovereignty began under the name of the Protectorate, passing gradually into more than kingship. This change from Government by the Rump and its successor, to Government by a single military lord protector, was according to his council was regarded by many as treason to the republican cause, and divided those who had hitherto been the united Commonwealth's men into the "Pure Republicans," represented by such men as Bradshaw and Vane, and the "Oliverians," adhering to the Protector. Milton, whose boundless admiration of Cromwell had shown itself already in his Irish tract of 1649 and in his recent sonnet, was recognized as one of the Oliverians. He remained in Oliver's service and was his Latin secretary through the whole of the Protectorate. For a while, indeed, he was regarded as a British descent Cromwell's assistant, though he had been employed on his march across the Continent, with a Philip Meadows under him, at a salary of 800 a year, as deputy for the blind Milton in foreign correspondence and translations. The reason for this temporary exemption of Milton from routine duty may have been that he was then engaged on an answer to the pamphlet from the Hague entitled Regii sanguinis clamor ad coelum adversus pellucidas anglicanas (March 1653). Salmusius was now dead, and the Commonwealth was too stable to suffer from such attacks; but no Royalist pamphlet had appeared so able or so venomous as this in continuation of the Salmasian controversy. All the reason for the delay was in the main a libel on Milton himself a reply from his pen seem necessary. It came out in May 1654, with the title Joannis Miltoni Angli pro populo Anglicano defensor secunda (Second Defence of John Milton, Englishman, for the People of England). The author of Regii sanguinis clamor was Dr Peter de Moulin the younger, a naturalized French Presbyterian minister, then moving about in English society, close to Milton; but, as that was a profound secret, and the work was universally attributed to the Continent to an Alexander More or Morus, a French minister of Scottish descent then a professor at Middelburg, who had certainly managed the printing in consultation with the now deceased Salmusius, and had contributed some portion of the matter—Milton made More the responsible person and the one object of his invective. The savage attack on More's personal character, however, is but part of the Defensio secunda. It contains passages of singular autobiographical and historical value, and includes laudatory sketches of such eminent
Milton

Commonwealth's men as Bradshaw, Fairfax, Fleetwood, Lambert and Overton, together with a long panegyric on Cromwell himself and his career, which remains to this day unapproached for elaboration and grandeur by any estimate of Cromwell from any later pen.

From about the date of the publication of the Defensio secunda to the beginning of 1655 the only specially literary relics of Milton's life are his translations of Ps. i.-viii. in different moods, done about August 1654 in his translation of the Psalms, and done probably about the same time, and two of his Latin "Familiar Epistles." The most active time of his secretaryship for Oliver was from April 1655 onwards. In that month, in the course of a general revision of official salaries under the Protectorate, Milton's salary of £288 a year hitherto was reduced to £200 a year, with a kind of redefinition of his office, recognizing it, we may say, as a Latin secretaryship extraordinary. Philip Meadows was to continue to do all the ordinary Foreign Office work, under Thurloe's inspection; but Milton was to be called in on special occasions. Hardly was the arrangement made when a signal occasion did occur. In May 1655 all England was horrified by the news of the massacre of the Vaudois Protestants (Waldenses) by the troops of Emanuele II., duke of Savoy and prince of Piedmont, in consequence of their disobedience to an edict requiring them either to leave their native valleys or to conform to the Catholic religion. Cromwell and his council took the matter up with all their energy; and the burst of indignation on the subject despatched in that month and the next to the duke of Savoy himself, Louis XIV. of France, Cardinal Mazarin, the Swiss cantons, the states-general of the United Provinces, the Kings of Sweden and Denmark, was an outburst all by Milton. His famous sonnet "On the Late Massacre in Piedmont" was his more private expression of feeling on the same occasion. This sonnet was in circulation, and the case of the Vaudois Protestants was still occupying Cromwell, when, in August 1655, there appeared the last of Milton's Latin pamphlets. It was his Pro se defensio ... in answer to an elaborate self-defence which More had put forth on the Continent since Milton's attack on his character. In that year also appeared Milton's Scriptum domini prioriter contra hispanos. Throughout the rest of Cromwell's Protectorate, Milton's life was of comparatively calm tenor. He was in much better health than usual, bearing his blindness with courage and cheerfulness; he was steadily busy with important despatches to foreign powers on behalf of the Protector, then in the height of his great foreign policy; and his house in Petty France seems to have been, more than at any previous time, since the beginning of his blindness, a meeting-place for friends and visitors, and a scene of pleasant hospitalities. The four sonnets now numbered xix.-xxii., one of them to young Lawrence, the son of the president of Cromwell's council, and two of the others to Cyriack Skinner, once his pupil, belong to this time of domestic quiet, as do all no fewer than ten of his Latin "Familiar Epistles." His marriage with Katherine Woodcock on the 12th of November 1656 brought him a brief period of domestic happiness; but, after only fifteen months, he was again a widower, by her death in childbirth in February 1657/8. The child dying with her, only the three daughters by his first marriage remained. The touching sonnet which closes the series of Milton's Sonnets is his sacred tribute to the memory of his second marriage and to the virtues of the wife he had so soon lost. Even after that loss we find him still busy for Cromwell. Andrew Marvel, in September 1657 succeeded Meadows, much to Milton's satisfaction, as his assistant secretary; but this had by no means relieved him from duty. Some of his greatest despatches for Cromwell, including letters, of the highest importance, to Louis XIV., Mazarin and Charles Gustaves of Sweden, belong to the year 1658.

There is, unfortunately, no direct record to show what Cromwell thought of Milton; but there is ample record of what Milton thought of Cromwell. "Our chief of men," he had called Cromwell in his sonnet of May 1658; and the opinion remained unchanged. He thought Cromwell the greatest and best man of his generation, or of many generations; and he regarded Cromwell's assumption of the supreme power, and his retention of that power with a sovereign title, as no real suppression of the republic, but as absolutely necessary for the preservation of the republic, and for the safeguard of the British Islands against a return of the Stuarts. Nevertheless, under this prodigious admiration of Cromwell, there were political doubts and reserves. Milton was so much of a modern radical of the extreme school in his own political views and sympathies that he cannot but have been vexed by the growing conservatism of Cromwell's policy through his Protectorate. To his grand panegyric on Oliver in the Defensio secunda of 1654 he had ventured to append cautions against self-will, over-legislation and over-policing; and he cannot have thought that Oliver had been immaculate in these respects through the four subsequent years. The attempt to revive an aristocracy and a House of Lords, on which Cromwell was laterly bent, cannot have been to Milton's taste. Above all, Milton dissented in lato from Cromwell's church policy. It was Milton's fixation to his son Richard. Milton and Marvell continued in their posts, and a number of the Foreign Office letters of the new Protectorate were of Milton's composition. In October 1658 appeared a new edition of his Defensio prima, and, early in 1659, a new English pamphlet, entitled Treatise of Civil Power in Ecclesiastical Causes showing that it is not lawful to compel in Matters of Religion, in which he advocated the separation of Church and State. To Richard's Protectorate also belongs one of Milton's Latin "Familiar Epistles." The last of his known official performances in his Latin secretariate are two letters in the name of Richard Lenthall, as the speaker of the restored Rump, one to the king of Sweden and one to the king of Denmark, both dated the 15th of May 1659. Under the restored Rump, if ever, he seemed to have a chance for his notion of church-disestablishment; and accordingly, in August 1659, he put forth, with a prefatory address to that body, a pamphlet entitled Considerations touching the likelest means to remove Hirelings out of the Church. The restored Rump had no time to attend to such matters. They were in struggle for their own existence with the army chiefs; and to prevent the restoration of the monarchy, to argue against it and fight against it to the last was the work of Cromwell. Milton set himself; the preservation of the republic in any form, and by any compromise of differences within itself, had become his one thought, and the study of practical means to this end his most anxious occupation. In a Letter to a Friend concerning the Ruptures of the Commonwealth, written in October 1659, he had propounded a scheme of a kind of dual government for reconciling the army chiefs with the Rump; through the following winter, marked only by two of his Latin "Familiar Epistles," his anxiety over the signs of the growing enthusiasm throughout the country for the recall of Charles II. had risen to a passionate vehemence which found vent in a pamphlet entitled The Ready and Easy Way to Establish
a Free Commonwealth, and the Excellence thereof compared with the Inconveniences and Dangers of readmitting Kingstip to this Nation. An abridgment of this pamphlet was addressed by him to General Monk, in a letter entitled "The Present Means and Brief Delineation of a Free Commonwealth" (March 1666). Milton's proposal was that the central governing apparatus of the British Islands for the future should consist of one indissoluble grand council or parliament, which should include all the political chiefs, while there should be a large number of provincial councils or assemblies sitting in the great towns for the management of local and county affairs.

Not even when the king's cause was practically assured would Milton be silent. In Brief Notes upon a late Sermmon, published in April 1666, in reply to a Royalist discourse by a Dr Matthew Griffith, he made another protest against the recall of the Stuarts, even hinting that it would be better that Monk should become king himself; and in the same month he sent forth a second edition of his Ready and Easy Way, more frankly earnest than even the first, and containing additional passages of the most violent denunciation of the royal family, and of prophecy of the degradation and disaster they would bring back with them. This was the dying effort. On the 25th of April the Convocation of Parliament rest of the residuary business was to be read and approved unanimously that the government by King, Lords and Commons should be restored; and on the 29th of May, Charles II. made his triumphant entry into London. The chief republicans had by that time scattered themselves, and Milton was hiding in an obscure part of the city.

How Milton escaped the scaffold at the Restoration is a mystery now, and was a mystery at the time. The Commons voted that he should be taken into custody by the sergeant-at-arms, for prosecution by the attorney-general on account of his Eikonoklastes and Defensio prima, and that all copies of those books should be called in and burnt by the hangman. There was a story that Milton had once protected Davenant and now owed his immunity to him; but it is more likely that he was protected by the influence of Marvell, by Arthur Annesley, afterwards earl of Anglesey, and by other friends who had influence at court. At all events, on the 29th of August 1666, when the Indemnity Bill did come out complete, with the king's assent, Milton did not appear as one of the exceptions on any ground or in any of the grades. From that moment, therefore, he could emerge from his hiding, and go about as a free man. Not that he was yet absolutely safe. There were several public burnings by the hangman at the same time of Milton's condemned pamphlets; and the appearance of the blind man himself in the streets, though he was legally free, would have caused him to be mobbed and assaulted. Though the special prosecution ordered against him by the Commons had been quashed by the subsequent Indemnity Bill, the sergeant-at-arms had taken him into custody. Entries in the Commons journals of the 17th and 19th of December show that Milton complained of the exorbitant fees charged by the sergeant-at-arms for his release, and that this matter was referred to a committee at the instance of Andrew Marvell.

Milton did not return to Petty France. For the first months after he was free he lived as closely as possible in a house near what is now Red Lion Square, Holborn. Thence he removed, apparently early in 1667, to a house in Jewin Street, in his old Aldersgate Street and Barbican neighbourhood. In Jewin Street Milton remained for two or three years, or from 1661 to 1664. This is the time of which he says:

"...On evil days though fallen, and evil tongues round, in darkness, and with dangers compassed round, And solitude."

The "evil days" were those of the Restoration in its first or Clarendonian stage, with its revenges and reactions, its return to high Episcopacy and suppression of every form of dissent and sectarianism, its new and shameless royal court, its open proclamation and practice of anti-Puritanism in morals and in literature no less than in politics. For the main part of this world of the Restoration Milton was now nothing more than an infamous outcast, the detestable blind republican and regicide who had, by too great cleverness, been left unchanged. The friends that adhered to him still, and came to see him in Jewin Street, were few in number, and chiefly from the ranks of those nonconforming denominations, Independents, Baptists or Quakers, who were themselves under similar obloquy. Besides his two nephews, the faithful Andrew Marvell, Cyriack Skinner and some others of his former admirers, English or foreign, we hear chiefly of a Dr Nathan Paget, who was a physician in the Jewin Street neighborhood, and of Severin, and most of all of the wife he married with him by turns, partly to act as his amanuensis, and partly for the benefit of lessons from him—one of them a Quaker youth, named Thomas Ellwood. With all this genuine attachment to him of a select few, Milton could truly enough describe his condition after the Restoration as one of "solitude." Nor was this the worst. His three daughters, on whom he ought now to have been able principally to depend, were his most serious domestic trouble. The poor motherless girls, the eldest in her seventeenth year in 1662, the second in her fifteenth and the youngest in her eleventh, had grown up, in their father's blind direction, and in the great self-education all had been cooked and partly educated; and the result now appeared. They "made nothing of neglecting him"; they rebelled against the drudgery of reading to him or otherwise attending on him; they "did combine together and counsel his maid-servant to cheat him in her marketings"; they actually "had made away some of his books, and would have sold the rest."

It was to remedy this state of things that Milton consented to a third marriage. The wife found for him was Elizabeth Minshull, of a good Cheshire family, and a relative of Dr Paget. They were married on the 24th of February 1665/6, the wife being then only in her twenty-fifth year, while Milton was in his fifty-fifth. She proved an excellent wife; and the Jewin Street household, though the daughters remained in it, must have been under better management from the time of her entry into it. Meanwhile, he had found some solace in renewed industry of various kinds among his books and tasks of scholarship, and more particularly he had been building up his Paradise Lost. He had begun the poem in earnest, we are told, in 1658 at his house in Petty France, not in the dramatic form contemplated eighteen years before, but deliberately in the epic form. He had made but little way when there came through his hands the proofs of Paradise Lost preceding the Restoration and of the Restoration itself; but the work had been resumed in Jewin Street and prosecuted there steadily, by dictations of twenty or thirty lines at a time to whatever friendly or hired amanuensis chanced to be at hand. Considerable progress had been made in this way before his third marriage; and after that the work proceeded apace, his nephew, Edward Phillips, who was then out in the world on his own account, looking in when he could to revise the growing manuscript.

It was not in the house in Jewin Street, however, that Paradise Lost was finished. Not very long after the third marriage, probably in 1664, he removed to another house, with a garden, in "Artillery Walk, leading to Bunhill Fields." Here Paradise Lost was certainly finished before July 1667—Aubrey says in 1663—for when Milton and his family, to avoid the Great Plague of London, went into temporary country-quarters in a cottage in Chalfont St Giles, Buckinghamshire, the finished manuscript was taken with him, in probably more than one copy. This we learn from Thomas Ellwood, who had taken the cottage for him, and was allowed to take a copy of the manuscript with him for personal, during Milton's stay at Chal.

The delay in the publication of the poem may be explained partly by the fact that the official licenser hesitated before granting the necessary imprimatur to a book by a man of such notorious republican antecedents, and partly by the paralysis of all business in London by the Great Fire of September 1666. It was not till the 27th of April 1667 that Milton concluded an agreement, still preserved in the British
MILTON

489

Museum, with Samuel Simmons, printer, of Aldersgate Street, London, to dispose of the copyright for £5 down, the promise of another £5 after the sale of the first edition of 1300 copies, and the further promise of two additional sums of £5 each after the sale of two more editions of the same size respectively. It was as if an author now were to part with all his rights in a volume for £10, or a contract for £52, ros. more in three equal instalments. The poem was duly entered by Simmons as ready for publication in the Stationers' Registers on the 20th of the following August; and shortly after that date it was put out in London as a reprinted small quarto, with the title Paradise Lost: A Poem written in Ten Books: By John Milton. The reception accorded to Paradise Lost has been quoted as an example of the neglect of a great work, but the sale of an edition of 1300 copies in eighteen months proves that the poem found a wide circle of readers. "This man cuts us all out, and the nearest approach to saying anything attributed to Dryden on the occasion; and it is the more remarkable because the one objection to the poem which at first, we are told, "stumbled many," must have "stumbled" Dryden most of all. Except in the drama, rhyme was then thought essential in anything professing to be a poem; blank verse was hardly regarded as verse at all; Dryden especially had been and was the champion of rhyme, contending for it even in the drama. That, notwithstanding this obvious blow struck by the poet at Dryden's pet literary theory, he should have welcomed the poem so enthusiastically and proclaimed its merits so emphatically, says much at once for his critical perceptions, and much more for his temper. Toleration, Dryden requested Milton's leave to turn the poem into a rhymed drama, and was told he might "tag his verses if he pleased." The result is seen in Dryden's own, The State of Innocence and the Fall of Man (1675). One consequence of Milton's renewed celebrity was that visitors of all ranks again sought him out for the honour of his society and conversation. His obscure house in Artillery Walk, Bunhill, we are told, became an attraction now, "much more than he did desire," for the learned notabilities of his time.

Accounts have come down to us of Milton's personal appearance and habits in his later life. They describe him as being even other day led about in the streets in the vicinity of his Bunhill residence, a slender figure, of middle stature or a little less, generally dressed in a grey cloak or overcoat, and wearing sometimes a small shawl or hood. He was, it was said, "not only boisterous but still looking as a young man, with his lightish hair, and his fair, rather than aged or pale, complexion. He would sit in his garden at the door of his house, "as the father of gree graver men," and so, as well as in his room, received the visits of people of distinguished parts, as well as quality." Within doors he was usually dressed in neat black. He was a very early riser, and very regular in his dutees. He was a hospitable host, of good cheer, and "and so, as well as in his room, always in his own room, amid his books, with an amanuensis to read for him and write to his dictation. Music was always a chief part of his afternoon and evening relaxation, whether he was by himself or when friends were with him. His manner with friends and visitors was extremely courteous and affable, with just a shade of stateliness. In free conversation, either at the midday dinner, when a friend or two happened, by rare accident, to be present, or more habitually in the evening and at the light supper which concluded it, he was the life and soul of the company, from his "flow of subject" and his "unaffected cheerfulness and civility," through an "unbroken cordiality to talk, state, and explain," to his "wares in jesting when they come to smile," but still looking as a young man, with his lightish hair, and his fair, rather than aged or pale, complexion. He would sit in his garden at the door of his house, "as the father of gree graver men," and so, as well as in his room, received the visits of people of distinguished parts, as well as quality." Within doors he was usually dressed in neat black. He was a very early riser, and very regular in his dutees. He was a hospitable host, of good cheer, and..."
circumstances to make good. The daughters, with the Powells probably abetting them, went to law with the widow to upset the will; and the decision of the court was that they should receive only from Milton the 1500 pounds left, the widow, after some further stay in London, retired to Nantwich in her native Cheshire. There, respected as a pious member of a local Baptist congregation, she lived till 1727, having survived her husband fifty-three years. By that time all the three daughters were also dead. The eldest, Ann Milton, who was somewhat deformed, had died not long after her father, having married "a master-builder," but left no issue; the second, Mary Milton, had died, unmarried, before 1694; and only the third, Deborah, survived as long as her stepmother. Her father, with a half-sister, shortly before her father's death, she had married an Abraham Clarke, a silk-weaver in Dublin, with whom she returned to London about 1684, when they settled in the silk-weaving business in Spitalfields, rather sinking than rising in the world, though latterly some public attention was paid to Deborah, by Addison and others, on her father's account. One of her sons, Caleb Clarke, had gone out to Madras in 1703, and had died there as "parish-clerk of Fort George" in 1719, leaving children, of whom there are some faint traces to this day. In the year 1729, a year after Deborah's death, the prospect of a more untraced descent from this Indian grandson of Milton, the direct descent from him came to an end in his granddaughter, Elizabeth Clarke, another of Deborah's children. Having married a Thomas Foster, a Spitalfields weaver, but afterwards set up a small chandler's shop, first in Holloway and then in Shoreditch, she died at Islington in 1754, not long after she and her husband had received the proceeds of a performance of Comus got up by Dr Johnson for her benefit. All her children had predeceased her, leaving no issue. Milton's brother Christian, who had always been at the opposite side in politics, rose to the questionable honour of a judgeship and knighthood in the latter part of the reign of James II. He had then become a Roman Catholic—which religion he professed till his death in retirement at Ipswich in 1692. Descendants from him are traceable a good way into the 18th century. Milton's two nephews and pupils, Edward and John Phillips, both of them known as busy and clever hack-authors before their uncle's death, continued the career of hack-authorship, most industriously and with the most farfetched success; and the whole of their lives: Edward in a more reputable manner than John, and with more of enduring admiration to the memory of his uncle. Edward died about 1695; John was alive till 1706. Their half-sister, Ann Agar, the only daughter of Milton's sister by her second husband, had married, in 1673, a David Moore, of Sayes House, Chertsey; and the most flourishing of all the lines of descent from the poet's father was in this Agar-Moore branch of the Miltons.

Of masses of manuscript that had been left by Milton, some portions saw the light posthumously. Prevented, in the last years of his life from publishing his Latin State Letters in the same volume with his Latin Familiar Epistles, he had committed the charge of the State Letters, prepared for the press, together with the completed manuscript of his Latin Treatise of Christian Doctrines, to a young Cambridge scholar, Daniel Skinner, who had been among the last of his amanuenses, and who was employed by him especially for copying and arranging those two important MSS. Negotiations were on foot, after Milton's death, between this Daniel Skinner and the Amsterdam printer, Daniel Elzevir, for the publication of both MSS, when the English government interfered, and the MSS. were sent back by Elzevir, and thrown aside, as dangerous rubbish, in a cupboard in the State Paper Office. Meanwhile, in 1676, a London bookseller, who had somehow got into his possession a less perfect, but still tolerably correct copy of the same Letters, had brought out a surreptitious edition of them, under the title Litterae pseudo-senatus anglicani, Cromptii ... nomine et fuisse conscriptae a Johanne Youvilio. A second, rather poorer, but publicable, edition appeared in 1681, when another bookseller put forth a slight tract entitled Mr. John Milton's Character of the Long Parliament and another unfortunate character. Whilom, in 1614, consisting of a page or two, of rather dubious authenticity, and said to have been withheld from his History of Britain in the edition of 1670. In 1682 appeared A Brief History of Moscow, and of other less-known Countries lying Eastward of Russia as far as Cathay ... undoubtedly Milton's, and a specimen of those prose compilations with which he sometimes occupied his leisure. Of the fate of his collections for a new Latin Dictionary, which had swelled to three folio volumes of MS., all that is known is, that after having been used by Edward Phillips for his Enchiridion Thomisticum, 1723, they had been preserved as Cambridge scholars, and were used for that Latin dictionary of 1693, called The Cambridge Dictionary, on which Ainsworth's Dictionary was later compiled in 1698. These three large volumes, under the editorship of John Toland, the first collective edition of Milton's prose works, professing to have been printed at Amsterdam, though really printed in London. A very interesting folio volume, published in 1743 by "John Nickolls, junior," under the title of Original Letters and Papers of State addressed to Oliver Cromwell, consists of a number of intimate Cromwellian documents that had somehow come into Milton's possession immediately after Cromwell's death, and were intended to be published confidentially to the Quaker Ellwood. Finally, a chance search in the London State Paper Office in 1823 having discovered the long-lost parcel containing the MSS. of Milton's Latin State Letters and his Latin Treatise of Christian Doctrine, as these had been sent back from Amsterdam a hundred and fifty years before, the Treatise on Christian Doctrine was, by the command of George IV., edited and published in 1825 by the Rev. C. R. Summer, keeper of the Royal Library, and afterwards bishop of Winchester, under the title of Joannis Miltoni Angli de doctrina christiana libri duo posthumi. An English translation, by the editor, was published in the same year. Those state papers of Milton which had not been destroyed were edited by W. D. Hamilton for the Camden Society, in 1859.

Milton's literary life divides into three almost mechanically distinct periods: (1) the time of his youth and minor poems, (2) his middle twenty years of prose polemics, and (3) the time of his later Muse and greater poems.

Had Milton died in 1640, when he was in his thirty-second year, and had his literary remains been then collected, he would have been remembered as one of the best Latinists of his generation and one of the most exquisite prose stylists in the English language. More particularly, he would have taken his place as one of that interesting group or series of English poets, coming in the next forty years after Spenser, who, because they all acknowledged a filial relationship to Spenser, may be called collectively the Spenserians. In this group or series, counting in it such other true poets of the reigns of James I. and Charles I. as Phineas and Giles Fletcher, William Browne and Drummond of Hawthorne, Milton would have been entitled, by the small collection of pieces he had left, and which would have included his Ode on the Nativity, his L'Allegro and II Penseroso, his Comus and his Lycidas, to recognition as indubitably the very highest and finest. There was in him that peculiar Spenserian something which might be regarded as the poetic faculty in its essence, with a closeness and perfection of verbal finish not to be found in the other Spenserians, or even in the master himself. Few as the pieces were, and owning discipleship to Spenser as the author did, he was a Spenserian with a difference belonging to his own constitution—which prophets, and indeed already exhibited, the passage of English poetry out of the Spenserian into a kind that might be called the Miltonic. This Miltonic something, distinguishing the new poet from other Spenserians, was more than mere perfection of literary finish. It consisted in an avowed consciousness already of the os magna sonituum, "the mouth formed for great utterances," that consciousness resting on a peculiar substratum of personal character that had occasioned a new theory of literature. "He who would not be frustrated of his hope to write well hereafter on laudable things ought himself to be a true poem was Milton's own memorable expression afterwards of the principle that had taken possession of him from his earliest days; and this principle of moral manliness as the end and foundation of all genuine art and entertainment is the identity of all literary productions in kind, and their coequality in worth, with the personality in which they have their origin, might have been detected, in more or less definite shape, in all or most of the minor poems. It is a specific form of that general Platonic doctrine of the invincibility of virtue which runs through his Comus."

That a youth and early manhood of such poetical promise should have been succeeded by twenty years of all but incessant prose polemics has been a matter of regret with many. But this
is to ignore his political and social side. If Burke, whose whole public career consisted in a succession of speeches and pamphlets, is looked back upon as one of the greatest men of his century on their account, why should there be regret over the fact that Milton, after having been the author of *Comus* and *Lycidas,* became for a time the prose orator of his earlier and more tumultuous generation? Milton was not only the greatest pamphleteer of his generation—head and shoulders above the rest—but there is no life of that time, not even Cromwell's, in which the history of the great Revolution in its successive phases, so far as the deep underlying ideas and speculations were concerned, may be more intimately and instructively studied than in Milton's. Then, on merely literary grounds, what an interest in those prose remains! Not only of his *Areopagitica,* admired now so unreservedly because its main doctrine has become axiomatic, but of most of his other pamphlets, even those the doctrine of which is least popular, it may be said confidently that they answer to his own definition of "a good book," by containing somehow "the precious life-blood of a master-spirit." From the entire series there might be a collection of specimens, unequaled anywhere else, of the capabilities of that older, grander and more elaborate English prose of which the Elizabethans and their immediate successors were not ashamed. Nor will readers of Milton's pamphlets continue to accept the hackneyed observation that his genius was destitute of humour. Though his prevailing mood was the severely earnest, there are pages of youthful mirthfulness both in *Paradise Lost* and *Paradise Regained,* that, reaching sometimes to outrageous farce, and some of them as worthy of the name of humour as anything in Swift. Here, however, we touch on what is the worst feature in some of the prose pamphlets—their measureless ferocity, their boundless licence in personal scurrility.

While it is wrong to regard Milton's middle twenty years of prose polemics as a degradation of his genius, and while the fairer contention might be that the youthful poet of *Comus* and *Lycidas* actually promoted himself, and became a more powerful agency in the world and a more interesting object in it for ever, by consenting to lay aside his "singing robes" and spend a portion of his life in great prose oratory, who does not exult in the fact that such a life was rounded off so miraculously at the close by a final stage of compulsory calm, when the "singing robes" could be resumed, and *Paradise Lost,* *Paradise Regained* and *Samson Agonistes* could issue in succession from the blind man's chamber? Of these three poems, and what they reveal of Milton, no need here to speak at length. *Paradise Lost* is one of the few monumental works of the world, with nothing in modern epic literature comparable to it except the great poem of Dante. This is best perceived by those who penetrate beneath the beauties of the merely terrestrial portion of the story, and who recognize the coherence and the splendour of that vast symbolic phantasmany by which, through the wars in heaven and the subsequent revenge of the expelled archangel, it paints forth the connexion of the whole visible universe of human cogniscence and history with the grander, pre-existing and still environing world of the eternal and inconceivable. To this great epic *Paradise Regained* is a sequel, and it ought to be read as such. The legend that Milton's later epic is in a large measure inferior to the larger is quite the incorrect. All that is authentic on the subject is the statement by Edward Phillips that, when it was reported to his uncle that the shorter epic was "generally censured to be much inferior to the other," he "could not hear with patience any such thing." The best critical judgment now confirms Milton's own, and pronounces *Paradise Regained* to be not only, within the possibilities of its briefer theme, a worthy sequel to *Paradise Lost,* but also one of the most artistically perfect poems in any language. Finally, the poem in which Milton bade farewell to the Muse, and in which he reverted to the dramatic form, proves that to the very end and his right hand had lost none of its power or cunning, *Samson Agonistes* is the most powerful drama in the English language after the severe Greek model, and it has the additional interest of being so contrived that, without any deviation from the strictly objective incidents of the Biblical story which it enshrines, it is yet the poet's own epitaph and his condensed autobiography.

Much light is thrown upon Milton's mind in his later life, and even upon the poems of that period, by his posthumous Latin *Treatise of Christian Doctrine.* It differs from all his other prose writings of any importance in being cool, abstract and didactic. Professing to be a system of divinity derived directly from the Bible, it is really an attempt to make his metaphysics and of his reasoned opinions on all questions of philosophy, ethics and politics. The general effect is to show that, though he is rightly regarded as the very genius of English Puritanism, its representative poet and idealist, yet he was not a Puritan of what may be called the first wave, or that wave of Calvinistic orthodoxy which broke in upon the absolutism of Charles and Laud, and set the English Revolution aging. He belonged distinctly to that larger and more persistent wave of Puritanism which, passing on through Independency, and an endless variety of sects, many of them rationalistic and freethinking in the extreme, developed into what has ever since been known as English Liberalism. The treatise makes clear that, while Milton was a most fervid theist and a genuine Christian, believing in the Bible, and valuing the Bible over all the other books in the world, he was at the same time one of the most intrepid of English thinkers and theologians.

Considerable interest attaches among collectors to the variety of prints representing portraits of Milton. So far as the original *Portraits* of Milton are concerned, which have inspired the large number of engravings, the following may be mentioned: (1) The existing Jassens painting, 1618 ("aetatis sue 10"), which belonged to Mrs Milton. (2) An unknown painting of 1623 (?1620), from which was taken an engraving in the * Gentleman's Magazine* for September 1787 ("aet. sue 12 "). (3) The "Onslow" painting of Milton when a Cambridge scholar (lost), which belonged to Mrs Milton and in 1794 was in Lord Onslow's possession; a copy by Van der Gucht was made for Lord Harcourt and is still at Nancham. (4) A miniature to which Milton was a contributor, in *Areopagitica,* (lost). (5) A painting by Pieter Van der Planck (d. 1704) in the National Portrait Gallery. (6) An oil painting at Christ's College. (13) The "Woodcock" miniature of Milton when about forty-eight. In Poets' Corner, Westminster Abbey, a bust by Rysbrack was put up in 1737. A monument in St. Giles, Cripplegate, by John Bacon, R.A., was erected by Samuel Whitbread in 1793; and a modern statue by Horace Montford also stands there. A memorial window in St Margaret's, Westminster, with an inscription by J. G. Whittier, was presented by G. W. Childs, of Philadelphia.

**BIBLIOGRAPHY.**—MSS. of the poems of Milton's earlier period in his own handwriting are preserved in the library of Trinity College, Cambridge. These are not enumerated among the gifts made by Sir Henry Newton Fuckering in 1601, but presumably belonged to him, and came to the library at his death in 1700, as they were found by Charles Mason, a fellow of the college, among papers and books which had been his. They were bound in a folio volume by the care of Thomas Clarke, afterwards Master of the Rolls, in 1736. Besides the poems, with many interlinear additions and corrections, the volume contains some small essays in Latin, and plans, for works generally dramatic in form. This manuscript volume, invaluable as an index to Milton's methods of work, was reproduced in facsimile (Cambridge, 1899) by W. Aldis Wright.

The first complete edition of *The Poetical Works of Mr John Milton,* was printed by Jacob Tonson in 1695. In 1752 Richard Bentley put forward a curious edition of *Paradise Lost* in which long passages were rejected and placed in the margin on the ground that they were interpolations made possible by Milton's blindness. The Latin and Italian poems, with a translation by William Cowper,
MILTON—MILWAUKEE

were printed by W. Hayley in 1808. The most important of the numerous later editions of Milton's poetical works are by H. J. Todd (6 vols., 1801); J. Mitford ("Aldine edition," 3 vols., 1832); T. Keightley (2 vols., 1829), a new and improved edition, retaining the peculiarities of the earlier printed copies, by H. C. Beeching ("Oxford edition," 1904); and another, with variant readings, by W. Aldis Wright (Cambridge ed., 3 vols., 1884). The first edition was partly collected in 1667. They were edited by J. Toland (3 vols., 1698), by C. Symmons (7 vols., 1806) by Pickering (8 vols., 1851) with the poetical works, and by J. A. St John for Blackwood, 1848-1853.

There are numerous annotated editions of separate works.

The earliest life of Milton is contained in Wood MS. D. 4 in the Bodleian Library, Oxford, and was printed in the Engl. Worth a book account of the life given by Anthony a Wood in Fasti oxfordensia (1691). Wood was also indebted to John Aubrey, whose Brief Lives were not printed until later. The life by his nephew Edward Phillips was published in 1737, and is of great merit and importance, especially as far as it concerns Milton's early life, available in the State Papers, were first made use of by H. J. Todd in a third edition (1829) of his Milton. All the available information was gathered in Professor Masson's Life of Milton (published in Collected Essays, the Poetical, Political and Literary History of his Time (6 vols., 1859-1860, with index, 1804; new ed., vol. 1, 1881) which contains ample reference to original authorities. Shorter works are Milton and seine Zell (1870, 1879), by E. S. Parsons in the "English Men of Letters" series, and Life of John Milton (1890) by Dr Richard Garrett in the "Great Writers" series, with a biography by J. P. Anderson.

The sources of Paradise Lost have given rise to much discussion. It has been supposed to owe something to Adamo, a comedy by Giovanni Battista Andreini (1578-1652), to the Paraphrase associated with Annales of John Milton, which was published at Cambridge in 1655 by Francis Jusinius, and to the Lucifer and other plays of Joost van den Vondel. Parallelisms between Vondel and Milton were pointed out by Mr Edmund Gosse in Literature of Northern Europe (1879), and the comparison was carried further in Mr G. Edmundson's Milton and Vondel; A Curiosity of Literature (1885), a book which aroused much discussion. A valuable contribution to Miltonic criticism was made in 1933 by Mr Robert Bridges in an essay on Milton's Prodigy. This was reprinted in 1903, with some additional matter and an essay on "Classical Metres in English Verse" by W. J. Stone. Amongst other critical essays should be mentioned E. K. Chambers (in Edinburgh Review, 1893); Walter Bagelot (Library Studies, vol. 1, 1879); S. T. Coleridge (Seven Lectures on Shakespeare and Milton 1856); Edward Dowden (Transcripts and Studies of Sir John Sather, ed. by Sir A. S. Köhler (Paris, ed. in voll., 1882); Auguste Birrell (Obiter dicta, second series 1887); Walter Raleigh (Milton, 1900); E. Allodioli, Giovanni Milton e l'Italia (Prato, 1907).

Copies of Milton's Poetical Works were compiled by G. L. Prendergast (Madras, 1859-1857); by C. J. Cleveland (1867), based on a verbal index used in an American edition 1855, of the Poetical Works; by John Bradshaw (1854); by L. E. Lockwood, Lexicon to the English Poetical Works of John Milton (New York, 1897).

The tercentenary of Milton's birth was celebrated in 1908 in Cambridge, London and elsewhere. An exhibition of the portraits of Milton, and an exhibition of poetical works collected with great care and skill for the tercentenary of the poet's works, was held in June and July at Christ's College, Cambridge. The catalogue of this exhibition, drawn up by Dr G. G. Willianston, forms a valuable bibliography and iconography of the poet. A collection of Milton autographs, early copies of translations, and portraits was also held in December at the British Museum, and the anniversary itself was celebrated by a special meeting of the Royal Society, at which papers by Professors W. J. Courthope, Edward Dowden and others were read. There was a religious service at St Mary-le-Bow, Cheapside, and a banquet at the Mansion House.

MILTON, a town of N.E. Norfolk county, Massachusetts, U.S.A., about 7 m. S. of Boston, the Neponset river forming a large part of its N. and N.W. boundary. Pop. (1890), 4275; (1900), 6578 (1840 being foreign-born); (1900), state census, 7054; (1910), 7068. It is situated on the New York, New Haven, Hartford railway, and is primarily a residential suburb of Boston, with which it is connected by electric lines. The township covers an area of about 13 sq. m., and includes the villages of Milton, East Milton and Mattapan. The country is rolling and hilly, the Blue Hills (with the exception of a part included in Braintree in 1712 and now in Quincy) lying in Milton. On Great Blue Hill, the highest (635 ft. above tide-level), great fires were kindled at the news of the repeal of the Stamp Act, of the adoption of the Declaration of Independence, and of the surrenders of Burgoyne and Cornwallis; beacon fires were burned during the American and later Independence festivals. A lighthouse was built at an early date; and in 1853 the Blue Hill Observatory for meteorological investigation was established by Abbott Lawrence Rotch (b. 1861), who made important investigations concerning clouds, and attracted attention by his use of kites for obtaining meteorological data. Milton Academy (a non-sectarian school) was founded in 1798, opened in 1805, and suspended in 1867; a new academy was opened in 1885. There is a public library, which was opened in 1871, and in 1909 had more than 20,000 volumes. Cunningham Park is under the control of the trustees of a fund left for the benefit of the town, and contains a gymnasium, skating-pond, tennis courts, &c., open to townpeople only. Hutchinson Field, another public park, is a part of the estate of the last royal governor, Thomas Hutchinson; Governor Jonathan Belcher also lived in Milton for a time. There are two granite quarries in the township immediately north-west of the Blue Hills; the granite is of the "dark Quincy" variety—dark bluish grey in colour—and is used chiefly for monuments. Milton, originally a part of Dorchester, was first settled in 1640, and was called Uncataquisset. The township was separated from Dorchester and incorporated in 1662. It owes its name either to its early place of great and grist mills (Milton being abbreviated from Milltown) or to Milton Abbey, Dorset, whence members of the Tucker family came; it is supposed, to Milton about 1662. In 1712 the Blue Hill lands were divided between Milton and Braintree, and in 1868 part of Milton was included in the new township of Hyde Park. In Milton, on the 9th of September 1774, at the house of Daniel Vose, a meeting, adjourned from Dedham, passed the bold "Suffolk Resolves" (Milton then being included in Suffolk county), which declared that a sovereign who breaks his compact with his subjects forfeits their allegiance, that parliament's legislative measures were unconstitutional, that tax-collectors should not pay over money to the royal treasury, that the towns should choose militia officers from the patriot party, that they would obey the Continental Congress and that they favoured a Provincial Congress, and that they would seize crown officers as hostages for any political prisoners arrested by the governor; and recommended that all persons in the colony should abstain from lawlessness.

MILTON, a borough of Northumberland county, Pennsylvania, U.S.A., on the Susquehanna river at the mouth of Limestone Run, about 66 m. N. of Harrisburg. Pop. (1890), 5371; (1900), 6175 (166 foreign-born); (1910), 7450. It is served by the Pennsylvania, and the Philadelphia & Reading railways, and is connected with Lewisburg and Watsontown by an electric line. Milton has an attractive public park, is in an agricultural region, and has various manufactures. It was founded in 1792, and incorporated as a borough in 1817. In 1880 it was in great part destroyed by fire.

MILWAUKEE, a city and the county-seat of Milwaukee county, Wisconsin, U.S.A., the largest city of the state, at the mouth of the Milwaukee river on the W. shore of Lake Michigan, about 85 m. N. of Chicago. Pop. (1900), 285,315; (1910), 373,875. The Milwaukee river entering the city from the north is joined by about 1/2 m. from its mouth by the Menominee flowing from the west and a short distance from the lake by the Kinhikinnick flowing from the south. These rivers are navigable for lake traffic into the heart of the city. Milwaukee Bay, into which their combined waters empty, is a capital harbor, the construction of extensive piers and breakwaters a fine harbour of refuge has been created; and its inner harbour is deep enough for the largest lake-steamers.
From the shore of the lake the land rises, rather abruptly in most places, to a height of from 75 to 100 ft. From a broad plateau overlooking the lake the land slopes gradually westward to the river, again rising on the north, west and south to a height of 125 ft. or more. The rivers separate the city distinctly marked divisions of varying character known as the east, west and south sides. The manufactories are largely on the "flats" along the rivers and on the south side. The extensive use as building material of cream-coloured brick made in the vicinity gives the city its nickname, "the Cream City."

The city has many beautiful parks and squares, the most picturesque of which is Juneau Park, along the lake bluff. It contains the memorials to Ericsson and Solomon Juneau. Other parks are Lake Park, also along the shore, and South Shore, at North Point, where stands the waterworks pumping station, together with its Riverside and Kilbourn Parks, east and west respectively of the upper Milwaukee river, in the center of the city, Washington Park and the west side, containing a menagerie and a herd of deer; Sherman Park on the west side, and Kosciusko, Humboldt and Mitchell Parks on the south side. McKinley Park on the lake shore south of the city, and Whitewater Bay 6 m. north of the city, are popular bathing resorts. In addition to the statues in Juneau Park and in Washington Park there is a statue of Kosciusko in the park of that name; one of Washington and a soldiers' monument on Grand Avenue; a statue of Henry Bergh in front of the city hall; one of Robert Burns in the First Ward Park, and, in Washington Park, a replica of Ernst Rietschel's Schiller-Goethe monument in Jena, given to the city in 1908 by the Germans of Milwaukee.

Of the several cemeteries, that of Forest Home, south-west of the city, is the largest and most beautiful. The city is well sewered and has an excellent water-supply system owned by the municipality and representing an investment of more than $5,000,000. The water is obtained in Lake Michigan through an intake far out in the lake. Through a tunnel, 3 m. long, constructed in 1888, water is pumped by means of one of the largest single pumps in the world from the lake into the upper Milwaukee river, which is thus completely flushed by fresh water every twenty-four hours.

Milwaukee is one of the most healthful of the larger cities of the United States. Its average annual death-rate for 1900-1904 was 13.6. The proximity of Lake Michigan cools the atmosphere in summer and tempers the cold in winter. As a result, the extremes of heat and cold are not as great as those in most inland localities, and the temperatures vary between 20° in January and 70° in July, with extremes of 100° and -25°.

The annual mean precipitation is 31.4 in.

Suburbs.—Milwaukee proper occupies 221 sq. m. a small area as compared with other cities near it in population—Detroit (36 sq. m.) and Washington, D.C. (694 sq. m.). As a result, the population has overflowed into several populous suburbs industrially a part of Milwaukee and forming an extension of the metropolitan area. These are the township of Wauwatosa (pop., 1905, 11,132; 1910, 11,536), and the city of the same name, separated from the township in 1897 and having in 1910 a population of 3346; the city and township on the Menominee river, immediately adjoining the city on the west. The first settlement was made here in 1835. Wauwatosa has important manufactures, including machinery, brick, lime, beer, chemicals and wood-working, and extensive market gardens and nurseries and valuable farms. The Carntwell family and the Religious Girls of the Christian Order of St. Joseph's Academy, a convent of the Oblates of Mary of the Sacred Heart, and the Roman Catholic Academy, are educational institutions in the city. The city covers an area of 26.6 sq. m. and its population, according to the United States census of 1910, was 9057.

Public Buildings, Institutions, &c.—The principal public building in the city is the Federal building (1835-1898), the post office, custom-house and local headquarters for the United the manufacture of coal, grist mill, flour and various products of the city's own manufactures. Milwaukee is an important grain shipping port—In 1908 it shipped 28,618,519 bushels of grain and 3,752,923 barrels of flour, and its exports this year surpassed those of any other port. Milwaukee is the city of the largest distributing centres in the country for coal, which is received by lake, and stored in enormous coal docks for transshipping by rail throughout the west and north-west. The city is a port of entry, and in 1908 its total value of imports and exports was $3,600,457, and its exports at only $75,525.

Manufactures.—In 1905 the value total of Milwaukee's factory production was $438,881.545, 25.3% more than in 1900. In the manufacture of malt Milwaukee is among the largest of the cities of the United States and of the world. This value of liquor was $29,899,245, of which $22,134,580 was the value of malt liquors and $7,774,665 was the value of malt. In the manufacture of flour and meal, Milwaukee was 10th in the state and 7.4% of the entire product of the entire state. These products exceeding $1,000,000 in value were: leather ($1,294,007), Milwaukee being second in the manufacture of leathers among the states of the United States; foundry and machine
shop products ($10,212,723); iron and steel ($7,010,793); flour and grist-mill products ($6,329,428); slaughtering and meat-packing products ($5,058,518); men's clothing ($4,750,548); boots and shoes ($2,929,408); electrical machinery, apparatus, and supplies ($2,720,638); and ($1,966,930) and cigars and cigarettes ($1,320,019); furniture ($1,767,250); trunks and valises ($1,623,310); bosiery and knitting goods ($1,515,176); confectionery ($1,372,797); stores and groceries ($1,207,553); structural iron work ($1,307,217); wooden packing boxes ($1,024,750); and paints ($1,015,774).

Among Milwaukee's largest industrial establishments were the Allis-Chalmers Company at West Allis, employing about 5000 men and making engines of all kinds; and the plant of the Milwaukee Road, in South Milwaukee, with sidings which covers 154 acres. The flour mills of Milwaukee have a capacity of about 13,000 barrels a day.

Two of the city's tanneries are among the largest in America. In the Menominee river valley the peculiar cream-coloured Milwaukee bricks are made. North of the city on the Milwaukee river are extensive cement works.

Newspapers.—The first newspaper in Milwaukee, the Advertiser, began publication in 1836. The first German newspaper was established in 1834. In 1909 there were eleven daily newspapers, as follows: Evening Wisconsin (1847; Republican), Free Press (1901; Independent Republican), Journal (1882; Independent Democrat), News (1886; Independent, and Sentinel (1837; Republican), the oldest paper in continuous publication, Daily Commercial Letter (Commercial), Reporter (legal and commercial), Daily Commercial Letter (French); Allens (1888; Republican; Polish); Germania Abendpost (1872; Independent; German); and Der Herald (1834; Independent; German). Of more than a hundred other publications, one was published monthly, or quarter-monthly, and 5 were published weekly in German. There are 5 Polish weekly publications, 3 Bohemian, 1 Italian and one periodical for the blind.

Population.—The population of Milwaukee in 1840 was only 1712. During the following decade there was a steady flow of immigrants from the eastern states and from Europe, with the result that in 1850, two years after the admission of Wisconsin to the Union, the population was 20,661. The population at the succeeding decennial censuses was as follows: (1860), 45,245; (1870), 71,440; (1880), 115,587; (1890), 204,468; (1900), 283,315. In 1905, according to the census, the population was 312,948. The fact that out of a population of 285,315 in 1900, 88,991 were foreign-born, and 235,880 were of foreign parentage, that 53,854 were born in Germany, that 124,211 had both parents born in Germany, and that 26,934 additional had one or the other parent born in Germany, emphasizes the character of Milwaukee's population. The negro population in 1900 was only 862. The proportion of illiterates is small. Of the male population, aged 10 years or more, only 3269 (2068 foreign-born whites; 1944 native-born whites) were illiterate in 1900.

Government.—Milwaukee is governed under a city charter of 1874, providing for the form of city government most common in America, a mayor (elected biennially) and a single board of aldermen. There are the usual administrative boards whose members are appointed by the mayor, some of them with the approval of the board of aldermen, though the board of school directors is elected by direct popular vote. Two boards of civil service commissioners, one for fire and police departments and one for all other departments, have supervision over the city's civil service.

The assessed valuation of taxable property, in the city, in August 1906 was $201,583,127, of which $175,611,960 represented reality and $25,971,367 personality. The valuation is about 40 % of its actual value. The tax rate for all purposes in that year was $2.26 per $100. According to a special report of the census the cost of the government of Milwaukee in 1906 was smaller per capita than that of any other city in the country with a population of over 300,000. At the close of the year 1906 the total debt was $8,835,049, and the funded debt was $8,106,600.

History.—The first Europeans known to have visited the site of Milwaukee were Father Jacques Marquette, the Jesuit missionary, and his companion, Louis Jolliet, who on their return in the autumn of 1673 to the mission of St Francis Xavier at De Bourg, Sault Ste Marie, took the upper Mississippi, skirted the west shore of Lake Michigan in their canoes and returned. Milwaukee Bay is distinctly marked in the map attributed to Marquette, the original of which is now in the Jesuit College at Montreal, Canada; it was discovered in a convent in Montreal by Felix Martin (1804–1886), of the Society of Jesus, and was copied by Parkman. In 1790 La Salle and his party probably stopped here on their way south, and in the Jesuit Relations of that year the name Milwaukee first appears, as "Mililoke." This, and the various other spellings of the name, attempted to reproduce the Indian name of the village here, which Kelton thinks was pronounced Minewagi and meant "there is a good point," or "there is a point where huckleberries grow," in allusion to the fertile soil. Doubtless the name was well known at this time began to frequent the Wisconsin forests, touched at the bay many times within the succeeding years as the place was known to be a favourite rendezvous of the Fox (or Outagamie) Indians. In 1699–1700 Father St Cosme, a Recollect friar, was here, finding bands of Mascoutens, Fox, Winnebago and Potawatomi. He called the river "Melvarik," "Melvarik," or "Melvarik.

For more than half a century no definite reference to the place can be found. In 1760 its advantageous situation attracted the attention of a 1795 travelling trader, Alexander Henry, the first Englishman known to have visited the spot. Three years later there was a French fur-trading post here, but it is uncertain just when it was established or how long it was maintained. In 1795 Jacques Vieu, a Frenchman in the employ of the North-Western Fur Company, established a permanent post here, which seems to have continued, under his direction, with practically no interruption until 1820, when it was superseded by that of Astor's American Fur Company. Vieu built a dwelling and a warehouse and conducted extensive trading operations. In 1818 and 1819 the settlement was named "St. Lawrence," or "St. Lawrence," or "St. Lawrence.

The name of the village was changed to "Milwaukee," and the treaty of the 8th of February 1837 speaks of the "Milwaukee or Manawukey River." Morgan L. Martin (1805–1887) of Green Bay, a lawyer and judge, and a delegate to Congress in 1835–1847 from Wisconsin territory, explored the harbour facilities in 1835 and made a map of the place which he called "Milwaukee." He entered into an agreement later in the same year with Juneau and Michael Dousman for its development. A saw-mill was built in 1834, and settlers began to arrive. The east side was platted in the summer of 1835, and very soon afterward the plat of a settlement on the west side was also recorded, Byron Kilbourn being the chief projector and proprietor of the latter. The rival settlements, officially known as Milwaukee East Side and Milwaukee West Side, bore the popular designations of "Juncutown" and "Kibbourtown." A third settlement, begun on the south side by George H. Walker and known as "Walker's Point," was subsequently platted independently. The rivalry between the east and west townships was intense, the plat was so surveyed that the streets did not meet at the river, and there were bitter quarrels over the building of bridges. Milwaukee county was set off from Brown county in 1834, and in 1836 the establishment of Wisconsin was authorized. Under this act the east and west sides were independently incorporated in February 1837. A realization that the continuation of independent and rival corporations retarded growth eventually led to a compromise by which the two were united as two wards of the same village in 1839, the autonomy of each being still recognized by an odd arrangement whereby each maintained practically independent management of its finances and affairs. Walker's Point, the south side, was annexed as a third ward in 1845, and in 1846 the three wards were incorporated as the city of Milwaukee, of which Solomon Juneau was elected first.
MIMETITE—MIMICRY

MIMETITE, a mineral consisting of lead chloro-arsenate, (PbCl)Pb4(AsO4)3, crystallizing in the hexagonal system and closely resembling pyromorphite (q.v.) in appearance and general characters. The arsenic is usually partly replaced by equivalent amounts of phosphorus, and there may thus be a gradual passage from mimetite to pyromorphite. The two species can, as a rule, only be distinguished by chemical analysis, and because of their close resemblance the less frequently occurring chloro-arsenate was named mimetite or mimesite, from Gr. mimetis, imitator. Crystals of pyromorphite though usually optically uniaxial are sometimes biaxial, but in mimetite this anomalous character is almost always present; a cross-section of a hexagonal prism of mimetite shows a division into six optically biaxial sectors or a complex lamellated structure. In colour mimetite is usually yellow or brown, rarely white or colourless; the lustre is vitreous to pearly; the hardness is 3½, and the specific gravity 7·0-7·25. Like pyromorphite, mimetite is found in the upper parts of veins of lead ore, where it has been formed by the oxidation of galena and mispickel. When found in large amount it is of importance as an ore of lead.

The best crystallized specimens are those from Johanneorgenstein-stadt in Saxony and Wheal Unity in Cornwall. It was formerly found in considerable amount at Dry Gill in Cumberland, as six-sided barrel-shaped crystals of a brownish-red or orange-yellow colour and containing a considerable proportion of phosphoric acid; this variety has been called campylite, from Gr. kaupklados, curved, on account of the remarkable curvature of the faces of the crystals. (L. J. S.)

MIMICRY, in zoology, the deceptive and advantageous resemblance presented by defenceless and edible species of animals to other species of animals living in the same locality, which are harmful or distasteful and are consequently avoided by all or by a majority of the enemies of the class to which the mimic and usually the mimicked species belong. Mimicry is a special form of protective resemblance, differing from ordinary protective resemblance as exemplified by the similarity of the coloring matter of the leaf and the seed of the same plant, the red gnat-sucker to a piece of bark or of leaf-and stick-insects to the objects after which they are named, in that the imitated object belongs to the animal kingdom and not to the vegetable kingdom or to inorganic nature. Although, like protective resemblance, quite independent of affinity between the organisms concerned in the likeness, mimicry occurs most commonly between animals structurally similar, and therefore related, to one another, the relationship may be close or remote. For instance, the commonest and best-known cases are found in insects where both mimic and model may belong to the same genus, sub-family, family or order, or to different orders. More rarely it occurs between members of distinct classes of the same sub-kingdom, i.e. between spiders and ants or spiders and beetles; yet even in this case both mimic and model have in common certain fundamental structural points to which the finishing touches completing the mimetic likeness are superadded. Still more rarely mimicry exists between totally unrelated species like caterpillars or snakes or spiders and snails. But in no case does it appear that the modifications in shape and colour, which contribute to bring about a mimetic resemblance, are greater and more elaborate than those which result in the simpler examples of ordinary resemblance.

The principle of protective resemblance, for which the term mimicry, as above defined, was originally employed, was first explained by H. W. Bates. Subsequently the meaning of the word was extended by F. Müller to include cases of mutual resemblance between two or more noxious species inhabiting the same area. Hence the resemblances belonging to the first category are commonly termed "Batesian mimicry," and those belonging to the second category "Müllerian mimicry," or more properly "Müllerian resemblance." The difference between the two phenomena is essential and evident; but without an additional mental information as to palatability it is impossible to know with certainty to which of the two a particular case of mimicry is to be assigned. Over and over again extended knowledge on this point and inferences drawn from other facts have shown the certainty or probability of examples of mimicry being in reality "Müllerian," which were previously accepted without question as "Batesian." A simple illustration will serve to explain these two aspects of mimicry and to show the advantage in the struggle for existence which that mimicry confers upon the species concerned.

There is a common British wasp, called the 'hornet,' which is known as the drone-fly from its resemblance to a large hive or honey bee. Honey bees are protected from a large number of insect enemies because they sting and are distasteful. Insect-eating birds soon learn to associate distastefulness with the size, form and colour of the bees, and consequently leave them alone after one or more trials. But flies of the drone-fly kind cannot sting, and, so far as is known, are perfectly innocuous and edible. The advantage to the fly of its deceptive resemblance to the bee is theoretically perfectly evident and practically can be demonstrated by experiment. It is in the first place a matter of common knowledge that human beings who have been taught to avoid handling bees invariably fear to touch drone-flies, unless specially trained to distinguish the one from the others. Moreover, Professor Lloyd Morgan found that young birds that had tasted and rejected workers of the hive bee as unpalatable subsequently refused to taste not only drones, which have no stings, but also drone-flies. So far as our information at present extends the resemblance between these two insects is a simple case of mimicry in the Batesian sense of the word. That is to say, an edible species is protected by resembling one that is inedible. But if it be discovered, as is possible, that the drone-fly is also inedible, the mimicry must be ascribed to the Müllerian category, and the reason for it becomes less evident. In what way, it may be asked, are two or more distasteful species of insects, occurring in the same locality, benefited by resembling each other? The ingenious explanation suggested by Fritz Müller for similar cases met with in butterflies is probably the true answer. This explanation depends upon what is now an experimentally demonstrated fact that insectivorous birds, and probably other animals, have no instinctive knowledge of what insects are edible and what is inedible. This knowledge is acquired by experience; and since it is not, at all events as a rule, taught by the first taste to any individual bird, it is reasonable to infer that a considerable amount of injury, sufficient to disable if not to kill, is annually inflicted upon insects belonging to species protected by distastefulness or kindred qualities. Now insects that possess noxious attributes, and the same is true of other animals, usually have a conspicuous warning coloration which appeals to the eyes of enemies and helps them to remember more easily the cause of an
MIMICRY

unpleasant experience, helps in fact to establish a psychological association between a particular style of coloration and a nasty taste or a painful wound. This being so, it is evident that all the distasteful species in a given area are differently coloured, and that some individuals of all the species will be annually subjected to the experimental tasting of insects both before and after the numerous lessons of the season. But if all the species in question resemble each other the resemblance will be mutually beneficial to them because the association between the two attributes they have in common, namely distastefulness and a particular scheme of colour, will be rapidly established. One lesson only, instead of many, has to be learnt; and once learnt at the expense of a few individuals of one or two species it will thereafter be applied indiscriminately to all. This type of mimicry has been well defined by Professor E. B. Poulton as the unification of warning colours.

Since belief in the adequacy of the two theories, above outlined, to account for the facts they profess to explain, depends ultimately upon the testimony that can be brought forward of the usefulness of warning characters, of the deception of mimicry and of the process for learning by experience possessed by enemies, it is necessary to give some of the evidence that has been accumulated on these points.

(1) In South America there are butterflies formerly grouped as Heliconius and composed of species in which the larvae are distasteful and the adults have peculiar coloration. It is abundant in individuals so as to be susceptible of easy capture. They possess scent glands. By observation and experiment it was discovered independently by Mesers Bates, Wallace and Bell that the caterpillars by birds are not recognised by them, and that they prey upon unprotected Lepidoptera. (2) As a result of a series of trials made in Calcutta, Mr. Finn came to the conclusion that young birds have no instinctive knowledge of unpalatable insects, and that no warning colouring is forthcoming in spite of the fact that experimental tasting soon teaches them to recognize and avoid species they have previously rejected with dislike, and that having once learnt the lesson they long remember it. (3) That birds may also be deceived by insects that mimic those they have found to be unpalatable has been shown by the above-quoted experiment with the drone-fly and the honey-bees made by Professor Lloyd Morgan. He also found the chinkapinquirrel placed upon glass slips banded black and yellow, afterwards refused to touch meal moistened with water and spread upon the same slips, although they had previously eaten it with readiness off plain coloured slips. With two exceptions, these chickens that had learnt to associate black and yellow banding with a bitter taste also refused to touch the caterpillar of the cinnamon moth (Euchloe jacobaeae), which is banded with these colours. Moreover, young birds that had been taught by experience that these caterpillars are unpalatable also left wasps untouched. (4) Guy Marshall once offered to a baboon a dish of food presented in such a way as to display its bright red and black markings to the monkey. It was taken but rejected after being tasted. A specimen of another butterfly (Precis sexsama) which mimics the Arazas was therefore offered to the baboon. He ate the baboon's fruit held it a few moments, and then let it escape uninjured without trying to taste it. But when another butterfly of the same species, but with the wings cut off, was offered to the baboon it promptly ate it without showing any dislike. The results of this experiment with the baboon and of those with the birds are precisely what would be expected if the theory of mimicry is true. Experiments to test distastefulness have also been made with various kinds of insectic- orous Arthropoda, like spiders and mantises. These experiments have shown that Arthropods also have their likes and dislikes in the matter of insect-food and frequently refuse to eat insects which are warningly coloured and are distasteful to vertebrate enemies. They appear, however, to have no appreciation of mimetic and warn- ing colours, and have therefore not influenced in any way the evolu- tion of the latter phenomena derived from hunger. Nevertheless, as explained below, it seems to be highly probable that anti-mimetic insects and spiders, when the resemblance is dependent to a greater extent upon size, shape and movement than upon tint, have acquired their mimetic likeness especially to protect them from the attacks of such insect-enemies as preda- ceous wasps of the family Pompilidae, flies of the family Asilidae, and from so- called scorpion-flies of the family Ichneumonidae, as well as from other insect-eating Arthropoda.

The term mimicry has also been applied to resemblances of a different kind from the two enumerated above—resemblances, that is to say, by which predaecous species are supposed to be enabled to approach or mix without detection with animals they prey upon or victimize in other ways. To this end the resemblance may be actually to the species victimized or preyed upon or else to a species which the species preyed upon does not fear. This phenomenon is termed "aggressive mimicry" as opposed to the Batesian and Müllerian phenomena, which are termed "protective mimicry." A few possible cases of aggressive mimicry are enumerated below. It is evident that cases of mimicry in different classes of the animal kingdom; but the phenomenon is of comparatively rare occurrence, and the supposed instances may be susceptible of other interpretations, excluding them altogether from mimicry, or bringing them under the Batesian or Müllerian interpretation of the phenomenon.

Among mammals there are no certain instances of mimicry known. It has been claimed that the resemblance between some of the predaceous species of ants and the larvae of the inchworms, a peculiar species of caterpillar which has no protective likeness, has been obtained by the ants imitating the inchworm in form and action, and that they have been able to deceive wasps in the manner of an inchworm. But the supposed instances are not convincing, and the resemblance is probably to be regarded as due to the resemblance between the animals, which are of the same order, instead of as an instance of mimicry.

In East and South Africa there is a genus of Mustelidae called Ichneumon (Zorilla) which possesses a foetid odour and is warningly coloured, and is the prey of the curly-tailed lizard (Uromastyx), so that it is probably an instance of mimicry. There also occurs in South Africa another member of this family (Poecilogale albinucha), which is very similarly coloured. It is possible that this resemblance is mimetic in the Batesian sense of the word, and that the Poecilogale, if it should profit by its likeness to the highly offensive and warningly coloured Ichneumon, is, or may be, one of the members of the same tribe. If this be the case the two species probably furnish an instance of true Müllerian mimicry.

In South America there is considerable superficial resemblance between the little bush dog (Caralæus cupreus) of Brazil and the guaquus of the same region, which is the prey of the weaver-spider (Heteropoda braziliensis) of the same country. The animal of the same name—the tayra (Galera barbara). The tayra is, when adult, black beneath and on the legs, and not uncommonly has a considerable quantity of greyish hair on the head. In these particulars, as in size and shortness of leg, the dog resembles the weasel; and since there are good reasons for believing that the latter is protected alike by ferocity and stink-glands, it is quite possible that the dog, of unusual coloration and form for the Canidae, is protected from the attacks of pumas, jaguars and ocelots by his likeness to the tayra.

A few cases of mimicry have been recorded in birds. The common cuckoo (Cuculus canorus) of both the tropics inhabiting Africa and Asia closely resembles sparrow-hawks. Some cuckoos are singular for their habit of using the nests of smaller birds to lay their eggs in, so that the young cuckoo thus hatched are reared by parents of a different species. It has been suggested that the object of the likeness exhibited to the hawk was to deceive the cock cuckoo either to frighten the small birds away from their nests or to lure them in pursuit of him, while the hen bird quietly removed to another nest. According to this explanation, both sexes of the cuckoo resemble the hawk does not necessarily prove this suggested explanation to be false: but if it be true that the smaller passerine birds are duped by the similarity to the bird of prey, it may be that the cuckoos themselves escape molestation from larger hawks on account of their resemblance to the sparrow- hawk. Another species of this group, the black cuckoo of India, apparently mimics the black drongo-shrike (Dicrurus ater), the resemblance between the two species being very close. The drongo is a fierce and powerful bird which will not tolerate a strange bird of the size of a cuckoo near its nest, yet on account of its resemblance to the drongo, the black cuckoo is able to lay her egg in the nest of the drongo, which mistakes the cuckoo for one of its own kind. In this case also both sexes of the cuckoo mimic the drongo, whereas according to the theory it would be expected that the drongo, in the case of the two species, the resemblance to the pugnacious drongo may be beneficial in protecting the defenceless cuckoo from enemies. Further observations have been made by Mr. Marshall on the inedibility of certain birds suggest that the resemblance between cuckoos and hawks on the one hand and cuckoos and drongos on the other may be susceptible of another explanation in full agreement with the theory of mimicry as a means of protection. The African drongo (Dicrurus (Buchango) assimilis) was rejected after one or two attempts to eat it by a hungry mongoose (Herpestes gala) which had been starved for purposes of the experiment. After the drongo had been killed, it was, however, devoured. The same mongoose also refused to eat a kestrel (Cernhus rapi- loidea) and a hobby (Falco subbuteo), although it devoured certain
MIMICRY

other birds that were given to it. It is clearly possible, therefore, that cuckoos which mimic drongos and hawks may be protected from those enemies which find these birds distasteful.

Instances of mimicry in birds is presented by a Madagascar thrush or habbard (Ovul Eduard), which resembles the feather for feather a shrike (Xenopirostris pelloni), from the same island. The Tylas has departed from the normal coloration of its green plumage, so that in the white-backed variety of this species the green of the plants frequented by the birds, wherever the green portions were rendered invisible by the same background. Antedemeridae are also believed to be mimics. The plant juices of the Indian species of Mantidae, again, several species of this order have become profoundly modified in form in imitation of inedible plants for their defence. The nature of the warning colors, for instance, in theヅcarius mimics Phereus phereus, a species of the family, which, like the Madame miller, has on the shors huese in the coloration of a species of Acrorystus, a hard and inedible weevil (Curculionidae); and Phorazis, a kind of grass hopper similarly resembles ladybirds (Coccinellidae). A species of the family of Mantidae (Genus Denticolus, from South America) also is the imitative mimicry of a species allied to Gammarortletix not only in shape and coloration but also in the habitat of remaining still when disturbed. In the phalanges, the orange babbler (Ailurus flavigula), another example of mimicry, is said to resemble warningly a longish, slender, vinegar-like creature, which, like so many wasp-like Hymenoptera, has the body banded red and black. This beetle probably mimics the Australian hornet (Vespa tropica). In the European Longicorn (Clytus arietis), the beetle on the other hand, the elytra are of normal length and are banded with yellow stripes. The beetle, moreover, is of slender build and all its actions are suggestively wasp-like. This may, however, be an instance of Müllerian mimicry rather than of Batesian mimicry, the beetle being itself inedible; for Schellford has stated his conviction that the Bornean representatives of the sub-family (Clytinae), to which the beetle belongs, are exceptionally short the wings and that therefore they are never captured by ants. Again, the terminal portion of the antenna being extremely fine as to be almost invisible. Similar modification of the antennae in the Longicorn Eutelminus variabilis brings about the resemblance between this beetle and a beetle, Eutelminus chenin- s, one of the Phytophaga of the family Hippidae. Numerous instances of mimicry in this order of insects have recently been recorded from Borneo by R. W. C. Shelford, a large number of them being of the sub-family Aethinae.

Instances of ant-mimicry, unique in the method employed to bring about the resemblance, are supplied by some insects of the family of the ants. We refer to the group commonly called Membracidae. In one of these (Heterotrobus trivolosus), the dorsal area of the forepart of the thorax is developed into a plate which projects backwards over the body of the insect, which retains its normal form, and conceals all but the head, wings and legs. This shield if shaped in such a manner as to resemble closely the body of an ant, the median portion of the shield being represented in some cases by a row of bristles or spines, is almost sub-globular like the abdomen of the ant. This insect comes from Central America. Still more curious is the mimicry of another of these insects from Venezuela which is found in company with the cane-beetle (COLOMENIA INCISA). In pursuing their operations of leaf-storage, these ants present the appearance of a crawling crowd of leaf-particles, fragments of leaves being carried by the insects in such a way as to conceal a great part of the beetle. The whole body is black, the dark coloured legs project beyond the burden. The immature form of the above-mentioned species of Membracidae mimics both ant
and leaf-particle. The legs and lower part of the body are dark coloured, but the dorsal surface of the thorax and abdomen is coloured green and is raised so as to be in closest contact with the three exceedingly reproductively delicate margin of a leaf-cut out by the mandibles of the ant. In Borneo the Homopperon Issus bruchoides mimics a species of Curculionid beetle of the genus *Aulacophora*.

In the Hemipterous group of the Rhynchota ant-mimicry is illustrated by the larva of a British species of Reduvitidae (*Nabis latunensis* in which the foreparts of both the snout and the insect's white head is located in the same neighbourhood. Another instance in this group is supplied by a Bornean species of Reduvitidae which mimics a species of the genus *Brachionus*, one of the parasitic Hymenoptera.

The larvae of the *Lepidoptera* (flies) are in general form aculeate Hymenoptera belonging to the families of bees and wasps. The changes in colour and structure required to complete the resemblance to particular species are comparatively slight and much less complicated than those needed to produce a likeness to other protected insects. Hence we find that the majority of flies that mimic insects of other orders have bees or wasps for their models. Many of the Syrphidae are banded black and yellow and present a general resemblance to wasps, especially when they alight, the resemblance being enhanced by a twitching action of the abdomen imitating the similar action so familiar in species of the Hymenoptera. These peculiar bars are the result of an instinctive form of flight. They commonly hang poised in the air, then dart with lightning swiftness to another spot and pose themselves again. This habit, the origin of the name *Syrphus* ([*Syrphidae*]), also resembles the mimicry of the *Syrphus*. If they flew like ordinary flies their resemblance to Hymenoptera would be obscured by the rapidity of their flight and they might be caught on the wing by insectivorous birds or other insects; but when poised they display their coloration. When the latter is lost during flight, the rapidity of their movement defies pursuit. The particular likeness to a honey-bee presented by one member of the genus *Eristalis* (*Eristalis tenax*), has been already referred to. But the likeness probably goes deeper than superficial resemblance that appeals to the eye, for spiders which distinguish flies from bees by touch and not by sight, treat drone-flies after touching them fearlessly and try to catch them in webs. This is probably the reason why so many spiders possess a resemblance to flies. If a spider did not hesitate to ascribe the resemblance to them presented by the Pierine, *Dismorphia* (*Leptus*) orise, to mimicry, believing *Dismorphia* to be unprotected and noting that it departed widely in the matter of colouration from spiders generally, the spider would still belong. "Although mimicry in the Lepidoptera has been carried to a greater extreme in South America than in any other country of the world, examples of the phenomenon are found in the Ethiopian and Oriental regions. A classical and highly complex case first investigated and explained by R. Trimen is that of *Papilio dardanus* which is widely distributed in Africa and is represented by several sub-species or geographical races. The most primitive of these is *antinoris* from Abyssinia, which is non-mimetic and has the two sexes nearly alike. The males of other sub-species are much like the males of *antinoris* but the females are more different and mimic *Amauris* melanurn, which has the two sexes closely alike. The larva of this *Papilio* is chiefly protected by its coloration. antennae, etc. It has been found that boas which are afraid of snakes are also afraid of the snake-like larva of the South African *Choracnops ossiris*. Finally Shelford states that the anterior end of a Bornean species (C. myodon) offers a striking and detailed resemblance to the head of a snake (*Dendrhopis picta*). The mimicry of an ant is sometimes confined to the larval stage. The early larval stage of the "Lobster Moth" (*Staurophora fagi*), for example, presents a general resemblance, due to a combination of shape, hair and colour, to a larval ant of the genus *Oecophylla* (moths).*Oecophylla smaragdina* in this case also the posterior end of the larva represents the anterior end of the ant. Another instance of mimicry affecting the larval form is supplied by the moth Endromis versicolor, the caterpillar of which resembles a larval ant (Euphydryas latimeri) with two tentacles respectively representing the abdomen and antenna-bearing head of the model. A parallel case of mimicry exists at Singapore between the larva of a Bornean fly and Protocerus (Hymenoptera: *Oecophylla smaragdina*). In this case also the posterior end of the larva represents the anterior end of the ant. A different mode of mimicry affecting the larval form is supplied by the moth *Euphydryas latimeri*, the caterpillar of which resembles a larval ant (Euphydryas latimeri) with two tentacles respectively representing the abdomen and antenna-bearing head of the model. A parallel case of mimicry exists at Singapore between the larva of a Bornean fly and Protocerus (Hymenoptera: *Oecophylla smaragdina*). In this case also the posterior end of the larva represents the anterior end of the ant. Another instance of mimicry affecting the larval form is supplied by the moth *Euphydryas latimeri*, the caterpillar of which resembles a larval ant (Euphydryas latimeri) with two tentacles respectively representing the abdomen and antenna-bearing head of the model. A parallel case of mimicry exists at Singapore between the larva of a Bornean fly and Protocerus (Hymenoptera: *Oecophylla smaragdina*). In this case also the posterior end of the larva represents the anterior end of the ant. Another instance of mimicry affecting the larval form is supplied by the moth *Euphydryas latimeri*, the caterpillar of which resembles a larval ant (Euphydryas latimeri) with two tentacles respectively representing the abdomen and antenna-bearing head of the model. A parallel case of mimicry exists at Singapore between the larva of a Bornean fly and Protocerus (Hymenoptera: *Oecophylla smaragdina*). In this case also the posterior end of the larva represents the anterior end of the ant.
mimetic Lepidoptera. The first is the occurrence of mimicry only in the female sex. The reason for this is to be found in the ovarian development of the female which is slower in flight than the male and is exposed to special danger of attack when resting to lay her eggs. The second noteworthy phenomenon is the mimicry of the ant. It is more correctly the species of insects by members of a single species. This is a not uncommon mode of life in the two major families of Bateian mimicry the explanation is probably this. When an edible species gains protection by mimicking a distasteful one, there is a second step in the process of the one that is not protected by one species should be less than those of the model; and this appears to be achieved in some cases by the individuals of the mimic species being smaller than the model.

Spiders furnish numerous instances of mimicry. Though simple in many, these are as perfect illustrations of the phenomenon as any found in the animal kingdom. Amongst the orb-weavers of the family Argyopidae there are species belonging to the genera Cyclosa and Cryptophora which closely resemble small snail-like gastropods as they cling to the underside of leaves with their legs drawn up. Other members of the same family—e.g. Araneus cucumontis, and Paraphidias thoracis—imitate beetles of the family Cocculididae which are known to be distasteful; and certain genera of the family Salticidae (Hoplocnemus, etc.) the females of which are particularly marked, resemble butterflies in the possession of the same type of coloration by two or more protectants inhabiting the same district. The significance of this phenomenon, as already stated, was first explained by Fritz Müller; but although the term “Mullerian mimicry” is generally used, its Synaposemy is Müllerian mimicry. Finally, the likeness of an edible species to a warningly coloured inedible one in the same natural region is usually termed “Kalliantha” or “Stackelberg’s mimicry.” It is not strictly speaking cases of mimicry at all but of warning coloration. Poisonous or noxious animals usually have some special characteristic, attribute, sometimes the display of conspicuous coloration, as in the skunk; sometimes the emission of sound as in the rattlesnake; sometimes a combination of the two, as in the common porcupine and the large black scorpions of Africa and India. Such characters have been termed by Professor Poulton “aposematic.” Neither of the above-mentioned animals is mimicked; but where two or more noxious animals, inhabiting the same region, resemble each other, both being aposematically or warningly coloured, the phenomenon is said to be of the Synaposemy of Müllerian mimicry. Finally, the likeness of an edible species to a warningly coloured inedible one in the same natural region is usually termed “Kalliantha” or “Stackelberg’s mimicry.” It is not strictly speaking cases of mimicry at all but of warning coloration. Poisonous or noxious animals usually have some special characteristic, attribute, sometimes the display of conspicuous coloration, as in the skunk; sometimes the emission of sound as in the rattlesnake; sometimes a combination of the two, as in the common porcupine and the large black scorpions of Africa and India. MIMNERMUS—MINA

cited above, with the exception of the first, the synapomorphies are vastly in excess of the pseudapomorphy; this appears to be the general rule elsewhere. Frequently the groups are composed solely of protected species, so far as is at present known; and some time, it is usually, the probabilities of unpaired species as exceptions of course of the model. An example of the latter occurs in Singapore where the vicious red-spreading-ant (Oechopryma marmorata) is mimicked by the larva of a species of Hippodamia, and by some spider wasps, Natutic平州ani, Satulics platzeleoides (Salticidae) and Amelesia fortipes (Thomisidae), there being no reason to suppose that either the host larvae or the spiders are protected forms. Mimicry among many groups of species similar to those mentioned above have been found in other countries; but the instances cited are sufficient to show how widespread are the influences of mimicry and how profoundly it has modified the insect fauna in various parts of the world.

When stimulated—say, at the axis of one of the secondary petals—the leaflets move upwards on each side towards a tip, the movement being propagated centripetally. It may then be communicated to the leaflets of the other secondary petals, which close (the petals, too, converging), and thence to the main petiole, which sinks rapidly downwards towards the stem, the bending taking place at the petiole (θ in figure) or swollen base of the leafstalk. When shaken in any way, the leaves close and droop simultaneously, but if the agitation be continued, they reopen as if they had become accustomed to the shock.

The common sensitive plant of hot countries is M. pudica, a native of tropical America, but now naturalized in corresponding latitudes of Asia and Africa, as well as many other places, especially on seedling plants. In the so-called "sensitive plants" these movements not only take place under the influence of light and darkness, but can be easily excited by mechanical and other stimuli.

When opened—say, at the axis of one of the secondary petals, the leaflets move downwards on each side towards the stem, and are at the same time spread out, the leafstalk becoming swollen, and the petiole remaining fixed. When shaken in any way, the leaves close and droop simultaneously, but if the agitation be continued, they reopen as if they had become accustomed to the shock. The common sensitive plant of hot countries is M. pudica, a native of tropical America, but now naturalized in corresponding latitudes of Asia and Africa, as well as many other places, especially on seedling plants. Branch and leaves of the sensitive plant (Mimosa pudica), showing the petiole in its erect state, a, and in its depressed state, b; also the leaflets closed (c), and the leaflets expanded (d); b, pulvinus.

MIMULUS, in botany, a genus (nat. order Scrophulariaceae), of showy, hardy or half-hardy, herbaceous, rarely shrubby plants, natives of the extra-tropical or mountainous parts of both old and new worlds excepting Europe, but chiefly America. The plants have opposite, undivided leaves, and auxillary, generally solitary flowers with a two-lobed, gaping corolla. The flower is M. pudica, a native of tropical America, but now naturalized in corresponding latitudes of Asia and Africa, as well as many other places, especially on seedling plants. In the so-called "sensitive plants" these movements not only take place under the influence of light and darkness, but can be easily excited by mechanical and other stimuli.

MINA, FRANCISCO ESPOZ Y (1781-1836) Spanish guerrillero leader and general, was born at Ydozin in Navarre on the 17th of June 1781. His father, Juan Esteban Espoz y Mina, and his mother Maria Teresa Huncain y Ardaiz, belonged to the class of yeomen. Mina remained working on the small family inheritance till 1808. When Napoleon endeavoured to seize Spain in that year he enlisted in the regiment of Doyle, and then passed to the guerrilla band commanded by his nephew Xavier Mina. When Xavier was captured by the French on the 21st of March 1810, seven men of the band elected to follow him to France; and on the 26th of April of the same year, when the Junta of Aragon gave him the command of the guerrilleros of Navarre. His first act was to arrest and shoot at Estella, one Eschevarria, who, under pretence of being a patriotic guerrillero, was in fact a brigand. The national government at Cadiz gave him rank, and by the 7th of September 1812, he had been promoted to commander-in-chief in Upper Aragon, and on the left bank of the Ebro. In the interval he claimed that he had fought 143 actions big and little, had been repeatedly wounded with bullet, sword and lance, had taken 13 fortified posts, and 14,000 prisoners, and had never been
MINARET—MINAS GERAES

surprised by the French. Though some maintain that he was not at his best as a leader in battle, as a strategist he was very successful, and he displayed great organizing capacity. The French authorities were compelled to allow him to levy customs dues on all goods imported into Spain, except contraband of war, which passed without payment. He was able to avoid levying excessive contributions on the country and to maintain discipline among his men, whom he had brought to a respectable state of efficiency in 1812. Mina claimed that he immobilized 65,000 French troops which would but for him have served with Marmont in the Salamanca campaign. In the campaign of 1813 and 1814 he served with distinction under the duke of Wellington. After the restoration of Ferdinand he fell into disfavour. On the 25th and 26th of September he attempted to bring about a rising at Pamplona in favour of the Liberal party, but failed, and went into exile. His political opinions were democratic and radical, and as a yeoman he disliked the hidalgos (noble).

The revolution of 1820 brought him back, and he served the Liberal party in Galicia, Leon and Catalonia. In the last district he made the only vigorous resistance to the French intervention in favour of Ferdinand VII. On the 1st of November 1825 he was compelled to capitulate, and the French allowed him to escape to England by sea. In 1830 he took part in an unsuccessful rising against Ferdinand. On the death of the king he was recalled to Spain, and the government of the regent Christina gave him the command against the Carlists in 1835, though they feared his Radicalism. By this time, years, exposure and wounds had undermined his health. He was also opposed to Thomas Zumalacarregui (q.v.), an old officer of his in the War of Independence, and an even greater master of irregular mountain warfare. His health compelled him to resign in April 1836, and his later command in Catalonia was only memorable for the part he took in forcing the regent to grant a constitution in August 1836. He died at Barcelona on the 24th of December 1836. Mina was a brave soldier and a mastermind who conducted the war against the French in 1810-12 with humanity if they had helped him, but as they made a practice of shooting those of his men whom they took, he was compelled to retaliate. He finally forced the French to agree to an exchange of prisoners.

AUTHORITIES.—In 1825 Mina published A Short Extract from the Life of General Mina, in Spanish and English, in London. Mention is made of him in all histories of the affairs of Spain during the first third of the 19th century. His full Memoirs were published by his widow at Madrid in 1851-1852.

MINARET (from the Arabic mandal; manar or minor is Arabic for a lighthouse, a tower on which nart, fire, is lit), a lofty tower or column, bearing a muazzin or muezzin, and usually surmounted by a circular, or in some cases by a square or octagonal, minaret. The word is derived from that of the Pharos, the great lighthouse of Alexandria, in the top storey of which the Mahomedan conquerors in the 7th century placed a small praying chamber. The light-house form is perpetuated in the minarets which are found attached to all Mahomedan mosques, and probably had considerable influence on the evolution of the Christian church tower (see an exhaustive study in Hermann Thiersch, Phare Antikes, Islam und Oecident, 1900).

The minaret is always square from the base to the height of the wall of the mosque to which it is attached, and very often of circular section. The upper portion is divided into two or three stages, the wall of the upper storey being slightly set back behind the one below, so as to admit of a narrow balcony, from which the asam, or call to prayer, is chanted by the muezzin (muæzin, moeddin). In order to give greater width to the balcony it is corbeled out with stalactite vauling.

The balconies are surrounded with stone balustrades, and the upper storeys are richly decorated; the top storey being surmounted with a small bulbous dome. The earliest minaret known is that which was built by the caliph Walid (A.D. 703) in the mosque of Damascus, the next in date being the minaret of the mosque of Tulun at Cali (A.D. 879), with an external spiral flight of steps like the crenellations of towers in Assyrian architecture. This minaret as also the example of El Hakim (906), is raised on great square towers. The more remarkable of the other Cairene minarets are those of Imam esh-Shafi (1218), Muristan al Kalaum (1280), Hassan (1354), Barkuk (A.D. 1382) and Kait Bey (A.D. 1468). Of the same type are the two minarets added to the mosque of Damascus in the 15th century. In Persia the minarets are generally circular, with a single balcony at the top, corbelled out and covered over. In India, at Ghausni, there are no balconies, and the upper part of the tower tapers upwards; the same is noticed in Persia. Usually the minaret of Kutub is divided into six storeys with balconies at each level. In the well-known tomb of the Taj Mahal the four minarets are all built in white marble, in three storeys with balconies to each storey, and surmounted by open lanterns. The minarets of Constantinople are very lofty and wire-drawn, but contrast well with the domes of the mosques, which are of slight elevation as compared with those at Cairo.

MINAS [MINOIDES] (q.v. 1790-1850), Greek scholar, was a native of Macedonia. During the Greek War of Independence he migrated to Paris, where he tried to enlist the sympathies of Europe on behalf of his countrymen and to promote the study of ancient and modern Greek. But his chief claim to recognition consists in his discovery of two important MSS. (amongst others) in the monastery of Mt Athos during his exploration of the libraries of Turkey and Asia, at the instance of M. Villemin, minister of public instruction in France. One of these contained the last part of a treatise on the Refutation of all Hostes, now generally admitted to be the work of Hippolytus (q.v.), the other the greater portion of the Fabulae of Babrius.

MINAS GERAES (i.e. "general mines"), popularly Minas, an inland state of Brazil, bounded N. by Goyaz and Bahia, E. by Bahia, Espirito Santo and Rio de Janeiro, S. by Rio de Janeiro and Sao Paulo, and W. by Sao Paulo, Matto Grosso and Goyaz. It is very irregular in outline and covers an area of 221,861 sq. m. upon the great Brazilian plateau. Among the Brazilian states it is fifth in size and first in population—3,184,099 in 1830, and 3,504,471 in 1900.

The surface of Minas Geraes is broken by mountain ranges and flows of watercourses, the latter forming fertile valleys shut in by barren uplands, or campos. The reckless destruction of forests along the watercourses also adds to the barren aspect of the country. The principal mountain ranges are the Serra da Mantiqueira on its southern frontier and its N. extension, the S. do Espinhalho, which runs parallel to the Serra do Mar, or coast-range, and separates the inland or campo region from a lower forested zone between the two ranges. Most of the wooded district south of the Mantiqueira belongs to the states of Sao Paulo and Rio de Janeiro, but east of the Espinhalho it belongs to Minas Geraes and extends eastward to the Serra das Aymores, on the frontier of Espirito Santo. This zone has an abundant rainfall, dense forests and a fertile soil. It is drained by the Doce, Mucury, Jequitinhonha and Pardo, which have their sources on the eastern slopes of the Espinhalho and cut their way through the Aymores to the sea. The tributaries of the Rio Doce cover the slopes of the Serra do Espinhalho for a distance north and south of about 200 m. The southern part of this region is well populated, and is covered with coffee and sugar plantations. On the western frontier a northern extension of the great central chain of Goyaz forms the water-parting between the drainage basins of the Sao Francisco and Tocantins, and is known at different points as the Serra do Paranam, Serra de Sao Domingos and Serra das Divisoes. South-east of this chain, between the headwaters of the Paran and Sao Francisco, are the Serra da Canastra and Serra da Matta de Corde, an irregular chain of moderate elevation running north and south. The highest elevations in the state, so far as known, are Itatiaia (8858 ft.) in the Serra da Mantiqueira, and Caraça (6414 ft.), near Ouro Preto, in the Serra do Espinhalho. In the central part of the state the rainfall is heavy, and Minas Geraes is extremely complicated. The Mantiqueira-Espinhalho chain shuts out the streams flowing directly east to the Atlantic, and the boundary ranges on the west shut out the streams that flow into the Tocantins, though their sources are on the actual threshold of the state. Between these two mountain chains the head streams of the Paran and Sao Francisco are intermingled—the one flowing inland and
southward to the great La Plata estuary, the other northward and eastward across the arid highlands of Brazil to the Atlantic coast in 10° 30' S. lat. Less than 100 m. from the city of Rio de Janeiro and about 60 m. from the coast is the source of the Rio Grande, the larger of the two rivers that form the Paraná. It rises near the peak of Itatiya, on the northern slopes of the Mantiqueira, and flows north-west and west across the Minas plateau, receiving several large tributaries from the south. North and parallel with its course is a low watershed, which separates its drainage basin both from that of the São Francisco and from that of the Parnaíba, the northern confluent of the Paraná. The latter rises on the western slopes of the Serra da Mantiqueira, and from one of its southern tributaries has its source in a "knot" of the Serra dos Rosires, from which streams flow eastward to the São Francisco and northward to the Tocantins. The central and greater part of the state, however, is included in the drainage basin of the upper São Francisco. Its source is in the Serra da Canastra, and its general course across the state is north by east, during which it receives the Paracatú, Uruçula, Pardo and Carinhahua from the west and the Verde Grande and Vélas from the east. Part of these rivers are navigable for small steamers, and the São Francisco is some 600 miles long. They have been important in the development of Central Brazil. All these rivers of the Brazilian plateau are interrupted by falls and rapids.

The climate of Minas Geraes is characterized by high sun temperatures and cool nights, the latter often dropping below the freezing point on the higher campos. The mean annual temperature is about 85° in the São Francisco valley, 77° on the campos of the S.E., and 70° on the campos of the W. The year is divided into two seasons—warm and dry—the former lasting from November to May. This division is not so clearly marked in the south, especially in the "matta" (forest) region, where the rainfall ranges from 50 to 65 in. There is much variation in the wooded districts of the east and on the higher campos, where the daily extremes of temperature are great, lung and bronchial diseases are common. Some of the high plains, however, as at Barbacena, serve as health resorts for the coast districts.

Minas Geraes is a mining state, though the mining industry has lost much of its importance through the decline in the output of gold and diamonds. Gold is widely diffused, and abandoned "washings" all over the state show how general the industry was at one time. There were in 1908 five deep mines worked by English companies and one by a French company with most of these, the Morro Velho mine, belonging to an English company, is not only the deepest gold-mine in existence (over 2000 ft.), but it has been worked since 1725, and since 1835 by its present owners. Silver is not mined by itself, but is found in combination with gold. In 1908 a rich goldfield was discovered in the northern part of the state, 5 m. from Montes Claros, in the valley of the Verde Grande River, and attracted large numbers of miners. There are many rich deposits of iron ores in the state, but they only produce a small quantity of charcoal iron for local consumption. Manganese ore is mined for export, and bismuth is reported to have been discovered. Minas Geraes is most widely known for its diamonds, which are found in widely separated parts of the state. The largest and most productive field is that of Diamantina (q.v.) on the head-waters of the Jequitinhonha River, where diamonds were discovered about 1725, and where the celebrated "diamond reservation"—an oval-shaped territory 8 leagues wide by 16 leagues long (Mawe), with Tefuco, now Diamantina, very nearly in the centre—was established in 1730. The mines became crown property, gold-mining was forbidden, and no one was permitted to enter the reservation without a licence. The state monopoly was abolished in 1832, and mining has since been carried on by private enterprise. John Mawe estimates that the annual product was 1000 oz. during the first twenty years, and Castelnau estimates the value of the total output down to 1849 at 300,000,000 fr. No estimate can be made of the contraband, which must have been large. A great decline in the output occurred during the last half of the 19th century; but a new field was discovered in 1908 at Abbadia dos Dourados, in the western part of the state.

Other valuable stones, the topaz, chrysolite, aquamarine, amethyst and tourmaline are found.

Agriculture and grazing have become the main dependence of the population—the former in the lower, forested region of the south-east, where coffee and sugar-cane are the principal products, and the latter on the higher campos and river valleys, and on the mountain slopes, where large herb of cattle are to be found, and milk, butter and cheese are produced. The shipping of fresh milk to Rio de Janeiro and butter-making are comparatively new industries. The river valleys of the campo region are also cultivated to some extent. Among the general products of the state are tobacco, manioc, beans, cotton and pork. Wheat has been produced in some localities, but not on a paying basis, and experiments have also been made with tea. There is a large variety of fruits, and the cultivation of grapes for wine-making is developing into a profitable industry. Railway communication with Minas Geraes includes the following lines: the Central do Brazil (formerly known as the Dom Pedro II.), which starts from Rio de Janeiro and penetrates nearly to Pirapora (its objective point), at the head of navigation of the São Francisco River, with branches into neighbouring districts; the Leopoldina, from the frontier town of Tangará da Serra to its junction with the Minas and Rio, from Cruzeiro, on the São Paulo branch of the Central do Brazil, into southern Minas; the Mogiana, from Campinas, São Paulo, and runs to Uberaba in western Minas, and is intended to cross into Goyas; and the Bahia & Minas, from the port of Caravelas, in southern Bahia, which runs a short distance into Minas Geraes, and is planned to extend to Philadelphia and beyond. Another line from the port of Victoria, Espirito Santo, northward to Diamantina, Minas Geraes, was under construction in 1908. River transport has some local value on the upper São Francisco and its larger tributaries, and this will be greatly increased when the Central do Brazil railway reaches the head of navigation on that river.

The population of Minas Geraes is chiefly of Portuguese origin, which has been constantly strengthened by immigrants from the mother country. A considerable admixture from other nationalities has resulted from the influx of mining adventurers, and some German colonies have been established in the state. The negro population is large, and there is a still larger contingent of mixed races. The capital is Belo Horizonte (q.v.), or Cidade de Minas. Other important cities and towns are: the former capital, Ouro Preto, Barbacena, Diamantina, Baependy (pop. 22,817 in 1890), on the head-waters of the Rio Verde, the centre of a rich tobacco-producing district; Curvelo (8071), north of Sabará in the Rio das Velhas Valley, the centre of a cotton-growing district and cotton manufactures; Entre Rios (7681), in the coffee district of south-east Minas; Januária (8888), a river port of the São Francisco in northern Minas; Juiz de Fora; Marianna (4751), an episcopal town east of Ouro Preto, Mar de Hespanha (5712), the centre of a productive and populous agricultural municipality of south-east Minas; Paracatú (21,418), an important commercial centre of western Minas near the Goyaz frontier; Queluz (12,000), on the Central do Brazil railway; Congonhas do Campo (10,902), in the municipality of Queluz, celebrated for its miracle-working image, its great church and chapels, and the pilgrimages to its shrine; Sabará (4595), a railway junction on the Central do Brazil, and port on the Rio das Velhas; Congonhas de Sabará (14,060), in the municipality of Sabará, where the celebrated Morro Velho gold-mine is situated; São João de' El-Rei (5,826) an important commercial mining and pastoral centre, near the Rio das Mortes, connected with the Central do Brazil railway by a branch called the Oeste de Minas; and Uberaba (12,231), a commercial town of the western campos of Minas, connected with São Paulo by the Mogiana and São Paulo railways.

Minas Geraes was first explored by Fernando Dias Paes Leme between 1664 and 1677, though he was not the first European to penetrate it. The discovery of gold in 1692-1695 by bands of adventurers from the São Paulo settlements, led to every occupation and profession being abandoned in the mad rush for the new mines. Minas Geraes at first formed part of the
capitania of São Paulo, but in 1720 it became a separate govern-
ment and was brought more directly under the Portuguese crown.
The arbitrary restrictions imposed upon the colonists aroused dis-
atisfaction and resentment, and led to conspiracy in 1729, in-
spired by a fear that the Portuguese government was
about to enforce the collection of its “fifths” of the mining
output, which had largely fallen into arrears. Among the
conspirators was one José Alves Maciel, who had just returned
from France where he had met Thomas Jefferson and had
become infected with French revolutionary ideas. A number of
residents became involved, among them the poet Thomaz
Antonio Gonzaga. Keckless talk in public places led to the
arrest of the conspirators. Only one was executed, a poor,
unemployed man named Joaquim José da Silva Xavier, nicknamed O Tiradentes (the Tooth-puller), the others
being imprisoned or banished. Tiradentes has since been glorified
as the pro-martyr of Brazilian independence. In 1822 Minas
became a province of the empire created by Dom Pedro I.,
though a revolutionary outbreak had occurred in Ouro Preto
the year before. In 1842 a long series of quarrels in Rio de
Janeiro culminated in a revolution in Minas Geraes and São
Paulo, which was suppressed at Santa Luzia, Minas Geraes, on
the 20th of August of that year. The abolition of slavery in 1888
caused much discontent among the planters and in the following
year many of them adhered to the declaration of the
republic in Rio de Janeiro.

MINBAR, or MIRBAR, a term in Mahomedan architecture for
the pulpit in a mosque from which the Friddy or Mahomedan
Sabbath sermon is given (see PULPIT).

MINBU, a district and division of Upper Burma. The district has an area of 3,299 sq. m., and a population (1901) of 233,377,
showing an increase of 8% in the decade and a density of 71
inhabitants to the sq. m. The district may be said to consist of
low plain-land towards the Irrawaddy, and of undulating
country inland. The district was, in 1816, named in Arakan
hills. Between the plains and the Arakan Yoma range is a
distinct line of hills running north and south, and usually
called the Nwa-Madaung hills. The submontane valleys are
largely cultivated, but are deadly except to those born in them.
The chief streams besides the Irrawaddy are the Môn, the Maw,
and the Salin, which are largely used for irrigation. At Minbu
town the Irrawaddy is 3 miles wide, with many islands and sand-
banks. There are considerable fisheries along the Irrawaddy and
on the Paungtin lake, which is a lagoon fed from the Irra-
way, and contains a great yearly fur and fishery, and realize
an average of £1,000. Oil has been discovered near the mud
volcanoes of Minbu, but it seems to lie at too great a depth to be
profitably worked.

There is a large area of reserved forest in the district. The chief crops raised are rice, gram, millet, beans, peas, sesamum and
tobacco. The betel-vine is largely cultivated along the Môn
River. The district, which was in a chronically disturbed state
before the annexation, was not reduced till two years afterwards,
many officials losing their lives, among them Phayre, the first
deputy-commissioner. The annual rainfall varies greatly over the
district. It is very considerable on the banks and under the Arakan
Yomas, and very slight towards the Irrawaddy. The thermo-
meter rises to over 108° in the hot months, and the mean of
minimum in December is about 49°. Minbu, the district head-
quarters, stands on the Irrawaddy. It had a population of
57,800 in 1901. The river steamers in the dry season can come
no nearer than two miles to the south of the town.

The division includes the districts of Thayetmyo, Pakkókké,
Minbu and Magwe. It has a total area of 17,172 sq. m. and a
population (1901), of 1,976,280, showing an increase of 8% in the
decade and giving a density of 65 inhabitants to the square
mile. It borders the Irrawaddy. (J. G. Sc.)

MICHINHAMPTON, a town in the Stroud parliamentary
division of Gloucestershire, England, 4 m. S.E. of Stroud. Pop.
(1901), 3,727. It lies high on a slope of the Cotswold Hills;
Minchinhampton Common being a fine open upland. The church
of Holy Trinity, largely reconstructed, contains many brasses
and memorials. The manufacture of woollen cloth is the long-
established staple of Minchinhampton. Prehistoric remains
have been discovered on the common, and earthworks are also
seen; while the name of Woeful Dane Bottom, a neighbouring
hill, perhaps indicates the scene of a defeat of the Danes
c. (918).

MINDEN, a town of Germany, in the Prussian province of
Westphalia, 44 m. by rail to the W.S.W. of Hanover, on the left
bank of the Weser, which is spanned by two bridges. Pop.
(1905), 25,428. The older parts of the town retain their narrow
and crooked streets. The cathedral tower dating from the 11th
century, illustrates the first step in the growth of the Gothic
spire in Germany. The nave was erected at the end of the 13th
century, and the choir in 1377-1379. Among the chief edifices are
the old church of St Martin; the town hall, with a Gothic facade;
the law courts and the government offices, constructed, like many
of the other buildings, of a peculiar veined brown sandstone found
in the district. The town has a statue of Frederick William I.,
the great elector of Brandenburg. Minden contains a gymnasium
and several hospitals, besides other charitable institutions.
Its industries include linen and cotton weaving, dyeing, calico
printing, brewing, ship-building and the manufacture of tobacco,
glass, soap, chocolate, leather, lamps, and chemicals.
There is also some activity in the building of small craft.
Minden (Mindun, Mindo), apparently a trading place of some
importance in the time of Charlemagne, was made the seat of
a bishop by that monarch, and subsequently became a flourishing
member of the Hanseatic League. In the 13th century it was
surrounded with walls. Punished by military occupation and a
fine for its reception of the Reformation, Minden underwent
similar trials in the Thirty Years' War. In 1648 the bishopric
was converted into a secular principality under the elector of
Brandenburg. From 1807 to 1814 Minden was included in the
kingdom of Westphalia, and in the latter year it passed to
Britain. In February 1815 at the Battle of the Weser (after the Seven Years' War, were restored
and strengthened, and as a fortress of the second rank it remained
the chief military place of Westphalia down to 1873, when the
works were finally demolished. About 3 m. to the south of
Minden is the so-called "Porta Westfalica," a narrow defile by
which the Weser quits the mountains. The bishopric of Minden
embraced an area of about 400 sq. m. and had about 70,000
inhabitants.

The battle of Minden was fought on the 1st of August 1759
between the Anglo-Allied army commanded by duke Ferdinand
of Brunswick and the French under Marshal Coutades, the latter
being defeated. The most brilliant episode of the battle was the
entire defeat of the French cavalry by the British infantry
(with whom there were some Hanoverian troops); but Minden,
though it is one of the brightest days in the history of the British
army, has its dark side also, for the British cavalry commander
Lord George Sackville (see SACKVILLE, VICOUNT) refused
to obey the order to advance, several times sent by Duke Ferdinand,
and thereby robbed the victory of the decisive results which were
to be expected from the success of the infantry. For an account
of the battle and of the campaign of which it is the centre, see
SEVEN YEARS' WAR.

See Stoy, Kurzer Abriss der Geschichte Mindens (Minden, 1879);
Bölsche, Skizzen aus Mindens Vergangenheit (Minden, 1897);
Holscher, Beschreibung des vormaligen Bistumes Minden (Münster,
1877).

MINEHEAD, a market town and seaside resort in the Welling-
ton parliamentary division of Somersetshire, England, 188 m.
W. by S. of London by the Great Western railway. Pop. of
urban district (1901), 25,311. The town has three parts: the
Upper, built on the sides of a lofty foreland known as North Hill;
the Lower, and the Quay Town, with many ancient houses,
stretching for about a mile beside the harbour. It is much visited
for the sake of its mild climate, the grand cliffs, moors and
hills of the neighbourhood, and the beach, admirably suited for
bathing. St Michael's, the parish church, has a striking Perpen-
dicular tower, an arch of carved oak dividing its nave and
chancels, a magnificent rood-loft, and a 13th-century monument
doubtfully described as the tomb of Bracton, the famous lawyer,
whose birthplace, according to local tradition, was Bratton
Court in the vicinity. Coaches for Porlock and Lynston start
from the town.

There is no evidence of the existence of Minehead (Mannhevere,
Mannehuse, Mynheveden) in Roman or Saxon times. The town
owed its origin and growth to its position on the south side of the
Bristol Channel, and its good harbour developed an overseas
trade with Bristol, South Wales and the Irish ports. The De
Mohun family were overlords of the town from 1286 to the
14th century, when they were followed by the Luttrelts, who are
the present owners. It is possible that Minehead had a corporate
existence during the 13th century, as certain documents executed
by the portreeve and burgesses at that date are preserved, but
no record of the grant of a charter has been found. A charter of
incorporation given by Elizabeth in 1558 vested the government
in a portreeve, a steward and twelve burgesses, the continuance
of the corporation being subject to the port and harbour being
kept in repair. This condition being unfulfilled, the charter
lapsed in the reign of James I, and an attempt to obtain its
renewal in the 18th century failed. The corporation was replaced
by two constables chosen annually in the court leet of the manor
until 1894, when an urban district council was appointed. The
borough returned two members to parliament from 1555 until
disfranchised by the Reform Act of 1832. A weekly market on
Tuesdays and a fair (Sept. 29 to Oct. 2) were held by the lord
of the manor from the 13th century, but the date of the grant
has not been found. In 1465 a second annual fair on the 1st of
May was granted by Edward IV, which is still held on the
Wednesday in Whitsun week. The fair has been discontinued,
and the market day has been changed to Wednesday.
During the 16th, 17th and 18th centuries Minehead had a con-
siderable coastwise trade in wool, grain and wine, but began to
decline owing to the migration of the woollen industry to the
north of England, and to the decay of the herring fishery.
A renewal of prosperity began when it acquired a reputation as a
watering-place.

See Victoria County History: Somerset; F. Handcock, Parish and

MINEO, a town of the province of Catania, Sicily, 34 m. S.W. of
Catania by rail. Pop. (1901), 9828. It occupies the site of the ancient
Menaemon, founded by Duceitus in 459 B.C. There is
some doubt as to whether this town was also the birthplace of
Duceitus, owing to confusions in nomenclature (see E. A. Free-
man, History of Sicily, ii. 361). Remains of ancient fortifica-
tions still exist, though it seems uncertain whether they are of
Greek or of Byzantine origin (Notizie degli Scavi, 1899, p. 70).
Four miles to the north is the Lacus Palicornis in which there is
a lake of salt water, which still sends up carbonic acid gas.
By it was the temple of the Palici, twin Sicel gods, the most holy place in Sicily,
where an oath taken was especially binding, and an inviolable
asylum for fugitive slaves. There is now nothing to suggest twin
deities; in ancient times there were probably two craters, whereas
now there is only one. It was here that Duceitus, a few years
later, founded a new seat for his power, the city of Palica.

MINERAL DEPOSITS. The subject of mining (q.v.) can only be
understood after the general features of mineral deposits have been elucidated.
In this article deposits of all kinds of useful minerals are included, whether they are metalli-
f erous or earthy. In general practice it is customary to treat
the former under the name "ore-deposits" and the latter as the
"non-metalliferous". This is warranted because in a large degree
different geological problems are presented and different methods
of mining are pursued. Nevertheless there are other important
similar or common features and they may be classed together
without great disadvantage.

The word "ore" is used in several meanings, each of which
depends for its special significance upon the connexion. In
purely scientific applications "ore" implies simply
a metalliferous mineral, and in this sense it appears
in works on mineralogy and petrology. In former years and in
connexion with practical mining an ore was defined as a compo-
und of metal or of metals with one or more non-metallic
elements, called mineralizers, of which oxygen and sulphur were
the chief. The ore must, in addition, be sufficiently rich to
be mined at a profit. Native metals not being compounds
were not considered ores. The product of the copper mines on
Keweenaw Point, Lake Superior, was of a great extent
of iron, so that the rock rather than copper ore, as the native
gold in quartz is often described as gold quartz rather than
gold ore, but these restrictions are gradually disappearing.
An ore may therefore be defined as a metalliferous mineral
or aggregate of metalliferous minerals mingled with a greater
or less amount of barren materials called the "gangue," and
yet rich enough to be mined at a profit. When not
proved to be sufficiently rich to be remunerative, the aggre-
gate is called "mineral." The "mineral" of to-day may be
changed by the advent of a railway or the rise in the price of
metal into the "ore" of to-morrow. The question has re-
peatedly appeared in litigation involving contracts or property
rights.

Since the greater number of the ores are believed to have been
precipitated from aqueous solution, or to have been otherwise
formed through the agency of water, the term "ore-deposit"
has resulted; and insasmuch as nearly all the other useful minerals
owe their origin to the same agent, the term "mineral deposit"
is equally well justified. A few, however, have been produced
in a different way, such as certain iron ores of igneous origin;
As in the Central Cordilleran region of North America, in the
province of British Columbia, or in the province of South America, in the case of
granite; and the accumulations of vegetable material in coal beds.
These latter, the igneous masses and the vegetable accumula-
tions, being placed in two divisions by themselves, we may
group the larger number into two main classes, depending on
their precipitation from solution or from suspension. In the
case of solution we will further subdivide on the place, and there-
fore in large part on the cause, of precipitation, since these are
the questions chiefly involved in actual development.

Especially in connexion with ore-deposits widening experience has
modified the older conceptions of relative values in the several
types. In the early days of geology, Cornwall and Saxon were
the two regions where the most active and influential students
of ore-deposits were trained and where the principal books relat-
ing to mining originated. The pronounced and characteristic
fissure veins of England and Germany became the standards
to which the phenomena met elsewhere were referred, and by
means of which they were described. This particular form, the
fissure vein along a fault, assumed a predominating importance,
both in the thought and in the literature of the day. Widening
experience, however, especially in the Cordilleran region of North
America, and in the province of South America, has given more
type into equally great and deserved prominence. Comprehensive treatment to-day there-
fore departs somewhat from earlier standards.

As far as analyses and estimates permit, the common useful
metals occur in the earth's crust in approximately
the following percentages:

    Occurrence:

1. Aluminum 8-13 7. Copper 0-000005
2. Iron 4-71 8. Lead 0-00005
5. Cobalt 0-000005 11. Gold 0-00000005
6. Tin 0-00000000005 12. Platinum 0-00000000005

By the letter x is meant some undetermined digit in the corre-
sponding place of decimals. Apart from aluminum, iron, manganese and nickel, the figures show how small is the con-
tribution made by even the commoner metals to that portion of
the mass of the globe which is open to observation and
investigation.

As compared with the earth's crust at large certain of the
metals are known to be locally present in favourable, usually
igneous rocks, in which they are not in contact with any
other elements. These are the metals which have been made up
and samples of carefully selected materials.

Copper, 0-00005; lead,
MINERAL DEPOSITS

...iron and aluminium seldom fail, and vary from 1 to 2\% as a minimum, up to 25\% as a maximum.

In order that the several metals may constitute ores, their concentrations must be the following—the percentages of each vary with favourable or unfavourable conditions. The ore, as it is formed, and can therefore be expressed only in a general way; ores favourable to milling and concentration may go below these limits, and the mingling of two metals of which one facilitates the extraction of the other may also reduce the percentages:

Cobalt is a by-product in the metallurgy of nickel and is usually in much inferior amount to the latter.

When we compare the first and second tabulations with the third it is at once apparent that with the possible exception only occasional exception of iron the production of an ore-body from the normal rocks which constitute the outer mass of the earth requires the local concentration of each of the metals by one or several geological processes, and to a degree that is only occasionally attained in the ordinary course of nature. It is, therefore, an instance of somewhat exceptionally good fortune when one is discovered, and it is only the part of ordinary prudence to develop and utilize it as one would treat a resource which is limited and subject to exhaustion.

The ores which constitute ore-bodies are divided into two great classes: the ores proper, which contain the metals, and the barren minerals or gangue, which reduce the yield.

The ores are generally and naturally subdivided into two groups: first, the sulphides and related compounds containing arsenic, antimony, tellurium and selenium; and, second, the oxidized compounds (embracing oxides, carbonates, sulphates, silicates, phosphates, arsenates, chromates, and oxides. With the oxides are placed, because of related geological occurrence, a few rare compounds with chlorine, bromine and iodine into which silver more than any other metal enters, and to the same group we may add a few metals which occur in the native state. Iron, manganese, aluminium and tin differ from the rest of the metals in their original occurrence in the oxidized form, whereas the others with the exception of gold, platinum, and possibly copper, in their first position are the one in the form of sulphides or related compounds. Only by subsequent changes, characteristic of the upper parts of the deposits, do they pass by oxidation into the minerals of the second group.

With regard to the nature and source of the water which serves to gather up the widely disseminated metals and concentrate them in ore-bodies two contrasted views are now current, not necessarily antagonistic but applied in different degrees by different observers. The older view attributes the water primarily to the rainfall, and therefore it is called meteoric water. After falling upon the surface the meteoric water divides into three parts. The first, and smallest, evaporates; the second, the largest portion, joins the surface drainage and is called the run-off; while the third, intermediate in amount, sinks into the ground and mingles with the ground-waters. The ground-waters rise in springs, usually fed from no great depth, and themselves pass into the surface drainage after a small subterranean journey. While as a rule the ground-water level is fairly definite, yet it sometimes displays even in the same mining district great irregularity.

The solution of active circulation and work of the descending meteoric waters between the surface and the ground-water level was called by Franz Posey (1835-1859) the vadose or shallow region ("Genesis of Ore-deposits," Trans. Amer. Inst. Min. Eng., xxiii., xxiv., 1893; reprinted as a book, 2nd ed., 1902). It has been long recognized by miners as the home of the oxidized ores, and the place of the work of the descending waters. The deep-waters are relatively motionless and their movements as far as visible are comparatively slow. But the really important feature of the ground-water as regards the filling of veins is the depth to which it extends. This remained a somewhat indefinite matter until L. M. Hoskins showed mathematically that cavities in the firmest rocks have appreciable possibilities at about 10,000 metres. Down to such some limiting depth as the ground-water was believed by many to descend; to migrate laterally; to experience the normal increase of temperature with depth; the effect of pressure; the increased efficiency as a solvent peculiar to the conditions; and finally with a burden of dissolved gauge and ore to rise again, urged on by the "head" of the descending column. In its ascent it was supposed to fill the veins. Mining experience has, however, indicated that the known ground-waters are comparatively shallow and seldom extend lower than 500-600 metres. It is conceivable that during faulting and the formation of great dislocations this upper reservoir might be tapped into greater depths and set in limited circulations through deeper-seated rocks. But so far as these objections have weight they have greatly restricted the vertical range of the meteoric ground-waters as they were formerly believed to exist.

In contrast with the meteoric waters outlined above, other waters are believed by many geologists to be given off by the deep-seated intrusive rocks, and are generally called magmatic. We are led to this conclusion by observing the vast quantities of steam and other associated vapours which are emitted by volcanoes; by the difficulty of accounting in any other way for the amount and composition of certain hot springs; and by the marked and characteristic association of almost all ore-deposits in the form of veins with eruptive rocks. That igneous masses have been connected with the formation of veins is further brought out by the following general consideration, which has hitherto received too little attention. Aside from pegmatites, veins rich enough to be mined and even large veins of the same gangue-shape are exceptional phenomena when we compare the regions containing them with the vast areas of the earth which have been carefully searched for them and which have failed to reveal them. As components of the earth's crust the useful metals except iron and aluminium are extremely rare. Some sharply localized, exceptional, and briefly operative cause must have brought the veins into being. The universal circulation of the ground-water of meteoric origin fails to meet this test, since if it is effective we ought at least to find veins of quartz and calcite fairly universal in older rocks. In North America, for example, the masses of quartz veins have been studied date from the Mesozoic and Tertiary times. The ore deposits of older date are chiefly of iron and manganese and can be satisfactorily explained in many cases by the reactions of the vadose region, or by crystallization from molten masses.

In summary it may be stated that the meteoric waters are of great importance and of unquestioned efficiency in the shallow vadose region, or, as named by C. R. van Hise, "the zone of weathering." In it the disintegration of rocks exposes them to the searching action of solutions, and the portions of ore-bodies already deposited undergo great modifications. The deeper and far more immovable ground-water probably extends to but moderate depth and is chiefly affected as regards movement by the head of waters entering heights of land and by local intrusions of igneous rocks. It is very doubtful if the normal increase of temperature with depth produces much effect. The meteoric waters are of altogether predominant importance in all surface concentrations of a mechanical character. The magmatic waters, on the other hand, seem to be of paramount importance and of great efficiency producing the deposits of iron and copper in the great land volcanics, and in the formation of veins which are reasonably to be attributed to uprisings heated waters in regions of expiring vulcanism. They start with their burden of dissolved metals and minerals under great heat and pressure, amid conditions favouring solution, and migrate to the upper world into cooling and greatly contrasted conditions which favour precipitation. Undoubtedly they are responsible for many low-grade deposits
which have later been enriched by the action of descending meteoric waters. They are more copiously yielded, so far as we may judge, by acidic magmas than by basic ones.

The natural waterways are furnished by the cavities in rocks. They vary in size from very minute pores, where movement is slow because of friction, but where solution takes place, through others of all dimensions up to great fault-zones. The smallest cavities are the natural pores of minerals; cleavage cracks; the voids along the contacts of different minerals; cracks from crushing during dislocation; cellular lavas; volcanic necks; voids among the grains of the jebbles, or boulders of fragmental rocks; joint spaces, and faults. So far as waters have deposited ores and yielded ore-bodies by subterranean circulation the latter are guided by some such controlling influence as these in all cases, and they will be selected as the governing principle in a large part of the scheme of classification. The type will be reviewed in the following order:

I. Of Igneous Origin.

A. Eruptive masses of non-metalliferous rock.
B. Basic segregations from fused and cooling magmas.
C. Deposits produced in contact metamorphism, most commonly by the action of intrusive masses on limestones.
D. Pegmatites.

I. Precipitated from Solution.

A. Surface deposits.
B. Impregnations in naturally open-textured rocks.
C. Impregnations and replacements of naturally soluble rocks.
D. Deposits along broken antclinal summits and in synclinal troughs.
E. Deposits in shear zones.
F. Deposits in faults.
G. Deposits in volcanic necks.

II. Deposited from Suspension.

A. Placers.
B. Residual deposits.

IV. Carbonaceous Deposits from Vegetation.

I. Of Igneous Origin.

A. Eruptive Masses of Non-Metalliferous Rock.—Among the non-metallic objects of mining and quarrying which are of interest for the building stone, building, or ornamental work. There is a great variety of rocks and sizes of which the magmas and crystallizes. Such magmatic granites, syenites, and other light-coloured rocks are the most important. These rocks occur as intrusive masses called bosses when limited extent and diameter, and batholiths when of vast, irregular area. The main point of importance is the jointing and cleavage, which should in each case yield blocks as nearly rectangular as possible so as to save tool treatment. Dark, basic igneous rocks in dikes, sills and surface flows are employed for macadam, and are often of excellent quality for that purpose.

B. Basic Segregations from Fused and Cooling Magmas.—A few ore-bodies, of which the best-known involve iron, are believed to result directly from the decomposing processes which motion rock cools and crystallizes. Thus magnetite, a common iron ore, is a widely distributed component in the eruptive rocks, rarely if ever failing in any variety. It is one of the first minerals to crystallize, and has the higher specific gravity than the other constituents. There is reason, therefore, to believe that, forming in some molten magmas in relatively large quantity, it sinks to or toward the bottom of the mass until the latter is at least greatly enriched with it, if not actually changed to iron ore. If the molten rock, after passing through a stage of partial crystallization, moves toward the surface of the earth, the body of ore may occupy almost any position in it other than the bottom. The floating of the magma in original movements or from pressure sustained in subsequent metamorphic processes, or both, may give the ore the lenticular shape which is characteristic of magnetic bodies the world over. Almost all iron ores of recognized eruptive origin contain titanium oxide in amounts from a few units to over 40%. They are most frequently found in dark basic rocks. These ores are not at present of much commercial value because of the difficulties of treating titanianiferous varieties in the modern blast furnace practice, but there is little doubt that in the near future they will be exploited commercially.

Non-titaniferous magnetites, which often form lenses in gneissoid rocks of more acidic character than those with which the titaniferous are associated, are likewise believed by some observers to be of igneous origin. They are especially abundant in sediments of sedimentary deposition followed by metamorphism.

Besides magnetite, chromite is a characteristically igneous mineral, and is always found in the richly maganese rocks. Whether the relation is direct, i.e., that which appears from the mineral appearances from fusion, or whether they have segregated from a finely disseminated condition during the change of the original eruptive to serpentine, is a matter of dispute, but the general trend of later opinion is toward an original igneous origin. Although not strictly an ore, corundum is another mineral which is the direct product of igneous action.

A. Ore-body which marks a connecting and transitional member between those just treated and those of the next group is furnished by the sulphides of iron, nickel and copper which are found in the outer borders of basic igneous intrusions. Observers differ somewhat as to the ratio of the sulphides to the original igneous rock, and perhaps even more as to the purity of the nature of crystallization from fusion or those brought about by the agency of gases or other highly heated solvents in the cooling stages. The most important example is the so-called nickeliferous laterite, the laterite mass is generally called and carry over. On the nickel. With the base metal there are also found minute traces of the metals of the platinum group. Wherever these ores bodies have been recorded it has been in the borders of intrusive magmas. The sulphides constitute an integral part of the rocky mass, which shows almost no signs of alteration or vein production in the ordinary sense. Only some slight modifications have subsequently taken place through the agency of water, but all this is a small factor in the total.

B. Ore-Bodies produced by Contact Metamorphism.—Great bodies of ore have been formed in a molten and highly decomposed condition through other rocks when at a distance below the surface of the earth. After coming to rest they have remained during the cooling stages for long periods in contact with the surrounding walls. All igneous rocks are to a greater or less richly aqueous vapour, doubtless in a dissociated state; with carbonic acid and probably with other gases, especially those involving sulphur. When the cooling commences, the gases, with them silica, iron, alumina and metallic elements in less amount, of which copper is the commonest, but among which are also numerous lead, zinc, gold and silver. If the rock standing next the intrusive mass is limestone, the silica and iron, and to a small extent the alumina, combine with the lime to the elimination of the carbonic acid and produce extensive zones of lime silicates, of which garnet is the most abundant. Disseminated throughout these garnet-zones are small or broken small masses of pyrite and chalcopyrite occurring in amounts sufficient to yield large ore-bodies. Again in the limestone outside the garnet-zones, but none the less closely associated with them are bodies of calcite and pyrite, these with ores of bisbee and Morenci, Arizona, of Aranzazu near Conception del Oro, Mexico, and of many other parts of the world not yet studied in detail are of this type. The eruptive which most frequently produces contact zones is a mineralized character, since among eruptives these are the ones most richly charged with gases. When the copper ores are of low-grade in their original deposit it often happens that processes of secondary enrichment, which are later described, are required to bring them up to a richness which warrants mining. Less often than copper appear lead, zinc or gold ores in the same relations.

C. Ore-Bodies produced from Solution.—Out of the mass of eruptive activity needs also to be briefly mentioned before passing to the discussion of the ore-bodies, which have hitherto chiefly occupied students of the subject. In the regions surrounding intrusive masses of granite we almost always find small bodies of pyrite and chalcopyrite, the veins in amounts sufficient to yield large ore-bodies. Again in the limestone outside the garnet-zones, but none the less closely associated with them are bodies of calcite and pyrite, these with ores of bisbee and Morenci, Arizona, of Aranzazu near Conception del Oro, Mexico, and of many other parts of the world not yet studied in detail are of this type. The eruptive which most frequently produces contact zones is a mineralized character, since among eruptives these are the ones most richly charged with gases. When the copper ores are of low-grade in their original deposit it often happens that processes of secondary enrichment, which are later described, are required to bring them up to a richness which warrants mining. Less often than copper appear lead, zinc or gold ores in the same relations.

III. Precipitated from Solution.—A Surface Deposits.—The chief ore-body under this type is furnished by iron. The peculiar chemical property possessed by this metal of having two oxides, a ferrous, which is relatively soluble, and a ferric, which is insoluble, leads to its frequent precipitation of stability in comparatively quiet waters. Ferruginous minerals of all sorts, but more particularly pyrite and siderite, pass into solution in the descending celestite. The carbonate of ferrous iron or as salts of organic acids, or ferrous carbonate, the last-named dissolved in an excess of carbonic acid. On being exposed to the atmosphere when the solutions come to rest, or to the breaking up of organic acids, or to all of these changes, they form a fresh-water algae, the hydrated sesquioxide 2FeO•3H2O is precipitated as the familiar beds of bog ore. The ore usually forms earthy aggregates or crusts and cakes, but may also, as in the interesting case of the Preakness silver deposit, consist of a small deposit, the former being very rich in iron and are apt to have much sand and clay intermingled. If subsequently buried under later sediments they may become detached from the contact zones which were formed in the case of some of the Clinton iron ores of the eastern United States. These widely extended beds in the lower strata of the Upper Silurian are often oolitic red hematites, consisting of concentric shells of iron oxide and carbonates which are more resistant than the matrix.
chaledonic silica, deposited around grains of sand. The most extensive of all ore-beds of this type and the mainstay of the German and Belgian smelting industry, are the Jurassic ores, locally called mieren. In England and the German territories, the principal and several subordinate beds are distinguished, which furnish a product ranging from 30 to 40% of iron and between 1 and 2% of phosphoric acid (H₂P0₄). They are generally believed to have been formed by the repeated formation and deposition of the oxide. The iron was furnished by the drainage of the land and was precipitated, according to Van Werweke, as silicate, carbonate, sulphide and native metallic iron oxides. More than two billions of tons are believed to be available. Very similar deposits occur in the Cleveland district, England, in the Middle Lias.

In the presence of much organic matter which creates reducing conditions, interpretation of the beds as the ore are formed by the oxidation of the pyritic sulfur may result and afford the ores of this type extensively utilized in the Scottish iron industry and formerly of some importance in the eastern United States.

The Silurian deposits often have more or less manganese, and manganese ores themselves may result by closely related reactions, since manganese is very similar to iron in its chemical properties. Aluminium is yielded by deposits of bauxite, hydrated oxide, which in the states of Georgia and Alabama, of the United States, are the result of surface precipitations. In the depths it is believed that pyritic shales exist. The oxidation of the pyritic sulphides supplies sulphuric acid, the result of the oxidation of organic matter. Rising to the surface along a marked series of faults, the aluminium sulphate meets calcium carbonate in an overlying limestone, and the aluminium hydrate is precipitated as concretions at the vents of the springs.

Of scientific importance but as yet of no commercial value are the siliceous sintered deposits around the vents of hot springs which yield very high percentages of siliceous and other metals. While surface precipitations in every particular, they are yet chiefly important in casting light on the processes of vein formation in the depths.

Metallic deposits in which are deposited from solution on the surface of the earth are the salines, rock-salt, related potassium salts, gypsum and the rarer nitrates. The alkaline chlorides and gypsum are derived, in nearly all cases, from impounded bodies of sea-water, which, exposed to evaporation with increase of density, finally yield beds of rock-salt and related minerals. Shallow estuaries cut off from the sea, it may be by the sudden rising of a bar, may on their interior brine, form the same silt or a shallow connection as in the "bar theory" of Ockhnius, have given rise to the great stores of rocks which are so extensively mined. The potassium compounds have only been found as yet in large quantities in the Steffert region of Germany, and seem to be due to the fact that in this locality the mother-liquors of the rock-salt deposits failed to escape, and were evaporated to dryness. The nitrates are chiefly obtained in northern Chile and are the result of the evaporation of nitrites in solution in the alluvial minerals and under conditions where there is enough but not too much water.

A very important mineral found in surface deposits formed from solution is asphalt. It has happened in various parts of the world, but especially on the island of Trinidad, in the Caribbean Sea, that petroleum with an asphalt base has reached the surface, has been impregnated into the rock, and when the rock has been broken, has formed asphaltic deposits in the shales of suitable asphalt for street-paving or other purposes. So-called pitch-lakes are afforded which may be of great commercial value.

Again, if large sheets, crusts, stalactites and stalagmites, deposited from calcareous water by the escape of the soluble carbonic acid, beautiful ornamental stones are afforded, generally known as Mexican onyx.

**B. Impregnations in Open-textured Rocks.** — In a number of instances in various parts of the world naturally open-textured rocks have been discovered so richly impregnated with the metallic minerals as to be ores. The enriching minerals have been introduced during the process by which the rock has become loose, or by the escape of a mineralious fluid of asphalt suitable for street-paving or other purposes. So-called pitch-lakes are afforded which may be of great commercial value.

Again, if large sheets, crusts, stalactites and stalagmites, deposited from calcareous water by the escape of the soluble carbonic acid, beautiful ornamental stones are afforded, generally known as Mexican onyx.

**C. Impregnations and Replacements of Naturally Soluble Rocks.**—

Ore-deposits of great importance appear in different regions which have been produced by the replacement of some or all of a rock with the metal. The most common rock to yield in this way is limestone, because of its soluble nature, but important cases occur of others composed of silicates. Replacement implies the removal of a certain part of the rock by a solvent, and the introduction of the replacement is a salt or a mineral, a similar salt or mineral, in the place of the original rock. In this way, rocks are developed which are rich in metallic ore, and which have the same form as the rock from which they were derived. Such a rock is called a replacement rock, and the process of replacement is called replacement.

Some water must of course introduce the ore-bearing solutions, but it may be slight compared with the great size of the resulting ore-bodies. Lead and zinc ores, often carrying some silver, are those most widely distributed, as they were also among the first recognized in deposits of rock are not to be confined to any other metals and their association with limestone is pronounced.

The replacements may be found near the surface fissure as in the great zinc deposits near Aachen, or the surface fissures may be observed at Leadville. While the limestone, they are often close along with its surface contact with a relatively impervious stratum, which seems partly to have directed the circulatory process of the solution. While precipitation took place. With the lead and zinc sulphate deposits and chalcopyrites are commonly associated in greater or less degree, the copper increasing locally. All the sulphides are exposed to oxidation above the ground-waters and mining in the upper levels has been often directed against the carbonate and sulphate of lead, or the mingled carbonate and hydrated silicate of zinc.

A non-metallic deposit formed by replacement and of much scientific interest is sulphur, which is furnished by pyrites, as in the Sicilian and other localities of Europe.

**D. Deposits along Anticlinal Summits and in Synclinal Troughs.**—

When the strata in which they are contained are square, they are said to be impure or to have impure impregnations, and, if stiff or brittle like limestone, often crack in limited fissures, which in anticlines open upward and in synclines downward. They thus yield joints in relatively great numbers. Sorter rocks, such as shales, are moulded by the strata without fracturing. Very gentle folds seem to have yielded such abundance of cracks in the lead and zinc district of the Upper Mississippi Valley as to cause the so-called "gash veins" which have been worked for many years. The crevices are not vertical, but often run horizontally and are due to the parting and buckling of individual beds. The resulting ore-bodies are chiefly limited to a single great stratum, and are being developed both by the introduction of galena, blende and pyrite from overlying formations.

When strata are stiff enough to buckle under violent folding and part so as to produce openings of a crescentic cross-section which after a time have been filled by the leakage of an ore-bearing fluid, as that of the gold veins of Victoria, Australia, and in pitchtings of an anticline of a much larger character in Nova Scotia. Geologically, the general occurrence of ore-beds of a highly and generally as the iron ores of the Lake Superior region, now the most productive of all the iron-mining districts. In a series of sedimentary formations, generally of Huronian age, and with associated eruptives, there occur strata consisting of a cherty iron carbonate, which were probably originally marine deposits akin to glauconite. They rest upon relatively impervious rocks, and are often penetrated by basaltic dikes. The entire series has been folded, so that the cherty carbonates have been bent and broken, and it is very likely that the veins of relatively tightly, impervious rocks. The descending surface waters have next altered them, have taken the iron into solution, and have produced deposits of the type of the Illinois, the Green bay and red hematite. The siliceous has usually been precipitated elsewhere.

The most important of the non-metallics which occur along anticlinal summits are petroleum and natural gas, but it is true only in a very limited form that they draw their origin from the accumulation of gases in sedimentary rocks. The general cause of the accumulation is, however, the same as that of the metallic minerals, i.e. that storage cavities are afforded. In the most productive oil-fields it is the geologic structure of the rocks and the geological conditions which prevail, either sediments or limestones, at the crests of anticlines and beneath impervious shales which do not shatter or crack with gentle folding.

**Residual Deposits in Sedimentary Rocks.**—Deposits of both types, both in massive rocks and in sediments that strains of compression have been eased by local crushing along comparatively narrow belts without appreciable or measurable displacement of the sides such as on the edges of a bed or of a ridge. Chemical changes have become quite widely used in recent years as a descriptive term applicable to these cases.
MINERAL DEPOSITS

The gold-bearing reefs of the Transvaal present a good illustration. Beds of conglomerate containing gold and quartz are often broken and granulated, and have had their natural porosity much enhanced by these after-effects. Solutions of gold, coming through, have encountered pyrite and have had the gold precipitated out of solution, often broken and granulated. In other regions shearing has led to sheeting and opening of the rocks by many parallel cracks but almost always with such marked displacement that the next type most correctly describes the point of change. The next zone is a natural transition to the fault and closely related to it.
